1 DR. SIESS: The meeting will now come to order. This
2 is a meeting of the Advisory Committee on Reactor Safeguards
3 Subcommittee on Hope Creek Generating Unit.

4 I am C. P. Siess, Subcommittee Chairman.

5 The other ACRS members present today are, starting
6 on my left, Mr. Carbon, Mr. Ebersole, Mr. Michelson; and we
7 also have a consultant, Mr. Pomeroy.

8 The purpose of the meeting is to review the applica-
9 tion filed by Public Service Electric and Gas Company for a
10 license to operate Hope Creek Generating Station Unit 1.

11 This meeting is being conducted in accordance with
12 the provisions of the Federal Advisory Committee Act and the
13 Government in the Sunshine Act, and the designated Federal
14 employee for the meeting is Mr. Gary Quittschreiber, at the
15 end of the table; and Mr. Med El-Zeftawy, on my right, of the
16 ACRS staff is helping in that respect.

17 The rules for participation in today's meeting have
18 been announced as part of the notice of this meeting previously
19 published in the Federal Register on November 9 and November 21,
20 1984.

21 A transcript of the meeting is being kept and will
22 be made available as stated in the Federal Register Notice. It
23 is requested that each speaker first identify himself or herself
24 and speak with sufficient clarity and volume, and I replace that
25 phrase, use the microphone. I don't know if volume is going to

3
1 help you without a microphone in here, so he or she can be
2 heard, not only by the audience, but by the reporter.

3 We have received no written statements from members
4 of the public. We have received no requests for time to make
5 statements from members of the public. We have the most
6 recently revised agenda. Do all the members of the subcommittee
7 have the most recent one?

8 MR. QUITTSCHREIBER: It is in the book.

9 DR. SIESS: Okay. I haven't looked at the book yet,
10 which calls for the meeting to start at 2:00 o'clock, and to go
11 this afternoon until about 6:00 o'clock. We are starting about
12 a half an hour late, which suggests on the basis of my exper-
13 ience that we will be ending somewhat more than a half hour
14 late today. But we will try to keep within the allotted times.
15 And I use the "we" advisedly because it is usually the sub-
16 committee that is responsible for overruns, rather than the
17 presenters.

18 Was there something postponed? I&E was
19 scheduled for this afternoon and had to be postponed or are
20 they scheduled for tomorrow?

21 MR. EL-ZEFTAWY. No, Region I, they will appear
22 tomorrow at 10:25; Item 2-B.

23 DR. SIESS: Okay. So we gain a short amount on
24 Item 2-B, Construction Experience -- Noncompliance During
25 Construction, the report from Region I. I still call them I&E,

1 but they are officially a region now. Mr. Starstucky from the
2 region will be in tomorrow to give that report.

3 We have tried to include on the agenda those matters
4 that it is customary to look at, as well as those matters which
5 are of particular interest to the ACRS at this time. We may not
6 have succeeded. And occasionally we may need to deviate. I
7 believe that there were some questions posed by members of the
8 subcommittee during the site tour this morning that answers will
9 be provided some time today or tomorrow. If those answers
10 should come at appropriate places within the subject matter,
11 fine. If not, if the applicant will let us know whether they
12 are prepared to present those, we will set aside a sufficient
13 amount of time. And, if there are some that still remain un-
14 answered, we can defer answers to the full committee meeting.
15 But I would prefer not to do that because we will obviously
16 have more time today and tomorrow than we will have during the
17 full committee meeting.

18 Does that take care of your open questions?

19 Max, do you have anything?

20 DR. CARBON: No.

21 DR. SIESS: Are there any comments on the agenda
22 from members of the subcommittee? If you look through it and
23 see items you would like to add, just let me know. Equally
24 important, if there are some items that you would personally
25 prefer to delete, or truncate, and if there is any sort of a

1 consensus on that, we will so inform the people that are
2 planning to present it.

3 We should not, however, defer portions to the full
4 committee meeting. Rather, we should try to take care of as
5 many things here as we can that we can eliminate from full
6 committee consideration. We have a good representation here.

7 Did all of you get the staff's SER in time to
8 look at it? One day?

9 DR. EBERSOLE: That was a special case.

10 DR. MICHELSON: I had plenty of time.

11 DR. SIESS: You had plenty of time.

12 Max, did you have plenty of time? I had a good
13 amount of time.

14 So I am going to suggest that people that are
15 making presentations can make an assumption that -- and this
16 applies somewhat to the staff more than the licensee -- I will
17 have to keep calling you an applicant. You are a licensee for
18 another plant. And I think it will apply in particular to the
19 staff's presentation, because that is their document. But you
20 can assume we have at least looked at it, and maybe read it.
21 Or those portions of it. Nobody has read it, I am sure.

22 Have you read it?

23 MR. WAGNER: I have read it.

24 DR. SIESS: You have read it all. That is one
25 person in the NRC that has read the whole thing.

1 MR. WAGNER: But I may not have retained it all.

2 DR. SIESS: Yes. It is unbelievable, but I will --
3 we will start off with the staff. Mr. Wagner is Licensing
4 Project Manager, and I will turn it over to you. And I think
5 we can do this in a lot less than an hour.

6 MR. WAGNER: We will try.

7 Thank you, Dr. Siess.

8 Good afternoon, ladies and gentlemen. My name is
9 David Wagner and I am the Licensing Project Manager for the
10 Hope Creek Generating Station for the NRC. Other staff members
11 with me here today include Mr. Albert Schwencer, Chief of
12 Licensing Branch No. 2 sitting at the table. In the audience
13 we have John Chen, Fred Allenspach, and Phyllis Sobel from NRC.

14 Tomorrow we will be joined by Region 1 personnel.
15 Right now we expect Richard Starstucky and Bill Bateman, the
16 Hope Creek Resident Inspector, to be in attendance.

17 Many of you may remember the Hope Creek Generating
18 Station as the Newbold Island Nuclear Generating Station. In
19 1970, Public Service applied for a construction permit for the
20 Newbold Island Nuclear Generating Station. The site for New-
21 bold Island Station was in the top of Bordentown, in Burlington
22 County, New Jersey, which is about six miles south of Trenton
23 on the Delaware River.

24 Due to population concerns, the physical plant of
25 Newbold Island was relocated to Artificial Island, New Jersey,

1 adjacent to Public Service's Salem Generating Station, which was
2 then under construction.

3 In December of 1982, Public Service announced
4 the cancellation of Hope Creek Unit 2, which was then about
5 eight percent completed. With the exception of the containment,
6 Hope Creek is very similar to other plants recently reviewed by
7 the NRC, such as Limmerick and Susquehanna.

8 (Slide.)

9 MR. WAGNER: By the way, all these slides are in
10 your handout, the NRC presentation.

11 Major licensing activities, and whether they were
12 or will be completed are shown on this slide. As indicated, the
13 OL application was docketed in March of 1983. In June of 1984,
14 the draft environmental statement was issued. The final
15 environmental statement is scheduled to be issued within the
16 next couple of days. Of course, the staff's safety evaluation
17 report was available earlier this month.

18 (Slide.)

19 DR. SIESS: I think you can skip that slide. ASLB
20 and ACRS are separate distinct entities and we don't usually
21 get involved in their business and they don't usually get
22 involved in ours.

23 (Slide.)

24 MR. WAGNER: A number of the key design features
25 included the safety auxiliary's cooling system and concrete

1 secondary containment building.

2 Regarding the safety auxiliary's cooling system,
3 which Public Service calls the Sacks, I think it is important
4 to note that the Sack system forms an intermediate closed
5 cooling loop. On one side, you have the station service water
6 system. On the other side of the loop you have plant systems.
7 So regarding brackish water intake, the safety auxiliary's
8 cooling system essentially is a barrier to other plant systems
9 from this brackish water.

10 In fact, the only components the brackish water from
11 the Delaware Estuary sees are the four Sacks heat exchangers.

12 Regarding the concrete secondary containment, some
13 of the other BWR plants are not fully reinforced concrete, as
14 are Hope Creek. On Hope Creek, the lower levels, the upper
15 levels and the roof are reinforced concrete. On some other
16 plants, although the lower levels are reinforced concrete, the
17 upper levels and roof may be comprised of sidings.

18 The staff's safety review is based on the Hope Creek
19 FSAR through Amendment No. 7 and additional reports submitted
20 in support of the FSAR. Additionally, numerous site visits,
21 audits and meetings were conducted in the course of the review.

22 The safety review to date, we have approximately
23 15 open items, 37 confirmatory items, and 7 proposed license
24 conditions.

25 (Slide.)

1 MR. WAGNER: Could you go up one more slide, please?
2 (Slide.)

3 MR. WAGNER: Projected now is a table of the open
4 items. The staff has classified as open items for which a tech-
5 nical resolution has not been reached at this date.

6 DR. SIESS: What I would ask Mr. Wagner to do is put
7 this list up and let's see which ones the subcommittee would
8 like to hear more about. He has a slide for each of these with
9 a little more detail, if you don't remember it. But, first, you
10 just defined open items, and I still, except for OI initials,
11 I am slightly confused between outstanding issues and open
12 items.

13 MR. WAGNER: They are the same, sir.

14 DR. SIESS: I use all that plus open issues
15 while I am writing it down.

16 You say there are things for which a resolution
17 has not been --

18 MR. WAGNER: Reached.

19 DR. SIESS: -- reached.

20 But this list really falls into two categories.
21 There are several of these items where the resolution hasn't
22 been reached simply because you haven't finished your review.

23 MR. WAGNER: That is true.

24 DR. SIESS: Which could have been said about
25 anything a few months ago, and presumably you will finish your

1 review. When you finish your review, they may still be
2 unresolved issues at that point. You don't know now.

3 MR. WAGNER: That is right.

4 DR. SIESS: There are others where there is a
5 difference of opinion or position between the staff and the
6 applicant as to whether they have properly met the NRC licensing
7 criteria.

8 MR. WAGNER: Well, we really don't see any differing
9 technical positions on any of these open items as yet.

10 DR. SIESS: Okay.

11 Now I would like to know what the status of the
12 Riverborne missile is, and how it might be resolved.

13 MR. WAGNER: First, would you like the status of
14 what the issue is.

15 DR. SIESS: Well, you can put the next slide up and
16 tell us briefly.

17 DR. MICHELSON: Are we going to leave this one now?

18 DR. SIESS: This is number one.

19 DR. MICHELSON: Just number one, all right

20 MR. WAGNER: All right. I will leave it to you
21 folks to read the summary that has been provided. Basically,
22 during the probable maximum hurricane, the ten percent exceedence
23 high tides, the staff and applicant agree that about 12.3 feet
24 of water will flood the site. That is a depth above site of
25 12.3 feet of water. The basis of our concern is standard

1 review plan section 3.5.1.4, entitled "Missiles Generated by
2 Natural Phenomena" in which it states the staff reviews possible
3 hazards due to missiles generated by design basis flood.

4 DR. SIESS: Has that always been in the standard --

5 MR. WAGNER: It has since the --

6 DR. SIESS: This is the first time I have seen the
7 issue raised. I am not saying it is not a legitimate issue, but
8 missiles generated by natural phenomena has nearly always been
9 tornadoes.

10 MR. WAGNER: There is another section about tornadoes.
11 I think this is the first time floating missiles have ever
12 been investigated. I don't know that for a fact.

13 DR. SIESS: Not the first time they have ever had
14 the potential but the first time anybody ever thought of them
15 under 5.51.

16 MR. WAGNER: Well, I don't know about that.

17 DR. SIESS: We just went through the SEP plants
18 most of which get flood levels well above grade, and nobody
19 thought of it there.

20 MR. WAGNER: Well, location has a lot to do with
21 this. Specifically, the staff is concerned about Riverborne
22 traffic, either breaking loose in Philadelphia or out in
23 the bay.

24 DR. SIESS: Something that is big enough to damage
25 a plant but small enough to float.

1 MR. WAGNER: That is right.

2 DR. SIESS: When you say 12.3 feet above the site
3 grade, how do you define the site grade? Is that ground level
4 outside the building -- service water building, and somebody
5 said the flood level was up to the top of that concrete
6 structure.

7 MR. WAGNER: I think it is important first to really
8 ize what elevations the plant is at. At the service water
9 intake structure, the plant is elevated, either surface is
10 at 10.5 mean sea level.

11 Going up to the plant itself, it is at 12.5 mean sea-
12 level. That is the outside.

13 DR. SIESS: So there is only two feet difference?

14 MR. WAGNER: That is right. It slopes up.

15 DR. SIESS: Then whoever told us that was wrong
16 because that building is at least 20 feet high.

17 MR. WAGNER: Well, flood protection doesn't always --
18 it doesn't singularly occur. I am talking about the elevation
19 of the soil. Now the service water intake structure is flood
20 protected up to an elevation of 39 feet, which is about 27, 28
21 feet above the level of the site at that point.

22 Flood protection means it is protected against the
23 static and dynamic effects.

24 DR. SIESS: Okay. So your concern here is that
25 something with a draft less than 12.3 feet could float in and

1 hit the building.

2 MR. WAGNER: Yes.

3 DR. SIESS: Was it the building or was it the
4 waterproof doors? Which is your principal concern, or both?

5 MR. WAGNER: Right now the principal concern has to
6 do with the door.

7 DR. CARBON: The doors of the intake structure.

8 MR. WAGNER: Floods of the safety-related structure.

9 DR. SIESS: To protect the plant against floods of
10 this level, they have to be water-tight doors that are normally
11 accessed.

12 What does it take to resolve this, and what -- I will
13 ask the applicant to tell us what his proposal is. You can
14 just tell me his proposal if you think you are near resolution.

15 MR. WAGNER: Okay. Right now the applicant has
16 submitted a probability analysis on this event, and the staff
17 is reviewing it. In fact, we have hired a wind engineering
18 consultant from the National Bureau of Standards to look at
19 some of the assumptions Public Service has made. The time line,
20 conclusion of Public Service's report is that the probability
21 of this occurring, a ship or any, really any type debris; a
22 car, some kind of tank floating down the river during PMH and
23 compromising plant safety is of the order of ten to the minus
24 eight.

25 DR. SIESS: Why was a probabilistic approach taken

1 rather than a deterministic approach of seeing what the doors
2 could resist because nobody could decide what force would be
3 on the doors?

4 MR. WAGNER: For static flood protection --

5 DR. SIESS: No, I mean for the barge or something
6 that hits a door.

7 MR. WAGNER: We really haven't gotten that far into
8 the review.

9 DR. SIESS: That is not in the review if it is
10 probabalistic. Ten to the minus eight, you forget about it.

11 MR. SCHWENCER: Al Schwencer from NRC staff.

12 At the time the question came up, our review plan
13 does permit another applicant to take a probabilistic approach
14 in this area. We did pose that question and they, at that
15 point, may wish to speak with us further today, but at that
16 point, they -- they did not choose to address what it would
17 take to fix the "what if" that you are asking.

18 DR. SIESS: Yes. Well, it is not a question that
19 needs to be answered. There are two possible approaches and
20 I think I know why they took the probabilistic one, because
21 somebody would have to define what force that door has to
22 resist. I don't know whether that is any easier or more diffi-
23 cult than a signing probabilities.

24 What is that reason or have you got a better one?

25 MR. PRESTON: Bruce Preston, Licensing Manager,

1 Public Service. We plan to have a full presentation on this
2 topic tomorrow.

3 DR. SIESS: We don't really want a real long presen-
4 tation, if the thing is -- something has been proposed.

5 MR. PRESTON: Okay.

6 DR. SIESS: And the possibility that the staff
7 accepts it, you see, then why should we listen to the argument?

8 MR. PRESTON: Yes. We have done some additional
9 analysis that indicates the doors could withstand the forces
10 of a certain spectrum of missiles. It is the large craft that
11 the probability case rests on.

12 DR. SIESS: Okay. Now you came up with ten to the
13 minus eight. That must be at least in two parts. One is
14 the part the site will be flooded to that depth and the second
15 is the part that there will be a craft that gets loose some-
16 where. I guess there could be a third part, that it actually
17 hits a particular target.

18 MR. PRESTON: Yes.

19 DR. SIESS: What is the probability for it?

20 MR. PRESTON: I would like to call Bob Douglas up to
21 discuss the numbers.

22 DR. SIESS: How many of these open issues are you
23 planning to make presentations on because they are open issues?

24 MR. PRESTON: The most specific one was the flood.

25 DR. SIESS: That was the only specific one?

1 MR. PRESTON: We also plan to make a presentation
2 on generic material problems.

3 DR. SIESS: Yes. Well, that is a generic issue.

4 MR. PRESTON: In a sense it could relate to the
5 ISI issue. That is an open item.

6 DR. SIESS: We want to hear that.

7 DR. DOUGLAS: Bob Douglas, Manager, Licensing
8 Analysis, Public Service. The probability of the flood level
9 of 12 feet existing on site that could cause the floating
10 missiles to impact on safety-related structures is about ten
11 to the minus fifth per year.

12 DR. SIESS: So you have got the other ten to the
13 minus three on the missile being there and hitting a certain
14 thing, or did you assume if it was there it would hit the door?

15 DR. DOUGLAS: We looked at the number of potential
16 missiles that would be within a certain radius of the site and
17 the probability of those ships and other missiles, then,
18 getting on to the site. And then hitting an area which defined
19 all the safety-related structures. The combination of those
20 factors times the probability of the MH condition that gave
21 us the overall factor of approximately ten to the minus eight.

22 DR. SIESS: At what level does the staff say no
23 problem? Is ten to the minus eight your criterion or ten to
24 the minus seven or six?

25 MR. SCHWENCER: Dave, help me if I don't remember

1 this correctly. But if it is a conservative analysis, we have a
2 threshold of ten to the minus six.

3 DR. SIESS: Okay.

4 MR. SCHWENCER: If it is a nonconservative --

5 DR. SIESS: Let's say realistic.

6 MR. SCHWENCER: Ten to the minus seven.

7 DR. SIESS: They have got a factor of ten, depending
8 on the analysis. You have got a consultant looking at this,
9 you said?

10 MR. WAGNER: Yes.

11 DR. SIESS: Who?

12 MR. WAGNER: We have Emil Simiu from the National
13 Bureau of Standards. Dr. Simiu.

14 DR. SIESS: What is he, a statistician?

15 MR. WAGNER: His official title is wind engineer.

16 DR. SIESS: Well, that is pretty good. Anybody
17 else want to explore this issue? Get the list back up for us,
18 please, the previous slide.

19 (Slide.)

20 DR. SIESS: No. 3, equipment qualification.

21 Yes?

22 DR. MICHELSON: Yes, I have a few questions on it.
23 The difficulty is, as pointed out in the slide to be used,
24 the staff is just getting started, so to speak, looking at the
25 details. I looked at the licensee's presentation, or

1 applicant's presentation, and didn't really find any appropriate
2 category comparable to equipment qualification. Maybe I missed
3 it. Is there going to be no discussion of equipment -- yes,
4 excuse me. 9:15 tomorrow morning, "Environmental Qualification
5 of Equipment". I will hold my questions until then.

6 DR. EBERSOLE: I have a few questions.

7 DR. SIESS: You might want to look through the book
8 at that part of it and see if it is covered.

9 Jesse?

10 DR. EBERSOLE: I read what I could find in the SER
11 on that topic and found nothing that satisfies this question.
12 I see no explicit language that says we know in fact that the
13 valves in this plant have dynamic competence to intercept
14 faulted flows. It is the old question, you know, which erupted
15 years ago when we found out the containment butterfly valves
16 used for purging were not even specified to close against the
17 dynamic flows which would emerge from a LOCA, thus the contain-
18 ments were nonexistent.

19 It is part of 3.10 in the SER. As a matter of
20 fact, it is C-E.

21 DR. SIESS: Yes, but what I was going to say,
22 Jesse, is that is not equipment qualification in the sense that
23 it is used here.

24 DR. EBERSOLE: I read it, however -- seismic and
25 dynamic qualification is packaged in one topical area.

1 DR. SIESS: Let me ask the staff. Is that type
2 of qualification included under the equipment qualification
3 review?

4 MR. WAGNER: Yes, I believe it is.

5 DR. EBERSOLE: I found again as I usually find,
6 no explicit --

7 DR. SIESS: They haven't done it yet.

8 DR. EBERSOLE: They don't say they are going to do it.

9 MR. WAGNER: We are going to do it.

10 DR. EBERSOLE: Okay.

11 DR. MICHELSON: I assume tomorrow morning at 9:15
12 we will find out what the applicant has done or is doing
13 or intends to do.

14 DR. SIESS: Is that correct?

15 MR. PRESTON: That is correct.

16 DR. SIESS: Fine.

17 There are other items in the same category. Pre-
18 service inspection program, you are still reviewing, am I
19 correct?

20 MR. WAGNER: Yes, we are.

21 DR. SIESS: Or you will review it when you get it.

22 MR. WAGNER: They have submitted a preservice
23 inspection program. One of the next slides might state our
24 concern. That is it. Generally the staff believes the pre-
25 service inspection plan looks pretty good except for one area

1 having to do with some corrosion resistance cladding applied to
2 from recirculating line welds.

3 DR. SIESS: The concern is about being able to
4 detect flaws through the cladding.

5 MR. WAGNER: Yes, they have applied inside and
6 outside diameter cladding to the welds.

7 DR. SIESS: This is unique to Hope Creek.

8 MR. PRESTON: No, sir. Other utilities are
9 utilizing this particular method to protect themselves against
10 intergranular stress corrosion cracking.

11 DR. CARBON: I am puzzled. Why is there a question
12 here?

13 DR. SIESS: I think the question is whether the
14 measure that has been taken to prevent cracking also prevents
15 the ultrasonic testing needed to detect cracking if you didn't
16 take measures to prevent cracking.

17 DR. CARBON: Estuary either it is being done
18 differently here or --

19 MR. PRESTON: I can just bring you up to date on
20 this particular issue. We did have a meeting with the staff
21 on Monday of this week, where we made a demonstration to them
22 of our ability to inspect this type of clad pipe. The issue
23 we still have is the staff would like us to demonstrate that we
24 can effectively determine the crack on a piece of pipe that is
25 actually intergranularly stress corrosion cracked. We have

1 been unable to obtain a piece of pipe that has that type of
2 a crack in it, and is also clad the way our pipe is clad. That
3 is basically where we stand at the moment.

4 DR. SIESS: There have been tests made of UT tech-
5 niques on actual cracks, haven't they, in the more recent
6 rounds? Some of the earlier tests were made on artificially
7 formed cracks but they have taken out some actual pipe that had
8 intergranular cracks and tested them.

9 MR. SCHWENCER: But I am not aware of in this
10 configuration.

11 DR. SIESS: No, but there are none with the clad?

12 MR. SCHWENCER: None I am aware of, no.

13 DR. SIESS: Is the issue the clad itself or surface
14 of the clad?

15 MR. PRESTON: Sir, I believe the issue we have
16 with the staff is the fact that our pipe is both OD and ID clad.
17 The demonstration we did for them on Monday, the only pipe we
18 could get that resembled our pipe was pipe that I believe had
19 what they call a belly band applied to it, or OD. What they
20 would like is a pipe that is OD and ID clad that has cracks in
21 it, and then for us to demonstrate we can adequately see those
22 cracks.

23 DR. SIESS: What piping is this used on?

24 MR. PRESTON: It is the recirculation piping.

25 DR. SIESS: All the recirculation? There is sort of

1 a Catch-22. If the thing really works, you will never find any
2 cracks in a pipe to test it on. So if you have got a really
3 good system to prevent intergranular stress corrosion cracking,
4 you can't use it. The more perfect the system is, the less
5 chance there is of being able to use it because if it is perfect,
6 you are never going to find a pipe that was naturally cracked.
7 So how do we get out of this one?

8 MR. SCHWENCER: I don't know whether we know today
9 how we are exactly going to get out of it. I can conceive ask-
10 ing for something as a licensing condition that says we might
11 like to take a look at sample or require some demonstration as
12 he has indicated. We had asked to see if we could get a speci-
13 man to demonstrate that it can do it. Whether they can develop
14 a laboratory between now and the time we would consider it
15 timely resolved, they can find a test specimen, that may be one
16 way it gets resolved.

17 DR. SIESS: It would be nice if they could demon-
18 strate it, but I think before I would want to ask them to do it,
19 I would like to be sure it is possible to do it. I hate to ask
20 somebody to do something that is impossible. I wonder if you
21 metallurgists or metallurgical consultants have suggested it
22 is possible to produce an intergranular stress corrosion crack
23 in something like this.

24 MR. SCHWENCER: I think the safe thing to say is it
25

1 is under active discussion and they may convince us on argument
2 that they are okay, but at present, we have a concern, but
3 we are not satisfied yet.

4 DR. SIESS: You have one obvious approach. That is
5 to let it go as it is, and when it cracks, you will find out.
6 We seem to be accepting the leak-before-break concept.

7 DR. SIESS: Right now I would say there has been
8 enough intergranular stress corrosion cracking in BWR piping
9 system that I don't particularly feel uncomfortable about it
10 being a calamity. It is going to be detected, and it is going
11 to be fixed. A lot of the cracks we found weren't found by
12 UT. A lot were found by water coming out of them. The first
13 we found, if I recall, at Nine Mile Point was the leak detec-
14 tion system was it dripped on somebody's head.

15 MR. SCHWENCER: That certainly would be one way
16 if that became the first specimen to test.

17 DR. SIESS: It would be a nice way because you
18 might never get it.

19 Yes?

20 DR. MICHELSON: Clarification.

21 Is Hope Creek now going to use four injection lines
22 for LPCI, directly into the vessel side? I read it two
23 different ways in two different parts.

24 DR. SIESS: The Newbold Island modification, does
25 it stay for Hope Creek?

1 MR. PRESTON: Yes, sir; that is correct.

2 DR. SIESS: How did you make the attachments to the
3 vessel and what are the materials for the piping system?

4 MR. PRESTON: For that question I would like to
5 bring up Mr. Rogozenski to respond to that.

6 DR. MICHELSON: While he is coming up, you can
7 answer a couple other questions. The HPCI, as I understand it,
8 will inject into the core spray line. Is that still the case?

9 DR. SIESS: The HPCI goes in through four nozzles.

10 DR. MICHELSON: No, that is the LPCI. I read one
11 place it sent through core spray and read another place one
12 of the alternate flow paths would be to the feedwater line. So
13 I am not sure which is which. What is the intention?

14 MR. PRESTON: The HPCI injects into the core spray
15 line.

16 DR. MICHELSON: Core spray sparger. What material
17 are you building the core spray line out of?

18 MR. PRESTON: Mr. Rogozenski will address that.

19 DR. MICHELSON: Another related question, not a
20 materials question, that is, this is a question to the staff:
21 Is there any other plant in operation already that uses HPCI
22 injection into the core spray sparger?

23 MR. SCHWENCER: I don't know. We will have to check.

24 DR. MICHELSON: I will be surprised, but perhaps
25 there is one around somewhere. I would like to know what

1 knowledge we have of the hydraulic instabilities that you will
2 get into when you have a depressurizing reactor flashing steam
3 in a core spray sparger and injecting cold water with a HPCI at
4 the same time.

5 DR. SIESS: I thought high-pressure core sprays were
6 standard now.

7 DR. MICHELSON: No, but the standard is to inject
8 into the feedwater.

9 DR. SIESS: No high-pressure core spray.

10 DR. MICHELSON: Yes, but there are none of those in
11 operation. We don't have the experience yet. We don't get
12 accidents --

13 DR. SIESS: That particular item is of interest
14 because it was a Newbold item feature intended to make the plant
15 safer.

16 MR. PRESTON: I would like to clarify a response
17 that I gave you, Mr. Michelson. I think this might clear up
18 some of the discrepancies in the literature. One of the changes
19 we initially made at Newbold Island, Hope Creek, was with the
20 high pressure coolant injection system. It was redesigned to
21 permit injection through the core spray sparger rather than
22 into the down-comer region through the feedwater system. As a
23 result of ATWS considerations, a later change was made such that
24 high pressure injection would be made through both the core
25 spray and feedwater systems.

1 DR. MICHELSON: That is the present arrangement.

2 MR. PRESTON: Yes, sir.

3 DR. MICHELSON: So part is going into the core
4 spray sparger. So to the extent it goes into the sparger might
5 question pertains. If you don't inject in the sparger the
6 problem goes away. But I would like to see addressed somewhere
7 your understanding and knowledge or test data, whatever, on
8 what happens when you inject cold water into a confined core
9 spray sparger in a reactor which is depressurizing, and there-
10 fore the sparger water is also depressurizing, it is partly
11 flashed to steam already, and you are injecting cold water into
12 the system.

13 MR. PRESTON: Sir, that would be from a material
14 point of view.

15 DR. MICHELSON: From the -- mostly the hydraulic
16 instability you get into from water hammers, condensing knocks
17 and whatever. That reflects on materials of construction.

18 DR. SIESS: Let me ask a question. I thought that
19 many of the changes that were made for Newbold Island became
20 standard in subsequent BWR designs. Am I completely wrong on
21 that? I thought the high-pressure core spray was in BWR 5's
22 and 6's.

23 DR. MICHELSON: Yes, but they are not in operation
24 yet. The ones you could get some experience on. You have got
25 to be in operation a while and get a depressurization and an

1 injection before you will ever see the phenomenon.

2 DR. SIESS: That was the last of the fours, was it,
3 and Limmerick was done before this, and Susquehanna.

4 DR. MICHELSON: Limmerick, remember, we asked the
5 same questions.

6 DR. EBERSOLE: Carl, I would like to get further
7 into that because I think GE experimentation and testing has
8 shown the actual literal spray function is no longer needed
9 with the countercurrent flow phenomenon. So this would tend
10 to imply that who cares if the spray ring falls down as long as
11 the water goes in.

12 DR. MICHELSON: You do care, of course, if the,
13 if you somehow break the pipe outside the reactor vessel in
14 the process of doing this.

15 DR. EBERSOLE: Oh, yes, outside, I agree.

16 DR. MICHELSON: It is a stainless steel pipe and
17 you introduce a water hammer --

18 DR. EBERSOLE: You are talking about the external
19 portion of the cracking? I see that clarifies it. I thought
20 you were talking about the ring itself.

21 DR. MICHELSON: No, I am not too concerned about
22 that. The problem originates from the confinement of the ring.

23 DR. SIESS: You have raised a concern. I am trying
24 to figure how it might be addressed. Obviously Hope Creek does
25 not have any operating experience. I gather from what response

1 we have gotten that this isn't something tha' has come up
2 before that you have thought about, is it, or GE has thought
3 about?

4 MR. PRESTON: To my knowledge, no, sir.

5 DR. SIESS: Is it something you would like to have
6 them try to address at the full committee meeting, consider
7 it a generic matter we should explore --

8 DR. MICHELSON: We have already explored it a little
9 in discussing this potential with core spray systems in general.
10 I just wondered since this is now a specific example of a
11 plant about to go on line, I wondered if they had any experimen-
12 tal information or otherwise on it?

13 MR. PRESTON: Sir, we would attempt to provide the
14 additional information before the two days are over in response
15 to Mr. Michelson's questions.

16 DR. SIESS: Okay. If you can get something at this
17 meeting, if not we will decide whether we want to hear it at
18 the full committee meeting.

19 DR. MICHELSONS: I would like to get the material
20 answers which the gentleman was going to give us.

21 DR. SIESS: What materials are used in the piping
22 that leads into the vessel?

23 DR. MICHELSON: Yes, both the LPCI and HPCI.

24 MR. ECKERT: While he comes up, the other question
25 you asked, if we can't get back to you today or tomorrow, we

1 will certainly try to get to you before the full committee
2 meeting.

3 DR. MICHELSON: I am not trying to trap you or
4 anything. I just wondered what information you might have or
5 what thoughts you have on the matter, whatever.

6 MR. ECKERT: We will get it to you.

7 DR. ROGOZENSKI: Joe Rogozenski, Principal Engineer,
8 Piping and Materials, Public Service.

9 I would like to address the safe-end connections
10 to the reactor pressure vessel nozzles. There are questions
11 regarding the low-pressure injection. That is carbon steel
12 and for the core spray, 304(1) grade. We would have 304(1) grade
13 for the -- so as far as investigation corrosion cracking, we
14 have applied a remedy through the application of the low carbon
15 grade stainless steel.

16 DR. MICHELSON: The LPCI injection then will be a
17 stagnant leg in a carbon steel system, then, below the water
18 line? Is that right?

19 DR. ROGOZENSKI: Non-flowing, right. It would be
20 stagnant.

21 DR. MICHELSON: Do you have any comments on the
22 water chemistry control for that leg?

23 DR. ROGOZENSKI: Sir, I would have to defer the
24 water chemistry, quality of the water to the --

25 DR. MICHELSON: That is all right.

1 DR. SIESS: They are going to address water chemistry
2 tomorrow.

3 DR. MICHELSON: Thank you.

4 DR. SIESS: Max.

5 DR. CARBON: My curiosity is getting the better of me.
6 With regard to item three, why wouldn't it be practical to take
7 a piece of pipe with some stress core erosion cracking in it
8 and then plate it and see if you can detect it ultrasonically?

9 MR. PRESTON: The pipe that is currently available
10 that has been stress corrosion cracked and cut out of various
11 plants, they have applied the belly band fix as a temporary
12 measure. We can get that particular pipe to sample. The prob-
13 lem is that when they applied the belly band material, or
14 cladding, that the cracks closed up. Therefore, to detect a
15 closed crack kind of defeats the purpose.

16 DR. CARBON: I guess you are saying there is no way
17 to take it.

18 MR. PRESTON: We are anxious, of course, to reach
19 resolution on the issue, and we are looking at a way to resolve
20 the staff's concerns with an actual specimen.

21 DR. SIESS: Did the question come up in your own
22 mind? Did you plan to do UT on this pipe?

23 MR. PRESTON: Yes, sir.

24 DR. SIESS: When you plan it, did this issue come up
25

1 in your own minds, effectiveness of going through the plan?

2 MR. PRESTON: I would like to defer to Mr. Bob
3 Brandt responsible for our SI programs.

4 DR. MICHELSON: I have one more question for the
5 staff.

6 To your knowledge, are there any boiling water
7 reactors now with direct LPCI injection in operation? Is
8 this the first with direct LPCI --

9 MR. WAGNER: Into the core spray spargers?

10 DR. MICHELSON: No, low-pressure injection.

11 MR. WAGNER: I don't know.

12 DR. SIESS: This was a Newbold Island feature again.

13 DR. MICHELSON: This is the only plant that that --
14 with that feature?

15 DR. PRESTON: We understand Limmeric has direct
16 LPCI injection.

17 DR. MICHELSON: Gee, I missed it somehow.

18 DR. BRANDT: I am Bob Brandt, Nuclear Plant Services
19 Engineer.

20 We have been looking at this problem since 1979
21 since we first decided to go with the CRC overlay. At that
22 time it was mutually agreed upon between General Electric,
23 Bechtel and Public Service that the overlay could be inspected,
24 rather, that a code inspection could be performed on this type
25 of joint, based on calibration standards, existing standards.

1 We had the same problem then we have today, in that
2 we couldn't get a clad specimen with a crack in it. We put the
3 cladding on so we don't get cracking.

4 DR. SIESS: Of course, in 1979 we were a lot more
5 optimistic about detecting cracks in anything.

6 DR. BRANDT: Absolutely. Since there there have been
7 a couple of changes. We decided ourselves that just the fact
8 we could see a notch, a code notch in the calibration standard
9 wasn't acceptable to us, either. We have been working with
10 Southwest Research, our ISI contractor and EPRI concurrently
11 on the problem.

12 Until recently we had seriously considered going to
13 field X-ray. The Minac approach since then we have decided
14 against it, because of recent work done on the UT based on
15 Nine Mile Point and Peach Bottom problems, there have been a lot
16 of new developments. And as Mr. Preston pointed out, at our
17 recent demonstration we had Southwest Research demonstrate a
18 technique that will provide considerably improved sensitivity.

19 We still have the same problem with the crack. Our
20 demonstration was two pieces. One was a clad mock-up with the
21 cladding on both the ID and OD, but no crack. Also on a speci-
22 men that had a crack that was developed for one of a series of
23 specimens developed for EPRI by IHI that has a crack in it.
24 These pieces we are working with now. The NRC Materials
25 Engineering Branch is asking us, though, to go further and try

1 to demonstrate on some kind of a crack specimen. That is
2 what we are trying to obtain right now.

3 DR. SIESS: The one you have from IHI, what was
4 that, a fatigue crack.

5 DR. BRANDT: No, an artificially induced stress
6 corrosion crack but it has no cladding on it.

7 DR. SIESS: What is the material, 304(L)?

8 DR. BRANDT: 304(L).

9 DR. SIESS: Anything else on this item?

10 DR. BRANDT: Excuse me. I beg your pardon. The
11 recirculation loop is regular grade, solution-treated.

12 DR. SIESS: Solution-treated?

13 DR. BRANDT: Right.

14 DR. SIESS: Okay.

15 The next item is the GDC-51 compliance, the drawer
16 prevention criteria.

17 (Slide.)

18 DR. SIESS: As I recall, the only issue there are
19 some feedwater valves, and the solution would be some ISI.

20 MR. WAGNER: That is right, augmented ISI.

21 DR. SIESS: Anybody interested in following that up?
22 I didn't think we would be.

23 The next item is solid-state logic modules. As I
24 read the staff report, the question really relates to one type
25 of module and demonstrating its reliability. As I recall I

1 didn't really appreciate that 862, but after the visit this
2 morning, I saw Bailey about 500 times. How many of those are
3 there in the plant?

4 MR. WAGNER: Sir, I don't know.

5 DR. SIESS: Can applicant tell me how many
6 Bailey 862 solid-state logic modules there are? Are we talking
7 about hundreds?

8 MR. PRESTON: I would like to call on Mr. Joe
9 Yaworsky up.

10 MR. YAWORSKY: Joe Yaworsky, Chief Control Center
11 Electrical Engineers.

12 The approximate count is around 2,000, slightly
13 higher.

14 DR. SIESS: The issue suddenly got larger, didn't it?
15 Is the concern with the physical reliability or logic? It
16 says common manual and automatic initial capability. Can staff
17 explain that briefly?

18 Go ahead.

19 MR. YAWORSKY: The concern is that manual and auto-
20 matic calls for the same module. Now according to -- 1979
21 and according to regular guide 1.62, one should keep the
22 commonality of such manual and automatic initiation to a mini-
23 mal. Our position is that we do have redundant circuits which,
24 in case of failure of their module, would still provide a safe
25 operation or shutdown, as the case may be.

1 DR. SIESS: In other words, if one of those several
2 thousand modules failed, it would disable both manual and
3 automatic initiation through that module?

4 MR. YAWORSKY: Through that module.

5 DR. SIESS: What is the staff's position with
6 regard to resolution to this? What are the possible resolutions
7 and where do you stand?

8 MR. WAGNER: I hate to use a cliché, but the
9 Instrumentation and Control Systems branch is reviewing this
10 item.

11 DR. SIESS: That is not a cliché, that is a
12 redundancy.

13 MR. WAGNER: Well, that is the status of it right
14 now.

15 DR. SIESS: What are they reviewing, the whole
16 logic to see if they agree with the level of redundancy?

17 MR. WAGNER: Yes.

18 DR. SIESS: I would have thought that would have
19 been the question they raised in the first place. I mean I
20 would have thought this became an issue because the staff looked
21 at it and said, "Gee, that is not redundant."

22 MR. WAGNER: I believe the staff's concern was
23 more of a separation concern.

24 DR. SIESS: Is anybody interested enough in follow-
25 ing this up that we should try to get somebody from the staff

1 in or should we just leave it to them?

2 DR. MICHELSON: I have one question but not related
3 to the particular concern.

4 DR. SIESS: Can you find another place to ask it?

5 MR. MICHELSON: No, this is the place to ask it.

6 DR. SIESS: Then ask it.

7 DR. MICHELSON: The question is, of the applicant,
8 in the environmental qualification of these modules, what
9 temperature are you qualifying them to?

10 MR. YAWORSKY: These modules meet the environmental
11 qualifications in the mild environment that they are.

12 DR. MICHELSON: Does that mean none of them are
13 located in areas that become -- well, what is your definition
14 of mild environment, temperature-wise?

15 MR. YAWORSKY: Mr. McGuire will answer this
16 question.

17 DR. MCGUIRE: Tim McGuire, Controls Engineer.

18 The equipment of concern here has been qualified
19 to 104 degrees.

20 DR. MICHELSON: One hundred four?

21 DR. MCGUIRE: Correct.

22 DR. MICHELSON: Am I to assume in no location do
23 you exceed 104 degrees on these modules?

24 DR. MCGUIRE: That is correct.

25 DR. MICHELSON: Does that mean all the modules are

1 in the control room or switch gear room.

2 DR. MCGUIRE: They are all located in the control
3 equipment, elevation 102.

4 DR. SIESS: That is the one two stories below the
5 control room?

6 MR. WAGNER: That is correct.

7 DR. EBERSOLE: Is this equipment in cabinets of
8 some sort?

9 DR. MCGUIRE: Yes.

10 DR. EBERSOLE: Do the cabinets, in order to maintain
11 the local temperature low enough, do they have their own
12 little fan systems?

13 DR. MCGUIRE: Yes.

14 DR. EBERSOLE: What happens if I let a painter in
15 some day, and he decides to put drop cloths over everything,
16 including the side-by-side redundant modules, and this equipment
17 is not intelligent enough to know it has got a fever and may do
18 things disruptive to the safety logic.

19 DR. MCGUIRE: First of all, the fan systems provided
20 do have alarms on them and there is a temperature monitor in
21 the cabin. So if the temperature does rise, the operator in the
22 control room is made aware of it.

23 DR. EBERSOLE: I see. So you have, what is it,
24 audible alarm and a drop?

25 DR. MCGUIRE: Yes, an annunciator window, digital

1 logic trunk.

2 DR. MICHELSON: Perhaps I misunderstood your mild
3 environment of 104. Is that actual temperature to which the
4 module was exposed during its test? And then if it is, how does
5 this relate to an all-cabinet situation where the module may be
6 high in the cabinet and must still stay below 104 degrees and
7 what room temperatures are we dealing with?

8 DR. MCGUIRE: The cabinet itself would be in a room
9 at a temperature of 104 degrees.

10 DR. MICHELSON: The cabinet is in a room at 104.
11 So you qualified the modules at somewhat higher temperature
12 then?

13 DR. MCGUIRE: Bailey has assured us in their design
14 rates testing of the modules that they will operate to 104
15 degrees. Above 104 degrees they will experience some drift.

16 DR. MICHELSON: Wait a minute. Now, 104 room temper-
17 atures or actual module temperature.

18 DR. MCGUIRE: I will have to check that.

19 DR. MICHELSON: Because there is quite a difference.
20 The modules may be in cabinets that have heavy heat loads. Is
21 104 the maximum temperature your control room and auxiliary instru-
22 ment room will ever reach?

23 DR. MCGUIRE: I believe the 104 figure was arrived
24 at by assuming that the redundant HVAC systems were lost for a
25 period of 24 hours.

1 DR. MICHELSON: I can't lay my finger on it for a
2 moment because I read so much but I thought somewhere I read
3 under certain loss of power and other circumstances that some
4 of these rooms reached 120 degrees. Maybe I misread. You are
5 saying none ever reach over 104?

6 DR. MCGUIRE: Not the control room or control
7 equipment.

8 DR. MICHELSON: All right.

9 DR. EBERSOLE: It is fair to say then that the
10 operation of the plant is in fact dependent on the air condition-
11 ing system?

12 DR. MCGUIRE: Yes.

13 DR. EBERSOLE: Because what is the safety? I have
14 an observation, not necessarily. Is that correct?

15 DR. MCGUIRE: Operation of the circuits is somewhat
16 questionable above 104 degrees.

17 DR. SIESS: Are these circuits control circuits
18 or protection circuits, or both?

19 DR. MCGUIRE: Control circuits basically. Protec-
20 tion circuits are within the GE cabinets.

21 DR. EBERSOLE: If I go to the control center, do
22 they depend upon the circuits to do what they have to do?

23 DR. MCGUIRE: Referring to the shutdown valves?
24 No, not at that point.

25 DR. EBERSOLE: So you can achieve safe shutdown

1 without the modules?

2 DR. McGUIRE: That is correct.

3 DR. EBERSOLE: So you can argue then that the safety
4 is not dependent on them.

5 DR. MICHELSON: One more clarification. Are your
6 GE modules rated for higher temperatures than Bailey?

7 DR. McGUIRE: I believe GE was given the same
8 temperature.

9 DR. MICHELSON: Generally it is 104. I don't
10 disagree. I just want clarification. So you are talking about
11 both protection system and control systems.

12 DR. McGUIRE: Certainly they are in the same
13 environment.

14 DR. MICHELSON: I think their ratings are probably
15 the same although you have to tell me that.

16 DR. McGUIRE: We will doublecheck.

17 DR. SIESS: Anything else?

18 The next item is Possible Accident Monitoring
19 Instrumentation. Reg. Guide 197, which I have a notice
20 under review.

21 MR. WAGNER: I can elaborate on that, Dr. Siess.
22 The applicant has responded to Reg. Guide 197.2. Just
23 recently the results of the review came back in. Generally,
24 Hope Creek looks okay except for four specific instruments. In
25 fact, I don't even think the applicant knows this.

1 DR. SIESS: That is four out of the entire list?

2 MR. WAGNER: That is right.

3 DR. SIESS: What is a passing grade?

4 MR. WAGNER: Well, I think we will have a meeting
5 to discuss these even further.

6 DR. SIESS: I think we can leave that. I didn't
7 think anybody could get all of them. You don't know what the
8 issues are?

9 MR. WAGNER: The instruments?

10 DR. SIESS: No, the issue. Is it the classification
11 of the instrument, or whether it is there, or range?

12 MR. WAGNER: A little of all issues.

13 DR. SIESS: Okay.

14 The next item, I guess, is the question of minimum
15 separation between non-class 1-E conduits and class 1-E
16 cable trace. I understand there were tests made. Staff wasn't
17 satisfied. I think I heard this morning more tests were being
18 submitted. Is that correct?

19 MR. WAGNER: I don't know if more are being sub-
20 mitted.

21 DR. SIESS: Can you bring us up to date?

22 MR. PRESTON: Yes, that is correct. We do plan to
23 make another submission on that particular open item.

24 DR. SIESS: The test will simulate the situation you
25 have.

1 MR. PRESTON: Yes.

2 DR. SIESS: Of a conduit in a -- cable in a conduit
3 and another cable not in a conduit, is that the issue?

4 MR. PRESTON: That is correct.

5 DR. SIESS: Control of heavy loads.

6 DR. WAGNER: Yes. Regarding control of heavy loads,
7 we have issued our status on phase one and phase two of the
8 control of heavy loads at Hope Creek. We did that in the draft
9 SER. Not SER regarding phase one the applicant recently pro-
10 vided information with which the staff feels we can close out
11 phase one.

12 Now, regarding phase two, I have a report from the
13 Auxiliary Systems Branch who does review this area that there
14 are no problems regarding phase two. We don't anticipate any
15 problems.

16 DR. SIESS: You know, I found the staff's review of
17 that rather interesting. I don't know how many of you read it
18 in detail, but there are conclusions in it, like, these are
19 the legalistic-type things. Design is in compliance with
20 general design criteria, X, Y, Z, but it is not in compliance
21 with the guidelines in regulatory guide, or guideline in a
22 branch technical position.

23 Now, if it is a guideline that it is not in com-
24 pliance with, they are free to argue an alternate way of
25 accomplishing it, right?

1 MR. WAGNER: As long as the alternate method is
2 acceptable.

3 DR. SIESS: Has the staff ever accepted an
4 alternate method to their own guidelines? I sort of get the
5 impression that the staff reviewers say, "This is what the SRP
6 says. These are our guidelines. This is what we will accept."
7 And if somebody comes in with something different and staff
8 finally accepts it, do they put that in the SRP as being an
9 acceptable way or do they still make the next guy argue the same
10 thing through?

11 MR. SCHWENCER: I think practically speaking the
12 standard review plan is like changing the constitution. It
13 is very difficult and time consuming to do that. Chances are
14 the review plan will stay consistent. But what I can say is
15 that when the staff has found an approach acceptable generally
16 industry by their NOPAD method or whatever very quickly learns
17 of this new way of getting something done. Once we have done
18 it, a particular way and it is generic in nature, we do pursue
19 that on the next case.

20 DR. SIESS: Is it harder to change the standard
21 review plan than it is a rule I presume about the same?

22 MR. SCHWENCER: No, rules are harder.

23 DR. MICHELSON: On the control of heavy loads, can
24 you tell me what is the current situation relative to the cask
25 drop, potential cask drop accident?

1 DR. SIESS: Which end are you concerned about, the
2 craft or what it drops on?

3 DR. MICHELSON: I am concerned about the floor it
4 drops on. To help you along, I thought I read "applicant found
5 that it could not tolerate the cask drop. There weren't details
6 as to why. As a consequence, you are focusing on the unlikely
7 nature of the incident instead of on the consequence.

8 MR. SCHWENCER: I think that is essentially correct.
9 I think we have considered the crane is essentially very high
10 reliability, but I am not sure. Have we completed our review
11 of the area, Dave?

12 MR. WAGNER: No, we haven't.

13 DR. MICHELSON: Will there be better information
14 at the time of the full committee meeting on this issue?

15 MR. WAGNER: We can certainly try, Doctor.

16 DR. MICHELSON: Yes, I would like to hear why.
17 Also at that time would you tell me what other plants can't
18 tolerate cask drops and, you know, kind of in general why that
19 is okay now?

20 DR. SIESS: What part of the floor can't tolerate a
21 cask drop? Which area? I thought the cask drop into the spent
22 fuel pool was settled ten years ago.

23 DR. MICHELSON: No. This is the cask drop into the
24 truck loading area. The torus is directly below the floor
25 and you wouldn't want it to go through the floor.

1 DR. SIESS: What is below it?

2 DR. MICHELSON: The torus. If you rupture
3 the torus, then you lose the torus water and you are in poten-
4 tial difficulty if this all causes an isolation as well.

5 DR. EBERSOLE: I would like to comment on that.

6 DR. SIESS: That is an old problem.

7 DR. MICHELSON: Yes. I thought it had gone away
8 long ago.

9 DR. SIESS: It went away with the Mark 29.

10 DR. MICHELSON: That would also help, yes.

11 DR. EBERSOLE: Let me comment. This plant is, I
12 don't know whether it is unique, but certainly it is not
13 designed to tolerate a loss of water in the donut. If it is
14 true, a cask drop would penetrate the concrete above the torus
15 and knock a hole in the torus. I think the consequences get
16 extremely complex after that and possibly lead to the loss of
17 the station. I don't know.

18 It seems that is a place where you could easily pack-
19 age up a small PRA, but it should involve taking the can off
20 the crane, gear boxes and so forth and examining very carefully
21 what failure modes are within the crane, and coming to a con-
22 clusion about a real best estimate of the probability of that
23 accident happening, along with an analysis of what would
24 result from loss of the water in the torus. It is just
25 another, I think, PRA exercise which is well worth your while.

1 MR. PRESTON: Since this particular question did come
2 up on the tour, we do plan to respond in more detail. In a
3 deterministic fashion, I would like to point out we have a
4 failure-proof crane-lifting device to preclude losing the cask
5 on to the floor. But we do plan to look at the consequences
6 and to have some further discussion on this over the next two
7 days, or tomorrow.

8 DR. EBERSOLE: It just proves you will come up with
9 low numbers.

10 DR. SIESS: No. It is single failure-proof. Not
11 quite the same as failure-proof when you start looking at
12 low probabilities.

13 DR. MICHELSON: That is entirely different. You
14 end up with failures that are much higher than you can tolerate.

15 DR. SIESS: You said something about the cask going
16 over certain areas. Cask has to go over the truck area,
17 doesn't it?

18 MR. PRESTON: Yes. What we hope to do is take a
19 look at exactly where on the floor that cask could possibly hit.
20 How much energy it would have coming through the floor area,
21 et cetera. And what proximity that is in relation to the
22 torus, which is really the key point.

23 DR. SIESS: You might consider having the truck
24 always parked under there when the cask -- I think it would
25 absorb a certain amount of energy and spread some load. Well,

1 it would spread some load. How thick is that slab, if a con-
2 crete man can ask a question?

3 MR. PRESTON: Chuck Churchman, could you respond to
4 that?

5 DR. MICHELSON: The same kind of a question is asked
6 which the applicant said he would get information on on the
7 dropping of the drier separator into its pool to make sure the
8 concrete floor is adequate. I assume those areas have been long
9 looked at.

10 DR. SIESS: We looked at the present fuel pool way
11 back but the other I remember being looked at but I don't
12 remember what the answer was. If he is in the back of the room,
13 forget about it.

14 DR. CHURCHMAN: Reinforced concrete slab is at a
15 minimum one foot thick.

16 DR. SIESS: That is not very thick for a cask
17 dropping a hundred feet, is it? Let's go on.

18 The next item is alternate and safe shutdown.
19 What is the issue there?

20 MR. WAGNER: The issue here is that the staff has
21 not completed its review yet.

22 DR. SIESS: You haven't found anything wrong, you
23 just haven't finished?

24 MR. WAGNER: That is correct.

25 DR. MICHELSON: One small question. Which

1 environmental control system maintains the environment in that
2 area?

3 MR. WAGNER: The safe shutdown panel?

4 DR. MICHELSON: Yes. Applicant would probably have
5 to answer.

6 DR. SIESS: Did you hear the question?

7 DR. MICHELSON: Which environmental control system
8 maintains the environment in the shutdown body area?

9 MR. PRESTON: You mean what heating and ventilation
10 system?

11 DR. MICHELSON: Yes. How do you keep it cool enough?

12 MR. PRESTON: Mr. Pavincich will address this.

13 DR. PAVINCICH: There are a number of areas
14 associated with alternate shutdown requirements. The two most
15 significant ones are mode shutdown panel and the second is
16 diesel generator control area. Each of these units is fed by
17 two completely different HVAC units, one is a safety-related
18 unit. The other is a nonsafety-related unit which has power
19 droll that can be hooked up to safety-related systems.

20 It would be possibly triple failure consideration
21 to consider the loss of the areas necessary for us to man the
22 alternate shutdown stations.

23 I think we mentioned earlier those areas would be
24 the cable-spreading room and control equipment room. Fire in
25 this area would not necessarily impinge upon either the two

1 necessary alternate shutdown areas, HVAC systems. We did, how-
2 ever, go to do a further study and ascertain that temperatures
3 within the remote shutdown panel area would not exceed a hundred
4 degrees Fahrenheit for well over 21 hours if it were to lose
5 all its HVAC system. So we have even under a double contingency
6 failure, 21 hours to reconnect that power system.

7 DR. SIESS: Is that with the door to the hallway
8 open?

9 DR. SIESS: What is behind the panel in the room?

10 DR. PAVINCICH: There is about two, three more feet
11 of space, sir, and then there is a wall that joins the reactor
12 building wall.

13 DR. MICHELSON: In the diesel generator area, what do
14 you think the temperatures are going to be?

15 DR. PAVINCICH: In the diesel generator control area?

16 DR. MICHELSON: Yes.

17 DR. PAVINCICH: For what conditions, sir?

18 DR. MICHELSON: For the condition wherein you
19 have had to evacuate the control room and go to the shutdown --

20 DR. PAVINCICH: They should remain at design
21 considerations.

22 DR. MICHELSON: What do you think that is?

23 DR. PAVINCICH: That is about --

24 DR. MICHELSON: This is with engines running and
25 so forth.

1 DR. PAVINCICH: Yes, sir. In that area it is designed
2 about 77 degrees Fahrenheit.

3 DR. MICHELSON: That is the normal temperature.

4 DR. PAVINCICH: Normal, 72 to 77.

5 DR. MICHELSON: With the engines running?

6 DR. PAVINCICH: Yes, sir. They are in a different
7 room.

8 DR. MICHELSON: Then maybe I saw the wrong room.

9 DR. PAVINCICH: Nos, sir. You are looking at, sir,
10 the panels at the end of the diesel --

11 DR. MICHELSON: That is right. I was told those
12 had to be manned during this time in order to get to safe shut-
13 down.

14 DR. PAVINCICH: No. Pointed out to you on elevation
15 137 the switch gear area, that panels --

16 DR. MICHELSON: This is the panel directly in
17 front of the diesel engines. We were told each of those, there
18 is a man down there that could man those. He had a three-way
19 telephone --

20 DR. MICHELSON: Maybe I misunderstood.

21 DR. PAVINCICH: You did, sir.

22 MR. SCHWENCER: I overheard that conversation also
23 and that is what you were told, that there were two people that
24 went different directions. One went directly to start a diesel
25 and the other went to the shutdown --

1 DR. MICHELSON: I understood --

2 DR. PAVINCICH: That is correct, but none of that,
3 sir -- I was the gentleman who told you. I am not likely to
4 change my mind. It was up at the diesel --

5 DR. MICHELSON: I didn't hear well.

6 DR. PAVINCICH: It was diesel generator area where
7 the switch gear was. I showed you the sequence to one side,
8 diesel generator control panels on the other side and I showed
9 you the key and lock switch that would be necessary from the
10 control room. No one has to be in the diesel generator room
11 proper at all.

12 DR. MICHELSON: I thought he did. That was why he
13 had three ways --

14 DR. PAVINCICH: No, sir. The man communicates with
15 the diesel panel. Immediately joining --

16 DR. MICHELSON: Immediately adjoining the diesel
17 generator.

18 DR. PAVINCICH: No, sir.

19 DR. MICHELSON: Right in front of it. Kind of the
20 next compartment over.

21 DR. PAVINCICH: It was a very robust tour, sir.
22 You were no doubt confused.

23 DR. SIESS: That was not in the diesel generator
24 room. We went up on a little platform.

25 DR. PAVINCICH: Yes.

1 DR. SIESS: No, it was in the room next to it.

2 DR. PAVINCICH: The upshot of your question is
3 it would take a triple contingency failure to jeopardize the
4 FVAC system --

5 DR. SIESS: The local --

6 DR. MICHELSON: In the room right in front of the
7 engine. I am looking right at it.

8 DR. SIESS: Let's get one thing straight. Local
9 control for the diesel generator is not required to run the
10 alternate shutdown --

11 DR. PAVINCICH: Oh, yes, it is part of our plan.
12 An operator may be required; may.

13 DR. SIESS: May have to go there?

14 DR. PAVINCICH: May have to go to the diesel generator
15 control panel which is not the panel that Mr. Michelson thinks
16 is in front of the machine.

17 DR. MICHELSON: Okay. Next floor up?

18 DR. PAVINCICH: It is the next floor up.

19 DR. SIESS: Okay.

20 DR. EBERSOLE: Then the alternate shutdown process
21 involves working the alternate --

22 DR. PAVINCICH: It is where the switch gear was.

23 DR. EBERSOLE: Involves working this panel in
24 conjunction with working this other center we were talking
25 about.

1 DR. PAVINCICH: That is correct.

2 DR. EBERSOLE: Using voice transmission in some
3 fashion.

4 DR. PAVINCICH: They have sound-powered phones, a
5 PA system and two-way radios.

6 DR. EBERSOLE: Does this mean the man at the
7 alternate shutdown panel is really sort of a dispatcher, func-
8 tion dispatcher by voice control?

9 DR. PAVINCICH: Senior reactor operator would be
10 the --

11 DR. EBERSOLE: Can functions eliminate from the
12 alternate shutdown panel by hard wire?

13 DR. PAVINCICH: Yes, sir.

14 DR. EBERSOLE: It is capable if something malfunc-
15 tions within it.

16 DR. PAVINCICH: When the shutdown panel is manned and
17 transfer switches are thrown, he is connected hard wire.

18 DR. EBERSOLE: It can also send control signals
19 out by hard wire.

20 DR. PAVINCICH: Yes, sir.

21 DR. EBERSOLE: As well as voice control.

22 DR. PAVINCICH: Oh, yes, sir. He is controlling.
23 The man dispatched to diesel generator is only under hypothetical
24 condition got a fire-induced standing trip, could be on the
25 diesel generator control circuitry. When the gentleman goes to

1 the area, by throwing the area he removes that interface with
2 the main control room. He then starts the diesel, and everything
3 takes off on its own. He doesn't do anything else essentially
4 unless additional problems may come up.

5 DR. EBERSOLE: If I were to hypothetically go blow
6 up the alternate shutdown panel, what would happen?

7 DR. PAVINCICH: Nothing. You would have interfered
8 with the control on one mechanical division. This would have
9 caused the operator in the main control room to bring the unit
10 down.

11 DR. EBERSOLE: On another channel.

12 DR. PAVINCICH: Yes, sir.

13 DR. EBERSOLE: Thank you.

14 DR. MICHELSON: Now that I have got straightened
15 out as to where the diesel control area is, let me ask the
16 question. You say it is about 77 degrees there. Is this with
17 or without normal ventilation, keeping in mind normal ventila-
18 tion may or may not be available during a fire?

19 DR. PAVINCICH: That would be with normal ventilation
20 that would normally feed that would be available immediately,
21 assuming even loss of off-site power, the ventilation would be
22 immediately available upon starting of that diesel generator
23 unit.

24 DR. MICHELSON: Okay.

25 DR. PAVINCICH: It would load up automatically and

1 load up its one ventilating system that was supporting --

2 DR. MICHELSON: There is no reason to believe the
3 fire and smoke would in any way interfere with that particular
4 ventilation?

5 DR. PAVINCICH: No, sir, not in its origin place.

6 DR. SIESS: Thank you.

7 The next item has to do with the diesel. Staff
8 tells me this has been resolved because applicant has described
9 how he will deliver fuel oil.

10 MR. WAGNER: Yes, sir.

11 DR. SIESS: And it is acceptable to the staff.

12 DR. EBERSOLE: I see no other place to open this
13 topic so I have to do it here.

14 DR. SIESS: Well, no, you don't. Do it at the end
15 of this if it is not on this list.

16 DR. EBERSOLE: You want to relate it to the diesel
17 generator at this time?

18 DR. SIESS: No. This is a particular open item.
19 We will take them up one by one. Then we will go back to
20 general things.

21 DR. MICHELSON: Does this open item include the
22 problem of the diesel storage tanks in the basement of the
23 diesel area?

24 DR. SIESS: This open item dealt only with how fuel
25 oil would be delivered to the site from the flood waters 12 feet

1 overgrade.

2 DR. MICHELSON: Some other time we will discuss the
3 fire protection problem. Okay.

4 DR. SIESS: What subject, fire?

5 DR. MICHELSON: Fire protection.

6 DR. SIESS: 3.6 is the next item, "Filling of Key
7 Management Positions". Staff couldn't sign off because all the
8 positions haven't been filled. They have a description but they
9 don't have the names of the people going into them. Is that a
10 fair statement?

11 MR. WAGNER: Yes. I think I should set the scene
12 here first. Public Service underwent a rather large corporate
13 reorganization right as --

14 DR. SIESS: We are familiar with that. Let's just
15 stick to what the issue is. Assume we know the background.

16 MR. WAGNER: Okay.

17 DR. SIESS: Any questions on this?

18 Next is a series of items all relating to the
19 training program. You might just summarize the status on that.

20 MR. WAGNER: Yes. Let me elaborate on some of these.
21 Since the SER was issued, we have had a meeting with the appli-
22 cant. And generally, the applicant has satisfied us on most
23 of these concerns. We do have one outstanding concern. That
24 has to do with a response to generic letter 84-10.

25 To be more specific, Public Service was planning, is

1 calling RO experience at Salem as comparable experience to be
2 used on Hope Creek.

3 In accordance with, I believe 5525(b) of the
4 Commission's regulations.

5 DR. SIESS: Where does that come in on this? That
6 would seem to be operator qualification?

7 MR. WAGNER: I don't know. I would have to look at
8 it. That is essentially the only thing we consider outstanding.

9 DR. SIESS: You are talking about what?

10 MR. WAGNER: Generic letter 84-10.

11 DR. SIESS: Interesting. That related to training?

12 MR. SCHWENCER: Generic letter 84-10 related primarily
13 to the experience that the operating license --

14 DR. SIESS: That is what I thought.

15 MR. SCHWENCER: -- would have in initially --

16 DR. SIESS: That is my problem.

17 MR. SCHWENCER: I think what Dave was saying, if I
18 understood correctly is, in the process of going through these
19 items with the applicant we learned --

20 DR. SIESS: Okay.

21 MR. SCHWENCER: The plans to use experience at Salem
22 as qualified filing, meaning this industry guidelines would be
23 acceptable. The concern the staff has, of course, is that
24 Salem is a PWR.

25 DR. SIESS: We have another item on the agenda for

1 staffing somewhere. Current status of staff is on the agenda
2 under nuclear-related operating experience of key personnel. We
3 will hear about that whenever that comes up. We will want to
4 hear a lot about that. So we will get back to that item and you
5 can explain the situation.

6 Item 13 is a computer model. You must provide a
7 description and you haven't gotten it yet. Is that the situation?

8 MR. WAGNER: Yes, sir.

9 DR. SIESS: I know of other plants that have
10 developed this sort of thing. Is the staff reviewing the
11 whole computer model or has industry sort of gotten together
12 on the models and it is just a question of site-specific charac-
13 teristics?

14 MR. WAGNER: Dr. Siess, I don't know the details of
15 the model.

16 DR. SIESS: Let me ask applicant. Have you developed
17 your own computer model for this dose assessment thing or is
18 that say one previous people are using?

19 MR. PRESTON: I would like to have Mr. Yewdall come
20 up and respond to this.

21 DR. SIESS: I don't want details of the model. Are
22 you doing your own?

23 DR. YEWDALL: Bob Yewdall, Public Service.

24 We are currently planning to use Pickard, Lowe and
25 Garrick's model. That is I think a well known model and will

1 be put on Public Service hardware. Thank you very much.

2 Procedures generation package has not been submitted.

3 MR. WAGNER: That is right. The submission date is
4 January 1985.

5 DR. SIESS: This is all procedures, not just emergency
6 procedures or is it emergency procedures?

7 MR. PRESTON: Dr. Siess, that is emergency procedures.

8 DR. SIESS: Any questions?

9 The last item on my list and your list is human
10 factors engineering, an area in which we are all expert.

11 MR. WAGNER: Maybe a brief summary would help.

12 Chapter 18 of the SER. It is noted the staff does
13 an audit, in this case of Hope Creek, of the control room
14 design, does an audit of the control room design review. We
15 also review the SBDS. Recently the control room design review
16 was performed. And the staff results from that indicate Hope
17 Creek is doing well. They have done a good job of identifying
18 the human engineering discrepancies, and they are on a good
19 course towards resolving these discrepancies. As far as SPDS
20 goes, we are expecting a report on the -- expecting the safety
21 analysis in December.

22 DR. SIESS: What did the review team think of the
23 extensive use of the CRT? Was that good or bad, or did they
24 ignore it because it is not hard-wired?

25 MR. WAGNER: I don't know what their purposes were

1 on the CRT. I will try to find out.

2 DR. SIESS: Is that review done by staff or staff
3 consultants?

4 MR. WAGNER: It is done by the staff.

5 DR. SIESS: Any questions?

6 Staff has a long list of --

7 DR. MICHELSON: Before we leave outstanding items, I
8 do have a question but I thought you meant on the first fifteen
9 items.

10 DR. SIESS: That is exactly what I meant.

11 DR. MICHELSON: I think I would like a clarification
12 on whether or not there are two additional items, or what status
13 is. One is fire protection. By the absence of fire protection
14 as an outstanding item, how do I interpret it?

15 MR. WAGNER: We have addressed it in section nine
16 point five.

17 DR. MICHELSON: No. I mean in the list. I gather
18 there are no more outstanding issues on fire protection;
19 correct?

20 MR. WAGNER: That is right, except for --

21 DR. MICHELSON: The next one is, I know applicant
22 used fibrous insulation throughout inside of containment.

23 MR. WAGNER: Yes, they do.

24 DR. MICHELSON: You address this in the SER by saying
25 it doesn't plug the sump, therefore it is a nonproblem. I

1 think there is more to it than that. So when will be the appro-
2 priate time to pursue the applicant's view on the presence of
3 fibrous insulation on the use of cyclone separators to clean
4 the water for their RHR and core spray pumps?

5 DR. SIESS: Well, there is a place on the agenda
6 we will find and if there is not we will put one there.

7 DR. MICHELSON: Okay.

8 DR. SIESS: We should give the applicants some
9 warning though as to what the subject is. They need to get
10 people in if they haven't already. Did you hear the question?

11 MR. PRESTON: Yes, sir. This morning that was
12 brought to our attention on the tour. We are currently research-
13 ing the fiber glass and possible impact on the bearings, et .
14 cetera. We are looking at that. We hope to have some further
15 discussion on it tomorrow.

16 DR. SIESS: If you have something, let us know.

17 DR. MICHELSON: Yes, I think if they are not
18 prepared, it would be better just to let it be a five-minute
19 presentation at the full committee or something.

20 DR. EBERSOLE: May I ask a little refinement?
21 These seperators must certainly in the engineering design of a
22 source term for the contaminants which they are suppos to
23 remove. I would like to know what that material is, the con-
24 text of what it is and what its concentration is. It is
25 density relative to earth.

1 MR. PRESTON: The fiber glass material?

2 DR. EBERSOLE: Not merely that. Dirt. Whatever
3 else you may regard as the integrated contaminant mixed with
4 that little machine must clean up.

5 MR. PRESTON: Yes, we will attempt to provide that
6 also.

7 DR. MICHELSON: That takes care of it.

8 DR. SIESS: Okay. I would suggest that confirmatory
9 items, in most cases they are just that. If there might be
10 some of those somebody would like to know a little more about
11 the status of, did any of those come up in anybody's mind? SER
12 did a pretty good job of explaining the status. I looked at
13 the list of license conditions. That is where we find the
14 cask drop accident. But that didn't relate to our question.
15 That simply related to how they kept it from going over certain
16 areas, I believe.

17 Are there any of those anybody would like to hear
18 more about? It seemed to be an unusually short list.

19 MR. WAGNER: Dr. Siess, I would like to add that
20 there are no differing professional opinions.

21 DR. SIESS: All right. Thank you. Okay. If I
22 find my agenda. It seems that covers staff items A and C.

23 MR. WAGNER: That is right.

24 DR. SIESS: We will have something from I&E tomorrow.
25 From here on out we will be basically hearing presentations

1 initiated by the applicant, but with the staff on a stand-by
2 basis as needed.

3 I think without further ado, I am going to go as
4 long as I can stand it without a break. We got started about
5 2:30 and I am aiming for no later than about 6:30 tonight, I
6 think, though if we are in the middle of something I might
7 stretch it. If anybody has a dinner engagement, that doesn't
8 apply to the committee. They are used to working late.

9 DR. EBERSOLE: Chet, I have been looking around.
10 Even in the topical, in the index, I didn't find anything much
11 in the matter of the mainfeed water analysis. It is not even
12 listed as a topic. Yet I see in one of these listed there
13 is an interim, what is it, short-term feedwater analysis said
14 to be on 6.2.3.

15 DR. SIESS: These are confirmatory items, Jess?

16 DR. EBERSOLE: Yes, yet I don't find anything,
17 as a matter of fact, 6.2.3 is secondary containment. So there
18 is some kind of misprint or foulup.

19 MR. WAGNER: I will claim responsibility for that.

20 DR. EBERSOLE: Mainly I open the topic because I
21 think we all know the main feedwater system is the most fre-
22 quent culprit in excessive shutdown frequency. I think we
23 would like to hear why we can't begin to approach the Japanese
24 frequency of trips which is one every three years, especially
25 in the feedwater control area, not invoking SCIC or other main

1 feedwater sources after you get a trip or certainly not
2 inducing trips. In short, I found nothing on what I think is
3 the most critical system in respect to causing spurious shut-
4 downs, at a million dollar a crack and challenge to the safety
5 system.

6 DR. SIESS: You said you saw nothing?

7 DR. EBERSOLE: Nothing in the index, nothing in the
8 text.

9 DR. SIESS: Index of what?

10 DR. EBERSOLE: SER.

11 DR. SIESS: Is there a standard review on trips
12 caused by main feedwater?

13 MR. WAGNER: Just a moment, please.

14 DR. SIESS: I think maybe it is not a safety issue.

15 DR. EBERSOLE: Typically the minimal challenges a
16 year has not impressed the staff. That is a linear effect on
17 safety.

18 DR. SIESS: Applicant might be thinking about this.

19 DR. EBERSOLE: It has a linear relationship on
20 safety. Frequently you have to ask it to do what it is to do.

21 DR. SIESS: I think the staff's only concern is
22 that it trip.

23 DR. EBERSOLE: Tripping is the first stage of
24 getting into trouble.

25 DR. SIESS: I tell you what, let's go on and let

1 the staff be thinking about this and see -- you understand my
2 question, don't you? I am not sure the staff considers feed-
3 water mismatched trips to be a safety issue.

4 MR. WAGNER: I will check on that, Dr. Siess.

5 DR. SIESS: Mr. Ebersole thinks any challenge to
6 the trip function is something to be avoided, but I don't
7 think that is in your standard review plan or in the regulations
8 anywhere.

9 DR. EBERSOLE: We are finding that a little more
10 especially if it involves invoking new emergency equipment
11 response.

12 DR. SIESS: Yes. The applicant, I am sure, has a
13 concern about this because it affects his availability and reli-
14 ability. He may want to think about it in the meantime, too,
15 but I believe the general design criteria simply say the plant
16 shall trip when you want it to trip and doesn't care how many
17 times it trips.

18 DR. EBERSOLE: That is right. I might observe my
19 feelings are reinforced by recent findings, of course.

20 DR. SIESS: No statements, just questions. Remember
21 the rules.

22 DR. EBERSOLE: Right.

23 DR. SIESS: New rules, but I am going to enforce
24 them as much as I can.

25 We will turn this over to Mr. Eckert.

1 MR. ECKERT: Thank you, Mr. Chairman.

2 Good afternoon, gentlemen.

3 DR. SIESS: I needn't remind you, try not to repeat
4 what we heard this morning.

5 MR. ECKERT: Yes. I do have a couple comments I
6 thought I might make before we started here.

7 DR. SIESS: I know there are some items here on
8 status, plant start schedule. I thought we got that at the
9 training center this morning.

10 MR. ECKERT: You may notice on the agenda that item
11 3.3, "Seismic Design of Plant and Equipment" is scheduled for
12 later on today. We are running late. Our concern is that our
13 consultant who is going to have part of this story can only be
14 here today. So we can't let that carry over until tomorrow.

15 DR. SIESS: Right. We know that.

16 MR. ECKERT: We may try to push things around a little
17 in order to accommodate that situation.

18 DR. SIESS: You can put it on right now if you want.

19 MR. ECKERT: I would propose to go through the first
20 introduction which is pretty short. Then rather than going
21 into organization and management section, we will put him on
22 next and come back later with the organization --

23 DR. SIESS: Fine.

24 MR. ECKERT: We will start our presentation with a
25 brief overview of the Hope Creek Plant and its features.

1 Following that, we will move into organizational technical discussion
2 in accordance with the agenda. Much of what I will say here
3 you have picked up through the course of the tour. We thought
4 it would be appropriate to put it on the record at this time.

5 To start, let me talk briefly about Hope Creek
6 Generating Station. It is a single unit BWR, net electrical
7 output of 1,067 megawatts. Public Service owns 95 percent of
8 the plant and Atlantic Electric owns the other five percent.
9 It will be operated by Public Service Electric and Gas Company.
10 Bechtel was the architect engineer constructor with a major
11 assist by Public Service people.

12 The nuclear steam supply and turbine generator
13 manufacturers was General Electric. The plant will be operated
14 by Public Service Electric and Gas Company. The site, as you
15 know, is on the Delaware River immediately adjacent to our
16 generating station and it is a -- Salem Generating Station and
17 it is a cooling turbine installation. Preconstruction ACRS
18 review resulted in a favorable letter in 1974. The construction
19 permit was issued in 1974 but construction did not start until
20 1976, following protracted state environmental reviews.

21 Hope Creek was originally a two-unit plant. The
22 second unit was cancelled in 1981 when our load projections
23 could no longer support the need for the unit. We are sched-
24 uled to load fuel on Hope Creek on January of 1986. We are
25 working for a target date, instead of January, December 1st of

1 1985. We hope to be on the December 1984 ACRS full committee
2 agenda.

3 Very briefly that is my introduction. I would like
4 to now turn the discussion over to Bill Gailey who will give you
5 an overview of the Hope Creek plant.

6 Bill?

7 MR. GAILEY: Thank you, Dick.

8 (Slide.)

9 MR. GAILEY: Good afternoon. My name is Bill
10 Gailey, Chief Project Engineer of Hope Creek for Public Service.
11 I am going to give you a summary of certain Hope Creek design
12 features which are either unique or will enhance the safe
13 operation of the plant. This overview is intended as an intro-
14 duction to our technical presentations which will follow this
15 afternoon and tomorrow.

16 Many of the things I intended to give an overview
17 on were touched on either during the tour this morning or in
18 the discussion this afternoon. So I will try to pass over
19 there in the interest of time.

20 Hope Creek is a BWR 4-5 NSSS system. It has a Mark
21 1 containment which is the inverted light bulb and suppression
22 chamber. Ultimate heat sink for the plant is the Delaware
23 River which feeds the service water system. Waste heat from
24 the condenser is dissipated by the circulating water system
25 through the cooling tower.

1 (Slide.)

2 MR. GAILEY: Next I will discuss certain aides
3 which enhance engineering of the plant over the years. First,
4 scaled model of the plant was developed. I believe you saw
5 the drywall model of unit 2 in the training center this morning.

6 PSE&G personnel spent more than 20,000 manhours
7 conducting design reviews which utilized the model. Major con-
8 cerns such as ALARA, studies on maintainability and accessibil-
9 ity, as well as equipment and constructionability were addressed
10 addressed.

11 There is a picture of the model.

12 (Slide.)

13 MR. GAILEY: You can see the blue tag in the front
14 right under, about in the center of the slide. That was put
15 on by our operations people to reserve space for accessibility
16 for the equipment removal.

17 (Slide.)

18 MR. GAILEY: In 1977, we conducted a control room
19 operability review using a full scale control room mock-up.
20 The review team was made up of Public Service Engineering and
21 Operation personnel, General Electric, Bechtel, Bailey Meter
22 Company, and significantly, Peach Bottom Operations personnel.

23 The purpose was to make sure from a human engineer-
24 ing standpoint that the latest industry experience including
25 actual plant operations, were being factored into the Hope

1 Creek Control Room design.

2 (Slide.)

3 MR. GAILEY: Third is the simulator which you saw
4 this morning which is identical to the control room. I won't
5 dwell anymore on that.

6 I would now like to cover certain features of
7 Hope Creek which are unique. First is the reactor building;
8 secondary containment, a cylindrical reinforced concrete struc-
9 ture with a reinforced steel-lined dome. The purpose of this
10 particular design is to provide as low a leakage structure as
11 possible.

12 FRVS, filtration, recirculation and ventilation sys-
13 tem has been included to recirculate and filter the atmosphere
14 in the reactor building. This system has six-25 percent
15 capacity recirculation units which include charcoal filters
16 and provide cooling and filtration to the entire reactor
17 building.

18 FRVS is designed to collect air-borne contamination
19 released to the reactor building and by mixing, filtering and
20 maintaining negative pressure minimized radio active releases.

21 DR. MICHELSON: I have a question for clarification.
22 The reactor building appeared originally to kind of be just the
23 cylindrical portion. Later you expanded into the corner rooms
24 to incorporate them as part of the reactor building. Are the
25 corner rooms included as a part of the FRVS system? Its fans

1 are in the cylindrical portion but does the ventilation, duct-
2 ing and everything come from the corner room areas?

1 MR. GAILEY: It primarily handles the cylindrical
2 portion, certain -- in the square area of blowout panels.

3 DR. MICHELSON: I am thinking of normal ventilation
4 which I thought --

5 MR. GAILEY: Normal_y FRVS would handle everything
6 within the cylindrical part.

7 MR. PRESTON: Roger will provide additional
8 information.

9 DR. MICHELSON: This is where you get confusion
10 between what you call the reactor building and what used
11 to be the reactor building. What you now --

12 DR. DREWNOWSKI: Ron Drewnowski, supervising
13 site engineer. You are correct. We are using the square
14 section also as the reactor building. That area is serviced
15 by the FRVS system.

16 DR. MICHELSON: Does its duct work come through
17 into the cylindrical portion up to the fans, which I think
18 those fans are in the top portion of the cylindrical part
19 of the reactor building?

20 MR. DREWNOWSKI: They are in the same --

21 DR. MICHELSON: So the duct work comes back and
22 forth through the concrete wall.

23 MR. DREWNOWSKI: That is correct.

24 MR. GAILEY: In addition to the two main normal
25 isolation stop valves, a third valve has been added to each

1 main steam line. This was added because of its low leakage
2 characteristics to minimize leakage during shutdown.

3 (Slide.)

4 MR. GAILEY: In addition, a seal air system
5 was added to further reduce leakage during main steam
6 isolation.

7 (Slide.)

8 MR. GAILEY: Another unique feature is the main
9 control room. Although not unique to public service, which
10 has implemented its concepts for the last 20 years, it
11 does differ from the standard BWR plant. Our control room
12 utilizes low voltage, compact layouts, panel arrangements you
13 saw this morning, and computerized display system.

14 The control room provides operators with an
15 effective and reliable means for the safe operation of the
16 plant.

17 DR. EBERSOLE: May I ask about the third stop
18 valve and all the investment in it? Is that put in on the
19 thesis that you are trying to stop the flow of contaminated
20 steam from a damaged core?

21 MR. GAILEY: Not necessarily from a damaged core.
22 It was put in, it is a slow acting valve. It was put in to
23 prevent leakage through the normal two fast-acting main
24 steam isolation valves into the turbine area during shutdown.

25 DR. EBERSOLE: For an undamaged core?

1 MR. GAILEY: It would apply to both.

2 DR. EBERSOLE: Say again?

3 MR. GAILEY: Pardon me?

4 DR. EBERSOLE: What do you say?

5 MR. GAILEY: It was for an undamaged core, but
6 would apply to both.

7 DR. EBERSOLE: Right. What was the explicit dose
8 problem resulting from a minor leakage in the turbine hull?

9 DR. SIESS: At Newbold Island, it was considerable.
10 These were all Newbold Island features, close in population.
11 The changes made for Newbold Island, most of which has just
12 been mentioned, were to reduce the calculated design basis
13 accident doses.

14 DR. EBERSOLE: That is why, for damaged core.

15 DR. SIESS: No, no damage core. We didn't
16 think of damaged cores ten years ago. It was design basis
17 accidents. LOCA..

18 DR. EBERSOLE: When the reactor is depressurized?

19 DR. SIESS: Yes.

20 DR. EBERSOLE: And these valves aren't pressure-
21 paths from a depressurized vessel to atmosphere?

22 DR. SIESS: Now, the other changes, containment
23 building, it was the same thing. It was designed to release
24 the off-site, reduce off-site releases following a design
25 basis accident. Changes to the high-pressure core spray and

1 LPCI were in response to ACRS concerns of the period which
2 were improved ECCS. That was one of our major issues at
3 that time. Those were changes made to meet our demands for
4 improved ECCS.

5 DR. EBERSOLE: So, Chet, this third valve is a
6 piece of history from the days when the large LOCA predominated,
7 and one was looking at large LOCA core damage in the context
8 of having leakage through the main steam lines?

9 DR. SIESS: That is correct. It was simply a
10 result of calculating Chapter 15 accident doses.

11 DR. EBERSOLE: Would it be put in today, do you
12 think?

13 DR. SIESS: No, of course not. It wasn't put in
14 any plants then except at Newbold. Newbold Island site was
15 comparable to Indian Point. It was comparable to Indian
16 Point, actually, a little worse than Zion. These were all
17 features put in during extensive review of a large reactor
18 at a very highly populated site.

19 DR. EBERSOLE: Yes.

20 DR. SIESS: Then they were maintained after
21 the plant was moved to the other side to expedite licensing.
22 The staff said if you move it and don't change anything, don't
23 change too much, we will get you a new SER out in six months.
24 I think they did.

25 DR. EBERSOLE: I can think of better places to

1 put that big valve.

2 DR. SIESS: That is the trouble with ACRS designing
3 reactors. ACRS changes by the time they get it built.

4 MR. GAILEY: Next, certain design features later
5 incorporated into other BWR plants. High pressure coolant
6 in vehicles via cool spray sparger, and later through both
7 core spray and feed water systems was discussed earlier.

8 In addition, the turbine-driven HPCI pump was
9 redesigned, provides about an additional 12 percent of flow
10 of water to the core. Direct low-pressure cooling system
11 injection was redesigned so that it was direct to the core,
12 four separate penetrations through the core flowed rather
13 than recirc lines.

14 MR. GAILEY: As briefly mentioned earlier, another
15 feature we consider significant is the safety auxiliary
16 cooling system, that it is closed loop and only its heat
17 exchangers are exposed to the brackish Delaware River water.

18 (Slide.)

19 MR. GAILY: In addressing the subject of ATWS,
20 we have incorporated what is known as the ATWS-3A modifica-
21 tions. This provides for automatic initiation of standby
22 control system, tripping recirc pumps, alternate rod insertion
23 and feed water runback.

24 Recently there was an industry concern about
25 blocked walls in nonseismic Class I -- in seismic Class I

1 equipment areas. I would like to point out Hope Creek
2 has no block walls or nonseismically qualified walls in
3 its seismic class I equipment areas.

4 (Slide.)

5 MR. GAILEY: This concludes my presentation. I
6 would like to introduce Pete Landrieu, construction manager,
7 who will present a statement on construction status and start-
8 up.

9 DR. SIESS: Any questions?

10 MR. LANDRIEU: Good afternoon. Since we did go
11 through a lot of similar material this morning, I am going
12 to move rather rapidly unless you want me to change this.
13 So far, as the Hope Creek engineering and construction PSE&G is
14 to interface with Bechtel and GE on the project, we have had
15 a project team which is designed somewhat in the mirror
16 image of the Bechtel typical matrix organization. I would
17 like to simply say that on that team, we have a majority
18 of people with previous Salem experience and the majority
19 have been with the Hope Creek Project since prior to first
20 concrete. So we do have continuity of management in that
21 team and our interface relationships with Bechtel and General
22 Electric.

23 Our fall load data is January 15, 1986.

24 (Slide.)

25 MR. LANDRIEU: Our current schedule analysis,

isl 1 critical path analysis, we have been positive to that date for
2 some time.

3 (Slide.)

4 MR. LANDRIEU: For that reason we have been working
5 for the past several months to a target fuel load schedule of
6 December 1, 1985. We are working toward that schedule.

7 In order to build assurance that when things can
8 and do go wrong, as they sometimes do during startup of a
9 plant like this, that we will still be able to accommodate
10 that kind of happenstance.

11 Construction status is approximately 93 percent
12 complete.

13 (Slide.)

14 MR. LANDRIEU: Bulk commodity installations, as
15 you can see, are just about complete. Wire and cable
16 terminations being the ones with the majority to go.

17 (Slide.)

18 MR. LANDRIEU: This busy graph simply compares Hope
19 Creek percent complete versus months to fuel load with a
20 number of other similarly sized plants. I simply show this
21 to indicate that we are not out in the woods on the right or
22 left of other people's experience.

23 What we have ahead of us, we feel it is aggressive
24 but attainable. Our startup status is 34 percent complete
25 at this time.

js? 1 As you can see, we are slightly ahead on our
2 startup program; the blue line being the January 15 schedule,
3 red line being the schedule that would support the December 1st
4 date.

5 As you can see, we are behind December 1st but
6 ahead of January.

7 (Slide.)

8 MR. LANDRIEU: As Roger mentioned, approximately
9 a third of the systems have been turned over to Public
10 Service for operation, maintenance and testing.

11 (Slide.)

12 MR. LANDRIEU: One thing I would like to mention
13 which will allow us to achieve some of the things we have out
14 ahead of us is the control room you did see, which was
15 completed and turned over to Public Service for testing in
16 December a year ago.

17 (Slide.)

18 MR. LANDRIEU: At that time, we began a six-month
19 integrated checkout of the different circuitries in that
20 control complex and completed that integrated checkout one
21 month early, in May of this year.

22 We feel that having that circuitry checked out and
23 behind us as we go into the heavy system turnovers is going
24 to serve us very well in getting through an ambitious program.

25 I would now like to introduce Stan LaBruna, who

js3 1 will speak to maintenance.

2 MR. LA BRUNA: Good afternoon.

3 (Slide.)

4 MR. LA BRUNA: Stan La Bruna, Assistant General
5 Manager of Hope Creek Operations.

6 Several topics, Planning for Maintenance,
7 In-Service Inspection, and Preoperational Test. I am basically
8 going to be reflecting on these from an operational readiness
9 for the Hope Creek operations team as we are participating in
10 these activities.

11 (Slide.)

12 MR. LA BRUNA: The first is Planning for Maintenance.
13 The maintenance program established for Hope Creek is based
14 upon our past experience and maintenance enhancement resulting
15 from our nuclear department improvement programs.

16 A fundamental aspect of maintenance at all PSE&G
17 facilities during the past decade has been our repair and
18 maintenance procedures systems, better known as RAMPS. This
19 defines requirements for a planned approach to maintenance
20 activities using detailed procedures and all phases of plant
21 maintenance to assure a structured approach to maintainance
22 that results in quality and efficient use of personnel.

23 (Slide.)

24 MR. LA BRUNA: The managed maintenance program
25 reflected by this Busy display indicates an expanded program

js4 1 and concept to complete an integrated approach to maintenance
2 planning, monitoring and control.

3 This automated data base approach to maintenance
4 assures the effective control of our corrective, preventive
5 and predictive maintenance activities.

6 As you can see in this slide, and from the
7 discussions at our planning office this morning, I realize
8 some of these gentlemen didn't have the opportunity to share
9 with our maintenance manager the programs we do presently have
10 in place to take care of our present PM activities and
11 corrective maintenance activities, but this approach provides
12 our personnel with the adequate tools to plan, schedule and
13 control these maintenance activities.

14 (Slide.)

15 MR. LA BRUNA: Obviously the cornerstones of the
16 managed maintenance program are the preventive-predictive-
17 corrective maintenance and integrated spare parts and component
18 data file that we use.

19 Preventive maintenance program, schedule of
20 surveillances and planned inspections and calibrations is
21 based on vendor recommendations in addition to our own
22 experience at other facilities and knowledge of anticipated
23 environment and equipment qualifications.

24 Predictive maintenance program is based on trend
25 analysis of in-service pump and valve performance, including

js5
1 valve signature analysis, to which we are gaining that baseline
2 through our preservice inspection program.

3 DR. MICHELSON: What type of valve signature
4 analysis are you doing?

5 MR. LA BRUNA: We are going to be using a motor
6 operator technique, testing rig, which is in calibration
7 right now. We expect to be using that for our operators to
8 provide us with a baseline of current versus actual force.

9 DR. MICHELSON: Who is the supplier of that piece
10 of equipment?

11 MR. LA BRUNA: Offhand I don't have that information.
12 Perhaps our startup manager, Mr. Suconi --

13 DR. MICHELSON: Maybe you could tell me in the
14 morning.

15 MR. LA BRUNA: Sure.

16 DR. MICHELSON: I'm curious because we are very
17 much interested in signature analysis.

18 DR. CARBON: In terms of your preventive maintenance,
19 do you get input from EPRI and other BWR operators, and is it
20 of any help to you?

21 MR. LA BRUNA: We --

22 DR. CARBON: I mean do you expect it will be?
23 Of course, you're not doing it now.

24 MR. LA BRUNA: Certainly from an NPRDS standpoint,
25 that some of the concerns have been already in the industry,

js6
1 certainly through our programs. - I will speak a little about
2 that later on.

3 From our operating experience standpoint, generally
4 that is a reflection of some of the concerns already identified
5 in the industry that we are including in our procedures,
6 whether it be a concern or improved maintenance practice or
7 precaution in performing these activities.

8 So in that respect we are participating and
9 reflecting activities of the industry in our programs.

10 DR. CARBON: I'm still not clear. If there is some
11 type of valve or pump or something on BWRs that is continually
12 giving problems, you will learn that from someone else, or
13 only from your own experience?

14 MR. LA BRUNA: That is my point. Through the
15 program of LERs, SOERs, operation and maintenance reminders
16 and through the general SILS and TILS program, we feel we
17 have a very firm grasp on things that can protect us.

18 The corrective maintenance program is a prioritized
19 approach to preplanned activities for a responsible manager
20 to assure plant equipment availability.

21 Essentially we are talking about classifying work
22 orders as they come in. Those that have to be worked
23 immediately and those that can be deferred and planned
24 logically in the best interest of use of personnel.

25 Spare parts inventory coordination is an important

js7
1 part of our managed maintenance program, assuring adequate
2 inventory levels and shelf-life controls.

3 Accurate technical and quality classification
4 information. At Hope Creek the component data file, master
5 equipment lists and spare parts data base are integrated to
6 provide a wealth of technical, manufacturer, vendor,
7 documentation and quality classification information for a
8 consistent and reliable source for our maintenance and
9 engineering personnel.

10 All of these programs are supported by computerized
11 inspection order and work order initiation program, as you
12 saw this morning.

13 This also provides the ability for closing
14 management review and program activities which aid and are
15 historical tracking of work completed on components and
16 systems, as well as complementing our records for preservation
17 and retrieval for future audit or recall for follow-up on
18 review of past work.

19 (Slide.)

20 MR. LA BRUNA: Our managed maintenance program.
21 Effective procedures. Trained maintenance personnel in the
22 support of our on-site engineering staff of cognizant
23 engineers, all of which are in place functionally during the
24 preoperational test program, provide resources for an
25 effective approach at Hope Creek.

js8
1 (Slide.)

2 MR. LA BRUNA: I would like to take a few minutes
3 to talk about our planning for in-service inspection.

4 Planning for the Hope Creek in-service inspection
5 program started during design phase of the plant.

6 (Slide.)

7 MR. LA BRUNA: PSE&G, Bechtel Engineering and
8 Southwest Research Institute analyzed ASME code, section 11
9 and 10, CFR 50, Appendix J, to assure that the plant design
10 supported access and instrumentation required for inspection
11 and test.

12 We see that paying off particularly from the
13 standpoint of accessibility.

14 (Slide.)

15 MR. LA BRUNA: Within the nuclear department our
16 nuclear site maintenance group is responsible for the
17 identification action, direction and conduct of preservice
18 inspection activities as personnel are temporarily assigned
19 to the preoperational program startup manager.

20 It is the same group of nuclear department
21 personnel who will implement the in-service inspection plan
22 for the operating facility. This participation provides the
23 following benefits:

24 Develops personal experience to support operating
25 inspections.

js9

1 It optimizes the procedures for future testing and
2 assures the test implementation is suitable for both
3 preservice and future in-service inspections.

4 And in-service inspection problems will be
5 recognized and corrected to support future needs.

6 At present our preservice inspection program is
7 in progress and will attain the key baseline data for
8 volumetric and surface examination of piping system welds,
9 some of which we have already talked about and some of the
10 problems we have currently.

11 Examination of related hangers and supports,
12 valve and penetration leak rate testing, pump and valve
13 testing in accordance with ASME 11.

14 (Slide.)

15 MR. LA BRUNA: During plant operation the nuclear
16 service department will coordinate in-service inspection and
17 surveillance activities, analyze test results with our
18 performance and reliability group of Hope Creek operations
19 technical department.

20 The test data trending and assessment of the results
21 for adherence to section 11 and requirements will also support
22 the predictive maintenance program requirements to assure
23 component reliability.

24 The personnel and procedures supporting these
25 activities for preservice inspection program will assure

jsl0
1 successful transition to the testing programs for the
2 operating plant.

3 (Slide.)

4 MR. LA BRUNA: Planning for preoperational test.

5 (Slide.)

6 MR. LA BRUNA: Preoperational test program is the
7 integrated effort between engineering construction and nuclear
8 department personnel under the direction of the startup
9 manager. The testing program commences with the jurisdictional
10 system and equipment turnover to PSE&G and ends with initial
11 fuel loading.

12 First stage of the preoperational test program
13 includes instrument calibration, energized checkout of the
14 electrical power and control systems, piping flushes and
15 isolated equipment operation.

16 The second stage of the program demonstrates the
17 capability of systems to satisfy design intent.

18 All records generated during the testing program
19 will, in accordance with the Reg Guide 168, be retained
20 for the full life of the plant. This includes the preservation
21 of records, microfilming and indexing, using our document
22 retrieval programs.

23 This will support the retrieval for future review
24 and audit or reference for maintenance and modification
25 retest requirements.

1 To help accomplish these testing activities, the
2 Hope Creek operations staff supports the testing implementation
3 with a permanent staff of supervisors and craft personnel
4 trained to perform equipment operation, calibration and test
5 of maintenance and components, some of which you saw this
6 morning in our INC shop.

7 Certainly, I think you saw the capability at our
8 training center to train the appropriate crafts whether it be
9 INC, mechanical or electrical maintenance. We are certainly
10 very proud of the staff we have in place today.

11 By doing this work ourselves and minimizing use
12 of contractors, the operations staff has the clear advantage
13 of retaining the experience gained during the preoperational
14 testing program.

15 This integrated support and involvement of the
16 operations personnel and these activities provides the oppor-
17 tunity to develop, exercise and optimize our plant
18 administration, equipment operation and repair and maintenance
19 procedures prior to plant operation.

20 It also complements the classroom training of
21 personnel to enhance their qualifications.

22 (Slide.)

23 MR. LA BRUNA: Our Hope Creek operations planning
24 plan is nearing completion. This program of early management
25 has assured availability of highly trained and experienced

jsl2
1 staff who will continue to develop in the unique aspects of
2 Hope Creek during the next year of preoperational testing.

3 Thank you very much.

4 I would like to introduce our next speaker, Bill
5 Gailey, our chief project engineer.

6 DR. SIESS: Mr. Gailey, this item that relates to
7 previous ACRS letters, I would suggest that you need not
8 address anything in a letter that clearly was related to the
9 Newbold Island site, since we are no longer at the Newbold
10 Island site. I am not sure how much that leaves you.

11 MR. GAILEY: Let me explain. There are two letters
12 I was going to discuss. The first was the Hope Creek letter
13 in 1974. And I was going to discuss the three items that were
14 identified as requiring further attention.

15 DR. SIESS: Okay.

16 MR. GAILEY: The second letter was specifically the
17 Newbold Island letter. So I will just not discuss that, if
18 that is what you are saying.

19 DR. SIESS: I don't believe there was anything in
20 the Newbold Island letter as an ACRS concern that in the
21 current context carries over to Hope Creek. If I can find
22 my copy of the letter, I will check that.

23 Why don't you start, at least, with the Hope Creek
24 letter?

25 MR. GAILEY: The purpose is to discuss the two

jsl3
1 previous ACRS letters which identify three items in each
2 requiring attention.

3 In the '74 Hope Creek letter, the first item
4 identified was a request to reevaluate core operating limits
5 as a result of what was then recently promulgated acceptance
6 criteria for emergency core cooling.

7 (Slide.)

8 MR. GAILEY: 10 CFR 5046. This is commonly known
9 as the -- case study. This reevaluation was done back in the
10 1974 time frame. Of course, as is consistent with current
11 staff practice and requirements, we are currently redoing that
12 analysis which is normally done about a year prior to fuel
13 load.

14 (Slide.)

15 MR. GAILEY: The second item addressed was although
16 Hope Creek was very close to Salem and was expected to have
17 essentially the same seismological, geological and foundation
18 conditions as Salem, Hope Creek had committed to undertake an
19 extensive soil boring and testing program, and a specific Hope
20 Creek design would be reviewed with the regulatory staff.

21 The programs were undertaken and completed. They
22 have been satisfactorily reviewed with the staff. And they
23 have resulted in no open items in the SER.

24 (Slide.)

25 MR. GAILEY: The third concern identified in the

isl4 1 letter was a commitment on our part to conduct an analysis,
2 probability analysis, of waterborne accidents that could
3 affect plant safety. These are accidents on the Delaware
4 River.

5 That analysis was completed, and indicated a very
6 low probability of an accident occurring. It was reviewed
7 with the NRC staff, and the conclusion was that because of the
8 low probability waterborne accidents need not be considered
9 as a design basis for Hope Creek.

10 Those were the three items in the Hope Creek
11 letter that required further attention.

12 DR. SIESS: Okay. Thank you.

13 In the Newbold Island letter there was one
14 paragraph in that which has been addressed.

15 MR. GAILEY: That is correct.

16 DR. SIESS: Thirteen years ago. There was a
17 paragraph on hydrogen control, and recommendation that the
18 containment should be inerted, which has been followed. In
19 addition to which you have the recombiners.

20 MR. GAILEY: That is correct.

21 DR. SIESS: Then there was an item -- that is, a
22 paragraph, that ends up, that the applicant should make
23 design provisions to reduce the quantity of reactor coolant
24 discharged to the reactor building in the event of a process
25 line break.

15
1 This has to do with instrument lines, which, as I
2 recall, were a particular concern of ours in those days.
3 Something like 150 instrument lines that went through the
4 dry well, and they had flow restricting orifices.

5 Do you remember in particular whether anybody has
6 done anything about that? I think it was fairly standard
7 comment for BWRs, and I don't remember the resolution. It
8 was not a Newbold Island item.

9 It was also mentioned in the Hope Creek Subcommittee
10 minutes. I checked that.

11 MR. GAILEY: As far as instrument lines are
12 concerned, the orifices were retained, in addition to excess
13 flow check valves. I believe it has been concluded the
14 instrument lines were not a further concern.

15 As far as process line breaks are concerned, the
16 intent was to provide some features to keep the off-site
17 releases well within the 10 CFR 100 guidelines.

18 DR. SIESS: You are right. It was the process
19 lines. That was the concern.

20 And it said previous to that although the off-site
21 doses from such an accident would be well within the part 100
22 guidelines, it would be comparable to greater than doses
23 calculated for other less probable accidents.

24 DR. EBERSOLE: May I comment?

25 DR. SIESS: Let's see if we have got response to

16 1 this.

2 MR. GAILEY: Yes, that has been addressed in our
3 design. We feel with the combination of the isolation
4 features in the process lines and pipe whip restraints, which
5 have been extensively addressed in Hope Creek, we have seen
6 that the off-site releases are well within 10 CFR 100
7 guidelines at the Hope Creek site.

8 DR. SIESS: Jesse?

9 DR. EBERSOLE: Yes. That was a period, I guess I
10 will call it an era of darkness, a little bit, because I
11 noticed in particular that one focused on was release of
12 radioactive nuclides in the stream of water which came out.

13 Yet, the implications of anything beyond just a
14 modest dose was not even looked at at all. Those implications
15 are that you are going to pollute the environments of critical
16 electrical equipment and places where people have to live,
17 and that in the context of direct radiation release is really
18 of no particular consequence.

19 What is of consequence is you are going to disable
20 potentially large amounts of apparatus which continue to cool
21 the core after it is tripped. So there is sort of a distortion
22 in the rationale in looking just at the dose consequences and
23 not looking at the environmental impact on critical
24 equipment and people.

25 I certainly think you better look at it in this

17
1 new context. It is part of the environmental qualification
2 process.

3 DR. SIESS: You are speaking of environmental
4 qualification?

5 DR. EBERSOLE: Yes.

6 MR. GAILEY: Our qualification for harsh environ-
7 ments takes into consideration these --

8 DR. EBERSOLE: These emissions?

9 MR. GAILEY: Radioactive releases.

10 DR. EBERSOLE: I have no interest in the radioactive
11 component.

12 DR. SIESS: Temperature and moisture.

13 MR. GAILEY: That is correct, they are considered.
14 Yes.

15 DR. EBERSOLE: Condensation on surfaces which lead
16 to short circuits, etc.?

17 MR. GAILEY: If condensation is a problem, yes.

18 DR. EBERSOLE: The equipment is normally at ambient
19 temperatures. So you wet down many terminal boards, many
20 stud connectors.

21 DR. SIESS: We have an item tomorrow on environmental
22 qualification.

23 DR. EBERSOLE: Right, but it directly related to
24 the emission problem.

25 DR. SIESS: Among others. That wasn't what we had

18
1 in mind in the letter.

2 MR. GAILEY: Yes.

3 DR. SIESS: That was strictly doses.

4 Thank you, Mr. Gailey.

5 MR. GAILEY: You're welcome.

6 DR. EBERSOLE: We would like to move to Mr.
7 Churchman.

8 DR. SIESS: Yes. Before he starts, I looked through
9 section 12. I think I need to clarify the concern of the
10 ACRS in the seismic area and to define it somewhat more
11 narrowly, maybe, than it was interpreted to be.

12 I don't think at this point in time and at this point
13 and at this plant we are particularly concerned about the
14 seismic design basis as it was done at the CP.

15 We have only a minor interest in comparison with
16 the uniform hazards' curve. I am perfectly happy to accept a
17 statement by the staff that it was done and it compared well
18 with your design spectrum.

19 In terms of margins, this is a generic issue that
20 we are pursuing with the staff and research and following the
21 industry work. I was in attendance at the EPRI workshop. Right
22 now we don't have any immediate major concerns we could look
23 at at Hope Creek in terms of seismic margins for structures,
24 components and piping.

25 Not that we are not concerned, but those issues

19
1 are not the uppermost in our minds.

2 Margins, of course, many margins for earthquakes
3 larger than the design basis, larger than the SSE, outside of
4 the licensing criteria. Although on the East Coast, once the
5 position of the Geological Survey on Charleston was
6 clarified, is that the word, if there was ever misused, that
7 will go down in history.

8 I will put it my way. Once they unloosed Charleston
9 on us up and down the Atlantic Seaboard, the licensing-
10 regulatory implications of an earthquake larger than the SEE
11 that had been previously accepted may loom somewhere in the
12 future.

13 There are two things we would like to address here.
14 You may have to repeat this for the full committee. One is
15 we are interested in the way the staff has treated more recent
16 information regarding SSE, which in this case I think is the
17 New Brunswick earthquake, which was real, and the unleashing
18 of Charleston, which may or may not be real.

19 Both of these are addressed in the SER, and we
20 probably ought to hear briefly from staff on that.

21 But in terms of the seismic margins, the one
22 concern we're looking at, would like to discuss briefly,
23 would be the soil conditions and liquefaction.

24 Again, what we're concerned about with respect to
25 margins is whether there is a cliff out there, and how close

20
1 to the edge of it we might be. If the cliff is three times the
2 SSE out there, we feel one way. If there is a cliff out
3 there and it is 1.2 times the SSE, we are obviously going to
4 feel very differently. ~~And there is some concern that~~

5 And there is some concern that liquefaction might
6 be the cliff that is most likely for some sites, because we
7 know from history that some of the sites we reviewed met the
8 SSE for liquefaction, but nobody really looked at them for
9 anything higher.

10 So I guess to this plant we would like to know if
11 you have some information from your consultants about the
12 liquefaction possibility at earthquakes greater than the SSE;
13 and if you have not, tell us what you do know about it.

14 And I think I would like to start off by hearing
15 from staff on their treatment of contemporary knowledge
16 regarding earthquakes on the Eastern Seaboard.

17 DR. MICHELSON: Wouldn't this be a good time for a
18 break, before we go into this subject?

19 DR. SIESS: It all depends on whether your
20 consultant has a plane.

21 MR. ECKERT: How are we doing? We could break
22 first.

23 DR. SIESS: We will take 10 minutes.

24 (Recess.)

25 DR. SIESS: We are on the seismic issue, and the

21
1 first speaker will be Phyllis Sobel.

2 Are you a geologist, or seismologist?

3 MS. SOBEL: Seismologist.

4 DR. SEISS: That's the best kind.

5 MS. SOBEL: I'm Phyllis Sobel, and I would like to
6 give a brief description of two issues which were treated in
7 the staff's SER: the 1886 Charleston earthquake and 1982
8 New Brunswick earthquake.

9 (Slide.)

10 MS. SOBEL: To set the stage for the New Brunswick
11 earthquake issue, I will use a seismicity figure of the
12 Eastern United States. This is a recent instrumental
13 seismicity, and this figure is from a recent bulletin of the
14 Northeast U.S. Seismic Network.

15 The asterisk in the southwest part of New Jersey
16 is the Hope Creek site.

17 The maximum historic events within about 200 miles
18 of the Hope Creek site were of about epicentral intensity 7,
19 and about maximum estimated magnitude 5. These events
20 occurred in Asbury Park, New Jersey, which is on the northern
21 coast of New Jersey, near New York City, Wilmington, Delaware,
22 and Richmond, Virginia.

23 The January 1982 New Brunswick earthquake, of
24 magnitude 5-3/4, occurred in a cluster of seismicity at about
25 latitude 47 degrees.

22
1 Although about 700 miles from the Hope Creek site,
2 this New Brunswick event is significant because it occurs
3 in the New England-Piedmont tectonic province. The closest
4 approach to the province is about 18 miles northwest of the
5 site.

6 Now, as I said, the maximum events within about
7 200 miles of the site were about estimated magnitude 5. The
8 maximum events within about 50 miles of the site were about
9 magnitude 4. This is discussed in the SER, so the staff did
10 not see, did not believe it was possible for a magnitude
11 5-3/4 event to occur within about 200 miles of the Hope Creek
12 site.

13 However, by examining the seismicity, we found
14 that the largest event would probably occur near the fault
15 zone which is about 18 miles from the site. So to be
16 conservative, we looked at the possibility of a magnitude 5-3/4
17 event occurring about 18 miles from the site.

18 (Slide.)

19 MS. SOBEL: As an appendix to the SER, there is a
20 study by Lawrence Livermore of site-specific response spectra
21 for the Hope Creek site. One of the cases they looked at
22 was magnitude 5-3/4 event at about a distance of 18 miles
23 from the site.

24 They looked at strong ocean recordings on sites
25 that were deep soil sites.

23
1 On this figure you see the Hope Creek SSE, which
2 is .2 G, Reg Guide .06 spectra, and you also see the 50 and
3 84 percentile site-specific spectra for the magnitude 5-3/4
4 event at 18 miles.

5 You can see the SEE envelopes the 84 percentile.
6 So staff found that the site SSE was adequate for describing
7 the ground motion effects of the New Brunswick earthquake
8 at 18 miles from the site.

9 (Slide.)

10 MS. SOBEL: This figure shows seismicity recorded
11 by the Southeastern U.S. Seismic Network. This may be the
12 first time you've seen this particular figure. It is from
13 the latest bulletin of the Southeastern U.S. Seismic Network.

14 The events that were believed to be reservoir-
15 induced or quarry blasts have been eliminated from the figure.
16 As you can see, I have sketched in the fall zone as a dashed
17 line. It is a boundary between the Piedmont province to
18 the northwest and Coastal Plain to the southeast.

19 Hope Creek site again is the asterisk. The Coastal
20 Plain is virtually aseismic except for the area around
21 Charleston, South Carolina.

22 As you know, during past licensing decisions the
23 NRC has held to the position that the relatively high seismic
24 activity within the Coastal Plain province in the vicinity of
25 Charleston, including the 1886 intensity 10 earthquake,

24
1 was for licensing decisions related to a unique tectonic
2 structure there.

3 However, because of the variety of possible
4 source mechanisms that have developed for the Charleston
5 seismicity, the USGS, as Dr. Siess says, clarified their
6 position in a letter to the NRC, dated November, 1982.

7 The staff's position with respect to that letter is
8 in the SER. The staff's position was presented also to the
9 ACRS in April of 1983. I will be giving you a short update
10 now.

11 If you remember, the position includes both the
12 deterministic and probabilistic studies. The deterministic
13 study should reduce the uncertainty by better defining the
14 causal mechanism of the Charleston earthquake.

15 One significant deterministic study has been
16 trenching of liquefaction features in the South Carolina
17 Coastal Plain. Researchers at the University of South
18 Carolina have been trenching a sampler, which is recorded
19 as being due to the 1886 earthquake.

20 In addition, both the USGS and University of South
21 Carolina have discovered liquefaction features due to
22 pre-1886 events.

23 As an aside, during the excavation for Hope Creek,
24 the applicant and the staff geologist examined the foundation
25 for evidence of earthquake-induced structures, and they found

25
1 no liquefaction features in the faces of the excavation.
2 The foundation strata belonged to the Vincentown Formation,
3 which is at least 53 million years old.

4 The second part of the staff's Charleston program
5 is a probabilistic program. This is being done by Lawrence
6 Livermore National Laboratories. It includes the use of
7 expert panels for seismicity and ground motion inputs and
8 sensitivity studies. The basic objective is to identify those
9 sites which have a high hazard with respect to their design.

10 The Hope Creek site is not one of the first 10
11 test sites. In fact, the staff does not know of any uniform
12 hazard response spectra for the Hope Creek site.

13 Progress to date, the final calculations for the
14 first 10 test sites are in program. There is a NUREG on the
15 interim results for these 10 sites. But the final calculations
16 are in progress now, and a report on them is expected in
17 winter of 1985.

18 EPRI is running a similar parallel hazard study,
19 and those results should be available in April or May of 1985.
20 Then there will be a comparison period, comparing the two
21 programs, and finally, Livermore will extend their runs to
22 include all of the remainder of the nuclear powerplant sites
23 in the Eastern United States.

24 So to conclude that topic, given the speculative
25 nature of the hypothesis with respect to the recurrence of a

26
1 large Charleston-size earthquake and the low probability
2 associated with such events, the staff does not see a need
3 for any action for specific sites at this time.

4 We have evaluated the possibility of the recurrence
5 of an event the size of the 1886 earthquake occurring in the
6 vicinity of Charleston and found the effects of the state are
7 less than the SSE.

8 That concludes my presentation. Dr. John Chen, who
9 is the staff geotechnical engineer, is available for any
10 questions on liquefaction.

11 DR. SIESS: Thank you, Phyllis.

12 I think we will hear from the applicant, first,
13 on liquefaction. Then if necessary, we will call on John.

14 MR. POMEROY: Phyllis, I wanted to explore, first,
15 the logic between, if you will, your using the New Brunswick
16 earthquake, which I understand your position to be that it is
17 not associated with a specific tectonic feature, and there-
18 fore should be moved to the nearest point of approach to the
19 plant site of the tectonic province it occurred in.

20 With your treatment of the Charleston earthquake,
21 which you also have no evidence in my belief, that would
22 associate it with a particular tectonic feature and yet, the
23 staff is choosing to leave it at Charleston. There is an
24 inconsistency in that logic.

25 MS. SOBEL: First, with respect to the Charleston

27
1 earthquake, our position has been based on larrgely statements
2 made by the USGS in the past, which have relied heavily on
3 the fact that seismicity since 1886 has been concentrated
4 in the Coastal Plain in the vicinity of Charleston.

5 And granted, that is not -- there is no known,
6 definite known source mechanism. But studies are underway.
7 We are optimistic.

8 In terms of the New Brunswick earthquake, it is
9 still an open issue. Not in terms of this site, but in
10 terms of our generic studies, whether or not New Brunswick
11 is associated with structure.

12 There are after-shocks associated with conjugate
13 fault plains in the area. It seems as if the seismicity is
14 being localized to a structure. It is just a question of
15 whether or not similar structures could exist throughout the
16 Piedmont Province.

17 MR. POMEROY: I have another question with regard
18 to your seismicity, instrumental seismicity maps.

19 DR. SIESS: I didn't get the answer there. You
20 referred back to the previous USGS position on Charleston.

21 MS. SOBEL: Yes.

22 DR. SIESS: But you sort of ignored the clarifi-
23 cation.

24 MS. SOBEL: The clarification is that we are
25 allowing the possibility of the event occurring in other parts

28
1 of the Eastern Seaboard by following through with
2 probability studies.

3 DR. SIESS: On a probabilistic basis?

4 MS. SOBEL: Right.

5 DR. SIESS: I see.

6 Go ahead.

7 MR. POMEROY: Then did I understand you to say the
8 staff has no best estimate of the seismic hazard at this
9 site?

10 MS. SOBEL: There is no uniform hazard response
11 spectrum.

12 MR. POMEROY: I guess I'm asking for site-specific
13 seismic hazard curves other than those being, that may be
14 generated in the future by Lawrence Livermore.

15 MS. SOBEL: You're talking about response
16 spectra, probabilistic response spectra?

17 MR. POMEROY: I'm talking about a seismic hazard.

18 DR. SIESS: Seismic hazard. I don't think the
19 staff has done a seismic hazard except Livermore, have they?

20 MS. SOBEL: That's correct.

21 DR. SIESS: Applicants have done them, right?

22 MR. POMEROY: Could I pose the question to the
23 applicant at this time?

24 DR. SIESS: Yes, I think so.

25 MR. POMEROY: Does the applicant have any best

29 1 estimate or any seismic hazard curve for the Hope Creek site?

2 MR. PRESTON: I would like to introduce Chuck
3 Churman, who will address your question.

4 MR. CHURCHMAN: Good afternoon. I'm Chuck
5 Churchman, Southern Engineering Manager for Public Service.

6 We did do a site-specific hazard spectrum analysis
7 for Hope Creek for comparison purposes. Essentially what
8 we have done is following the methodology used by Lawrence
9 Livermore for those 10 other sites. We have engaged Dr.
10 Robin McGuire. I would like Dr. McGuire to further address
11 your question.

12 MR. POMEROY: Thank you.

13 DR. MC GUIRE: My name is Robin McGuire. In
14 order to give the applicant some perspective on seismic
15 hazards associated with Hope Creek, we undertook a study
16 which involved replication of the assumptions used in the
17 Lawrence Livermore study for the Hope Creek side.

18 (Slide.)

19 DR. MC GUIRE: We have elected to consider a
20 subset of all the many options produced by Lawrence Livermore
21 which we feel gives an accurate, reasonable representation of
22 what the Lawrence Livermore study would have produced at Hope
23 Creek had it been run at that site.

24 That subset consisted of using the source zones
25 specified by 11 seismicity experts. The best estimate source

30
1 zones and best estimate seismistic parameters for the source
2 zones. Also, using the best estimate attenuation function
3 specified by each of the four attenuation experts. So in
4 all there were 11 seismicity experts times four attenuation
5 functions, or 44 sets of curves.

6 The parameters we looked at were peak acceleration
7 and spectra velocity at 9 Hz and at 1 Hz. This represents a
8 summary of those 44 assumptions on seismic sources and
9 attenuation functions, showing the 16th, 50th and 84th
10 percentile, which give a reasonable representation of the
11 hazard which would have been produced under the assumptions
12 of a Lawrence Livermore study.

13 (Slide.)

14 DR. SIESS: Robin, where did -- I'm trying to recall
15 from the Lawrence Livermore study where the experts put
16 Charleston.

17 DR. MC GUIRE: That varied among the experts.
18 Some of them had relatively small zones in the Southeast.
19 Some of them allowed it to migrate up and down the East
20 Coast.

21 DR. SIESS: They did. And that was sort of
22 factored in on the expert basis.

23 DR. MC GUIRE: Yes, sir.

24 DR. SIESS: Were those opinions before or after
25 USGS? And if so, do you think they were influenced by it?

31
1 DR. MC GUIRE: I'm sure they were influenced by
2 it.

3 (Slide.)

4 DR. MC GUIRE: The next slide shows similar results,
5 being annual probability of exceedance versus spectral
6 velocity for the 9 Hz and 1 Hz spectral velocities. Again,
7 this is a summary for each frequency of the 44 hazard runs.

8 DR. SIESS: Would you put the previous slide back
9 on for a minute?

10 (Slide.)

11 DR. SIESS: What do we get at the 50th percentile,
12 2/10 G, about 7 or 8 times 10 to the -4?

13 DR. MC GUIRE: I believe it is about 2 to 3 times
14 10 to the -4.

15 DR. SIESS: That is in the range we've been talking
16 about, isn't it? 1,000 to 10,000 years.

17 (Slide.)

18 DR. MC GUIRE: Using that set of results we
19 constructed an approximate uniform hazard spectrum by adopting
20 the 1,000-year peak acceleration as the high frequency
21 asymptote, amplifying -- using the 9 Hz and 1 Hz 1,000-year
22 spectral velocities to draw quasi-uniform hazard curves.
23 That was done for a 1,000-year return period and for the
24 10,000-year return period.

25 Those are shown here on the third slide. Compared

32
1 to those spectra on this slide are the Hope Creek Reg
2 Guide 160 spectrum spectrum, .2 g, and also the Lawrence
3 Livermore site-specific spectrum, which is for 5½ magnitudes
4 at near field distances and small buildings.

5 In this case, the later spectrum at high
6 frequencies is very close to the Lawrence Livermore, what
7 we estimate to be the Lawrence Livermore median 1,000
8 spectrum. The Reg Guide falls slightly below that, but still
9 in the range between the 1,000 and 10,000-year spectrum.

10 DR. SIESS: I would like to ask a question. I'm
11 not sure you are the one to answer it, but I wanted to ask
12 while this is still on the screen.

13 What frequencies are of particular concern in
14 relation to soil liquefaction?

15 High or low will be a satisfactory answer.

16 DR. MC GUIRE: I'll defer that question to another
17 consultant.

18 DR. SIESS: We can defer the question, but save
19 the slide.

20 DR. DREWNOWSKI: The frequencies that are of
21 interest are in the low frequency range, generally less
22 than 1 Hz.

23 DR. SIESS: Thank you.

24 DR. DREWNOWSKI: If you look at the curve, it is
25 a very good question, because it indicates the --

33 1 DR. SIESS: Identify yourself.

2 DR. HASKIL: I'm Harskil, with Dames and Moore.

3 The frequencies of interest are generally less
4 than 1 Hz. As you can see from this particular curve, there
5 is an ample safety margin with the use of the Hope Creek
6 response spectra, which corresponds to Reg Guide 160.

7 DR. SIESS: Thank you.

8 DR. MC GUIRE: That concludes my presentation.

9 DR. SIESS: Thank you very much.

10 MR. POMEROY: Is it possible for us to get a copy
11 of those slides, Robin?

12 DR. MC GUIRE: Of course.

13 MR. ECKERT: Now Mr. Churchman will make his
14 presentation on the rest of it.

15 DR. CHURCHMAN: Good afternoon. I'm Chuck
16 Churchman, site engineering manager. This subject of seismic
17 design encompasses an area of many sub-subjects, such as
18 geology, seismology, soil structure interaction, soil
19 sensitivity studies and structural seismic analysis.

20 We realize that the ACRS current review emphasis
21 has been centered on the adequacy of design input notion,
22 seismic design margins and recent seismic developments.
23 Within the limitation of time and your specific request, we
24 will tailor our overview to that interest.

25 We have engaged Dr. Allin Cornell of Stanford

34
1 University, Jim McWhorter of Dames & Moore, Richard Holt of
2 Weston Geophysical and Dr. Robin McGuire. They are available
3 for further discussion regarding seismology and seismicity.

4 Professor Harry Bolton Seed and John Lysmer of the
5 University of California at Berkeley are also present to
6 discuss seismic analysis, particularly in the area of soil
7 structure interaction and soil liquefaction.

8 Our next slide shows the topics to be presented
9 during the overview. We are going to look at earthquake
10 ground motion, seismic design major conservations, New
11 Brunswick sequence, soil liquefaction, site-specific response
12 spectra and seismic margins.

13 Dr. Siess, we now understand, would like to
14 streamline this more directly to the soil liquefaction area.
15 To do this, I would like a minute concerning the conservatisms
16 inherent in our design SSE.

17 For the earthquake ground motion and location of
18 epicenters, we go to the next two slides.

19 (Slide.)

20 DR. CHURCHMAN: Looking at the next slide,
21 location of the epicenters, we show a 50-mile radius from the
22 site. At the center you see a green-colored circle, which is
23 the site. Elsewhere, you see squares which represent
24 earthquakes.

25 All known earthquakes within a 50-mile radius

35
1 have magnitudes of 4.0 or less. Approximately 15 miles
2 to the north of the site is a square in the Wilmington,
3 Delaware area.

4 (Slide.)

5 DR. CHURCHMAN: We have searched the historic
6 record, which is more than 200 years, and have found within
7 the site vicinity the 1871 Wilmington, Delaware earthquake
8 to be the largest event with a modified Mercalli intensity
9 of 7.

10 Based on rather moderate fault area and limited
11 damage, the 1871 Wilmington earthquake was probably no greater
12 magnitude than 4.0. Based on 10 CFR 100, Appendix A, we
13 have arrived at an SSE of intensity 7, which the NRC staff
14 has correlated to a magnitude of 5.3.

15 This is very conservative, compared to the
16 Wilmington event, with a magnitude of 4.0. We have used the
17 Trifunac and Brady correlation, a more conservative
18 correlation than the other popularly accepted correlation
19 by Murphy and O'Brien.

20 Using the Trifunac and Brady correlation we came
21 up with .13 G. If we had used Murphy and O'Briens, the
22 result would have been approximately 10 G. Hence, we are
23 more conservative.

24 While the standard industry practice is to use
25 this mean value, .13 G in our case, we made it more

36
1 conservative by going more than 1 standard deviation from
2 the mean value, and used .20 G for our SSE input.

3 For the OBE we were following the Code of
4 Federal Regulation, which required us to specify the OBE as
5 one-half the SSE. So the OBE is 1. G.

6 I will move quickly through some of the other areas
7 you have asked me to skip.

8 MR. POMEROY: Before you skip ahead, I really
9 do want to ask you a couple of questions.

10 In the FSAR, in Table 2.5. or -1 -- I forget which
11 it is -- you have a list that purports to be all of the
12 earthquakes within a 50-mile radius of the site, I believe.
13 And the last entry on that list is in 1980, I believe.

14 My first question is is that list, in your
15 estimation, a complete list?

16 DR. CHURCHMAN: Yes, it is.

17 MR. POMEROY: There are two events that I am aware
18 of that are February 10th, 1977 and April 28, 1974, with
19 magnitudes w.6 and 2.2, respectively, that occurred in the
20 Wilmington area, according to the Delaware Geological Survey.

21 If you put those points on your seismicity plot,
22 or indeed, if you put them on the seismicity plots shown by
23 the staff, that would begin to change the perception in that
24 Wilmington area to some extent.

25 My other question has to do with, are you aware

37
1 of any significant activity in the Wilmington area more
2 recently than 1977 or so?

3 DR. CHURCHMAN: We have researched the record over
4 the past 200 years and made a recent recheck. What we tried
5 to highlight today was the greatest magnitude in the 50-mile
6 radius, particularly the Wilmington event, 15 miles to the
7 north.

8 MR. POMEROY: That's correct. You did that properly.
9 I'm not objecting to that.

10 DR. CHURCHMAN: Okay.

11 MR. POMEROY: I'm just concerned that there are
12 events in the Wilmington area that are missing from the
13 tabulation and from your maps that I think might change the
14 perceptions somewhat of people looking at the seismicity
15 map.

16 But I don't want to pursue that especially because
17 I'm more interested in the second question, which has to do
18 with the more recent activity in the Wilmington area.

19 DR. CHURCHMAN: Regarding more recent activity
20 I would like to ask Jim McWhorter to answer that question.

21 MR. MC WHORTER: My name is Jim McWhorter, with
22 Dames & Moore.

23 Regarding your first question, Paul, I think many
24 of the events reported in the Wilmington area, especially
25 those noted by the Delaware Geologic Survey, are so small

38
1 in magnitude that they are very, very poor epicentral
2 locations.

3 We did not include those very small magnitude
4 events for that reason. There are several events that have
5 been noted in the Table 2.51 that you referred to that have,
6 you know, essentially fault events, but not located very well.

7 The most recent events I'm aware of which occurred
8 after the most recent staff review were I guess December of
9 last year, November-December last year. I don't think that
10 would change dramatically our perception of the seismicity
11 within 50 miles of the site.

12 MR. POMEROY: I have a November 17, 1983, 2.9 event.
13 December 12, 1983, 2.4 event. February 15, 1984, 1.5 event.
14 And January 19, 1984, 2.5 event. All of those, with the
15 exception of the 1.5 magnitude, probably would certainly
16 fall on your map if it included that more recent activity.
17 Again, that would change your perception.

18 I guess the question I would pose to you, Jim,
19 although I realize there may not be an answer, is would you
20 attach any significance to the occurrence of a number of
21 earthquakes in the Wilmington area, and at least to the
22 extent possible from intensity surveys, all of those events
23 are occurring in the same general area, which is an area on
24 the Brandywine River.

25 MR. MC WHORTER: Yes. We are well aware the

39 1 Wilmington area has been the scene of recurrent activity.

2 One thing I would like to add is that during the
3 PSAR level at Hope Creek we did extensive mapping in the
4 region -- excuse me -- I mean to say the Delmarva Summit site
5 PSAR, we did extensive geologic mapping in the area of the
6 Summit site. Before that, the Red Lion site.

7 There are many exposures afforded to us -- Route
8 295, Route 95 exposures -- that cut through the Coastal Plains.
9 We are looking at some linears that -- from the Delaware
10 Geologic Survey had pointed out in one of his studies,
11 Spolarik's studies, that he felt perhaps could be related to
12 seismicity in that region.

13 We also did several deep borings to try to track
14 some of the mid-tertiary geologic structures in the area.
15 We did not see any geologic phenomena at the surface that
16 would be indicative of liquefaction phenomena we see in other
17 areas in the Coastal Plain.

18 So we do attach some significance to the fact
19 that Wilmington is the seat of recurring seismicity, but it
20 has been of a low magnitude, as you know.

21 MR. POMEROY: Thank you. I would like to pose the
22 same question to the staff, if I could. Do you attach any
23 significance to this kind of activity in the Wilmington area?

24 MS. SOBEL: We have been in touch with the people
25 at the Delaware Geological Survey. It seems to be their

40
1 impression, and ours, that this is an area of some recurring
2 minor seismicity. There was an event in 1871; we're not too
3 sure about seismicity surrounding that event.

4 Then it seems as if there was no record of
5 seismicity until just before the 1973 magnitude 3.8 event
6 at Wilmington, which has been the largest event in the last
7 14 years or so.

8 They are not required to report events below
9 magnitude 3, but they discussed the events near Wilmington,
10 and staff has been looking at it.

11 DR. CHURCHMAN: Proceeding with soil liquefaction.

12 (Slide.)

13 DR. CHURCHMAN: Liquefaction potential for
14 Category 1 structures was determined by comparing the shear
15 stresses induced in the soil by the SSE with the cyclic
16 shear strength of the soil in the field condition.

17 The maximum shear stresses at various points in
18 the foundation were obtained from dynamic analysis. The
19 dynamic strengths of the foundation soils were determined
20 primarily by laboratory test data, correlated with field data.

21 The Hope Creek Project has three major Category 1
22 foundation systems: power block, service water intake, and
23 the service water pipeline.

24 Due to unique schemes and construction methods I
25 will address each separately. The power block extends

41 1 approximately 62 feet below grade, and is supported rather
2 directly on -- which extends from Vincentown to the bottom
3 of the concrete foundation.

4 The results of our analysis show that the
5 foundation media of the power block, consisting of engineer
6 backfill and Vincentown formation, have factors of safety
7 against liquefaction in excess of 2 under the postulated
8 condition.

9 . Material sloping from the Vincentown elevation
10 up to approximately 150 feet horizontally from the power
11 block have been excavated and replaced with engineered
12 backfill. This further enhanced the stability of the power
13 block against sliding.

14 MR. POMEROY: Excuse me, Mr. Churchman. Can I
15 just ask a question for clarification there?

16 When you say you have a factor of 2, does that
17 imply to me, compared to SSE conditions, does that imply to
18 me that if at something like .4 G that liquefaction might
19 occur?

20 DR. CHURCHMAN: I'll get to that in a minute.

21 In our evaluation of the factor of safety against
22 sliding of the power block structures, we were requested by
23 the NRC staff to conservatively assume the upper 30 feet of
24 soil liquefies under the SSE condition.

25 Even under these extreme loading conditions, the

42 1 analysis proved acceptable, factor of safety, against sliding.

2 We would like to address the intake structure
3 next. It extends approximately 75 feet below grade and is
4 supported on competent Vincentown Formation. The results
5 show the foundation has a factor of safety against
6 liquefaction in excess of 2 under a postulated SSE condition.

7 DR. MIESS: What does a factor of safety mean in
8 this case? Ratio of what to what?

9 DR. CHURCHMAN: Factor of safety is a ratio
10 comparing the shear stresses induced in the soil by the SSE
11 with the cyclic shear strength of the soil in the field
12 condition.

13 DR. SIESS: Can you translate that into a seismic
14 margin and tell me at what SSE level, assuming the same
15 spectrum --

16 DR. CHURCHMAN: I'm preparing to get to that in a
17 minute for all three structures.

18 DR. SIESS: Okay.

19 DR. CHURCHMAN: The service water pipelines are
20 located in a trench approximately 95 feet wide. The in situ
21 material was excavated down to Kirkwood Clay Formation and
22 replaced with engineered backfill. The pipelines which are
23 located at approximately 15 feet below grade use only a
24 15-foot wide space near the center of the trench.

25 The foundation of the pipeline consists of

43
1 engineered backfill, Kirkwood clay, Basil sand and Vincenttown
2 sand.

3 DR. EBERSOLE: Apart from seismic liquefaction,
4 if you were to experience a failure in one of the service
5 water lines, would it scour the region in the vicinity of
6 the failure and simultaneously cause collapse of both pipes?

7 DR. CHURCHMAN: Loss of one of the pipes has been
8 evaluated, and the plant, it would have an acceptable effect
9 upon the others in the vicinity.

10 DR. EBERSOLE: How far apart are the pipes?

11 DR. CHURCHMAN: Approximately 15 feet.

12 MR. POMEROY: I'm a little confused. That is the
13 second time you have used the word "acceptable." Could you
14 quantify that for me just a little bit?

15 DR. CHURCHMAN: For instance, with the factors of
16 safety I've been talking about for the SSE event, I've been
17 pointtting to, for instance, for sliding conditions, a 1.1
18 factor of safety as required by the Standard Review Plan,
19 3.8.5.

20 DR. EBERSOLE: I guess I didn't get an answer.
21 Did you say you have examined this problem and you don't
22 find any problem?

23 DR. CHURCHMAN: That's correct. The factors of
24 safety against liquefaction we have discussed are in general
25 based primarily upon laboratory test data which tend to

44 1 underestimate these values due mainly to sample disturbance.

2 The in situ factors of safety are very likely to
3 be considerably higher. To assess this, we have retained
4 Professor Seed from the University of California at Berkeley
5 for his evaluation of seismic margin against liquefaction.

6 Based on Professor Seed's evaluation using field
7 performance data, it is judged that the foundation of the
8 power block, intake structure and pipelines have ample
9 margins of safety against design acceleration level of .2 G,
10 and also against significantly increased SSE acceleration
11 levels.

12 DR. SIESS: That is all very interesting, but it
13 hasn't addressed the issue I raised, the one we were interested
14 in.

15 DR. CHURCHMAN: All right, Dr. Ebersole --

16 DR. SIESS: I would appreciate it if you would
17 get on with it because you're telling us a lot of stuff
18 we're not particularly interested in at this time.

19 DR. CHURCHMAN: I would like to introduce
20 Professor Seed to provide a brief summary review concerning
21 the basis for these judgments.

22 MR. SEED: My name is Harry Seed. And I am
23 professor at the University of California-Berkeley,
24 consultant to Geotechnical Engineering and Earthquake
25 Engineering.

45

1 I have been retained by the applicant to evaluate
2 the safety margins against liquefaction for the soils at
3 the Hope Creek site. As Mr. Churchman just told you, when
4 the liquefaction factors of safety were evaluated at the time
5 the plant was designed, it was done by comparing the cyclic
6 loading resistance of the soils as measured by laboratory
7 tests with the estimated stresses to be induced in the
8 ground, postulated SSE.

9 That comparison led to a factor of safety of 2.
10 That was done about eight years ago, I think. At the time
11 that was the recognized and accepted method of evaluating
12 liquefiability of sandy deposits.

13 Since that time a number of changes have taken
14 place. One of the major changes has been the recognition by
15 the geotechnical engineering world that when we take samples
16 of relatively dense sands that they were inevitably disturbed
17 in the sampling process. And that disturbance leads to a
18 reduction in the cyclic loading resistance of the sands.

19 I would like to show you a Vugraph to show you a
20 typical example of that reduction in cyclic loading resistance.

21 (Slide.)

22 MR. SEED: The upper line in the plot shows the
23 cyclic loading resistance. That is, the cyclic stress ratio
24 plotted on the vertical axis is against a number of cycles
25 required to cause a core pressure ratio of 100 percent, which

46
1 is interpreted by some people as being indicative of
2 liquefaction, for a deposited dense sand.

3 That deposit was large enough to be tested in a
4 large, very large-scale cyclic load test. So that is the
5 property of a large block of sand.

6 An identical block of sand was made and samples
7 were extracted from the large block of sand using conventional
8 undisturbed sampling procedures and handled as samples of the
9 parent block. The samples were extruded from the sampling
10 tubes and tested as samples, 2.8-inch diameter samples in
11 conventional cyclic loading tests in the laboratory.

12 The results of that set of tests are shown by the
13 lower curve on the plot. And the comparison between the
14 properties of the soil after sampling and the properties of
15 the soil as compacted, indicates that the measured cyclic
16 loading resistance of these samples of dense sands were
17 reduced from their actual values by a factor of about 4 in the
18 sampling process.

19 This kind of result has been determined in the
20 United States and also in Japan, and is characteristic of the
21 kind of behavior that occurs in relatively dense sands during
22 the sampling process.

23 At the Hope Creek site we find ourselves dealing
24 with a lot of relatively dense sands. The properties of
25 these sands in the initial studies were measured by laboratory

47
1 loading tests. As such, the results of those tests are
2 likely to provide a very, very considerative estimate of the
3 true liquefaction resistance of the deposits at the site.
4 This problem has been recognized by the geotechnical
5 engineering profession.

6 And to circumvent the problem, new procedures have
7 been developed which evaluate liquefaction resistance without
8 resorting to the problems of sampling.

9 As a matter of fact, it is recognized now, I
10 believe, that the only way that a truly undisturbed sample of
11 sand could be obtained for testing in the laboratory would
12 be to freeze the sand in situ, and then extract the frozen
13 soil from the ground, bring it to the laboratory and thaw it.
14 That is extremely expensive, but it is being done in some
15 parts of the world.

16 An alternative to that is to do an in situ test
17 on the sand. In situ test is usually a penetration test,
18 and usually, the standard penetration test. And by going
19 throughout the world, deservng sites which liquefy during
20 earthquakes and sites which do not liquefy during earthquakes,
21 using actual field behavior and standard products to penetrate
22 the resistance of sands to the liquefaction resistance of
23 sands.

24 A plot showing the present correlation for that
25 purpose which has been developed over a period of about

1 15 years is shown on the next Vugraph.

2 (Slide.)

3 MR. SEED: This plot shows maybe 150 sites that
4 have been investigated. Sites which have liquefied during
5 earthquakes.

6 Open circles show sites which have not liquefied
7 during earthquakes. Cyclic stress ratio developed during the
8 earthquakes is plotted on the vertical axis and the
9 penetation resistance of the sands at the sites is plotted
10 on the horizontal axis.

11 A line is drawn separating liquefiable sites from
12 nonliquefiable sites. The line is drawn quite conservatively
13 so that almost -- very few of the solid black points fall
14 below that line, whereas a lot of the open circles, which
15 are known liquefiable sites, fall above it.

16 It is a near lower bound line. And that, plots
17 of that type are being used widely nowaways to evaluate the
18 liquefiability of sand products and the factors of safety
19 for those sandy products against earthquake-induced
20 liquefaction.

21 The particular plot you see is a plot developed
22 from magnitude $7\frac{1}{2}$ earthquakes. It is possible to extend
23 plots like that to other magnitude earthquakes. Such a plot
24 is shown on the next Vugraph.

25 (Slide.)

49 1 MR. SEED: If the magnitude goes down, then the
2 boundary line separating liquefiable sites from nonliquefiable
3 sites moves upwards.

4 Turn it that way.

5 The plot labeled $N = 7\frac{1}{2}$ on this plot is exactly
6 the same as the line I showed you on the preceding plots.
7 The other lines on the plot have been developed on the basis
8 of that line, extrapolating to smaller magnitude and
9 slightly larger magnitude earthquakes on the basis of the fact
10 that the lower magnitude earthquakes produce smaller numbers
11 of stress cycles due to the shorter duration of shaking.

12 On that basis, the results of the $7\frac{1}{2}$ magnitude
13 earthquakes can be extrapolated to smaller magnitude
14 earthquakes. This kind of approach is considered by most
15 people in geotechnical engineering to be the most reliable
16 way of evaluating liquefaction resistance of sand deposits
17 at the present time.

18 Therefore, that is the approach I have chosen to
19 use to evaluate the liquefaction resistance and factor of
20 safety against liquefaction for the soil deposits at the
21 Hope Creek site.

22 Now, if we could go back to the cross-section
23 we showed you earlier, I will discuss with you the factors of
24 safety found for the various soil deposits using that approach.

25 (Slide.)

1 MR. SEED: And possibly what they mean with regard
2 to safety margins. The main power block structure, as you
3 see in this slide, is supported directly on compacted
4 backfill, shown by the cross-hatched line, and the backfill
5 sits on top of Vincenttown sand.

6 The compact backfill has been densified to a
7 degree of compaction of 98 percent based on the modified
8 compaction test. That is an extremely dense condition.
9 There are very few sands in any projects anywhere that
10 have been placed so densely.

11 Because of its dense condition it has a very high
12 liquefaction resistance. My evaluation of the factor of
13 safety of that deposit, backfill against liquefaction,
14 for the postulated SSE for the Hope Creek Project, is that
15 the factor of safety is at least 4, and probably larger.

16 The compacted backfill in turn rests on
17 Vincenttown Formation. We know the penetration resistance of
18 the Vincenttown Formation. Using the penetration resistance
19 approach, the in situ testing approach, combined with field
20 performance data for previous earthquakes, reached the
21 conclusion that the factor of safety against factor of
22 safety is at least 4, and probably larger.

23 Thus, the power block sits on two soils, both
24 of which have a factor of safety against liquefaction of the
25 order of 4 or more.

51
1 DR. SIESS: Does factor of safety, can I
2 translate factor of safety as a ratio of the G value that
3 would cause liquefaction to the design G value?

4 MR. SEED: That's right. What that means, in
5 fact, is acceleration could be 4 times higher than the
6 postulated SSE value, and that would not bring those soils
7 to a condition of failure.

8 DR. SIESS: Assuming the spectrum was the same.

9 MR. SEED: Right.

10 DR. SIESS: Now, on the Vincentown, as I recall,
11 and somewhat confirmed by the staff SER, there was quite a
12 range of density. It says here from 16 blows per foot up
13 to refusal.

14 MR. SEED: That's right.

15 DR. SIESS: Was your evaluation based on --

16 MR. SEED: It was based on what I would call the
17 30 percentile value of the penetration resistance values?

18 DR. SIESS: How many blows, do you remember?

19 MR. SEED: Twenty-five, 26, thereabouts.

20 DR. SIESS: Twenty-five, 26?

21 MR. SEED: I could look it up.

22 DR. SIESS: That's all right.

23 MR. SEED: I would rather tell you. Twenty-five.

24 DR. SIESS: Twenty-five.

25 MR. SEED: That brings us to the intake structure

52 1 which, as you see, sits on concrete which, in turn, sits on
2 Vincenttown Formation, which we have already discussed. Its
3 factor of safety is 4 or more.

4 That presents no problem and provides a large
5 margin of safety against liquefaction. The service water
6 pipeline actually is surrounded by compacted sand because
7 the hydraulic fill surrounding the service water pipeline
8 has been removed as also has the river bottom sand which
9 you see in this profile.

10 Those two materials are replaced by compacted
11 sand, the same compacted sand we have under the main structure.
12 That is extremely dense, has a factor of safety of 4 or
13 better. That is underlain by the Kirkwood Formation, which
14 is clay and is simply nonliquefiable, so the issue doesn't
15 arise.

16 Kirkwood Formation is underlain by a very thin
17 layer of Basil sand. We don't have an awful lot of data
18 with that Basil sand because it is hard to get penetration
19 resistances in the Basil sand because of its very small
20 thickness.

21 Based on laboratory tests the factor for the
22 Basil sand is 2. It's relatively dense material. We would
23 expect that to be a lower bound value for the same reasons
24 I have discussed with the other sands in the project.

25 We have -- do have some limited penetration test

1 data for the Basil sand, and that limited data indicates the
2 factor of safety with that layer also is of the order of 3 or
3 4.

4 Thus, all the structures of this project are
5 supported on soils which have a high margin of safety against
6 liquefaction. And I don't think -- and I consider personally
7 that that margin of safety is ample for any earthquake that
8 we might want to consider for this particular site.

9 DR. SIESS: What about the hydraulic fill in the
10 upper part, there? Nothing is on it. But it can represent
11 a lateral load on the intake structure.

12 MR. SEED: That's right.

13 DR. SIESS: Has that been looked at.

14 MR. SEED: Yes. In analyzing the intake structure
15 the hydraulic fill has been considered to have liquefied
16 during the earthquake and the pressures on the structure are
17 representative of the pressures of liquefied hydraulic fill
18 acting on the structure. That still provides an adequate
19 factor of safety against sliding of the structure due to
20 those pressures.

21 The interesting thing about that is that while
22 the factor of safety comes out to be a number like 1.25 or
23 thereabouts, since higher accelerations can't do more than
24 cause it to liquefy; doubling acceleration does not reduce
25 that factor of safety hardly at all.

1 The hydraulic fill only liquefies just the same.

2 DR. SIESS: Yes.

3 Questions?

4 MR. POMEROY: Did you say that the river bottom
5 sand had about the same factor of safety as the engineering
6 backfill?

7 MR. SEED: No, I didn't say that. I said the
8 bottom sands under the surface water pipeline had been removed
9 and therefore didn't have relevance to the issue.

10 MR. POMEROY: Yes. Could you comment briefly
11 on possible differences in frequency content between
12 intraplate earthquakes and interplate earthquakes that might
13 give rise -- does the difference in frequency content and
14 perhaps duration of the signal have any effect on the
15 liquefaction?

16 MR. SEED: Yes. Frequency content has an
17 influence on liquefaction. High frequency content. High
18 frequencies of motion. What really counts in liquefaction is
19 the number of stress cycles induced by the earthquakes
20 regardless of their frequency.

21 To explore that we have over a long period of
22 time examined the number of stress cycles induced by a lot
23 of the accelograms representative of earthquakes of
24 magnitude 5, $5\frac{1}{2}$, 6, $6\frac{1}{2}$, 7, and so on and so forth, and
25 considered that in the whole analysis procedure.

55
1 MR. POMEROY: If you had a large number of cycles
2 of, say, 30 or 40 Hz, that would --

3 MR. SEED: That would make a large difference.
4 If you get 30 or 40 cycles, you would be talking about a
5 magnitude $8\frac{1}{2}$, $8\frac{1}{2}$ earthquake, actually.

6 MR. POMEROY: We have seen them in the Eastern
7 United States at smaller magnitudes than that. But thank
8 you very much.

9 DR. SIESS: Thank you, Harry.

10 MR. SEED: Thank you.

11 DR. CHURCHMAN: Thank you, Dr. Seed.

12 Based upon Dr. Seed's discussion we have judged
13 that the Category 1 foundations for the Hope Creek Project
14 are not only adequate for the design SSE of .2 G, but also
15 has sufficient seismic margin.

16 (Slide.)

17 DR. CHURCHMAN: Streamlining the remainder of the
18 talk, according to Dr. Siess' request, in conclusion, we have
19 high confidence in our seismic design because we have
20 incorporated many conservative factors.

21 We judge that the final product is truly
22 conservative.

23 I would now like to introduce Joe Yaworks, Chief
24 Controls and Electrical Engineer --

25 MR. ECKERT: We readjusted the schedule, Chuck,

56
1 to put you on this afternoon.

2 DR. SIESS: We are still readjusting schedules.
3 But before we leave the seismic issue I have a question. It
4 is a secondhand question. I won't identify the author. Take
5 it from me, if you want. But I don't expect the staff to
6 be able to answer today. Maybe not ever.

7 But the question has to do with the NRC taking a
8 look at this plant to get some idea of the seismic risk of
9 the plant as a whole. You know, seismic PRA-type approach.
10 Limerick had a seismic PRA. It has some features similar
11 to this plant.

12 I think Livermore, in connection with the SSP,
13 was going to look at a BWR. I think the one they are looking
14 at is Lasalle, which isn't this plant, but would give some
15 idea whether BWRs are a little different than PWRs.

16 The author of the question also mentioned a
17 Brookhaven report on seismic risk. I don't know where in the
18 staff that question goes, but I would appreciate if you could
19 answer any of that. Fine.

20 MR. CHEN: Maybe I will want to say something.

21 DR. SIESS: This is risk, now.

22 MR. CHEN: My name is John Chen, engineer with
23 the NRC.

24 First I want to make a few comments with regard
25 to the factor of safety so far in the presentation. We have

57

1 this understanding, apparently from the applicant. It seems
2 to indicate the factor is real high values. But from our
3 staff point of view, when that level increase your time
4 duration associated with high escalation earthquakes will
5 be different. The factor on the side will be substantially
6 different.

7 Our evaluation so far, we examined the site. All
8 the safety class structures -- containment building, power
9 blocks -- there is no problems. The factor of safety
10 probably in the range of, from our estimate, maybe somewhere
11 about 3.

12 DR. SIESS: You're talking about liquefaction?

13 MR. CHAN: Liquefaction.

14 DR. SIESS: Okay.

15 MR. CHAN: Now, for the pipeline itself, because
16 we have this river bottom stand, at higher levels pour
17 pressure would build up. The pour pressure has been
18 evaluated but only for .2 G.

19 If it goes higher, you would have certain amount
20 of soil sand become liquefied. That effect would affect
21 the pipelines.

22 For the intake structure, we have evaluated
23 certain amount of these sliding stabilities and also the
24 overturning mode for the intake structures.

25 If at the higher levels the sliding of this

58
1 structure could be affected, because there is a lot of sand
2 on the south side of the intake structures, we are not able,
3 not capable to provide residence, moving into the Delaware
4 River.

5 There is nother thing. On the side of the intake
6 structures there is a crane with a coffer that was not
7 considered as safety class structures. That has a marginal
8 stability in the current conditions. Means under current
9 SSE conditions it is above unity, or acceptable to us right
10 now.

11 DR. SIESS: This is a crane, you said?

12 MR. CHEN: A coffer that encloses the crane next
13 to the intake structure.

14 DR. SIESS: How is that safety-related?

15 MR. CHEN: If that failed under the seismic
16 condition, especially if that one, liquefaction of the
17 hydraulic fill taking place and river bottom sand taking
18 place, the materials could be washed into the area close to
19 the intake structure. Block the function of the intake
20 structure itself.

21 DR. SIESS: You're going to have river sands
22 flowing into the intake structure or stuff behind it flowing
23 around?

24 MR. CHEN: Right.

25 DR. SIESS: Which? Or both?

1 MR. CHEN: The river bottom sand hydraulic fill
2 all being retained by the coffer.

3 DR. SIESS: That is the sheet pile --

4 MR. CHEN: Sheet pile coffer --

5 DR. SIESS: At the far end.

6 MR. CHEN: Either end of the intake structures.

7 DR. EBERSOLE: Do I understand you're telling me
8 the suction, uptakes of the service water pumps would be
9 jeopardized by incoming sand?

10 MR. CHEN: I am saying that is a possibility.
11 That means the margin of safety for that cofferdam is 1.1
12 for sliding.

13 DR. EBERSOLE: What is it?

14 MR. CHEN: Steel pile driven down on top of the
15 Vincenttown.

16 DR. EBERSOLE: Does it have any --

17 MR. CHEN: Very minimal.

18 DR. SIESS: So if the cofferdam slides out into
19 the river because the sand behind it liquefies, your concern
20 is that the sand would go out behind it, fill around and
21 block the intakes?

22 MR. CHEN: Yes.

23 MR. CHURCHMAN: If I could interject --

24 MR. CHEN: What we are thinking about is, we
25 envision for this above SSE concern. It should be a

60
1 progressive-type of event occurring whenever you have SSE
2 above what the current design for. This is essentially the
3 PRA-type of study.

4 DR. SIESS: Do you have something?

5 DR. CHURCHMAN: Yes. Chuck Churchman.

6 I would like to add that we have looked at the
7 cofferdam, sheet pile cofferdam, and looked at the aggregate,
8 3/4-inch and 1/2-inch aggregate. It is fully grouted. We
9 have made an analysis to indicate that pseudo-static
10 analysis that indicated it would be standing with a factor of
11 safety of greater than 1.1 under .2 SSE.

12 DR. SIESS: If you assume it liquefies at 1.1
13 times 2 SSE, it doesn't make any difference whether it is
14 4/10 or 6/10, it's liquefied, period. So that is not
15 linear. Right?

16 But your point is that that factor, 1.1, means
17 it would liquefy at something not too much above the SSE?

18 MR. CHEN: Right.

19 DR. SIESS: If that cofferdam failed, we would
20 then have a problem.

21 MR. CHEN: Yes.

22 DR. SIESS: So to avoid the situation, you would
23 say the probability was high that that cofferdam would fail
24 if it was 2 SSE?

25 MR. CHEN: Yes.

61 1 DR. SIESS: Why? The pressure on it isn't going
2 to be any greater than it was at 1.1 SSE, is it?

3 MR. CHEN: It is not -- the force acting on the
4 cofferdam will be different when you have a higher --

5 DR. SIESS: How can it be higher than liquefied
6 lateral -- I mean somebody correct me if I'm wrong, because
7 I haven't been in soil mechanics in 30 years. But I
8 thought once I got something liquefied, it was liquid, I
9 treated it as a heavy liquid. Get the lateral load as a
10 density times the height and now how do I get it any higher
11 than that, than liquid lateral load?

12 MR. CHEN: Let me just remind Dr. Siess, on the
13 dam, when you have a dam retaining a body of water --

14 DR. SIESS: You're talking about dynamic effects,
15 then. Dynamic loads transmitted through the soil.

16 MR. CHEN: Yes. This is essentially the same
17 phenomena as retaining water behind a dam.

18 DR. SIESS: You have done some analyses of
19 those, or you just think they are higher than static?

20 MR. CHEN: I think there is a lot of article
21 talk about that, higher than the static, on the dam. There
22 are also some measurements indicate that.

23 DR. EBERSOLE: Did the applicant have any shutdown
24 mode which is effective without the presence of service water?

25 MR. PRESTON: No, sir, that is our ultimate heat
sink.

dhl

1 DR. SIESS: Has this study you have mentioned appeared
2 in any of the documentation?

3 MR. CHEN: Talk of hydro-dynamic effect on the dam?

4 DR. SIESS: Well, the thing you are talking about here.
5 You see, normally in the SER we don't see anything beyond the
6 SSE.

7 MR. CHEN: Right.

8 DR. SIESS: And the study you are talking about,
9 looking at beyond the SSE, has that been reported in something?

10 MR. CHEN: No. I think that is based on the judgement
11 factor, based on the design margins at this point we have.

12 DR. SIESS: So in your view of Hope Creek, you are
13 satisfied it is okay at two tenths SSE?

14 MR. CHEN: Right.

15 DR. SIESS: But if you were pressed for a margin,
16 if somebody came along and said Yes, we have got to really move
17 Charleston up there, somewhere in the neighborhood, and it goes
18 up to .25, you would have to start over.

19 MR. CHEN: We have to carry on some additional
20 studies, yes.

21 DR. SIESS: I see.

22 You think of a seismic PRA was done, this would be
23 a major thing to be addressed?

24 MR. CHEN: Yes, I think PRA would show the ranking,
25 the overall ranking of these effects.

dh2
1 DR. SIESS: It can happen. Of course, it is quite
2 serious; this is the ultimate heat sink.

3 MR. PRESTON: We would like to provide additional
4 comment on the NRC's statements if we may.

5 DR. SIESS: Fine.

6 DR. CHURCHMAN: Dames & Moore, Dr. Harskil.

7 DR. HARSKIL: My name is Harskil, with Dames & Moore.

8 Dr. Siess, I think the two things that ought to be
9 borne in mind with respect to the numbers that have been bandied
10 about in the discussions that have ensued, factor of safety of
11 1.1, assumes extreme loading conditions. It assumes that the
12 hydraulic fill globally liquifies. The hydraulic fill is
13 composed of irregular and somewhat discontinuous layers of
14 silty clays. Clay silts and silty sands with organics in most
15 parts of the layer.

16 These materials are not liquifiable. Between certain
17 gaps, especially around 10 to 15 feet, there are sporadic thin
18 layers of sand, of fine to medium consistency. These sands are
19 loose to medium consistency with N-values between 2 to 10 blows
20 per foot.

21 We are of the opinion that the hydraulic fill will not
22 globally liquify. If we make the assumption the hydraulic
23 fill does globally liquify, then the factor of safety against
24 sliding for the intake structure is 1.1. So, factor of safety
25 for sliding of the intake structure is considerably higher than

dh3
1 1.1.

2 The second comment was with respect to the buildup of
3 pressure in the Basil sands. It has been said that if a higher
4 seismic design, higher G value for the site was imposed, that
5 there would be higher forward pressure built up in the Basil
6 sands. Right now, using laboratory tests and conservatively
7 associated with sampling, transportation and testing of samples,
8 we have determined a factor of safety in the Basil sands of 2.

9 The pressure built up using this very conservative
10 measure of analysis is relatively low. It is my perception,
11 and prior presentation has verified that, using field performance
12 data, factor of safety in the basil sands are higher, which
13 leads me to conclude that the poor water pressure buildup in
14 the Basil sands will be even less than that predicted from
15 laboratory testing.

16 I think these two very important considerations ought
17 to be taken into account when we consider the potential for
18 liquifaction and consequences of the potential for liquefaction
19 at the site.

20 DR. SIESS: Thank you. Regarding the hydraulic fill,
21 I am reading the SER. It says, it is composed of irregular,
22 sometimes miscellaneous layers of clays, clay silts and silty
23 sands with organics in some places. There are -- 2 to 10 is
24 really loose. That refers to non-granular materials.

25 DR. HASKIL: That's correct.

dh4
1 DR. SIESS: I think this has been interesting. It is
2 another issue peculiarly related to licensing because it is
3 beyond the design basis issue. I do believe, though, that the
4 discussion has brought out the fact that there might be some
5 things out there if we have to go to higher earthquakes or if
6 we really ought to start thinking about seismic margins.

7 What has been postulated by the staff is a very
8 serious thing. If we block another intake structure, that is
9 the surest way to get this plant in really serious trouble.
10 To prove you can't block it involves something I think just
11 the start of the art almost. It is trying to predict
12 liquefaction in a very mixed soil, then worrying about dynamic
13 effects of a heavy liquid.

14 And a factor of 2 is pretty big in some things. But
15 if what happens out at the end of that factor of 2 is total
16 disaster, it is not very big. I am not sure if even a coffer
17 dam fails it is total disaster. It may not block everything.
18 I would have to think about it. I don't think we will reach a
19 conclusion on this and I am not sure what the full committee
20 will want to do.

21 They might end up with a paragraph in the letter
22 suggesting you continue to look at this. And if somebody ever
23 gets Charleston up there we will all be looking at it.

24 Any other comments?

25 MR. CHEN: I have one more comment, with regard to the

dh5
1 coffer dam stability analysis. For that particular analysis,
2 the staff did not require applicant to assume the hydraulic fill
3 and the river bottom sands liquified for that analysis.

4 The safety factor for that, based upon applicant's
5 analysis for the sliding failure mode is 1.3, but for the over-
6 turning mode, it is 1.14.

7 DR. SIESS: Overturning in this case means overturning
8 about that concrete or overturning above that? I mean, there is
9 a column there, a structure. Then there is another equal amount
10 of concrete down below it. Are they tied together so that the
11 whole thing has to overturn or can you just tip over the
12 service water --

13 MR. CHEN: Just turning toward the river --

14 MR. SCHWENCER: No.

15 DR. SIESS: I am trying to find out what overturns.
16 Have I got something 50 feet high or 100 feet?

17 MR. CHEN: The entire coffer dam is 60 feet.

18 DR. SIESS: Can somebody give us that slide, please?

19 MR. CHEN: I have a slide.

20 DR. SIESS: Do you know what I mean by treatment
21 concrete?

22 MR. CHEN: Yes, but I am not sure there is treatment
23 concrete in that, in the coffer dam.

24 DR. SIESS: Oh, in the coffer dam area.

25 MR. CHEN: Just to set the record straight --

dh6
1 DR. SIESS: I think we have gone far enough on it.
2 We understand the concern and the possibilities. I understand
3 1.1s and 1.3s, which don't help me very much at this stage.
4 They help me for licensing the plant, but not for determining
5 seismic margin.

6 Yes, do you have something you want to add?

7 DR. MC GUIRE: Let me make a parenthetical comment
8 which I should have made during my presentation, which perhaps
9 bears on the committee's consideration of accelerations above
10 the SSE. That is the results I showed which are derived from
11 the Lawrence Livermore study should be considered as conserva-
12 tive in terms of the absolute numbers of probability.

13 That is based on several conservative assumptions
14 used in the preliminary round by Lawrence Livermore, and I
15 believe is also the stated position of members of the NRC staff;
16 that those results are probably conservative by at least a
17 factor of 3. That may bear on the subcommittee's consideration
18 of the potential effects of accelerations above the SSE level.

19 DR. SIESS: I don't remember -- see, I don't know how
20 to read your curves on that because you had different curves for
21 different Ms. If I put 7 and a half there, that was Charleston
22 I guess, right? Magnitude 7 and a half?

23 DR. MC GUIRE: Charleston earthquake is estimated to
24 have body weight magnitude around 6 and a half.

25 DR. SIESS: Okay.

dh7

1 DR. MC GUIRE: Six and three-quarters.

2 DR. SIESS: You see, I don't know at what probability
3 I am comfortable about shutting off the service water. 10 to
4 minus 4, you know --

5 DR. MC GUIRE: I am not sure what probability you
6 should be comfortable with, either.

7 DR. SIESS: This is our problem, you know. We are
8 talking about probabilities, nobody knows what they are worried
9 about.

10 DR. MC GUIRE: My only point was the curves which I
11 showed which you will get a copy of should be considered as
12 conservative estimates of those probabilities.

13 DR. SIESS: Conservative estimate of the probability,
14 I think means a factor of 10.

15 DR. MC GUIRE: I think I said about a factor of at
16 least 3.

17 DR. SIESS: Oh. That's nothing on probabilities. You
18 know. We are dealing with just exponents.

19 DR. SEED: Mr. Chairman, since I started this, could
20 I say a word or two?

21 DR. SIESS: Sure.

22 DR. SEED: I think one of the things that has to be
23 borne in mind, we have to look at the coffer dam problem. But
24 we will do that tonight. The issue about the intake structure,
25 it has to be borne in mind whether we analyze structures like

dh8
1 this that liquefaction doesn't happen the instant the earthquake
2 begins. On a magnitude 5 and three-quarter earthquake, the total
3 length of shaking is not more than a few seconds. It is going
4 to take all of those seconds for the soil to liquify.

5 By the time the soil realizes it's liquified, the
6 earthquake is probably going to be over. So it is not always
7 necessary to combine dynamic forces with the pressures on
8 liquified soil at the same time. Soil is likely to liquify
9 at the time the peak acceleration develops during the earth-
10 quake if it is going to do it at all.

11 And by that time the inertia forces produced by the
12 combination of liquified soil and subsequent motions is not
13 going to be the combination of the maximum dynamic effect
14 together with the pressures of liquified soil. These are
15 important considerations and I feel they are being overlooked
16 in the way the staff is examining this problem.

17 And I think the sequence of the evengs going on needs
18 consideration in evaluating the factors of safety.

19 DR. SIESS: You are simply saying it is more compli-
20 cated than we think it is.

21 DR. SEED: I am suggesting it is not more complicated
22 than I thought it was.

23 (Laughter.)

24 DR. SIESS: I didn't say that. But when we are
25 what-if'ing, we like to simplify things. It helps.

1 MR. ECKERT: Can we move to another subject?

2 DR. SIESS: I am going to poll the committee. We
3 have finished the seismic issue for the moment. It is now 6:30.
4 We can go back and talk about corporate organization, which
5 would put us back in order. It seems to me we could do some
6 trimming in there, if you wanted to.

7 I don't know how much of this the committee is inter-
8 ested in at this time. I would think that; would you like to
9 work until 7 o'clock on whatever we have got?

10 DR. MICHELSON: I would like to suggest that in the
11 case of Section 3.2 of the agenda that we simply look over the
12 material tonight and ask any questions we have in the morning.
13 Most of the other handouts seem to be reasonably comprehensive.
14 I assume these are, too. One could simply read through it and
15 ask questions in the morning where it isn't there.

16 DR. SIESS: How would that do with you?

17 MR. ECKERT: The only problem with that is, all you have
18 there are the slides.

19 DR. MICHELSON: Yes.

20 MR. ECKERT: There isn't any text at all.

21 DR. MICHELSON: That's right.

22 DR. SIESS: Slides give some idea of the score.

23 MR. MARTIN: There is some text.

24 MR. ECKERT: Is there text in the book, too?

25 DR. MICHELSON: We have text in the SER that will also

h10
1 guide us.

2 MR. ECKERT: I can make two minutes' worth of comments
3 on it and let it go to that.

4 DR. MICHELSON: I would like to reserve the right to
5 ask questions after I look at it.

6 MR. ECKERT: Of course.

7 DR. SIESS: I think we are about at a point of quitting.

8 DR. MICHELSON: Why don't we suggest they make a five
9 minute summary statement in the morning, followed by questions
10 on that section?

11 DR. SIESS: Well, those issues, I believe the committee
12 is clearly interested, I think Items A, B and C are for infor-
13 mation. They can get a lot of that off the slides. And ask
14 questions. But D and E, I don't see how they can be separated.
15 This is the operating experience of the people in the plant.
16 We want to know what you are doing about qualified operators,
17 the question the staff raised earlier about the six months'
18 experience on Salem. And how many people you expect to have
19 and so forth.

20 This has been another issue with the committee over
21 plant. As near as I can tell, that is what D and E addresses;
22 right?

23 MR. MARTIN: That's correct.

24 MR. PRESTON: That's correct, yes.

25 DR. SIESS: It's not so much current status, because

1 you are a year from full load, as where you expect to be then.

2 MR. ECKERT: You will see those statistics in the book.

3 DR. SIESS: Okay. What is your target on that?

4 Item F, we will see how much interest there is on that.

5 I will propose people take the notebook with them tonight. We

6 will start off tomorrow morning with a brief presentation on

7 that and then questions and answers.

8 MR. ECKERT: Okay, we will give you --

9 DR. SIESS: D and E, I think, after I look at what is
10 in the book, I will tell you how much of that we want. It
11 won't be all of it. Okay.

12 MR. ECKERT: We will pick up A, B and C in about two
13 or three minutes in the morning, I think is what you are saying.

14 DR. SIESS: It might end up a lot longer than if
15 people ask questions.

16 MR. ECKERT: Fine.

17 DR. SIESS: Then on the other items, there are a few
18 near the end that we can save some time on if we have to. I
19 have already looked ahead at some of the content. And things
20 we are interested in, we could easily just skip. In fact, most
21 of it, a lot of the stuff --

22 MR. ECKERT: If you see some you would rather see a
23 condensed version, if you could identify those, it would
24 certainly help the people tonight.

25 DR. SIESS: Most of these are pretty condensed

dh12

1 already. Something we have down for 15 minutes means somebody
2 planned to present it in about 7.

3 MR. ECKERT: Exactly.

4 DR. SIESS: Emergency planning, which is strictly
5 the same as Salem, I am not sure there is any point in listening
6 to it. Fitness for duty and personnel selection; people can
7 look through that and decide whether they want to ask questions
8 about it. I have looked at that. I think we might want to hear
9 something on it.

10 Training, as I look through that, a lot of it is
11 organization charts which I think we can skip and get into cri-
12 teria, selection and things of that sort. 3.16(b) is emergency
13 operating procedures development, and I think there is some
14 interest in that. Communications. I am not sure we can't drop
15 that. And the radiation protection program, the original
16 part of it, that is the first part, I think we could skip.
17 And then the second party, absent Dr. Molar, I am not sure.
18 We might want to save something for him to bring up at the
19 full committee meeting.

20 But I can see some saving in the late afternoon
21 tomorrow. We will have a chance tomorrow to go over that with
22 you so it won't be just cold.

23 MR. ECKERT: All right.

24 DR. SIESS: So we are going to recess the meeting
25 until 8:30 tomorrow morning in this room.

dh13

1 I assume you can leave things here. Don't leave too
2 much. Thank you very much.

3 MR. ECKERT: I think you can leave anything here
4 you want to.

5 DR. SIESS: Okay.

6 (Whereupon, at 6:40 p.m., the meeting was adjourned.)
