February 1, 1985
RBG-20062
File No. G9.5,
G9.8.6.2

Mr. Harold R. Denton, Director
Office of Nuclear Reactor Regulation
U. S. Nuclear Regulatory Commission
Washington, D. C. 20555

Dear Mr. Denton:

River Bend Station-Unit 1
Docket No. 50-458

Enclosed is the Gulf States Utilities Company (GSU) response to Safety Evaluation Report (SER) Confirmatory Item #19 - Hydrogen Control (SER Section 6.2.5, Page 6-32/33.) Attachment 1 contains the GSU endorsements for various Hydrogen Control Owners Group (HCOG) submittals. These letters should be utilized to provide background and reference material for SER Confirmatory Item #19. Attachment 2 contains a revision to the Request for Additional Information (RAI) on the Hydrogen Ignition System (HIS) transmitted to W. J. Cahill (GSU) by A. Schwencer (Nuclear Regulatory Commission - NRC) on December 2, 1983 and supercedes the original GSU response from J. E. Booker (GSU) to H. R. Denton (NRC) dated December 30, 1983 (GSU Letter No. RBG-16679).

Enclosure 1 contains a revised response to FSAR Question 480.40 (Section 6.2) providing additional information on a RBS-specific Hydrogen Control Program. An FSAR description of the Hydrogen Ignition System based on the information noted above will be provided to the Staff by March 29, 1985. In addition, GSU will submit the results of the CLASIX-3 Computer Code (used to predict containment temperature and pressure) by February 15, 1985. Also the results of a limited equipment survivability analysis and a specific program plan addressing the generic HCOG efforts will be provided by March 15, 1985.

Sincerely,

J. E. Booker
Manager-Engineering,
Nuclear Fuels & Licensing
River Bend Nuclear Group

HYDROGEN CONTROL OWNERS GROUP (HCOG) SUBMITTALS
APPLICABLE TO RIVER BEND STATION

HGN-001, January 15, 1982, from J. D. Richardson (Chairman, HCOG) to H. R. Denton (Director, NRC-NRR) "Hydrogen Control Owners Group (HCOG) BWR-6 Mark III Containment Sensitivity Study for Hydrogen Generation Event".

HGN-003, April 8, 1982, from Richardson (Chairman, HCOG) to Denton (Director, NRC-NRR) "Hydrogen Control Owners Group (HCOG) BWR-6 Mark III Report on Hydrogen Control Accident Scenarios, Hydrogen Generation Rates and Equipment Requirements".

HGN-014, February 9, 1984, from S. H. Hobbs (Chairman, HCOG) to Denton (Director, NRC-NRR) "Hydrogen Control Owners Group BWR-6 Mark III Final 1/20th Scale Test Report".

HGN-016, April 2, 1984, from Hobbs (Chairman, HCOG) to Denton (Director, NRC-NRR) "Hydrogen Control Owners Group Responses to NRC Requests for Additional Information".

HGN-017, June 7, 1984, from Hobbs (Chairman, HCOG) to Denton (Director, NRC-NRR) "Mark III Hydrogen Control Owners Group Final Whiteshell Ignition Test Report".

HGN-024, December 14, 1984, from Hobbs (Chairman, HCOG) to Denton (Director, NRC-NRR) "Hydrogen Control Program Plan".

ATTACHMENT 2

REQUEST FOR ADDITIONAL INFORMATION FOR USE IN THE EVALUATION OF THE HYDROGEN IGNITION SYSTEM FOR THE RIVER BEND STATION, UNIT 1 MARK III CONTAINMENT

1. Provide a detailed description of the Hydrogen Ignition System (HIS) and its power supplies; include the total number of igniters, the numbers of circuit breakers, and a simplified electrical system schematic showing all the above stated items and any other major components.

RESPONSE

The design of the Hydrogen Control System (HCS) is based on the concept of providing distributed ignition sources so that hydrogen combustion is accomplished in a controlled manner. The HCS consists of a total of 104 igniters, powered by two physically separate and electrically independent divisions each containing 52 igniters. Division I is powered from motor control center 1EHS*MCC2A and Division II is powered from motor control center 1EHS*MCC2K. A simplified electrical schematic showing the HCS power distribution and associated circuit breakers is provided in TAB I. The HCS power distribution for the HCS includes combination starters with remote control switches for each electrical division in the main control room. The main transformers for each division are 15 KVa, 480 Volt to 120 Volt transformers. The main distribution panels are 120 Volt with five molded case circuit breakers utilized in each panel.

The control circuits for the igniters are provided in TAB II

2. Provide the following igniter information:

a. Vendor;

b. Model;

c. Qualification Program; and

d. Design Criteria

RESPONSE

The HCS igniter assembly is supplied by the Power Systems Division of Morrison-Knudson (Model No. 6043). These igniters meet the QA requirements of GSU's 10CFR50, Appendix B program and are qualified to IEEE-323-1974 and IEEE-344-1975, ("Hydrogen Igniter Nuclear Environmental Qualification Report", No. A-554-83, by Power Systems Division).

3. Provide a detailed description of the preoperational surveillance and periodic testing programs, as expected to be reflected in the River Bend Technical Specifications of the HIS. Specifically, the response should include the following information:

   a. How will the system be tested? Specifically, what indication will be available to show that a particular igniter is or is not functioning properly?

   b. Specify the frequency of testing.

   RESPONSE

   GSU and the Hydrogen Control Owners Group (HCOG) are participating in a joint effort to address HCS Technical Specifications. Limiting Conditions for Operation and Surveillance Requirements will be addressed by this joint effort. Igniter operability will be demonstrated by direct observation of energized igniters in accessible areas of the containment or by measurement of current demand for igniters in inaccessible areas. The minimum number of igniters required to be operable will be based on RBS igniter locations and acceptance criteria. When the HCOG effort is complete, this information will be used to revise the RBS HCS technical specification.

4. Describe the glow plug igniter selection program; i.e., how will actual igniters be selected for installation in the assemblies.

   RESPONSE

   Igniters are tested to demonstrate acceptable performance prior to installation in the assemblies. Each of the installed General Motors AC Division Model 7G igniter glow plugs is required to attain a minimum surface temperature of 1500°F at a normal input voltage of 120 Vac $\pm$ 10%, 60 Hz $\pm$ 10% before installation. After installation at RBS, the igniters will be tested to demonstrate that the minimum surface temperature of 1700°F is maintained with a nominal 120 Vac, 60 Hz input.

5. Provide construction drawings for several typical igniter mounts in the wetwell and containment regions. Also, provide a complete list of the approximate elevation, azimuthal and radial coordinates for each igniter in containment, and the corresponding elevation coordinate of the nearest ceiling (include a description of the nearest ceiling, i.e., open, solid, grated). Indicate whether all enclosed regions of the containment are served by redundant igniters.

RESPONSE

RBS has finalized the igniter locations in the containment and drywell. The hydrogen igniters have been located in accordance with the following location criteria.

a. Hydrogen can be released to the containment atmosphere through the safety relief valves or through the drywell vents. In both cases hydrogen exhausts through the suppression pool. Therefore, igniter assemblies are located in a ring above the suppression pool as well as at other locations throughout the containment.

b. Hydrogen can be released to the drywell atmosphere through a pipe break in the drywell. Therefore, igniter assemblies are located throughout the drywell.

c. In open areas of the containment and the drywell, igniter assemblies are located in accordance with the following criteria:

   i. Assuming only one Class 1E divisional power supply is functional following an accident, a maximum distance of 60 ft. exists between the operable igniters.

   ii. Assuming both Class 1E divisional power supplies are functional following an accident, a maximum distance of 30 ft. exists between the operable igniters.

d. Igniters are located in all enclosed volumes/areas within the containment subject to possible hydrogen accumulation and pocketing. At least two igniters are located in each volume/area and are powered from separate Class 1E divisional power sources.

e. Hydrogen has a very large difference between the upward and downward flame propagation limits (4.1% hydrogen by volume for upward, 9% for downward and 6% for horizontal - refer to NUREG/CR-2530 (SAND82-0218) draft report "Review of the Grand Gulf Igniter System", Sandia National Laboratory). Igniter assemblies at RBS are positioned so that they can burn out large volumes of lean mixtures with upward propagation of flames (with the exception of igniters which are located close to the surface of the containment dome because of lack of structural supports in the dome). Igniters are located near or below the mid-plane regions of volumes/areas being protected and, where possible, away from large, solid surfaces, including surfaces above the igniters (i.e., ceilings or other structures).

f. In open spaces in the containment and the drywell, locations of the igniter assemblies at the same elevation are alternated with respect to their Class 1E divisional power source. In addition, igniter assemblies are symmetrically staggered in azimuthal positions with respect to those located on the next lower and higher elevations in order to maximize the number of likely hydrogen ignition points.

g. Two igniters, powered from separate Class 1E divisional power sources, will be located within 30 ft. of each hydrogen mixing system inlet terminal. Two igniters located within 30 ft. of each hydrogen mixing system fan exhaust and each of these two igniters is powered from separate Class 1E divisional power source.

h. Igniters are located in the chimneys (hoist space and staircases at aximuth positions 150^{o}, 225^{o}, and 315^{o}) at each floor elevation and powered by either Class 1E divisional power sources.

TAB III gives the igniter locations. The igniter locations are approximate since some relocation may be necessary to facilitate mounting. All enclosed regions within the containment are served by redundant igniters. Mounting details for the igniters in the containment dome are provided in TAB IV.

6. For each floor level within the containment annular region and within the drywell, provide the cross-sectional flow area through the floor and identify the various areas, such as gratings, solid regions, or equipment blockages.

RESPONSE

A tabular list for each floor elevation in the containment and drywell indicating total surface area and total clear area is provided in TAB V.

7. Discuss the adequacy of the igniter assembly design to withstand the effects of pool swell events and the drywell negative pressure transient.

RESPONSE

The hydrogen igniter assemblies are qualified to withstand LOCA loads. The ability of the igniter assembly to withstand a negative pressure transient is being evaluated by HCOG (see RAI No. 15).

8. Provide full size (Size E) sectional drawings of the containment; and identify on these drawings the location of each igniter, its electrical division, the location of the drywell mixing system lines and the containment fan coolers/ducting.

Also, provide a list, including the location on the sectional drawings of the equipment required to accommodate hydrogen burning.

RESPONSE

The locations of the hydrogen igniters are included in TAB VI. The locations of the hydrogen mixing/purge system and the containment fan cooler and ducting are provided in TAB VII. A list of equipment required to survive a hydrogen burn is given in TAB VIII. This equipment was selected based on the following criterion.

- Equipment and systems required to mitigate the consequences of the event
- Equipment and structures required to maintain the integrity of the containment pressure boundary
- Systems and components required to recover the core
- Instrumentation and systems required to monitor the course of the event

The effects of hydrogen combustion are limited to the containment and drywell. Only equipment located in these two compartments has been evaluated for inclusion on the survivability list.

In addition, components have been excluded from the list of equipment required to survive a hydrogen generation event based on their failure mode or prior operation. Degraded core accidents evolve over a relatively long period of time before zircaloy oxidation begins. Many components will have performed their safety function before hydrogen combustion can begin. If these components are not required to function during or after hydrogen combustion, and if failure of the component will not compromise plant safety, then the component is not required to survive these accidents.

Specific exclusions used in developing the RBS equipment list are as follows:

- Components which have performed their active safety function prior to a hydrogen burn.
- Isolation valves which remain in the closed position; i.e., fail closed or "as is."
- Isolation valves which are open post-LOCA, fail in the "as is" position and also have a redundant motor-operated isolation valve outside containment for functional backup.

- Check valves which are qualified for reactor pressure and temperature with no safety-related instrumentation or electrical function are assumed to mechanically survive a hydrogen burn.

- Equipment and/or components which fail in a safe condition with no subsequent functional requirement.

- Manually operated valves or dampers which remain in the "as is" position (i.e., normally open or normally closed) are assumed to survive a hydrogen burn.

9. Discuss the consideration of the effects of local jet impingement on the igniter assembly due to the LOCA break.

RESPONSE

The hydrogen igniter locations are being evaluated for the effects of local jet impingement in the RBS high energy line break (HELB) analysis. The effect of local jet impingement on overall HCS performance will be evaluated. If the analysis indicates that the hydrogen igniter system function would be adversely affected by local jet impingement due to a LOCA break, it will be included and evaluated in the HELB analyses.

10. Discuss the effect of temporary water submergence on igniter performance. For these igniters, describe the testing which will be performed to assure igniter performance before, during and after being subjected to submerged conditions.

RESPONSE

The hydrogen igniters are required to be operable after being temporarily submerged in water. Testing procedure and test results are as reported in Morrison-Knudsen's Power Systems Report #A-554-83.

11. Considering the actuation criteria for safety systems, including operator action:

a. Under what conditions are the containment fan coolers activated?

b. How long after the containment fan coolers are actuated do the fan coolers attain full flow rate?

c. During an emergency situation, when would the HIS be activated?

d. What role, if any, would the hydrogen recombiner play with respect to the HIS?

RESPONSE

The containment unit coolers operate continuously under normal conditions. The unit coolers are automatically loaded onto the emergency diesels within 10 minutes following a loss of offsite power. Two of the three unit coolers are engineered safety features and operate automatically within 10 minutes after receiving a high drywell pressure signal (see FSAR Section 6.2.2.2). No operator action is required to actuate the containment unit coolers. The unit cooler fans attain full flow rate within 8 seconds of being actuated. GSU is participating in the BWROG Emergency Procedure Committee along with the other HCOG members in developing a generic Mark I, II, and III Emergency Procedure Guideline for hydrogen control. When the generic guideline is finalized, it will be incorporated into the RBS Emergency Operating Procedures. These procedures will contain guidance for the operator on activation of the HCS and the operation of the hydrogen recombiners.

12. Regarding the containment atmosphere mixing/cooling mechanisms:

a. Describe the distribution of the flow rate and the expected flow patterns of the containment unit coolers in the containment/wetwell regions. Discuss the differences if either Train A or Train B is activated and if both trains are activated at the same time.

b. What are the elevations and radial positions of the ducting?

c. Describe the sprays, fans or other systems. Identify and include available non-safety systems, e.g., fire protection devices or drywell coolers that could move air or provide cooling in the drywell, containment or wetwell regions and estimate the air velocities and the cooling effects in the respective regions due to these systems. If non-ESF systems are assumed to be available during the accident period, discuss the operator action necessary to actuate/ operate such systems.

RESPONSE

a. The containment ventilation system consists of three 50% capacity unit coolers each capable of providing 50,000 cfm. During normal operation two of the three unit coolers operate to maintain design ambient conditions. Following a LOCA, one containment cooler (two of the three are designed as engineered safety features) is required to operate (with the second on standby) as part of the containment heat removal system to condense steam. The ventilation system ductwork provides for distribution of the flow throughout the containment as shown on FSAR Figure 9.4-7c. Following a LOCA, if the duct distribution

system is available, approximately 15,000 cfm is distributed above the refueling floor (el 186'3"). Approximately 8,000 cfm is supplied directly into the wetwell region via 4 ducts attached to the grating at the HCU floor (el 114'0"). The remaining 27,000 cfm is distributed at various locations in the containment between el 114'0" and 186'3". Flow distribution is nearly identical no matter which unit cooler is in operation. During normal operation, when two unit coolers are in operation concurrently, all flow rates are approximately doubled.

It should be noted that the containment ventilation system distribution network is seismically supported but is not designed for post-LOCA service. Pressure relief dampers are located in the safety related portion of the ductwork connecting the two ESF coolers. These dampers open under a positive differential pressure of 15" WG and remain open to protect the ESF fans and motors from a post-LOCA containment pressurization transient. After the relief dampers open, the operating ESF unit cooler recirculates air from the containment volume between el 162'3" and 186'3".

b. The Reactor Plant Ventilation System P&ID is shown in FSAR Figure 9.4-7c. The referenced drawings of TAB VII list the elevations, radial positions, flow rate and flow direction of the release points.

c. Four non safety related recirculation fans are located above the polar crane. These fans, which are described in FSAR Section 9.4.6.2.1, provide continued movement of air in the containment dome when operating. These fans are not designed to operate post LOCA.

The drywell ventilation system as described in FSAR Section 9.4.6.2.2 is not nuclear safety related and would not be operable immediately following a LOCA but would be available following loss of offsite power. There are no fire protection sprinklers in the containment or drywell. The systems assumed to be available during an accident period are discussed in the FSAR Section 6.2.2.

13. Describe the operation of the Combustible Gas Control System (CGCS), e.g., drywell mixing fans, and the containment fan coolers during hydrogen burns. Include the conditions leading to and consequences from these systems on the burning of hydrogen; such as, will the fan coolers promote hydrogen burning or will the ducting for the fan coolers be crushed by a pressure pulse?

RESPONSE

The Combustible Gas Control System (CGCS) will be operational as will the containment unit coolers during hydrogen burns. In addition, the Hydrogen Mixing System will continue to operate after initiation since the flow path is pipe rather than ducting. The containment ventilation system is protected from external overpressure transients by relief dampers. In addition, localized crushing of ducting does not affect the heat removal function of the unit coolers or their mixing function. Portions of the containment ductwork may deform in the vicinity of local burning but general crushing is not expected for scenarios with diffusion burning. Operation of these systems promotes mixing of the containment and drywell volumes. The operation of the containment ventilation system enhances the natural convection patterns and supply of oxygen to areas of diffusive burning.

The potential for existence of combustion phenomena unique to the drywell will be evaluated by HCOG. The RBS hydrogen mixing system design and operation will be included in this evaluation. If the HCOG criteria for the existence of inverted diffusion flames in the drywell is satisfied, a program will be established to quantify the effect of inverted diffusion flames.

14. Provide the following plant specific CLASIX-3 (with the recommended passive heat transfer model described in NUREG-0588) containment transient analysis. Also, provide and justify the assumptions to be used.

a. SORV Base Case Transient

b. Small Break LOCA Base Case

c. Provide plant unique parametrics; i.e., the effects on pressure/temperature of: 1) the various containment safety systems; and 2) the various input assumptions that need to be made.

RESPONSE

The HCOG is currently evaluating whether to incorporate the NUREG-0588 heat transfer model or some less conservative model into the CLASIX-3 computer code. GSU is incorporating the NUREG-0588 heat transfer model in our CLASIX-3 analysis even though we believe that the 8% revaporization given in this NUREG is overly conservative and that bases exist can be made for using a 12% revaporization based on the Carolina-Virginia Test Reactor (CVTR) experiments. GSU has not performed our base case CLASIX-3 analyses. But, when completed, this analysis will include the SORV Base Case Transient and the Small Break LOCA Base Case. These analyses will incorporate our plant unique safety systems and containment design.

Plant unique parametrics due to variations in input assumptions will not be performed. GSU feels that these parametrics are not required since the HCOG Containment Sensitivity Study (HGN-001) adequately addressed the variation of temperature and pressure with input assumptions.

The RBS containment analysis will utilize more conservative hydrogen burn parameters than the proposed HCOG containment response analysis acceptance criteria. The parameters to be used are:

1)	Minimum hydrogen volume fraction required for ignition.	0.08
2)	Minimum hydrogen volume fraction to support flame propagation.	0.08
3)	Hydrogen fraction burned (Burn completeness)	0.85
4)	Minimum oxygen volume fraction to support ignition.	0.05
5)	Minimum oxygen volume fraction to support combustion.	0.0
6)	Speed of propagation (flame speeds)	6 ft/sec

GSU feels that the hydrogen burn parameters used in the HCOG acceptance criteria are more realistic and can be justified based on current experimental evidence; however, GSU has elected to use higher values for additional conservatism.

Initial conditions for analysis for oxygen, nitrogen and steam partial pressures will be calculated from compartment temperatures, pressures and relative humidities.

Hydrogen release histories generated by a recognized industry code, such as MARCH or BWR HEATUP CODE will be used as input to the containment response analysis.

15. Provide an evaluation of the consequences of the most severe pool dynamic loads created by the combustion of hydrogen. It is necessary to address the effects on both structures and equipment. Your evaluation should consider the effects of combustion in the drywell and combustion in the wetwell and containment. For events which produce combustion in the containment and which cause pool water to reverse flow into the drywell, your analysis should consider the cooling effect of the spilled water acting as a spray to the drywell atmosphere and its effects on the pressure transient.

RESPONSE

The HCOG is evaluating the potential for positive and negative pool swell. If this evaluation concludes that loads are in excess of those currently predicted for DBA conditions, then GSU will determine if any essential drywell structures or equipment required to survive a hydrogen burn should be reanalyzed for pool swell loads.

16. Provide an evaluation of the consequences of the most severe negative and positive pressure differentials created by the combustion of hydrogen considering the following:

a. The steel containment structure and penetrations (include the long term effects of oxygen depletion).

b. The drywell structure

c. Personnel air locks and equipment hatches

d. The equipment between the drywell and containment (e.g., drywell mixing system).

RESPONSE

The evaluation of the ultimate pressure retaining capacity of the containment, drywell, equipment hatches, personnel air locks and penetrations was provided in a letter submittal dated September 30, 1983 from J. E. Booker to H. R. Denton. This evaluation demonstrated that the containment can withstand 56 psig which compares favorably with 26.3 psig obtained from the preliminary River Bend Station specific CLASIX-3 analysis. The ability to withstand negative pressure differentials was provided in a letter submittal dated June 25, 1984 from J. E. Booker to H. R. Denton. The ultimate negative (reverse) pressure capability of the containment is -4.82 psid. The maximum calculated negative containment pressure resulting from complete combustion of an amount of hydrogen corresponding to a 75% metal-water reaction, oxygen depletion and subsequent cooldown of the containment atmosphere is -3.1 psid. This is a very conservative estimate of the negative containment pressure due to the assumption of zero relative humidity both before and after the hydrogen burn event and the assumption that there was no additional positive pressure due to hydrogen or steam remaining in the containment. The design negative pressure for the drywell including the drywell wall, hatches, doors, and penetrations is -20.0 psid. When the Base Case CLASIX-3 analysis is complete the negative pressures produced by hydrogen burns will be compared with these pressure differentials.

The hydrogen mixing system, as well as other penetrations, has the same integrity as the remainder of the drywell boundary. When initiating the mixing system inlet valves must be opened prior to the actuation of the exhuast valves. The mixing system fan cannot be activated until the inlet and outlet valves are

open. When the drywell and containment pressures are equalized by opening the inlet valves and when the outlet valves are opened the differential pressure across the fan is negligible.

17. Are there accident sequences that might lead to the introduction of hydrogen and steam directly into the containment without having passed through the suppression pool? Include the potential of using the drywell mixing fans and the associated drywell line penetrations which provide a bypass path around the pool.

RESPONSE

There are no credible accident sequences that might lead to the introduction of hydrogen and steam directly into the containment without having passed through the suppression pool. All sequences evaluated require multiple equipment failures and/or operator error and are therefore not considered to be credible. Operation of the hydrogen mixing system will be addressed in the River Bend Station Emergency Operating Procedures.

18. Provide an evaluation of the potential and consequences of flame acceleration in the various containment regions including consideration of circumstances leading to a transition to detonation.

RESPONSE

No areas of the River Bend Station containment were identified that are conducive to flame acceleration or which will provide conditions leading to a transition to detonation.

19. Provide a discussion of the emergency procedure guidelines to be followed for actuation of the igniter system, the Combustible Gas Control System, the containment fan coolers, ADS, and post-accident purging/venting. This discussion should address the evaluation of the following items:

a. Justification for manual instead of automatic actuation

b. Interfaces with existing BWR EPG package (Rev. 2)

c. Justification for the time available for operator action

d. Justification for the signals/setpoints intended to direct action and the impact of using such signals both on core recovery procedures and containment environmental transients.

RESPONSE

GSU is participating in a joint HCOG/BWROG effort to develop a generic hydrogen control Emergency Procedure Guideline. This

guideline will be incorporated into the RBS Emergency Operating Procedures when finalized.

20. Considering River Bend's unique containment safety system with respect to other Mark III's, discuss how the HCOG research program will be applicable to the River Bend design.

RESPONSE

The unique River Bend Station containment design features (unit coolers instead of sprays and the RBS containment configuration) are included in the Quarter Scale Test Program being conducted by the Hydrogen Control Owners Group (HCOG) of which Gulf States Utilities is a member. Other aspects of the HCOG Hydrogen Control Program which address RBS plant unique features are the evaluation of the drywell response to degraded core accidents and generation of a combustible gas control EPG.

21. Discuss how the results of the HCOG tests and plant specific analysis will be used to determine the most severe thermal environment in the drywell and containment/wetwell regions of River Bend for evaluating the thermal response of the equipment required to survive hydrogen burning.

RESPONSE

The results of the HCOG tests and the River Bend Station specific CLASIX-3 analysis will be used to determine the thermal environment within the containment and drywell to demonstrate equipment survivability. The thermal environments produced by diffusion flames, deflagrations and if necessary inverted diffusion flames shall be defined as appropriate for the locations of equipment required to survive a hydrogen generation event. The most severe environment will be the case which results in the most severe thermal loading on the equipment analyzed. The thermal profiles used in the survivability analysis will be based on realistic empirical data and/or analysis. Factors of conservatism will not be applied to the definition of the thermal environment.

DESCRIPTION SUMMARY 10 ADD CONDUITS

REMARKS 11 SUPERSEDES E&DCR P-21,763A

PROBLEM DESCRIPTION 12

1. CONDUITS ARE REQUIRED FOR ROUTING ADDITIONAL CABLES TO THE HYDROGEN IGNITERS INSIDE THE CONTAINMENT.
2. LOCATIONS ARE REQUIRED FOR VARIOUS IGNITERS IN REACTOR BLDG CONTAINMENT.

REASON FOR CHANGE

CONDUIT ICC500RQ1-3/4" IS CALLED OUT AS NR IWC525R04 BUT IS SHOWN GOING THRU IWC525R04 (PAGE 4).
TWO DIFFERENT CONDUIT ID'S ARE CALLED OUT GOING TO IHCS*IGN21A, ICC500RQ1-3/4 & RQ2-3/4 (PAGE 4).
IHCS*IGN21A IS AN INCORRECT EQPT CALLOUT (PAGE 4).
CONDUIT ICC500RQ8-1½ THRU IWC538R04 DOES NOT GO THRU A SLEEVE AS SHOWN (PAGE 4).
CONDUIT ICC504BF8-3/4 THRU IWC502B01 IS AN INCORRECT CALLOUT FOR THE SLEEVE (PAGE 7).
CONDUITS ICC507BC6-3/4", BC7-3/4" & BC8-3/4" ARE CALLED OUT AS NR IWC522B04 BUT ARE SHOWN GOING TO 1*JB5486

DESCRIPTION SUMMARY 10: VARIOUS DUCTWORK MODIFICATION
REMARKS 50: SUPERSEDES C-13952

PROBLEM DESCRIPTION 12:

① A 24x20 DUCT LINE, EL. 93'-5" AZIMUTH 160°, IS IN INTERFERENCE WITH AN ELECTRICAL JUNCTION BOX. THE 45° ELBOW NEEDS TO BE DELETED FOR REGISTER INSTALLATION PURPOSES.

② A 24"x 26" DUCT LINE, EL. 106'-6" AZIMUTH 310° IS IN INTERFERENCE WITH A PIPE STRUT AT ITS DESIGNED LOCATION. THIS DUCT NEEDS TO BE LOWERED TWO INCHES AND MITERED FOR PROPER INSTALLATION.

③ A 32"x32" DUCT RISER AT AZIMUTH 53° IS IN INTERFERENCE WITH A ELECTRICAL CONDUIT AT EL. 131'-0" WITH TERMINATED WIRES. THIS DUCT NEEDS TO BE MITERED FOR PROPER CLEARANCE.

④ A 24"x20" DUCT RISER, AZIMUTH 133° EL. 142'-0" NEEDS TO BE MITERED WITH A 1" OFFSET FOR PROPER FLOOR PENETRATION.

REV A PROBLEM ② NEEDS TO BE REVISED TO ALSO ADDRESS AN INTERFERENCE WITH A SVV LINE WHEN THE PIPE IS IN ITS PROPER LOCATION.

DESCRIPTION SUMMARY: DUCTWORK LOCATION CHANGES

REMARKS: N/A

PROBLEM DESCRIPTION

(1) A DUCT RISER LOCATED ON AZIMUTH 241°, EL. 175' OF THE REACTOR BLDG. NEEDS TO BE RELOCATED TO 2'-2" FROM THE CONTAINMENT WALL TO BE IN ALIGNMENT WITH THE FLOOR PENETRATION AT EL. 186'.

(2) TWO 12"×18" SUPPLY AIR REGISTERS LOCATED IN THE MAIN STEAM TUNNEL, APPROX. 20° IN THE REACTOR BLDG., NEEDS TO BE RELOCATED TO SHOW REVISED DIMENSIONS DUE TO THE CONFIGURATION OF THE VENDOR SUPPLIED DUCTWORK.

(3) THE 24"×24" DUCT SYSTEM AT APPROX. EL. 130', AZIMUTH 50° NEEDS TO BE MODIFIED DUE TO THE PHYSICAL CONFIGURATION OF THE DUCTWORK.

PROBLEM SOLUTION (CONT.)

THE AS-BUILT CONFIGURATION OF THE DUCT SYSTEM IN QUESTION IS AS DEPICTED ON PAGES 4 THRU 8 OF THIS E&DCR.

THE AFFECTED AREAS OF THE DESIGN DWGS. ARE SHOWN ON PAGES 9 THRU 11.

EB-15F AND 15R SHALL BE REVISED INCORPORATING THE INFORMATION CONTAINED ON PAGES 4 THRU 8 OF THIS E&DCR.

DESCRIPTION SUMMARY: ADDITION OF DEBRIS SCREENS

REMARKS: SUPERCEDES C-13,392

PROBLEM DESCRIPTION

ORIGINAL PROBLEM

TO MEET THE REQUIREMENTS OF BTP CSB 6.4, DEBRIS SCREENS ARE TO BE INSTALLED IN THE CONTAINMENT PURGE SYSTEM TO PROTECT THE CONTAINMENT ISOLATION VALVES 1HVR* AOV 123 & 128.
DETAILS SHOWING THE LOCATION OF THE DEBRIS SCREENS 1HVR* S01, S02 NEED TO BE INCORPORATED ONTHE DESIGN DRAWINGS.

REVISION A

TO IMPROVE THE CONSTRUCTABILITY THE ORIGINAL 4"x4"x¼" ANGLE RING WILL BE REPLACED WITH A ½" THICK PLATE. THE DETAILS FOR CONSTRUCTION WILL BE INCLUDED IN SPEC. 216.140 SEPARATELY.

DESCRIPTION SUMMARY: DUCT TAP OUT OF LOCATION

REMARKS: N/A

PROBLEM DESCRIPTION

THE DUCT RISER TAP ON THE RING DUCT AT 287° IN THE REACTOR BLDG. AT THE DRYWELL IS LOCATED WITH ITS CENTERLINE ON 287°. THIS TAP NEEDS TO BE RELOCATED 3" NORTH OF 287° TO KEEP THE 48"x36" DUCT RISER ON LOCATION. TO GET BACK ON LOCATION CONSTRUCTION REQUEST TO OFFSET THE DUCT PIECE ADJOINING THE REFERENCED DUCT TAP.

PROBLEM DESCRIPTION 12

ORIGINAL PROBLEM

(1) THE 28" x 30" 45° SUPPLY AIR ELBOW (AZIMUTH 310°, EL 151') WOULD BE IN INTERFERENCE WITH ELECTRICAL CONDUIT IF INSTALLED.

(2) ON EB-15H-8, COOR. I-5, AN INCORRECT DETAIL IS REFERENCED FOR THE 6" DIA. EXHAUST HOOD.

(3) DETAILS FOR CONSTRUCTION ARE REQUIRED FOR FOUR SCREENED OPENINGS @ AZIMUTH 270°, TOP EL. 180'-0".

REV. A

CONSTRUCTION REQUEST AN ALTERNATE METHOD ~~DETAIL~~ FOR ATTACHING THE SCREENED OPENINGS REFERENCED IN PROBLEM (3) ABOVE.

REMARKS 11 N/A

PROBLEM DESCRIPTION 12

(1) THE DRYWELL RING DUCT LOCATED ABOVE THE HOIST PULL AREA NEAR AZIMUTH 230°, EL. 154'-9" NEEDS TO BE REDESIGNED DUE TO INTERFERENCES WITH CONDUIT AND THE HOIST RAIL/TROLLY.

(2) THE CONTAINMENT DUCTWORK AT AZIMUTH 225°, EL 158'-0" NEEDS TO BE LOWERED 2" DUE TO THE ELEVATION OF THE EXISTING CONCRETE PENETRATION IN WHICH THIS DUCTWORK PENETRATES.

(3) THE DISCHARGE DUCTWORK FROM 1HVR*UC1A, 1B AND 1HVR-UC1C NEEDS TO BE REVISED TO SHOW THE DELETION OF RTD THERMOWELLS.

JOB ORDER NO. 12210

PROJECT/CLIENT: RIVER BEND PROJECT UNIT No 1 / G.S.U.

P.O. NO (S&W): N/A | REASON CODE (S): V | EQUIP. I.D. NO (S)/SYS. CODE (S): 1 HVR * "DUCT"

REFERENCE DOCUMENTS: EB-15R-8 EB-15J-8

SUPPLIER (OR SUBSUPPLIER) NAME: N/A

DESCRIPTION SUMMARY: REVISE DUCTWORK

REMARKS: THIS E&DCR SUPERCEDES C-12,521

PROBLEM DESCRIPTION

30"x54" DUCTWORK SHOWN ON EB-15J-7 [LOCATION D-5, E-5] SPLITS INTO 30"x18" ELBOW AND 30"x36" DOUBLE ELBOW DUCT. THIS DUCT FITTING CANNOT BE FABRICATED WITH MAKING ONE BULKY AND HEAVY DUCT PIECE. McCROSKEY REQUEST TO REVISE THE ELEVATION OF 30"x18" ELBOW BRANCH TO SIMPLIFY DUCT FABRICATION.

ADDITIONAL PROBLEM

THE 30"x18" ELOW REFERENCED IN THE ORIGINAL PROBLEM OF E&DCR C-12,521 NEEDS TO BE REVISED TO ALTER THE DOWNSTREAM DUCT LINE DUE TO AN INTERFERENCE WITH STRUCTURAL STEEL. TO RELOCATE THIS DOWNSTREAM DUCT BACK ON LOCATION A MITERED OFFSET NEEDS TO BE INCORPORATED IN THIS LINE.

ENGINEERING & DESIGN COORDINATION REPORT — E&DCR NO. C-13,646A

PROJECT/CLIENT: RIVER BEND PROJECT UNIT #1 / G.S.U. — JOB ORDER NO. 12210

P.O. NO (S.E.W.): N/A — REASON CODE (S): V — EQUIP. ID NO (S)/SYS. CODE (S): 1HVR* DUCT

REFERENCE DOCUMENTS: EB-15K-8 — SUPPLIER(OR SUBSUPPLIER)NAME: N/A

DESCRIPTION SUMMARY: DUCTWORK RELOCATIONS — REMARKS: THIS E&DCR SUPERSEDES C-13,646

PROBLEM DESCRIPTION: ORIGINAL PROBLEM

(1) DUE TO THE CONJESTED AREA AT PLAN EL. 162'-3", 328° THE FIELD FORCES HAD TO CUSTOM FIT THE 60°-34' TRANSITIONING ELBOW. THE TRANSITION PIECE BEYOND THIS ELBOW HAD TO BE MODIFIED DUE TO THE LOCATION OF A DRAIN LINE.

(2) 1HVR-DMP209 AT EL. 162'-3", 250° NEEDS TO BE RELOCATED DUE TO THE RE-ORIENTATION OF THE DAMPER IN REFERENCE TO THE DUCT, NOT THE CONCRETE WALL.

(3) THE 4" DIA. EXHAUST DUCT FROM 1SSR-PNL 121 (PLAN EL. 162'-3", 300°) NEEDS TO BE RE-ORIENTED BY CHANGING THE 90° ELBOW TO A 51° ELBOW TO MAINTAIN CLEARANCE FROM A SMALL BORE PIPE SUPPORT.

REVISION A

DUE TO MODIFIED CONSTRUCTION TECHNIQUES (SWEDGING OF SHEETMETAL) THE 51° ELBOW DUCT PIECE WILL BE RETURNED TO A 90° ELL (AS ORIGINALLY SPECIFIED) BUT SLOPED DOWN 30° BEFORE CONNECTING TO 1SSR-PNL 121.

DESCRIPTION SUMMARY: DUCT TAP DIMENSION REVISED

REMARKS: 3.5 12/21/83 REVISION THIS E&DCR SUPERSEDES E&DCR C-12,857

PROBLEM DESCRIPTION

DUE TO THE MISFABRICATION OF SEVERAL MITER JOINTS IN A DUCT LINE, LOCATED ON ELEVATION 186'-3" IN THE REACTOR ANNULUS, THE 12"x12" SCREENED OPENINGS HAVE BEEN MISLOCATED. REQUEST EB DRAWINGS BE REVISED TO SHOW AS-BUILT CONDITIONS.

ADDITIONAL PROBLEM

THIS E&DCR IS NEEDED FOR CLARIFICATION OF THE PROBLEM DESCRIPTION.

3.5 12/21/83 REVISION

THE ALTERED PIECES OF DUCT WERE FABRICATED CORRECTLY WITHIN TOLERANCE. HOWEVER, THE CUMMILATIVE EFFECTS OF THE DUCT CONSTRUCTION TOLERANCES COMBWED WITH CONCRETE IRREGULARITIES AND EMBED PLATE LOCATIONS POSED AN INSTALLATION PROBLEM FOR THIS DUCTWORK. THE 12"x12" SCREENED OPENINGS NEED TO BE RELOCATED TO BEST SUITE THE EXISTING CONDITIONS.

CC: L. FERRINGO
D. BRADBERRY
R. BUELL

From:	Name	Company
From:	J.K. HAM	S&W - SEG
To:	R. BROWN / S. VISICHIO	S&W - HVAC SPECIALIST.

TOPIC:

DISCUSSION:	ACTION REQUIRED:
NOTE 11 ON DRAWING EB-15R STATES SCREENS WILL BE PROVIDED OVER THE OPEN RETURNS ON UNIT COOLERS 1HVR*UC1A, 1B & 1C AND 1DRS*UC1A, 1B, 1C, 1D, 1E, & 1F. STEVE VISICHIO SAID THAT THE PURPOSE OF SCREENS OVER RETURN OPENINGS IS TO PROTECT THE FINS ON THE COOLING COIL FROM BEING DAMAGED BY WORKMAN. RETURN AIR OPENINGS HAVE BEEN PROVIDED WITH FILTER RACKS, THAT WILL REMAIN AS A PERMANENT PART OF THE EQUIPMENT, AND THE FILTERS WILL BE IN PLACE UNTIL CONSTRUCTION IS COMPLETED AND FUEL HAS BEEN BROUGHT ON SITE.	
THE COILS WILL BE PROTECTED FROM DAMAGE DURING CONSTRUCTION BY THE FILTERS. AFTER THE CONSTRUCTION PHASE THE COILS WILL NOT BE SUBJECT TO BEING DAMAGED BECAUSE OF THE LIMITED ACCESS TO THE CONTAINMENT AND DRY WELL AREAS OF THE REACTOR BUILDING.	

E&DCR-#C-13,417

J.O. No. 12210 ~~XEL-CORE-NOTE~~ Copy to:

Job Book 1070

TIME	DATE
10:00	2/9/88

Name	Company
From: J.K. HAM	S&W-SEG
To: R. BROWN/S. VISICHIO	S&W-HVAC SPECIALIST

TOPIC:

DISCUSSION:	ACTION REQUIRED:
I DISCUSSED THIS WITH MR. R. BROWN ON FEB. 9, 1988. WE BOTH CONCLUDED THAT THE SCREENS WERE NOT NEEDED TO PROTECT THE COOLING COILS IN THE CONTAINMENT AND DRYWELL AREAS, AND THAT THE NOTE REQUIRING THEIR INSTALLATION BE REMOVED FROM THE DRAWINGS.	
SEG WILL INITIATE AN E&DCR TO REMOVE NOTE 11 FROM DRAWING EB-15R.

DESCRIPTION SUMMARY: SCREENED OPENING RELOCATIONS

REMARKS: SUPERSEDES C-13,431

PROBLEM DESCRIPTION

ORIGINAL

DUE TO THE CUMULATIVE EFFECTS OF DUCT FABRICATION TOLERANCES AND AS-BUILT CONDITIONS OF THE SUPPORT STRUCTURE CONSTRUCTION REQUEST TO RELOCATE SCREENED OPENING DIMENSIONS ON THE RETURN AIR RISERS ABOVE THE CONTAINMENT VESSEL IN THE REACTOR BLDG.

~~FE~~ 15.2-3947 THESE RISERS (TOTAL OF FOUR) ARE SHOWN ON SECT. 28-28, EB-15Q-7.

REVISION A

THE DIMENSIONS ON C-13,431 ARE NOT TYPICAL FOR ALL FOUR RISERS. THE SCREENED OPENINGS FOR EACH RISER ARE SPECIFICALLY LOCATED.

EQUIPMENT REQUIRED TO
SURVIVE A HYDROGEN BURN

Equipment Not Included On Essential Equipment List

1. CMS-Containment Atmosphere Monitoring-Drywell Temperature Monitoring

   Justification: Previous revisions of the Hydrogen Control Emergency Procedure Guideline contained a Hydrogen Deflagration Temperature Limit (HDTL) upon which various operator actions were to be taken. This curve will probably be removed from the EPG since it is expected that the Hydrogen Deflagration Overpressure Limit (HDOL) will be more limiting. No operator actions will be based on temperature.

2. CMS-Containment Atmosphere Monitoring

   The majority of the CMS sampling points are not required. Therefore, the solenoid valves (SOV33A, SOV33AA, SOV33C, SOV33G, SOV33J, SOV33S, SOV33U and SOV33W) are not included. The remaining solenoid valves provide two sample points in the drywell (1 per division) and two sample points for the containment (1 per division).

3. HCS-Hydrogen Recombiner

   The Hydrogen Recombiners were not included since they will only be used during this event, within their design limits. The recombiners will be secured at a hydrogen concentration of 6%.

4. SWP-Service Water

   The service water supply valves for the unit coolers are notincluded since they will have performed their function prior to significant hydrogen generation.

5. CMS-Containment Atmosphere Monitoring-Containment Temperature Monitors

   These temperature monitors were deleted for the same reasons as the drywell temperature monitors.

QUESTION 480.40 (6.2)

The accident at Three Mile Island, Unit 2 involved a large amount of metal-water reaction in the core with resulting hydrogen generation well in excess of the amounts considered in 10 CFR Section 50.44 of the Commission's regulations. During the past year the staff has been studying the potential of excess hydrogen generation, the effects such concentrations of hydrogen would have on the various types of plants, and the effectiveness of various mitigation systems in protecting the plant against such situations. The results of our studies to date are presented in the SECY 80-107 series of documents. In these reports, we recommend that all BWR Mark I and II containment plants be inerted and that owners of all other plants be required to provide an analysis and/or proposed design (or designs) to mitigate the consequences of large amounts of hydrogen in containment. The associated proposed interim rule was published in The Federal Register on October 2, 1980.

Subsequent to the issuance of SECY 80-107, a substantial amount of additional work has been performed on this issue with emphasis on ice condensers. With respect to ice condensers, and specifically Sequoyah, the Commission has decided that the matter of hydrogen control for degraded core accidents in plants with small containments needs to be resolved in the near term, i.e., the resolution should not be deferred to rulemaking.

In SECY 80-107, the staff showed that Mark III containments are similar to ice condenser containments in regard to their ability to accommodate large amounts of metal-water reaction without jeopardizing containment integrity.

We, therefore request a description of the program to improve the hydrogen control capability at the River Bend Station, Units 1 and 2. In addition provide the analysis of hydrogen generation based on 75% metal-water reaction.

RESPONSE

GSU is a member of the BWR/6 Mark III Containment Hydrogen Control Owners' Group (HCOG) which was formed to address the hydrogen control issue on a generic basis for BWR/6 plants.

Results of the evaluations and studies performed under the auspices of the HCOG will be used to develop a River Bend Station specific hydrogen control program. Additional information on the River Bend Station hydrogen control program, including an analysis of hydrogen generation, will be provided 6 months prior to fuel loading. 5

In addition to the HCOG evaluation and study results, RBS specific analyses and reports will be submitted under separate cover, in accordance with the final rule. 6
