

**List of Leaks and Spills at Operating U.S. Commercial Nuclear
Power Plants October, 2020**

Introduction

This is a list of operating reactor sites that experienced a radioactive leak or spill to the onsite owner controlled area where the concentration of tritium in the leak source, or in a groundwater sample exceeded 20,000 pCi/L at some time since initial startup. A tritium concentration of 20,000 pCi/L is used as the threshold for inclusion in the list because it is the drinking water standard in EPA's Safe Drinking Water Act. This version updates the October 2019 list of leaks and spills.

Source of Information

Recent information was compiled by NRC staff based on input from the nuclear power plant staff, Annual Radioactive Effluent Release Reports and Annual Radiological Environmental Operating Reports (see the NRC's web site for each site's detailed annual reports at <https://www.nrc.gov/reactors/operating/ops-experience/tritium/plant-info.html>). Historical information is based on Annual Radioactive Effluent Release Reports, Annual Radiological Environmental Operating Reports, Groundwater Questionnaires, Preliminary Notifications, Event Notifications, Licensee Event Reports, NRC Inspection Reports, Special Reports, and other documents submitted by the licensees to the NRC.

Contents

After a radioactive leak or spill, tritium is generally the first radionuclide to be identified in groundwater. This is because tritium travels as a form of water through the soil faster than other radionuclides. The tritium concentrations for each plant documented in the list below consist of (1) the historical maximum concentration and (2) the "current" concentration. These values provide a reasonable approximation of the magnitude and extent of the historical leaks and spills as well as the current conditions.

The value listed as the "Historical Maximum Concentration of Tritium in a Leak Source or in a Groundwater Sample" is an approximation of the historical maximum tritium concentration from abnormal releases in which tritium from reactor operations contacted the onsite soil since initial startup. The timeframe in which the historical maximum tritium releases occurred is listed next to the maximum concentration value.

The value listed as the "Current Maximum Groundwater Sample Tritium Concentration" is a reasonable approximation of the current maximum tritium concentrations based on reported abnormal releases to onsite groundwater, or groundwater samples that have been collected and analyzed by the licensee. If a value has not been updated from the one listed in the previous version, it indicates the value continues to be a good approximation of the current conditions.

As documented in the licensee annual reports, groundwater samples were collected from onsite locations and analyzed including both drinking water wells and non-drinking water sample points (e.g., groundwater monitoring wells, storm drains, man holes, bore holes, piezometer tubes, surface water, puddles, and rain water). Although some values in the list exceed 20,000 pCi/L, none of those samples were collected from a drinking water well or from a municipal drinking water system. None of the samples collected from drinking water wells and municipal drinking water systems have ever exceeded the EPA drinking water standard of 20,000 pCi/L.

Summary

There are 57 nuclear power plant sites in the United States that are currently operating. Historical records indicate 40 of these sites have at one time or another had leaks or spills that involved tritium concentrations greater than or equal to 20,000 pCi/L. Eleven sites are currently reporting tritium in groundwater, from a leak or spill, in excess of 20,000 pCi/L. No site is currently detecting tritium in groundwater in the offsite environment, or in drinking water, in excess of 20,000 pCi/L. Tritium rapidly disperses and dissipates in the environment, and as a result, tritium from leaks and spills is typically not detected outside the facility boundary.

List of Historical Leaks and Spills at Operating U.S. Commercial Nuclear Power Plants

It is important that the preceding paragraphs accompany any reproduction of this list so that the information is communicated in the proper context.

October, 2020 Updates

Plant	Historical Maximum Concentration of Tritium in a Leak Source or in a Groundwater Sample, pCi/L	Timeframe of Historical Maximum Concentration of Tritium in a Leak Source or in a Groundwater Sample, pCi/L	Current Maximum Groundwater Sample Tritium Concentration, pCi/L
Beaver Valley	25,583	September, 2010	2,180
Braidwood	247,000	1998	1,320
Browns Ferry	36,444	March, 2016	7,480
Brunswick	19,000,000	December, 2010	184,000
Byron	82,000	February, 2006	566
Callaway	1,600,000	July, 2014	933
Catawba	47,500	October, 2007	10,500
Columbia	270,000	March, 1993	12,000
Davis-Besse	37,500	October, 2008	825
Dresden	10,312,000	July, 2004	31,800
Duane Arnold	2,150,000	October, 2012	90,728
Fitzpatrick, J.A.	105,000	April, 2010	Not detectable
Ginna, R.E.	20,000	1995	603
Grand Gulf	2,240,000	March, 2014	2,350
Hatch, E.I.	6,840,000	September, 2011	803,000
Indian Point	14,800,000	February, 2016	90,600
Limerick	3,950,000	February, 2009	772
LaSalle	1,230,000	July, 2010	3,970
