U.S. Nuclear Regulatory Commission ATTN: Document Control Desk Washington, D.C. 20555

Subject: Waterford 3 SES Docket No. 50-382 License NPF-38 Mobil SHC-32 Lubricant in Reliance Motors

This is in response to the verbal request by Mr. J.R. Boardman, NRC Region IV, for information regarding the use of Mobil SHC-32 lubricant in Reliance Motors at Waterford 3 SES. Enclosed herewith are the following:

- a) Evaluation letter, #W3M84-0446, dated October 15, 1984
- b) Mobil Tech Topics, File 10-21

Additionally, the EQ Maintenance Input instructions are being revised to reflect the use of Chevron SRI #2, or <u>equivalent</u>, with the equivalent being the Mobil SHC-32 lubricant in accordance with Plant Lubrication Manual 457000237.

Should further information be needed, please contact L.L. Bass at (504) 467-2791, extension 327.

Very truly yours,

Bush

R.F. Burski Nuclear Safety & Regulatory Affairs Acting Manager

W3M84-0446

K.W. Cook TO:

R.P. Barkhurst FROM:

Evaluation of Audit Finding SA-W3-QA-84-39 SUBJECT:

- REFERENCES: (a) PRE-84P-040 dated September 17, 1984 (b) Licensing Commitment Tracking Log No. LIR 84-072
 - dated September 14, 1984
 - (c) QA Audit SA-W3-QA-84-39, Findings 2 and 5
 - (d) Denkevitz Letter W3K84-2144 dated September 12, 1984
 - (e) NRC Inspection Report 50-382/84-25 dated July 31, 1984
 - (f) W3P84-2386 dated September 13, 1984 (K.W. Cook to J.T. Collins)

This letter serves as an update to references (a) and (b) and the followup to plant staff response for corrective step number 3 under 4.a.6 of reference (f).

Project Evaluation Request No. 70023 was closed out and included in CIWA's 010596 and 010597 (copies attached) on October 12, 1984. This documentation justifies the use of Mobil Type SHC-32 lubricant in lieu of the Chevron Type SRI as recommended in the motor vendor manual.

In reviewing the above engineering evaluations and in conducting research on the facts relevant to reference (c), we feel that there are no generic problems with respect to proper lubrication of safety related equipment. We do concede, however, that there are some documentation and inconsistency problems with certain aspects of the plant lubrication program. These problems will be addressed by the additional actions/precautionary efforts indicated in reference (a).

If you need additional information on this subject, please contact Dennis Kruer at extension 3193 or John McGaha at extension 3138.

SUBJECT

Engineering evaluation of Chevron SRI-2 grease and mobile temp. 3HC-32 grease for substitution equivilancy in Environmentally Qualified Reliance Electric Motor Bearings.

Specific Review

Determination of equivilancy for substitution of mobiltemp SCH 32 for Chevron SRI-2 grease in containment fan motors.

References

- 1. Chevron Teknifax: Chevron SRI Grease
- 2. Mobil Tech Topics File 13.36 Mobilgrease 28

Waterford 3 SES (W-3)

The containment cooler fans were supplied by Joy Manufacturing Co. (JOY) with Reliance type TEAD frame 449T motors. The fan motor unit was qualified for nuclear use by Joy and Reliance. The qualification report is contained in Environmental Qualification file 4.1W3.

The W3 containment is maintained at 120°F (50°C) for normal environments consideration. For radiation exposure, the total integrated dose is 3.3E7. A specific corrolation of the test report and requirements is contained in file 4.1W3 and is not incorporated here except by reference.

A review of the EQ files relating to lubrication in general showed that in all cases even when a specific oil or grease was used during the qualification testing and was identified the as preferred lubricant the qualifiers of the equipment included the words "or equal" and many specifically listed several oils and greases which they considered equal. The following is a tabulation of specific characteristics of Chevron SRI-2 and Mobil SHC 32.

Grease Property	Chevron SRI	Mobil Temp SHC 32	
NLGI	Grade 2	Grade 1	
Thicker	Polyurea	Non Soap	
011 base	Refined mineral oil	Synthetic Hydrocarbon	
Additives (inhibitors)	Rust and oxidation	Rust and oxidation	
Temperature Range	-30°C to 175°C	-54°C to 177°C	a serie de la la
Penetration	195 - 265	290 - 340	@ 77°F wked
Drop Point	470 ASTM °F	500 ASTM °F	ASTM D 2265/566
Radiation Resis	2.0E8	3.0E8	15-20% change in penetration
Rubber swell	9%	6%	FTM 3603
Bearing life	150°C (300°F) 3000 hrs 177°C (350°F) 500 hrs	150°C (300°F) 2000 hrs 177°C (350°F) 500 hrs	ASTM D 3336

	Texico - Premium Union - Hitemp 2 Gulf - Unite Exxon Andox	RB	mentarion. These grease meet the grease characteristics
			for sub- stitution.

-2-

.

From the above data, it can be seem that there is little difference in overall lubricating properties. There is additional data of test on each of the above greases which is not practically tabulated due to different trat methods used.

An arrehenious analysis was performed on both of the above greases to determine the long term life due to temperature. Both greases meet and exceed the base requirements for use at W3 elevated temperature.

Conclusion

Based on the detailed review and the comparison of lubricating characteristics in both radiation and temperature degredation mobiltemp SHC 32 is a suitable substitution for Chevron SRJ grease which does substantiate and maintain the equipment qualification of the motors.

Mr. Scott Stocklager Reliance Electric 201 Evans Rd. Suite 406 New Orleans, La. 70123

RE: Instruction Manual B-3645 Substitution of Mobil SHC-32 Grease For Chevron SRI-2 Grease in Reliance Motor Bearings

Dear Mr. Stocklager:

As a follow-up to your conversation with our Mr. Dale Gallodoro, we are sending you a copy of the documentation proving the suitability of Mobil Mobiltemp SHC-32 Grease as a substitute for the Chevron SRI-2 Grease which you recommend in your instruction manuals. As you recall, you told Dale that Reliance might not be able to stand behind our motors without proper documentation of this substitute grease evaluation.

We would appreciate your contacting us regarding this substitution as soon as you have evaluated its acceptability. If there is anything you need in order to expedite your evaluation, do not hesitate to call Dale Gallodoro at 464-3238.

Please send the results of your evaluation to the return address, attention Dale Gallodoro.

457000106 and 457000237 are Reliance Motor Vendor Technical Manuals. They now suggest lubricating their motors with chevron SRI-2 grease. Plant Staff is presently using Mobil-Mobil Temp.-SHC-32 grease. A spare part Equivalency evaluation has been done and documented on speer-84-021. Also see Mobil Oil letter dated August 22, 1984 to Dennis Kruer, Plant Lubrication Coordinator. Flease make a change to these manuals to allow for substitution of Mobil Temp SRC-32 for Chevron SRI-2.

August 22, 1984

Mr. Dennis Kruer Louisiana Power & Light Waterford #3 Hwy 18 Taft, Louisiana 70066

Subject: Radiation Testing - Mobiltemp SHC 32

Dear Mr. Kruer:

Per your telephone request of this date, following is the Radiation Exposure information on Mobiltemp SHC 32:

Product	Date tested	Maximum Rad Levels			
Mobiltemp SHC 32	1983	3 X 10 ⁸ (note 1)			

Note 1: Value based on 15-20% chance in penetration.

For your information, gamma irradiation studies were carried out in a 5MW reactor under static conditions immediately after reactor shutdown. Typical dosage rate varied between 2 X 108 rad/hour to 2 X 106 rad/hour.

As concerning your question about using Mobiltemp SHC 32 in Reliance Motors that are environmentally qualified, we offer the following comment.

To the best of our knowledge, per your Mr. John McGaha, the Reliance equipment in question was environmentally qualified by the manufacturer using Chevron SRI #2 grease. Per Reliance, environmental qualification requires the continued use of all components in service during the EQ process.

Although Reliance is not EQ'ed with Mobiltemp SHC 32, a satisfactory substitute for Chevron SRI #2 is Mobiltemp SHC 32. Due to the nature of this product we would expect equal, if not superior, performance to SRI #2. Mr. Dennis Kurer August 22, 1984 page 2

INDUSTRIAL PRODUCTS Lubricating Greases (continued)

Turex[®] Wheel Mounting Compound is a blended product of boiled linseed oil and white lead. It is designed to assist in the assembly and disassembly of railroad car wheels and axles. It is approved against the Association of American Railroads' specification as illustrated in the Wheel and Axle Manual.

Gargoyle³ Grease B No. 2 is an amber colored, lime soap cup grease of smooth buttery texture. It is suited to the lubrication of bearings operating under low torque conditions. This makes it particularly suitable for belt conveyors, especially on long outdoor installations subjected to low temperatures.

Mobil® Block Grease Medium and T are hard greases furnished in block form for use in the grease pockets of plain bearings. Within the temperature range for which each is recommended, they maintain their consistency, have minimum tendency to char or glaze in service, and are uniformly consumed. Two grades are marketed for temperatures ranging from 80°F to 350°F (27°C to 177°C) and higher:

Mobil Block Grease Medium Mobil Block Grease T

Mobilith® 21 and 22 smooth, high temperature lithium complex multipurpose greases were developed for use in industrial applications, having an operational range from -30°F (-34°C) to 350°F (177°C). They have a dropping point of 500°F. The combination of a stable soap base, high quality mineral oil and a very effective additive package provides excellent mechanical stability, nigh resistance to oxidation, good rust protection and excellent break-away torque. The greases do not contain extreme pressure additives.

Mobilplex* 44 semifluid EP grease was developed for the lubrication of gear cases on underground mining equipment where high oil leakage rates exist. This product has exceptional oxidation stability and excellent corrosion prevention properties. It is not recommended for use in gear cases at temperatures below 32°F (0°C) as it would be too stiff for proper distribution and channeling may occur.

Mobilplex 45, 46, 47 and **48** calcium EP complex, multiservice greases will satisfy all applications except eccentric bearings or where excessive vibration is a major consideration. The greases may be dispensed by any common dispensing method except spring loaded grease cups or central systems where infrequent cycle times are involved. Low-cycle rate central systems require special engineering consideration. As a result of the addition of special EP materials, these greases have high load carrying ability. In addition, they have excellent chemical and structural stability up to operating temperatures of 300°F (149°C). They will adsorb water which will affect their consistency depending on the percentage adsorbed. **Mobilplex 45, 46, 47** and **48** are resistant to washout by water, emulsions or mild acids. They are recommended for use in plain and antifriction bearings.

Mobiltemp* SHC 32 nonscap, synthetic-hydrocarbon base fluid provides extremely low breakaway and running torque values, resists water washout and maintains

Lubricating Greasos (continued)

consistency over a wide operating range. In addition, it provides long service life due to its superior resistance to oxidation and exhibits good antiwear characteristics. **Mobiltemp SHC 32** is recommended for the lubrication of plain and colling element bearings, splines, screws and some enclosed gearing with temperature ranges from -65° F to 350°F (-54° C to 177°C).

INDUSTRIAL PRODUCTS

Mobiltemp 0, 1 and 2 nonscap high temperature greases, with good dispensing properties, are designed for industrial applications where the service range of conventional greases may be exceeded, or cycling from normal to extremely high temperatures may occur. These greases contain effective oxidation and rust inhibitors, have excellent resistance to water washing and are recommended for the lubrication of bearings operating continuously at temperatures in the 300°F (149°C) range.

Mobiltemp 78 nonscap grease is used where high temperatures and heavy loads are encountered in sleeve and antifriction bearings. It contains MoS2 (molybdenum disulfide) which imparts "staying power" in those situations where the grease itself has been depleted in use and where only the MoS2 remains to prevent wear until more grease is applied. This grease has shown outstanding ability to lubricate such components as conveyor bearings on high temperature ceramic and paint baking ovens, rotary steam joints on paper machine dryers and calenders, and antifriction bearings on preconditioning drums of paper corrugators. Its ability to resist thinning at temperatures up to 500°F (260°C) makes it especially suited for high temperature applications.

Mobilux® EP 0, EP 1 and EP 2 unleaded lithium 12 hydroxystearate EP greases satisfy the need for multipurpose extreme pressure products to lubricate both antifriction and plain bearings, under wet and dry conditions, in the temperature range of -20°F to 250°F (-29°C to 121°C). Their smooth texture and excellent low temperature pumping characteristics make these products ideal for central dispensing systems. Their superior resistance to oxidation is combined with the ability to protect against corrosion of copper alloys and the rusting of steel even in the presence of alkaline water.

Mobiliux EP 023 unleaded, semifluid, lithium 12 hydroxystearate EP grease was developed for the lubrication of gear cases found on underground coal mining equipment.

Mobilux EP 111 EP lithium grease is a black, tacky grease made from an extremely heavy base cil and contains an oil soluble molybdenum disulfide additive package. Mobilux EP 111 resists centrifugal separation of oil from the scap at extremely high rotating speeds, making this grease particularly well suited for the lubrication of heavily loaded and misaligned gear couplings.

Mobilux EP Arctive Cheaded, semifluid, lithium 12 hydroxystearate EP grease is designed for low-temperature applications, down to -50°F ambient. It performs well in centralized grease systems on shovels and other mining equipment operating during cold winter months at mining locations.

SUMMARY: (INCLUDING DECISIONS AND OR COMMENTS)

Scott Stocklager returned my call of earlier that day. He told me that he was told of my concern of substituting Mobil Temp SHC-32 for Chevron SRI-2 in their Class 1E Motors.

I discussed with him my findings on the characteristics of the two Greases and told him that LP&L's evaluations showed that Mobiltemp SHC-32 was the better Grease of the two.

He said he could not make any decision about the equivalency of the Greases on the phone, but if I would send him the documentation we used to evaluate the substitution he would get in touch with me if reliance had any problems with it. He said, if the documentation is in order and, it could be proven that Mobiltemp SHC-32 is a suitable substitute for Chevron-SRI-2, that no problems should occur.

LUBRICANTS IN NUCLEAR PLANTS

The advent of nuclear energy has added a new dimension to the requirements of lubricants and other petroleum products in industrial applications. Equipment in the nuclear industry — research and power reactors: fuel processing machinery; conveyors, manipulators, cranes, etc., in irradiation facilities: viewing windows and shield doors in hot cells; and heat exchange units — all require oils, greases, and organic fluids to perform conventional and special functions in radiation atmospheres.

Nowhere are the operating conditions of radiation, temperature, and atmosphere more demanding than in the power reactor field. At the outset of the nuclear power industry, equipment was designed to operate without conventional petroleum lubricants because little was known of the behavior of petroleum products under irradiation and the exact severity of the application was overestimated. This placed a design and economic burden on nuclear power generation. As experience was gained in operation of these plants, the original position was reconsidered. First, specific operating parameters (Table I) of radiation flux, temperature, etc., were obtained which realistically established the requirements and, secondly, research in the radiation resistance of petroleum materials showed that conventional lubricants could withstand doses up to 10¹-10⁸ rads. This has led to an increase of the use of petroleum lubricants in new generation plants.

Effects of Radiation

The additional environmental factor of radiation in nuclear applications affects lubricants in much the same manner as heat. Both are modes of energy, and lubricants, like all organic materials, undergo major structural changes when certain thresholds of absorbed energy are reached. We know that patroleum products undergo thermal cracking and polymerization at certain temperatures and likewise, that cleavage and crosslinking of molecules occurs at certain radiation dosage thresholds.

Two measurement methods are utilized to express the radiation energy. One measures the quantity of energy to which the material is exposed and is called the roentgen; the other is the amount of energy which the material absorbs and is called the rad. For gamma radiation, the exposure unit, the roentgen, is defined as the quantity of electromagnetic radiation which imparts 83.8 ergs of energy to one gram of air.

The radiation dosage of a material is defined as an absorption of 100 ergs of energy from any type of radiation by one gram of material. Actually, absorbed energy will vary with the type of radiation, and the effect will depend on the material exposed. However, for gamma radiation, one rad absorbed is approximately equivalent to 1.2 roentgens of radiation dosage. The rad is useful for comparing the equivalent energy of mixed radiation fluxes but does not distinguish between types.

From a radiation damage standpoint, one rad of neutron flux causes ten times more biological damage to living tissues than an equivalent absorbed energy of gamma rays. For petroleum products, however, the dosage, as measured by such effects as viscosity increase, is practically equivalent for the two types.

The general levels of radiation damage are as follows:

Dosage (Roentgens)

Effect

200 to 800 < than 5 million 5 million to 10 billion > 10 billion Lethal to humans Negligible to petroleum products Damaging to petroleum products Survived by only most resistant organic structures Based on experimental work to date, the damage to petroleum products may be summarized as shown below. It must be appreciated, however, that the intensity of these effects or, in fact, the incidence of one or more of these will depend on the amount of absorbed energy, the exact composition of the specific petroleum material, and environmental conditions such as temperature, pressure, and gaseous composition of the atmosphere. The effects are as follows:

- 1. Liquid products (fuels and oils) darken and acquire an acrid, oxidized odor.
- 2. Hydrogen content decreases and density increases.
- 3. Gases evolve such as hydrogen and light hydrocarbons.
- 4. Physical properties change, higher and lower molecular weight materials are formed, and olefin content increases.
- 5. Viscosity and viscosity index increases.
- 6. Polymerization to solid state may occur.

Properties of Irradiated Materials

¢

The physical and chemical properties of hydrocarbon fluids which make them important as lubricants change during irradiation to varying degrees based on their chemical composition and the presence of additives. Investigations have shown that both carbon-hydrogen and carbon-carbon bonds can be broken by radiolysis and that the former change is more readily achieved due to the lower bond dissociation energy required. The dissociated or ionized molecules can condense, rearrange, form olefins, or be destroyed depending on the environment.

Since most petroleum lubricants are combinations of saturated and unsaturated aliphatics and aromatic compounds, the reactions of these principal hydrocarbon classes have been studied under the influence of ionizing radiation. These studies (Table II) indicate that, as would be suspected, unsaturated hydrocarbons are most reactive and aromatics are least affected. Saturated compounds fall somewhere between the two extremes. The results are expressed as G values, that is, the number of molecules reacting or produced for each 100 ev of ionizing radiation.

METHODS OF EVALUATION. Petroleum lubricants and synthetic organic fluids have been evaluated for radiation resistance, and the mechanism of radiolysis studied using various radiation sources. These include encapsulated cobalt-60 isotopes, spent fuel elements, swimming pool reactors, material testing reactors. Van de Graff accelerators, and electron linear accelerators.

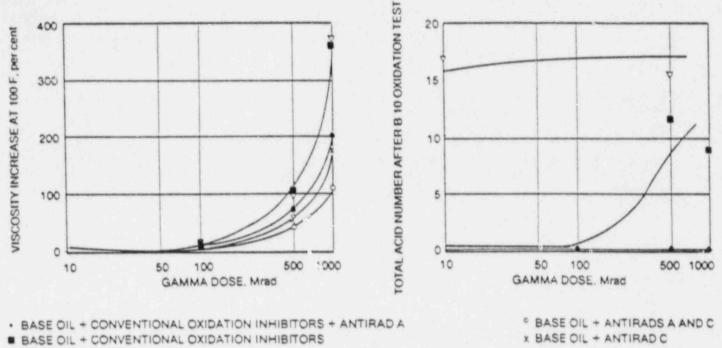

The evidence of radiation stability, or conversely, the amount of radiation damage, is measured using conventional physical and chemical analyses and comparing the results with the unirradiated material. In addition, standard performance tests are performed both on the previously irradiated material and as a dynamic procedure during irradiation.

PERFORMANCE TESTING. While the chemical and physical tests indicate the resistance to change of the oil or grease under irradiation, for an evaluation of the actual lubricating ability of the material, it is necessary to conduct performance tests under conditions simulating the intended use. To date, a large majority of the radiation stability evaluations have been conducted on samples statically irradiated and subjected to performance testing after irradiation. This is especially true of fluid lubricants. Greases have been tested by static irradiation followed by dynamic performance tests and by dynamic testing during irradiation. Appreciable differences have been found in performance between the static and dynamic irradiation of greases. It has been found that two greases successfully lubricated irradiated antifriction bearings at elevated temperatures at double the radiation dose necessary to damage them severely under static conditions at room temperature. Little has been done to evaluate oils under dynamic irradiation conditions, but it is reasonable to expect similar anomalies.

Petroleum Oil Irradiation

Extensive studies have been made on the radiation stability of crude stocks and refined lubricating oils with and without additive packages. Crudes with high sulfur content and other components, e.g., metallic poryphyrin complexes, which act as protection against radiolysis, showed better radiation stability than the refined products using the same crudes. Additional studies were made on a range of petroleum oils representative of typical paraffinic, naphthenic, and aromatic materials varying in sulfur content. These data show that as the aromatic content increases, the viscosity increase is less in almost a linear relationship. The effect of sulfur content is similar but more marked. Further, it was noted that radiation damage appears greatest for oils having the highest initial viscosity.

In summary, high quality conventional lubricating oils are suitable for doses up to 10⁴ rads. Further radiation resistance can be formulated into a good quality petroleum oil by use of antirads such as radical scavengers or aromatic structures (Fig. 1).

V BASE OIL

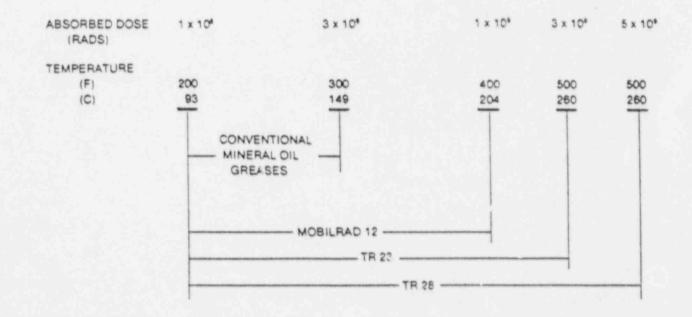

FIG. 2 - EFFECTIVE RANGES OF RADIATION RESISTANT GREASES

Grease Irradiation

The damage caused by high energy radiation on greases is a dual effect. Initially, the radiation attacks the thickening structure causing separation and fluidity. Following this continued irradiation causes polymerization of the base oil to the original thickened condition and finally solidification. The precise pattern of change is dependent on the type of thickener, the gel structure, and the radiation stability of the thickener and base oil.

Various nonsoap thickeners are available which form good radiation resistant greases with both mineral oil and synthetic fluid bases (Fig. 2). These thickeners may be grouped as follows:

- Modified clays and silicas Typical of the modified clays are Bentone 34 and Baragel, which are formed by a cation exchange reaction between a montmorillonite clay and a quatenary ammonium salt.
- 2. Dye pigments Organic toners or dye pigments are utilized as grease thickeners; for example, indathrene.
- Organic thickeners Typical of this type are the substituted aryl ureas characterized by the diamide-carbonyl linkage

TABLEI

Nuclear Reactor Systems

Estimated Dose to Components - Rads/Yr(1)

Component	Pressurized	Boiling	Organic	Liquid Metal	Gas
	Water	Water	Moderated	Cooled	Cooled
	Reactor	Reactor	Reactor	Reactor	Reactor
Control Rod Mechanisms Fuel Handling Devices Primary Coolant Pumps Auxiliary Pumps Auxiliary Motors, etc. Turbogenerator and auxiliaries	10 ⁵ -10 ⁸ 10 ⁶ -10 ⁷ 10 ⁶ -10 ⁷ 10 ⁴ -3 x 10 ⁶ 10 ⁵ -3 x 10 ⁷ Negligible to 10	10° max 	10 ⁶ -10 ⁸ 0-10 ² 0-10 ² Negligible to 25	0-10 ⁵ 0-10 ⁸ Negligible 0-10 ⁶ Negligible to 25	10 ³ -10 ⁵ 10 ² -10 ⁵ 10 ³ max 10 ⁴ max 10 ⁴ max Negligible to 5 x 10 ³

(1) The rad, a unit of dose, is the absorption of 100 ergs of radiation energy per gram of material.

TABLE II

Summary of Radiation Changes in Organic Compounds

		G Values	
	Saturated Hydrocarbons	Unsaturated Hydrocarbons	Aromatic Hydrocarbons
Polymerization Cross Linking	None 1	10-10.000	None 2
H, Evolution	2-6 0.06-1	1 0.1-0.4	0.04-0.4
CH, Evolution Destruction of irradiated Material	4-9	6-2000	0.001-0.8

G = Molecules produced, destroyed, or reacted per 100 electron volts of energy absorbed.
