Abstract

These calculations contain an unverified assumption(s) that must be verified later. Yes () No (X)

The purpose of this revision is to determine if the weighing of the ice baskets can be further delayed until January 22, 1989, by determining if a sufficient amount of ice will be available to ensure the integrity of the primary containment in the event of a design basis accident. Based on the current schedule, which changed after Revision 0 of this calculation was issued, the Unit 2 fuel cycle is expected to end on January 22, 1989.

A calculation (SQNAPS2-001 Rev 0) was previously performed that determined the average sublimation rate for the entire ice condenser. However, it was determined that this calculation was not sufficient to ensure that the ice was dispersed relatively evenly over all the baskets. Therefore, another calculation was performed in which sublimation rates were determined for at least six of the nine rows of each group of bays (group-row combinations), as well as for each of the 24 individual bays as a whole. These rates could then be used to determine the expected ice weight per basket for each group-row combination and for each bay at a 95% level of confidence. This calculation would then ensure whether there is sufficient technical justification for the Tech Specs surveillance requirements of section 3/4.6.5 to be delayed.

Based on the numerical analysis and on the reasons presented in this report, an extension of the ice weighing date for unit 2, as required by Tech Spec 3/4.6.5, from December 4, 1988 to January 22, 1989, will not impact the ability of the ice condenser to perform its intended safety function.

CALCULATION DESIGN VERIFICATION (INDEPENDENT REVIEW) FORM

SONAPS2-110

Calculation No.

1

Revision

Method of design verification (independent review) used (check method used):

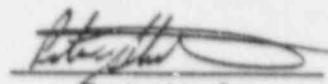

- 1. Design Review
- 2. Alternate Calculation
- 3. Qualification Test

X

Justification (explain below):

- Method 1: In the design review method, justify the technical adequacy of the calculation and explain how the adequacy was verified (calculation is similar to another, based on accepted handbook methods, appropriate sensitivity studies included for confidence, etc.)
- Method 2: In the alternate calculation method, identify the pages where the alternate calculation has been included in the calculation package and explain why this method is adequate.
- Method 3: In the qualification test method, identify the QA documented source(s) where testing adequately demonstrates the adequacy of this calculation and explain.

This calculation revision supports a 3 day extension of the ice condenser weighing interval approved by revision 0. The calculation is a straight forward extension of the methodology used in revision 0 as only the resulting ice weight values changed while the conclusions of the calculation which support a temporary tech spec change for the current fuel cycle only remain the same. Since the output of the calculation is reasonable after considering the input, point 8 of Attachment 10 of NEP 3.1 is satisfied. This is the only point of Attachment 10 that applies to this calculation.

THIS SHEET CORRECTED BY REVISION 1

Rev 1 Prepared by BSS 8/12/88
Rev 1 Reviewed by JT 8/16/881.0 PURPOSE/INTRODUCTION

The purpose of this ~~calculation~~ revision to this calculation is to determine if the weighing of the ice condenser ice baskets can be delayed on the current fuel cycle only. The Sequoyah Nuclear Plant Technical Specifications (Tech Specs) require that the ice be weighed on December 5, 1988 (12 + 3 months after the last weighing performed on September 4, 1987). However, based on the current schedule, the Unit 2 fuel cycle is expected to last until January 22, 1989. Therefore, this calculation will determine if the weighing of the ice baskets can be delayed until January 22, 1989, by determining if a sufficient amount of ice will be available to ensure the integrity of the primary containment in the event of a design basis accident.

Sublimation in the ice condenser continually diminishes the amount of ice in the baskets. In general, the rate of sublimation is very slow. However, a slow rate can cause a relatively large change in ice weight if given an adequate amount of time. Therefore, this calculation will attempt to determine the sublimation rates based on known ice weight data taken over the last six years.

In order to ensure a sufficient quantity of ice is available, the Tech Specs Surveillance Requirement 4.6.5.1 requires that a sample of at least 144 ice baskets be weighed on a twelve month basis. (Currently, this time span may be extended for three additional months if needed). This sample includes one basket from six rows (radial rows 1, 2, 4, 6, 8, and 9) of each of the twenty-four bays. If any basket is found to contain less than 1200 pounds of ice, an additional 20 baskets must be weighed. The rows are then subdivided into three groups (Group 1 - bays 1 through 8, Group 2 - bays 9 through 16, Group 3 - bays 17 through 24). The minimum average weight of the sample baskets in the radial rows of each group must not be less than 1200 pounds per basket at a 95% level of confidence. In addition, these basket weights shall be used to determine that the overall ice weight is not less than 2,333,100 pounds.

A calculation (SQM:PS2-081 Rev 0) was performed that determined the average sublimation rate for the entire ice condenser. However, it was determined that this calculation was not sufficient to ensure that the ice was dispersed relatively evenly over all the baskets. Therefore, another calculation was performed in which sublimation rates were determined for at least six of the nine rows of each group of bays (group-row combinations), as well as for each of the 24 individual bays as a whole. These rates could then be used to determine the expected ice weight per basket for each group-row combination and for each bay at a 95% level of confidence. This calculation would then ensure whether there is sufficient technical justification for the Tech Specs surveillance requirements of section 3/4.6.5 to be delayed.

3.0 DOCUMENTATION OF ASSUMPTIONS

3.1 Assumption 2.1

Assumption 2.1 assumes that the sublimation data calculated from historical data is applicable to the current ice condenser weights and configuration. The ice condenser data used to determine the sublimation rate was taken during the period when the plant was actively producing power. The amount of ice lost was based upon the difference in ice weighings prior to and after plant power operation. SQNP unit 2 was granted a full power operating license on September 15, 1981 (see Reference 5.2) and produced power until it was shutdown on August 21, 1985 (see Page I-3 of reference 5.3) because of equipment qualification concerns.

Ice condenser weight data during this period can be used to determine ice loss during either power operation or extended maintenance periods because during power operation, temperatures of the heat sources providing the driving force for sublimation are greater than during idle plant periods. However, it should be noted that improper maintenance operations on the ice condenser can increase sublimation rates above that expected for an idle or power producing plant.

The functional requirements of the glycol cooling system and ice condenser air handling units have not changed appreciably from the original design (see reference 5.6). Therefore, the assumption that the sublimation rates during previous power operation are applicable to current power operation is valid.

3.2 Assumption 2.2

Assumption 2.2 assumes that the sublimation rate will be determined only from plant data for time periods between ice weighings of approximately six months or more. Sublimation of ice in the ice condenser is a slowly occurring process. However, the performance of maintenance operations such as defrosting (i.e. the melting of ice) result in rapid losses of ice. Also, ingress and egress result in increased sublimation by the introduction of dry air into the ice condenser. Therefore, a statistical evaluation based on a longer sampling period will provide a more accurate estimate of the sublimation rate since the effect of the short term perturbations will be minimized. Furthermore, ice is generally added during maintenance periods which invalidates sublimation calculations for these periods.

Sequoia - Unit 22.0 ASSUMPTIONS

- 2.1 The sublimation rates calculated from plant historical data is applicable to the current ice condenser weights and configuration.
- 2.2 The sublimation rates will be determined from plant ice weighing time differentials of approximately six months or more.
- 2.3 Once non-nuclear heatup began during Unit 2 restart, sublimation rates will be based on those calculated for normal power operation.

NOTE: Assumptions 2.1, 2.2, and 2.3 were obtained directly from SQNAPS2-081 Revision 0 because they are directly applicable to this calculation.

Sequoyah -- Unit 2

3.3 Assumption 2.3

The use of the sublimation rate as calculated for normal power operation to determine ice sublimation during non-nuclear heatup for the restart of unit 2 will result in the calculation of increased ice bed sublimation. This result will occur because the heat load to the containment during non-nuclear heatup is less than the heat load during normal power operation. As is shown in the analysis section, the increased heat loads during power operation significantly increase the ice bed sublimation rate, as opposed to sublimation rates during plant shutdown. Therefore, this assumption conservatively increases the ice bed sublimation rate during the time period from the onset of non-nuclear heatup to the beginning of power operations.

NOTE: Documentation of assumptions 3.1, 3.2, and 3.3 were obtained directly from SQNAPS2-081 Revision 0 because they are directly applicable to this calculation.

6.0 COMPUTATIONS/ANALYSES

For this calculation, sublimation rates for two cases were analyzed. The first case was performed for each one of the eighteen group-row combinations, while the second case was performed for each one of the twenty-four bays.

For the first case, the 95% low limit values were obtained from information provided in Appendix I of Reference 5.9. This information was created using the ICE Version SQ1.0 program (Reference 5.8). The theory and methodology used by this program is described in Appendix A of this calculation. Since the ICE Version SQ1.0 program is set-up to determine the 95% low limit values for each group-row combination, the numbers were already available for use to determine the sublimation rates (which will be explained later). *

For the second case, however, the ICE Version SQ1.0 program could not be used to determine the 95% low limit values for each bay. Instead a file was created using the LOTUS 1-2-3 spreadsheet software to compute the 95% low limit value, using the same theory as the ICE Version SQ1.0 program. Individual data points, as well as the average weight per bay (both of which were obtained from actual ice weight data given in Appendix I of Reference 5.9) were input into the spreadsheet. The spreadsheet was then set-up to calculate the standard deviation and the 95% low limit value using the appropriate equations shown in Appendix A. These calculations are shown in Table 6.1. Once these 95% low limit values were known, the sublimation rates were calculated for both cases. These rates were computed for the following five different time intervals:

Item No.	Beginning Date	Ending Date	Comments
1	May 26, 1982	November 20, 1982	Power Operation
2	December 21, 1982	July 28, 1983	Power Operation
3	September 21, 1983	October 11, 1984	Power Operation
4	November 26, 1984	September 13, 1985	Power Operation
5	September 13, 1985	July 5, 1987	Plant Shutdown

Using the 95% low limit values, the sublimation rates were then calculated as follows:

* The values calculated by the ICE Version SQ1.0 program for the 95% low-limit values during the 1982-83 timeframe were incorrect. However, these values did not impact the results of this calculation, because of reasons explained in Section 8.0.

$$\text{SUBLIMATION RATE} = \frac{W_i - W_f}{\Delta T} = \# \text{ pounds lost per day}$$

or,

$$\text{SUBLIMATION RATE} = \frac{(W_i - W_f) 100\%}{(W_i) (\Delta T)} = \text{percentage weight loss per day}$$

where W_i = initial weight (lbs) W_f = final weight (lbs) ΔT = time interval (# of days)

Again, the LOTUS 1-2-3 spreadsheet program was used to compute these rates. The results for both the group-row combinations and the bays are given in Tables 6.2 and 6.3, respectively.

Once computed, the sublimation rates were applied to ice weight data taken on September 4, 1987 (the last time the ice was weighed). For the group-row combination, the 95% low limit values on this date were known from the information shown in Reference 5.9. The 95% low limit values for the bays were calculated as previously explained. The sublimation rates were then averaged on an individual group-row basis and an individual bay basis to determine a typical sublimation rate for each group-row combination and bay. (NOTE: Only the rates corresponding to the power operation time intervals were averaged. In addition, if the ice weight increased over time for a particular group-row combination or bay (as designated by the presence of a negative sign in Tables 6.2 and 6.3), the rate was assumed to be zero for conservatism. In other words, no credit was taken for an increase in ice weight over time.) These rates were then applied to the data taken on September 4, 1987. Since the plant was considered to be shutdown between September 4, 1987 and February 6, 1988, the appropriate shutdown rate was used for this time period of 155 days. From February 6, 1988 to January 19, 1989, the appropriate operating rate was used. The final result will then yield the expected average weight of the ice per basket on February 19, 1989 at a 95% level of confidence. These results for the group-row combinations and the bays are shown in Tables 6.4 and 6.5, respectively.

Sequoyah -- Unit 2

An additional calculation was performed using the most rapid sublimation rate for each individual group-row combination and bay instead of the average rate. Although this calculation is not expected to be representative of the current actual sublimation rates, it provides a worst-case observation of the known data. The exact same method as used in the previous paragraph was repeated for the worst-case rate. The results for the group-row combinations and bays are shown in Tables 6.5 and 6.7, respectively.

A discussion of all results is given in Section 7.0 of this calculation.

NOTE: The group-row calculations to determine the 95% low-limit values, which were performed by the ICE Version SQ1.0 program, only included the printed data points shown in Appendix I of Reference 5.9.

The hand-written data points were not included in the group-row calculations, but were included in the bay calculations. It did not matter whether the hand-written data points were included or omitted in the final results.

UNITED STATES GOVERNMENT

Memorandum

TENNESSEE VALLEY AUTHORITY

TO : P. G. Trudel, Project Engineer, Sequoyah Engineering Project, DSC-E,
Sequoyah Nuclear Plant

FROM : S. J. Smith, Plant Manager, POB-2, Sequoyah Nuclear Plant

DATE :

SUBJECT: SEQUOYAH NUCLEAR PLANT (SQN) - POST MODIFICATION TEST PROGRAM (PMT) 108 -
TRANSMITTAL OF MOTOR DATA

Attached for your review is the motor data acquired in accordance with PMT-108/Work Plan (WP) 7245-02. This data supercedes only the motor data transmitted by my memorandum to you dated August 10, 1988 (S57 880810 858).

In accordance with the request by Nuclear Engineering (NE) Electrical Engineering Branch (EEB) representative D. B. Murray, a review of PMT-108 motor data was performed by Systems Engineering. This review included test data, chronological log, data tapes, and Dranetz 808 manual and revealed that the data tapes were misinterpreted by the Division of Power Systems Operation personnel at the time of the test. The corrected data sheet is attached to facilitate your motor horsepower evaluation.

This PMT-108 motor data review has been coordinated by R. S. Brackett at extension 7756 and R. D. Moore at extension 6614, (Systems Engineering) and D. B. Murray, (EEB).

S. J. Smith

RMM:ABD:RSB:SSB
cc: RIMS, MR 4N 72A-C

This memorandum was prepared principally by R. S. Brackett.

7.0 DISCUSSION OF RESULTSRev 1 Prepared by 888 8/11/88
Rev 1 Reviewed by LT 8/16/88

This discussion will be separated into two parts: First, a discussion of the results based on the average sublimation rates for each group-row combination and bay, and secondly, a discussion based on worst-case rates.

From the results Table 6.4, it is seen that using the expected sublimation rate (average rate), five group-row combinations (group 1-row 1, group 2-row 1, group 2-row 2, group 3-row 1, and group 3-row 2) have an average weight that is less than the 1200 pound limit. Two of these five sets are within three pounds of the 1200 pound limit. Similarly, from the results Table 6.5, it is seen that using the expected sublimation rate (average rate), only one bay (bay 24) has an average weight that is less than the 1200 pound limit. However, all of the group-row combinations and bays are well in excess of the number $1200 - (10\%)(1200) = 1080$ pounds, an analytical limit which takes into account the amount of ice loss allowed between successive weighings and is the amount taken credit for in all containment safety analyses.

However, from the results given in Table 6.6, the worst-case rate creates eight group-row combinations which are less than the 1200 pound limit on January 19, 1989. Similarly, from the results given in Table 6.7, the worst-case rate creates six bays which are less than the 1200 pound limit. In addition, one group-row combination (group 1-row 1) and one bay (bay 24) are below the 1080 pound analytical limit by about 20 pounds. The average weight per basket for each group in the group-row

combinations is ~~1207.14~~ pounds for Group 1, ~~1270.5~~ pounds for Group 2, and ~~1232.74~~ pounds for Group 3. The overall average weight per basket based on the group-row combinations calculations is ~~1237.14~~ pounds ~~1232.98~~

~~2.397~~ $\times 10^6$ pounds. The average weight per basket based on the bay calculations is ~~1238.22~~ pounds, which indicates a total ice condenser weight of ~~(1237.14)(81)(24)~~ $\times 10^6$ pounds. The overall weight of the ice condenser based on the both the group-row combinations and bays is considerably greater than the minimum allowable amount of 2,333,100 pounds listed in the Tech Specs. 8.0 CONCLUSIONS

Looking back through the history surrounding the Sequoyah ice condenser, many documents were written discussing sublimation rates. One such document is a memo (Reference 5.10) which discusses problems with the sublimation rates in unit 2 following an evaluation of the ice weighing data of November and December of 1982. It was discovered that the sublimation rate for unit 2 was extremely higher than unit 1, but that the reason for this anomaly was unknown. In addition, it was discovered that critical localized areas (group 1-row 1 and bays 1 and 24) required special attention. (Virtually all utilities with ice condenser plants were experiencing similar problems). Therefore, around the end of 1982 and the beginning of 1983, an ice condenser improvement program was implemented (Reference 5.11) to identify probable causes for the problems. For the most part, these large scale problems were resolved during 1983 (Reference 5.12).

The data from 1982 and 1983 provide much higher sublimation rates in the critical localized areas compared with the 1984 and 1985 data. It is believed that this change is due to the corrections that were made to the ice condenser in 1983. Although small improvements have been made more recently, the major effort that was made in 1983 provided the overall improvement to the sublimation rates in the critical localized areas. For this reason, it is believed that the high sublimation rates that were happening in the critical areas during the 1982 and 1983 operating cycles should not be considered appropriate for use in determining current sublimation rates. Therefore, the weight of the group 1-row 1 combination and bay 24 will be considerably higher than the ~~1058~~ pounds on January ~~1982~~ 1989 which was predicted using the worst case rates. In fact, if the average sublimation rate is used (which still factors in the high sublimation rates which occurred in 1982 and 1983), the weight of each basket at a 95% level of confidence for group 1-row 1 is ~~1134~~ 1136 pounds and for bay 24 is ~~1150~~ 1157 pounds. | RI

Based on the numerical analysis and on the reasons presented in this report, an extension of the ice weighing date for unit 2, as required by Tech Spec 3/4.6.5, from December 4, 1988 to January ~~1982~~ 1989 will not impact the ability of the ice condenser to perform its safety function. | RI

APPENDIX A

ICE 501.0

THEORY

PAGE 1 - 1

1. THEORY

The following sections describe the statistical methods used by ICE. The program assumes that the ice basket weights approximate a normal distribution.

1.1 Sample Mean

The sample mean is calculated using the following equation.

$$\bar{X} = \frac{\sum_{i=1}^n X_i}{n}$$

where, X_i = individual basket weights
 n = total number of baskets weighed

1.2 Sample Standard Deviation

The sample standard deviation, S , is then computed using the following equation.

$$S = \sqrt{\frac{\sum_{i=1}^{n-1} (X_i - \bar{X})^2}{n-1}}$$

1.3 Confidence Interval

For this problem, the confidence interval can be described as follows.

The probability that $(\bar{X} - \bar{X}_{low}) > 0.95$

where, \bar{X} = true population mean

\bar{X}_{low} = calculated low limit mean

For a 95% confidence interval ($\alpha=0.05$), we have the following, one-tailed distribution curve.

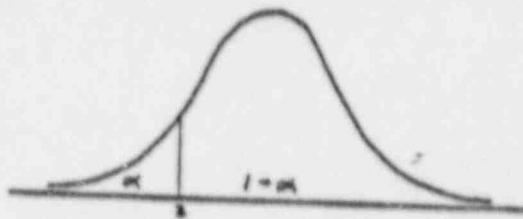

* This information was obtained from Reference 3.8

APPENDIX A

- ICB 501.0

THEORY

PAGE 4 - 2

The low limit population mean is then given by the following expression.

$$\bar{x}_{\text{low}} = \bar{x} - \left(\frac{z * s}{\sqrt{N}} \right) \quad \text{where, } z = z\text{-score as described in the next sections}$$

4.3.1 Z-score for $N < 30$

For a sample size of less than 30, z must be determined using the T-distribution tables for $\alpha = 0.05$ and $v = N-1$ degrees of freedom. The following is an excerpt from this table.

v	$\alpha = 0.05$	v	$\alpha = 0.05$
1	6.314	16	1.786
2	2.920	17	1.780
3	2.353	18	1.734
4	2.132	19	1.729
5	2.015	20	1.725
6	1.943	21	1.721
7	1.895	22	1.717
8	1.860	23	1.714
9	1.833	24	1.711
10	1.812	25	1.708
11	1.795	26	1.706
12	1.782	27	1.703
13	1.771	28	1.701
14	1.761	29	1.699
15	1.753	inf	1.645

4.3.2 Z-score for $N \geq 30$

For a sample size of 30 or more, the standard normal distribution is used for $\alpha = 0.05$. The z -score in these cases equals 1.645.
