1. Description of the Event

On 2/19/86 with Unit 2 at cold shutdown and with 'A' residual heat removal (RHR) heat exchanger and 'B' RHR pump in service, operators were performing PT 41.2 (Cold Shutdown Testing of Component Cooling Check Valves). As part of the preparation to test the component cooling (CC) check valve on the 'A' CC loop to the 'A' RHR heat exchanger, operators were required to place the 'B' RHR heat exchanger in service. Due to miscommunication with the control room operator, the operator performing the valve lineup believed that the 'B' heat exchanger was already in service. In fact, the 'A' heat exchanger was in service. After the test rigs were in place, operators continued the valve lineup which included closing TV-CC-209A (CC return from 'A' RHR heat exchanger containment trip valve). This resulted in isolating CC flow to the 'A' RHR heat exchanger for a short period while the check valve was being tested.

The event was discovered when operators were preparing to test the check valve on the 'B' CC loop to RHR. It was then noted that CC flow had been isolated to the 'A' heat exchanger, and that RHR flow had been isolated to the 'B' heat exchanger. This is contrary to Technical Specification 3.1.A.d.2.

2. Safety Consequences and Implications

The RHR system is designed to remove core decay heat and control reactor coolant system (RCS) temperature and pressure when the reactor is shutdown and the RCS system is below 350°F/450#. During the short time CC was isolated to the 'A' RHR heat exchanger (approximately 10 minutes), RCS temperature and pressure were closely monitored and no abnormal increases were noted. In addition, operators performing the test would have been instructed to reopen the CC valves if the RCS temperature and pressure had significantly increased. Therefore, this event did not constitute an unreviewed safety question, and the health and safety of the public were not affected.

3. Cause

The root cause of this event was human error in that the operator failed to follow the steps in the written procedure which would have ensured the proper valve lineup. A contributing factor was poor communication between the control room operator and the operator performing the valve lineup.

4. Immediate Corrective Actions

Since CC had been fully restored to the operating heat exchanger at the time of discovery, no immediate actions were required.

5. Additional Corrective Actions

None required.

RC Form 366A

6. Actions Taken to Prevent Recurrence

Operators involved in performance of the PT were directed to prepare a significant event report describing the circumstances surrounding this event. This report will be placed in the operations required reading manual in order to preclude a similar occurrence.

In addition, this event will be evaluated by the Human Performance Evaluation Coordinator, and a report will be submitted to station management.

7. Generic Implications

None.
