EXECUTIVE SUMMARY

This Annual Radiological Environmental Operating Report describes the Catawba Nuclear Station Radiological Environmental Monitoring Program and the results of the program for the 1987 calendar year.

Included in the report are identification of sampling locations, descriptions of environmental sampling and analysis procedures, comparisons of present environmental radioactivity levels and preoperational environmental data, analysis of trends in the environmental radioactivity levels since the beginning of station operation, comparisons of doses calculated from environmental measurements and doses calculated from effluent data, the results of the 1987 program, a summary of these results, discussion of the results, and discussion of the quality assurance activities associated with the program. Deviations from program requirements are also included.

Sampling activities were conducted as prescribed by Technical Specifications. Required analyses were performed and detection capabilities met Technical Specification requirements.

Radioactivity clearly attributable to the operation of Catawba was detected in the following media, all at the discharge canal:

Surface water: H-3 increasing

Fish: Co-58 decreasing
Co-60 steady
Cs-137 decreasing

Shoreline Sediment: Mn-54 steady
Co-58 steady
Co-60 steady
Cs-134 steady
Cs-137 steady

Bottom Sediment: Mn-54 increasing
Co-58 steady
Co-60 increasing
Cs-134 steady
Cs-137 steady

No other significant trends were evident in the sampling results.

Catawba's contribution to environmental radioactivity is small. All positive indications of radioactivity due to plant operations were less than the reporting levels imposed by Technical Specifications. Operation of the Station has had no significant radiological impact upon the health and safety of the general public.

Doses calculated from environmental measurements and doses calculated from effluent data were compared. In some cases agreement was good. In others the doses disagreed by two orders of magnitude. This disagreement is discussed in this report. We consider this disagreement to be acceptable considering the low activity levels involved.

SECTION 2

INTRODUCTION

2.1 SITE DESCRIPTION AND SAMPLE LOCATIONS

Duke Power Company's Catawba Nuclear Station (CNS) is a two-unit facility located on the shore of Lake Wylie in York County, South Carolina. Each of the two essentially identical units employs a pressurized water reactor Nuclear Steam Supply System furnished by Westinghouse Electric Corporation. Each generating unit is designed to produce a net electrical output of approximately 1145 MWe. Units 1 and 2 achieved initial criticality on January 7, 1985 and May 8, 1986, respectively. During 1987, Units 1 and 2 attained net capacity factors of 64% and 71%, respectively.

Condenser cooling is accomplished utilizing a closed cycle system incorporating cooling towers, instead of utilizing lake water directly. Liquid effluents are released into Lake Wylie via the station discharge canal, and are not accompanied by the large additional dilution water flow associated with "once-through" condenser cooling. This design difference results in greater radionuclide concentrations in the discharge canal given comparable liquid effluent source terms.

A map depicting the site and the area within one mile of CNS can be found in Figure 2.C. An area map encompassing a ten mile radius from the plant can be found in Figure 2.D.

The CNS Radiological Environmental Monitoring Program (REMP) sampling locations are summarized in Tables 2.A and 2.B. Table 2.A lists the environmental Thermoluminescent Dosimeter (TLD) locations. Table 2.B lists all other sampling locations. The REMP sampling and analysis procedures are summarized in Appendix A.

Figures 2.C, 2.D, and 2.E are maps depicting the specific positions of all REMP sampling locations. The location numbers shown on these maps correspond to those listed in Tables 2.A and 2.B. Figure 2.C comprises all sample locations within one mile of CNS. Figure 2.D comprises all remaining locations. Figure 2.E identifies Location 208 (Discharge Canal) shoreline sediment (1S, 2S, and 3S) and bottom sediment (1M, 2M, and 3M) sampling points. Of these six sediment samples, only shoreline sediment at location 208-1S is required by CNS Technical Specifications; the remaining five are supplemental samples first collected during 1986.

2.2 SCOPE AND REQUIREMENTS OF THE ENVIRONMENTAL MONITORING PROGRAM

The Radiological Environmental Monitoring Program required by CNS Technical Specification 3/4.12.1 provides representative measurements of radiation and radioactive materials in those exposure pathways and for those radionuclides that lead to the highest potential radiation exposures of members of the public resulting from plant operation. This monitoring program implements Section IV.B.2 of Appendix I to 10 CFR Part 50 and thereby supplements the Radiological Effluent Monitoring Program by verifying that the measureable concentrations of radioactive materials and levels of radiation are not higher than expected on the basis of effluent measurements and modeling of environmental exposure pathways. Guidance for this monitoring program is provided by the Radiological Assessment Branch Technical Position on Environmental Monitoring.

The Annual Land Use Census required by CNS Technical Specification 3/4.12.2 is performed to ensure that changes in the use of areas at or beyond the site boundary are identified and that modifications to the Radiological Environmental Monitoring Program are made if required by changes in land use. This census satisfies the requirements of Section IV.B.3 of Appendix I to 10 CFR Part 50. The results of this census are required to be included in this Annual Radiological Environmental Operating Report by Technical Specification Administrative Control 6.9.1.6.

Participation in an approved Interlaboratory Comparison Program as required by CNS Technical Specification 3/4.12.3 provides for independent checks on the precision and accuracy of REMP environmental radionuclide measurements. Such checks shall be performed as part of the quality assurance program for environmental monitoring in order to demonstrate that the results are valid for the purposes of Section IV.B.2 of Appendix I to 10 CFR Part 50.

This Annual Radiological Environmental Operating Report is required by CNS Technical Specification Administrative Control 6.9.1.6. This report adheres to the content specifications of Control 6.9.1.6.

CNS Technical Specification 3.12.1 (Table 3.12-1) specifies the conduct of the Radiological Environmental Monitoring Program. The Duke Power Company Offsite Dose Calculation Manual further defines the specific types, frequencies, and locations of sampling and measurement.

Technical Specification Table 3.12-2 provides reporting levels, as a function of sample type and radionuclide. If sample radionuclide activity exceeds 100% of reporting level (when summed over all detected nuclides having a reporting level for the applicable sample type, and when the sums are averaged by location over the applicable calendar quarter) a special report must be submitted to the Nuclear Regulatory Commission. When radionuclides other than those listed in Table 3.12-2 are detected, they shall be addressed in this annual report. Not all radionuclides have a reporting level for a given sample type. For example, there are no reporting levels for gross beta analysis of any sample type, and sediment samples have no reporting levels for any radionuclides.

Technical Specification Table 4.12-1 lists required Lower Limit of Detection (LLD) capabilities for REMP sample analyses, as a function of sample type and radionuclide. Refer to Section 2.3.2 for the definition of LLD and Minimum Detectable Activity (MDA). Not all radionuclides have a required LLD for a given sample type. Any analyses for which the required LLDs were not achievable shall be discussed in this annual report.

Technical Specification Tables 3.12-2 and 4.12-1 list thirteen radionuclides; H-3, Mn-54, Fe-59, Co-58, Co-60, Zn-65, Zr-95, Nb-95, I-131, Cs-134, Cs-137, Ba-140, and La-140. These thirteen radionuclides are collectively referred to throughout this annual report as "Radionuclides Listed in Technical Specifications".

2.3 STATISTICAL AND CALCULATIONAL METHODOLOGY

2.3.1 ESTIMATION OF THE MEAN VALUE

There was one (1) basic statistical calculation performed on the raw data resulting from the environmental sample analysis program. The calculation involved the determination of the mean value for the indicator and the control samples for each sample medium. The mean (\bar{x}) is a widely used statistic. This value was used in the reduction of the data generated by the sampling and analysis of the various media in the Environmental Monitoring Program. The following equation was used to estimate the mean:

$$\bar{x} = \frac{\sum_{i=1}^N x_i}{N} \quad (\text{eq. 2-1})$$

where, \bar{x} = estimate of the mean,
 i = individual sample,
 N = total number of samples with a net activity (or concentration),
 x_i = net activity (or concentration) for sample i .

NOTE: "Net activity (or concentration)" is the activity (or concentration) determined to be present in the sample. No "Minimum Detectable Activity", "Lower Limit of Detection", "Less Than Level", or negative activities or concentrations are included in the calculation of the mean.

2.3.2 LOWER LEVEL OF DETECTION AND MINIMUM DETECTABLE ACTIVITY

The Lower Level of Detection (LLD) and Minimum Detectable Activity (MDA) are used throughout the Environmental Monitoring Program, both in the Technical Specifications and in the implementation of the specifications.

The LLD, as defined in the Technical Specifications, is the smallest concentration of radioactive material in a sample that will yield a net count, above system background, that will be detected with 95% probability with only 5% probability of falsely concluding that a blank observation represents a "real" signal. The LLD is an a priori lower limit of detection. The actual LLD is dependent upon the standard deviation of the background counting rate, the counting efficiency, the sample size (mass or volume), the radiochemical yield, and the radioactive decay of the sample between sample collection and counting. The "required" LLD's for each sample medium and selected radionuclides are given in the Technical Specifications.

The MDA may be thought of as an "actual" LLD for a particular sample measurement remembering that the MDA is calculated using a sample background instead of a system background. In gamma spectroscopy analyses, the sample background may be elevated above the system background due to the continuum produced by higher energy gammas from other radionuclides (either man-made or naturally produced). The continuum increases the smallest concentration of a particular radionuclide that could be positively identified in the sample. Therefore, to insure that the "required" LLD is not exceeded for any radionuclide in a sample medium, the MDA is calculated based on the actual background in the area of the identifying gamma energy and is compared to the "required" LLD. If the MDA exceeds the "required" LLD, the sample is counted for a longer time period so that the standard deviation of the sample background is minimized. If the "required" LLD exceeds the MDA, then the analysis of the sample meets the requirements for the detection capability for environmental sample analysis.

For "gross" counters (such as alpha/beta proportional counters and liquid scintillation counters), the MDA is calculated using a batch background count. This MDA is then compared to the "required" LLD. If the MDA exceeds the "required" LLD, the sample is counted for a longer time period so that the standard deviation of the batch background is minimized. If the "required" LLD exceeds the MDA, then the analysis of the sample meets the requirements for the detection capability for environmental sample analysis.

2.3.3 TREND IDENTIFICATION

One of the purposes of an environmental monitoring program is to determine if there is a buildup of radionuclides in the environment due to the operation of the nuclear station. This is traditionally done by looking at historical data (including preoperational data) and determining if a trend exists. Trends, if they exist, may be either positive or negative. Since nuclear reactor operations do not normally remove radioactivity from the surrounding environment, a negative trend in a particular radionuclide's concentration in an environmental medium does not indicate that reactor operations are removing radioactivity from the environment but that reactor operations are not adding that radionuclide to the environment in quantities exceeding the preoperational level and that the normal removal processes (radioactive decay, deposition, resuspension, etc.) are influencing the concentration.

In some cases, visual inspection of tabular or graphical presentations of data may be sufficient to determine if a trend exists. In other cases, it may not be so obvious. Therefore, it is desirable to obtain a single numerical value from the data which will permit a meaningful interpretation of the relationship existing between the variations in the data. If it is assumed that a linear relationship exists between the time after startup of the reactor and the amount of radionuclides in a particular environmental medium, the least squares regression method may be used to define the linear relationship. To determine if the data actually correlate to the straight line assumption, the theoretical variance is compared to the actual variance. The numerical value that summarizes this comparison is known as the correlation coefficient. This correlation coefficient, symbolized by "r", is a determination of how closely the data fit a straight line and may be calculated from the following equation:

$$r = \frac{N\sum XY - \sum X \sum Y}{\sqrt{[(N\sum X^2 - (\sum X)^2) (N\sum Y^2 - (\sum Y)^2)]}} \quad (\text{eq. 2-2})$$

where, r = correlation coefficient for the data set of X and Y ,
 X = the year or point in time,
 Y = the radionuclide concentration associated with X ,
 N = number of observations.

The range of values as calculated by the correlation coefficient lies between positive one (+1) and negative one (-1). The absolute value of the correlation coefficient represents the probability of a trend. Zero (0) represents no indication of either a positive or negative trend. A positive (+) correlation coefficient indicates an increasing trend, and, conversely, a negative (-) correlation coefficient indicates a decreasing trend. The ranges of a correlation coefficient may be summarized as on the next page.

$1 \geq |r| > 0.7$ High to moderate probability of a trend.
 $0.7 \geq |r| > 0.3$ Moderate to poor probability of a trend.
 $0.3 \geq |r| \geq 0$ Poor to no probability of trend.

Identifying a trend by using the correlation coefficient is only useful for the time periods where the discharge from the nuclear plant is relatively stable and no other sources of radioactivity are present. Substantial increases or decreases in the amount of a particular radionuclide's release from the nuclear plant will greatly affect the resulting environmental levels; therefore, a knowledge of the release of a radionuclide from the nuclear plant is necessary to completely interpret the trends, or lack of trends, determined from the environmental data. Other factors that may affect environmental levels of radionuclides include prevailing weather conditions (periods of drought or heavier than normal precipitation), construction in or around either the nuclear plant or the sampling location, addition or deletion of other sources of radioactive materials (such as the Chernobyl accident), etc.. Some of these factors may be obvious while others are sometimes unknown to the plant personnel.

The recent change in the method of calculating the mean (using only net positive results) will also affect the apparent trends.

Because of the above considerations, how trends are identified will depend not only on the least squares regression method, but will include some judgement by plant personnel on the factors affecting environmental levels.

SECTION 3

RADIOLOGICAL ENVIRONMENTAL MONITORING PROGRAM - DISCUSSION, INTERPRETATION, AND TRENDING OF RESULTS

GENERAL INFORMATION

Before discussing each sample type specifically in Sections 3.1 - 3.11, the following general information is best discussed separately.

Sections 2.1 and 2.2 describe the CNS site, REMP sample locations, and requirements of the environmental monitoring program. Appendix A summarizes the environmental sampling and analysis procedures, and discusses changes in the procedures occurring during 1987. In addition to the "required" sampling and analyses described in Technical Specification Table 3.12-1, the following "supplemental" measures were taken during 1987. These supplemental measures were first adopted during 1986:

- 1) Shoreline sediment, requiring collection at only one point along the CNS Discharge Canal (Location 208-1S), was collected at three points (Locations 208-1S, 208-2S, and 208-3S).
- 2) Shoreline sediment, requiring collection semiannually, was collected quarterly. The first and third quarter samples from Locations 208-1S, 210, and 215 were considered to be the required samples and all remaining samples were considered supplemental.
- 3) Fish, requiring collection from Locations 208 and 216 semiannually, were collected quarterly. The first and third quarter samples were considered to be the required samples and the second and fourth quarter samples were considered supplemental.
- 4) Bottom sediment, not requiring collection at all, was collected during the first, second, and fourth quarters at CNS Discharge Canal Locations 208-1M, 208-2M, and 208-3M. These were considered to be supplemental samples.

All deviations from the sampling and the analytical requirements of Technical Specification Table 3.12-1 which occurred during 1987 are addressed in Appendices C and D, respectively. For all required 1987 CNS REMP analyses performed, the 1LD capability requirements of Technical Specification 4.12.1 were met. For all 1987 CNS REMP samples collected, the reporting level limitations of Technical Specification 3.12.1 were not exceeded.

The quality assurance programs associated with radiological environmental monitoring are summarized in Section 5. Section 5.3 includes the results of Duke Power Company's Environmental Radiological Laboratory's participation in the EPA Interlaboratory Comparison Program.

All 1987 CNS REMP sample analysis results are submitted in Appendix E. These include results for the "supplemental" samples described earlier.

Summary tables covering 1987 for each REMP sample type, containing the information required by CNS Technical Specification Administrative Control 6.9.1.6, can be found in Appendix B. These summary tables are based upon required sample results only, the supplemental sample results are not reflected in these tables. The mean values tabulated in these 1987 summary tables are based upon detectable measurements only, whereas the summaries submitted with all previous CNS Annual Radiological Environmental Operating Reports contain mean values based upon net activities for all measurements, even for negative net activities and non-detectable measurements. A number of additional summaries were generated in order to facilitate thorough evaluation of 1987 REMP data; however, these additional summaries have not been included in this annual report.

Section 4 contains an evaluation of estimated doses to members of the public based upon REMP results as compared to doses based upon effluent release calculations. Doses based upon REMP results were estimated using data from the summary tables of Appendix B. Doses based upon effluent release calculations were taken from 1987 CNS Liquid and Gaseous Effluent Reports.

As mentioned in Appendix A, the Nuclear Data ND6620 gamma spectroscopy system (which was used to analyze CNS REMP samples collected during 1984, 1985, 1986, and most of 1987) was replaced by the Nuclear Data ND9900 gamma spectroscopy system effective September 1, 1987. When the ND6620 system was used to analyze samples prior to September 1, 1987, a small but steady percentage of most activation and fission radionuclide measurements (approximately 5%) yielded detectable low-level activity, even when the presence of such activity was highly unlikely as for control location samples and preoperational samples collected during 1984. This phenomenon has not occurred using the ND9900 system, thus ending this trend and suggesting that the ND6620 system may have been vulnerable to false-positive results, possibly due to the method by which it estimated net activity even when its peak search routine failed to detect a peak. Based on the best available evidence, it appears that the ND6620 system was probably vulnerable to a small but steady percentage of low-level false-positive results, and that the ND9900 system is sufficiently sensitive to meet the LLD capability requirements of CNS Technical Specification 4.12.1.

During 1984, the last completely preoperational year at CNS, H-3 and Cs-137 were detected with sufficient frequency to imply their existence as background radioactivity. Table 3.E summarizes the fraction and percent of nuclide measurements performed during 1984 which yielded detectable activity, as well as the predominant nuclides detected. These figures encompass measurements of the thirteen radionuclides listed in technical specifications, and do not reflect other nuclides which were detected (such as many naturally-occurring nuclides). There appears to be no reliably discernable difference between the control and indicator locations (for a given sample type) in terms of the data incorporated in Table 3.E. Note that for ground water, drinking water, and surface water samples, H-3 was frequently detected (at levels of about 300 pCi/liter), and I-131 was occasionally detected in surface water at all three locations when performing low-level radioiodine analysis (at levels ranging from 0.3 to 1.7 pCi/liter).

For all sample types other than water, Cs-137 was detected occasionally during 1984. Note that for shoreline sediment, Cs-134 was detected at all three locations in four of six samples at levels ranging from 24 to 39 pCi/liter. For the reasons discussed earlier (ND6620 sensitivity phenomenon), the predominant nuclides of Table 3.E are likely to be the only nuclides listed in technical specifications that actually existed in these preoperational samples.

All 1987 REMP analysis results were carefully reviewed in order to detect and identify any significant trends. Many sources of information were examined to accomplish this, and the resultant trending observations were included in Sections 3.1 - 3.11. Quarterly REMP verification reports were generated in order to track technical specification requirements, and these reports were also used to evaluate trends occurring during periods shorter than a year. The 1987 Summary of Analysis Results tables from Appendix B, as well as the analogous tables for 1984, 1985, and 1986, were reviewed.

To aid in trending, additional summaries were generated for each individual location for each sample type, as well as for key groups of locations for each sample type. These additional summaries were not included in this annual report. With exception of certain 1986 results affected by the Chernobyl accident, these summaries incorporated all REMP sample results, required as well as supplemental. These summaries contain the following three parameters for each radionuclide listed in technical specifications: 1) the average nuclide activity for all detectable measurements performed during a year, 2) the average nuclide activity for all measurements performed during a year (with non-detectable measurements being averaged in as zero activity), and 3) the fraction and percentage of all measurements performed during a year that yielded detectable activity. These three parameters were denoted as to whether or not they exceeded the corresponding control location parameter. The highest parameter out of all indicator locations for a given sample type was specially denoted. These parameters were generated for 1986 and 1987 (at a minimum) and parameter ratios between two successive years were calculated. Parameters for 1987 were also compared to the analogous parameters for 1984 (the last preoperational year) for those nuclides predominantly detected during 1984 (see Table 3.E).

Technical Specification 3.12.1 addresses the actions to be taken when nuclides other than the thirteen radionuclides listed in technical specifications are detected in REMP samples. If such nuclides are detected and are not the result of plant effluents, the condition shall be reported and described in this annual report. Table 3.D summarizes all such occurrences during 1987. The naturally occurring radionuclides of Table 3.D were considered to have resulted from natural background radioactivity, not plant effluents. This is supported by the frequency with which they were detected at both indicator and control locations, and during preoperation. Co-57 detected in bottom sediment at the discharge canal is assumed to have resulted from CNS liquid effluents, which often contained Co-57. The remaining six occurrences of detection of Sn-113, Cr-51, Ce-141, Ce-143, and Ce-144 listed in Table 3.D, were not considered to have resulted from CNS effluents, for the following reasons. Sn-113, detected in a Location 201 air filter paper sample, was not an airborne effluent from CNS during 1987.

Cr-51, detected in a Location 215 surface water sample, was listed as a significant liquid effluent; however, Location 215 is a control location situated approximately four miles upstream from CNS. Ce-143 and Ce-141, detected in different broadleaf vegetation samples taken from Location 200, were not airborne effluents. Ce-141, detected in a Location 210 shoreline sediment sample, was not a CNS effluent during 1987. Ce-144, detected in a Location 216 fish sample, was listed as a significant liquid effluent; however, Location 216 is a control location situated approximately four miles upstream from CNS.

An informative first overview of 1987 CNS REMP sample analysis results can be found in Table 3.B. This overview can be compared to the analogous preoperational overview of Table 3.E. For all sample types except ground water, milk (control), broadleaf vegetation, shoreline sediment, and fish, 1987 percent detected values for indicator and control locations were less than 1984 values. Note that for 1987 milk and broadleaf vegetation samples, the percent detected values are less for indicator locations than for control locations. Furthermore, all 1987 percent detected values were less than the corresponding 1986 values, except for fish collected at control location 216. This "apparent" decrease in probability of detection from 1986 to 1987 (41% decrease from 6.1% to 3.6% for all control samples, and 18% decrease from 6.6% to 5.4% for all indicator samples) is probably mainly due to the change of gamma spectroscopy systems and the associated sensitivity difference discussed earlier. Since the ND9900 system was used to analyze approximately one-third of all 1987 samples, one would predict about a 33% decrease in detectable control location measurements based on the postulated sensitivity difference alone. When considering the above summary evidence, it is clear that 1987 shoreline sediment, fish, and bottom sediment samples contain radioactivity resulting from plant operation. In order to specifically determine how these samples were impacted, or if any other sample types were impacted, a more detailed examination of data has been performed and the conclusions submitted in Sections 3.1 - 3.11.

Technical Specification Table 3.12-2 provides reporting levels, as a function of sample type and radionuclide. If sample radionuclide activity exceeds 100% of reporting level (when summed over all detected nuclides having a reporting level for the applicable sample type, and when the sums are averaged by location over the applicable calendar quarter) a special report must be submitted to the Nuclear Regulatory Commission. Table 3.C contains the maximum percent of reporting level (when averaged over a calendar quarter) reached during 1987 for each sample type and location combination. Note that no such values are listed for shoreline sediment or bottom sediment, as there are no corresponding technical specification reporting levels. With one exception, all of these maximum percent of reporting levels were less than 8.3%, well below the 100% action level. By far the highest value reached was 47%, for surface water collected during the third quarter at CNS Discharge Canal Location 208. Tritium accounted for most (30%) of this figure, and two consecutive biweekly low-level I-131 results (7/15 - 8/12/87) accounted for the remainder (17%) of this figure. The percent of reporting level values for surface water at Location 208 for the five calendar "quarters" of 1987 (12/2 - 12/30/87) was composited as the fifth "quarter" to complete the year) were 24%, 26%, 47%, 36%, and 10%, respectively.

The following Sections 3.1 - 3.11 discuss 1987 REMP results for each sample type specifically. Unless otherwise noted, these discussions are based on all REMP sample results, required as well as supplemental (with exception of certain 1986 results affected by the Chernobyl accident). In order to properly interpret the following discussions, the reader must be comfortably familiar with Section 2, the general information of Section 3, and Tables 3.B, 3.C, and 3.E.

3.1 AIRBORNE RADIOIODINES AND PARTICULATES

3.1.1 RADIOIODINES

All radionuclides listed in technical specifications were detected in indicator location air charcoal cartridge samples with frequencies ranging from 0.5% to 8.2%. No single location (including the control location) appeared to have any significantly higher or lower activities or detection frequencies for any nuclide. The maximum quarterly percent of reporting level was 0.15%; this occurred at indicator Location 212 during the first quarter (mainly due to detection of I-131 in one weekly sample).

I-131 was detected with only 0.8% frequency (2/259, both at indicator Location 212) with activities of 1.10E-2 and 1.66E-2 pCi/cubic meter. Cs-137 was the predominant nuclide, detected with a frequency of 8.2% (17/207) for all indicator locations and 7.7% (4/52) for control Location 217. These Cs-137 frequencies decreased from the analogous 1986 values of 16.3% and 22.2%, respectively. They are also lower than the 1984 preoperational frequency of 13.8%. For 1984, 1986, and 1987, detectable Cs-137 results for all locations were typically about 9E-3 pCi/cubic meter.

Due to the ND6620 sensitivity phenomenon, it is questionable whether any of the nuclides listed in technical specifications actually existed in airborne radioiodine samples, with the possible exception of Cs-137. This is further supported by the high probability that the activity (for most all of these nuclides) should have been filtered out by the air filter paper and therefore would not have collected in the charcoal cartridge. It appears that if Cs-137 truly existed in these samples, it originated from background radioactivity, not CNS operation.

3.1.2 PARTICULATES

All radionuclides listed in technical specifications were detected in indicator location air filter paper samples with frequencies ranging from 0.5% to 5.8%. No single location (including the control location) appeared to have any significantly higher or lower activities or detection frequencies for any nuclide. The maximum quarterly percent of reporting level was 0.19%; this occurred at indicator Location 205 during the first quarter (solely due to a 2.21E-2 pCi/cubic meter I-131 measurement in a single weekly sample).

A predominant nuclide was Zr-95, detected with a frequency of 5.8% (12/207) for all indicator locations and 5.8% (3/52) for control Location 217. These frequencies increased from the analogous 1986 values of 2.8% and 2.2%, respectively. They are also higher than the 1984 preoperational frequency of 5.3%. For 1984, 1986, and 1987, detectable Zr-95 results for all locations were typically about 1E-2 pCi/cubic meter.

Due to the ND6620 sensitivity phenomenon, it is questionable whether any of the nuclides listed in technical specifications actually existed in airborne particulate samples. If some did, they existed in very low levels comparable to control location levels.

3.2 GROUND WATER

Only two nuclides listed in technical specifications, H-3 and Nb-95, were detected in indicator ground water samples from Locations 200 and 252 (there is no control ground water location). Both were detected with 25% (1/4) frequency, except for Nb-95 at location 200, which was detected with 50% frequency. These frequencies are less than for 1984 and 1986, with exception of Nb-95 which was not detected during 1984.

The average activity of detectable measurements in 1987 was comparable to those for 1986, except for H-3 at Location 200, which increased from 250 pCi/liter to 660 pCi/liter. The average detectable activity for H-3 at Locations 200 (660 pCi/liter) and 252 (480 pCi/liter) exceeded the average 1984 activity of 285 pCi/liter. The maximum quarterly percent of reporting level was 7.53%; this occurred at indicator Location 200 during the second quarter (solely due to a single 30.1 pCi/liter Nb-95 measurement).

3.3 DRINKING WATER

Six of the nuclides listed in technical specifications were infrequently detected in drinking water samples; however, no single nuclide was predominant. The frequencies of detection of these nuclides were significantly lower in 1987 than in 1984 or 1986, but average detectable activities were comparable. Due to the ND6620 sensitivity phenomenon, it is questionable whether these nuclides actually existed in these samples. Tritium, which is not analyzed using the ND6620, was the only such nuclide detected at control Location 218, where it was detected only once of five times with a concentration of 480 pCi/liter. Tritium was detected only one other time, at indicator location 214, where it was detected only once of five times with a concentration of 780 pCi/liter. These low levels are roughly comparable to each other and to those of 1984; however, in 1984, H-3 was detected with much greater frequency (92%, 11/12). The maximum quarterly percent of reporting level was 3.90%; this occurred at indicator Location 214 during the second quarter (solely due to the single 780 pCi/liter H-3 measurement).

3.4 SURFACE WATER

Seven of the nuclides listed in technical specifications were detected in surface water samples; however, only H-3 and I-131 were detected with significant frequency, and only at CNS Discharge Canal Location 208.

H-3 was detected at Location 208 with a frequency of 100% (5/5) and an average concentration of 4170 pCi/liter. While this frequency was the same as in 1986, the activity was 78% greater than the average 1986 concentration of 2340 pCi/liter. In comparison, H-3 was detected with only 20% frequency (1/5) at control Location 215, with a single 620 pCi/liter measurement. H-3 was detected with 100% frequency (12/12) during 1984, with the highest activity equal to 630 pCi/liter.

I-131 was detected (using low-level radioiodine analysis) at Location 208 with a frequency of 19.2% (5/26) and an average detectable concentration of 0.697 pCi/liter. These values increased sharply from the analogous 1986 values of 12.5% (3/24) and 0.253 pCi/liter. In comparison, I-131 was not detected at control Location 215 during 1987. I-131 was detected with 20.8% frequency (5/24) during 1984, with the highest activity equal to 1.70 pCi/liter. Despite comparable values for 1984 and 1987, 1987 I-131 concentrations are considered to be true activity because of the gamma spectroscopy system difference and because of the significant activity differences between Location 208 and control Location 215 during 1987.

The percent of reporting level values for surface water at Location 208 for the five calendar "quarters" of 1987 (12/2 - 12/30/87 was composited as the fifth "quarter" to complete the year) were 24%, 26%, 47%, 36%, and 10%, respectively. During all quarters, H-3 was responsible for the vast majority of the reporting level activity.

3.5 MILK

Seven of the nuclides listed in technical specifications were detected in milk samples; however, only Cs-137 was detected with significant frequency. Cs-137 was detected during 1987 with frequencies of 30.4% (7/23), 25.0% (6/24), 21.4% (3/14), and 50.0% (12/24) at indicator Locations 209, 219, and 220, and at control Location 221, respectively. The respective average detectable Cs-137 activities were 4.95, 4.67, 3.61, and 5.53 pCi/liter. While these values are roughly comparable to each other and to 1986 values, control Location 221 yielded the highest frequency of detection and activity for Cs-137 during 1987. During 1984, Cs-137 was detected with 15.0% frequency (12/80). Based on this information, Cs-137 activity in milk samples cannot reasonably be attributed to CNS operations. The maximum quarterly percent of reporting level was 8.24%; this occurred at indicator Location 220 during the third quarter.

3.6 BROADLEAF VEGETATION

Eight of the nuclides listed in technical specifications were detected in broadleaf vegetation samples; however, only Cs-137 was detected with significant frequency. Cs-137 was detected during 1987 with frequencies of 0.0% (0/12), 83.3% (10/12), 33.3% (4/12), and 66.7% (8/12) at indicator Locations 200, 201, and 226, and at control Location 217, respectively. The respective average detectable Cs-137 activities were 0.0, 61.1, 31.4, and 51.2 pCi/wet kilogram. During 1984, Cs-137 was detected with 25.0% frequency (9/36). No trend is apparent at any of the locations when comparing 1986 and 1987 values. While indicator Location 201 yielded a slightly higher detection frequency and average detectable concentration for Cs-137 as compared to control Location 217, the difference is not significant enough to reasonably attribute this Cs-137 activity to CNS operations. The maximum quarterly percent of reporting level was 4.33%; this occurred at indicator Location 201 during the third quarter and was due primarily to Cs-137 activities.

3.7 SHORELINE SEDIMENT

Seven of the nuclides listed in technical specifications were detected in shoreline sediment samples; however, only Mn-54, Co-58, Co-60, Cs-134, and Cs-137 were detected with significant frequency, and only at CNS Discharge Canal Locations 208-1S, 208-2S, and 208-3S. No reliably significant differences could be found among the three discharge canal locations, therefore, the following observations are based on the three locations collectively. During 1984, low levels of Cs-134 and Cs-137 were detected with 66.7% (4/6) and 33.3% (2/6) frequency, respectively. Considering the ND6620 sensitivity phenomenon, and the low detection frequencies and levels of the above five significant nuclides at control Location 215, occurrence of these five nuclides (discussed below) at Location 208 is the result of CNS operations. The evidence below shows that concentrations of these five nuclides at Location 208 have leveled off and possibly even decreased slightly from 1986 to 1987.

Mn-54 was detected at Location 208 with a frequency of 66.7% (8/12) and an average detectable concentration of 88.3 pCi/dry kilogram. Respective values for 1986 results were 87.5% (7/8) and 109 pCi/dry kilogram, roughly comparable to 1987.

Co-58 was detected at Location 208 with a frequency of 83.3% (10/12) and an average detectable concentration of 408 pCi/dry kilogram. Respective values for 1986 results were 87.5% (7/8) and 379 pCi/dry kilogram, comparable to 1987.

Co-60 was detected at Location 208 with a frequency of 100.0% (12/12) and an average detectable concentration of 161 pCi/dry kilogram. Respective values for 1986 results were 87.5% (7/8) and 205 pCi/dry kilogram, roughly comparable to 1987.

Cs-134 was detected at Location 208 with a frequency of 66.7% (8/12) and an average detectable concentration of 60.8 pCi/dry kilogram. Respective values for 1986 results were 100.0% (8/8) and 65.0 pCi/dry kilogram, comparable to 1987.

Cs-137 was detected at Location 208 with a frequency of 91.7% (11/12) and an average detectable concentration of 126 pCi/dry kilogram. Respective values for 1986 results were 100.0% (8/8) and 161 pCi/dry kilogram, roughly comparable to 1987.

3.8 FISH

Eight of the nuclides listed in technical specifications were detected in fish samples at the CNS Discharge Canal Location 208. Three of these nuclides, Co-58, Co-60, and Cs-137 were predominant. Of the eight nuclides, only Cs-137 was predominant in control Location 216 fish samples. REMP results were reviewed by type of fish, and no reliable activity trends could be seen except possibly that Location 208 predators (bass) contained more Cs-134 and Cs-137, and that Location 208 foragers (shad) contained more Co-58 and Co-60. In light of this, the following observations are based on all three types of fish collectively. During 1984, only Cs-137 was detected with significant frequency (16.7%, 2/12).

Co-58 was detected at Location 208 with a frequency of 41.7% (5/12) and an average detectable concentration of 182 pCi/wet kilogram. Respective values for 1986 results were 33.3% (3/9) and 558 pCi/wet kilogram. Co-58 was not detected in 1987 control Location 216 fish samples.

Co-60 was detected at Location 208 with a frequency of 41.7% (5/12) and an average detectable concentration of 115 pCi/wet kilogram. Respective values for 1986 results were 33.3% (3/9) and 120 pCi/wet kilogram. Respective values for 1987 control Location 216 results were 8.3% (1/12) and 9.81 pCi/wet kilogram.

Cs-137 was detected at Location 208 with a frequency of 83.3% (10/12) and an average detectable concentration of 51.2 pCi/wet kilogram. Respective values for 1986 results were 100.0% (9/9) and 92.9 pCi/wet kilogram. Respective values for 1987 control Location 216 results were 41.7% (5/12) and 25.9 pCi/wet kilogram.

Comparing 1987 and 1986 results, while detection frequencies for Co-58, Co-60 and Cs-137 were comparable, and activity for Co-60 was comparable, activity for Co-58 and Cs-137 decreased by roughly 50%. For all three nuclides, indicator Location 208 results were significantly higher than control Location 216 results and 1984 preoperational results. Therefore, occurrence of these nuclides at indicator Location 208 is primarily the result of CNS operations. This is further supported by similar occurrences of these nuclides in shoreline and bottom sediment at Location 208. The maximum quarterly percent of reporting level was 7.70%; this occurred at indicator Location 208 for forager (shad) fish during the third quarter.

3.9 DIRECT GAMMA RADIATION (TLD)

Fourty Thermoluminescent Dosimeters (TLDs) are located in the vicinity of CNS in order to monitor direct gamma (whole-body) radiation. The TLD locations can be divided into four major groups; three control locations (217, 247, and 251), sixteen site boundary ring locations (one in each meteorological sector), sixteen 4-5 mile radius ring locations (one in each meteorological sector), and five special interest locations.

Review of 1984 - 1987 TLD results quickly reveals that natural background levels vary considerably from location to location. Furthermore, in order to conclude whether a sufficiently small net dose rate above natural background is significant, average dose rates for groups of TLDs (not single TLDs) must be compared. In other words, the larger the number of locations which are averaged, the smaller the average dose rate difference which can be detected. Therefore, no reliable conclusions could be reached when individual locations were evaluated, but the following observations could be made when comparing groups of TLD locations for 1984, 1985, 1986, and 1987.

When considering all TLD locations collectively, the average annual 1987 exposure was 90.0 mR, 9% higher than for 1984 (preoperation), and 9% lower than for 1986. These percent differences in themselves do not necessarily reflect CNS operations; TLD location subgroups must be compared in order to assess the impact of CNS operations. The difference in annual exposure from year to year is likely due to the same conditions which cause variation in exposure among calendar quarters.

The average annual 1987 exposure for the three control TLD locations was 84.7 mR. The respective values for 1984, 1985, and 1986 were 79.3 mR, 108.9 mR, and 94.4 mR.

The average 1987 exposure for the sixteen site boundary ring TLD locations was 97.0 mR, 14.5% greater than the control average. In comparison, the average site boundary ring location exposure was 10.3%, 7.3%, and 10.5% greater than the control average during 1984, 1985, and 1986, respectively. Using 1984 as a basis, the net average exposure for the site boundary ring was -3.2 mR, 0.2 mR, and 3.6 mR during 1985, 1986, and 1987, respectively. These net average exposures do not differ from zero enough to conclude that a trend exists or that site boundary ring TLDs were affected by CNS operations.

The average annual 1987 exposure for the sixteen 4-5 mile ring TLD locations was 87.4 mR, 3.2% greater than the control average. In comparison, the average 4-5 mile ring location exposure was 4.2%, -0.2%, and 4.3% greater than the control average during 1984, 1985, and 1986, respectively. Using 1984 as a basis, the net average exposure for the 4-5 mile ring was -4.8 mR, 0.1 mR, and -0.9 mR during 1985, 1986, and 1987, respectively. These net average exposures do not differ from zero enough to conclude that 4-5 mile ring TLDs were affected by CNS operations.

The average annual 1987 exposure for the five special interest TLD locations was 78.6 mR, 7.2% less than the control average. In comparison, the average special interest location exposure was 10.2%, 9.5%, and 9.2% less than the control average during 1984, 1985, and 1986, respectively. Using 1984 as a basis, the net average exposure for the special interest locations was 0.8 mR, 0.9 mR, and 2.5 mR during 1985, 1986, and 1987, respectively. These net average exposures do not differ from zero enough to conclude that a trend exists or that special interest TLDs were affected by CNS operations.

During 1984, 1985, 1986, and 1987, 4-5 mile ring TLD Location 237 yielded the highest annual average exposure. During 1987, this average was 117.6 mR, 38.8% higher than the control average. In comparison, the average Location 237 exposure was 59.9%, 29.3%, and 42.4% greater than the control average during 1984, 1985, and 1986, respectively. The 59.9% value for 1984 is considered to be unrealistically high, 40% is more representative for natural background at Location 237. Based upon 40%, the net average exposure for Location 237 was -11.7 mR, 2.2 mR, and -1.0 mR during 1985, 1986, and 1987, respectively. These net average exposures do not differ from zero enough to conclude that Location 237 TLDs were affected by CNS operations.

3.10 LAND USE CENSUS

The 1987 Annual Land Use Census was conducted as described in Section A.10 of Appendix A. Table 3.A summarizes the census results. No changes were required or made in the CNS Radiological Environmental Monitoring Program on the basis of the census results. However, a number of changes in land use were observed during the survey:

1. Most building sites are either already occupied or are owned by Crescent Land and Timber and are not designed for residential use. This has contributed to fewer changes in the location of the nearest residence. In addition, most new homes are permanent year-round residences rather than part-time seasonal homes which were more prevalent at the time the station was constructed.
2. The number of gardens located during this year's census was approximately 1/3 the number of gardens located during the 1986 census. The gardens were also considerably smaller than those located during 1986. None of the gardens are irrigated with lake water.
3. The number of meat/milk animals within a 5-mile radius around the station has decreased from the 1986 census. No dairies were located within a 5-mile radius of the station; therefore, when the census was conducted, it was assumed that a milk animal could also be considered a meat animal.

3.11 BOTTOM SEDIMENT

Five of the nuclides listed in technical specifications were detected in bottom sediment samples with predominant frequency; Mn-54, Co-58, Co-60, Cs-134, and Cs-137. These five nuclides were predominant at all three bottom sediment sampling points (CNS Discharge Canal Locations 208-1M, 208-2M, and 208-3M). These same five nuclides were predominant in shoreline sediment, where average detectable activities were considerably lower. Fe-59, Nb-95, Zr-95, and I-131 were also detected in bottom sediment, but with lower frequencies and not at all three locations. The following observations are based on all three sampling points collectively. Note that there is no bottom sediment control location, and that bottom sediment was first collected during 1986.

Mn-54 was detected with a frequency of 77.8% (7/9) and an average detectable concentration of 723 pCi/dry kilogram. Respective values for 1986 results were 100% (6/6) and 360 pCi/dry kilogram. Thus, detection frequency decreased slightly, but average detectable concentration doubled from 1986 to 1987.

Co-58 was detected with a frequency of 77.8% (7/9) and an average detectable concentration of 1730 pCi/dry kilogram. Respective values for 1986 results were 83.3% (5/6) and 1310 pCi/dry kilogram, roughly comparable to 1987.

Co-60 was detected with a frequency of 88.9% (8/9) and an average detectable concentration of 2460 pCi/dry kilogram. Respective values for 1986 results were 100.0% (6/6) and 964 pCi/dry kilogram. Thus detection frequency decreased slightly, but average detectable concentration increased by 155% from 1986 to 1987.

Cs-134 was detected with a frequency of 66.7% (6/9) and an average detectable concentration of 166 pCi/dry kilogram. Respective values for 1986 results were 100.0% (6/6) and 171 pCi/dry kilogram, roughly comparable to 1987.

Cs-137 was detected with a frequency of 100.0% (9/9) and an average detectable concentration of 403 pCi/dry kilogram. Respective values for 1986 results were 100.0% (6/6) and 348 pCi/dry kilogram, comparable to 1987.

During 1987, bottom sediment detection frequencies and activities for Location 208-1M were very similar to those for Location 208-2M, but were often substantially greater than those for Location 208-3M (the sampling point furthest from CNS).

SECTION 4

EVALUATION OF DOSE FROM ENVIRONMENTAL MEASUREMENTS VERSUS ESTIMATED DOSE FROM RELEASES

4.1 DOSE FROM ENVIRONMENTAL MEASUREMENTS

Doses for Catawba Nuclear Station for environmental samples taken during 1987 were calculated by using the methodology presented in NRC Regulatory Guide 1.109 and the measured concentrations of radionuclides in direct pathways to man. The highest annual mean values for each sample type (airborne particulate, airborne radioiodine, broadleaf vegetation, drinking water, fish, milk and shoreline sediment) and radionuclide identified were used for the calculations after the background concentrations, as measured at the control location, had been subtracted. Per NRC Regulatory Guide 4.8, the mean values were calculated using only those samples that had detectable radionuclides; therefore, the maximum doses given below significantly overestimate the true doses that would be received from exposure to the environment since very few radionuclides are identified in every sample and neither "zeros" nor "MDA" values are included in the calculation of the means. The maximum exposed individual's doses are summarized below:

<u>Organ</u>	<u>Critical Age</u>	<u>Critical Pathway</u>	<u>Maximum Dose (mrem/yr)</u>
Skin	Teen	Shoreline Sediment (assuming lake shore)	7.35E-03
Bone	Infant	Drinking Water	0.569
Liver	Infant	Drinking Water	0.799
T. Body	Child	Drinking Water	0.279
Thyroid	Child	Drinking Water	3.11E-02
	Child	Airborne Particulate	0.359
Kidney	Infant	Drinking Water	0.216
Lung	Infant	Drinking Water	0.103
	Teen	Airborne Radioiodine	0.122
GI-LLI	Adult	Drinking Water	0.800

4.2 ESTIMATED DOSE FROM RELEASES

Throughout the year, doses were estimated from the releases that were occurring. These estimated doses are calculated using GASPAR and LADTAP which are computer programs that also use the methodology presented in NRC Regulatory Guide 1.109. The maximum exposed individual's doses estimated by GASPAR and LADTAP were given in the Semi-Annual Radioactive Release Report dated March 1, 1988, and are summarized below.

DOSE ESTIMATES FROM EFFLUENT RELEASES

LIQUID RELEASES

<u>Organ</u>	<u>Critical Age</u>	<u>Critical Pathway</u>	<u>Maximum Dose (mrem/yr)</u>
Skin	Teen	Shoreline Sediment (assuming river shore)	6.68E-02
Bone	Child	Fish	1.046
Liver	Teen	Fish	1.338
T. Body	Adult	Fish	0.912
Thyroid	Child	Fish	0.436
Kidney	Teen	Fish	0.498
Lung	Teen	Fish	0.242
GI-LLI	Adult	Fish	1.850

GASEOUS RELEASES

<u>Organ</u>	<u>Critical Age</u>	<u>Critical Pathway</u>	<u>Maximum Dose (mrem/yr)</u>
Thyroid	Child	Vegetation	0.666
T. Body		Noble Gas Exposure	0.892
Skin		Noble Gas Exposure	2.46

4.3 COMPARISON OF DOSES

Because of the differences in critical pathway between doses calculated using the environmental sample results and the estimates made from effluent releases, both the drinking water pathway and the fish pathway were compared for all age groups. The information for the effluent releases was obtained from a special run of the LADTAP computer program. The doses for the fish pathway differ from the information given above because, in the Semi-Annual Radioactive Release Report, the total liquid pathway dose (dose from fish + dose from drinking water + dose from shoreline sediment) was used with the critical pathway being the largest contributor to the dose. The data is summarized below.

Organ	Infant Drinking Water		Child Drinking Water		Child Fish	
	Env. Dose	Eff. Dose	Env. Dose	Eff. Dose	Env. Dose	Eff. Dose
Bone	0.569	0.00523	0.55	0.00627	0.0294	1.03
Liver	0.799	0.0204	0.638	0.0203	0.0386	1.11
T. Body	0.257	0.0191	0.279	0.0196	0.0181	0.225
Thyroid	0.0305	0.0936	0.0311	0.0665	0.0	0.357
Kidney	0.216	0.019	0.21	0.0194	0.011	0.365
Lung	0.103	0.0185	0.0928	0.0189	0.00329	0.14
GI-LLI	0.254	0.0199	0.426	0.0213	0.0362	0.47

Organ	Teen Drinking Water		Teen Fish	
	Env. Dose	Eff. Dose	Env. Dose	Eff. Dose
Bone	0.189	0.00208	0.0233	0.823
Liver	0.31	0.0106	0.0443	1.27
T. Body	0.173	0.0102	0.024	0.517
Thyroid	0.0162	0.0296	0.0	0.347
Kidney	0.106	0.0101	0.013	0.431
Lung	0.0494	0.00985	0.0041	0.175
GI-LLI	0.509	0.0128	0.104	1.29

Organ	Adult Drinking Water		Adult Fish	
	Env. Dose	Eff. Dose	Env. Dose	Eff. Dose
Bone	0.192	0.00217	0.0218	0.78
Liver	0.333	0.0146	0.0432	1.24
T. Body	0.269	0.0144	0.0324	0.887
Thyroid	0.023	0.037	0.0	0.374
Kidney	0.117	0.0142	0.0126	0.425
Lung	0.0526	0.0139	0.00336	0.152
GI-LLI	0.800	0.0183	0.15	1.82

It is usually expected that the dose estimates from effluent releases will exceed the doses as calculated from environmental samples; however, as seen above, this is not the case for the drinking water pathway for all organs except the thyroid. The difference ranges almost up to two orders of magnitude. While this appears to be large, it is not unreasonable for these low doses and concentrations. These elevated environmental dose calculation results were principally caused by a single finding of Cs-137 for Location 213 at a concentration of 3.34 pCi/liter. This activity was 19% of the technical specification LLD, and only 7% of the technical specification reporting level. Moreover, Cs-137 was detected in only one sample out of thirteen collected at Location 213.

It is questionable whether Cs-137 actually existed in this sample. This is supported by the fact that Cs-137 was found in discharge canal surface water samples only one time out of thirteen and at a concentration of 9.95 pCi/liter. Radioactivity would undergo a great deal of dilution between the discharge canal and the drinking water intake.

Differences between dose estimates based upon effluent releases and doses calculated using environmental sample results will continue to be examined so that it can be assured that doses to the public continue to be maintained within regulatory guidelines.

Although doses from drinking water were higher than expected based on effluent release estimates, all environmental doses were still within the limits specified in Technical Specifications 3.11.1.2, 3.11.2.2, 3.11.2.3, and 3.11.4.

SECTION 5.
QUALITY ASSURANCE

5.1 DUKE POWER COMPANY'S ENVIRONMENTAL LABORATORY

The Environmental Radiological Laboratory (ERL) participates in the EPA Interlaboratory Comparison Program and the Duke Power corporate cross-check program. The EPA sample types include mixed gamma in water (2-3 times per year), mixed gamma in milk (1-2 times per year), low-level iodine in milk (1-2 times per year), tritium in water (3 times per year) and alpha-beta in water (3 times per year). The ERL prepares and analyzes each sample as quickly as possible and performs and documents follow-up investigations should the data obtained by the ERL be out of limits. The ERL code designation in the EPA program is "CP". The corporate cross-check sample types included mixed gamma in many forms (body-burden standards, Marinelli beakers, filters), alpha-beta on filters, and tritium in water. The frequency of each cross-check is variable. As with EPA checks, an investigation is performed and documented should the data not meet the acceptance criteria.

In conjunction with the EPA and corporate quality assurance programs, the ERL has an internal quality assurance program which monitors each type of instrumentation for reliability and accuracy. Daily source checks ensure that the instruments are in proper working order and these checks are used to monitor instrument performance. Additionally, standards are analyzed as unknowns at various frequencies ranging from weekly to annually to verify that efficiency calibrations are valid. The frequency is dependent upon instrument use and performance. Investigations are performed and documented should calibration verification data fall out of limits.

To ensure that ERL data is accurate and reliable, the NRC performed an audit of its operations in 1986. They also visited for an Inspector Follow-up Item in May, 1987. The inspectors found no violations or problems with laboratory operations and the associated data. An in-house assessment was performed in 1987 in order to demonstrate an ability and willingness to perform self-audits and also aid the ERL in performing its duties.

5.2 CONTRACTOR LABORATORY

No contractor laboratories were used.

5.3 EPA INTERLABORATORY COMPARISON PROGRAM

As described in Section 5.1, the ERL participates in the EPA Inter-laboratory Comparison Program. The performance by the Laboratory is documented in Table 5.3-1.

Of the forty analyses performed in 1987, three analyses were out of EPA limits (three normalized deviations). The missed analyses and actions taken are described below.

5.3.1 Gamma in Water (Zn-65 and Ru-106 on 2/6/87; Ru-106 on 6/5/87)

Both of these analyses yielded acceptable results for Cr-51, Co-60, Cs-134 and Cs-137. Daily source checks were reviewed and were acceptable. All calibration verifications also provided acceptable results. An investigation indicated that the erroneous data came from detectors contained in shields manufactured in-house. New low background shields were budgeted in 1986 for 1987 in anticipation of this problem, which was identified in 1986. The new shields were delivered September, 1987 and Zn-65 and Ru-106 values were acceptable in subsequent cross-checks.

5.3.2 Gamma in Water (Cr-51 on 10/9/87)

This cross-check had a Cr-51 normalized deviation that exceeded acceptance limits. Daily source checks and calibration verifications yielded valid results indicating that the existing calibration can be used with confidence. Of the 101 laboratories participating in this cross-check analysis, 42 (41.6%) submitted results outside the EPA acceptance limits. There is no reason to indicate that EPA is correct and 41.6% of the responding laboratories are incorrect, therefore no further action is needed at this time.

5.4 DUKE POWER COMPANY'S DOSIMETRY LABORATORY

Duke Power Company's Dosimetry Laboratory routinely participates in environmental dosimetry measurement programs with the State of North Carolina, and the United States Department of Energy (DOE). The Department of Human Resource's Radiation Protection Section conducts the state programs, while the federal program is conducted by the DOE Environmental Measurements Laboratory. Duke Power participated in both programs during 1987. State program results are found in Table 5.4-1 DOE program results are as yet unavailable due to data analysis. A brief description of the two programs follows:

North Carolina State Program - Conducted by the Radiation Protection Section of the Department of Human Resources every six to eight months for all nuclear facilities within the state. Environmental dosimeters are irradiated by the state, returned, and processed by the nuclear facilities, and results are compared to the estimated delivered exposure.

DOE Program - Sponsored by the DOE Environmental Measurements Laboratory every one to two years. Intercomparison program studies are international in scope, typically attracting 125 participants from thirty countries. The objective of these studies is to assess the state-of-the-art of environmental dosimetry as indicated by statistical analysis of the results. Participants compare their performance with the delivered exposures, and the performance of their counterparts in other laboratories.

APPENDIX A

ENVIRONMENTAL SAMPLING AND ANALYSIS PROCEDURES

Adherence to established procedures for sampling and analysis of all environmental media at Catawba was required to ensure compliance to the Station Technical Specifications. Analytical procedures were employed to ensure that Technical Specification Detection capabilities were achieved.

Environmental sampling and analyses were performed by the Duke Power Environmental Radiological Laboratory group.

Starting at Appendix A.1 the remainder of this Appendix describes the environmental sampling and analysis procedures by media type.

CHANGE OF ANALYSIS METHODS

The Environmental Laboratory placed a new gamma spectroscopy system (Nuclear Data ND9900) into service, effective September 1, 1987. The new system uses more up-to-date software and an energy versus channel slope of 0.5 KeV per channel. Additionally, the database stores activity/concentration values in the form of actual activities (when peaks are found by the software) or MDAs (when peaks are not found by the software), rather than best estimates (whether or not peaks are found by the software), as was done on the system used prior to September 1, 1987 (Nuclear Data ND6620).

Lower Limits of Detection

There were no LLD's missed for any of the analyses performed at the Environmental Radiological Laboratory (ERL) in 1987. This is due to upgrading of existing equipment and improvements in analysis methods made in 1986. The purchase of a new gamma spectroscopy system which became operational September 1, 1987, further enhanced the ERL's capabilities.

CHANGES TO CATAWBA SAMPLING PROGRAM

Broadleaf Vegetation - Effective January 1, 1987 location number 203 was replaced by location number 200. Location number 200 is a higher D/Q area and is co-located with an existing air sampling site. These factors facilitate even better compliance with Technical Specifications.

Milk - Scism's dairy at location number 220 went out of business effective August 12, 1987. No replacement dairy could be identified within a five mile radius of the station. Since the other milk samples collected from area dairies constitute an excess of Technical Specification requirements the lack of a replacement does not cause non compliance.

A.1 AIRBORNE PARTICULATES AND RADIOIODINE

Airborne particulate and radioiodine samples at each of 5 locations were composited continuously by means of continuous air samplers. Air particulates were collected on a particulate filter and radioiodines were collected in a charcoal cartridge situated behind the filter in the sampler. Filters and cartridges were collected weekly. A weekly gamma analysis and gross beta analysis was performed on each filter and a weekly gamma analysis was performed on each charcoal cartridge.

A.2 GROUND WATER

Ground water grab samples were collected quarterly from residential wells at 2 locations. A gamma analysis, low level I-131 analysis and tritium analysis was performed on each sample.

A.3 DRINKING WATER

Drinking water composite samples were collected biweekly from each of 3 Drinking Water Treatment Plants. A low level I-131 analysis was performed on each biweekly sample. Two biweekly samples were composited to form a monthly composite for each location and a gamma analysis and gross beta analysis was performed on each monthly composite. Monthly composites were retained and composited quarterly for tritium analysis.

A.4 SURFACE WATER

Surface water composite samples were collected biweekly from each of 3 locations. A low level I-131 analysis was performed on each biweekly sample. Two biweekly samples were composited to form a monthly composite for each location and a gamma analysis was performed on each monthly composite. Monthly composites were retained and composited quarterly for tritium analysis.

A.5 MILK

Milk grab samples were collected semimonthly from 4 dairies. A low level I-131 analysis and a gamma analysis was performed on each sample. The number of dairies dropped to 3 in August (see above).

A.6 BROADLEAF VEGETATION

Broadleaf vegetation samples were collected monthly from each of 4 locations. A gamma analysis was performed on each sample.

A.7 SHORELINE SEDIMENT

Shoreline sediment samples were collected semiannually from 3 locations. A gamma analysis was performed on each sample.

A.8 FISH

Three types of fish samples were collected semiannually from each of 2 locations. The types of fish collected represented a predatory fish, a forage fish and a bottom feeder fish. A gamma analysis was performed on the edible portions of each sample.

A.9 DIRECT RADIATION (TLD)

Thermoluminescent dosimeters (TLD) were collected quarterly from each of 40 locations. The TLDs were placed surrounding the CNS site as follows: Sixteen TLDs were located in an inner ring, one TLD in each of the meteorological sectors, in the general area of the site boundary. Sixteen TLDs were located in an outer ring, one TLD in each of the meteorological sectors, at approximately 6 to 8 km from the site boundary. The remaining eight TLDs were placed in special interest areas (schools, recreation areas) and control locations. A gamma dose and dose rate were reported quarterly for each location.

A.10 ANNUAL LAND USE CENSUS

The 1987 CNS Annual Land Use Census was conducted on June 17, 18, and 19. The census identified the location, within 8 km of the station in each of the sixteen meteorological sectors, of the nearest residence, meat animal, cow, goat, and garden producing broadleaf vegetation over an area greater than 50 square meters. The census utilized a sector grid having a center of reference located exactly between the two unit vents. The grid was developed from aerial photographs taken in 1985.

The census included a visit to the nearest locations identified during the 1986 census. For each sector, the areas between the 1986 locations and the site boundary were surveyed in order to ensure identification of the nearest current locations. Based upon the above findings for each sector, the entire sector area within 8 km of the station was surveyed whenever necessary.

APPENDIX B

RADIOLOGICAL ENVIRONMENTAL MONITORING PROGRAM SUMMARY OF ANALYSIS RESULTS

INDEX

- B.1 Airborne Radioiodines and Particulates
 - B.1.1 Radioiodines
 - B.1.2 Particulates
- B.2 Ground Water
- B.3 Drinking Water
- B.4 Surface Water
- B.5 Milk
- B.6 Broadleaf Vegetation
- B.7 Shoreline Sediment
- B.8 Fish
- B.9 Direct Gamma Radiation (TLD)

Environmental Radiological Monitoring Program Summary

Fraction of detectable measurements at specified locations is indicated in parentheses. (Fraction)

Zero range indicates no detectable activity measurements

If LLD is equal to 0, then LLD is not required by Technical Specifications

Location 208 = Discharge Canal

Location 216 = Hwy. 49 Bridge

Environmental Radiological Monitoring Program Summary

Page : B.9

Name of Facility : CATAWBA NUCLEAR STATION
 Location of Facility : YORK COUNTY, S.C.
 Time Report Generated : 20-APR-1988 10:28:17

Docket Number : 50-413,414
 Reporting Period : 1-JAN-1987 through 31-DEC-1987
 Database Name : \$DISK1:[USER.ASC]CNS87.SAF;1

Medium or Pathway Sampled (Units)	Type & Total Number of Analyses Performed	Lower Limit of Detection (LLD)	All Indicator Locations Mean (Fraction) Range	Location with Highest Mean			Control Locations * Mean (Fraction) Range	No. of Non-Routine Report Meas.
				Location Code	Distance and Direction	Mean (Fraction) Range		
DIRECT RAD-TLD (mR/hr)				237	(4.8 mi SSE)			
40 Locations	MR/HOUR 152	0.00E+00	1.03E-02(140/ 140) 4.00E-03-- 1.50E-02			1.33E-02(4/ 4) 1.00E-02-- 1.50E-02	9.83E-03(12/ 12) 5.00E-03-- 1.60E-02	0

Mean and range based upon detectable measurements only

Fraction of detectable measurements at specified locations is indicated in parentheses. (Fraction)

Zero range indicates no detectable activity measurements

If LLD is equal to 0, then LLD is not required by Technical Specifications

* Control Locations = Location 217 (10.0 mi SSE),
 Location 247 (7.5 mi ESE),
 and Location 251 (9.8 mi WNW).

Location 237 = 4-5 mile radius.

APPENDIX C

SAMPLING DEVIATIONS

<u>SAMPLE (LOCATION #)</u>	<u>DATE</u>	<u>REASON AND CORRECTIVE ACTION</u>
A. Airborne Radioiodines and Particulates		
1. (205)	1/14-1/21/87 <u>Actual</u> - 1/14-1/18/87	Sampler blew a fuse after running for 86.6 hours. <u>Action:</u> Replaced fuse on 1/21/87.
2. (201)	5/6-5/13/87 <u>Actual</u> - 5/6-5/11/87	Sampler blew a fuse after running for 122.3 hours. <u>Action:</u> Replaced fuse on 5/13/87.
3. (205)	9/16-9/23/87 <u>Actual</u> - 9/16-9/19/87	Sampler blew a fuse after running for 66.6 hours. <u>Action:</u> Replaced fuse on 9/23/87.
4. (205)	9/23-9/30/87 <u>Actual</u> - 9/23/87	Sampler blew a fuse after running for less than two minutes; therefore, the sample was not analyzed. <u>Action:</u> Replaced fuse on 9/30/87.
5. (201)	11/11-11/18/87 <u>Actual</u> - Unknown	Sampler was found to be running, but had run for only 43.1 hours. A power outage was suspected. <u>Action:</u> Sampler and timer verified on 11/18/87 to be operating properly.
B. Drinking Water		
1.	(214) 12/31 - 1/28/87 1st biweekly: 12/31-1/14/87 2nd biweekly: 1/14-1/28/87 <u>Actual</u> - 1/21-1/28/87	The intake waterline valve was inadvertently turned off sometime between 1/14-1/21/87. <u>Action:</u> Opened valve on 1/21/87. Posted a sign on the valve as a reminder to keep valve open and included the name and phone number of a contact person in the event of a problem.

SAMPLE (LOCATION #)	DATE	REASON AND CORRECTIVE ACTION
2.	(213) 1/28-2/25/87 1st biweekly: 1/28-2/11/87 <u>Actual</u> - 2/11/87 (Grab) 2nd biweekly: 2/11-2/25/87 <u>Actual</u> - 2/11-2/20/87 and 2/24-2/25/87	City workers placed tools and equipment on top of intake drum tubing which cut off the sample flow. A grab sample was collected on 2/11/87. <u>Action:</u> Replaced the tubing on 2/11/87. Sampler was turned off between 2/20-2/24/87 for maintenance.
3.	(214) 2/25-3/25/87 1st biweekly: 2/25-3/11/87 2nd biweekly: 3/11-3/25/87	<u>Action:</u> Maintenance was completed on 2/24/87. Sampler was turned off for five hours on 2/26/87 while piping and barrels were replaced.
4.	(218) 2/25-3/25/87 1st biweekly: 2/25-3/11/87 2nd biweekly: 3/11-3/25/87	<u>Action:</u> None required. Sampler was turned off for five hours on 2/25/87 while piping and barrels were replaced.
5.	(213) 5/20-6/17/87 1st biweekly: 5/20-6/3/87 <u>Actual</u> - 6/3/87 (Grab) 2nd biweekly: 6/3-6/17/87 <u>Actual</u> - 6/12-6/17/87	<u>Action:</u> None required. Elbow joint cracked causing sampler barrel to leak and sample was lost. A grab sample was collected on 6/3/87. <u>Action:</u> Elbow joint was repaired on 6/12/87.
6.	(214) 12/2-12/30/87 1st biweekly: 12/2-12/16/87 <u>Actual</u> - 12/16/87 (Grab) 2nd biweekly: 12/16-12/30/87	Drain valve was left open after barrels were cleaned on 12/2/87. <u>Action:</u> Valve was closed on 12/16/87.

<u>SAMPLE (LOCATION #)</u>	<u>DATE</u>	<u>REASON AND CORRECTIVE ACTION</u>
C. Surface Water		
1.	(208) 2/25-3/25/87 1st biweekly: 2/25-3/11/87 2nd biweekly: 3/11-3/25/87	Sampler was turned off for five hours on 3/2/87 while piping and barrels were replaced. <u>Action:</u> None required.
2.	(211) 2/25-3/25/87 1st biweekly: 2/25-3/11/87 Actual - 2/25-3/4/87 2nd biweekly: 3/11-3/25/87 Actual - 3/19-3/25/87	Pump sampled irregularly until it tripped off on 3/4/87 because the foot valve was cluttered with trash and the pump pressure switch was faulty. The resulting abbreviated composite samples were collected on 3/11/87 and 3/25/87. <u>Action:</u> Submitted work request HPS-615. Repairs were completed 3/19/87.
3.	(215) 2/25-3/25/87 1st biweekly: 2/25-3/11/87 2nd biweekly: 3/11-3/25/87	Sampler was turned off for five hours on 3/3/87 while piping and barrels were replaced. <u>Action:</u> None required.
4.	(208) 3/25-4/22/87 1st biweekly: 3/25-4/8/87 Actual - 4/8/87 (Grab) 2nd biweekly: 4/8-4/22/87	The transfer hose was clogged with dirt which blocked water flow. A grab sample was collected on 4/8/87. <u>Action:</u> Replaced the transfer hose on 4/8/87.
5.	(215) 4/22-5/20/87 1st biweekly: 4/22-5/6/87 2nd biweekly: 5/6-5/20/87 Actual - 5/20/87 (Grab)	The interval sampler was out of order. A grab sample was collected on 5/20/87. <u>Action:</u> Replaced the interval sampler on 5/20/87.

SAMPLE (LOCATION #) DATEREASON AND CORRECTIVE ACTION

6. (211) 8/12-9/9/87
1st biweekly: 8/12-8/26/87
2nd biweekly: 8/26-9/9/87
Actual - 9/9/87 (Grab)
- The interval sampler pump head was not adjusted properly causing the tubing to feed out of the intake barrel. A grab sample was collected on 9/9/87.
- Action: Readjusted the pump head on 9/9/87.
7. (208) 9/9-10/7/87
1st biweekly: 9/9-9/23/87
Actual - 9/23/87 (Grab)
2nd biweekly: 9/23-10/7/87
- The interval sampler was out of order. A grab sample was collected on 9/23/87.
- Action: Replaced the interval sampler on 9/23/87.
8. (215) 12/2-12/30/87
1st biweekly: 12/2-12/16/87
2nd biweekly: 12/16-12/30/87
Actual - Unknown
- Water pump on pier lost its prime (suction) sometime between 12/16-12/30/87. The resulting abbreviated composite sample was collected on 12/30/87.
- Action: Pump was primed on 12/30/87.

D. Milk

1. (220) 8/12/87

Dairy was found to be out of business on 8/12/87, the routine bimonthly scheduled collection date.

Action: A replacement collection location could not be identified and appropriate DPC Personnel were notified to remove Location 220 as a milk collection site from the ODCM. Broadleaf samples are currently collected from the two directions at the site boundary with the highest D/Q, therefore, the unavailability of a replacement milk sample does not affect the Station's compliance with Technical Specification 3/4.12.1.

SAMPLE (LOCATION #) DATEREASON AND CORRECTIVE ACTIONE. TLD's

1.	(207)	12/18-3/19/87	Missing from collection location.
2.	(223)	12/18-3/19/87	Missing from collection location.
3.	(224)	12/18-3/19/87	Missing from collection location.
4.	(228)	12/18-3/19/87	Missing from collection location.
5.	(201)	3/19-6/18/87	Missing from collection location.
6.	(203)	3/19-6/18/87	Missing from collection location.
7.	(223)	3/19-6/18/87	Missing from collection location.
8.	(249)	9/17-12/17/87	Missing from collection location.

APPENDIX D

ANALYTICAL DEVIATIONS

NOTE: For all 1987 CNS REMP analyses performed, the LLD requirements of CNS Technical Specification Surveillance Requirement 4.12.1 were met.

	<u>SAMPLE (LOCATION #)</u>	<u>DATE</u>	<u>REASON AND CORRECTIVE ACTION</u>
A.	<u>Milk</u>		
1.	(209)	1/28/87	Original sample of milk intended for low-level I-131 analysis was lost during preparation due to excessive vacuum in vacuum system. Backup sample was accidentally prepared for low-level I-131 analysis prior to performing normal gamma analysis. Therefore, the low-level I-131 analysis was valid; however, normal gamma analysis could not be performed. <u>Action:</u> Adjusted vacuum system.

APPENDIX E

RADIOLOGICAL ENVIRONMENTAL MONITORING PROGRAM ANALYSIS RESULTS

INDEX

E.1 Airborne Radioiodines and Particulates

E.1.1 Radioiodines

- E.1.1.1 Location 200
- E.1.1.2 Location 201
- E.1.1.3 Location 205
- E.1.1.4 Location 212
- E.1.1.5 Location 217

E.1.2 Particulates

- E.1.2.1 Location 200
- E.1.2.2 Location 201
- E.1.2.3 Location 205
- E.1.2.4 Location 212
- E.1.2.5 Location 217

* NET ACTIVITY < CRITICAL LEVEL. (LTL = ACTIVITY + 1.65*SIGMA)

COMMENTS: Ab peak identified for Br-15 at 757 keV, MDT=8; on Bala-140 at 1596 keV,
MDT=2 net counts. Cs-134 at 796 keV not identified by Peak Search or MDT,
MDT=5 net counts.

NPBe-7	1.45E-01	4.2E-02
NPK-40	2.11E-01	7.4E-02

* NET ACTIVITY < CRITICAL LEVEL. (LTL = ACTIVITY + 1.65*SIGMA)

COMMENTS: Nb-95 at 766 keV, NDA=13 net counts, not identified as a peak.
NPBe-7 at 473 keV and NPK-40 at 1461 keV identified by Peak Search and NID.

* NET ACTIVITY < CRITICAL LEVEL. (LTL = ACTIVITY + 1.65*SIGMA)

COMMENTS: The composite period from 5/30 - 6/3/87 was a deviation and a grab sample was obtained on 6/3/87. For the composite period from 6/3 - 6/17/87, the sample was not collected for the entire composite period. The actual period was from 6/12 - 6/17/87 due to repairs required at this collection site.

COMMENTS: Nb-95 at 766 kev not identified by Peak Search or NID, MDA = 16 net counts.
Anal#2 was a deviation. This sample was a "grab sample" due to a broken sampler.
The sample was collected on the 5-20-87.
