1.0 INTRODUCTION

1.1 Background

During the summer of 1986, the U.S. Nuclear Regulatory Commission (NRC) began a review of concerns relating to the adequacy of construction practices at the Tennessee Valley Authority's (TVA) Watts Bar Nuclear Plant (WBN). The review identified that many of the concerns centered on potential damage to electrical cables due to alleged improper or inadequate cable installation practices. Accordingly, the NRC performed a comprehensive review to determine if significant damage had occurred to cables during their installation at WBN. Since TVA's Sequoyah Nuclear Plant (SQN) and WBN are based on the same overall design, the NRC extended the evaluation of the cable installation concerns to the SQN plant. The Technical Evaluation Report (TER) describing the NRC's evaluation, conclusions, and recommendations regarding the concerns relating to potential abuse of electrical cable from installation practices at SQN was provided to TVA via reference 1.

TVA performed an extensive and comprehensive evaluation of those SQN issues for which the TER determined implementation was required prior to startup of that plant (reference 2). These issues were successfully resolved at SQN and its cable installation practices in these areas were demonstrated to have resulted in adequate cable installation (reference 3).

As a result of generic reviews of the Condition Adverse to Quality Reports (CAQRs) issued to document the potential conditions at SQN, these same cable installations concerns have been identified at Browns Ferry Nuclear Plant (BFN).

In order to evaluate the extent to which these concerns applied to BFN and to determine whether significant damage had occurred to cables during their installation, TVA implemented an individual indepth review on BFN. The review was structured to address the following:

- Determine if significant differences existed between the cable installation practices and procedures utilized in the construction of BFN and those utilized in the industry during the time period of BFN's construction.
- Perform plant walkdowns to review specific installation practices and assess the overall quality of the cable installation.
- Determine the extent to which the installed cables at BFN are enveloped by the SQN cable issue resolution program.
- Establish, as necessary, a BFN corrective action program for resolution of the cable installation concerns.

1.0 INTRODUCTION (Cont'd)

1.1 Background (Cont'd)

The result of this review was the issuance of four reports (references 4 through 7) addressing the above listed actions. The summary report (reference 4) was transmitted to the NRC via reference 8 on July 18, 1988.

A meeting was held with the NRC on July 21, 1988 to discuss TVAs approach to resolution of the cable issues at BFN and the summary report recommendations. At this meeting, the NRC indicated that a testing program similar to that of SQN was preferred over the approach proposed by TVA in the cable issues summary report.

During a subsequent meeting with the NRC on September 12, 1988, TVA presented preliminary information on testing of cables performed at BFN for Environment Qualification (EQ) and routine maintenance. TVA proposed that review of the test data, when combined with the previous walkdown (reference 7) and corrective actions of the summary report, would provide a sound basis for resolution of the BFN cable issues.

This report provides the evaluations and conclusions from the review of previous BFN cable test data.

1.2 Purpose

The purpose of this evaluation is to determine the scope of BFN cable testing to date, analyze the types of testing performed and the cables tested for applicability to resolution of the cable issues, review actual test data, and establish conclusions from the review to facilitate resolution of the BFN specific cable installation concerns.

1.3 Approach

The approach utilized in the evaluation of historical cable test data at BFN is summarized as follows:

1. Research BFN historical records to establish scope of cable testing to date, with emphasis on dc high potential testing.
2. Research BFN historical records and compile cable test data/documentation.
3. Analyze data to assess cable failure rate, failure cause, and categorize findings.
4. Determine applicability of test data to electrical cable issues.
5. Make conclusions and recommendations.

1.0 INTRODUCTION (Cont'd)

1.3 Approach (Cont'd)

For the purposes of this report, it was decided to limit review of cable test data to dc high potential ("withstand" and "time-leakage current") tests and EQ testing. This data is more likely to detect cable damage caused by installation practices than insulation resistance (IR) test data. In addition, medium voltage shielded cable, to which dc high potential testing solely applies, is considered more susceptible to damage due to jamming, bend radius, sidewall pressure (SWP) and vertical support concerns, than the majority of other cable types used at BFN.

All of the BFN cable test instructions/procedures referenced in this report require IR testing using a 500V insulation resistance tester for various durations (dependent upon test purpose and associated equipment) on low voltage power and control cable/equipment. For 4kV equipment and cables, a 2500V insulation resistance tester is used. The IR tests are performed for both initial acceptance and maintenance testing. Review of the cable test data indicates that IR test documentation exists in great abundance at BFN. Samples of IR test data were pulled and reviewed to determine the extent and application of IR testing, however a detailed review of IR test results was not performed.

To date, dc high potential testing of low voltage cable (cable rated at 600V and less) has not been performed at BFN.

Maintenance procedure EPI-0-000-TST-002, Electrical Preventive Instruction, "Surge Comparison Testing of Electrical Equipment" test data was not reviewed as part of this report effort. EPI-0-000-TST-002 was implemented on May 10, 1988 to supersede EMI-71. Considering the limited amount of test data that could be generated in the short time frame since implementation, it was decided not worthwhile to retrieve EPI-0-000-TST-002 test data for this evaluation.

Test records for temporary cables, cables not associated with the permanent plant (warehouse/office feeds, etc.), and pre-installation (cable on the reel) tests were not included in this evaluation.

2.0 DESCRIPTION OF BFN CABLE TESTING PRACTICES

2.1 Installation, Modification and Maintenance Cable Testing

The cable installation practices report (reference 5) was issued to establish the application of TVA cable installation, testing, and maintenance specifications, procedures, and instructions, both past and present, to BFN cable practices. The main focus of the report is cable installation requirements. Although testing is addressed by reference 5, it is not covered in great detail.

TVA documents identified in reference 5 that contain cable test requirements are BF-17, MAI-13, MAI-45, and EMI-71 (See Attachment A for titles). The cable test date research performed for this report indicates the following additional BFN documents contain cable test requirements:

PSO Field Test Manual	Division of Power System Operation (PSO) Field Test Manual, Section D3, "High-Voltage Cables", and Section G3, "High-Potential Testing"
BF-14	Document not retrievable. Preceded BF-17. Test records exist which reference this document. The records are similar in format to BF-17 test records.
EMSIL - 50	Electrical Maintenance Section Instruction Letter 50, "Megger, Bridge, and High Potential Testing of Electrical Equipment".
EMI-58	Electrical Maintenance Instruction 58, "Splicing of Medium and Low Voltage Signal, Low and Medium Voltage Power, and Control Cables - Critical and Non-critical".
EPI-0-000-TST-002	Electrical Preventive Instruction, "Surge Comparison Testing of Electrical Equipment"

Attachment A lists all BFN specifications/procedures containing cable test requirements and describes their scope, application to each phase of installation, modification, or maintenance, and effective dates.

It should be noted that all BFN procedures/instructions which require initial acceptance dc high potential tests refer to the Division of Power System Operation (PSO) Field Test Manual which establishes test voltages, durations, and actual test procedure. This document is a common thread which provides consistency to past cable test practices at BFN. This is evidenced by the consistency of documentation produced in accordance with several different procedures/instructions spanning the years from the early 1970s to the present.

2.0 DESCRIPTION OF BFM CABLE TESTING PRACTICES (Cont'd)

2.2 Environmental Qualification (EQ) Testing

Other cable testing performed at BFN, but not covered in Attachment A, is the EQ testing performed in accordance with IEEE 323 (reference 9) as part of resolution of EQ concerns which are addressed by the Browns Ferry Nuclear Performance Plan (BFNPP) Volume 3, Section 1.0 (reference 10) and documented by Wyle Laboratories Nuclear Equipment Qualification Test Report No. 17745-1 (reference 11).

2.3 Test Methodologies and Basis

The various BFN cable tests considered by this report, and described in paragraphs 2.1 and 2.2 above, can be summarized into three basic categories. The categories are discussed below:

Category 1 - Installation and Modification DC High Potential Testing

This category includes dc high potential "time-leakage current tests" performed for acceptance and proof testing. Acceptance tests were performed after initial cable installation (including splices and terminations) by application of 25kV dc for 15 minutes. Acceptance criteria was a decreasing, or not increasing, leakage current with respect to time. Proof tests were performed when a cable required testing after the initial acceptance test. Situations requiring proof tests include disconnection/reconnection of splices or terminations, partial cable replacement, etc. Proof tests were performed at 18.7kV or 17.6kV dc for 5 minutes. Acceptance criteria is the same as for initial acceptance tests.

As depicted in Attachment A, BFN procedures/instructions which require(d) tests as defined by this category are BF-14, BF-17, MAI-13, MAI-45 and EMI-58 (See Attachment A for titles).

The basis for the Category 1 test methodology is Table D3-1 of the PSO Field Test Manual. The "after installation" values provided in the table are derived from NEMA WC-3 (reference 12) for rubber-insulated cables and NEMA WC-5 (reference 13), and NEMA WC-7 (reference 14) for polyethylene and cross-linked polyethylene insulated cables. The test values in the PSO Field Test Manual Table D3-1 are also consistent with the test values recommended by IEEE 400 (reference 12) which establishes current industry practice.

Category 1 test records are summarized in Attachment E.

2.0 DESCRIPTION OF BFN CABLE TESTING PRACTICES (Cont'd)

2.3 Test Methodologies and Basis(cont'd)

Category 2 - Maintenance DC High Potential Testing

This category includes dc high potential "withstand" tests, performed periodically to assess the condition of 4kV motor windings. The tests were applied to the feeder cables and motor windings simultaneously and are therefore useful in assessing age related cable degradation resulting from, or enhanced by, cable installation practices. These tests are performed in 1kV increments of three (3) minutes in duration up to 8kV dc. The test voltage is limited to 8kV to preclude detrimental effects of high voltage stress on the motor winding insulation. The tests are performed periodically, usually during each outage, or following a circuit trip. Acceptance criteria is a linear versus non-linear incremental increase in leakage current.

As depicted in Attachment A, BFN procedures/instructions which required tests as defined by this category are EMSIL-50 and EMI-71 (See Attachment A for titles). The basis for the Category 2 test methodology is TVA document N75M5 (See Attachment for title) which specifies an 8kV upper limit, stepped dc high potential test for 4kV motors and associated feeder cables. The industry basis for the test methodology and limiting the test voltage is ANSI/IEEE 43 (reference 17). Maintenance testing guidelines for cables are provided by ANSI/IEEE 400 (reference 12) Appendix A.1.2.

Category 2 test records are summarized in Attachment D.

Category 3 - EQ Testing

This category of tests encompasses cable samples representative of the various cable types, configurations, and manufacturers that have been EQ tested in accordance with IEEE 323 by an independent test agency. For the purposes of this report, only cable samples that were obtained by removal from actual service and routed at least partially in conduit are considered. The EQ test sequence, methodology and parameters are as specified in IEEE 323 (reference 9) and documented by reference 11. In addition to the test requirements of IEEE 323, the test samples were subjected to a 2.2kV ac high potential test after exposure to a Loss of Coolant Accident (LOCA) environment.

3.0 RESULTS OF CABLE TEST DATA REVIEW AND APPLICATION TO CABLE ISSUES

Category 1 test results are applicable to the TER cable issues with the exception of pullbys and use of condulets. As recommended by reference 4, corrective action walkdowns have been performed on BFN Unit 2 4kV Class 1E cables to determine the extent and severity of bend radius and cable support violations. The Category 1 test data applies to the same group of cables addressed by the corrective action walkdown (i.e. 4kV circuits). A review of test records for cables addressed by the corrective action walkdown shows that Category 1 test records were available for 93% of the cables. This is a substantial sample. Review of conduit configuration data produced by these walkdowns shows that condulets were not used in conduits containing 4kV cable. Pullbys do not typically occur in power feed conduits.

Although this report does not cite specific examples of Category 1 conduits that have conduit/cable configurations applicable to the issues of jamming, SWP, and bend radius, the Category 1 test review results have application to these issues in that existence of a "testing program" is demonstrated. It can be concluded that existence of a "test program" which is consistent with current practice would have detected significant cable damage resulting from jamming, excessive SWP, or bend radius violations.

Five hundred fifty-seven (557) Category 1 cable test records were produced as part of the data research which included four-hundred eighty-eight (488) individual cables. Refer to Attachment E for a detailed summary. Records retrieved do not document 100% of the safety-related cables at BFN, however the records found and reviewed are in sufficient quantity to demonstrate that an initial acceptance test program was in place and was effective in evaluating cable quality prior to placement in service.

Category 1 test records, although not complete, are considered a very comprehensive sample. Review of Category 1 test records indicate zero (0) cable insulation failures resulting from cable acceptance testing. The records document five (5) splice and termination failures (cable nos. 3ES4090-II, PP1154, PP1159, PP65, and PP66 which had terminations/splices repaired and retested). The acceptance test records also document new cable installation to replace previous cable for various reasons, including in-service failures. Test records for cables PP1150, (7/17/78), PP1151 (7/19/78), and PP1173 (6/16/78) indicate that in-service failures occurred on the previously installed cables. Further research was performed, but the specific cause of the in-service failures for these three (3) cables could not be determined. All three (3) cables are feeds from the 4kV cooling tower switchgear A and C to various 480V cooling tower unit substations. Although the purpose of this report is not to investigate in-service failures, the research into these three (3) cables revealed that the majority of documented cable, splice, and termination failures at BFN have occurred in circuits associated with the cooling towers.

3.0 RESULTS OF CABLE TEST DATA REVIEW AND APPLICATION TO CABLE ISSUES (Cont'd)

Documented cooling tower cable failures have included overheating of aluminum to copper splices/terminations, insulation failure due to electro-chemical treeing, insulation damage resulting from collateral work activities and unexplained failures. No documented failures attributable to insulation damage caused by installation were found. Cables PP1150, PP1151, and PP1173 have approximately 80% of their installed lengths in cable trench with removable covers and the remaining 20% in embedded conduits/ductbank. Conclusions regarding the specific failure mechanisms for cables PP1150, PP1151, and PP1173 cannot be drawn, however it is evident from the review of documented BFN cable failures that materials and practices used in the installation of cooling tower cables/terminations do not seem representative of the balance of BFN cable work.

Test records for cables 1PP1000, 1PP1001, 1PP1002, 1PP1050, 1PP1051, and 1PP1052 (12/22/78) indicate the previous cables were replaced due to "stress basket damage". These cables are reactor recirculation pump feeds from the Unit #1 Motor-Generator (MG) set generators to the Recirculation Pump Trip Boards, and are routed entirely in cable tray. The cables are supported from the MG set terminal boxes by wire baskets grips. Damage resulting from these cable supports are considered not applicable to the cable issues discussed in the SQN TER as they are not in conduit and are designed cable supports (as opposed to no design).

It is known that several medium voltage shielded power cables for the 6 conductor per phase circuit between the 4kV Bus Tie Board and the 4kV Cooling Tower Switchgear failed dc high potential tests (See Reference 18). The research for this report did not recover these test records. The cable failures were attributable to damage from collateral work activities and electro-chemical treeing and therefore are not related to the SQN TER cable issues.

Category 2 test records apply to the same cable issues, cable types, and voltage class as Category 1 with the exception of jamming and SWP. With respect to SWP, walkdowns of conduit configuration and performance of SWP calculations were not attempted to show application of test results to specific cable/conduits. The basis for this decision are References 4 and 7 and the TVA Cable Sidewall Bearing Pressure Test Report (reference 16) which show that SWP violations are highly unlikely considering BFN conduit installation practices (high SWP limits and high population of pull points). The Category 2 test data applies to the same group of cables addressed by the corrective action walkdown. Attachment C depicts how fourteen (14) walkdown conduits with cable tested under this category apply to the cable issues. Review of the Category 2 dc high potential test records for all BFN Units, both safety and non-safety related, produced five-hundred seventeen (517) records which applied to one-hundred eighteen (118) individual cables. One-hundred sixteen (116) of the Category 2 records apply to twenty-four (24) Unit 2 and Common Unit safety related cables.

3.0 RESULTS OF CABLE TEST DATA REVIEW AND APPLICATION TO CABLE ISSUES (Cont'd)

Detailed review of the available BFN Category 2 test records revealed zero (0) cable insulation failures. Five (5) failures of motor windings were documented. The results of this review are tabulated in Attachment D.

Category 3 test results are contained in reference 11. Of the forty-six (46) cable samples tested for EQ, eleven (11) with at least partial routing in conduit, were obtained by removal from service. Below is a listing of the cables removed from service, their corresponding specimen number in reference 11, and the EQ test result.

<u>Cable No.</u>	<u>Specimen No.</u>	<u>Test Result</u>
L36	40 (A & B)	Passed
M935	30 (A & B)	Passed
1NM1256	33 (A & B)	Passed
2ES2726-II	29 (A & B)	Passed
2V42	28 (A & B)	Passed
2V1200	26 (A & B)	Passed
2V1218	23 (A & B)	Passed
3ES2501	32 (A & B)	Passed
3PL575	25 (A & B)	Passed
3PL800	31 (A & B)	Passed
3V1255	27 (A & B)	Passed

Cables removed from service were receipt inspected by the independent test agency. Damage is described in Notice of Anomaly No. 1 to reference 11, but was judged not to affect qualification.

The applicability of EQ cable test record review results to each cable issue is summarized in Attachment B. Category 3 test data results can be applied to the "use of conduit" cable issue.

4.0 CONCLUSIONS AND SUMMARY

The review results of the Category 1 test data (initial acceptance and proof tests) provides substantial evidence that medium voltage (4kV) cables were handled and installed in such a manner to preclude cable damage. Review of five-hundred fifty-seven (557) Category 1 test records revealed zero (0) cable insulation failures. From these results it can be concluded that BFN medium voltage cable installation practices relating to the issues of jamming, SWP, and bend radius, were adequate in the prevention of significant cable insulation damage. This conclusion can be extended to the remaining low voltage and instrumentation cables at BFN, as medium voltage shielded cables are more susceptible to damage resulting from the cable issues of jamming, SWP, and bend radius.

Age or environment related deterioration could result from, or be accelerated by, cable abuse during installation. However, the review results of Categories 2 and 3 test data (maintenance testing and EQ testing) provide evidence that medium voltage (4kV) and EQ test sample cables have not shown age or environment related deterioration.

This finding is especially noteworthy in consideration of bend radius and vertical support concerns. Bend radius violations severe enough to result in shield distortions may result in failure over time due to corona discharge between the shield and insulation. Vertical support violations, especially those with cable weight bearing on a surface with a small radius (such as conduit bushing, or inside radius of a condulet), may show failures due to insulation creep caused by time and high temperature. Although the results to date of the corrective action walkdown indicate a substantial amount of bend radius and vertical support violations, the review of Category 2 test records indicates zero (0) cable insulation failures from a total test sample of five-hundred seventeen (517).

4.0 CONCLUSIONS AND SUMMARY (Cont'd)

The data reviewed in this evaluation, although substantial, cannot be considered comprehensive. It cannot be established that all BFN cable test documentation was reviewed. The data is however, a significant statistical sample which allows credible conclusions. The size of the data sample also supports the argument that any failures that may result from cable installation practices would be random occurrences.

In summary, it can be concluded from a review of PFN historical cable test data that:

1. Cable tests were performed; and the type of testing was adequate to detect cable installation abuse initially and over time.
2. Cable test results have application to the cable issues of jamming, SWP, bend radius, vertical supports, and use of condulets.
3. Cable test data allows conclusion that installation practices have not resulted in significant cable insulation damage.

A significant finding of the BFN cable test data review is that programmatic acceptance testing was performed at the time of initial cable installation, and that the testing methodology used is consistent with current practices. Of equal importance is that periodic dc high potential maintenance testing and EQ testing of in-service cable samples have not detected cable insulation failures resulting from age or operating environment influences.

These conclusions, evidenced by documented tests, when combined with the comprehensive walkdown effort described in references 4 and 7, demonstrates the integrity of cable installed at BFN.

Implementation of the recommendations provided in reference 4, along with the upgraded installation/maintenance procedures recently issued and trending of any cable failures, will ensure that integrity is maintained.

ATTACHMENT C

BFN Unit 2, Walkdown Cables/Conduits That Have Been Maintenance Hi-Pot Tested
- Application to Cable Issues

ATTACHMENT C

LEGEND

Abbreviations: A - Aluminum Conduit
COND - Conduit
IR - Intermediate Rigid Steel Conduit
NO - Number

Data Codes: I - Indeterminate (see below)
N - No Application to Cable Issue
Y - Yes - Applicable to Cable Issue
N/A - Not Applicable - Cable Not Installed in Conduit

Cable Data: Cable data codes are in accordance with TVA Design Standard DS-E12.1.13.

See Attachments F and G for supporting evaluations/calculations for information in this table. The nature of BFN documentation on conduit/cable installation (i.e. workplans) makes determination of application to pullbys extremely difficult. This research was not pursued. See Paragraph 3.0 for discussion of SWP application.

ATTACHMENT D

Summary of TVA PFTI 8kV dc Hi-Pot Test Reports

ATTACHMENT D

LEGEND

Abbreviations:	APH -	A Phase
	AUX -	Auxiliary
	BIOTHR -	Biothermal
	BOOST -	Booster
	BPH -	B Phase
	CCW -	Condenser Circulating Water
	COND -	Condensate
	CPH -	C Phase
	CRD -	Control Rod Drive
	CT -	Cooling Tower
	DOC -	Documentation
	HP -	High Potential
	HTC -	High temperature circulating
	LTC -	Low temperature circulating
	MG -	Motor Generator Set
	MTR -	Motor
	RCW -	Raw Cooling Water
	RECIRC -	Recirculation
	RHR -	Residual Heat Removal
	RHRSW -	Residual Heat Removal Service Water
	RSIS -	Resistance

Data Codes: MOTOR - Abbreviated description of motor tested. A question mark (?) indicates missing descriptive data on test records.

UNIT - 0 - Common equipment to all Units.
 1 - Unit 1 equipment
 2 - Unit 2 equipment
 3 - Unit 3 equipment

DATE - Date test was performed

CSSC - Y - Indicates that motor is a "critical structure, system, or component" i.e. safety related. See note below.
 N - Indicates that motor is not a "critical structure, system, or component" i.e. not safety related. See note below.

BRIDGE - Y - Indicates bridge resistances for each phase are within one percent.
 N - Indicates bridge resistance differences are greater than one percent.
 Blank - Missing data sheet or bridge reading not performed.
 NR - Data not readable (illegible).

PI - Polarization index value

Note: The term "CSSC - critical structure, system, or component", is no longer used at BFN to identify safety related equipment. The term is used in this summary because it is part of data retrieved from historical records.

ATTACHMENT D (cont'd)

LEGEND

DCHP - Y - Indicates 8kV dc high potential maintenance test results are satisfactory.
N - Unsatisfactory test results
Blank - Missing data sheet or high pot test not performed.

DATA - E50 - Data retrieved from test documentation prepared in accordance with BFN procedure EMSIL-50.
E71 - Data retrieved from test documentation prepared in accordance with BFN instruction EMI-71.

ATTACHMENT E

TVA BFN Cable Acceptance Test Records Summary

C194

ATTACHMENT E

LEGEND

Abbreviations: AFT - After
AUX - Auxiliary
CT - Cooling Tower
DMGE - Damage
kV - Kilovolt
MIN - Minute
NO - Number
PH - Phase
PRO - Procedure
RCW - Raw Cooling Water
REP - Repair
RPLCD - Replaced
SRVC -- In-service

Data Codes: CABLE NO - Cable number from test record.
DATE - Date test was performed.
DOCUMENT - Test record document number.
PRO - Referenced procedure on test record or documentation to which test record is attached.
Blank indicates no procedure referenced.
kV - Test voltage as recorded
1 MIN - Microampere reading at one (1) minute.
5 MIN - Microampere reading at five (5) minutes.
15 Min - Microampere reading at fifteen (15) minutes.

For microampere readings—"A", "B", and "C" suffixes indicate that readings were taken for each phase. A simple numerical entry indicates all phases were tied together for test. A "T" suffix indicates the cable was tied to another cable for the test.

SUBJECT CABLE ISSUES EVALUATION

Attached are the advance evaluations for the fourteen cables you requested. This evaluation consisted of 1) determining the cables are in compliance with the bend radius criteria of Design Standards DS-E12.1.5/E12.1.13 as specified by General Construction Specification G-38 and 2) determining the requirement for vertical support as required by Design Guide DC-E13.1.1 and construction specification C38.

This information will be contained in the final report with the remaining cables evaluated being prepared for transmittal to TVA.

ORIGINAL

Abstract

These calculations contain an unverified assumption(s) that must be verified later. Yes No

FSAR COMPLIANCE**VERIFIED** 9/23/88

- (1) THIS CALCULATION PROVES THAT NEITHER MAXIMUM ALLOWABLE PULL FORCE NOR MAXIMUM SIDEWALL PRESSURE COULD HAVE BEEN EXCEEDED DURING THE INSTALLATION OF EXISTING CABLE (INM1256) AND CONDUIT (INM1263).
- (2) THIS CALCULATION PROVES THAT THE JAM RATIO FOR THE CABLES WALKED DOWN IS IN THE ACCEPTABLE RANGE.
- (3) THIS CALCULATION DETERMINES JAM RATIO FOR SOME CABLES WHERE THE INPUT DATA IS NOT ADEQUATE FOR QA PURPOSES. THIS IS ACCEPTABLE BECAUSE THE DETERMINATION IS FOR INFORMATION ONLY AND WILL NOT BE USED. THESE CABLES ARE DENOTED *

Revision

Method of design verification (independent review) used (check method used):

- 1. Design Review
- 2. Alternate Calculation
- 3. Qualification Test

Justification (explain below):

Method 1: In the design review met'd, justify the technical adequacy of the calculation and explain how the adequacy was verified (calculation is similar to another, based on accepted handbook methods, appropriate sensitivity studies included for confidence, etc.).

Method 2: In the alternate calculation method, identify the pages where the alternate calculation has been included in the calculation package and explain why this method is adequate.

Method 3: In the qualification test method, identify the QA documented source(s) where testing adequately demonstrates the adequacy of this calculation and explain.

This Calculation is technically adequate based on the use of proper design input and mathematical computation methods as required by Browns Ferry Design Criteria BPN-50-758, and accepted handbook methodology found in Construction Specification C-38

1- PURPOSE

TO DETERMINE THE JAM RATIO FOR THE WALKDOWN
CABLES AND CONDUITS, AND SIDEWALL PRESSURE
OF CABLE INM 1256 / CONDUIT INM 1263

2- ASSUMPTIONS (NONE. SEE EXPLANATION BELOW)

THE INFORMATION FOR CABLES WITH * IS UNVERIFIED.

CABLE MARK LETTER NOT GIVEN IN WALKDOWN PACKAGES.

MARK LETTER TAKEN FROM AS-DESIGN CABLE SCHEDULE.

THIS IS ACCEPTABLE SINCE THESE ARE USED FOR INFOR-

MATION ONLY AND DO NOT REQUIRE QA LEVEL DATA.

5.0 CALCULATIONS

5.1 JAM RATIO

ED-Q2999-880544

COMPUTED TYP DATE 9-23-88

CHECKED WJ DATE 9-23-87

5. CALCULATION (continued)

JAM RATIO IS DETERMINED BY RATIO BETWEEN THE CONDUIT INSIDE DIAMETER (D) AND A CABLE OVERALL DIAMETER (d)

$$\text{JAM RATIO} = \frac{D}{d} \quad (\text{REF. # 3.4})$$

e.g. INM 1256

$$\text{JAM RATIO} = \frac{D}{d} = \frac{1.61}{.405} = 3.98$$

THE JAM RATIO FOR OTHER CABLES:

SEE TABLE 5.1 (REF 3.1, 3.2, 3.6)

ED-Q 2999- 880544
