> Every environmental report prepared for the construction permit stage of a light-water-cooled nuclear power reactor, and submitted on or after September 4, 1979, shall take Table S-3, Table of Uranium Fuel Cycle Environmental Data, as the basis for evaluating the contribution of the environmental effects of uranium mining and milling, the production of uranium hexafluoride, isotopic enrichment, fuel fabrication, reprocessing of irradiated fuel, transportation of radioactive materials and management of low level wastes and high level wastes related to uranium fuel cycle activities to the environmental costs of licensing the nuclear power reactor. Table S-3 shall be included in the environmental report and may be supplemented by a discussion of the environmental significance of the data set forth in the table as weighed in the analysis for the proposed facility.

Specific categories of natural resource use included in Table S-3 relate to land use; water consumption and thermal effluents; radioactive releases; burial of transuranic waste, HLW, and LLW; and radiation doses from transportation and occupational exposures. The contributions in the table for reprocessing, waste management, and transportation of wastes are maximized for either of the two fuel cycles (uranium only and no recycle); that is, the cycle that results in the greater impact is used. For each resource area, Table S-3 presents a result that has been integrated over the entire fuel cycle except the reactors. The only exception to this is that the waste quantities provided under the entry called “solids (buried onsite)” also includes wastes generated at the reactor.

The environmental impact values are expressed in terms normalized to show the potential impacts attributable to processing the fuel required for the operation of a 1,000-MWe nuclear power plant for one year at an 80 percent availability factor to produce about 800 MW-yr (0.8 GW-yr) of electricity. This is referred to as 1 reference reactor year (RRY).

A detailed discussion of impacts associated with the production and processing of fuel needed for one reference reactor year operation of the model light water reactor was provided in the 1996 GEIS (NRC 1996). Included in the discussion were the collective offsite radiological impacts that would be associated with radon-222 and technetium-99 releases to the environment during the fuel cycle operations, which Table S-3 does not address. The 1996 GEIS also provided a discussion on the sensitivity of the impacts to recent changes in the fuel cycle (Section 6.2.3 in the 1996 GEIS). For example, when Table S-3 was originally prepared, the model reactor was assumed to be refueled once a year, and the fuel was assumed to remain in the reactor to a burnup level of 33,000 MWd/MTU. The 1996 GEIS discussed the effects of higher fuel burnups up to 62,000 MWd/MTU and the fact that most reactors now refuel once every 18 months or 24 months. The technological changes in the various fuel cycle operations (e.g., the in situ mining of uranium rather than the open pit mining assumed in WASH-1248, and the potential for using more efficient isotopic enrichment processes through the gaseous centrifuge rather than the energy-intensive gaseous diffusion process that was and is still being used in the United States) were also discussed. It was concluded that even though certain fuel cycle operations and fuel management practices have changed over the years, the assumptions and methodology used in preparing Table S-3 were conservative enough that the impacts described by the use of Table S-3 would still be bounding. The NRC believes that this conclusion still holds.

One part of the fuel cycle that was not discussed either in the technical support documents for the original Table S-3 or in the 1996 GEIS was the disposition of the depleted UF_6 tails generated during the enrichment process. Originally, these tails were intended to be used as a feedstock to make fuel for proposed fast breeder reactors. However, the United States abandoned the fast breeder reactor program in 1978. Before the creation of the United States Enrichment Corporation in 1993, DOE was the custodian of all the depleted UF_6 generated in the United States at the three gaseous diffusion plants (in Oak Ridge, Tennessee; Portsmouth, Ohio; and Paducah, Kentucky). DOE prepared several NEPA documents evaluating the impacts associated with the disposition of approximately 700,000 MT (1.54 billion lb) of depleted UF_6 (DOE 1999, 2004a,b, 2007). DOE decided to convert the depleted UF_6 back to U_3O_8 and dispose of it as LLW (DOE 2004c,d). The results of these analyses indicate that the operational impacts of the depleted UF_6 management facilities would not be very different from the impacts estimated for other parts of the fuel cycle in Table S-3. In particular, the impacts of the depleted UF_6 conversion facilities, where the depleted UF_6 is converted to U_3O_8, would be similar to the impacts of the UF_6 production facilities, where U_3O_8 is converted to UF_6. If the depleted uranium oxide is disposed of as LLW, the conversion product corresponding to one reference reactor year would be in addition to the LLW quantities already listed in Table S-3. This value is

Table 4.12-1. Table S-3 Taken from 10 CFR 51.51 on Uranium Fuel Cycle Environmental Data
(Normalized to model light water reactor annual fuel requirement [WASH-1248] or reference reactor year [NUREG-0116])[(a)]

Environmental Considerations	Total	Maximum Effect per Annual Fuel Requirement or Reference Reactor Year of Model 1,000 MWe Light Water Reactor
Natural Resource Use		
Land (acres)		
Temporarily committed[(b)]	100	
Undisturbed area	79	
Disturbed area	22	Equivalent to a 110 MWe coal-fired power plant.
Permanently committed	13	
Overburden moved (millions of MT)	2.8	Equivalent to 95 MWe coal-fired power plant.
Water (millions of gallons)		
Discharged to air	160	Equal to 2 percent of model 1,000 MWe light water reactor with cooling tower.
Discharged to water bodies	11,090	
Discharged to ground	127	
Total	11,377	Less than 4 percent of model 1,000 MWe light water reactor with once-through cooling.
Fossil Fuel		
Electrical energy (thousands of MW-hour)	323	Less than 5 percent of model 1,000 MWe output.
Equivalent coal (thousands of MT)	118	Equivalent to the consumption of a 45 MWe coal-fired power plant.
Natural gas (millions of scf)	135	Less than 0.4 percent of model 1,000 MWe energy output.
Effluents – Chemical (MT)		
Gases (including entrainment)[(c)]		
SO_x	4,400	
NO_x[(d)]	1,190	Equivalent to emissions from 45 MWe coal-fired plant for a year.
Hydrocarbons	14	
CO	29.6	
Particulates	1,154	
Other gases		

Table 4.12-1. (cont.)

Environmental Considerations	Total	Maximum Effect per Annual Fuel Requirement or Reference Reactor Year of Model 1,000 MWe Light Water Reactor
F	0.67	Principally from UF_6 production, enrichment, and reprocessing. Concentration within range of State standards and below level that has effects on human health.
HCl	0.014	
Liquids		
SO^-_4	9.9	From enrichment, fuel fabrication, and reprocessing steps. Components that constitute a potential for adverse environmental effects are present in dilute concentrations and receive additional dilution by receiving bodies of water to levels below permissible standards. The constituents that require dilution and the flow of dilution water are NH_3: 600 cfs, NO_3: 20 cfs, fluoride: 70 cfs.
NO^-_3	25.8	
Fluoride	12.9	
Ca^{++}	5.4	
$C1^-$	8.5	
Na^+	12.1	
NH_3	10.0	
Fe	0.4	
Tailings solutions (thousands of MT)	240	From mills only—no significant effluents to environment.
Solids	91,000	Principally from mills—no significant effluents to environment.
Effluents – Radiological (curies)		
Gases (including entrainment)		
Rn-222	–	Presently under reconsideration by the Commission.
Ra-226	0.02	
Th-230	0.02	
Uranium	0.034	
Tritium (thousands)	18.1	
C-14	24	
Kr-85 (thousands)	400	
Ru-106	0.14	Principally from fuel reprocessing plants.
I-129	1.3	
I-131	0.83	
Tc-99	–	Presently under consideration by the Commission.
Fission products and transuranics	0.203	
Liquids		
Uranium and progeny	2.1	Principally from milling—included tailings liquor and returned to ground—no effluents; therefore, no effect on the environment.
Ra-226	0.0034	From UF_6 production.

Table 4.12-1. (cont.)

Environmental Considerations	Total	Maximum Effect per Annual Fuel Requirement or Reference Reactor Year of Model 1,000 MWe Light Water Reactor
Th-230	0.0015	
Th-234	0.01	From fuel fabrication plants—concentration 10 percent of 10 CFR Part 20 for total processing 26 annual fuel requirements for model light water reactor.
Fission and activation products	5.9×10^{-6}	
Solids (buried onsite)		
Other than high level (shallow)	11,300	9,100 Ci comes from low-level reactor wastes and 1,500 Ci comes from reactor decontamination and decommissioning—buried at land burial facilities. 600 Ci comes from mills—included in tailing returned to ground. Approximately 60 Ci comes from conversion and spent fuel storage. No significant effluent to the environment.
Transuranic and high level waste (deep)	1.1×10^{7}	Buried at Federal Repository.
Effluents – Thermal (billions of Btu)	4,063	Less than 5 percent of model 1,000 MWe light water reactor.
Transportation (person-rem)		
Exposure of workers and general public	2.5	
Occupational exposure	22.6	From reprocessing and waste management.

(a) In some cases where no entry appears, it is clear from the background documents that the matter was addressed and that, in effect, the table should be read as if a specific zero entry had been made. However, there are other areas that are not addressed in the table. Table S-3 does not include health effects from the effluents described in the table, estimates of releases of radon-222 from the uranium fuel cycle, or estimates of technetium-99 released from waste management or reprocessing activities. These issues may be the subject of litigation in the individual licensing proceedings.
Data supporting this table are given in the *Environmental Survey of the Uranium Fuel Cycle*, WASH-1248, April 1974; the *Environmental Survey of the Reprocessing and Waste Management Portion of the LWR Fuel Cycle*,' NUREG-0116 (Supp. 1 to WASH–1248); the *Public Comments and Task Force Responses Regarding the Environmental Survey of the Reprocessing and Waste Management Portions of the LWR Fuel Cycle*, NUREG-0216 (Supp. 2 to WASH-1248); and in the record of the final rulemaking pertaining to *Uranium Fuel Cycle Impacts from Spent Fuel Reprocessing and Radioactive Waste Management*, Docket RM-50-3. The contributions from reprocessing, waste management, and transportation of wastes are maximized for either of the two fuel cycles (uranium only and no recycle). The contribution from transportation excludes transportation of cold fuel to a reactor and of irradiated fuel and radioactive wastes from a reactor, which are considered in Table S-4 of Section 51.20(g). The contributions from the other steps of the fuel cycle are given in columns A–E of Table S-3A of WASH-1248.
(b) The contributions to temporarily committed land from reprocessing are not prorated over 30 years, since the complete temporary impact accrues regardless of whether the plant services one reactor for one year or 57 reactors for 30 years.
(c) Estimated effluents based upon combustion of equivalent coal for power generation.
(d) 1.2 percent from natural gas use and process.
Source: 10 CFR 51.51

estimated to be approximately 12 Ci (4.4×10^{11} Bq) (35 MT of uranium per RRY multiplied by 0.34 Ci/MT of depleted uranium).

Consideration of Environmental Justice

As stated in NRC's *Policy Statement on the Treatment of Environmental Justice Matters in NRC Regulatory and Licensing Actions* (69 FR 52040), "An NRC EJ [environmental justice] analysis should be limited to the impacts associated with the proposed action (i.e., the communities in the vicinity of the proposed action). EJ-related issues differ from site to site and normally cannot be resolved generically. Consequently, EJ, as well as other socioeconomic issues, are normally considered in site-specific EISs. Thus, due to the site-specific nature of an EJ analysis, EJ-related issues are usually not considered during the preparation of a generic or programmatic EIS. EJ assessments would be performed as necessary in the underlying licensing action for each particular facility."

The environmental impacts of various individual operating uranium fuel cycle facilities are addressed in separate EISs prepared by NRC. These documents include analyses that address human health and environmental impacts to minority and low-income populations. Electronic copies of these EISs are available through the NRC's public Web site under Publications Prepared by NRC Staff document collection of the NRC's Electronic Reading Room at http://www.nrc.gov/reading-rm/doc-collections/; and the NRC's Agencywide Documents Access and Management System (ADAMS) at http://www.nrc.gov/reading-rm/adams.html.

Transportation Impacts

The impacts associated with transporting fresh fuel to one 1,000 MWe model light water reactor and with transporting spent fuel and radioactive waste (LLW and mixed waste) from that light water reactor are provided in Table S-4 in 10 CFR 51.52. Similar to Table S-3, and as indicated in 10 CFR 51.52, every environmental report prepared for the construction permit stage of a commercial nuclear power plant must contain a statement concerning the transport of fuel and radioactive waste to and from the reactor. A similar statement is also required in license renewal applications. Table S-4 forms the basis of such a statement and is presented as Table 4.12-2.

A discussion of the values included in Table S-4 and how they may change during the license renewal term was included in Section 6.3 of the 1996 GEIS. However, after the 1996 GEIS was issued and during the rulemaking process for codifying Table B-1 in 10 CFR Part 51, a number of comments were received from the public that raised some questions about the adequacy of Table S-4 for license renewal application reviews. As a result, the NRC reevaluated the transportation issues and the adequacy of Table S-4 for license renewal application reviews. In

1999, the NRC issued an addendum to the 1996 GEIS (NRC 1999a) in which the agency evaluated the applicability of Table S-4 to future license renewal proceedings, given that the spent fuel is likely to be shipped to a single repository (as opposed to several destinations, as originally assumed in the preparation of Table S-4) and given that shipments of spent fuel are likely to involve more highly enriched fresh fuel (more than 4 percent as assumed in Table S-4) and higher-burnup spent fuel (higher than 33,000 MWd/MTU as assumed in Table S-4). In the addendum, the NRC evaluated the impacts of transporting the spent fuel from reactor sites to the candidate repository at Yucca Mountain and the impacts of shipping more highly enriched fresh fuel and higher-burnup spent fuel. On the basis of the evaluations, the NRC concluded that the values given in Table S-4 would still be bounding, as long as the (1) enrichment of the fresh fuel was 5 percent or less, (2) burnup of the spent fuel was 62,000 MWd/MTU or less, and

Table 4.12-2. Table S-4 Taken from 10 CFR 51.52 on the Environmental Impact of Transporting Fuel and Waste to and from One Light-Water-Cooled Nuclear Power Reactor[(a)]

Normal Conditions of Transport			
		Environmental Impact	
Heat (per irradiated fuel cask in transit)		250,000 Btu/hr	
Weight (governed by Federal or State restrictions)		73,000 lb per truck; 100 tons per cask per rail car	
Traffic density:			
Truck		Less than 1 per day	
Rail		Less than 3 per month	
Exposed Population	**Estimated No. of Persons Exposed**	**Range of Doses to Exposed Individuals[(b)] (per reactor year)**	**Cumulative Dose to Exposed Population (per reactor year)[(c)]**
Transportation workers	200	0.01 to 300 millirem	4 person-rem
General public:			
Onlookers	1,100	0.003 to 1.3 millirem	3 person-rem
Along route	600,000	0.0001 to 0.06 millirem	
Accidents in Transport			
		Environmental Risk	
Radiological effects		Small[(d)]	
Common (nonradiological) causes		1 fatal injury in 100 reactor years; 1 nonfatal injury in 10 reactor years; $475 property damage per reactor year	

(a) Data supporting this table are given in the Commission's *Environmental Survey of Transportation of Radioactive Materials to and from Nuclear Power Plants*, WASH-1238, December 1972, and Supp. 1, NUREG-75/038, April 1975.
(b) The Federal Radiation Council has recommended that the radiation doses from all sources of radiation other than natural background and medical exposures should be limited to 5,000 millirem per year for individuals as a result of occupational exposure and should be limited to 500 millirem per year for individuals in the general population. The dose to individuals due to average natural background radiation is about 130 millirem per year.
(c) Man-rem is an expression for the summation of whole body doses to individuals in a group. Thus, if each member of a population group of 1,000 people received a dose of 0.001 rem (1 millirem), or if 2 people received a dose of 0.5 rem (500 millirem) each, the total man-rem dose in each case would be 1 man-rem.
(d) Although the environmental risk of radiological effects stemming from transportation accidents is currently incapable of being numerically quantified, the risk remains small, regardless of whether it is being applied to a single reactor or a multireactor site.
Source: 10 CFR 51.52

(3) higher-burnup spent fuel (higher than 33,000 MWd/MTU) was cooled for at least 5 years before being shipped offsite. The conditions evaluated in Addendum 1 have not changed, and no new conditions have been introduced that would alter the conclusions in Addendum 1 (NRC 1999a). A later study found that the impacts presented in Table S-4 would bound the potential environmental impacts that would be associated with transportation of spent nuclear fuel with up to 75,000 MWd/MTU burnup, provided that the fuel is cooled for at least 5 years before shipment (Ramsdell et al. 2001). Table S-4 as currently encoded in 10 CFR 51.52 is provided.

Consideration of Environmental Justice

The human health impacts of transporting spent nuclear fuel are addressed in an addendum to the 1996 GEIS (NRC 1999a) in which the agency evaluated the applicability of Table S-4 to future license renewal proceedings given that the spent fuel is likely to be shipped to a single repository. As part of the site characterization and recommendation process for the proposed geologic repository at Yucca Mountain, Nevada, the DOE is required by the Nuclear Waste Policy Act of 1982 to prepare an EIS. By law, the NRC is required to adopt DOE's EIS, to "the extent practicable," as part of any possible NRC construction authorization decision. As a result, DOE prepared and submitted to NRC the *Supplemental Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada* (Repository SEIS) DOE/EIS-0250F-S1) (DOE 2008). This document includes analyses that address human health and environmental impacts to minority and low-income populations.

As noted in DOE's Repository SEIS, shipments of spent nuclear fuel (as well as fresh fuel) would use the nation's existing railroads and highways. DOE estimates that transportation-related impacts to land use; air quality; hydrology; biological resources and soils; cultural resources; socioeconomics; noise and vibration; aesthetics; utilities, energy, and materials; and waste management would be SMALL. The small effect on the population as a whole would be likely for any segment of the population, including minority and low-income populations, as well as members of American Indian Tribes.

DOE did not identify any potentially high and adverse impacts to members of the public from the transport of spent nuclear fuel. DOE determined that subsections of the population, including minority or low-income populations, would not receive disproportionate impacts, and no unique exposure pathways, sensitivities, or cultural practices that would expose minority or low-income populations to disproportionately high and adverse impacts were identified. DOE concluded that no disproportionately high and adverse impacts would result from the national transportation of spent nuclear fuel to Yucca Mountain (DOE 2008). On September 8, 2008, NRC staff recommended that the Commission adopt, with supplementation, DOE's Repository EIS and supplements (73 FR 53284).

In light of the recent DOE decision to not proceed with the Yucca Mountain nuclear waste repository and conduct a comprehensive reevaluation of policies for managing the spent fuel from the nation's nuclear power plants (see Section 4.11.1.3), some or all of the evaluations DOE did for Yucca Mountain may have to be redone.

Environmental Impact Issues of the Uranium Fuel Cycle

Nuclear fuel is needed for the operation of light water reactors during the license renewal term in the same way that it is needed during the current license period. Therefore, the factors that affect the data presented in Tables S-3 and S-4 of 10 CFR 51.51 and 51.52, respectively, do not change whether a light water reactor is operating under its original license or a renewed license. In the 1996 GEIS, there are nine issues that relate to uranium fuel cycle and waste management. Five of these issues that relate to waste management are addressed in Section 4.11.1.

The remaining four impact issues include the following:

- Offsite radiological impacts—individual impacts from other than the disposal of spent fuel and high-level waste (issue was renamed from the 1996 GEIS);
- Offsite radiological impacts—collective impacts from other than the disposal of spent fuel and high-level waste (issue was renamed from the 1996 GEIS);
- Nonradiological impacts of the uranium fuel cycle (issue was renamed from the 1996 GEIS); and
- Transportation (issue from the 1996 GEIS).

Offsite Radiological Impacts—Individual Impacts from Other than the Disposal of Spent Fuel and High-Level Waste

This issue addresses the radiological impacts on individuals who live near uranium fuel cycle facilities. The primary indicators of impact are the concentrations of radionuclides in the effluents from the fuel cycle facilities and the radiological doses received by an MEI on the site boundary or at some location away from the site boundary. As discussed in Section 3.9.1, an MEI can be exposed to radiation from radionuclides found in the effluents of nuclear fuel cycle facilities and from radiation "shine" from buildings, storage facilities, and storage tanks containing radioactive material. The basis for establishing the significance of individual effects is the comparison of the releases in the effluents and the MEI doses with the permissible levels in applicable regulations. The analyses performed by the NRC in the preparation of Table S-3 and found in the 1996 GEIS indicate that as long as the facilities operate under a valid license issued by either the NRC or an agreement State, the individual effects will meet the applicable regulations. On the basis of these considerations, the NRC has concluded that the impacts on individuals from radioactive gaseous and liquid releases during the license renewal term would remain at or below the NRC's regulatory limits. Accordingly, the NRC concludes that offsite radiological impacts of the uranium fuel cycle (individual effects from sources other than the disposal of spent fuel and high-level waste) are SMALL. The efforts to keep the releases and doses at ALARA will continue to apply to fuel-cycle-related activities. This was considered a Category 1 issue in the 1996 GEIS. No new information has been identified that would alter this conclusion.

Offsite Radiological Impacts—Collective Impacts from Other than the Disposal of Spent Fuel and High-Level Waste

The focus of this issue is the collective radiological doses to and health effects on the general public resulting from uranium fuel cycle facilities over the license renewal term. The radiological doses received by the general public are calculated on the basis of releases from the facilities to the environment, as provided in Table S-3. These estimates were provided in the 1996 GEIS for the gaseous and liquid releases listed in Table S-3 as well as for radon-222 and technetium-99 releases, which are not listed in Table S-3. The population dose commitments were normalized for each year of operation of the model 1,000-MWe LWR (RRY).

On the basis of the analyses provided in the 1996 GEIS, the estimated involuntary 100-year dose commitment to the U.S. population resulting from the radioactive gaseous releases from uranium fuel cycle facilities (excluding the reactors and releases of Rn-222 and Tc-99) was estimated to be 400 person-rem (4 person-Sv) for 1 RRY. Similarly, the environmental dose commitment to the U.S. population from the liquid releases was estimated to be 200 person-rem (3 person-Sv) per RRY. As a result, the total estimated involuntary 100-year dose commitment to the U.S. population from radioactive gaseous and liquid releases listed in Table S-3 was given as 600 person-rem (6 person-Sv) per RRY (see Section 6.2.2 of NRC 1996).

The 1996 GEIS also provided a detailed analysis of potential doses to the U.S. population from Rn-222 releases, which primarily occur during mining and milling operations and as emissions from mill tailings, and Tc-99 releases, which primarily occur during the enrichment process (Section 6.2.2 of NRC 1996). The U.S. population doses resulting from the Rn-222 releases and Tc-99 releases for 1 RRY are summarized in Table 4.12-3. The total population dose from all releases to the environment, including the Rn-222 and Tc-99 releases, is given as 938.6 person-rem (9.386 person-Sv) per RRY. Because of an oversight in the 1996 GEIS, the sum of population doses was given as 740 person-rem, and the total dose over the 20-year renewal period was listed as 14,800 person-rem (148 person-Sv) (740 person-rem per RRY multiplied by 20 years). The correct values would be approximately 940 person-rem per RRY and 18,800 person-rem (188 person-Sv) for 20 years.

Table 4.12-3. Population Doses from Uranium Fuel Cycle Facilities Normalized to One Reference Reactor Year

Source	Collective Dose (person-rem)[(a)]
Gaseous releases	400
Liquid releases	200
Rn-222 releases from uranium mining and milling	140
Rn-222 releases from unreclaimed open-pit mines	96
Rn-222 releases from stabilized tailings piles	2.6
Tc-99 releases from enrichment plants	100
Total	938.6

(a) To convert person-rem to person-Sv, multiply by 0.01.
Source: modified from NRC 1996

As discussed in the 1996 GEIS, the dose estimates given above were based on highly conservative assumptions (i.e., the doses are overestimated). In actuality, the doses received by most members of the public would be so small that they would be indistinguishable from the variations in natural background radiation. The 1996 GEIS further estimated the health effects on the general public in terms of cancer fatalities by multiplying the calculated doses by risk conversion factors obtained from the literature. The estimated health effect was stated as 0.6 cancer fatality per RRY, or 12 cancer fatalities for each additional 20-year LWR operating term. The 1996 GEIS also stated that these estimates were highly uncertain and that much of the calculated doses, especially the contribution of radon releases from mines and tailing piles, consisted of tiny doses summed over large populations. It was stated that this practice may result in health effect estimates that may not be meaningful.

There are no regulatory limits applicable to collective doses to the general public from fuel cycle facilities. All regulatory limits are based on individual doses. All fuel cycle facilities are designed and operated to meet the applicable regulatory limits.

As discussed in the 1996 GEIS, despite the lack of definitive data, some judgment as to the regulatory NEPA implications of these matters should be made and it makes no sense to repeat the same judgment in every case. The Commission concludes that these impacts are acceptable in that these impacts would not be sufficiently large to require the NEPA conclusion, for any plant, that the option of extended operation under 10 CFR Part 54 should be eliminated. Accordingly, while the Commission has not assigned a single level of significance for the collective effects of the fuel cycle; this issue was considered Category 1. No new information has been identified that would alter this conclusion.

Nonradiological Impacts of the Uranium Fuel Cycle

This section addresses the nonradiological impacts associated with the uranium fuel cycle facilities as they relate to license renewal. Data on the nonradiological impacts of the fuel cycle are provided in Table S-3. These data cover land use, water use, fossil fuel use, and chemical effluents. The significance of the environmental impacts associated with these data was evaluated in the 1996 GEIS on the basis of several relative comparisons. The land requirements were compared to those for a coal-fired power plant that could be built to replace the nuclear capacity if the operating license is not renewed. Water requirements for the uranium fuel cycle were compared to the annual requirements for a nuclear power plant. The amount of fossil fuel (coal and natural gas) consumed to produce electrical energy and process heat during the various phases of the uranium fuel cycle was compared to the amount of fossil fuel that would have been used if the electrical output from the nuclear plant were supplied by a coal-fired plant. Similarly, the gaseous effluents SO_2, NO, hydrocarbons, CO, and PM released as a consequence of the coal-fired electrical energy used in the uranium fuel cycle were compared with equivalent quantities of the same effluents that would be released from a 45-MWe coal-fired plant. It was noted that the impacts associated with uses of all of the above resources would be SMALL. Any impacts associated with nonradiological liquid releases from the fuel cycle facilities would also be SMALL. As a result, the aggregate nonradiological impact of the uranium fuel cycle resulting from the renewal of an operating license for a plant would be SMALL, and it was considered a Category 1 issue in the 1996 GEIS. No new information has been identified that would alter this conclusion.

Transportation

This section addresses the impacts associated with transportation of fuel and waste to and from one light water reactor during the license renewal term. Table S-4 in 10 CFR 51.52 forms the basis for analysis of these impacts in evaluating the applications for license renewal from owners of light water reactors. As discussed previously in this section, the applicability of Table S-4 for license renewal applications was extensively studied in the 1996 GEIS (NRC 1996) and its Addendum 1 (NRC 1999a). The impacts were found to be SMALL, and the findings were stated as follows:

> The impacts of transporting spent fuel enriched up to 5 percent uranium-235 with average burnup for the peak rod to current levels approved by NRC up to 62,000 MWd/MTU and the cumulative impacts of transporting high-level waste to a single repository, such as Yucca Mountain, Nevada are found to be consistent with the impact values contained in 10 CFR 51.52(c), Summary Table S-4, "Environmental Impact of Transportation of Fuel and Waste to and from One Light-Water-Cooled Nuclear Power Reactor." If fuel enrichment or burnup

conditions are not met, the applicant must submit an assessment of the implications for the environmental impact values reported in 10 CFR 51.52.

The issue was assigned to Category 1. No new information has been identified that would alter this conclusion.

4.12.1.2 Replacement Power Alternative Fuel Cycles

Fossil Fuel Energy Alternatives

The environmental consequences of the fuel cycle for a fossil-fuel-fired plant result from the initial extraction of the fuel from its natural setting, fuel cleaning and processing, transport of the fuel to the facility, and management and ultimate disposal of solid wastes resulting from combustion of the fuel.

The environmental impacts of coal mining vary with the location and type of mining technology employed, but generally includes:

- Significant change in land uses, especially when surface mining is employed.
- Degradation of visual resource values.
- Air quality impacts, including release of criteria pollutants from vehicles and equipment, release of fugitive dust from ground disturbance and vehicle travel on unpaved surfaces, release of VOCs from the storage and dispensing of vehicle and equipment fuels and the use of solvents and coatings in maintenance activities, and release of coalbed methane into the atmosphere as coal seams are exposed and overburden removed.
- Noise impacts from the operation of vehicles and equipment and the possible use of explosives.
- Impacts on geology and soils due to land clearing, excavations, soil and overburden stockpiling (for strip mining operations), and mining.
- Water resources impacts, including degradation of surface water quality due to increased sediment and runoff to surface water bodies, possible degradation of groundwater resources due to consumptive use and potential contamination (especially when shaft mining techniques are employed), as well as generation of wastewater from coal cleaning operations and other supporting industrial activities.

- Ecological impacts, including extensive loss of natural habitat, loss of native vegetative cover, disturbance of wildlife, possible introduction of invasive species, changes to surface water hydrology, and degradation of aquatic systems.

- Impacts on historic and cultural resources within the mine footprint, as well as additional potential impacts resulting from auxiliary facilities and appurtenances (e.g., access roads, rail spurs).

- Direct socioeconomic impacts from employment of the workforce and indirect impacts from increased employment in service and support industries.

- Potential environmental justice impacts as a result of the presence of low-income or minority populations in the surrounding communities and/or within the workforce.

- Potential health impacts on workers from exposure to airborne dust, gases such as methane, and exhaust from internal combustion engines on vehicles and mining machinery.

- Generation of coal wastes and industrial wastes associated with the maintenance of vehicles and equipment; increased potential for spills of fuels from onsite fuel storage and dispensing.

New Nuclear Energy Alternatives

Environmental impacts of the fuel cycle result from the initial extraction of the fuel from its natural setting, transport of the fuel to the facility, and management and ultimate disposal of solid wastes resulting from combustion of the fuel. For the fuel cycle associated with a nuclear power plant, these activities include uranium mining and milling, the production of uranium hexafluoride, isotopic enrichment, fuel fabrication, reprocessing of irradiated fuel, transportation of radioactive materials, and management of low-level wastes and high-level wastes (10 CFR Part 51). The NRC has summarized environmental data associated with the uranium fuel cycle in Table S-3 of 10 CFR 51.51. The analysis provides a basis for evaluating environmental effects of the fuel cycle for all nuclear power plants, regardless of site location. The information is based on a 1000-MW LWR with an 80 percent capacity factor. The impacts associated with the transportation of fuel and waste to and from a power reactor are summarized in Table S-4 of 10 CFR 51.52. Detailed analysis of the uranium fuel cycle is also considered in Section 4.12.1.1. Although it is specific to the impacts of license renewal, it is applicable to the new nuclear plant alternative because the advanced reactor designs use the same type of fuel as existing operational designs. One difference may be that the new reactor may have a power rating of greater than 1,000 MWe, which may exceed the power rating of the existing reactor. In those cases, the impacts would be proportionally higher. However, all impacts associated with the uranium fuel cycle, as discussed in Section 4.12.1.2, would still be SMALL.

Renewable Energy Alternatives

The term "fuel cycle" has varying degrees of relevance for renewable energy facilities. Clearly, the term has meaning for renewable energy technologies that rely on combustion of fuels such as biomass grown or harvested for the express purpose of power production. The term is somewhat more difficult to define for renewable technologies such as wind, solar, geothermal, and ocean wave and current. Those natural energy resources exist regardless of any effort to harvest them for electricity production. The common technological strategy for harvesting energy from such natural resources is to convert the kinetic or thermal energy inherent in that resource to mechanical energy or torque. The torque is then applied directly (e.g., as in the case of a wind turbine) or indirectly (e.g., for those facilities that utilize conventional steam cycles to drive turbines that drive generators) to produce electricity. However, because those renewable technologies capture very small fractions of the total kinetic or thermal energy contained in those resources, impacts from the presence or absence of the renewable energy technology are often indistinguishable.

Environmental consequences of fuel cycles for biomass (e.g., energy crops, wood wastes, municipal solid waste, refuse-derived fuel, landfill gas) include the following:

- Land use impacts from the growing and harvesting of the energy crops.
- Reduced impacts on land from the avoidance of land disposal of anthropogenic biomass feedstocks such as municipal solid waste and refuse-derived fuel.
- Visual impacts from the establishment of farm fields and forest areas and processing facilities for the growing, harvesting, and preparation of biomass feedstocks.
- Air impacts from operation of vehicles and equipment used in the planting, cultivating, and harvesting of energy crops.
- Reductions in greenhouse gas emissions from landfills as a result of the capture and destruction by combustion of landfill gas for energy production.
- Removal of greenhouse gases from the air (e.g., CO_2) by growing crops.
- Noise impacts from the operation of agriculture and silviculture equipment and transport vehicles in otherwise rural settings with low ambient noise levels.

- Soil impacts from the cultivation of fields and the potential for increased sediment in precipitation runoff.

- Hydrologic impacts from irrigation of the energy crops; impacts on groundwater resources from water removal for agricultural or silvicultural purposes or industrial water uses associated with the preparation of biomass feedstocks.

- Ecological impacts from the loss of habitat resulting from crop production; loss of hydrologic resources due to diversion for irrigation purposes; potential intrusion of invasive species on disturbed land surfaces, and potential contamination of adjacent habitat by pesticide and fertilizer runoff.

- Ecological impacts from the alteration of habitat due to human presence and activities in agricultural and silvicultural areas.

- Historic and cultural resource impacts from inadvertent destruction of resources in virgin fields that have not undergone appropriate efforts to survey, identify, and relocate cultural resources that may be present.

- Human health impacts from the exposure of workers to pesticides and fertilizers used in growing biomass fuels; work around mechanical planting, cultivating, and harvesting equipment; work in weather extremes; and exposure to dangerous plants and wildlife.

- Waste impacts in the form of residual wastes from the application of pesticides and fertilizers and wastes associated with the routine maintenance of equipment and vehicles used in crop production and transport (used lubricating oils, hydraulic fluids, glycol-based coolants, and battery electrolytes from maintenance of equipment and vehicles with internal combustion engines).

- Positive economic impacts from the creation of jobs in the agriculture, silviculture, and transportation sectors.

4.12.2 Environmental Consequences of Terminating Power Plant Operations and Decommissioning

This section describes the environmental impacts associated with the termination of operations and the decommissioning of a nuclear power plant and replacement power alternatives. All operating power plants will terminate operations and be decommissioned at some point after the end of their operating life or after a decision is made to cease operations. For the proposed action, license renewal would delay this eventuality for an additional 20 years beyond the current license period. The impacts of decommissioning nuclear plants were evaluated in the

Generic Environmental Impact Statement for Decommissioning Nuclear Facilities: Supplement 1, Regarding the Decommissioning of Nuclear Power Reactors, NUREG-0586 (NRC 2002a). For replacement power alternatives, the environmental consequences from the termination of power plant operations and the decommissioning a fossil fuel energy facility or renewable energy systems would be similar.

4.12.2.1 Termination of Operations and Decommissioning of Existing Nuclear Power Plants

This section describes and discusses the environmental consequences of terminating nuclear power plant operations and decommissioning, but the only impacts attributable to the proposed action (license renewal) are the effects of an additional 20 years of operations on the impacts of decommissioning. The majority of the impacts associated with plant operations would cease with reactor shutdown; however, some impacts would remain unchanged, while others would continue at reduced or altered levels. Some new impacts might also result directly from terminating nuclear power plant operations. Ancillary systems that are dedicated solely to reactor operations would cease operations completely; however, impacts from their physical presence could continue if they were not removed coincident with reactor shutdown. For sites with more than one unit, the operation of any ancillary systems that supported the units that continued to operate would be reduced in proportion to the reduced demand on them but would not stop entirely. Impacts associated with the mere physical presence of dedicated systems that remained in place or shared ancillary systems that continued to operate would remain unchanged.

Terminating nuclear power plant operations would result in the cessation of actions necessary to maintain the reactor, as well as a significant reduction in the workforce. NRC presumes that terminating nuclear power plant operations would not immediately lead to the dismantlement of the reactor or other infrastructure, much of which would still be in use to support other units onsite that continued to operate. Even for sites with just one unit, some facilities would remain in operation to ensure that the site was maintained in safe shutdown condition. Electrical generators might continue to operate as synchronous condensers to stabilize voltage on the bulk electricity grid to which the reactor was connected.

Three decommissioning options were analyzed in the decommissioning GEIS (NRC 2002a) and are referenced in this section: DECON, SAFSTOR, and ENTOMB. In the DECON option, the equipment, structures, and portions of a facility and site containing radioactive contaminants are removed and safety buried in a low-level radioactive waste landfill or decontaminated to a level that permits the property to be released for unrestricted use shortly after cessation of operations. In the SAFSTOR option, the nuclear facility is placed and maintained in such condition that the nuclear facility can be safely stored and subsequently decontaminated to levels that permit release for restricted or unrestricted use. Finally, with the ENTOMB option, radioactive contaminants are encased in a structurally long-lived material, such as concrete. The entombment structure is appropriately maintained and continued surveillance is carried out until the radioactivity decays to a level permitting unrestricted release of the property.

Land Use

The termination of nuclear power plant operations would cause a reduction in the workforce at a nuclear plant, and the value placed on the facility for tax purposes would likely depreciate. The impact on taxing authorities that receive revenue from the nuclear power plant would depend on the percentage of revenue that they derived from the plant. Depending on the future need to replace electrical generating capacity, a replacement power plant could change the tax base and impact offsite land use. However, existing substations are expected to remain and be maintained after the termination of reactor operations to support the power grid.

Temporary onsite land use changes during decommissioning are anticipated to be comparable to changes that occur during construction and operations and would not require additional land. The major activities that require land temporarily include the staging of equipment, accommodation of workers (e.g., parking, training, site security access, office space, changing facilities), and removal of large components. The locations of these areas would depend on the layout of the plant. Temporary changes in onsite land use would not change the fundamental use of the reactor site.

There would be no difference in offsite land use impacts whether decommissioning occurred at the end of its current 40-year operating license or following a 20-year license renewal term. In either case, the impact of license renewal after terminating plant operations and decommissioning on onsite and offsite land use would be SMALL and generic at all nuclear plants.

Visual Resources

Terminating nuclear power plant operations would not change the visual appearance of the nuclear power plant. The most notable change, however, would be the elimination of the condensate plumes from cooling towers (under certain meteorological conditions). The appearance of the plant would change as structures are removed.

Decommissioning may involve the demolition and dismantlement of one or more of the main buildings or structures at a nuclear power plant. A case study conducted for the 1996 GEIS found a limited number of situations in which the presence of nuclear power plants fostered perceptions of adverse impacts on visual resources. License renewal would delay decommissioning and prolong the visual impact. As discussed in the decommissioning GEIS

(NRC 2002a), the visual impact of the nuclear plant site may not improve following decommissioning because the site could remain in industrial use.

Transmission lines and ROWs are expected to continue operating and to cause little or no additional impacts beyond those that have already occurred. A 20-year delay caused by license renewal would have no visual impact from continued transmission line operation.

Visual resource impacts associated with terminating plant operations and decommissioning after a 20-year license renewal will not change as a consequence of the delay. The impact of license renewal on visual resources would be SMALL for all nuclear plants.

Air Quality

After the termination of operations, air emissions from the nuclear power plant would continue, but at greatly reduced levels. Air quality impacts would range from very small and would approach undetectable levels. Natural or mechanical draft cooling tower drift would be greatly reduced or would be eliminated. Air emissions from ancillary facility operations (e.g., boilers, emergency diesel generators) would continue until decommissioning.

The NRC evaluated the following activities in the decommissioning GEIS (NRC 2002a) that could impact air quality:

- Worker transportation to and from the site;
- Demolition of buildings and structures, including new structures added during refurbishment;
- Shipment of materials and debris to offsite locations;
- Operation of concrete batch plants (e.g., ENTOMB decommissioning option);
- Dismantling of systems and removing of equipment; and
- Movement and open storage of material onsite.

These activities typically occur over a period of years, from the time the facility ceases operation until the decommissioning is complete. The magnitude and the timing of the potential impacts of each decommissioning activity would vary from plant to plant.

Building and major plant structure demolition and the operation of the batch plant during decommissioning would have the greatest impact on air quality. Fugitive dust would vary in the size of the particles released. Depending on meteorological conditions, larger particles would settle to the ground near the demolition site.

Demolition would generally be limited to a small number of short-duration events. Mitigation measures, such as synchronized scheduling and the application of water sprays or chemical dust suppressants, could minimize the amount of fugitive dust released from the site.

The ENTOMB decommissioning option would require large amounts of concrete and aggregate. Unloading dry cement at the concrete batch plant and loading mixers or trucks would generate large amounts of dust. Depending on meteorological conditions, large particles of dust would settle out of the air quickly, and air quality impacts would be localized near the concrete batch plant. Dust control measures used at concrete batch plants include enclosed dumping and unloading areas and conveyors and filters and water sprays.

The NRC concluded that the impact of decommissioning on air quality would be SMALL for all plants in the decommissioning GEIS (NRC 2002a). The impact on air quality after the license renewal term is not expected to be different from the impact that would have occurred without license renewal.

Noise

During decommissioning, noise would generally be far enough away from sensitive receptors outside the plant boundaries that the noise would be attenuated to nearly ambient levels and would be scarcely noticeable offsite (NRC 2002a). However, during the demolition of concrete, the noise levels offsite could be loud enough (60 to 65 dB at the nearest receptor site) that activities might need to be curtailed during early morning and evening hours. It is highly unlikely, on the basis of past decommissioning experience, that the offsite noise level from a plant during decommissioning would be sufficient to cause hearing loss. However, in one case, noise from decommissioning of a spent fuel pool's cooling system was reported to be up to 107 dB near the source, but it dropped to 50 dB at distances less than 1 mi (1.6 km) away (NRC 2002a). Nearby residents complained about these noise levels; engineering changes were made to the fans that were causing the noise, and the issue was resolved. Noise abatement procedures could also be used during decommissioning in order to reduce noise.

The NRC concluded that the noise impact of decommissioning would be SMALL for all plants in the decommissioning GEIS (NRC 2002a). The noise impact from terminating nuclear plant operations and decommissioning after the license renewal is not expected to be different from the impact that would have occurred without license renewal.

Geology and Soils

Termination of nuclear plant operations is not expected to impact geology and soils. Heavy construction equipment would be engaged in demolition activities during decommissioning. These vehicles would primarily use paved surfaces, but would also cross open ground in some locations. This would create the possibility for soil erosion from areas formerly covered with lawns or natural grasses. The demolition and removal of buildings, foundation slabs, parking lots, and roads, would expose more soil to possible erosion.

High slopes and surface runoff increase erosion potential. The soil distribution across a site may include some soils that are more susceptible to water or wind erosion. The loss of soil increases the turbidity in surface water draining off the site.

Erosion problems could be mitigated by using BMPs during decommissioning. These include, but are not limited to, minimizing the amount of disturbed land; stockpiling topsoil before construction or regrading; replacing the topsoil and adding seed and mulch in disturbed areas as soon as possible after disturbance; using silt fences to reduce sediment loading to surface water; using check dams to minimize the erosive power of drainages or creeks; and installing proper culvert outlets to minimize erosion in creeks.

Site geologic resources would not be affected by decommissioning. Geologic resources in the form of gravel or crushed stone might be needed to construct temporary roads that would be used by the heavy equipment involved in demolition.

The impact from terminating plant operations and decommissioning on geology and soils after a license renewal is not expected to be significantly different from the impacts that would have occurred without license renewal.

Water Resources—Surface Water and Groundwater

After the termination of plant operations, water use would be dramatically reduced; however, water demands would continue for the service water system to support such activities as temperature control of the spent fuel pool and other miscellaneous industrial maintenance applications. Surface water or groundwater intake and consumptive use would be very low compared with use during the operational phase. Discharge of liquid wastes and biocides would also be proportionately reduced.

Because the site workforce would be reduced, the volume of sanitary sewage effluent would be less than it had been during the operational period. Pumping rates for groundwater used for the potable water system after the termination of plant operations would also decrease because of the reduced workforce.

Impacts to site hydrology and water quality from soil erosion and storm events are expected to be unchanged from the operational period. Such erosion would be mitigated as part of general site maintenance during any phase in the power plant's life cycle.

The possibility of groundwater becoming contaminated through chemical spills or radionuclide release would be smaller after operations cease.

Dewatering, if needed to maintain the stability of structure foundations, is expected to continue as it did during the operational phase.

During decommissioning, the activities that have the potential to affect water use include:

- Maintenance of the spent fuel pool,
- Staffing changes (generally the staff size is decreased),
- Cooling of cutting equipment during removal of the reactor vessel and internals,
- High-pressure sprays of water on surfaces during decontamination,
- Dust suppression during destruction of structures, and
- The making of concrete for facility entombment.

The activities identified in the decommissioning GEIS (NRC 2002a) that have the potential to affect water quality include:

- Maintenance of the spent fuel pool,
- Draining and flushing of the cooling systems and processing of the liquid,
- High-pressure sprays of water on surfaces during decontamination, and
- Management of water used in dust suppression during destruction of structures.

At individual sites, the source of water for each of these uses may be surface water or groundwater. The decision on which source of water to use may ultimately be based on a combination of availability, infrastructure, permitting, and water quality and chemistry.

Some of the activities listed above could affect surface water quality. These include the use of high-pressure sprays of water during decontamination, dust suppression, and equipment cooling, and the discharge of various process waters. For decontamination, BMPs would need to be followed to manage the sprayed water. Both the decontamination water and the process waters would need to be discharged in accordance with NPDES permit requirements.

The early stages of decommissioning and dismantling may involve a temporary, slight increase in the size of the overall workforce (NRC 2002a). The amount of sanitary system discharge would therefore increase slightly. Depending on when any onsite wastewater treatment plant, onsite septic system, or municipal sewage system connection would stop operating, temporary portable toilet facilities might be used for the decommissioning workforce. The number and capacity of such facilities would depend on the size of the workforce, which could vary during different phases of the decommissioning process.

In the decommissioning GEIS (NRC 2002a), evaluations focused on water use and water quality. The following activities were identified as having the potential to affect surface water:

- Cooling water systems,
- Discharge from dewatering systems, and
- Stormwater management and erosion control.

Surface water would remain the largest source of water used during decommissioning; it would be used to cool the spent fuel. However, this usage, as well as makeup water requirements, would be significantly smaller than during reactor cooling at an operating power plant. Demand for spent fuel cooling water would decrease over time as the fuel aged. Other activities listed above would also require amounts of water that would be low compared to cooling and makeup water requirements.

Dewatering systems would continue to discharge to surface water. The effect on surface water quality would be unchanged from the effect during the operational phase.

Stormwater management and erosion control would continue to be maintained during decommissioning to reduce the potential for effects on surface water quality, especially turbidity. Soil erosion can be minimized through BMPs, as discussed in Section 4.4.1. Chemical spills during decommissioning also have the potential to affect surface water quality. However, BMPs for handling fuels and other chemicals used in the operational phase should continue to be in place.

The natural variability in the climate, especially precipitation, has the potential to influence the availability of surface water. However, because it seems that there have not been any surface water availability problems at operating power plants with relatively higher water requirements for reactor cooling, severe drought is not expected to affect decommissioning.

In the decommissioning GEIS (NRC 2002a), the NRC concluded that the impacts on water use and water quality from decommissioning would be SMALL for all plants. The effect of license renewal on the water quality impacts from decommissioning was considered a Category 1 issue in the 1996 GEIS. On the basis of a review of current information, these conclusions are considered valid for surface water. An additional 20 years of operation during the license renewal term would not change the magnitude of these impacts.

The activities listed above include some that may affect groundwater quality through the infiltration of water used for various purposes (e.g., cooling of cutting equipment, decontamination spray, and dust suppression). Best management practices are expected to be employed as appropriate to collect and manage these waters.

In the decommissioning GEIS (NRC 2002a), evaluations focused on water use and water quality. The following activities were identified as having the potential to affect groundwater:

- Potable water from wells,
- Dewatering systems, and
- Leachate from rubble.

Potable water would be required during decommissioning. The typical source for this supply is onsite groundwater, though surface water or an offsite municipal source of surface water or groundwater may be used at some sites. The early stages of decommissioning and dismantling may involve a temporary, slight increase in the size of the workforce, and a proportional increase in the need for potable water may occur (NRC 2002a).

Dewatering is expected to continue as it does during the operational phase, without increased drawdown at nearby onsite or offsite wells.

The NRC proposed that groundwater chemistry may change as rainwater infiltrates through rubble. The increased pH could promote the subsurface transport of radionuclides and metals. However, this effect is expected to occur only over a short distance as a function of the buffering capacity of soil (NRC 2002a). Offsite transport of groundwater contaminants is not expected.

In the decommissioning GEIS (NRC 2002a), the NRC concluded that the impacts on water use and water quality from decommissioning would be SMALL for all plants. The effect of license renewal on the water quality impacts from decommissioning was considered a Category 1 issue in the 1996 GEIS. On the basis of a review of current information, these conclusions are considered valid for groundwater. An additional 20 years of operation during the license renewal term would not change the magnitude of these impacts.

Ecological Resources

The termination of nuclear power plant operations would reduce some impacts and eliminate others. Impacts from systems that continue operating to support other units (i.e., where the license term for each unit does not end at the same time) on the plant site may continue to affect terrestrial or aquatic biota, but at a reduced level of impact.

Impacting factors that would cease following reactor shutdown would include cooling tower drift, cooling system maintenance and effluent discharges, and atmospheric emissions of radionuclides. If there are other reactor units at the power plant and they continue to operate, these factors would be reduced, but not eliminated. A number of impacting factors would continue to affect terrestrial resources, however. Until removed during decommissioning, cooling towers and transmission lines would continue to be collision hazards for birds.

Impacting factors on aquatic resources that are expected to stop or decrease after reactor shutdown include the withdrawal of water for cooling, discharge of heated cooling water, dredging activities, and onsite construction activities. Cooling demands of a reactor in cold shutdown will be greatly reduced, as will be the rate of water withdrawal to maintain appropriate water volumes and chemical quality in the cooling system. However, water withdrawal may not be completely eliminated unless or until fuel assemblies are removed from the reactor core. Also, water withdrawal rates will continue unchanged to support other units and facilities onsite that remain operational. Nevertheless, the impingement and entrainment of aquatic organisms would substantially decrease after plant operations cease, and the potential for impacts on aquatic communities from these factors would be reduced. In general, the termination of entrainment and impingement would have positive effects on affected organisms.

As identified in Section 4.6.1.2, the discharge of heated cooling water during operations has the potential to affect aquatic resources by altering the thermal regimes to which aquatic organisms are exposed, lowering the level of dissolved oxygen, and promoting gas supersaturation. Because the plant would discharge significantly smaller volumes of heated water after operations cease, the NRC anticipates that the plant's influence on the thermal conditions in the receiving waters would be greatly reduced.

During the years of plant operations, it is likely that an aquatic community that was acclimated to warmer temperatures and biocides would have developed within the mixing zone. Some aquatic organisms may have become established in the mixing zone because of the warmer environment, and these organisms likely would be adversely affected as the water temperature cooled and the original conditions were restored within the body of water. Organisms susceptible to cold shock could be affected, depending on the timing and rate of change in water temperatures. Such effects, which occur primarily during winter months, would occur only during the initial period after the plant ceases operations, and they could be minimized by initiating reactor shutdown during seasons when cold shock would be less likely to occur and by gradually reducing inputs of heated effluent to the system. As a consequence of the return to a more natural thermal regime, it is anticipated that the composition of the aquatic organisms in that area would return to a composition similar to that in the surrounding areas of the receiving waters. Recovery of an aquatic community to the normal background composition is a process of variable duration that depends on the mobility of the organisms, sources of colonists, rate of growth and maturation of the species, and other factors (Cairns 1990). Populations of some invasive species, such as the water hyacinth (*Hydrilla verticillata*) that proliferates at the North Anna plant in Virginia as a result of the elevated temperature of discharges, may decline as water temperatures in the receiving body of water fall.

The impacts from the termination of nuclear power plant operations on a cooling pond depend largely on whether the pond continues to exist. For cooling ponds that are maintained during plant operation by pumping water from another water body, the ponds would likely revert to a terrestrial system after pumping stopped. Even if ponds are maintained by natural flow, water may no longer be impounded. Restoration of these previously impounded areas may be necessary to minimize adverse ecological impacts associated with the exposure of previously inundated substrates. If the ponds continued to exist, the nuclear plant's thermal effects on them would cease. Cessation of the heated effluent would change the composition and dynamics of the pond community until it resembled that of other ponds in the region not used for cooling.

Because there would no longer be a need to withdraw or discharge cooling water, it is also anticipated that dredging would no longer be needed in the vicinity of cooling water structures. Therefore, the potential for dredging to affect aquatic biota would also be eliminated, unless the cooling water system was still needed to cool other electrical generating systems. As described in Section 4.6.1.2, gas supersaturation has the potential to occur within the mixing zone of some power plants. Even though such effects have been reduced with mitigation measures, such as the use of diffusers in the discharge area, the potential for gas supersaturation and subsequent effects on biota as a result of plant operations would be eliminated or decrease from the potential under the proposed action. Activities that result in ground disturbance (e.g., new construction, maintenance of some areas) may also cease or decrease at power plants that are shut down as a consequence of the no-action alternative, but there would be some level of maintenance needed until the plant was decommissioned. This would result in a decrease or the cessation of potential effects on aquatic resources from the direct disturbance of aquatic habitats and the sedimentation that could occur as a result of ground disturbance in adjacent areas.

Because some structures may be left in place until decommissioning has been completed or longer, there is a potential for some effects on aquatic resources to continue regardless of whether or not the reactor at a plant is operating. For example, dams and associated reservoirs constructed to maintain supplies of water for operational needs may continue to prevent migration of anadromous fish unless the structures are removed. In addition, maintenance activities would continue along the transmission line ROWs regardless of whether the plant is operating or not.

At coastal plants, the termination of nuclear plant operations could have a beneficial impact on the Federally listed loggerhead sea turtle (threatened), green sea turtle (*Chelonia mydas*, threatened), leatherback sea turtle (endangered), hawksbill sea turtle (endangered), and Kemp's ridley sea turtle (endangered), which have been impinged at several nuclear power plants (e.g., St. Lucie and Oyster Creek). Similarly, potential benefits to the Federally endangered West Indian manatee and pinnipeds, protected under the Marine Mammal Protection Act, could occur. For example, the West Indian manatee has been impinged at St. Lucie, and incidental takes of harbor seals, gray seals, harp seals, and hooded seals occur at the Seabrook plant. Elimination of high-temperature discharges at plants in Florida may reduce habitat suitability for the West Indian manatee, particularly during winter. However, the West Indian manatee occupies other habitats in Florida that do not have artificially elevated temperatures, and it uses a number of thermal discharges from fossil fuel plants along both coasts of Florida (Laist and Reynolds 2005). Potential impingement and entrainment losses of special status fish species could also decrease. Reactor shutdown could also decrease impacts on EFH, although only minimal adverse effects have been identified for the operating plants for which EFH assessments have been prepared (e.g., Pilgrim, Vermont Yankee, and Oyster Creek plants).

The NRC evaluated the potential impacts of decommissioning on ecological resources in the decommissioning GEIS (NRC 2002a). The conclusions of that evaluation are summarized here, but the focus of the present evaluation is on the incremental effects that would result from deferring decommissioning to a later date as a result of renewing the license for plant operations. In the 1996 GEIS, the NRC concluded that the ecological impacts of decommissioning activities would be the same with or without license renewal and was designated a Category 1 issue.

The NRC (2002a) evaluated potential impacts on terrestrial ecological resources during the decommissioning process via both direct and indirect disturbance of native plant or animal communities in the vicinity of the plant site. In most cases, the impacting factors and the potential impacts from decommissioning activities are similar to impacts that could occur as a consequence of continued operations and refurbishment activities at operating facilities. Direct impacts of decommissioning on terrestrial ecological resources could result from activities such as the clearing of native vegetation or filling of a wetland. Indirect impacts could result from erosion, dust, or noise. In most cases, land disturbances during decommissioning would result in relatively short-term impacts, and the land would either recover naturally or would be landscaped appropriately for an alternative use after completion of decommissioning (NRC 2002a). The NRC determined that impacts on terrestrial resources from dust generation, noise, surface erosion and runoff, and migratory bird collisions associated with decommissioning would be minor and would continue only until decommissioning activities were completed (NRC 2002a). The effects of such impacts could be minimized by using standard best management practices.

At most commercial nuclear facilities, there is a relatively distinct operational area where most or all site activities occur. This operational area usually includes all areas within the protected area fence; the intake, discharge, cooling, and other associated structures; and adjacent paved, graveled, and maintained landscaped areas. The operational area may include the entire area disturbed during facility construction, but it is often considerably smaller. In most cases, the amount of land required to support the decommissioning process is relatively small and is a small portion of the overall plant site. Usually, the areas disturbed or used to support decommissioning are within the operational areas of the site and are also within the protected area. Decommissioning activities conducted within the operational areas are not expected to have a detectable impact on important terrestrial resources (NRC 2002a). However, it is expected that some sites will require the reconstruction or installation of new transportation links, such as railroad spurs, road upgrades, or barge slips, for the completion of decommissioning. The NRC (2002a) concluded that for facilities at which the decommissioning activities would be limited to existing operational areas, the potential impacts on terrestrial ecology would be SMALL. It was further concluded that if habitat disturbance beyond the operational areas is anticipated, the impact on terrestrial resources could be SMALL, MODERATE, or LARGE and would have to be determined through a site-specific analysis.

In most cases, the impacting factors and the potential impacts on aquatic resources from decommissioning activities are similar in nature to impacts that could occur as a consequence of refurbishment activities for operating facilities. Direct impacts of decommissioning on aquatic resources could result from activities, such as removing shoreline or in-water structures (i.e., the intake or discharge facilities); dredging a stream, river, or ocean bottom; or depositing fill in a stream or bay. Indirect impacts could result from effects such as runoff and sedimentation from disturbed upland areas (NRC 2002a). During decommissioning, aquatic habitats at the plant site might also be disturbed in order to construct support facilities, such as a dock for barges or a bridge over a stream or some other body of water. In addition, aquatic environments away from the plant site could be disturbed during the upgrading or installation of new transportation systems (e.g., a new rail line to support the removal of large components) or during the installation or modification of transmission lines. In most cases, aquatic habitat disturbances from decommissioning would result in relatively short-term impacts on small areas, and either the affected aquatic habitats would recover naturally or the impacts could be mitigated

(NRC 2002a). Typically, these impacts would be temporary and would not detectably alter or destabilize important ecological attributes (NRC 2002a).

If decommissioning did not include removal of shoreline or in-water structures and if all decommissioning activities were confined to the plant operational areas, impacts from decommissioning on aquatic resources would be expected to be minor and would result primarily from increased sediment from physical alterations of the site. In such cases, it is expected that the impact on aquatic resources would be nondetectable, nondestabilizing, and easily mitigated (NRC 2002a). Greater impacts on aquatic resources could occur if decommissioning entailed the removal of structures from the shoreline or in-water environment, removal of contaminated soil in or near an aquatic environment, or dredging and significant modification of barge loading facilities (NRC 2002a).

Permits for discharge to the aquatic environment during operations are almost always for discharge amounts that are greater than planned or realized during decommissioning. In almost all cases examined, licensees expect to restrict activities to previously disturbed areas and operate within the limits of operational permits (NRC 2002a). The NRC (2002a) concluded that for facilities at which the decommissioning activities would be limited to existing operational areas, the potential impacts on aquatic resources would be SMALL. It further concluded that if habitat disturbance beyond the operational areas was anticipated, the impacts on aquatic resources could be SMALL, MODERATE, or LARGE and would have to be determined through site-specific analysis.

In most cases, the impacting factors and the potential impacts on threatened or endangered species (including other special status species or habitats) from decommissioning activities are similar in nature to impacts that could occur as a consequence of refurbishment activities for operating facilities. These species could be affected during the decommissioning process, either through direct effects or through disturbances of habitats on which the species rely for food or shelter. If a nuclear plant ceased operations for an extended period of time, the situation could allow the establishment of onsite populations of protected species that could be adversely affected by subsequent facility decommissioning at the end of the storage period (NRC 2002a).

The greatest potential for impacts from decommissioning on protected species is associated with physical alteration or dismantlement of the facilities, landscape, or aquatic environment. The impacts of decommissioning could result from activities similar to those described for terrestrial and aquatic resources. The NRC (2002a) concluded that the potential impacts on threatened and endangered species may be SMALL, MODERATE, or LARGE and that the adverse impacts and associated significance of the impacts must be determined on a site-specific basis.

The impacts of decommissioning on ecological resources depend primarily on the types of decommissioning activities that are conducted and whether those activities occur inside or outside the existing operational area. Although many of the activities that could affect ecological resources during decommissioning are the same as the activities that occur during the normal operation of a nuclear power plant, the length of time that operations have been ongoing will not change the level of impacts associated with decommissioning. Therefore, deferring decommissioning by renewing a plant's license would have the same impacts on ecological resources, if any, as would occur as a result of starting decommissioning sooner. The impact from the termination of plant operations and decommissioning on ecological resources attributable to license renewal would be SMALL for all nuclear plants.

Historic and Cultural Resources

The termination of nuclear plant operations would not affect historic or cultural resources.

The NRC conducted an analysis of the potential effects of decommissioning on historic and archaeological (cultural) resources and found that the potential onsite impacts at sites where the disturbance of lands would not go beyond the operational areas would be SMALL (NRC 2002a). The continued operation of a plant under a renewed license would not be expected to alter this conclusion. Similar activities are expected to continue before and after license renewal. The majority of impacts on historic and cultural resources would have occurred during the original construction of the plant. Continued use has the potential to affect these resources, as discussed in Section 4.7.1. There is nothing inherent in using a plant for a longer time that would increase or decrease the impact on these resources from decommissioning. Adherence to procedures that take into account the impact on historic and cultural resources would mitigate any additional impacts.

Delaying decommissioning is not expected to have any effect on historic and cultural resources within a transmission line ROW. Impacts on historic and cultural resources would likely have occurred during initial construction. On the basis of these considerations, the effect of license renewal on the impacts from the termination of plant operations and decommissioning would be SMALL for all nuclear plant sites.

Socioeconomics

Terminating nuclear plant operations would have a noticeable impact on socioeconomic conditions in the region around the nuclear power plant. There would be immediate socioeconomic impacts from the loss of jobs (some, though not all, employees would begin to leave after power plant shutdown); and tax revenues generated by plant operations would also be reduced. Depending on the tax formula used to determine property tax payments, the amount of money paid to local taxing jurisdictions may be reduced. However, property tax payments would continue. Demand for services and housing would likely decline. Indirect employment and income created as a result of nuclear power plant operations would also be reduced.

Loss of employment at nuclear plants located in rural communities would likely mean workers and their families would leave in search of jobs elsewhere. The decrease in the demand for housing and the increase in available housing would depress rural housing market prices. Conversely, at nuclear power plants located in semi-urban areas, workers and their families may remain because of greater opportunities for new employment.

The impacts from the loss or reduction of tax revenue due to the termination of plant operations on community and public education services could range from SMALL to LARGE. Nuclear power plants generally provide a significant amount of tax revenue to local communities and public school districts. The loss or reduction in tax revenues from the nuclear plant could mean the reduction and/or the elimination of some community and public educational services. Traffic congestion caused by commuting workers and truck deliveries during plant operations would also be reduced. License renewal would only delay the timing of these impacts. Therefore, the incremental effect of license renewal would be SMALL for all nuclear plants. See Appendix J to NUREG-0586, Supplement 1 (NRC 2002a), for a discussion of the potential socioeconomic impacts of plant decommissioning.

Human Health

With the termination of plant operations, there would be a period between the time when a reactor stopped operating and when the decommissioning of the plant began that could range from months to years. During that period, the reactor would be placed in a cold shutdown condition and maintained. The fuel might be removed from the core and put in the spent fuel storage pool. Workers would continue to receive radiation exposure during work activities related to placing the reactor in shutdown status. Radioactive gaseous and liquid effluent releases to the environment would continue, although at a lower level, that would result in radiation exposure to the public. The regulatory requirements and dose limits during this period for workers and the public are the same as those for operating reactors (see Section 3.9.1.1). The radiological impacts on workers and members of the public during this time period would be less than those during current operations and those expected during decommissioning.

Public exposure to EMFs would decrease after transmission lines were de-energized. Power would still be provided to the site, and workers might be exposed to EMFs during this period. It is expected that the impacts from EMFs during this period would be less than the impacts from current operations.

Because reactor shutdown would result in the cessation or reduction of cooling system operations, the public's exposure to chemical and microbiological hazards associated with these operations would be reduced. The plant workers might be exposed to chemical, microbiological, and other hazards during this period, but the hazards would be SMALL and bounded by the hazards either during operations or decommissioning.

The remainder of this section evaluates the effects of license renewal on the human health impacts from the termination of nuclear power plant operations and decommissioning. The issues considered here include the impacts from radiological exposure and risk, chemical hazards, microbiological hazards, physical occupational hazards, and electrical hazards. Work during decommissioning activities is generally done according to an environmental safety and health plan that serves as a guidebook for anticipating hazards and preventing any injury or harm. In the 1996 GEIS, the NRC considered the effect of license renewal on only the radiation dose impacts of decommissioning.

The human health impacts from physical, chemical, and microbiological hazards during the termination of plant operations and decommissioning would be SMALL for all plants. The effect of license renewal on the impact from terminating plant operations and decommissioning on human health also would be SMALL at all plants. Doses to the public would be well below applicable regulatory standards, regardless of which decommissioning option was used. Collective occupational doses would increase no more than 0.1 person-rem, attributable to the buildup of long-lived radionuclides during the license renewal term, but the individual worker doses would be well below the existing dose limits. On the basis of these considerations, the NRC concludes that the effect of license renewal on the impact from decommissioning on human health would be SMALL for all nuclear plants.

Radiological Exposure

During decommissioning activities, workers are exposed to radioactive materials that are present in the reactor and support facilities, and members of the public may be exposed to radioactive materials that are released to the environment. The regulatory requirements and dose limits during decommissioning are the same as those for operating reactors (see Section 3.9.1.1). Many activities during decommissioning are similar to the activities that occur during normal maintenance outages, such as decontamination of piping and surfaces; removal of piping, pumps, and valves; and removal of heat exchangers. Some of the activities, such as removal of the reactor vessel or demolition of facilities, are unique to decommissioning. The decommissioning GEIS (NRC 2002a) evaluated the potential radiological impacts of decommissioning activities for both PWRs and BWRs. Public and occupational radiation exposures from decommissioning activities were evaluated on the basis of information derived from recent decommissioning experience.

Radiation Exposures to Plant Workers

Both the 1996 GEIS and the decommissioning GEIS provide estimated collective occupational radiation doses for decommissioning PWRs and BWRs for the three decommissioning options: DECON, ENTOMB, and SAFSTOR. The decommissioning GEIS also includes the estimated collective occupational radiation dose for plants that are currently in the decommissioning process. The DECON method had the highest dose, followed by ENTOMB and then SAFSTOR. According to the decommissioning GEIS, occupational doses to individual workers during decommissioning activities are estimated to average approximately 5 percent of the regulatory dose limits established in 10 CFR Part 20 and to be similar to, or lower than, the doses experienced by workers in operating facilities.

A 20-year extension in operations would increase the occupational doses from long-lived radionuclides such as niobium-94, but these increases would not be significant for the DECON option because short-lived radionuclides (primarily cobalt-60) are the principal contributor to the occupational dose (NRC 1996). For the SAFSTOR option, an additional 20 years of operations would increase the amount of niobium-94 by 50 percent. The contribution of niobium-94 to the collective dose for this decommissioning option for 40 years of plant operation is less than 0.2 person-rem; therefore, the increase in dose during decommissioning after 20 additional years of operations would be less than 0.1 person-rem. Total worker doses may increase, but individual worker doses would be well below the regulatory limits. The NRC concluded that the impact of an additional 20 years of plant operation on the radiological doses to workers would be of SMALL significance for all nuclear plants.

Radiation Exposures to the Public

According to the 1996 GEIS, the radiation dose to the public during decommissioning would result primarily from waste shipment for both PWRs and BWRs, and the dose would be almost exclusively attributable to the shipment of short-lived radionuclides, mainly cobalt-60. During decommissioning, the estimated increased risk of fatal cancer to an average member of the public would be much less than 1×10^{-6} (NRC 2002a). If a plant operated an additional 20 years, only the quantities of long-lived radionuclides would increase, and only the dose caused by the long-lived radionuclides would increase. As discussed in the 1996 GEIS, the dose to the public from long-lived radionuclides after 40 years of plant operation is expected to be negligible, and the increase in quantities of long-lived radionuclides after an additional 20 years would result in a negligible dose (less than 0.1 person-rem). Accordingly, the NRC concluded that the contribution of license renewal to radiological impacts to the public from decontamination would be of SMALL significance at all nuclear plants.

Chemical Hazards

Decommissioning involves many activities that expose workers to chemical hazards, including paints, asbestos, lead, polychlorobiphenyls, mercury, quartz, and other hazardous materials in building materials. During decommissioning, workers may also be exposed to fumes (that often include lead and arsenic) and smoke from flame cutting and welding. According to the decommissioning GEIS, with proper planning, workplace design, and engineering controls, supplemented by the use of personal protective equipment and administrative solutions, the impact of chemical hazards on workers would be of SMALL significance at all nuclear plants. A 20-year delay caused by license renewal would not change the projected human health impact from chemical hazards because (1) there would not be any more hazardous chemicals present, (2) the workers would still would have a proper work plan, and (3) all required controls would be in place.

Microbiological Hazards

During decommissioning, workers may be exposed to molds and other biological organisms that grow in and on buildings. Proven industrial hygiene principles mitigate the risk of developing diseases from these organisms. According to the decommissioning GEIS, if a thorough inspection of the facility is conducted and proper cleansing and personal protective equipment are used when biological agents are identified, the impacts of biological agents on workers would be SMALL. A 20-year license renewal would not change the microbiological hazards associated with decommissioning at any nuclear plant because the workers would still be using proper cleansing and personal protective equipment when biological hazards were identified.

Electromagnetic Fields

Operating transmission lines produce an EMF. When a nuclear power plant ceases to operate, no electricity is transmitted. Therefore, the public's exposure to EMF could decrease unless the power that was no longer being generated at the plant was replaced by new power generation. Power would still be provided to the site, and workers might be exposed to EMF during decommissioning. It is expected that the impacts during decommissioning would be bounded by the impacts from current operations. The EMF impact associated with decommissioning after a 20-year license renewal term would not differ from that without renewal.

Other Hazards

The major sources of physical occupational hazards during decommissioning involve the operation and use of construction and transportation equipment. Workers may be exposed to extreme temperatures while working outdoors. They may operate cranes near power lines, dig near buried cables, and encounter electrical hazards. During demolition or dismantlement, the workers may use cutting torches, which can start fires. It is expected that all of the activities would be anticipated in advance, and that proper precautions would be taken to minimize any adverse impacts. A 20-year delay in decommissioning caused by license renewal would have no effect on the projected human health impact from other hazards, because the workers would have the proper work planning, workplace design, and controls in place. Moreover, the conditions would not be more hazardous after an additional 20 years.

Accidents during the Termination of Nuclear Plant Operations and Decommissioning

The impacts of postulated accidents during the license renewal term are discussed in Section 4.9.1.2. The general characteristics, including the source terms, of postulated accidents are expected to be similar after reactor shutdown; therefore, the consequences would also be expected to be similar. Because of the enhanced aging management activities and extended life of certain systems, structures, and components, there may be small differences in the probabilities of occurrence of these accidents after reactor shutdown. These differences, however, are not expected to be significant, and the risks of accidents after reactor shutdown would be expected to be similar to or less than the risks discussed in Section 4.9.1.2 for the proposed action.

The impacts associated with accidents that can occur during the decontamination and decommissioning of nuclear power plants were analyzed in the Decommissioning GEIS (NRC 2002a). The radiological impacts of accidents were discussed in Section 4.3.9 of the same document, and nonradiological impacts were discussed in Section 4.3.10. Radiological accidents that were considered in the analysis included both those that relate to onsite storage and handling of spent nuclear fuel and those that are unrelated to spent nuclear fuel. The non-fuel-related accidents centered on decontamination, dismantlement, and storage-type accidents. The accidents included fires, handling accidents, explosions (e.g., explosion of liquid propane gas tanks), and accidental releases of liquid radioactive wastes from storage tanks.

Nonradiological accidents were considered under occupational issues and included physical, chemical, ergonomic, and biological hazards. The category of physical hazards included potential injuries or deaths resulting from the operation and use of construction and transportation equipment. Electrical hazards, including the potential for electrocution, were also considered. The potential exposure of workers to chemical and biological agents was considered under both normal operations and accidents. Ergonomic conditions were evaluated from the point of view of ergonomic stress such as discomfort and fatigue affecting the workers' performance and safety.

The NRC made the following conclusions regarding radiological accidents associated with decommissioning on the basis of the evaluations conducted for the decommissioning GEIS (NRC 2002a):

> The NRC has considered available information, including comments received on the draft of Supplement 1 of NUREG-0586, concerning the potential impacts of non-spent-fuel-related radiological accidents resulting from decommissioning. This information indicates that, with the mitigation procedures in place, the impacts of radiological accidents are neither detectable nor destabilizing. Therefore, the NRC makes the generic conclusion that the impacts of non-spent-fuel-related radiological accidents are SMALL. The NRC has considered mitigation and concludes that no additional measures are likely to be sufficiently beneficial to be warranted.
>
> The NRC has considered available information, including comments received on the draft of Supplement 1 of NUREG-0586, on the potential impacts of spent-fuel-related radiological accidents resulting from decommissioning. The NRC concludes that the impacts of spent fuel storage during the license renewal term are SMALL. The NRC concludes that additional mitigation measures are not likely to be sufficiently beneficial to be warranted.

The conclusion regarding the occupational issues, which included nonradiological accidents, was as follows:

> The NRC has considered available information, including comments received on the draft of Supplement 1 of NUREG-0586, on the potential impacts of decommissioning activities on occupational issues. This information indicates that the impacts on occupational issues are not detectable or destabilizing. Therefore, the NRC makes a generic conclusion that, for all plants, the potential impacts on occupational issues are SMALL. The NRC has considered mitigation measures and concludes that no additional mitigation measures are likely to be sufficiently beneficial to be warranted.

License renewal would merely delay when accidents associated with the termination of nuclear power plant operations and decommissioning could occur and would not significantly affect their probability or consequence.

Environmental Justice

Termination of power plant operations and the resulting loss of jobs, income, and tax revenue could have a disproportionate effect on minority and low-income populations. The loss of tax revenue, for example, could reduce the availability or eliminate some of the community services that low-income and minority populations may depend on. This situation could be offset with the construction and operation of replacement power generating facilities and the creation of other employment opportunities at or near the nuclear plant site.

Decontamination and decommissioning activities could affect air and water quality in the area around each nuclear plant site. This could cause health and other environmental impacts in minority and low-income populations, if present. Population groups with particular resource dependencies or practices (e.g., subsistence agriculture, hunting, fishing) could also be disproportionately affected.

Environmental impacts associated with decommissioning activities at each nuclear plant and the extent to which minority and low-income populations could be affected, are discussed in the decommissioning GEIS (NRC 2002a). License renewal would only delay, but not alter the impact of decommissioning on minority and low-income populations around each nuclear plant.

Waste Management and Pollution Prevention

After termination of nuclear plant operations, there would be a period before the beginning of decommissioning when the reactor would be placed in a cold shutdown condition and maintained. The fuel might be removed from the core and put in the spent fuel storage pool. There might also be activities related to placing the reactor in shutdown status that could result in the generation of some waste. The types of waste generated during this period would be the same as the types of waste generated during operations and decommissioning. The quantities of waste generated would be smaller than the quantities generated during either operations or decommissioning. The impacts associated with the management of LLW, hazardous waste, mixed waste, and nonradioactive and nonhazardous waste during operations and decommissioning would be SMALL. These impacts would also be SMALL when the reactor was in shutdown status pending decommissioning. All pollution prevention and waste minimization measures instituted during operations would likely continue to be used to minimize releases to the environment and minimize the quantities of waste generated. As discussed in Section 4.11.1.2, the NRC has determined that spent nuclear fuel could be stored onsite safely and with a minimal environmental impact during the license renewal term and the NRC is working on a separate rulemaking and EIS for the Waste Confidence Decision and Rule to address the period after the cessation of reactor operations.

The decommissioning process, by its very nature, generates wastes. The wastes generated are shipped offsite, where they are permanently disposed of, or stored onsite for a certain period or indefinitely. Under the three decommissioning options analyzed in the decommissioning GEIS (NRC 2002a), the DECON process would generate the most waste. In this process, the equipment, structures, and portions of the facility and site that contain radioactive contaminants are removed and decontaminated to a level that permits termination of the license after cessation of operations. In the SAFSTOR process or ENTOMB process, the materials are left onsite temporarily or permanently, respectively.

The impacts from decommissioning that result in the generation of wastes and their onsite management until they are loaded onto vehicles to be shipped offsite are addressed under other disciplines discussed in Section 4.12.2.1. This section addresses the impacts from transporting the wastes to disposal facilities and from their disposal. If there are interim locations offsite where wastes undergo treatment before being sent to a disposal facility, they are also discussed here.

The types of wastes generated during decommissioning would include LLW, mixed waste, hazardous waste, and nonradioactive, nonhazardous waste (see Section 3.11 for waste type definitions). No spent fuel, HLW, or transuranic waste would be generated during decommissioning because spent fuel would have been removed from the reactor and stored in either the reactor's spent fuel pool or in an ISFSI before the start of decommissioning.

It is expected that most of the waste generated during decommissioning would be LLW and nonradioactive, nonhazardous waste. There would be small quantities of mixed waste (mostly paints, waste oils, solvents, and metals such as lead or cadmium) that would be managed per the requirements of RCRA for its hazardous component and the Atomic Energy Act (AEA) for its radioactive component, as described in Section 3.11.3. The quantities of hazardous waste that would be generated would also be small and would mainly consist of paints, solvents, and batteries. Some of the materials used to decontaminate surfaces could also end up being classified as mixed waste. Both mixed wastes and hazardous wastes could be sent to an authorized waste treatment center for incineration or some other form of treatment before being sent to a disposal facility authorized to accept such waste. All of these activities would be conducted according to permits and requirements established under RCRA. The nonradioactive, nonhazardous waste, consisting mainly of rubble and debris, would be sent to a local landfill.

The impacts associated with transporting equipment and materials (radiological and nonradiological) offsite during decommissioning are analyzed in Section 4.3.17 of the decommissioning GEIS (NRC 2002a). The materials transported offsite would include all wastes generated onsite. Radiological impacts would include exposure of transportation workers and the general public along the transportation routes. Nonradiological impacts would include increased traffic volume, additional wear and tear on roadways, and potential traffic accidents. It was concluded that the transportation impacts would not be destabilizing. Therefore, the NRC made the generic conclusion that for all plants, the potential transportation impacts would be SMALL.

There might be small differences in the quantities and characteristics of the waste that would be generated during decommissioning after the license renewal term and the waste that would be generated after the original license period. If the plant license was not renewed, the reactor could be decommissioned at the end of the current license term, whereas if the license was renewed, the decommissioning would take place approximately 20 years later. Additional waste might accumulate at the site, or the radioactivity of some components undergoing decommissioning might be slightly higher at the end of the license renewal term. For example, if there were any refurbishment activities during the license renewal term that resulted in equipment (e.g., steam generators) being taken out of service and subsequently stored onsite awaiting disposition during decommissioning, the amounts of certain types of waste (e.g., LLW) generated from decommissioning under the proposed action would be more than the amounts generated during the original license period. Because of the differences in timing, some of the materials in and around the core of the reactor might have slightly higher radioactivity under the proposed action as a result of a buildup in long-lived radionuclides. This situation would mainly affect the amount of greater-than-Class C LLW at the site. Assuming that the spent nuclear fuel continued to be stored onsite during the license renewal term, there would also be more spent fuel to manage. Similarly, if certain LLW classes (e.g., Class A, B, and C wastes) had to be stored onsite for long periods (for the reasons discussed in Section 4.11.1), the amounts of those wastes that would have to be addressed during decommissioning might be larger after the license renewal term. However, because all radioactive waste must be handled in accordance with NRC regulations, it is not expected that these differences would significantly alter the practices employed to manage the wastes or the impacts associated with managing the wastes generated during decommissioning.

The decommissioning activities would be designed and implemented in ways to prevent pollution and minimize the amount of waste generated. All the methods mentioned in Section 3.11.5, including source reduction and recycling of materials either onsite or offsite, would be used. Under source reduction, the licensees would use decontaminating agents and technologies that would generate less waste, particularly mixed and hazardous waste. They would also implement procedures and practices that would be aimed at preventing or minimizing gaseous and liquid releases to the environment and the quantities of waste generated.

The quantity of LLW that would be generated from the decommissioning of a model 1,000-MWe power plant is included in the quantities of LLW reported on in Section 4.12.1.1. The quantities of mixed waste and hazardous waste that would be generated from decommissioning of nuclear power plants would be relatively small and managed in a way that would protect human health and the environment to meet RCRA requirements. Clean wastes (wastes that are neither radioactive nor hazardous) would be disposed of at a local permitted landfill. The transportation of wastes from a model LWR is also reported on in Section 4.12.1.1. The offsite transportation of equipment and wastes from a power plant undergoing decommissioning was also analyzed in the decommissioning GEIS (NRC 2002a), and the impact was found to be SMALL. On the basis of these considerations, the effect of license renewal would be SMALL for all plants.

4.12.2.2 Termination of Power Plant Operations and Decommissioning of Replacement Power Plants

Fossil Energy Alternatives

The environmental consequences from the termination of power plant operations and the decommissioning a fossil fuel energy facility are dependent on the decommissioning plan. It is reasonable to expect that decommissioning plans would include the following elements and requirements:

- Removal of all unneeded structures and facilities to at least 3 ft (1 m) below grade (in order to provide an adequate root zone for site revegetation).
- Removal of all coal, all coal combustion waste, and all flue gas desulfurization (FGD) sludge and/or byproducts.
- Removal of water intake and discharge structures.
- Dismantlement and/or removal of all ancillary facilities, including rail spurs, coal handling and preparation facilities, cooling towers, natural gas pipelines, onsite wastewater treatment facilities, and access roads.
- Removal of all surface water intake and discharge structures.
- Removal of all accumulated sludge, and closure and removal of all surface water impoundments.
- Proper closure of all onsite groundwater wells.
- An aggressive recycling program for removed equipment and dismantled building components; materials awaiting recycling would be stored at an offsite facility.
- Minimal delay times for removed materials and equipment at temporary laydown areas.
- Expeditious disposal of solid and hazardous wastes at approved facilities; as necessary, remediation of waste handling and storage areas.
- Cleanup and remediation of all incidental spills and leaks.
- Successful execution of an approved revegetation plan for the site.

- Other actions as necessary to ensure restoration of the site to a condition equivalent in character and value to the greenfield or brownfield site on which the facility was first constructed.

Assuming that decommissioning occurs according to a decommissioning plan as described above, environmental consequences (at either a greenfield site or a brownfield site) would include:

- Short-term impacts on air quality and noise from the operation of vehicles and equipment used to deconstruct structures and facilities and the increased number of workforce vehicles traveling to and from the site; impacts include release of criteria pollutants and generation of fugitive dust and noise (including from the possible use of explosives to deconstruct buildings or structures); impacts would be similar to, but of shorter duration than, those experienced during facility construction.

- Short-term impacts on land use and visual resources due to increased human activities on the site and establishment of temporary holding areas for dismantled components and other deconstruction debris (some of which may be at offsite locations—e.g., at rail headers).

- Short-term increase in local traffic as a result of increases in workforce personnel onsite and truck and rail traffic bringing deconstruction equipment to the site and transporting dismantled structures, removed equipment, and deconstruction debris.

- Long-term reestablishment of vegetation and wildlife communities.

- Restoration of visual values through removal of manmade structures and restoration of native vegetative and wildlife communities.

- Short-term increase in local economic activity with the increased dismantlement workforce and other related functions such as transportation, followed by a longer-term downturn of local economy due to loss of jobs of operational personnel.

- Reestablishment of original land use opportunities.

- Elimination of health and safety impacts on operating personnel and the general public from routine operation of the facility and as a result of accidents involving the facility; short-term increase in health and safety risk to decommissioning workforce due to complex and concentrated industrial activities, and short-term increase in risk of transportation-related accidents, due to increased traffic densities throughout decommissioning.

New Nuclear Alternatives

According to 10 CFR Part 52, decommissioning impacts for a nuclear power plant include all activities related to the safe removal of the facility or site from service and the reduction of residual radioactivity to a level that permits release of the property under restricted conditions or unrestricted use and termination of a license. The decommissioning process and the activities occurring during decommissioning would be similar to those associated with current reactors, (see Sections 2.1.3 and 4.12.2.1).

Environmental consequences would also be similar to those discussed in Section 4.12.2.1 and would include:

- Temporary impacts on land use and visual resources, including the construction of temporary buildings and parking lots and the addition or expansion of laydown areas. (Many plants have existing, previously disturbed areas available for these temporary land use activities.)

- Reduced (small) water use and water quality impacts as water consumption decreases significantly after cessation of operations. Dewatering and water used for spent fuel cooling would continue until spent fuel was removed from the site. Surface water runoff or release of substances would be possible but should not have a detectable effect on the environment.

- Temporary increases in local traffic that would result from the additional workforce onsite; truck and rail traffic bringing deconstruction equipment to the site; and the transport of dismantled structures, removed equipment, and waste from the site.

- Long-term reestablishment of vegetation and wildlife communities.

- Short-term improvements in the local economy because of the increased workforce for decommissioning activities, followed by a long-term downturn of the local economy because of the loss of jobs of operational personnel.

- Potential (regulated) radiological doses to the public and decommissioning workforce at the facility from activities such as removal of the reactor vessel and demolition of facilities.

- Increased but temporary occupational safety and health risk to the workforce due to complex and concentrated industrial activities.

Renewable Alternatives

The termination of power plant operations and the decommissioning of renewable energy systems would be similar to the impacts discussed in the previous sections. Decommissioning would follow a decommissioning plan and would involve not only removal of facility components and operational wastes and residues, but also reclamation of the land to its original state. Decommissioning scenarios are expected to involve the following actions:

- Removal of all unneeded structures and facilities to at least 3 ft (1 m) below grade (to provide an unencumbered root zone for site revegetation).
- Removal of all unspent biomass fuel and all solid wastes from combustion and facility maintenance.
- Removal of water intake and discharge structures (if present to support combustion facilities and steam cycles).
- Dismantlement and/or removal of all ancillary facilities, including rail spurs, biomass (and coal) fuel handling and preparation facilities, cooling towers, natural gas pipelines, onsite wastewater treatment facilities, and access roads.
- Removal of all surface water intake and discharge structures.
- Removal of all accumulated sludge, and closure and removal of all surface water impoundments.
- Proper closure of all onsite groundwater wells.
- Aggressive recycling program for removed equipment and dismantled building components; materials awaiting recycling would be stored at an offsite facility.
- Minimal delay times for removed materials and equipment at temporary laydown areas.
- Expeditious disposal of solid and hazardous wastes at approved facilities; remediation as necessary of waste handling and storage areas.
- Cleanup and remediation of all incidental spills and leaks.
- Successful execution of an approved revegetation plan for the site.

- Offsite ancillary facilities (access roads, utilities, pipelines, electrical transmission towers) would be removed unless it is determined that they can serve other purposes; buried utilities and pipelines could be abandoned in place if their removal would result in significant disruption to ecosystems.

- Other actions as necessary to ensure restoration of the site to a condition equivalent in character and value to the greenfield or brownfield site on which the facility was first constructed.

Termination of operations and decommissioning of offshore facilities could involve the following unique actions and strategies, depending on location:

- Wind turbine tower foundations and communication and power cables buried in the seafloor could be allowed to remain to avoid the disruption that would result from their removal.

- Underwater structures could be allowed to remain in place to serve as artificial fish habitats.

- Structures that served as electrical service platforms could be allowed to remain in place to serve as artificial reefs.

The termination of operations and the decommissioning of hydroelectric facilities could follow unique paths. For large store-and-release facilities, eliminating the dam and reservoir and restoring the river to its natural flow could have dramatic consequences to both upstream and downstream ecosystems. Especially where store-and-release dams serve purposes other than power generation (e.g., flood control and irrigation), complete elimination of the structures and reservoir and restoration of original river conditions could be at cross purposes. While turbines, generators, and other equipment associated with power production could be removed, the dam and reservoir would be expected to remain largely intact, as would fish ladders and passages. Penstocks and other devices that control the release of water from the reservoir are expected to remain functional. A reduced workforce would also remain to operate the dam for flood control and irrigation purposes. Impacts on upstream land uses would remain generally unaltered from the impacts during the dam's operating period.

Smaller scale, run-of-the-river dams (so called low-impact hydro facilities[e]) that have limited impact on upstream water levels and downstream water flow rates would likely be completely dismantled and removed during decommissioning.

(e) Low-impact hydro facilities are considered to have a power capacity of less than 30 MW.

4.12.3 Greenhouse Gas Emissions and Climate Change

The following sections discuss greenhouse gas (GHG) emissions from the nuclear lifecycle, replacement power alternatives, and climate change impacts.

4.12.3.1 Greenhouse Gas Emissions

This section discusses GHG emissions from the nuclear lifecycle and compares these emissions to those from fossil and other renewable energy sources. The nuclear lifecycle consists of the uranium fuel cycle phases, as discussed in Section 4.12.1.1, and nuclear power plant construction, operation, and decommissioning.

Existing Studies

The relative volumes of GHGs emitted by nuclear and other electricity generating methods have been widely studied. However, estimates and projections of the carbon footprint of the nuclear lifecycle vary depending on the type of study done. Additionally, considerable debate also exists among researchers on the relative effects of nuclear and other forms of electricity generation on GHG emissions. Existing studies on GHG emissions from nuclear power plants generally take two different forms:

(1) Qualitative discussions of the potential to use nuclear power to reduce GHG emissions and mitigate global warming.

(2) Technical analyses and quantitative estimates of the actual amount of GHGs generated by the uranium fuel cycle or entire nuclear lifecycle and comparisons to the operational or lifecycle emissions from other energy generation alternatives.

Qualitative Studies

The qualitative studies consist primarily of broad, large-scale public policy or investment evaluations of whether an expansion of nuclear power is likely to be a technically, economically, or politically workable means of achieving global GHG reductions. Studies found by the staff during the subsequent literature search include the following:

- Evaluations to determine if investments in nuclear power in developing countries should be accepted as a flexibility mechanism to assist industrialized nations in achieving their GHG reduction goals under the Kyoto Protocols (IAEA 2000; NEA and OECD 2002; Schneider 2000). Ultimately, the parties to the Kyoto Protocol did not approve nuclear power as a component under the Clean Development Mechanism due to safety and waste disposal concerns (NEA and OECD 2002).

- Analyses developed to assist governments, including the United States Government, in making long-term investment and public policy decisions in nuclear power (Hagen et al. 2001; Keepin 1988; MIT 2003).

Although the qualitative studies sometimes reference and critique the existing quantitative estimates of GHGs produced by the nuclear fuel cycle or lifecycle, their conclusions generally rely heavily on discussions of other aspects of nuclear policy decisions and investment such as safety, cost, waste generation, and political acceptability. Therefore, these studies are typically not directly applicable to an evaluation of GHG emissions associated with the proposed license renewal for a given nuclear power plant.

Quantitative Studies

A large number of technical studies, including calculations and estimates of the amount of lifecycle GHGs emitted by nuclear and other power generation options, are available in the literature and were useful to the staff's efforts in addressing relative GHG emission levels. Examples of these studies include—but are not limited to—Mortimer (1990), Andseta et al. (1998), Spadaro et al. (2000), Fritsche (2006), Parliamentary Office of Science and Technology (POST) (2006), AEA Technology (AEA) (2006), Weisser (2006), and Fthenakis and Kim (2007). In addition, Sovacool (2008) provides a review and synthesis of studies in existence through 2008. The Sovacool (2008) synthesis ultimately uses only 19 of the 103 studies initially considered; the remaining 84 were excluded because they were more than 10 years old, not publicly available, available only in a language other than English, or they presented methodological challenges by relying on inaccessible data, provided overall GHG estimates without allocating relative GHG impacts to different parts of the nuclear lifecycle, or they were otherwise not methodologically explicit. The Intergovernmental Panel on Climate Change (IPCC) has issued a special report on Renewable Energy Sources and Climate Change Mitigation (IPCC 2011). This report provides an assessment of previously published literature on lifecycle GHG emissions from various electricity generation technologies (nuclear, fossil fuel, and renewable energy sources). The IPCC report only included in its synthesis published literature that met the screening criteria for quality and relevance. Of the 2,165 references collected, 296 passed the screening criteria; for the nuclear lifecycle, 125 out of 249 references reviewed passed the screening criteria.

Comparing these studies and others like them is difficult because the assumptions and components of the lifecycles the authors evaluate vary widely. Examples of areas in which differing assumptions make comparing the studies difficult include the following:

- Energy sources that may be used to mine uranium deposits in the future

- Reprocessing or disposal of spent nuclear fuel

- Current and potential future processes to enrich uranium and the energy sources that will power them
- Estimated grades and quantities of recoverable uranium resources
- Estimated grades and quantities of recoverable fossil fuel resources
- Estimated GHG emissions other than carbon dioxide including the conversion to carbon dioxide equivalents per unit of electric energy produced
- Performance of future fossil fuel power systems
- Projected capacity factors for alternative means of generation
- Current and potential future reactor technologies.

Studies may vary with respect to whether all or parts of a power plant's lifecycle are analyzed. That is, a full lifecycle analysis will typically address plant construction, operations, resource extraction (for fuel and construction materials), and decommissioning, whereas a partial lifecycle analysis primarily focuses on operational differences. In addition, as Sovacool (2008) noted, studies vary greatly in terms of age, data availability, and in the disclosure of the study methods used.

In the case of license renewal, a GHG analysis for the portion of the plant's lifecycle attributable to license renewal (operation for an additional 20 years) would not involve GHG emissions associated with construction because construction activities have already been completed at the time of relicensing. In addition, the proposed action of license renewal would also not involve additional GHG emissions associated with facility decommissioning because decommissioning must occur whether the facility is relicensed or not. However, in many studies, the specific contribution of GHG emissions from construction, decommissioning, or other portions of a plant's lifecycle cannot be clearly separated from one another. In such cases, an analysis of GHG emissions would overestimate the GHG emissions attributed to a specific portion of a plant's lifecycle. As Sovacool (2008) noted, many of the available analyses provide markedly lower GHG emissions per unit of plant output, if one assumes that a power plant operates for a longer period of time. Nonetheless, available studies supply some meaningful information with respect to the relative magnitude of the emissions among nuclear power plants as compared to other forms of electric generation as discussed in the following sections.

In Tables 4.12-4, 4.12-5, and 4.12-6, the NRC presents the results of the above-mentioned quantitative studies to supply a weight-of-evidence evaluation of the relative GHG emissions that may result from the proposed license renewal as compared to the potential alternative use of coal-fired, natural gas-fired, and renewable generation. Most studies from Mortimer (1990) onward (through Sovacool 2008) indicate that uranium ore grades and uranium enrichment processes are leading determinants in the ultimate GHG emissions attributable to nuclear power generation. These studies show that the relatively lower order of magnitude of lifecycle GHG emissions from nuclear power, when compared to fossil-fueled alternatives (especially natural gas), could potentially disappear if available uranium ore grades drop sufficiently while enrichment processes continued to rely on the same technologies.

Table 4.12-4. Nuclear Greenhouse Gas Emissions Compared to Coal

Source	GHG Emission Results
Mortimer (1990)	Nuclear—230,000 tons CO_2/year Coal—5,912,000 tons CO_2/year Note: Future GHG emissions from nuclear to increase because of declining ore grade.
Andseta et al. (1998)	Nuclear energy produces 1.4 percent of the GHG emissions compared to coal. Note: Future reprocessing and use of nuclear-generated electrical power in the mining and enrichment steps are likely to change the projections of earlier authors, such as Mortimer (1990).
Spadaro et al. (2000)	Nuclear—2.5 to 5.7 g C_{eq}/kWh[(a)] Coal—264 to 357 g C_{eq}/kWh
Fritsche (2006) (values estimated from graph in Figure 4)	Nuclear—33 g C_{eq}/kWh Coal—950 g C_{eq}/kWh
POST (2006) (nuclear calculations from AEA 2006)	Nuclear—5 g C_{eq}/kWh Coal—>1,000 g C_{eq}/kWh Note: Decrease of uranium ore grade to 0.03 percent would raise nuclear to 6.8 g C_{eq}/kWh. Future improved technology and carbon capture and storage could reduce coal-fired GHG emissions by 90 percent.
Weisser (2006) (compilation of results from other studies)	Nuclear—2.8 to 24 g C_{eq}/kWh Coal—950 to 1,250 g C_{eq}/kWh
Sovacool (2008) (compilation of results from other studies)	Nuclear—1.4 to 288 g C_{eq}/kWh (average: 66 g C_{eq}/kWh) Coal —960 to 1,050 g C_{eq}/kWh (coal adopted from Gagnon et al. 2002)
IPCC (2011) (compilation of results from other studies)	Nuclear—1 to 220 g C_{eq}/kWh (median: 16 g C_{eq}/kWh) Coal—675 to 1689 g C_{eq}/kWh (median: 1001 g C_{eq}/kWh)

(a) g C_{eq}/kWh = grams of carbon equivalent per kilowatt-hour

Summary of Nuclear Greenhouse Gas Emissions Compared to Coal

Considering that coal fuels the largest share of electricity generation in the United States and that its burning results in the largest emissions of GHGs for any of the likely alternatives to nuclear power generation, many available quantitative studies focused on comparisons of the relative GHG emissions of nuclear to coal-fired generation. The quantitative estimates of lifecycle GHG emissions associated with nuclear power, as compared to an equivalent coal-fired plant, are presented in Table 4.12-4. The staff relied on current available information for its independent analysis. Although Table 4.12-4 does not include all existing studies, it gives an illustrative range of estimates developed by various sources.

Table 4.12-5. Nuclear Greenhouse Gas Emissions Compared to Natural Gas

Source	GHG Emission Results
Spadaro et al. (2000)	Nuclear—2.5 to 5.7 g C_{eq}/kWh[(a)] Natural Gas—120 to 188 g C_{eq}/kWh
Fritsche (2006) (values estimated from graph in Figure 4)	Nuclear—33 g C_{eq}/kWh Cogeneration Combined Cycle Natural Gas—150 g C_{eq}/kWh
POST (2006) (nuclear calculations from AEA 2006)	Nuclear—5 g C_{eq}/kWh Natural Gas—500 g C_{eq}/kWh Note: Decrease of uranium ore grade to 0.03 percent would raise nuclear to 6.8 g C_{eq}/kWh. Future improved technology and carbon capture and storage could reduce natural gas GHG emissions by 90 percent.
Weisser (2006) (compilation of results from other studies)	Nuclear—2.8 to 24 g C_{eq}/kWh Natural Gas—440 to 780 g C_{eq}/kWh
Sovacool (2008) (compilation of results from other studies)	Nuclear—1.36 to 288 g C_{eq}/kWh (average: 66 g C_{eq}/kWh) Natural Gas—443 g C_{eq}/kWh (natural gas adopted from Gagnon et al 2002)
IPCC (2011) (compilation of results from other studies)	Nuclear—1 to 220 g C_{eq}/kWh (median: 16 g C_{eq}/kWh) Natural gas—290 to 930 C_{eq}/kWh (median: 469 g C_{eq}/kWh)

(a) g C_{eq}/kWh = grams of carbon equivalent per kilowatt-hour

Weisser (2006) (compilation of results from other studies)	Nuclear—2.8 to 24 g C_{eq}/kWh Solar PV—43 to 73 g C_{eq}/kWh Hydroelectric—1 to 34 g C_{eq}/kWh Biomass—35 to 99 g C_{eq}/kWh Wind—8 to 30 g C_{eq}/kWh
Fthenakis and Kim (2007)	Nuclear—16 to 55 g C_{eq}/kWh Solar PV—17 to 49 g C_{eq}/kWh
Sovacool (2008) (compilation of results from other studies)	Nuclear—1.36 to 288 g C_{eq}/kWh (average: 66 g C_{eq}/kWh) Wind—9 to10 g C_{eq}/kWh Hydroelectric (small, distributed) —10 to13 g C_{eq}/kWh Biogas digester—11 g C_{eq}/kWh Solar Thermal—13 g C_{eq}/kWh Biomass—14 to 35 g C_{eq}/kWh Solar PV—32 g C_{eq}/kWh Geothermal (hot, dry rock)—38 g C_{eq}/kWh (Note: Solar PV value adopted from Fthenakis et al. 2008; all other renewable-generation values adopted from Pehnt 2006)

Table 4.12-6. (cont.)

Source	GHG Emission Results
IPCC (2011) (compilation of results from other studies)	Nuclear—1 to 220 g C_{eq}/kWh (median: 16 g C_{eq}/kWh) Wind—2 to 81 g C_{eq}/kWh (median: 12 g C_{eq}/kWh) Hydropower—0 to 43 g C_{eq}/kWh (median: 4 g C_{eq}/kWh) Biopower[(c)]—[-]633 to 360 g C_{eq}/kWh (median: 18 g C_{eq}/kWh) Solar PV—5 to 217 g C_{eq}/kWh (median: 46 g C_{eq}/kWh) Solar CSP[(d)]—7 to 89 g C_{eq}/kWh (median: 22 g C_{eq}/kWh) Geothermal—6 to 79 g C_{eq}/kWh (median: 45 g C_{eq}/kWh) Ocean Energy—2 to 23 g C_{eq}/kWh (median: 8 g C_{eq}/kWh)

(a) g C_{eq}/kWh = grams of carbon equivalent per kilowatt-hour
(b) Solar PV = solar photovoltaic
(c) Negative values for biopower refer to avoided emissions. Negative values are based on assumptions of avoided emissions by using wastes and residues from landfill disposals to produce electricity that are credited to the lifecycle of biopower (i.e., biomass is diverted from landfills and emissions that would normally be produced at the landfill are avoided). Avoided emissions are those that may be misplaced in time and location but which do totally remove GHGs from the atmosphere.
(d) CSP = concentrating solar power.

Summary of Nuclear Greenhouse Gas Emissions Compared to Natural Gas

The quantitative estimates of lifecycle GHG emissions associated with the nuclear power, as compared to an equivalent natural gas-fired plant, are presented in Table 4.12-5. The staff relied on current available information for its independent analysis. The staff notes that Table 4.12-5 does not include all existing studies. Table 4.12-5, however, gives an illustrative range of estimates developed by various sources.

Summary of Nuclear Greenhouse Gas Emissions Compared to Renewable Energy Sources

The quantitative estimates of lifecycle GHG emissions associated with the nuclear power, as compared to equivalent renewable energy sources, are presented in Table 4.12-6. Calculation of GHG emissions associated with these sources is more difficult than the calculations for nuclear energy and fossil fuels because of the large variation in efficiencies and capacity factors due to their different technologies, sources, and locations. For example, the efficiencies of solar and wind energy are highly dependent on the wind or solar resource in a particular location. Similarly, the range of GHG emissions estimates for hydropower varies greatly depending on the type of dam or reservoir involved (if used at all). Additionally, for biopower, the biomass source (energy crops, agricultural and livestock waste, etc.) and broad range of bioenergy technologies (direct combustion, biomass integrated gasification combined cycle, co-firing with coal) impact lifecycle GHG emissions estimates. For instance, emissions can be avoided if agricultural waste, that would typically decompose and emit GHGs, is used as the biomass source to produce electricity. However, biomass power plant operation, construction, and transportation still emit GHGs. On the other hand, if energy crops are used, GHGs are emitted from the manufacturing or harvesting of biomass, transportation, construction, and operation of the plant. Therefore, lifecycle GHG emissions estimates for these energy sources have a greater range of variability than the estimates for nuclear and fossil fuel sources. Table 4.12-6 gives an illustrative range of estimates developed by various sources.

Conclusions: Relative Greenhouse Gas Emissions

The sampling of data presented in Tables 4.12-4, 4.12-5, and 4.12-6 demonstrates the wide distribution of lifecycle GHG emission estimates of various electricity generation technologies and the challenges of any attempt to determine the specific amount of GHG emissions attributable to nuclear energy production sources, as different assumptions and calculation methods will yield differing results. The differences and complexities in these assumptions and analyses will further increase when they are used to project future GHG emissions. Nevertheless, several conclusions can be drawn from the information presented.

First, the various studies show a general consensus that nuclear power generation has lower lifecycle GHG emissions than electrical generation based on fossil fuel. The studies also give estimates of lifecycle GHG emissions from renewable energy sources based on current and available technology. The range of these estimates is wide, but the general conclusion is that current lifecycle GHG emissions from nuclear power generation are of the same order of magnitude as from the surveyed renewable energy sources.

Second, the studies show no consensus on future relative GHG emissions from nuclear power and other sources of electricity. There is substantial disagreement among the various authors about the GHG emissions associated with declining uranium ore concentrations, future uranium enrichment methods, and other factors, including changes in technology. Similar disagreement exists about future GHG emissions associated with coal and natural gas for electricity generation. Even the most conservative studies conclude that nuclear power generation currently produces fewer lifecycle GHG emissions than sources based on fossil fuel and is expected to continue to do so in the near future. The primary difference among the authors is the projected cross-over date (the time at which GHG emissions from the nuclear lifecycle exceed those of sources based on fossil fuel) or whether cross-over will actually occur.

Considering the current estimates and future uncertainties, it appears that GHG emissions associated with nuclear power plant relicensing actions are likely to be lower than those associated with energy sources based on fossil fuel. This conclusion is based on the following rationale:

- As shown in Tables 4.12-4 and 4.12-5, the current estimates of lifecycle GHG emissions from nuclear power generation are below those for energy sources based on fossil fuel.

- License renewal will involve continued GHG emissions due to uranium mining, processing, and enrichment but will not result in increased GHG emissions associated with plant construction or decommissioning (as the plant will have to be decommissioned at some point whether the license is renewed or not).

- Few studies predict that nuclear lifecycle emissions will exceed those of fossil fuels within a time frame that includes periods of extended operation. Several studies suggest that future extraction and enrichment methods, the potential for higher grade uranium resource discovery, and technology improvements could extend this time frame.

With respect to the comparison of GHG emissions among nuclear power plant license renewal and renewable energy sources, it appears likely that there will be future technology improvements and changes in the type of energy used for mining, processing, manufacturing, and constructing facilities of all types. Currently, lifecyle GHG emissions associated with nuclear power and renewable energy sources are within the same order of magnitude. Because nuclear fuel production is the most significant contributor to possible future increases in GHG emissions from nuclear power—and because most renewable energy sources lack a fuel component—it is likely that GHG emissions from renewable energy sources would be lower than those associated with nuclear power plant license renewal at some point during the period of extended operation.

4.12.3.2 Climate Change Impacts

This section briefly describes the environmental impacts that could occur from changes in global and regional climate conditions due to GHG emissions. Each subsection generically describes potential long-term impacts and provides examples of the resource changes that could occur due to climate change.

Land Use

Sea level rise could result in the loss of coastal lands, as well as the possible loss of man-made infrastructure as a result of inundation, flooding during storm events, or storm-triggered erosion. This could necessitate more-frequent infrastructure redesign and replacement or relocation away from potential hazards. As noted by the U.S. Global Change Research Program (USGCRP) (2009), the projected rapid rate and large amount of climate change over the next century will challenge the ability of society and natural systems to adapt. For example, it is difficult and expensive to alter or replace infrastructure designed to last for decades (such as buildings, bridges, roads, airports, reservoirs, and ports) in response to continuous and/or abrupt climate change. Sea-level rise and storm surge place many U.S. coastal areas at increasing risk of erosion and flooding, especially along the Atlantic and Gulf coasts, the Pacific

Islands, and parts of Alaska. Energy and transportation infrastructure and other property in coastal areas are also likely to be adversely affected.

Air Quality and Meteorology

The EPA annually publishes the official United States inventory of GHG emissions that identifies and quantifies the primary man-made sources and sinks of GHGs. The EPA estimates that energy-related activities in the United States account for more than three-quarters of human-generated GHG emissions, mostly in the form of carbon dioxide emissions from burning fossil fuels. More than half of the energy-related emissions come from major stationary sources like power plants, and approximately one-third comes from transportation. Industrial processes (production of cement, steel, and aluminum), agriculture, forestry, other land use, and waste management are also important sources of GHG emissions in the United States (EPA 2011).

Section 4.12.3.1 presents a discussion of the relative GHG emissions from nuclear power and other electricity generation options. The impacts of GHG emissions do not vary with the locations of the emissions sources, so the same impacts would result from the operation of those power plants regardless of where they are located. The USGCRP indicates that as much as 87 percent of GHG emissions are the result of generating electricity and heat using carbon-based fuels (USGCRP 2009).

With regard to the impact of GHG emissions, the USGCRP concludes in part that climate-related changes have already been observed globally and across the United States. Specifically, it notes the following changes: increases in air and water temperatures, reduced frost days, increased frequency and intensity of heavy downpours, a rise in sea level, and reductions in snow cover, glaciers, permafrost, and sea ice. Longer ice-free periods on lakes and rivers, lengthening of the growing season, and increased water vapor in the atmosphere have also been observed. These climate-related changes are expected to continue while new ones develop. Likely future changes for the United States and surrounding coastal waters include more-intense hurricanes with related increases in wind, rain, and storm surges (but not necessarily an increase in the number of these storms that make landfall), as well as drier conditions in such areas as the Southwest (USGCRP 2009). Climate model simulations presented by the U.S. National Oceanic Atmospheric Administration indicate a greater rate of warming (average temperature increase) over the entire continental United States for the 21st century than the 20th century observed rates, an increase in the number of days with a maximum temperature greater than 95˚F (35°C) in the Southwest and Southeast regions, a decrease in the number of days with minimum temperatures less than 10˚F (–12°C) in the Rocky Mountains and Northern regions, and an increase in the number of days with little or no precipitation (less than 0.04 in. [0.1 mm]) for Western and Southern regions by mid-century for a high-emissions scenario (continued increases in greenhouse gas emissions through the end of the century) (NOAA 2013). Observed changes in meteorological and climatological indicators specific to the continental United States are further discussed in Section 3.3.1 of this GEIS.

Water Resources

Climate change will affect water availability in every region of the United States, but the nature of the potential impacts varies. Drought-—related to reduced precipitation, increased evaporation, and increased water loss from plants in response to higher temperatures—is an important issue in many regions, especially in the West. Floods, as well as water quality problems, are likely to be amplified by climate change in most regions. Declines in mountain snowpack are important in the West and Alaska where snowpack provides vital natural water storage. In some regions, reductions in water supply due to decreases in precipitation and/or reduced snowmelt will increase competition for water among various sectors, including energy production (USGCRP 2009).

More specifically, the USGCRP projects a high likelihood that water shortages will limit power plant electricity production in some regions. USGCRP projects water constraints on electricity production by 2025 in Arizona, Utah, Texas, Louisiana, Georgia, Alabama, Florida, California, Oregon, and Washington State. Additional parts of the United States could face similar constraints as a result of drought, growing populations, and increasing demand for water for various uses during some or all seasons.

Finally, the issue related to water resources is not only one of water availability, but also of water temperature. Warmer water and higher air temperatures reduce the efficiency of thermal power plant cooling technologies. In addition, discharge-permit conditions may limit operations for some power plants as water temperatures rise (this has already occurred at some power plants during peak summer heat). In the aggregate, these changes may reduce the available power generating capacity during the summer, when demand is typically high. A relatively small change in available generating capacity could have significant implications for the total national electric power supply. An average reduction of 1 percent in electricity generated by thermal power plants nationwide would mean a loss of 25 billion kilowatt-hours per year—equivalent to the amount of electricity consumed by 2 million Americans. Such a power loss would need to be replaced or otherwise offset through improvements in energy efficiency (USGCRP 2009).

Terrestrial Resources

Climate change could affect terrestrial resources. Sea level rise could result in the loss of coastal marsh and cause saltwater intrusion into coastal forests (USGCRP 2009), thus eliminating habitat for wildlife. Global climate change could also cause shifts in species' ranges and migratory corridors, as well as changes in ecological processes (NRC 2011).

Climate change is already having effects on terrestrial animal and plant species throughout the United States. Some of the most obvious changes are related to the timing of the seasons, including when plants bud in spring and when birds and other animals migrate. Spring now arrives an average of 10 days to two weeks earlier than it did 20 years ago, and the growing season is lengthening over much of the continental United States. The ranges of many species in the United States have shifted northward in latitude and upward in elevation. As an example, the ranges of many butterfly species have expanded northward, contracted at their southern edges, and shifted to higher elevations as warming has continued. Also, horticultural hardiness zones (each zone represents a 10°F (5.6°C) change in minimum temperature) in the Midwest are likely to shift one-half to one full zone about every 30 years. Impacts on forests are likely to be mixed, with limited, positive effects of higher carbon dioxide levels potentially negated by the negative effects of decreased water supply (in the West) and more-frequent severe weather events like storms and droughts throughout the United States. On a broader scale, some common forests types are projected to expand, such as oak-hickory; others are projected to contract, such as maple-beech-birch. Still others, such as spruce-fir, are likely to disappear from the United States altogether (USGCRP 2009).

The potential for animals to shift their ranges to keep pace with the changing climate may be inhibited by major urban areas and by natural barriers like the Great Lakes. Insect pests that have historically been controlled by cold winters will more easily survive milder winters and may produce larger populations in areas that are already within their ranges. Further, increased temperatures, decreased rainfall, and more-severe droughts could also lead to the drying of lakes, ponds, and wetlands and the loss of riparian species (USGCRP 2009).

The Intergovernmental Panel on Climate Change has estimated that if a warming of 3.5 to 5.5°F (1.9 to 3°C) occurs, 20 to 30 percent of species that have been studied would be located in climate zones that are outside of their current ranges and would, therefore, likely be at risk of extinction. This high percentage is partly a result of pre-existing stresses, including habitat loss and continued overharvesting of some species (USGCRP 2009).

Aquatic Resources

The potential effects of climate change, whether from natural cycles or related man-made activities, could result in a variety of changes that would affect inland and coastal aquatic resources.

Water temperatures in lakes, streams, and rivers have been increasing across most of the United States and will continue to do so as air temperatures increase. According to USGCRP (2009), in some lakes for example, "this will lead to an earlier and longer period in summer during which mixing of the relatively warm surface lake water with the colder water below is reduced. In such cases, this stratification can cut off oxygen from bottom layers, increasing the risk of oxygen-poor or oxygen-free ‘dead zones’ that kill fish and other living things.” In lakes with contaminated sediment, warmer water and low-oxygen conditions can more readily mobilize mercury and other persistent pollutants. In cases where increasing quantities of contaminants are taken up in the aquatic food chain, there will be additional potential for health hazards for species, including humans, that eat fish from the lakes. “Populations of coldwater fish, such as brook trout, lake trout, and whitefish, are expected to decline dramatically, while populations of coolwater fish such as muskellunge, and warmwater species such as smallmouth bass and bluegill, will take their places” (USGCRP 2009). Overall, large declines in trout populations are projected to occur around the United States “Over half of the wild trout populations are likely to disappear from the southern Appalachian Mountains because of the effects of rising stream temperatures. Losses of western trout populations may exceed 60 percent in certain regions” (USGCRP 2009). Aquatic ecosystem disruptions are likely to be compounded by invasions of non-native species that tend to thrive under a wide range of environmental conditions.

The environmental factors of significance that could affect estuarine systems include sea level rise, temperature increases, salinity changes, and wind and water circulation changes (Kennedy 1990). Changes in sea level could result in effects to nearshore communities, including the reduction or redistribution of submerged and emergent aquatic vegetation, changes in marsh communities, and influences to other wetland areas adjacent to nearshore systems. Sea level rise may outpace the ability of estuarine systems to migrate, and thus some habitats may be lost altogether. Water temperature changes could affect spawning patterns and success, and may influence the distribution of important species (e.g., cold water species may move northward while the ranges of warm water species expand). Changes in salinity could also influence the spawning and distribution of important species and the range of invasive species. Fundamental changes in precipitation could influence water circulation, salinity and mixing patterns, and change the nature of sediment and nutrient inputs to the system. This could result in changes to primary production and influence the estuarine food web. Some fisheries and aquaculture enterprises might benefit from climate change while others might suffer (Kennedy 1990). However, climate change could increase the frequency of red tide blooms, with adverse impacts to many fish species (USFWS and NMFS 2009).

In marine ecosystems, climate change may trigger effects similar to those in estuarine ecosystems. Effects may additionally include adverse impacts to corals, clams, shrimp, and other organisms with calcium carbonate shells or skeletons due to increased acidity (a side-effect that occurs when increased atmospheric carbon dioxide concentrations diffuse into the oceans); coral bleaching and increases in the rate of disease in corals; and more-frequent die-offs of sponges, seagrasses, and other organisms could occur as sea temperatures increase (Florida Oceans and Coastal Council 2009).

Historic and Cultural Resources

Sea level rise and changes in meteorological conditions due to climate change could result in the loss of historic and cultural resources due to short-term flooding, erosion, or long-term inundation. Due to the differences in timing and rate of climate and sea-level changes, it is possible that some resources could be lost before they could be documented or otherwise studied.

Socioeconomics

Changes in climate conditions could have an impact on the availability of jobs in certain industries. For example, the USGCRP noted that tourism and recreation are major job creators in some regions, bringing billions of dollars to regional economies. Across the nation, fishing, hunting, skiing, snowmobiling, diving, beach-going, and other outdoor activities make important economic contributions and are also a part of tradition. A changing climate would mean reduced opportunities for some activities in some locations and expanded opportunities for others. Hunting and fishing opportunities will change as animals' habitats shift and as relationships among species are disrupted by their different responses to climate change. Water-dependent recreation in areas projected to get drier, such as the Southwest, and beach recreation in coastal areas (which are expected to see rising sea levels) will suffer. Some regions will see an expansion of the season for warm weather recreation such as hiking and bicycle riding, while other areas will see a decline in—or elimination of—cold-weather recreation (USGCRP 2009).

Human Health

Increasing temperatures due to changes in climate conditions could have an impact on human health. The ranges of disease-carrying insects and animals may expand. At the same time, hotter weather may increase the incidence of health-threatening air pollution events (USGCRP 2009). This is in addition to the risk to life and property resulting from sea-level rise, intense precipitation events, flooding, erosion, and storm surge. Unusually intense storm events can also overload drainage systems and water treatment facilities, increasing the risk of waterborne diseases (USGCRP 2009).

Environmental Justice

Changes in climate conditions could disproportionately affect minority and low-income populations. The USGCRP (2009) indicates that "infants and children, pregnant women, the elderly, people with chronic medical conditions, outdoor workers, and people living in poverty are especially at risk from a variety of climate-related health effects." Examples of these effects include increased heat stress, air pollution, extreme weather events, and diseases carried by food, water, and insects. The greatest health burdens related to climate change are likely to fall on the poor, especially those lacking adequate shelter and access to other resources such as air conditioning. Elderly people, who are more likely to be poor, are also more likely to have debilitating chronic diseases or limited mobility. In addition, the elderly have a reduced ability to regulate their own body temperature or sense when they are too hot. According to the USGCRP (2009), they "are at greater risk of heart failure, which is further exacerbated when cardiac demand increases in order to cool the body during a heat wave." The USGCRP study also found that people taking medications, such as diuretics for high blood pressure, have a higher risk of dehydration.

Cumulative Impacts

The USGCRP found that climate change will combine with other social, economic, and environmental stresses to create larger impacts than from any of these factors alone (USGCRP 2009). In addition, the cumulative impacts of climate change will be further examined in each site-specific SEIS.

4.13 Cumulative Impacts of the Proposed Action

Cumulative impact is defined by the CEQ in 40 CFR 1508.7. Actions to be considered in cumulative impact analyses include new and continuing activities, such as license renewal, that are conducted, regulated, or approved by a Federal agency. The cumulative impacts analysis takes into account all actions, however minor, since impacts from individually minor actions may be significant when considered collectively over time. The goal of the cumulative impact analysis is to identify potentially significant impacts to improve decisions and move toward more sustainable development (CEQ 1997; EPA 1999).

The analysis of cumulative impacts focuses on resources that could be affected by the incremental impacts from continued operations and refurbishment of the nuclear power plant associated with license renewal. The CEQ discusses the assessment of cumulative effects in detail in its report entitled, *Considering Cumulative Effects Under the National Environmental Policy Act* (CEQ 1997). On the basis of the guidance provided in the CEQ report, a cumulative impact analysis would consider the following:

> ***Definition of Cumulative Impact***
>
> The impact on the environment that results from the incremental impact of an action when added to other past, present, and reasonably foreseeable future actions, regardless of what agency (Federal or non-Federal) or person undertakes such other actions.

- The geographic scope (i.e., regions of influence). The regions of influence encompass the areas of affect and the distances at which impacts associated with license renewal may occur. Geographic boundaries may vary by resource area and the distances over which an impact may be experienced (e.g., the evaluation of impacts on air quality may have a greater regional extent than that of impacts on historic and cultural resources).

- The time frame for the analysis. The time frame incorporates the sum of the effects of license renewal in combination with past, present, and reasonably foreseeable future actions since impacts may accumulate or develop over time. The time frame for future actions is the 20-year license renewal term after the end of the original license term. Past and present actions include all actions up to and including the time of the license renewal application. Future actions are those that are "reasonably foreseeable"; that is, they are ongoing (and will continue into the future), are funded for future implementation, or are included in firm, near-term plans. Past and present actions are generally accounted for in the baseline assessment presented in the affected environment sections for each resource area in Chapter 3 of this GEIS. The direct and indirect impact analyses present in Chapter 4 address the incremental impacts of license renewal. These analyses are carried forward to the cumulative impact analysis, which expands the analysis to consider other past, present, and reasonably foreseeable future actions.

- The potential effects of each past, present, or reasonably foreseeable future action. Both the license renewal and other actions (related and nonrelated, including trends such as global climate change) will generate effects that could contribute to cumulative impacts. The impacts of activities associated with the proposed action (license renewal) are discussed for each resource area in this chapter. In cases where the contributions of activities to an impacting factor are uncertain or not well known, a qualitative evaluation is made.

For some resource areas (e.g., water and aquatic resources), the contributions of ongoing actions within a region to cumulative impacts are regulated and monitored through a permitting process (e.g., NPDES) under State or Federal authority. In these cases, it may be assumed that cumulative impacts are managed as long as these actions (facilities) are in compliance with their respective permits.

The following sections describe the environmental resource areas that could be affected by past, present, and reasonably foreseeable future actions that, combined with the effects of the proposed license renewal action, could result in cumulative impacts. For the most part, environmental conditions in the vicinity of nuclear power plants are not expected to change during the license renewal term much beyond what is currently being experienced. Cumulative impacts are considered a Category 2 issue requiring a plant-specific analysis as part of the license renewal environmental review.

4.13.1 Air Quality

Regional air quality conditions could deteriorate from the cumulative effects of emissions associated with past, present, and reasonably foreseeable urban, industrial, commercial, agricultural, and transportation development. These activities give rise to dust, exhaust, and evaporative emissions that degrade air quality. The magnitude of cumulative impacts would depend on the location of the nuclear power plant and the number, type, and intensity of development within the airshed and its location relative to air quality nonattainment areas.

4.13.2 Noise

Noise levels in the vicinity of a nuclear power plant could increase from planned activities associated with urban, industrial, and commercial development. The magnitude of cumulative impacts would depend on a nuclear plant's proximity to other noise sources.

4.13.3 Geology and Soils

Cumulative impacts on geologic resources relate to issues concerning access to mineral or energy resources, destruction of unique geologic features, and mass movement induced by construction activities. These impacts typically result from land disturbance activities (e.g., earthmoving, blasting, grading, and excavation) associated with urban development, industrial and commercial development, water projects, and transportation development. Existing land uses may also affect the access to mineral or energy resources. Impacts on soil resources relate to increases in the potential for soil erosion, which also occurs as a result of land disturbance activities. Vegetation clearing and grading can increase the potential for soil erosion in the absence of soil erosion protection measures. The magnitude of cumulative impacts would depend on the nature and location of the actions and whether appropriate mitigation measures are implemented to reduce the impacts.

4.13.4 Surface Water Resources

Cumulative impacts on surface water resources relate to issues concerning water use and quality. Impacts typically result from activities (e.g., water withdrawal, effluent discharges, accidental spills and releases) associated with urban development, industrial and commercial development, agricultural development, water projects (e.g., dredging), and grazing. Short-duration construction projects (e.g., road construction) can also result in surface water impacts if they increase soil erosion, which, in turn, increases sediment loading to nearby surface water bodies. The magnitude of cumulative impacts would depend on the nature and location of the actions relative to surface water bodies, the number of actions (facilities or projects), and whether facilities comply with regulating agency requirements (e.g., permitted discharge limits).

Perhaps the most important source of surface water impacts is the withdrawal of water for plant cooling systems (both once-through and closed-cycle). These impacts relate to water use conflicts with other users. Although once-through systems return most of their withdrawn water (minus evaporative losses of less than 3 percent), surface water withdrawals for closed-cycle cooling systems can have significant impacts. This is because consumptive losses are much higher (up to 60 percent), resulting in the return of less water (see Section 4.5). These impacts may be greater during times of drought, especially when temperatures are high.

4.13.5 Groundwater Resources

Cumulative impacts on groundwater resources relate to issues concerning water use and quality. Impacts typically result from the water demands associated with urban, industrial and commercial, and agricultural development. Short-duration construction projects could also result in groundwater impacts over time (e.g., from spills), unless BMPs (e.g., spill prevention and control plans and spill containment measures) are employed. The magnitude of cumulative impacts would depend on the number of actions (facilities or projects) that withdraw water from the aquifer, the overall demand on the aquifer, the hydrogeologic characteristics of the aquifer, and whether facilities follow BMPs to protect groundwater resources from degradation and overpumping.

4.13.6 Ecological Resources

Cumulative impacts on terrestrial habitats and wildlife include habitat loss and degradation, disturbance and displacement, injury and mortality, and obstruction of movement. Impacting factors include exposure to elevated noise levels and contaminants, altered surface water and groundwater quality and flow patterns, and hazards associated with direct contact with physical structures (e.g., bird collisions with buildings and other structures). Adverse impacts typically result from activities (e.g., construction) associated with urban sprawl, industrial and commercial development, agricultural development, transportation development, water projects, and regional tourism and recreation. Migratory species may be affected by activities carried out in locations remote from the nuclear plant sites. Plant communities (including floodplain and wetland communities) also may be affected by activities (e.g., clearing and grading) associated with these actions, creating conditions that favor the encroachment of invasive species. The magnitude of cumulative impacts resulting from all actions taking place within the region in which a power plant is located would depend on the nature and location of the actions relative to important wildlife habitats and plant communities, the number (and density) of actions, and the extent to which these actions (facilities or projects) employ mitigation measures to minimize such impacts.

Three scales of cumulative impacts on aquatic resources can be identified: (1) cumulative impacts due to the various impacts from an individual power plant (e.g., entrainment, impingement, thermal discharges, and chemical discharges), (2) cumulative impacts due to closely sited power plants, and (3) cumulative impacts due to multiple activities that affect the water body (e.g., dams, agriculture, urban, and industrial development) (York et al. 2005). Cumulative impacts on aquatic habitats and species include the (1) loss and degradation of habitat; (2) species disturbance, displacement, injury, and mortality; (3) obstruction of movement; and (4) the introduction and spread of invasive species. These impacts result from activities (e.g., increased water use and discharges to natural water bodies, increased and contaminated runoff) associated with urban sprawl; industrial, commercial, agricultural, and transportation development; water projects; and regional tourism and recreation. The magnitude of cumulative impacts would depend on the nature and location of the actions relative to important water bodies, the number (and density) of actions, and the extent to which these actions (facilities or projects) employ mitigation measures to minimize such impacts.

4.13.7 Historic and Cultural Resources

Cumulative impacts on historic and cultural resources relate to the damage or destruction of historic and cultural resources (i.e., archaeological sites, historic structures, and traditional cultural properties, or their context). These impacts typically result from land disturbance (e.g., earthmoving, blasting, grading, and excavation) or maintenance activities associated with urban, industrial and commercial, agricultural, and transportation development (e.g., vegetation clearing). Such activities may directly damage or destroy cultural artifacts or increase the potential for their exposure by accelerating erosion, leaving them vulnerable to theft and vandalism. The magnitude of cumulative impacts would depend on the nature and location of the actions and whether appropriate mitigation measures (in consultation with the SHPO) are implemented.

4.13.8 Socioeconomics

Employment and income are generated by the construction and operation of new industries, including the construction of new nuclear power plants, which can have a significant cumulative socioeconomic effect. Income generated by wages, salaries, and the increased demand for services creates additional demand for goods, public services, and housing. Employment in new industries increases the size of the population and the demand for public services, housing, and transportation. The magnitude of cumulative impacts would depend on the location of the existing nuclear power plant subject to license renewal and the number, type, and intensity of industrial development within the region of impact.

4.13.9 Human Health

Cumulative human health impacts relate to public exposure to radiological, chemical, and microbiological hazards and the potentially chronic effects of EMF exposure. Public exposures may occur as a result of environmental accumulations of harmful constituents released from various facilities associated with urban development, agriculture, and industrial and commercial development. The cumulative impacts of EMF exposure, while uncertain, would relate to activities (e.g., transmission lines and substations) associated with urban, industrial, and commercial development.

The magnitude of cumulative impacts would depend on the nature and location of the actions, the number of actions (facilities or projects), the level of the public's exposure, and whether facilities comply with regulating agency requirements (e.g., permitted discharge limits).

4.13.10 Environmental Justice

Cumulative impacts can result when impacts on various individual resources (air, land, water, and ecology) combine to produce human health and environmental impacts that could be cumulatively high and adverse. Whether these impacts are disproportionately high and adverse to minority and low-income populations depends on the unique characteristics of these populations residing in the vicinity of the nuclear power plant. Potentially adverse human health and environmental impacts from activities associated with industrial, commercial, agricultural, and transportation development can affect the resources on which these populations depend (e.g., fish, game animals, and native vegetation).

4.13.11 Waste Management and Pollution Prevention

Radioactive Waste—There are facilities other than the commercial nuclear power reactors and other uranium fuel cycle facilities that generate radioactive waste. Depending on the locations of these facilities and the locations of treatment and disposal facilities, there could be cumulative impacts resulting from the cumulative effects of transportation, treatment, and disposal activities. However, some nuclear power plants are likely to be the only significant generators of radioactive waste within the region. As a result, the cumulative impacts from radioactive waste management and pollution prevention would be similar to the impact from the overall incremental contribution of license renewal, as discussed in Sections 4.11.1 and 4.12.1.1.

Other Wastes—Waste-generating facilities must comply with Federal and State regulations in terms of storage, treatment, and disposal. In addition, facilities must employ procedures that ensure the proper handling and storage of wastes and monitoring for releases.

4.13.12 Global Climate Change

Global climate change is a global problem resulting from emissions of GHGs both within and beyond the region in which a power plant is located. Changes in climate over the license renewal term have the potential to contribute significantly to cumulative impacts on air and water resources, ecological resources, and human health as a consequence of changes in precipitation, temperature, frequency and severity of storms, sea level, floods, and droughts. Climate change observations and future climate scenarios are documented in reports developed by the U.S. National Oceanic Atmospheric Administration (NOAA 2013) and Intergovernmental Panel on Climate Change (IPCC 2007). The direction and nature of these changes are predicted to vary widely across the country and the regions in which operating nuclear power plants exist. Such effects are documented in the U.S. Global Change Research Program state of knowledge report, *Global Climate Change Impacts in the United States* (USGCRP 2009).

4.14 Resource Commitments Associated with the Proposed Action

This section addresses the resources that would be committed under the proposed action. In particular, it describes unavoidable adverse environmental impacts (Section 4.14.1), the relationship between short-term uses of the environment and the maintenance and enhancement of long-term productivity (Section 4.14.2), and the irreversible and irretrievable commitment of resources (Section 4.14.3) that would be associated with the proposed action (license renewal). Potential unavoidable adverse environmental impacts and irreversible and irretrievable resource commitments that would be associated with alternatives to the proposed action are also discussed.

4.14.1 Unavoidable Adverse Environmental Impacts

Unavoidable adverse environmental impacts are impacts that would occur after implementation of all feasible mitigation measures. Continued nuclear power plant operations and the implementation of any of the replacement power alternatives considered in this GEIS would result in some unavoidable adverse environmental impacts.

The impacts of continued nuclear power plant operations that are anticipated to occur are discussed for each resource area in Sections 4.1 through 4.11. Some of these impacts cannot be avoided because they are inherently associated with nuclear power plant operations and cannot be fully mitigated. Minor unavoidable adverse impacts on air quality would occur due to emission and release of various chemical and radiological constituents into the environment from plant operations. Nonradiological emissions are expected to comply with EPA emissions standards, though the alternative of operating a fossil-fueled power plant in some areas may worsen existing air quality attainment issues. Routine chemical and radiological emissions would not exceed the National Emission Standards for Hazardous Air Pollutants. Other unavoidable adverse impacts (depending on the plant) include the impact on land use and visual resources, some minor noise effects, surface water and groundwater use, thermal effluents emitted to the environment from the power conversion equipment, and entrainment and impingement of aquatic organisms in the cooling water system.

During nuclear power plant operations, workers and members of the public would face unavoidable exposure to radiation and hazardous and toxic chemicals, but releases would be controlled and the resulting exposures would not exceed any standards or regulatory limits. Workers would be exposed to radiation and chemicals associated with routine plant operations and the handling of nuclear fuel and waste material. Workers would have a higher risk of exposure than members of the public, but doses would be administratively controlled and would not exceed any standards or administrative control limits. Construction and operation of alternative replacement power energy generating facilities would also result in unavoidable exposure to hazardous and toxic chemicals to workers and the general public.

Also unavoidable would be the generation of spent nuclear fuel and waste material, including LLW, hazardous waste, and nonhazardous waste. Hazardous and nonhazardous wastes would also be generated at non-nuclear power generating facilities. Wastes generated during plant operations would be collected, stored, and shipped for suitable treatment, recycling, or disposal in accordance with applicable Federal and State regulations. Due to the costs of handling these materials, power plant operators would be expected to conduct all activities and optimize all operations in a way that generates the smallest amount of waste practical. Although pollution prevention and waste minimization efforts are intended to prevent emissions to the environment and prevent and/or minimize the quantities of waste generated, some waste and emissions cannot be entirely eliminated due to current technology.

Many of these unavoidable impacts are being mitigated by incorporating safety features and/or applying operational procedures at the plants and are monitored by the plant owners and State agencies. Thermal, entrainment, and impingement impacts at plants with once-through cooling water systems are unavoidable. However, these impacts could be reduced by modifying the once-through cooling system or by converting to a closed-cycle cooling system. Although closed-cycle cooling water systems can reduce thermal, entrainment, and impingement impacts, they increase water consumption (through cooling tower evaporation), fogging, icing, and salt drift.

Nuclear power plants being considered for license renewal already exist and have been operating for decades. The environmental impacts considered for license renewal are those associated with continued nuclear power plant operation and refurbishment. Replacement power and other alternatives to license renewal generally involve major construction impacts.

Therefore, unavoidable adverse impacts of a replacement power alternative could be greater than those associated with the continued operation of an existing nuclear power plant.

Unavoidable adverse impacts would vary among the nuclear power plants, and the scale of the impact would depend on the specific characteristics of each power plant and its interaction with the environment. These unavoidable adverse impacts are evaluated in plant-specific SEISs.

4.14.2 Relationship between Short-Term Use of the Environment and Long-Term Productivity

The operation of power generating facilities would result in short-term uses of the environment as described earlier in this Chapter. "Short term" is the period of time during which continued power generating activities would take place.

Power plant operations would necessitate short-term use of the environment and commitments of resources and would also commit certain resources (e.g., land and energy) indefinitely or permanently. Certain short-term resource commitments would be substantially greater under most energy alternatives, including license renewal, than under the no-action alternative due to the continued generation of electrical power as well as continued use of generating sites and associated infrastructure. During operations, all energy alternatives would entail similar relationships between local short-term uses of the environment and the maintenance and enhancement of long-term productivity.

Short-term use of the environment can affect long-term productivity of the ecosystem if that use alters the ability of the ecosystem to reestablish an equilibrium that is comparable to that of its original condition. An initial commitment regarding the trade-off between short-term use and long-term productivity at a nuclear power plant was made when the power plant was first constructed decades ago. Renewal of the operating license and the continued operation of the nuclear power plant would not alter any existing effects on long-term productivity, but they might postpone the availability of the power plant site for other uses. The no-action alternative would lead to a cessation of operations and shutdown of the power plant (an eventuality regardless of whether or not a license is renewed).

Air emissions from power plant operations would introduce small amounts of radiological and nonradiological constituents to the region around the plant site. Over time, these emissions could result in increased concentrations and exposure but are not expected to impact air quality or radiation exposure to the extent that public health and long-term productivity of the environment would be impaired.

Continued employment, expenditures, and tax revenues generated during power plant operations would directly benefit local, regional, and State economies over the short term.

Local governments investing project-generated tax revenues into infrastructure and other required services could enhance economic productivity over the long term.

The management and disposal of spent nuclear fuel, LLW, hazardous waste, and nonhazardous waste would require an increase in energy and would consume space at treatment, storage, or disposal facilities. Regardless of the location, the use of land to meet waste disposal needs would reduce the long-term productivity of the land.

Power plant facilities would be committed to electricity production over the short term. After decommissioning these facilities and restoring the power plant site, the land would become available for other productive uses.

The nature of the relationship between short-term use of the environment and long-term productivity would vary among plants and would depend on the specific characteristics of each plant and its interaction with the environment. This relationship is evaluated in plant-specific SEISs.

4.14.3 Irreversible and Irretrievable Commitment of Resources

Irreversible and irretrievable commitment of resources for electrical power generation would include the commitment of land, water, energy, raw materials, and other natural and manmade resources required for power plant operations during the license renewal term and any refurbishment activities that might be carried out that would not otherwise have taken place if the operating licenses had not been renewed. This section describes the irreversible and irretrievable commitments of resources that have been identified in this GEIS. A commitment of resources is irreversible when primary or secondary impacts limit the future options for a resource. An irretrievable commitment refers to the use or consumption of resources neither renewable nor recoverable for future use. In general, the commitment of capital, energy, labor, and material resources would also be irreversible.

Resources include materials and equipment required for nuclear power plant maintenance and operation, energy and water needed to run the plants, the nuclear fuel used by the reactors to generate electricity, and the land required to permanently dispose of the radioactive and nonradioactive wastes. Some of these resources could be retrieved and reused at the end of the license renewal term. For example, some reactor equipment can be used at other reactors or can be decontaminated and released for recycling or restricted or unrestricted use by others. However, some of the equipment and irradiated components that might be replaced during the license renewal term might not be reused or recycled and therefore need to be permanently disposed of. In addition, the fossil fuels used by power plants would be permanently lost. Most of the water used by power plants relying on once-through cooling is returned to the surface water bodies that supply the cooling water. The relatively small portion of the water that evaporates to the air would be lost to the local water bodies and the region but would be returned to the environment as part of the hydrologic cycle, potentially within another watershed. For closed-cycle cooling systems, a much larger percent of the water used for cooling would be lost to evaporation, but that, too, would be returned as part of the hydrologic cycle.

The most significant irreversible and irretrievable commitment of resources related to nuclear power plant operations during the license renewal term would be the nuclear fuel used to generate electricity and the land used to dispose and store wastes, including spent nuclear fuel generated during the license renewal term. The treatment, storage, and disposal of LLW, hazardous waste, and nonhazardous waste would require the irretrievable commitment of energy and fuel and could result in the irreversible commitment of space in disposal facilities. Some of the land used for the disposal of LLW may be available for other uses in a few hundred years because of the nearly complete decay of short-lived radionuclides in LLW, but most of the land used for the disposal of some mixed or hazardous wastes could be permanently lost to other users.

The irreversible and irretrievable commitment of resources would not be the same for all nuclear power plants and would depend on the specific characteristics of the power plant and its resource needs. This commitment is evaluated in plant-specific SEISs.

The implementation of any of the replacement power alternatives would entail the irreversible and irretrievable commitment of energy, water, chemicals, and, in some cases, fossil fuels. These resources would be committed over the entire life cycle of the power plant from construction, operation, and decommissioning, and would essentially be unrecoverable.

Energy expended would be in the form of fuel for equipment, vehicles, and power plant operations and electricity for power plant construction and facility operations. Electricity and fuels would be purchased from offsite commercial sources. Water would be obtained from existing water supply systems. These resources are generally available, and the amounts required are not expected to deplete available supplies or exceed available system capacities.

The irreversible and irretrievable commitment of material resources are the materials that cannot be recovered or recycled, materials that are rendered radioactive and/or cannot be decontaminated, and materials consumed or reduced to unrecoverable forms of waste. However, none of the resources used by these alternative replacement power generating facilities is in short supply, and, for the most part, readily available.

Various materials and chemicals, including acids and caustics, would be required to support operations activities. These materials would be derived from commercial vendors, and their consumption is not expected to affect local, regional, or national supplies.

Independent spent fuel storage installation (ISFSI): An ISFSI is designed and constructed for the interim storage of spent nuclear fuel and other radioactive materials associated with spent fuel storage. ISFSIs may be located at the site of a nuclear power plant or at another location. The most common design for an ISFSI, at this time, is a concrete pad with dry casks containing spent fuel bundles. ISFSIs are used by operating plants that require increased spent fuel storage capability because their spent fuel pools have reached capacity.

In situ: In its original place.

Integrated gasification combined cycle (IGCC) technology: An energy generation technology in which coal, water, and oxygen are fed to a gasifier, which produces syngas. This medium-Btu gas is cleaned (particulates and sulfur compounds removed) and fed to a gas turbine. The hot exhaust of the gas turbine and heat recovered from the gasification process is routed through a heat-recovery generator to produce steam, which drives a steam turbine to produce electricity.

Internal dose: That portion of the dose equivalent received from radioactive material taken into the body.

Ionizing radiation: Any radiation capable of displacing electrons from atoms or molecules, thereby producing ions. Some examples are alpha, beta, gamma, x-rays, neutrons, and ultraviolet light. High doses of ionizing radiation may produce severe skin or tissue damage.

Isotopic enrichment: A process by which the relative abundance of the isotopes of a given element is altered, thus producing a form of the element that has been enriched in one particular isotope and depleted in its other isotopic forms.

Landfill gas: Gas that is generated by decomposition of organic material at landfill disposal sites. The average composition of landfill gas is approximately 50 percent methane and 50 percent carbon dioxide and water vapor by volume. The methane percentage, however, can vary from 40 to 60 percent, depending on several factors including waste composition (e.g., carbohydrate and cellulose content). The methane in landfill gas may be vented, flared, or combusted to generate electricity or heat, or injected into a pipeline for combustion elsewhere.

Leachate: The liquid that has percolated through the soil or other medium.

License renewal: Renewal of the operating license of a nuclear power plant.

License renewal term: That period of time past the original or current license term for which the renewed license is in force. Although the length of license renewal terms can vary, they cannot exceed 20 years.

Appendix E

Environmental Impact of Postulated Accidents

E.1 Introduction

Chapter 5 of the *Generic Environmental Impact Statement for License Renewal of Nuclear Plants (*GEIS), Volumes 1 and 2 (NRC 1996, 1999)[a] assessed the impacts of postulated accidents at nuclear power plants on the environment. The postulated accidents included design-basis accidents and severe accidents (e.g., those with core damage). The impacts considered included:

- Dose and health effects of accidents (Sections 5.3.3.2 through 5.3.3.4);
- Economic impacts of accidents (Section 5.3.3.5); and
- Effect of uncertainties on the results (Section 5.3.4).

The estimated impacts were based on the analysis of severe accidents at 28 nuclear power plant sites[b] as reported in the environmental impact statements (EISs) and/or final environmental statements (FESs) prepared for each of the 28 plants in support of their operating licenses. With few exceptions, the severe accident analyses were limited to consideration of reactor accidents caused by internal events. The 1996 GEIS addressed the impacts from external events qualitatively.[c] The severe accident analysis for the 28 sites was extended to the remainder of plants whose EISs did not consider severe accidents (since such analyses were not required at the time the other plants' EISs were prepared). The estimates of environmental impact contained in the 1996 GEIS used 95th percentile upper confidence bound (UCB) estimates whenever available. This approach provides conservatism to cover

(a) The GEIS was originally issued in 1996. Addendum 1 to the GEIS was issued in 1999. Hereafter, all references to the "1996 GEIS" include the original GEIS and Addendum 1.

(b) The 28 sites are listed in Table 5.1 of the 1996 GEIS. There are a total of 44 units included in this list (at the 28 sites), but 4 of these units never operated (Grand Gulf 2, Harris 2, Perry 2, and Seabrook 2). For the purpose of this appendix, this list will be referred to as containing 28 nuclear power plants, but when mean values are calculated for this subset of nuclear power plants, all 40 units that operated are considered.

(c) See Section 5.3.3.1 of the 1996 GEIS, including a brief discussion of the external event risk assessments conducted by the staff prior to 1996, which included assessments for Zion 1 & 2, Indian Point 2 & 3, Limerick 1 & 2, Surry 1, Peach Bottom 2, and Millstone 3.

uncertainties, as described in Section 5.3.3.2.2 of the 1996 GEIS. The 1996 GEIS concluded that the probabilistically weighted impacts were small compared to other risks to which the populations surrounding nuclear power plants are routinely exposed.

The focus of this revision is on severe accidents since the impacts from design-basis accidents are SMALL and, as stated in Section E.3 of this revision, the U.S. Nuclear Regulatory Commission's (NRC's) assessment remains unchanged. Since the NRC's understanding of severe accident risk has evolved since issuance of the 1996 GEIS, this appendix assesses more recent information on severe accidents that might alter the conclusions in Chapter 5 of the 1996 GEIS. This revision considers how these developments would affect the conclusions in the 1996 GEIS and provides comparative data where appropriate. This revision does not attempt to provide new quantitative estimates of severe accident impacts. In addition, the revision only covers one initial license renewal period for each plant (as did the 1996 GEIS). Thus, the population projections, meteorology, and exposure indices used in the 1996 GEIS are assumed to remain unchanged for purposes of this analysis.

Finally, the format of this appendix follows the same format as used in Chapter 5 of the 1996 GEIS, including a discussion on uncertainties and severe accident mitigation alternatives (SAMAs).

E.2 Plant Accidents

A general description of plant accidents is contained in Section 5.2 of the 1996 GEIS. This description covered:

- The general characteristics of accidents;
- Fission product characteristics;
- Meteorological considerations;
- Exposure pathways;
- Adverse health effects;
- Avoiding adverse health effects;
- Accident experience and observed impacts;

- Mitigation of accident consequences; and

- Emergency preparedness.

This description is still valid and thus remains unchanged. Section 5.2 of the 1996 GEIS also mentions that as of 1990, there have been approximately 1,300 reactor-years of experience to support the safety of U.S. nuclear power plants. As with any technology, experience generally leads to improved plant performance and public safety. As of 2011, there has been approximately an additional 2,000 reactor-years of experience in the United States. This additional experience has contributed to improved plant performance (e.g., as measured by trends in plant-specific performance indicators), a reduction in operating events, and lessons learned that improve the safety of all of the operating nuclear power plants. Other examples of items contributing to improved safety include:

- Implementation of plant improvements identified through the Individual Plant Examination (IPE) and Individual Plant Examination: External Events (IPEEE) programs (e.g., strengthening of seismic supports; enhanced fire brigade training) (NRC 2003);

- Identification of specific aging mechanisms (e.g., cables; irradiation-assisted stress corrosion cracking) and development of programs to monitor and control these mechanisms (NRC 2001c);

- NRC staff actions on generic safety issues (e.g., Generic Safety Issue 191 on sump performance) (NRC 2008e); and

- Implementation of the NRC's Interim Compensatory Measures (ICMs) Order following the September 2001 terrorist attacks.[d]

Thus, the performance and safety record of nuclear power plants operating in the United States continues to improve. This is also confirmed by analysis which indicates that, in many cases, improved plant performance and design features have resulted in reductions in initiating event frequency, core damage frequency, and containment failure frequency.[e]

(d) The safety evaluations (SEs) for the operating license amendments associated with implementation of Section B.5.b. of Commission Order EA-02-026 provide background related to the implementation of particular portions of the ICMs. As an example, the reader is referred to the SE associated with Brunswick Steam Electric Plant, Units 1 and 2 (NRC 2007a).

(e) This statement is based on industry performance data provided in the NRC's *2007-2008 Information Digest* (NRC 2007b) and on the NRC's website (NRC 2008c), as well as information contained in Chapter 5 of site-specific EISs (the NUREG-1437 series of supplements).

E.2.1 Fukushima Earthquake and Tsunami

On March 11, 2011, a massive earthquake off the east coast of Honshu, Japan, produced a devastating tsunami that struck the coastal town of Fukushima. The six-unit Fukushima Dai-ichi nuclear power plant was directly impacted by these events. The resulting damage caused the failure of several of the units' safety systems needed to maintain cooling water flow to the reactors. As a result of the loss of cooling, the fuel overheated, and there was a partial meltdown of the fuel contained in several of the reactors. Damage to the systems and structures containing reactor fuel resulted in the release of radioactive material to the surrounding environment.

In response to the earthquake, tsunami, and resulting reactor accidents at Fukushima Dai-ichi (hereafter referred to as the "Fukushima events"), the Commission directed the staff to convene an agency task force of senior leaders and experts to conduct a methodical and systematic review of the relevant NRC regulatory requirements, programs, and processes, including their implementation, and to recommend whether the agency should make near-term improvements to its regulatory system. As part of the short-term review, the task force concluded that, while improvements are expected to be made as a result of the lessons learned from the Fukushima events, the continued operation of nuclear power plants and licensing activities for new plants do not pose an imminent risk to public health and safety (NRC 2011).

During the time that the task force was conducting its review, groups of individuals and non-governmental organizations petitioned the Commission to suspend all licensing decisions in order to conduct a separate, generic National Environmental Policy Act (NEPA) analysis to determine whether the Fukushima events constituted "new and significant information" under NEPA that must be analyzed as part of environmental reviews. The Commission found the request premature and noted, "In short, we do not know today the full implications of the [Fukushima] events for U.S. facilities."(f) However, the Commission found that if "new and significant information comes to light that requires consideration as part of the ongoing preparation of application-specific NEPA documents, the agency will assess the significance of that information, as appropriate."(g) The Federal courts of appeal and the Commission have interpreted NEPA such that an EIS must be updated to include new information only when that

(f) *Union Electric Co. d/b/a Ameren Missouri* (Callaway Plant, Unit 2), CLI-11-05, 74 NRC141, 167 (Sept. 9, 2011).
(g) *Id.*

new information provides "a seriously different picture of the environmental impact of the proposed project from what was previously envisioned."[(h)]

In the context of the GEIS, the Fukushima events are considered a severe accident (i.e., a type of accident that may challenge a plant's safety systems at a level much higher than expected) and more specifically, a severe accident initiated by an event external to the plant. The 1996 GEIS concluded that risks from severe accidents initiated by external events (such as an earthquake) could have potentially high consequences but found that external events are adequately addressed through a consideration of a severe accident initiated by an internal event (such as a loss of cooling water). Therefore, an applicant for license renewal need only analyze the environmental impacts from an internal event in order to adequately characterize the environmental impacts from either type of event. Prior to the Fukushima events, this GEIS examined more recent and up-to-date information regarding external events and concluded that the analysis in the 1996 GEIS remains valid.

As of the publication date of this GEIS, the NRC's evaluation of the consequences of the Fukushima events is ongoing. As such, the NRC will continue to evaluate the need to make improvements to existing regulatory requirements based on the task force report and additional studies and analyses of the Fukushima events as more information is learned. To the extent that any revisions are made to NRC regulatory requirements, they would be made applicable to nuclear power reactors regardless of whether or not they have a renewed license. Therefore, no additional analyses have been performed in this GEIS as a result of the Fukushima events. In the event that the NRC identifies information from the Fukushima events that constitutes new and significant information with respect to the environmental impacts of license renewal, the NRC will discuss that information in its site-specific supplemental EISs (SEISs) to the GEIS, as it does with all such new and significant information.

E.3 Accident Risk and Impact Assessment

The environmental impacts from design-basis accidents and severe accidents are assessed in Sections 5.3.2 and 5.3.3 of the 1996 GEIS, respectively. As stated in Section 5.3.2, the environmental impact from design-basis accidents was assessed in the individual plant-specific EISs at the time of the initial license application review. Since the licensee is required to

---

(h) *Id*. at 167-68 *quoting Hydro Resources, Inc.* (2929 Coors Road, Suite 101, Albuquerque, NM 87120), CLI-99-22, 50 NRC 3, 14 (1999) (citing *Marsh v. Oregon Natural Resources Council*, 490 U.S. 360, 373 (1989)). The Commission also noted that it can modify a facility's operating license outside of a renewal proceeding and made clear that "it will use the information from these activities to impose any requirement it deems necessary, irrespective of whether a plant is applying for or has been granted a renewed operating license." *Id.* at 164 *quoting Pilgrim & Indian Point:* Entergy's Answer Opposing Petition to Suspend Pending Licensing Proceedings (May 2, 2011) at 3.

maintain the plant within acceptable design and performance criteria, including during any license renewal term, these impacts are not expected to change. Therefore, additional assessment of the environmental impacts from design-basis accidents is not necessary, and the bulk of the 1996 GEIS evaluation focused on the environmental impact of severe accidents.

To assess the impacts from the airborne pathway, the 1996 GEIS relied on severe accident analyses provided in the EISs for the more recent sites. Table 5-1 in the 1996 GEIS lists the 28 nuclear power plants that included severe accident analyses in their plant-specific EISs. These plant-specific EISs used site-specific meteorology, land topography, population distributions, and offsite emergency response parameters, along with generic or plant-specific source terms, to calculate offsite health and economic impacts. The offsite health effects included those from airborne releases of radioactive material and contamination of surface water and groundwater.

The 1996 GEIS used the environmental impact information from the 28 plant-specific EISs and a metric called the exposure index to (1) scale up the radiological impact of severe accidents on the population due to demographic changes from the time the original EIS[i] was done until the year representing the mid-license renewal period and (2) estimate the severe accident environmental impacts for the earlier plants (whose EISs did not include a quantitative assessment of severe accidents). The exposure index method uses the projected population distribution around each nuclear power plant site at the middle of its license renewal period and meteorology data for each site to provide a measure of the degree to which the population would be exposed to the release of radioactive material resulting from a severe accident (i.e., the exposure index method weights the population in each of 16 sectors around a nuclear power plant by the fraction of time the wind blows in that direction on an annual basis). The exposure index metric was also used to project economic impacts at the mid-year of the license renewal period. A more detailed description of the exposure index method is contained in Appendix G of the 1996 GEIS. The use of the exposure index method remains valid.

Since 1996, developments in plant operation and accident analysis have taken place that could affect the assumptions made in the 1996 GEIS. These changes are grouped into the following areas and are each covered in the indicated section of this revision:

- Internal event risk (Section E.3.1);
- External event risk (Section E.3.2);

(i) The term “original EIS” describes an EIS issued by the NRC that is associated with the issuance of a plant’s initial operating license. This term is used in this appendix to differentiate it from an EIS prepared in conjunction with a license renewal environmental review.

- Updates in the quantification of accident source terms (Section E.3.3);
- Increases in licensed reactor power levels, i.e., power uprates (Section E.3.4);
- Increases in fuel burnup levels (Section E.3.5);
- Consideration of reactor accidents at low power and shutdown conditions (Section E.3.6);
- Consideration of accidents in spent fuel pools (Section E.3.7); and
- The BEIR VII report on the risk of fatal cancers posed by exposure to radiation (Section E.3.8).

Sections discussing uncertainties, SAMAs, and conclusions are also provided.

As discussed in the Section 5.3.3.1 of the 1996 GEIS, the environmental impacts from security-related events were not considered in that document. As stated, these types of events are addressed via deterministic criteria in Title 10, Part 73, of the *Code of Federal Regulations* (10 CFR Part 73), rather than by risk assessments. The regulatory requirements under 10 CFR Part 73 provide reasonable assurance that the risk from sabotage is small. This section goes on to state:

> Although the threat of sabotage events cannot be accurately quantified, the Commission believes that acts of sabotage are not reasonably expected. Nonetheless, if such events were to occur, the Commission would expect that resultant core damage and radiological releases would be no worse than those expected from internally initiated events.

The NRC continues to take this position. As a result of the terrorist attacks of September 11, 2001, the NRC conducted a comprehensive review of the agency's security program and made further enhancements to security at a wide range of NRC-regulated facilities. These enhancements included significant reinforcement of the defense capabilities for nuclear facilities, better control of sensitive information, enhancements in emergency preparedness to further strengthen NRC's nuclear facility security program, and implementation of mitigating strategies to deal with postulated events potentially causing loss of large areas of the plant due to explosions or fires, including those that an aircraft impact might create. These measures are outlined in greater detail in NUREG/BR-0314 (NRC 2004), NUREG-1850 (NRC 2006a), and Sandia National Laboratory's "Mitigation of Spent Fuel Loss-of-Coolant Inventory Accidents and Extension of Reference Plant Analyses to Other Spent Fuel Pools" (NRC 2006b).

The NRC routinely assesses threats and other information provided by a variety of Federal agencies and sources. The NRC also ensures that licensees meet appropriate security-level requirements. The NRC will continue to focus on prevention of terrorist acts for all nuclear facilities and will not focus on site-specific evaluations of speculative environmental impacts resulting from terrorist acts. While these are legitimate matters of concern, the NRC will continue to address them through the ongoing regulatory process as a current and generic regulatory issue that affects all nuclear facilities and many of the activities conducted at nuclear facilities. The issue of security and risk from malevolent acts at nuclear power facilities is not unique to facilities that have requested a renewal of their licenses (NRC 2006a).

Malevolent acts remain speculative and beyond the scope of a NEPA review. NEPA requires that there be a "reasonably close causal relationship" between the federal agency action and the environmental consequences. The environmental impact of a terrorist attack is too far removed from the natural, or expected, consequences of a license renewal action to warrant consideration under NEPA. However, as noted above, in the event of a terrorist attack, the consequences of such an attack would be no worse than an internally initiated severe accident, which has already been analyzed.

In a decision dated June 2, 2006, *San Luis Obispo Mothers for Peace v. NRC*, 449 F.3d 1016, 1028 (9th Cir. 2006) the U.S. Court of Appeals for the Ninth Circuit held that NRC could not categorically refuse to consider the consequences of a terrorist attack under NEPA and remanded the case to NRC. On remand, the Commission adjudicated the intervenors' claim that the NRC staff had not adequately assessed the environmental consequences of a terrorist attack on the Diablo Canyon Power Plant's proposed facility for storing spent nuclear fuel in dry casks. *See, Pacific Gas & Electric Co.,* (Diablo Canyon Power Plant Independent Spent Fuel Storage Installation), CLI-08-26, 68 NRC 509 (2009). The Commission ultimately determined that an EIS was not required in order to address land contamination and latent health effect issues (Diablo Canyon, CLI-08-26, 68 NRC at 521). Further, the Commission concluded that the staff's final, supplemental environmental assessment and finding of no significant impact, the adjudicatory record of the case, and its supervisory review of the non-public information underlying portions of the staff's analyses, satisfied the agency's NEPA obligations. *Id.* 525-26. The staff had found that even the most severe, plausible terrorist attack of those examined would not cause immediate or latent health effects. The staff also found that such an attack was improbable, but if one occurred, the likelihood of significant radioactive release was very low because the nature of the Diablo Canyon casks and site. *Id.* at 521. The U.S. Court of Appeals for the Ninth Circuit upheld the Commission's determination on appeal. *San Luis Obispo Mothers for Peace v. NRC*, 645 F.3d 1109, 1120-21 (9th Cir. 2011).

The Commission stated that it will adhere to the Ninth Circuit decision when considering licensing actions for facilities subject to the jurisdiction of that Circuit. *See Pacific Gas and Electric Co., (Diablo Canyon Power Plant Independent Spent Fuel Storage Installation*), CLI-07-11, 65 NRC 118 (2007). However, the Commission decided against applying that holding to all licensing proceedings nationwide. In one such proceeding, *Amergen Energy Co. LLC* (Oyster Creek Nuclear Generating Station), CLI-07-8, 65 NRC 124, 128-29 (2007), the New Jersey Department of Environmental Protection contended that NEPA requires an analysis of a terrorist attack. The NRC found that NEPA "imposes no legal duty on the NRC to consider intentional malevolent acts" because such acts are "too far removed from the natural or expected consequences of agency action." *Id.* at 129 (quoting the Board decision). The NRC also found that a terrorism review would be redundant because (1) "the NRC has undertaken extensive efforts to enhance security at nuclear facilities," which it characterized as the best mechanism to protect the public; *id.* at 130; (2) the GEIS had addressed the issue and concluded that "the core damage and radiological release from [terrorist] acts would be no worse than the damage and release to be expected from internally initiated events." On appeal, the Third Circuit agreed with the NRC and denied the petition. *See NJDEP v. NRC and Amergen Energy Co, LLC,* (Case No. 07-2271), 561 F.3rd 132 (3rd Cir. 2009). The Court found that, "the NRC correctly concluded that the relicensing of Oyster Creek does not have a 'reasonably close causal relationship' with the environmental effects that would be caused in the event of a terrorist attack." 561 F.3d at 143.

The Third Circuit disagreed with the Ninth Circuit's application of the relevant Supreme Court decisions. Instead, as the Commission had originally held, the Third Circuit concluded that the issuance of a facility license—here, the issuance of the 20-year extension for the Oyster Creek license—would not be the "proximate cause" of a terrorist attack on the facility.

Moreover, the Third Circuit noted that the GEIS for License Renewal had reviewed the possible impacts of a sabotage event, which is a form of terrorism. The GEIS found that the consequences of a sabotage event would be no worse than those expected from an internally initiated severe accident. The Third Circuit noted that the petitioner in the case before it (the State of New Jersey) had failed to demonstrate that the results of a terrorist attack would be any different than those of a severe accident, which had already been analyzed. The Third Circuit also noted that the NRC had prepared a site-specific EIS addressing the mitigation of severe accidents at Oyster Creek. As a result, the Third Circuit found that, even if the Commission were required to analyze the impacts of a terrorist attack, the NRC had prepared both generic and site-specific analyses of the impacts of a terrorist attack at Oyster Creek, and that the Petitioner had not shown that the NRC could evaluate the risks more meaningfully than it had already done.

Subsequent to the Third Circuit's determination, the Commission overturned the Board's decision to admit a NEPA terrorism contention in the Diablo Canyon License Renewal proceeding, a facility located in the Ninth Circuit. *Pacific Gas & Electric Co.* (Diablo Canyon Nuclear Power Plant), CLI-11-11, 74 NRC (slip op. at 40) (2011). The Commission reaffirmed that "the staff's determination in the GEIS that the environmental impacts of a terrorist attack were bounded by those resulting from internally-initiated events, was sufficient to address the environmental impacts of terrorism." *Id*.

In sum, the Commission has found that the issuance of a facility license is not the "proximate cause" of a terrorist attack at that facility. Thus, it is not required to prepare an EIS discussion on the potential impacts of a terrorist attack. However, due to the decision of the Ninth Circuit, the NRC will prepare an analysis of the environmental impacts of a terrorist attack for licensing actions of facilities within the geographical boundaries of the Ninth circuit. In addition, the Third Circuit has held that the GEIS for License Renewal constitutes such an analysis for license renewals.

E.3.1 Impact of New Information on Accidents Initiated by Internal Events

With few exceptions, the severe accident analyses formulating the basis for the 1996 GEIS were limited to consideration of reactor accidents caused by internal events. The GEIS addressed the impacts from external events qualitatively, and external events are covered in more detail in Section E.3.2 of this revision. The impacts from the 1996 GEIS were based on the original license EISs for the 28 nuclear power plant sites listed in Table 5.1 of the GEIS. The source terms and their likelihood used in the plant-specific original EISs to calculate the airborne pathway environmental impacts of accidents were, in turn, usually based upon information contained in NUREG-0773 (NRC 1982). NUREG-0773 is an update of the original Reactor Safety Study (NRC 1975). These source terms and frequencies were used along with site-specific meteorology, population distributions, and emergency planning characteristics to calculate the airborne pathway environmental impacts. These EISs were issued in the 1981 to 1986 time frame. Thus, while the GEIS was published in 1996, it was primarily based on information from the 1980s.

Since the publication of NUREG-0773, many additional studies have been completed on the likelihood and consequences of reactor accidents initiated by internal events at full power. These studies include NUREG-1150 (NRC 1990b), NUREG/CR-5305 (NRC 1992), and licensee responses to Generic Letter 88-20, Supplement 1 (i.e., the IPE program). Licensees have further developed their IPE-vintage probabilistic risk assessment (PRA) models to support risk-informed licensing actions, including license renewal SAMA analysis. In addition, the NRC has developed standardized plant analysis risk (SPAR) models for all operating plants which can be used to calculate core damage frequencies (CDFs) for internal events.

The purpose of this section is to assess how results from more up-to-date internal event information compare to those on which the 1996 GEIS was based. The evaluation contained in this section compares the CDFs that formed the basis for the 1996 GEIS, and offsite doses directly from the 1996 GEIS, to the newer information. The comparison is done for pressurized water reactors (PWRs) and boiling water reactors (BWRs) and covers each of the plants listed in Table 5.1 of the 1996 GEIS. Changes in source terms (i.e., the quantity, form, and timing of radioactive material released to the environment) are assessed in Section E.3.3.

E.3.1.1 Airborne Pathway Impacts

As a first step in the comparison, the CDFs from the original EISs are compared to the CDFs reported in the plant-specific IPEs for the PWRs and BWRs considered by the 1996 GEIS. Tables E-1 and E-2 show these comparisons. As can be seen in Tables E-1 and E-2, for many plants, the IPE CDFs are smaller than those from the original EISs, particularly for BWRs. The mean of the IPE CDFs listed in Tables E-1 and E-2 are lower than the corresponding mean EIS CDF by 30 percent for PWRs and by more than a factor of 3 for BWRs. Accordingly, the likelihood of an accident that leads to core damage would be comparable to or less for PWRs, and significantly less for BWRs, than that used as the basis for the 1996 GEIS.

Additional comparisons can be made using information from NUREG-0773 (NRC 1982), the original EISs, NUREG-1150 (NRC 1990b), the IPEs, NUREG/CR-5305 (NRC 1992), recent analysis using SPAR models, and license renewal applications received to date. These comparisons are shown in Table E-3. In general, the Level 1 (CDF) results are comparable to or less than the corresponding Level 1 information from the GEIS. Furthermore, the newer estimates (license renewal and SPAR) are up to a factor of 2.5 lower than the mean IPE CDFs from Tables E-1 and E-2.

The comparison of Level 3 (offsite consequences) information is made difficult due to differences in the values reported between older and newer assessments. Older assessments tended to provide mean and/or upper bound population doses for the entire region surrounding the nuclear power plant (as far as 1000 mi). Newer assessments tend to provide mean values within 50 mi. NUREG-1150 provided distributions for both within 50 mi and the site region and is used as a bridge in this comparison.

The mean of population dose results from the original EISs of the 28 sites that considered severe accidents are a factor of 2 to 4 lower than the mean of the plant-specific upper bound estimates used in the 1996 GEIS for those same 28 sites. The mean population doses from NUREG-1150 (site region results) are, in turn, a factor of 10 to 100 less than the original EIS mean value. In actuality, the difference is even larger, because the NUREG-1150 estimate covers a larger area (site region for NUREG-1150 versus 150 mi for the EISs). The NUREG-1150 results for a 50-mi radius are a factor of 4 to 10 lower than the site region results. The mean of license renewal results (for a 50-mile region) are somewhat higher than the mean results reported in NUREG-1150 for a 50-mile region, but are still well below the population dose values reported in the original environmental impact statements for the 28 sites and used in the 1996 GEIS.

Table E-1. PWR Internal Event (Full Power) Comparison

Plant	Original EIS Estimated CDF[a]	IPE CDF[b]

Wolf Creek 1	4.8×10^{-5}/yr	4.2×10^{-5}/yr
Mean value	8.4×10^{-5}/yr	5.9×10^{-5}/yr
Median value	4.8×10^{-5}/yr	4.9×10^{-5}/yr

(a) Obtained by summing individual atmospheric release sequences, including intact containment sequences.
(b) Source: NRC 2003, unless otherwise noted.
(c) Obtained from the licensee's IPEEE submittal.

To summarize, the general contribution to decreased estimated doses are a factor of 2 to 4 simply due to the conservatism built into the 1996 GEIS values. An additional decrease in estimated doses of 10 to 100 is seen when comparing the EIS results to the NUREG-1150 results and a factor of 5 to 33 when comparing the EIS results to license renewal SAMA results.

E.3.1.2 Other Pathway Impacts

Any change in the likelihood of accidents that release substantial amounts of radioactive material to the environment not only affects the airborne pathway, but also the surface water and groundwater pathways and the resulting economic impacts from any pathway. The information in Tables E-1, E-2, and E-3 indicate that the likelihood and impacts of airborne pathway releases is smaller than that used in the 1996 GEIS. Since this pathway directly

Table E-2. BWR Internal Event (Full Power) Comparison

Plant	Original EIS Estimated CDF[a]	IPE CDF[b]

Mean value	5.4×10^{-5}/yr	1.5×10^{-5}/yr
Median value	2.4×10^{-5}/yr	1.45×10^{-5}/yr

(a) Obtained by summing individual atmospheric release sequences, including intact containment sequences.
(b) Source: NRC 2003, unless otherwise noted.
(c) Revised 1998 IPE; obtained from NUREG-1437, Supp. 35, Appendix G.
(d) WNP-2 = Washington Nuclear Project 2 (i.e., Columbia).

affects the surface water pathway, it is reasonable to conclude that the likelihood of the surface pathway impacts would also be smaller and would continue to be bounded by the airborne pathway. The decreased likelihood of any pathway impacts would indicate the reduced likelihood of any subsequent economic impacts. This assumption is consistent with the results of the 1996 GEIS.

Furthermore, some information is available regarding basemat melt-through sequences, which could impact the groundwater pathway:

- WASH-1400 (NRC 1975) used a frequency of 4×10^{-5}/yr for basemat melt-through sequences;
- NUREG-0773 (NRC 1982) used a generic frequency of 3×10^{-5}/yr and a site-specific frequency of 1.1×10^{-5}/yr for Indian Point Units 2 and 3;
- NUREG-1150 (NRC 1990b) calculated the basemat melt-through frequencies for Surry and Sequoyah to be 2.4×10^{-6}/yr and 1×10^{-5}/yr, respectively;

		- LaSalle	4×10^{-5}/yr	1,500[f]	66[e]
		IPE			
		- Peach Bottom	5.5×10^{-6}/yr		
		- LaSalle	4.7×10^{-5}/yr		
		- Grand Gulf	1.7×10^{-5}/yr		

Reactor Type	Comparison	Information Source	CDF (mean/point estimate)	Person-Rem per Year (Mean, except as noted)	
				Region[a]	50-mi
		License Renewal[e]	1.4×10^{-5}/yr		14.5
		SPAR (v3.45)[b]	8×10^{-6}/yr		

(a) For the EISs and GEIS, the employed distance is 150 mi; for NUREG-1150 and NUREG/CR-5305, the employed distance is 1,000 mi.
(b) Based on Table 22 (CDF) of that document; PWR CDF cited is for Surry and BWR corresponds to Peach Bottom.
(c) Values are for those plants listed in Tables E-1 and E-2.
(d) Note that this is the mean of the distribution of 95th percent UCB values.
(e) Mean values for all plants that have applied for license renewal as of August 2008; in a few cases (Beaver Valley, Calvert Cliffs, Ginna, and Nine Mile Point), the site-specific population dose values used included both internal and external events.
(f) Includes both internal and external events.

- A sample of IPE results showed basemat melt-through frequencies ranging from 1×10^{-6}/yr to 4×10^{-6}/yr; and

- A sample of license renewal application results showed basemat melt-through frequencies ranging from 2×10^{-7}/yr to 6×10^{-6}/yr.

For the 1996 GEIS, a conservative value of 1×10^{-4}/yr was used (see Section 5.3.3.4 of the 1996 GEIS), which is higher than any of the values cited above. As such, it is concluded that the basemat melt-through frequencies used in the 1996 GEIS to assess the groundwater pathway are bounding.

For BWRs, no quantitative basemat melt-through information was available. It is expected that for BWRs, containment failure by overpressure would occur before basemat melt-though. In addition, if basemat melt-through sequences do occur, their frequency would be less than that for PWRs due to the lower CDFs for BWRs.

E.3.1.3 Conclusion

The PWR and BWR accident frequencies that form the basis for the environmental impacts shown in the 1996 GEIS are, in most cases, comparable to or higher than the updated accident frequencies shown in Tables E-1, E-2, and E-3. In addition, the population dose estimates presented in Table E-3 demonstrate the conservatism in the 1996 GEIS values, both from the standpoint of reduced population dose from more recent estimates and the conservatism built into the GEIS methodology.

E.3.2 Impact of Accidents Initiated by External Events

The 1996 GEIS included a qualitative assessment of the environmental impacts of accidents initiated by external events (see Section 5.3.3.1 of that document). The purpose of this section is to consider updated information regarding potential external event impacts. The sources of information used in this assessment are (1) NUREG-1150 (NRC 1990b) (and the supporting documentation in NUREG/CR-4551 [NRC 1990a]), which assessed seismic and fire events for two plants (Surry and Peach Bottom); (2) NUREG/CR-5305 (NRC 1992), which analyzed the risk from seismic and fire events for one plant (LaSalle); and (3) the results from the IPEEE program, as documented in NUREG-1742 (NRC 2003). The IPEEE program was initiated in the early 1990s and required all operating plants in the United States to do an assessment to identify vulnerabilities to severe accidents initiated by external events and report the results to the NRC, along with any identified improvements and/or corrective actions. NUREG-1742 documents the perspectives derived from the technical reviews of the IPEEE results.

Typically, the external events that contribute the most to plant risk are seismic and fires. In some cases, high winds, floods, and tornados may contribute to plant risk; however, these contributions are generally much lower than those from seismic and fire events. Therefore, the assessment of the environmental impact from external events provided here focuses on seismic and fire events. This is consistent with the results obtained from the IPEEEs and the perspectives articulated in NUREG-1742.

E.3.2.1 Airborne Pathway Impacts

The assessment in this section is based upon a comparison of the risks and environmental impacts from severe accidents initiated by external events to those initiated by internal events, based on the aforementioned information sources.

Level 1 Comparison (CDF)

From the IPEEE the following insights can be drawn:

(1) For a majority of plants, fire and/or seismic events are important contributors to risk.

(2) The contributions to CDFs from fire events are comparable to the contribution to CDFs from internal events. The IPEEE CDF values for fire-initiated events are shown in Tables E-4 and E-5 along with the IPE internal event CDFs. For the plants listed in Tables E-4, the PWR fire CDF is about half the internal event CDF. For the BWR plants in Table E-5, the fire CDF is roughly 50 percent higher than the internal events CDF. Section 3.3.1.1 of NUREG-1742 (NRC 2003) provides a comparison of fire and internal events for the entire fleet of plants, and similarly concludes that BWR results are comparable, while PWR results are slightly lower for fire CDF.

However, the IPEEE fire event CDFs are much lower than the internal event CDFs from the original EISs (basis for the 1996 GEIS). The mean value of the PWR fire event CDFs in Table E-4 is one-third of the PWR internal event CDF from the EISs (see Table E-1), and the mean value of the BWR fire event CDFs in Table E-5 is less than half the BWR internal event CDF from the original EISs (see Table E-2).

(3) The contributions to CDF from seismic events are comparable to the contribution from internal events. For plants listed in Tables E-1 and E-2 that reported seismic CDFs as part of their IPEEE submittals, these CDFs are contained in Tables E-4 and E-5. Although sparse, these values suggest seismic CDFs are lower than or comparable to internal event CDFs. Section 2.6.1 of NUREG-1742 considers all reporting plants, and states that the largest group of reported seismic CDFs were in the range of 1×10^{-5} to 1×10^{-4} (same order of magnitude as the basis for the 1996 GEIS), with the next largest

Table E-4. PWR Internal, Fire, and Seismic Event CDF Comparison (Full Power)[(a)]

Plant	IPE Internal Events CDF	IPEEE Fire CDF	IPEEE Seismic CDF (EPRI/Other/Update)	IPEEE Seismic CDF (LLNL)

Table E-6. NUREG-1150 and NUREG/CR-5305 Fire and Seismic CDFs

Plant	Internal Events (mean value)	Fire Events (mean value)	Seismic Events (mean value)[(a)]	1996 GEIS Basis Internal Events (mean value)
Surry (NUREG-1150)	4×10^{-5}/yr	1.1×10^{-5}/yr	1.9×10^{-4}/yr	8.4×10^{-5}/yr[(b)]
Peach Bottom (NUREG-1150)	4.4×10^{-6}/yr	2×10^{-5}/yr	7.5×10^{-5}/yr	5.4×10^{-5}/yr[(c)]
LaSalle (NUREG/CR-5305)	4×10^{-5}/yr	5.5×10^{-5}/yr	8×10^{-7}/yr	5.4×10^{-5}/yr[(c)]

(a) Based on the LLNL seismic hazard distribution results.
(b) This value is the mean of the CDFs of all PWRs listed in Table 5.1 of the 1996 GEIS.
(c) This value is the mean of the CDFs of all BWRs listed in Table 5.1 of the 1996 GEIS.

formed the basis for the 1996 GEIS). As can be seen in this table, the NUREG-1150 and NUREG/CR-5305 fire and seismic CDFs are comparable to those supporting the 1996 GEIS, with a number of both relatively lower and higher comparisons.[j]

In support of early site permits for new reactors, the NRC staff reviewed updates to seismic source and ground motion models provided by applicants. The updates to seismic data and models could result in estimated seismic hazard levels at some current central and eastern U.S. operating sites that would be higher than seismic hazard values used in design and previous evaluations (such as the IPEEEs). Due to its relevance for other licensing actions, the issue is being pursued as part of the Generic Issues Program, as Generic Issue 199 (GI-199). A preliminary assessment performed for the affected plants as part of GI-199 indicates that the average increase in seismic CDF relative to the IPEEE-era estimates would be about 1×10^{-5} per year. However, this assessment also indicates that on average, the updated seismic CDF remains slightly (approximately 30 percent) less than the internal events CDF.

Level 3 Comparison (Offsite Consequences)

To obtain quantitative information on the airborne pathway environmental impacts of severe accidents caused by external events, IPEEE, NUREG-1150, and NUREG/CR-5305 results can be used to compare against the internal event airborne pathway impacts contained in the 1996 GEIS. The following discussion summarizes the airborne pathway environmental impact information available.

The IPEEE provided external event environmental impact information (i.e., early fatalities, latent fatalities, and population dose) for Catawba and McGuire. This information showed the impacts of external events to be much less (i.e., one to two orders of magnitude) than those estimated for internally initiated events at full power in the 1996 GEIS for Catawba and McGuire (see Table E-7). Recall that while this is a comparison of mean values versus 95 percent upper confidence bound (UCB) values, the 95 percent UCB values are the ones used for the basis of the 1996 GEIS. Thus, this comparison shows that more realistic estimates are significantly lower than the conservative estimates used in the GEIS.

(j) The NUREG-1150 values represented best-estimate values at the time they were completed. For Surry, the Lawrence Livermore National Laboratory (LLNL) NUREG-1150 curve is uniformly higher than other seismic hazard estimates (e.g., the Electric Power Research Institute [EPRI] and LLNL curves used for the IPEEEs, recent United States Geological Survey curves). For Peach Bottom, the EPRI NUREG-1150 curve is uniformly lower.

Table E-7. Catawba and McGuire Results for Internal and External Events

Impact	Catawba External Events	Catawba Internal Events	Catawba 1996 GEIS Internal Events (95 percent UCB)	McGuire External Events	McGuire Internal Events	McGuire 1996 GEIS Internal Events (95 percent UCB)
Total person-rem per year	43.6	15.6	1,880	10.7	4.6	1,806
Total early fatality risk	7.8×10^{-6}/yr	5.9×10^{-6}/yr	1.7×10^{-2}/yr	2.2×10^{-6}/yr	8.2×10^{-7}/yr	1.0×10^{-2}/yr
Total latent fatality risk	2.7×10^{-3}/yr	9.4×10^{-4}/yr	1.4/yr[(a)]	7.4×10^{-4}/yr	3.2×10^{-4}/yr	1.4/yr[(a)]

(a) These values include the factor of 10 adjustment made in the 1996 GEIS (see Section 5.3.3.2.3 of the 1996 GEIS).

Fire Events

NUREG-1150 provides quantitative information on the airborne pathway environmental impact from fires for Surry and Peach Bottom. This information is shown in Tables E-8 and E-9 along with the full power, internal event environmental impact information from NUREG-1150 and the 1996 GEIS. NUREG/CR-5305 provides similar information for LaSalle, as presented in Table E-10. Tables E-8 through E-10 present 95th percentile results for all values. As can be seen from these tables, even 95th percentile values from NUREG-1150 and NUREG/CR-5305 are significantly lower (at least by 1 order of magnitude) than the conservative values used in the 1996 GEIS.

Seismic Events

Table E-11 presents mean results from the second-tier NUREG-1150 study documentation (NUREG/CR-4551; NRC 1990a) for impacts due to seismic initiators at Surry and Peach Bottom. As can be seen from this table, the mean results from the NUREG-1150 study are, in most cases, significantly smaller than the 95th percentile estimates used in the 1996 GEIS.

E.3.2.2 Other Pathway Impacts

With respect to the other pathways (open bodies of water and groundwater), the IPEEE, NUREG-1150, and NUREG/CR-5305 analysis did not address their impacts on human health. The 1996 GEIS estimated these impacts for reactor accidents from full power (internal events only) using the results from site-specific information on surface water and groundwater areas, volumes, flow-rates, and geology to assess contamination of water by comparing the site-specific information to that used in NUREG-0440 (NRC 1978), which assessed the contamination of surface water and groundwater from reactor accidents.

Table E-8. Impacts of Accidents Caused by Fire Events (Surry)

Impact	NUREG-1150 Fire Events (95th percentile)	NUREG-1150 Internal Events (95th percentile)	1996 GEIS Internal Events (95th percentile)
Individual risk			
- EF[(a)] (1 mi)	~1.5×10^{-10}/yr	~5×10^{-8}/yr	Not available
- LF[(b)] (10 mi)	~1.5×10^{-10}/yr	~1×10^{-8}/yr	Not available
Total person-rem per year (entire region)	~2	~150	1,200
Total early fatality risk	~1×10^{-8}/yr	~4×10^{-6}/yr	1.6×10^{-2}/yr
Total latent fatality risk	~6×10^{-4}/yr	~3×10^{-2}/yr	0.9/yr

(a) EF = early fatality risk. The individual early fatality risk within one mile (1.6 km) is the frequency (per year) that a person living within one mile (1.6 km) of the site boundary will die within a year due to the accident. The entire population within one mile is considered to obtain an average value.

(b) LF = latent fatality risk. The individual latent cancer fatality risk within 10 miles (16 km) is the frequency (per year) that a person living within 10 miles (16 km) of the plant will die many years later from cancer due to radiation exposure received from the accident. The entire population within 10 miles (16 km) is considered to obtain an average value.

Table E-9. Impacts of Accidents Caused by Fire Events (Peach Bottom)

Impact	NUREG-1150 Fire Events (95th percentile)	NUREG-1150 Internal Events (95th percentile)	1996 GEIS Internal Events (95th percentile)
Individual risk			
- EF[(a)] (1 mi)	~1.5×10^{-9}/yr	~2.5×10^{-10}/yr	Not available
- LF[(b)] (10 mi)	~1×10^{-8}/yr	~1.5×10^{-9}/yr	Not available
Total person-rem per year (entire region)	~700	~100	2,950
Total early fatality risk	~1.5×10^{-6}/yr	~1×10^{-7}/yr	4.2×10^{-3}/yr
Total latent fatality risk	~0.15/yr	~2×10^{-2}/yr	2.0/yr

(a) EF = early fatality risk. The individual early fatality risk within one mile (1.6 km) is the frequency (per year) that a person living within one mile (1.6 km) of the site boundary will die within a year due to the accident. The entire population within one mile is considered to obtain an average value.

(b) LF = latent fatality risk. The individual latent cancer fatality risk within 10 miles (16 km) is the frequency (per year) that a person living within 10 miles (16 km) of the plant will die many years later from cancer due to radiation exposure received from the accident. The entire population within 10 miles (16 km) is considered to obtain an average value.

Table E-10. Impacts of Accidents Caused by Fire Events (LaSalle)

Impact	NUREG/CR-5305 Fire Events (95th percentile)	NUREG/CR-5305 Internal Events (95th percentile)	1996 GEIS Internal Events (95th percentile)
Individual risk			
- EF[(a)] (1 mi)	~1.1×10^{-10}/yr	~1.5×10^{-10}/yr	Not available
- LF[(b)] (10 mi)	~1.0×10^{-8}/yr	~1.3×10^{-8}/yr	Not available
Total person-rem per year	~1,920	~2,600	2,898
Total early fatality risk	~9×10^{-9}/yr	~1.2×10^{-8}/yr	3.6×10^{-3}/yr
Total latent fatality risk	~0.3/yr	~0.4/yr	2.0/yr

(a) EF = early fatality risk. The individual early fatality risk within one mile (1.6 km) is the frequency (per year) that a person living within one mile (1.6 km) of the site boundary will die within a year due to the accident. The entire population within one mile is considered to obtain an average value.
(b) LF = latent fatality risk. The individual latent cancer fatality risk within 10 miles is the frequency (per year) that a person living within 10 miles (16 km) of the plant will die many years later from cancer due to radiation exposure received from the accident. The entire population within 10 miles (16 km) is considered to obtain an average value.

Table E-11. Impacts of Accidents Caused by Seismic Events

Impact	Surry		Peach Bottom	
	NUREG/CR-4551 Surry[(a)] LLNL (*EPRI*) Hazard Curve	1996 GEIS (95th percentile)	NUREG/CR-4551 Peach Bottom[(a)] LLNL (*EPRI*) Hazard Curve	1996 GEIS (95th percentile)
Individual risk				
- EF[(b)] (1 mi)	1.8×10^{-7}/yr (*1.8×10^{-8}/yr*)		1.6×10^{-6}/yr (*5.3×10^{-8}/yr*)	
- LF[(c)] (10 mi)	3.1×10^{-8}/yr (*3.8×10^{-9}/yr*)		3.4×10^{-7}/yr (*1.1×10^{-8}/yr*)	
Total person-rem per year	45 (*6.7*)	1,200	460 (*17*)	2,950
Total early fatality risk	9.3×10^{-5}/yr (*1.4×10^{-5}/yr*)	1.6×10^{-2}/yr	3.0×10^{-3}/yr (*8.8×10^{-5}/yr*)	4.2×10^{-3}/yr
Total latent fatality risk	3.9×10^{-2}/yr (*5.6×10^{-3}/yr*)	0.9/yr	2.5×10^{-1}/yr (*9.9×10^{-3}/yr*)	2.0/yr

(a) Mean values.
(b) EF = early fatality risk. The individual early fatality risk within one mile (1.6 km) is the frequency (per year) that a person living within one mile (1.6 km) of the site boundary will die within a year due to the accident. The entire population within one mile is considered to obtain an average value.
(c) LF = latent fatality risk. The individual latent cancer fatality risk within 10 miles (16 km) is the frequency (per year) that a person living within 10 miles (16 km) of the plant will die many years later from cancer due to radiation exposure received from the accident. The entire population within 10 miles (16 km) is considered to obtain an average value.

With the airborne pathway impacts from external events much less than the internal event airborne pathway impacts in the 1996 GEIS, it is reasonable to conclude that the impact of accidents caused by external events on surface water and groundwater contamination will also be much less than the impacts contained in the 1996 GEIS. Due to the longer time before the population is exposed and the effects of interdiction of contaminated food, only latent fatalities are expected to result from these pathways. Therefore, the environmental impacts of surface and groundwater contamination caused by accidents initiated by external events are bounded by the impacts stated in the 1996 GEIS. This same conclusion can also be drawn with respect to the economic impacts that are caused by the environmental contamination.

E.3.2.3 Conclusion

In summary, it is concluded that the CDFs from severe accidents initiated by external events, as quantified in NUREG-1150 (NRC 1990b) and the other sources cited above, are comparable to those from accidents initiated by internal events but lower than the CDFs that formed the basis for the 1996 GEIS. The environmental impacts from externally initiated events are generally significantly lower (one or more orders of magnitude) than those used in the 1996 GEIS.

E.3.3 Impact of New Source Term Information

The 1996 GEIS used information from 28 plant-specific EISs to project the environmental impact from all 118 plants analyzed (see Table 5.5 in the 1996 GEIS). The 28 sites chosen were those for which the impacts from severe accidents were analyzed in their plant-specific EISs. As stated in Section 5.3.3.1 of the 1996 GEIS, the source terms (i.e., the magnitude, timing, and characteristics of the radioactive material released to the environment) used in the EIS analyses for the 28 sites (and subsequently used to estimate the environmental impacts from all plants) were generally based on those documented in NUREG-0773 (NRC 1982). The NUREG-0773 source terms represented an update (re-baseline) of the source terms used in WASH-1400 (NRC 1975). The source terms in NUREG-0773 were developed for PWRs and BWRs and are shown in Tables 13 and 14A of that document. NUREG-0773 states that the provided source terms are based on models that have “known deficiencies which would tend to give overestimates of the magnitude of the releases.”

Since completion of NUREG-0773, additional information on source terms has been developed through experimental and analytical programs. The purpose of this section is to assess the impact of new source term information on the environmental impacts described in the 1996 GEIS. The new source term information assessed is that used in NUREG-1150 (NRC 1990b) as updated and simplified in NUREG/CR-6295 (NRC 1997b).

E.3.3.1 Airborne Pathway Impact

Tables E-12 and E-13 present a comparison of the results for large release sequences from NUREG-0773 (NRC 1982) and NUREG/CR-6295 (NRC 1997b). These sequences typically dominate the total risk from all severe accidents. In this case, large release sequences have been selected from the full set of sequences in each study based on a total iodine release fraction of 10 percent or higher. These tables present release frequencies, timings, and release fractions for iodine and cesium, which are the elements that contribute the most to early (iodine) and latent (cesium) fatalities. Only limited comparisons between the studies are possible due to differences in the sequences analyzed in each study and their associated release modes. Nevertheless the following observations can be made:

- The sum of the release frequencies from NUREG/CR-6295 is lower than those from NUREG-0773 for all containment types, with the exception of the NUREG/CR-6295 LaSalle sequences. However, the higher release frequency for LaSalle is offset by lower release fractions at LaSalle.

Table E-12. NUREG-0773 and NUREG/CR-6295 Large Source Terms (PWRs)

Source		Sequence	Frequency	Release Time (hr)	Release Duration (hr)	Post Core Uncovery Delta (hr)[a]	Iodine Release Fraction	Cesium Release Fraction
NUREG-0773	Surry	Event V (Bypass)	4×10^{-6}/yr	1	1	0.5	0.64	0.82

NUREG/CR-6295	Surry	RSUR1[b] (CF at VB)	2.9×10^{-7}/yr	6	2	1	0.35	0.31
		RSUR4[b] (Bypass)	1.6×10^{-6}/yr	1	2.5	0.7	0.12	0.12
		Sum	1.9×10^{-6}/yr					
	Sequoyah	RSEQ1[b] (CF during CD)	2.8×10^{-7}/yr	5.5	2	0.5	0.59	0.62
		RSEQ2[b] (CF at VB)	3.6×10^{-6}/yr	6	2	1	0.18	0.19
		RSEQ5[b] (Bypass)	3.1×10^{-6}/yr	1	2.5	0.7	0.12	0.12
		Sum	7×10^{-6}/yr					

(a) For NUREG-0773, this represents the interval of time between the decision to take protective measures and the start of the release; for NUREG/CR-6295, this represents the time between core uncovery and the start of the release.
(b) These source terms have multiple plumes, which have been summed here for ease of comparison.
Bypass = fission product released from the reactor bypass the containment.
CF = containment failure.
CD = core damage.
VB = reactor vessel branch.

Table E-13. NUREG-0773 and NUREG/CR-6295 Large Source Terms (BWRs)

Source		Sequence	Frequency	Release Time (hr)	Release Duration (hr)[(a)]	Post Core Uncovery Delta (hr)[(a)]	Iodine Release Fraction	Cesium Release Fraction
NUREG-0773	Peach Bottom	AEα' (CF before VB)	2×10^{-9}/yr	0.8	0.5	0.5	0.3	0.6
		AEα (CF before VB, scrub)	1×10^{-9}/yr	0.8	0.5	0.5	0.2	0.4
		TCγ' (CF before CD)	2×10^{-6}/yr	1.5	2.0	1.0	0.5	0.6
		TW γ' (CF before CD)	3×10^{-6}/yr	50	2.0	40	0.1	0.3
		Sum	5×10^{-6}/yr					
NUREG/CR-6295	Peach Bottom	RPB1[(b)] (CF at VB)	1.2×10^{-6}/yr	11.5	4.3	3.5	0.11	0.1
		RPB2[(b)] (CF at VB)	1.0×10^{-6}/yr	7.3	4.3	2.5	0.11	0.1
		RPB6[(b)] (CF at VB)	3×10^{-8}/yr	11.5	4.3	3.5	0.44	0.4
		Sum	2.2×10^{-6}/yr					
	LaSalle	RLAS1[(b)] (CF before VB)	6.3×10^{-6}/yr	58	13.5	4.8	0.16	0.17
		RLAS2[(b)] (CF at VB)	6.2×10^{-6}/yr	3.8	7.3	2.5	0.15	0.03
		RLAS3[(b)] (CF at VB)	1.2×10^{-6}/yr	16.9	6.3	5.8	0.11	0.07
		RLAS4[(b)] (CF before VB)	2.4×10^{-6}/yr	23.7	1.8	0.5	0.18	0.12
		Sum	1.6×10^{-5}/yr					
	Grand Gulf	RGG1[(b)] (CF at VB)	8.4×10^{-7}/yr	3.6	4	2.6	0.23	0.11
		RGG3[(b)] (Late CF)	1.2×10^{-6}/yr	14	4	13	0.15	0.01
		Sum	2×10^{-6}/yr					

(a) For NUREG-0773, this represents the interval of time between the decision to take protective measures and the start of the release; for NUREG/CR-6295, this represents the time between when the water level reaches 2 feet above the bottom of the active fuel and the start of the release.
(b) These source terms have multiple plumes, which have been summed here for ease of comparison.
CF = containment failure.
CD = core damage.
VB = reactor vessel branch.

- Where direct comparisons can be made (i.e., for bypass sequences in PWRs and containment failures before vessel breach in BWRs) the release fractions from NUREG/CR-6295 are significantly lower than those from NUREG-0773.

- For several sequences in NUREG/CR-6295, the release fractions appear to be comparable to or slightly greater than those from NUREG-0773 (e.g., PWR sequence RSEQ1 and BWR sequence RPB6 which have a release magnitude comparable to the largest PWR release and BWR release from NUREG-0773, respectively. However, the release frequencies reported in NUREG/CR-6295 for these sequences are one to two orders of magnitude lower than those from NUREG-0773, resulting in a lower risk impact.

- The release times and the difference in time between core uncovery and release to the atmosphere are generally comparable between the two studies.

Based on the comparisons provided above, the expected impacts, i.e., the frequency-weighted consequences, from the airborne pathway using the updated source term information would be much lower than previously predicted.

E.3.3.2 Other Pathway Impacts

Since the comparison of the new source term information to that used in the 1996 GEIS environmental impact projection shows that the amount of release of radioactive material in a severe accident is estimated to be less than estimated in the 1996 GEIS, the environmental impacts from the other pathways (contamination of open bodies of water, groundwater contamination, and the resulting economic impacts from any pathway) will also be less than estimated in the 1996 GEIS.

E.3.3.3 Conclusion

More recent source term information indicates that the timing from dominant severe accident sequences, as quantified in NUREG/CR-6295 (NRC 1997b), is comparable to the analysis forming the basis of the 1996 GEIS. In most cases, the release frequencies and release fractions are significantly lower for the more recent estimate. Thus, the environmental impacts used as the basis for the 1996 GEIS (i.e., the frequency-weighted consequences) are higher than the impacts that would be estimated using the more recent source term information.

It is worth noting that a significant effort is ongoing to re-quantify realistic severe accident source terms under the State-of-the Art Reactor Consequence Analysis (SOARCA) Project. Preliminary results indicate that source term timing and magnitude may be significantly lower than quantified in previous studies (NRC 2008a). This information will be incorporated, as appropriate, in future revisions of this document.

E.3.4 Impact of Power Uprates

Power uprates are defined as the process of increasing the maximum power level at which a nuclear power plant may operate. Although power uprates have been approved by the NRC since 1977, the effects of power uprates since 1996 were not taken into account for the GEIS. Extended power uprates began to be approved in 1998. For BWRs, it became common for a power uprate to be between 10 and 20 percent, and for PWRs, up to 5 percent. The purpose of this section is to provide an assessment of the impacts of power uprates on severe accident scenarios and their environmental impacts.

The process of license amendments for power uprates requires licensees to evaluate the effects of the uprate on the safety of the plant. Design-basis accidents were analyzed to determine the change in possible dose, should an accident occur. Most commonly, loss of coolant accidents, control rod drop accidents and fuel handling accidents were assessed. Whole body and thyroid doses were determined for the exclusion area boundary, the outer edge of the low population zone, and the main control room. These values must meet 10 CFR Part 100 and 10 CFR Part 50, Appendix A, General Design Criterion (GDC) 19 dose limits. The effects of power uprates on CDF and large early release frequency (LERF) are also assessed.

E.3.4.1 Airborne Pathway Impacts

Power uprates require using fuel with a higher percentage of uranium-235 or additional fresh fuel in order to derive more energy from the operation of the reactor. This results in a larger radionuclide inventory (particularly short-lived isotopes, assuming no change in burnup limits) in the core, than the same core at a lower power level. The larger radionuclide inventory represents a larger source term for accidents and can result in higher doses to offsite populations in the event of a severe accident. Typically, short-lived isotopes are the main contributor to early fatalities. As stated in NUREG-1449 (NRC 1993), short-lived isotopes make up 80 percent of the dose following early release.

LERF represents the frequency of sequences that result in early fatalities. Thus, the impact of a power uprate on early fatalities can be gauged by considering the impact of the uprate on the LERF metric. To this end, Table E-14 presents the change in LERF calculated by each licensee who has been granted a power uprate of greater than 10 percent. As can be seen, the increase in LERF ranges from a minimal impact to an increase of 30 percent (with a mean of 10.5 percent). This change is judged to be small to moderate.

Table E-14. Changes in LERF for Extended Power Uprates >10 Percent

Plant	Percent Increase in Power	Percent Increase in Internal Event LERF
Brunswick 1, 2	15	4.5
Clinton	20	5.5
Dresden 2, 3	17	10
Duane Arnold	15.3	16
Ginna	16.8	19
Hope Creek	15	30
Quad Cities 1, 2	17.8	4
Susquehanna 1, 2	13	<1
Vermont Yankee	20	5
Mean	16.4	10.5

E.3.4.2 Other Pathway Impacts

As discussed in previous sections, the change in impacts due to other pathways is viewed to be bounded by the change in the airborne pathway, consistent with the results obtained in the 1996 GEIS.

E.3.4.3 Conclusion

Power uprates would result in a small to (in some cases) moderate increase in the environmental impacts from a postulated accident. However, taken in combination with the other information presented in this appendix, the increases would be bounded by the 95 percent UCB values in Tables 5.10 and 5.11 of the 1996 GEIS.

E.3.5 Impact of Higher Fuel Burnup

There has been continued movement toward higher fuel burnup, to allow for more efficient utilization of the fuel and longer operating cycles. An environmental assessment (EA) was published by the NRC in 1988 on the effects of increased peak burnup (to 60 GWd/MT, 5 percent by weight uranium-235). NUREG/CR-5009 (NRC 1988) is the basis for the EA. NUREG/CR-6703 (NRC 2001a) is a more current analysis using updated designs and data, and peak burnup to 75 GWd/MT.

The purpose of this section is to include the updated information from NUREG/CR-6703 into the GEIS to account for the effect of current and possible future increased fuel burnup on postulated accidents. Future peak burnups being considered are 62 GWd/MT for PWRs and 70 GWd/MT for BWRs.

E.3.5.1 Airborne Pathway Impacts

The environmental impacts of accidents where high burnup fuel is being used (assuming no change in plant power level) are due to the effects of an increased inventory of long-lived fission products. Long-lived fission products contribute primarily to latent health effects, and thus latent fatalities are used here as a measure of the impact of higher burnup fuel. Since latent fatalities are directly scalable to dose, the assessment is based upon the increase in population dose due to the use of high burnup fuel.

NUREG/CR-6703 (NRC 2001a) analyzed design-basis accidents from full power for PWR and BWR reactors at different levels of fuel burnup. A PWR steam generator tube rupture and a BWR main steam line break were analyzed. Burnup was analyzed to 75 GWd/MT, at which point, fuel with more than 5 percent by weight uranium-235 would be required. As described on page 25 of that document, the models used do not account for natural processes and engineered safety features, so "more attention should be paid to trends in doses than to absolute values."

Table E-15 shows doses at the exclusion area boundary (EAB) and the total population dose stated in NUREG/CR-6703. The EAB dose includes contributions from inhalation, and external dose. The total population dose also includes contributions from contaminated foods as well. The increase in population dose is moderate (~38 percent) from 42 to 75 GWd/MT for PWRs. For BWRs, the net increase in population dose is small (~8 percent). Although the analysis in NUREG/CR-6703 is for design-basis accidents, the percentage increase in impacts would be generally similar for severe accidents.

Table E-15. LOCA Consequences as a Function of Fuel Burnup

Reactor Type	Peak-Rod Burnup (GWd/MT)	Individual Dose at 0.8 km[(a)] (rem)[(b)]	Mean Total Population Dose (person-rem)[(b)]
PWR	42	10	940,000
	50	10	1,100,000
	60	10	1,200,000
	62	10	1,200,000
	65	11	1,200,000
	70	11	1,300,000
	75	11	1,300,000
BWR	60	10	1,300,000
	62	10	1,300,000
	65	10	1,300,000
	70	11	1,400,000
	75	11	1,400,000

(a) 0.8 km = 0.5 mi.
(b) Note that these doses are on a per event basis, not a frequency (per year) basis.

E.3.5.2 Other Pathway Impacts

As discussed in previous sections, the change in impacts due to other pathways is viewed to be bounded by the change in the airborne pathway, consistent with the results obtained in the 1996 GEIS.

E.3.5.3 Conclusion

Increased peak fuel burnup from 42 to 75 GWd/MT for PWRs, and 60 to 75 GWd/MT for BWRs, results in small to moderate increases (up to 38 percent) in the environmental impacts in the event of a severe accident. However, taken in combination with the other information presented in this appendix, the increases would be bounded by the 95 percent UCB values in Tables 5.10 and 5.11 of the 1996 GEIS.

E.3.6 Impact from Accidents at Low Power and Shutdown Conditions

The 1996 GEIS did not include an assessment of the environmental impacts of accidents initiated at low power or shutdown conditions. These conditions include power levels less than 5 percent, shutdown (with or without maintenance or plant modifications under way), and fuel handling. The safety concern under these conditions is that plant configurations may be established where not all plant safety systems and features would be operable (e.g., containment integrity may not be required), and activities (e.g., plant modification) could be under way that could not be done while at full power. Accordingly, accidents initiated at such conditions may have different initiators, progress differently, and have different consequences than those initiated at full power conditions. In addition, operating experience has shown that events affecting fuel cooling do occur during shutdown operation. Accordingly, the industry implemented a number of voluntary measures in response to NRC generic letters and bulletins, and in 1991 developed guidelines for the assessment of shutdown management and implementation of safety improvements (NUMARC 1991). As discussed in SECY-97-168 (NRC 1997c), these voluntary industry initiatives resulted in improved safety.

The purpose of this section is to provide an assessment of the risk from postulated severe accidents at low power and shutdown conditions relative to the risk from postulated severe accidents at full power conditions, including a comparison against the findings in the 1996 GEIS.

The conditions assessed are:

- Plant operation at power levels between 0 and 5 percent;
- Shutdown with containment open; and
- Fuel handling inside the containment structure.

Several sources of information are available to support this assessment. These include studies that have been done assessing actual events and the risk from accidents at low power and shutdown conditions. These studies are: (1) NUREG-1449 (NRC 1993); (2) NUREG/CR-6143 (NRC 1995b); and (3) NUREG/CR-6144 (NRC 1995a). In addition, in 1997, the NRC staff recommended a proposed rule be considered to address shutdown conditions. Although the Commission did not approve going forward with the proposed rule (see SRM-97-168, NRC 1997d), the technical basis for the proposed rule provides additional useful information.

E.3.6.1 Airborne Pathway Impacts

NUREG-1449 (NRC 1993) presents an analysis of actual events that have occurred at low power and shutdown conditions. This analysis includes an estimate of the conditional core damage frequency associated with each event and an overall assessment of the range of total core damage frequencies (mean value) that could result from events at low power and shutdown conditions. This range was from 10^{-5}/yr to 10^{-4}/yr.

NUREG/CR-6143 (NRC 1995b) and NUREG/CR-6144 (NRC 1995a) provide low power and shutdown risk assessments for two plants (Grand Gulf and Surry). For Grand Gulf, the mean core damage frequency stated in NUREG/CR-6143 is approximately 2×10^{-6}/yr and for Surry (NUREG/CR-6144) it is 4×10^{-6}/yr. However, such core damage frequencies need to be considered with respect to their consequences. Due to the decay time associated with low power and shutdown conditions (i.e., decay of short-lived isotopes and lower decay heat) and, in most cases, longer times available to take mitigative action, the offsite consequences would be less than for accidents from full power. However, in certain plant operating states, the containment in those states may be open. Thus, a higher conditional probability for containment bypass might exist.

NUREG/CR-6143 and NUREG/CR-6144 also provide estimates of the offsite airborne pathway consequences on human health from accidents (internal events only) at low power and shutdown conditions. Tables E-16 and E-17 list these estimates for Grand Gulf and Surry, respectively. Also shown for each plant are the airborne pathway offsite consequence results for accidents from full power from NUREG-1150 (NRC 1990b) (for internal events) and from the 1996 GEIS. As can be seen, the airborne impacts (airborne pathway risk and probability-weighted consequences) from accidents at low power and shutdown are comparable to those from full power, as quantified in these studies. Although the impacts for low power and shutdown conditions are somewhat greater (by about a factor of 2 to 5) for certain metrics, these differences are small in an absolute sense. Moreover, the airborne impacts of accidents from low power and shutdown are significantly less than those stated in the 1996 GEIS (by more than an order of magnitude). Thus, even though the 1996 GEIS estimates regarding the airborne pathway environmental impact are for internal events at full power only, their conservatism causes them to bound the impacts from accidents at low power and shutdown.

E.3.6.2 Other Pathway Impacts

For the impacts from surface water and groundwater contamination from accidents at low power and shutdown, the estimates for accidents from full power (internal events only) in the 1996 GEIS can be used for comparison. In the 1996 GEIS, for the surface water pathways, it was estimated that the impacts from the drinking water pathway would be a small fraction of those for the airborne pathway. The risk associated with the aquatic food pathway was found to be

Table E-16. Airborne Impacts of Low Power and Shutdown Accidents (Grand Gulf)

Impact	Low Power/Shutdown Accidents NUREG/CR-6143 (95th percentile values)	Full Power Accidents Internal Events NUREG-1150 (95th percentile values)	Full Power Accidents Internal Events 1996 GEIS (95th percentile values)
Individual risk			
EF[(a)] (1 mi)	~3×10^{-10}/yr	~1.5×10^{-10}/yr	
LF[(b)] (10 mi)	~5×10^{-9}/yr	~1×10^{-9}/yr	
Total person-rem per year (entire region)	~28	~15	1,441
Total early fatality risk	~4×10^{-8}/yr	~2.5×10^{-8}/yr	2.8×10^{-3}/yr
Total latent fatality risk	~1×10^{-2}/yr	~2.5×10^{-3}/yr	1.0/yr
CDF	5.6×10^{-6}/yr	1.2×0^{-5}/yr	2.4×10^{-5}/yr[(c)]

(a) EF = early fatality risk. The individual early fatality risk within one mile (1.6 km) is the frequency (per year) that a person living within one mile (1.6 km) of the site boundary will die within a year due to the accident. The entire population within one mile is considered to obtain an average value.
(b) LF = latent fatality risk. The individual latent cancer fatality risk within 10 miles (16 km) is the frequency (per year) that a person living within 10 miles (16 km) of the plant will die many years later from cancer due to radiation exposure received from the accident. The entire population within 10 miles (16 km) is considered to obtain an average value.
(c) This is the CDF from the Grand Gulf original EIS.

Table E-17. Airborne Impacts of Low Power and Shutdown Accidents (Surry)

Impact	Low Power/Shutdown Accidents (NUREG/CR-6144) (95th percentile values)	Full Power Accidents Internal Events NUREG-1150 (95th percentile values)	Full Power Accidents Internal Events 1996 GEIS (95th percentile values)
Individual risk			
EF[(a)] (1 mi)	~7×10^{-9}/yr	~4×10^{-8}/yr	
LF[(b)] (10 mi)	~7×10^{-9}/yr	~1×10^{-8}/yr	
Total person-rem per year (entire region)	~1.3	~150	1,200
Total early fatality risk	~2×10^{-7}/yr	~4×10^{-6}/yr	1.6×10^{-2}/yr
Total latent fatality risk	~5×10^{-2}/yr	~2.5×10^{-2}/yr	0.9/yr
CDF	1.9×10^{-5}/yr	1.3×10^{-4}/yr	

(a) EF = early fatality risk. The individual early fatality risk within one mile (1.6 km) is the frequency (per year) that a person living within one mile (1.6 km) of the site boundary will die within a year due to the accident. The entire population within one mile is considered to obtain an average value.
(b) LF = latent fatality risk. The individual latent cancer fatality risk within 10 miles (16 km) is the frequency (per year) that a person living within 10 miles (16 km) of the plant will die many years later from cancer due to radiation exposure received from the accident. The entire population within 10 miles (16 km) is considered to obtain an average value.

also relatively small compared to the risks associated with the airborne pathway for most sites and essentially the same as the atmospheric pathway for the few sites with large annual aquatic food harvests. With the airborne impacts from accidents at low power and shutdown in NUREG/CR-6143, -6144, and NUREG-1150 estimated to be considerably less than the impacts from accidents at full power in the 1996 GEIS, the surface water pathway impacts should likewise be less, and thus, the risks portrayed in the 1996 GEIS should be bounding.

Section 5.3.3.4 of the 1996 GEIS concluded that the contribution of risk from the groundwater pathway for at-power accidents "generally contributes only a small fraction of that risk attributable to the atmospheric pathway but in a few cases may contribute a comparable risk." Groundwater contamination due to basemat melt-through would be less likely than for accidents at full power, due to the lower decay heat associated with low power and shutdown events. Thus, the risks portrayed in the 1996 GEIS are considered to be bounding.

With respect to the economic impacts regardless of contamination pathway, the lower estimated person-rem/yr from accidents at low power and shutdown should also result in lower economic impacts than from accidents at full power.

E.3.6.3 Conclusion

In summary, it is concluded that the environmental impacts from accidents at low power and shutdown conditions are generally comparable to those from accidents at full power when comparing the NUREG/CR-6143 (NRC 1995b) and NUREG/CR-6144 (NRC 1995a) values to NUREG-1150 (NRC 1990b) values. Although the impacts for low power and shutdown conditions could be somewhat greater than for full power (for certain metrics), the 1996 GEIS estimates of the environmental impact of severe accidents bound the potential impacts from accidents at low power and shutdown with margin. Finally, as cited above and discussed in SECY-97-168 (NRC 1997c), industry initiatives taken during the early 1990s have also contributed to the improved safety of low power and shutdown operation.

E.3.7 Impact from Accidents at Spent Fuel Pools

The 1996 GEIS did not include an explicit assessment of the environmental impacts of accidents at the spent fuel pools (SFPs) located at each reactor site. The 1996 GEIS did, however, discuss qualitatively (see Section 5.2.3.1) the reasons why the impact of accidents at SFPs would be much less than that from reactor accidents. Thus, in Table B-1 of 10 CFR Part 51, it was concluded that accidents at SFPs could be classified as Category 1 and not require further analysis in support of license renewal. This was primarily due to the fact that the resolution of Generic Safety Issue 82, "Beyond Design Basis Accidents in Spent Fuel Pools," concluded that the risk from accidents at SFPs was low and, accordingly, no additional regulatory action was necessary. The analysis supporting this conclusion is contained in NUREG-1353 (NRC 1989).

Since issuance of the 1996 GEIS, additional analysis of the risk from spent fuel pool accidents has been performed and documented. For example, in 2001, the NRC published NUREG-1738 (NRC 2001b), which evaluated SFP risk during decommissioning. As a result of the September 11, 2001, terrorist attacks, additional analysis has been performed on spent fuel pool (SFP) security, although much of this work is security-related information and not publically available. In addition, there are two other major activities of note: (1) a 2004 to 2005 study performed by the National Academies (National Research Council 2006b), and (2) a 2006 Petition for Rulemaking (see NRC 2008d).

The purpose of this section is to consider the risk from severe accidents in SFPs relative to the risk from severe accidents in reactors, including a comparison against the findings in the 1996 GEIS. The impacts considered are only those from spent fuel in the pool. Spent fuel assembly dry cask safety is not included, since cask safety is addressed under 10 CFR Part 72.

E.3.7.1 Airborne Pathway Impacts

The analysis contained in NUREG-1738 (NRC 2001b) assesses the impacts from accidents at a typical SFP at decommissioning nuclear power plants. The impacts assessed are those associated with the airborne pathway impact on human health. The analysis covers a range of decay times for the fuel stored in the pool, a number of initiating events, and some variations in emergency evacuation times, fission product releases, and seismic hazard. The initiating events included in the analysis are listed below.

- Seismic (for central and eastern U.S. sites)[k]
- Cask drop
- Loss of offsite power
- Internal fire

(k) The seismic risk analysis performed in NUREG-1738 was based on site-specific seismic hazard estimates for nuclear power plants in the central and eastern United States found in NUREG-1488, "Revised Livermore Seismic Hazard Estimates for 69 Nuclear Power Plant Sites East of the Rocky Mountains." As such, nuclear power plants in the western United States, such as Diablo Canyon, San Onofre, and Columbia, were not specifically considered in this study. Nothing in NUREG-1738, or the staff's reliance on it here, undermines the staff's initial conclusion in the 1996 GEIS that the impacts of SFP severe accidents will be comparable to reactor severe accidents for all facilities.

- Loss of pool cooling
- Loss of pool coolant inventory
- Accidental aircraft impact (although not deliberate impacts)
- Tornado missile

The SFP inventory assumed was 3½ core loads with an average fuel burnup of 60 GWd/MT. Although intended to be representative of the SFP in a typical decommissioning PWR or BWR, the assumed core inventory, burnup, and decay time range is also reasonably representative of that for operating PWRs and BWRs while at power. In addition to the above results, NUREG-1738 also assessed the risk from recriticality in the SFP and concluded that, given licensee surveillance and monitoring programs, the potential risk of such events is small.

The analysis conducted in NUREG-1738 assumed the plant was in its decommissioning phase and, thus, has fewer protective features for the prevention or mitigation of SFP accidents. Therefore, the impact analysis contained in NUREG-1738 is considered conservative. In addition, the NUREG-1738 impact analysis assumed that the zirconium fuel cladding would start to burn and the event would be nonrecoverable when the water level in the pool falls to within 3 feet (1 m) above the top of the assemblies' active fuel region. This is also conservative and does not credit potential operator actions to prevent or mitigate SFP accidents beyond that point, or the fact that for a wide range of conditions spent fuel can be air-cooled. Table E-18 summarizes the airborne pathway impact on human health from a severe accident in a SFP (from the NUREG-1738 analysis) for a time period of 1 month to 2 years (i.e., a typical operating reactor fuel cycle). Ranges are given to account for differences in emergency planning and seismic hazard assumptions. The site characteristics used in NUREG-1738 were those from the Surry plant. Thus Table E-18 also presents Surry's site-specific results from NUREG-1150 (NRC 1990b) and the 1996 GEIS.

As can be seen in Table E-18, the impacts from SFP accidents at Surry (as calculated in NUREG-1738) are generally comparable to or smaller than the analogous NUREG-1150 internal event reactor accidents when using the low ruthenium release source term.[l] For the high ruthenium release source term, the NUREG-1738 results are generally higher than the accompanying reactor results from NUREG-1150. For either source term, the NUREG-1738

(l) Due to a concern about the potential release of ruthenium isotopes from the spent fuel stored in the SFP, two sensitivity cases were analyzed in NUREG-1738: one with a ruthenium release fraction of 2×10^{-5} (called the base case or the low ruthenium release case) and another with a ruthenium release fraction of 1.0 (called the high ruthenium release case).

Table E-18. Impacts of Accidents at SFPs from NUREG-1738[a]

	Spent Fuel Pools[b] (1 month to 2 years decay time)		**Reactors**		
	NUREG-1738 Low Ru Release (range of means)	**NUREG-1738 High Ru Release (range of means)**	**NUREG-1150 Surry (mean)**	**NUREG-1150 Surry (95th percentile)**	**1996 GEIS Surry (95th percentile)**
Individual risk					
EF[c] (1 mi)	2×10^{-9} to 7×10^{-9}/yr	6×10^{-8} to 1×10^{-7}/yr	1.5×10^{-8}/yr	4×10^{-8}/yr	
LF[d] (10 mi)	1×10^{-8}/yr	2×10^{-7}/yr	1.5×10^{-9}/yr	1×10^{-8}/yr	
Total person-rem per year	2.5 to 12 (50 mi)	8 to 60 (50 mi)	6 (50 mi) 30 (entire region)	30 (50 mi) 150 (150 mi)	1,200 (150 mi)
Total early fatality risk	2×10^{-7} to 6×10^{6}/yr	1×10^{-5} to 5×10^{-4}/yr	1×10^{-6}/yr	3×10^{-6}/yr	1.6×10^{-2}/yr

(a) All values are approximate.
(b) Values are obtained from Figures 3.7-3, 3.7-4, 3.7-7, and 3.7-8 of NUREG-1738.
(c) EF = early fatality risk. The individual early fatality risk within one mile (1.6 km) is the frequency (per year) that a person living within one mile (1.6 km) of the site boundary will die within a year due to the accident. The entire population within one mile (1.6 km) is considered to obtain an average value.
(d) LF = latent fatality risk. The individual latent cancer fatality risk within 10 miles (16 km) is the frequency (per year) that a person living within 10 miles (16 km) of the plant will die many years later from cancer due to radiation exposure received from the accident. The entire population within 10 miles (16 km) is considered to obtain an average value.

impacts are much less than the conservative estimates of full power reactor accidents at Surry as estimated in the 1996 GEIS.

The impacts stated in NUREG-1738 are also similar to those calculated for the resolution of Generic Safety Issue 82, in which NUREG-1353 (NRC 1989) calculated a best-estimate population dose of 16 person-rem per year.[m] While the NUREG-1738 results are for the Surry site, individual risk metrics for early fatalities and latent fatalities should be relatively insensitive to the site-specific population (see pg. 3-28 of NUREG-1738) because these metrics reflect doses to the close-in population. In addition, while results are presented for both the low and high ruthenium source term, the low ruthenium source term is still viewed as the more accurate representation. Therefore, the risk and environmental impact from fires in SFPs as analyzed in NUREG-1738 are expected to be comparable to or lower than those from reactor accidents and are bounded by the 1996 GEIS.

Since the issuance of NUREG-1738 (NRC 2001b), and subsequent to the terrorist attacks of September 11, 2001, significant additional analyses have been performed that support the view that the risk of a successful terrorist attack (i.e., one that results in a zirconium fire) is very low at all plants. These analyses were conducted by the Sandia National Laboratories and are

(m) Taken from the Executive Summary of that report: total dose = 8×10^{6} person-rem; event frequency = 2×10^{-6} per year.

collectively referred to herein as the "Sandia studies." The Sandia studies are sensitive, security-related information and are not available to the public. The Sandia studies considered spent fuel loading patterns and other aspects of a pressurized-water reactor SFP and a boiling-water reactor SFP, including the role that the circulation of air plays in the cooling of spent fuel. The Sandia studies indicated that there may be a significant amount of time between the initiating event (i.e., the event that causes the SFP water level to drop) and the spent fuel assemblies becoming partially or completely uncovered. In addition, the Sandia studies indicated that for conditions where air cooling may not be effective in preventing a zirconium fire, there is a significant amount of time between the spent fuel becoming uncovered and the possible onset of such a zirconium fire, thereby providing a substantial opportunity for both operator and system event mitigation.

The Sandia studies, which more fully account for relevant heat transfer and fluid flow mechanisms, also indicated that air cooling of spent fuel would be sufficient to prevent SFP zirconium fires at a point much earlier following fuel offload from the reactor than previously considered (e.g., in NUREG-1738). Thus, the fuel is more easily cooled, and the likelihood of a zirconium fire is therefore reduced.

Furthermore, additional mitigation strategies implemented subsequent to September 11, 2001, enhance spent fuel coolability and the potential to recover SFP water level and cooling prior to a potential zirconium fire. The Sandia studies also confirmed the effectiveness of these additional mitigation strategies to maintain spent fuel cooling in the event the pool is drained and its initial water inventory is reduced or lost entirely. Based on the more rigorous accident progression analyses, the recent mitigation enhancements, and NRC site evaluations of every SFP in the United States, the risk of an SFP zirconium fire initiation is expected to be less than reported in NUREG-1738 (NRC 2001b) and previous studies. For additional information on SFP safety and security, the reader is referred to the NRC's response to a National Academy of Sciences study on the topic (NRC 2005a) and the NRC's response to a petition for rulemaking (NRC 2008d).

E.3.7.2 Other Pathway Impacts

The NUREG-1738 (NRC 2001b) analysis did not address the impacts with respect to the other pathways (open bodies of water and groundwater). The 1996 GEIS estimated these impacts for reactor accidents from full power (internal events only) using the results from plant-specific reactor accident analysis to assess contamination of open bodies of water and from the Liquid Pathway Generic Study (NUREG-0440; NRC 1978) to assess the contamination of groundwater from basemat melt-through accidents.

In both cases, the impacts on human health from surface water and groundwater contamination are only a small fraction of those impacts from the airborne pathway, except in a few cases where the impacts are comparable. With the impacts from the airborne pathway associated with spent fuel pool accidents (as stated in NUREG-1738) being comparable to the impacts from reactor accidents, as stated in NUREG-1150 (NRC 1990b), the impacts from SFP-related surface water and groundwater contamination may also be comparable, even though the SFP fuel inventory is several times that of the reactor. This is due to the lower probability of occurrence of SFP accidents, the effects of decay of the fission products on the radionuclide inventory, and the lower energy density of the fuel inventory, which makes basemat melt-through more unlikely.

The same conclusion can also be drawn with respect to the economic impacts. These impacts are related to the likelihood of the accidents and the cost of cleanup and food interdiction. Even with higher fuel inventories, the lower likelihood of accidents in the SFP reduces the economic impacts. For example, the UCB economic impact identified in Table 5.31 in the 1996 GEIS from full power reactor accidents at Surry is approximately $1.1 million/yr. The worst-case economic impacts estimated in past studies for SFP accidents ranged from approximately $18,000/yr to $120,000/yr.[n]

An issue related to the groundwater pathway that has received significant attention since the issuance of the 1996 GEIS is leakage of water from SFPs (or related systems) at Salem Unit 1, Indian Point Units 1 and 2, and Seabrook. Instances of this kind are adequately monitored and addressed via existing regulatory programs, and do not fall within the scope of this section. For more information on this topic, the reader is referred to NUREG-0933, Supplement 31, Section 3, Issue 202 (NRC 2007c) and NRC 2008b.

E.3.7.3 Conclusion

In summary, it is concluded that the environmental impacts from accidents at SFPs (as quantified in NUREG-1738 [NRC 2001b]) can be comparable to those from reactor accidents at full power (as estimated in NUREG-1150 [NRC 1990b]). Subsequent analyses performed, and mitigative measures employed since 2001, have further lowered the risk of this class of accidents. In addition, even the conservative estimates from NUREG-1738 are much less than the impacts from full power reactor accidents as estimated in the 1996 GEIS. Therefore, the environmental impacts stated in the 1996 GEIS bound the impact from SFP accidents.

E.3.8 Impact of the Use of BEIR VII Risk Coefficients

Section 5.3.3.2.2 from the 1996 GEIS discussed adverse health effects from exposure to radiation and referenced several National Academy of Sciences reports (BEIR I, III, and V)

(n) The former estimate uses information from Tables C.95 and C.101 of NUREG/BR-0184 (NRC 1997a), while the latter uses information from Tables 5.1.1 and 5.1.2 of NUREG-1353 (NRC 1989).

(National Research Council 1972, 1980, 1990) as sources of risk coefficients for fatal cancers (i.e., latent fatalities) associated with radiation exposure. Benchmark evaluations of the exposure index methodology employed by the 1996 GEIS were conducted using the MELCOR Accident Consequence Code System (MACCS), as described in Section 5.3.3.2.3 of the original GEIS. MACCS is the predecessor of the currently used MACCS2 code, and represented the state-of-the-art for assessing risks associated with postulated severe reactor accidents at the time of the original GEIS. That study used a linear cancer model based on the BEIR V report (National Research Council 1990). The code-to-code comparisons suggest that latent fatality values in the FESs are an order of magnitude too low. Therefore, to account for this, the latent fatality results predicted from the FES values were multiplied by a factor of 10 to obtain the final predicted latent fatality results in the 1996 GEIS. This adjustment in combination with the use of 95th percentile UCB values ensured that the basis for health effects would be conservative.

In 2006, the National Research Council's Committee on the Biological Effects of Ionizing Radiation (BEIR) published BEIR VII, entitled *Health Risks from Exposure to Low Levels of Ionizing Radiation* (National Research Council 2006a). BEIR VII provides estimates of the risk of incidence and mortality for males and females (see Section 3.9.1.4 and Appendix D of this report for more information). The BEIR VII report estimates that the fatal cancer risk coefficient is approximately 20 percent higher than the International Commission on Radiological Protection (ICRP) recommendation (as described in ICRP 1991). The difference of 20 percent is within the margin of uncertainty associated with these estimates (see Appendix D.8.1.4 for a detailed discussion of the BEIR VII report).

The NRC staff completed a review of the BEIR VII report and documented its findings in NRC 2005b. In this paper, the NRC staff concluded that the findings presented in the BEIR VII report agree with the NRC's current understanding of the health risks from exposure to ionizing radiation. The NRC staff agreed with the BEIR VII report's major conclusion that current scientific evidence is consistent with the hypothesis that there is a linear, no-threshold dose response relationship between exposure to ionizing radiation and the development of cancer in humans. This conclusion is consistent with the process the NRC uses to develop its standards of radiological protection. Therefore, the NRC's regulations continue to be adequately protective of public health and safety and the environment. This general topic is discussed further in a 2007 denial of a Petition for Rulemaking, as discussed in NRC 2007d.

E.3.9 Uncertainties

Section 5.3.5 in the 1996 GEIS provides a discussion of the uncertainties associated with the analysis in the GEIS and in the individual plant EISs used to estimate the environmental impacts of severe accidents. The uncertainties discussed covered:

- The probability of an accident.

- The quantity and chemical form of radioactivity released.

- Atmospheric dispersion modeling for the radioactive plume transport, including:
  - duration, energy release, and in-plant radionuclide decay time;
  - meteorological sampling scheme used;
  - emergency response effectiveness and warning time;
  - dose conversion factors and dose-response relationships for early health consequences;
  - dose conversion factors and dose-response relationships for latent health consequences;
  - chronic exposure pathways; and
  - economic data and modeling.

- Assumption of normality for random error components.

- The exposure-index method, and
  - selection of exposure index parameters;
  - selection of distances;
  - regressing early fatalities for only large plants; and
  - normalization of plants for latent fatalities, costs, and dose.

The 1996 GEIS recognized that the uncertainties in the estimated impacts could be large (i.e., from a factor of 10 to 1000). Reference was made to NUREG-1150 (NRC 1990b) as providing more state-of-the-art risk analysis that also considered uncertainties and that the cumulative effect of this analysis shows a reduction in risk.

In an attempt to help compensate for uncertainties, the 1996 GEIS used very conservative estimates of environmental impacts. These included:

- Use of the 95th percentile confidence values in estimating airborne pathway and economic impacts;

- Use of site-specific analysis for estimating surface water pathway impacts; and

- Use of NUREG-0440 (NRC 1978) results to bound the estimated groundwater pathway impacts.

It was generally concluded that even with uncertainties, the environmental impacts estimated in the 1996 GEIS were adequate for use.

Many of these same uncertainties also apply to the analysis used in this update. However, as discussed in Sections E.3.1 through E.3.8 of this revision, more recent information is used to supplement the estimate of the environmental impacts contained in the 1996 GEIS. In effect, the assessments contained in Sections E.3.1 through E.3.8 of this revision provide additional information and insights into items that could be considered areas of uncertainty associated with the 1996 GEIS.

This more recent information also provides insights on additional sources of uncertainty from those discussed in the 1996 GEIS. Each of these insights on additional sources of uncertainty is discussed below.

E.3.9.1 Emergency Planning (EP)

The 1996 GEIS (in Section 5.3.5.3) included a discussion on uncertainties associated with EP. However, no quantitative information on the magnitude of these uncertainties was presented. To provide a perspective on the magnitude of the uncertainty, the following information is provided.

NUREG-1150 (NRC 1990b) and the SFP accident analysis in NUREG-1738 (NRC 2001b) specifically assessed the effect of different EP assumptions on the airborne pathway impacts. NUREG-1150 assessed four alternative emergency response modes in addition to its base case (99.5 percent of the population within 10 mi was evacuated in 4.5 hours with no sheltering). These alternatives were assessed for reactor accidents from full power, with the Surry and Peach Bottom analyses including seismic and fire initiated events as well as internal events. For the worst case (no evacuation, no sheltering, and early relocation), the estimated early fatalities per year were approximately a factor of 10 higher than the base case.

The SFP accident analysis in NUREG-1738 also specifically assessed the effect of variations in emergency evacuation. The variations were assessed against the base case used in the NUREG-1150 risk analysis. Doses beyond 20 mi were not calculated. Cases where the evacuation was faster, slower, and where fewer people were evacuated were assessed. As can be expected, improved evacuation scenarios resulted in smaller impacts, and relaxed evacuation scenarios resulted in additional impacts. The impacts associated with relaxed evacuation scenarios did go up, but only a few percent in societal dose (i.e., person-rem) and up to a factor of 10 in early fatalities. However, these impacts are still far below the conservative characterization of the impacts for reactor accidents contained in the original GEIS.

E.3.9.2 Population Increase

The assessments of environmental impacts contained in NUREG-1150 (NRC 1990b), NUREG-1738 (NRC 2001b), NUREG-1449 (NRC 1993), NUREG/CR-5305 (NRC 1992), NUREG/CR-6143 (NRC 1995b) and NUREG/CR-6144 (NRC 1995a) are all based on populations that existed in the mid-1980s to mid-1990s. The 1996 GEIS estimated impacts at the mid-year of each plant's license renewal period (i.e., 2030 to 2050). To adjust the impacts estimated in the NUREGs and NUREG/CRs to the mid-year of the assessed plant's license renewal period, the information (i.e., exposure indexes [EIs]) in the 1996 GEIS can be used. The EIs adjust a plant's airborne and economic impacts from the year 2000 to its mid-year license renewal period based on population increases. These adjustments result in anywhere from a 5 to a 30 percent increase in impacts, depending upon the plant being assessed. Given the range of uncertainty in these types of analyses, a 5 to 30 percent change is not considered significant. Therefore, the effect of increased population around the plant does not generally result in significant increases in impacts.

E.4 Severe Accident Mitigation Alternatives (SAMAs)

In Section 5.4 of the 1996 GEIS, the purpose and role of severe accident mitigation design alternatives (SAMDAs) in the license renewal process are discussed. Severe accident mitigation alternatives (SAMAs) include design alternatives (SAMDAs) and alternatives that involve changes in procedures and training. With respect to this revision of the GEIS, the purpose and objectives of SAMAs remain unchanged.

The purpose of this section is to discuss the impacts on SAMA analyses of the assessments presented in this revision. It should be noted that since publication of this 1996 GEIS, many improvements have occurred that have enhanced reactor safety. These are discussed in Section E.2 of this revision and, as can be seen in improved plant performance measures, have been effective. Even so, the SAMA analyses that have been performed to date have found SAMAs that were cost-beneficial, or at least possibly cost-beneficial subject to further analysis, in approximately half of the plants. However, none of the SAMAs identified related to managing the effects of aging during the period of extended operation. Therefore, they did not need to be implemented as part of license renewal, pursuant to the regulations in 10 CFR Part 54. In general, the cost-beneficial SAMAs were identified for further evaluation by the licensee under the current operating license. In several cases, the applicant has decided to implement the modifications even though they were not related to license renewal (NRC 2006a).

The SAMA analysis performed in support of license renewal has focused on those areas of greatest risk (accidents initiated by internal and external events) and on measures that could result in the greatest risk reduction in a cost-beneficial fashion. Even though the 1996 GEIS did not explicitly consider accidents initiated by external events in estimating the environmental impacts from severe accidents, the environmental impacts from external events are included in an applicant's SAMA analysis for license renewal by following the guidance contained in NEI 05-01, Revision A (NEI 2005). This guidance (which is endorsed by the NRC in Regulatory Guide 4.2, Supplement 1, Revision 1, "Preparation of Environmental Reports for Nuclear Power Plant License Renewal Applications," [NRC 2013]) calls for the consideration of external events in assessing SAMAs. External events are considered by multiplying the internal event risk by a factor that accounts for any increase in risk caused by external events. The multiplication factor is determined on a plant-specific basis considering previous and current external event analyses (e.g., IPEEE). Given the existing information on the contribution to risk from external events, the approach described in NEI 05-01 continues to be a reasonable approach to address the external event risk contribution.

This GEIS revision has assessed other potential contributors to risk. Therefore, it is reasonable to assess whether those contributors should be included in the SAMA analysis. Specifically, these contributors are:

- Power uprates;
- The use of higher burnup fuel;
- Accidents from low power and shutdown conditions; and
- Accidents at SFPs.

With respect to power uprates and the use of higher burnup fuel, the increased impacts are small compared to the impacts in the 1996 GEIS, and these factors are included in any severe accident assessment for license renewal. Therefore, no additional SAMA analysis is required.

With respect to accidents from low power and shutdown conditions (which are not currently included in SAMA analysis), the CDFs are generally lower and the risks are comparable to those of accidents from full power. In addition, there have been industry initiatives to improve low power and shutdown safety. It is also likely that some SAMAs identified as a result of assessing risks from accidents at full power would provide benefits to accidents from low power. Therefore, the potential for cost-beneficial SAMAs related to low power and shutdown accidents is considered to be less than for accidents at full power. Accordingly, it is reasonable to continue to exclude low power and shutdown conditions from SAMA analysis consideration.

With respect to accidents in SFPs, the additional mitigative measures implemented following the attacks of September 11, 2001, have further lowered the risk of this class of accidents, and therefore make the potential for finding cost-effective SAMAs related to SFP accidents substantially less than for reactor accidents. Therefore, it is reasonable to conclude that accidents at SFPs do not need to be considered in the SAMA analysis.

With respect to which plants must submit a SAMA analysis, 10 CFR 51.53(c)(3)(ii)(L) states that, "[i]f the staff has not previously considered severe accident mitigation alternatives for the applicant's plant, in an environmental impact statement or related supplement or in an environmental assessment, a consideration of alternatives to mitigate severe accidents must be provided." Applicants for plants that have already had a SAMA analysis considered by the NRC as part of an EIS, supplement to an EIS, or EA, do not need to have a SAMA analysis reconsidered for license renewal. In forming its basis for determining which plants needed to submit a SAMA, the Commission noted that all licensees had undergone, or were in the process of undergoing, more detailed site-specific severe accident mitigation analyses through processes separate from license renewal, specifically the Containment Performance Improvement (CPI), Individual Plant Examination (IPE), and IPE for external events (IPEEE) programs (61 FR 28467). In light of these studies, the Commission stated that it did not expect future SAMA analyses to uncover "major plant design changes or modifications that will prove to be cost-beneficial." (61 FR 28467). The NRC's experience in completed license renewal proceedings has confirmed this prediction. As a result, the totality of these studies (the former SAMA analyses, the IPE, the IPEEE, and the CPI) provides a strong basis for the Commission's decision to not require applicants to perform an additional SAMA analysis in a license renewal application if the NRC had previously evaluated one for that plant. Therefore, applicants for license renewal of those plants that have already had a SAMA analysis considered by the NRC as part of an EIS, supplemental to an EIS or EA, need not perform an additional SAMA analysis for license renewal.

E.5 Summary and Conclusion

The 1996 GEIS estimated the environmental impacts on human health and economic factors from full power severe reactor accidents initiated by internal events. Sections E.3.1 through E.3.8 of this revision assessed the impacts of new information and additional accident considerations on the environmental impact of severe accidents contained in the 1996 GEIS. In addition, the impact of uncertainties associated with the new information is assessed in Section E.3.9. The purpose of this section is to discuss the aggregate effect of the new information on the environmental impacts and uncertainties stated in the 1996 GEIS and to state what conclusions can be drawn.

The different sources of new information can be generally categorized by their effect of decreasing, not affecting, or increasing the best-estimate environmental impacts associated with postulated severe accidents. Those areas where a decrease in best-estimate impacts would be expected are:

- New internal events information (decreases by an order of magnitude)
- New source term information (significant decreases)

Areas likely leading to either a small change or no change include:

- Use of BEIR VII risk coefficients

Lastly, those areas leading to an increase in best-estimate impacts would consist of:

- Consideration of external events (comparable to internal event impacts)
- Power uprates (small to moderate increase)
- Higher fuel burnup (small to moderate increases)
- Low power and shutdown events (could be comparable to full power event impacts)
- Spent fuel pool accidents (could be comparable to full power event impacts)

Given the difficulty in conducting a rigorous aggregation of these results (due to the differences in the information sources utilized), a fairly simple approach is taken. The latter group contains three areas where the increase could be comparable to the current risk and two areas where the increase could approach 30 to 40 percent. The net increase from these five areas would therefore be approximately 470 percent[o] (increase by a factor of 4.7). The reduction in risk due to newer internal event information would account for a decrease by a factor of 5 to 100. The net effect of an increase on the order of 500 percent and a decrease on the order of 500 percent to 10,000 percent would be a reduction in estimated impacts (as compared to the 1996 GEIS assessment).

Furthermore, even if one assumed that the net effect of the new information was no change in risk, the information provided throughout this appendix has demonstrated that the level of conservatism in the upper bound estimates utilized in the 1996 GEIS is much larger than the individual (or cumulative) deltas from the updated information. In particular, Section E.3.1 demonstrates that the GEIS values were a factor of 2 to 4 higher than the underlying EIS values.

(o) This approximation simply assumes that each comparable area results in an increase of 100 percent and the other two areas (uprates and burnup) each result in an increase of 35 percent.

With respect to uncertainties, the 1996 GEIS contained an assessment of uncertainties in the information used to estimate the environmental impacts. Section 5.3.5 of the 1996 GEIS discusses the uncertainties and concludes that they could cause the impacts to vary anywhere from a factor of 10 to a factor of 1,000. This range of uncertainties bounds the uncertainties discussed in Section E.3.9 above, which ranged from a factor of 3 to 10, as well as the uncertainties brought in by the other sources of new information.

Given the discussion in this appendix, the staff concludes that the reduction in environmental impacts from the use of new information (since the 1996 GEIS analysis) outweighs any increases resulting from this same information. As a result, the findings in the 1996 GEIS remain valid. Therefore, design-basis accidents remain a Category 1 issue, and although the probability-weighted consequences of severe accidents are SMALL for all plants, severe accidents remain a Category 2 issue to the extent that only the alternatives to mitigate severe accidents must be considered for all plants that have not previously considered such alternatives.

In addition, it is reasonable that in license renewal applications, the impacts from reactor accidents at full power, including internal and external events, should continue to be considered in assessing SAMAs. The impacts of all other new information do not contribute sufficiently to the environmental impacts to warrant their inclusion in the SAMA analysis since the likelihood of finding cost-effective plant improvements is small. Alternatives to mitigate severe accidents still must be considered for all plants that have not considered such alternatives. Table E-19 provides a summary of the conclusions discussed above.

Table E-19. Summary of Conclusions

Topic (Section)	Conclusions
New Internal Events Information (Section E.3.1)	New information on the risk and environmental impacts of severe accidents caused by internal events indicates that PWR and BWR CDFs are generally comparable to or less than those forming the basis of the 1996 GEIS. In some cases, these differences are significant (approaching one order of magnitude). Comparison of population dose from newer assessments illustrates a reduction in impact by a factor of 5 to 100 when compared to older assessments, and an additional factor of 2 to 4 due to the conservatism built into the 1996 GEIS values. This would also mean that contamination of open bodies of water and economic impacts would, in most cases, be significantly less. Additionally, the likelihood of basemat melt-through accidents is less than that used in the analysis supporting the 1996 GEIS.
Consideration of External Events (Section E.3.2)	The 1996 GEIS did not quantitatively consider severe accidents initiated by external events in assessing environmental impacts. When the environmental impacts of external events are considered, they can be comparable to those from internal events; however, they are generally lower than the estimates used in the 1996 GEIS for internal events. This conclusion would also apply to the contamination of open bodies of water and groundwater and economic impacts.

Table E-19. (cont.)

Topic (Section)	Conclusions
New Source Term Information (Section E.3.3)	More recent source term information indicates that the timing from dominant severe accident sequences, as quantified in NUREG/CR-6295, is comparable to the analysis forming the basis of the 1996 GEIS. In most cases, the release frequencies and release fractions are significantly lower for the more recent estimate. Thus, the environmental impacts used as the basis for the 1996 GEIS are higher than the impacts that would be estimated using the more recent source term information.
Power Uprates (Section E.3.4)	Based on a comparison of the change in LERF for extended power uprates, a small to moderate increase in environmental impacts results from the increase in operating power level.
Higher Fuel Burnup (Section E.3.5)	Increased peak fuel burnup from 42 to 75 GWd/MT for PWRs, and 60 to 75 GWd/MT for BWRs, is estimated to result in small to moderate increases in the environmental impacts in the event of a severe accident.
Consideration of Low Power and Shutdown Events (Section E.3.6)	The environmental impacts from accidents at low power and shutdown conditions are generally comparable to those from accidents at full power when comparing the values in NUREG/CR-6143 and NUREG/CR-6144 to those in NUREG-1150. Even so, the 1996 GEIS estimates of the environmental impact of severe accidents bound the potential impacts from accidents at low power and shutdown. Finally, as cited above and discussed in SECY-97-168, industry initiatives taken during the early 1990s have also contributed to the improved safety of low power and shutdown operation.
Consideration of Spent Fuel Pool Accidents (Section E.3.7)	The environmental impacts from accidents at SFPs (as quantified in NUREG-1738) can be comparable to those from reactor accidents at full power (as estimated in NUREG-1150). Subsequent analyses performed, and mitigative measures employed, since 2001 have further lowered the risk of this class of accidents. In addition, the conservative estimates from NUREG-1738 are much less than the impacts from full power reactor accidents that are estimated in the 1996 GEIS.
Use of BEIR VII Risk Coefficient (Section E.3.8)	Use of newer risk coefficients such as in BEIR VII is expected to have a small impact on the results presented in the 1996 GEIS.
Uncertainties (Section E.3.9)	The impact and magnitude of uncertainties, as estimated in the 1996 GEIS, bound the uncertainties introduced by the new information and considerations.
SAMAs (Section E.4)	The current process and scope of SAMA analysis are sufficient for determining the need for additional mitigative measures.
Summary and Conclusion (Section E.5)	Given the new and updated information, the reduction in estimated environmental impacts from the use of new internal event and source term information outweighs any increases from the consideration of external events, power uprates, higher fuel burnup, low power and shutdown risk, and SFP risk.

NUCLEAR REGULATORY COMMISSION

10 CFR Part 51

RIN 3150–AI42

[NRC–2008–0608]

Revisions to Environmental Review for Renewal of Nuclear Power Plant Operating Licenses

AGENCY: Nuclear Regulatory Commission.

ACTION: Final rule.

SUMMARY: The U.S. Nuclear Regulatory Commission (NRC) is amending its environmental protection regulations by updating the Commission's 1996 findings on the environmental effect of renewing the operating license of a nuclear power plant. The final rule redefines the number and scope of the environmental impact issues that must be addressed by the NRC during license renewal environmental reviews. This final rule also incorporates lessons learned and knowledge gained from license renewal environmental reviews conducted by the NRC since 1996.

DATES: This rule is effective on July 22, 2013. However, compliance is not required until June 20, 2014.

ADDRESSES: Please refer to Docket ID NRC–2008–0608 when contacting the NRC about the availability of information for this final rule. You may access information and comment submittals related to this final rulemaking, which the NRC possesses and is publicly available, by the following methods:

- *Federal Rulemaking Web site:* Go to *http://www.regulations.gov* and search for Docket ID NRC–2008–0608. Address questions about NRC dockets to Carol Gallagher; telephone: 301–492–3668; email: *Carol.Gallagher@nrc.gov.* For technical questions, contact the individuals listed in the **FOR FURTHER INFORMATION CONTACT** section of this final rule.
- *NRC's Agencywide Documents Access and Management System (ADAMS)*: You may access publicly available documents online in the NRC Library at *http://www.nrc.gov/reading-rm/adams.html.* To begin the search, select ''*ADAMS Public Documents*'' and then select ''*Begin Web-based ADAMS Search.*'' For problems with ADAMS, please contact the NRC's Public Document Room (PDR) reference staff at 1–800–397–4209, 301–415–4737, or by email to *pdr.resource@nrc.gov.* The ADAMS accession number for each document referenced in this notice (if that document is available in ADAMS) is provided the first time that a document is referenced. In addition, for the convenience of the reader, the ADAMS accession numbers are provided in a table in Section XII, ''Availability of Documents,'' of this document.
- *NRC's PDR:* You may examine and purchase copies of public documents at the NRC's PDR, One White Flint North, 11555 Rockville Pike, Rockville, Maryland 20852.

FOR FURTHER INFORMATION CONTACT: Mr. Stewart Schneider, Office of Nuclear Reactor Regulation, U.S. Nuclear Regulatory Commission, Washington, DC 20555–0001; telephone: 301–415–4123; email: *Stewart.Schneider@nrc.gov;* or Mr. Jeffrey Rikhoff, Office of Nuclear Reactor Regulation, U.S. Nuclear Regulatory Commission, Washington, DC 20555–0001; telephone: 301–415–1090; email: *Jeffrey.Rikhoff@nrc.gov.*

Executive Summary

Purpose of the Regulatory Action

The Atomic Energy Act of 1954 authorizes the NRC to issue commercial nuclear power plant operating licenses for up to 40 years. The NRC's regulations allow for the renewal of these operating licenses for up to an additional 20 years. The license renewal process includes reviewing a license renewal application, conducting the assessment, and then, if all applicable safety standards are met, renewing the license. The NRC's review of a license renewal application proceeds along two independent regulatory tracks: one for safety issues and another for environmental issues. The license renewal process is defined by a clear set of regulations that are designed to ensure safe operation and protection of the environment during the license renewal term. The NRC's regulations for the license renewal safety review are set forth in Part 54 of Title 10 of the *Code of Federal Regulations* (10 CFR). The NRC's environmental protection regulations are set forth in 10 CFR part 51.

The renewal application is the principal document that an applicant provides to both request and support renewal for a nuclear power reactor's operating license. The license renewal application includes both general and technical information that demonstrates that an applicant is in compliance with the NRC's regulations in 10 CFR part 54. During the renewal process, the license renewal applicant must confirm whether the design assumptions used for the original licensing basis will continue to be valid throughout the period of extended operation and that the aging effects will be adequately managed. The applicant must demonstrate that the effects of aging will be managed in such a way that the intended functions of ''passive'' or ''long-lived'' structures and components (such as the reactor vessel, reactor coolant system, piping, steam generators, pressurizer, pump casings, and valves) will be maintained during the license renewal term (also known as the period of extended operation). For active components, such as motors, diesel generators, cooling fans, batteries, relays, and switches, the Commission's ongoing regulatory oversight programs already ensure that the components continue to perform their intended function during the period of license renewal. This information must be sufficiently detailed in the application to permit the NRC staff to determine if the applicant's management of these issues is adequate to allow operation during the extended period of operation without undue risk to the public and workers' health and safety.

In addition to the safety assessment, the applicant must also prepare an evaluation of the potential impacts to the environment of facility operation for an additional 20 years. Under the NRC's environmental protection regulations in 10 CFR part 51, which implement the National Environmental Policy Act (NEPA), renewal of a nuclear power plant operating license requires the preparation of an environmental impact statement (EIS). To support the preparation of these EISs, the NRC issued a rule in 1996 to define which impacts would essentially be the same at all nuclear power plants (Category 1 issues) and which ones could be different at different plants and would require a plant-specific analysis to determine the impacts (Category 2 issues). For each license renewal application, those impacts that require a plant-specific analysis must be analyzed by the applicant in its environmental report and by the NRC in its associated EIS. The final rule amends those regulations by updating the Commission's 1996 rule. The final rule redefines the number and scope of the environmental impact issues that must be addressed by the NRC and applicants during license renewal environmental reviews. These changes are based primarily on lessons learned and knowledge gained from license renewal environmental reviews conducted by the NRC since 1996.

The NRC prepared a regulatory analysis to determine the expected quantitative and qualitative costs and benefits of the final rule. The analysis concluded that the final rule will result in net savings to the industry and the NRC. For more information, please see the regulatory analysis (ADAMS Accession No. ML110760321).

Summary of the Major Rule Changes

In the 1996 rule, there were 92 environmental impact issues, 23 of which required a plant-specific analysis (Category 2 issues) during license renewal environmental reviews. In the final rule, there are 78 environmental impact issues, 17 of which require a plant-specific analysis. The following bullets summarize the major changes to the rule:

- Based on the related nature of the issues, several Category 1 issues were consolidated with other Category 1 issues. This includes some issues that were changed from Category 2 to Category 1 and subsequently combined with other, related Category 1 issues. Similarly, several Category 2 issues were combined with related Category 2 issues.
- New Category 1 issues were added: geology and soils; effects of dredging on surface water quality; groundwater use and quality; exposure of terrestrial organisms to radionuclides; exposure of aquatic organisms to radionuclides; effects of dredging on aquatic organisms; impacts of transmission line right-of-way management on aquatic resources; employment and income; tax revenues; human health impacts from chemicals; and physical occupational hazards.
- Several issues were changed from Category 2 to Category 1: Offsite land use, air quality, public services (several issues), and population and housing.
- New Category 2 issues were added: Radionuclides released to groundwater, water use conflicts with terrestrial resources, water use conflicts with aquatic resources, and cumulative impacts.
- One uncharacterized issue was reclassified as Category 2: Environmental justice/minority and low-income populations.
- One Category 1 issue was revised to narrow the scope of its finding due to the United States Court of Appeals for the District of Columbia Circuit (D.C. Circuit) decision in *New York* v. *NRC,* 681 F.3d 471 (D.C. Cir. 2012), which vacated the NRC's 2010 Waste Confidence Decision and Rule (75 FR 81032 and 81037; December 23, 2010): Onsite storage of spent nuclear fuel.
- One Category 1 issue was reclassified as uncategorized due to the *New York* v. *NRC* decision: Offsite radiological impacts of spent nuclear fuel and high-level waste disposal.

SUPPLEMENTARY INFORMATION:

I. Background

Rulemaking History

In 1986, the NRC initiated a program to develop license renewal regulations and associated regulatory guidance in anticipation of receiving applications for the renewal of nuclear power plant operating licenses. In 1996, the NRC published a final rule that amended the environmental protection regulations in 10 CFR part 51 for applicants seeking to renew an operating license for up to an additional 20 years.[1] The 1996 final rule was based upon the analyses and findings of a May 1996 NRC environmental impact statement, ''Generic Environmental Impact Statement for License Renewal of Nuclear Plants,'' NUREG–1437 (the ''1996 GEIS'') (Vol. 1, ''Main Report,'' ADAMS Accession No. ML040690705; Vol. 2, ''Appendices,'' ADAMS Accession No. ML040690738).

Based upon the findings of the 1996 GEIS, the 1996 final rule identified those license renewal environmental impact issues for which a generic analysis had been determined to be appropriate and therefore, did not have to be addressed by a license renewal applicant in its plant-specific environmental report or by the NRC in its plant-specific supplemental environmental impact statements (SEISs) to the 1996 GEIS. Similarly, based upon the findings of the 1996 GEIS, the 1996 final rule identified those environmental impacts for which a site- or plant-specific analysis was required, both by the applicant in its environmental report and by the NRC in its SEIS. The 1996 final rule, amongst other amendments to 10 CFR part 51, added Appendix B to Subpart A of 10 CFR part 51, ''Environmental Effect of Renewing the Operating License of a Nuclear Power Plant.'' Appendix B included Table B–1, ''Summary of Findings on NEPA Issues for License Renewal of Nuclear Power Plants,'' which summarized the findings of the 1996 GEIS.

In preparing the 1996 GEIS, the Commission determined that certain environmental impacts associated with the renewal of a nuclear power plant operating license were the same or similar for all plants and, as such, could be treated on a generic basis. In this way, repetitive reviews of these environmental impacts could be avoided. The Commission based its generic assessment of certain environmental impacts on the following factors:

(1) License renewal will involve nuclear power plants for which the environmental impacts of operation are well understood as a result of lessons learned and knowledge gained from operating experience and completed license renewals.

(2) Activities associated with license renewal are expected to be within this range of operating experience; thus, environmental impacts can be reasonably predicted.

(3) Changes in the environment around nuclear power plants are gradual and predictable.

The 1996 GEIS improved the efficiency of the license renewal process by: (1) Providing an evaluation of the types of environmental impacts that may occur from renewing commercial nuclear power plant operating licenses; (2) identifying and assessing impacts that are expected to be generic (i.e., the same or similar) at all nuclear power plants or plants with specified plant or site characteristics; and (3) defining the number and scope of environmental impacts that need to be addressed in plant-specific SEISs to the 1996 GEIS.

In short, the 1996 final rule identified environmental impact issues (i.e., Category 1 issues)[2] that do not have to

[1] 61 FR 28467 (June 5, 1996).

[2] A Category 1 issue is one that meets the following criteria: (1) The environmental impacts

Continued

be addressed by licensees in environmental reports for nuclear power plant license renewal applications or by the NRC in plant-specific SEISs because these issues have been addressed generically for all nuclear power plants in the 1996 GEIS. Similarly, the 1996 final rule also identified environmental impact issues (i.e., Category 2 issues) [3] that must be addressed in plant-specific reviews by licensees in their environmental reports and by the NRC in the SEISs.

On December 18, 1996 (61 FR 66537), the NRC amended the final rule published in 1996 to incorporate minor clarifying and conforming changes and to add language omitted from Table B–1 in Appendix B to Subpart A of 10 CFR part 51 (hereafter ''Table B–1 in Appendix B to Subpart A of 10 CFR Part 51'' is referred to as ''Table B–1'').

1999 Final Rule

The NRC amended 10 CFR part 51, including Table B–1, on September 3, 1999 (64 FR 48496). This amendment expanded the generic findings pertaining to the environmental impacts resulting from transportation of fuel and waste to and from a single nuclear power plant. This amendment also incorporated rule language consistent with the 1996 GEIS, which addressed local traffic impacts attributable to the continued operations of a nuclear power plant during the license renewal term.

Current Rulemaking

As stated in the 1996 final rule that incorporated the findings of the GEIS in 10 CFR part 51, the NRC recognized that environmental impact issues might change over time and that additional issues may need to be considered. As further stated in the preamble to Table B–1, the NRC indicated that it intended to review the material in Table B–1 on a 10-year basis.

The NRC began this review on June 3, 2003, by publishing a notice of intent to revise the 1996 GEIS (68 FR 33209). As part of this process and pursuant to 10 CFR 51.29, the NRC conducted scoping and held a series of public meetings (*see* 74 FR 38119 for more details). The original public comment period began in June 2003 and closed in September 2003. The project was inactive for the next 2 years due to limited NRC staff resources and competing demands. On October 3, 2005 (70 FR 57628), the NRC reopened the public comment period and extended it until December 30, 2005.

On July 31, 2009 (74 FR 38117), the NRC published the proposed rule, ''Revisions to Environmental Review for Renewal of Nuclear Power Plant Operating Licenses,'' for public comment in the **Federal Register**. The proposed rule would amend Table B–1 by updating the Commission's 1996 findings on the environmental impacts related to the renewal of nuclear power plant operating licenses and other NRC environmental protection regulations (e.g., 10 CFR 51.53, which sets forth the contents of the applicant's environmental report). Together with the proposed rule, the NRC also published a notice of availability of the draft revised GEIS (ADAMS Accession No. ML090220654); a proposed Revision 1 of Regulatory Guide (RG) 4.2, Supplement 1, ''Preparation of Environmental Reports for Nuclear Power Plant License Renewal Applications'' (ADAMS Accession No. ML091620409); and a proposed Revision 1 to NUREG–1555, Supplement 1, ''Standard Review Plans for Environmental Reviews for Nuclear Power Plants'' (ADAMS Accession No. ML090230497), in the **Federal Register** (74 FR 38238). All of the documents requested public comments.

The proposed amendments were based on consideration of (1) Comments received from the public during the public scoping period, (2) a review of comments received on plant-specific SEISs completed since the 1996 GEIS was issued, and (3) lessons learned and knowledge gained from previous and ongoing license renewal environmental reviews. The history of this rulemaking is discussed in more detail in the July 31, 2009 (74 FR 38117), proposed rule. The draft revised GEIS provided the regulatory basis for the July 2009 proposed rule.

The proposed rule provided a 75-day public comment period, which closed on October 14, 2009. The NRC received requests to extend the comment period to provide the public more time to analyze and review the legal, regulatory, and policy issues covered by the proposed rule and supporting documents. On October 7, 2009 (74 FR 51522), the NRC granted the requests, and the public comment period for the proposed rule and the proposed revisions to the GEIS, the regulatory guide, and standard review plan was extended to January 12, 2010.

II. Public Meetings

During the public comment period, the NRC conducted six public meetings to solicit comments on the proposed rule, draft revised GEIS, and related draft guidance documents. The official transcripts, written comments, and meeting summaries for the following public meetings are available electronically for public inspection at the NRC's PDR or online in the NRC Library at *http://www.nrc.gov/reading-rm/adams.html:*

(1) September 15, 2009, Atlanta, GA (ADAMS Accession No. ML092810007);
(2) September 17, 2009, Newton, MA (ADAMS Accession No. ML092931681);
(3) September 24, 2009, Oak Brook, IL (ADAMS Accession No. ML092931545);
(4) October 1, 2009, Rockville, MD (ADAMS Accession No. ML092931678);
(5) October 20, 2009, Pismo Beach, CA (ADAMS Accession No. ML093070174); and
(6) October 22, 2009, Dana Point, CA (ADAMS Accession No. ML093100505).

A summary of these meetings is publicly available under ADAMS Accession No. ML093070141.

On June 21, 2011, the NRC conducted another public meeting to discuss final rule implementation in Rockville, MD. No public comments were solicited at this meeting because the public comment period for the proposed rule had closed on January 12, 2010. A summary of this meeting is publicly available in ADAMS under Accession No. ML11182B535.

III. Discussion

1996 GEIS

Under the NRC's environmental protection regulations in 10 CFR part 51, which implements Section 102(2) of NEPA, renewal of a nuclear power plant operating license requires the preparation of an EIS (*see* 10 CFR 51.20(b)(2)). The 1996 GEIS summarized the findings of a systematic inquiry into the environmental impacts of continued operations and refurbishment activities associated with license renewal. Of the 92 environmental issues identified and analyzed by the NRC, 69 issues were determined to be generic (i.e., Category 1); 21 were determined to be plant-specific (i.e., Category 2); and two did not fit into either category (i.e., uncategorized). Category 1 issues concern those potential environmental impacts resulting from license renewal that are common or generic to all

associated with the issue have been determined to apply either to all plants or, for some issues, to plants having a specific type of cooling system or other specified plant or site characteristic; (2) a single significance level (i.e., small, moderate, or large) has been assigned to the impacts (except for collective offsite radiological impacts from the fuel cycle and from high-level waste and spent fuel disposal); and (3) mitigation of adverse impacts associated with the issue has been considered in the analysis, and it has been determined that additional plant-specific mitigation measures are not likely to be sufficiently beneficial to warrant implementation.

[3] A Category 2 issue is one where one or more of the Category 1 criteria cannot be met, and therefore additional plant-specific review is required.

nuclear power plants (or for some issues, to plants having a specific type of cooling system or other specified plant or site characteristic). Category 2 issues concern those potential environmental impacts resulting from license renewal that are not common or generic to all nuclear power plants and, as such, require a plant-specific analysis to determine the level of impact. The two uncategorized issues would be addressed by the NRC in each SEIS. Table B–1 summarizes the findings of the environmental impact analyses conducted for the 1996 GEIS and lists each issue and its category level.

Impact levels (small, moderate, or large) were determined for most NEPA issues (e.g., land use, air, water) evaluated in the 1996 GEIS. A small impact means that the environmental effects are not detectable, or are so minor that they would neither destabilize nor noticeably alter any important attribute of the resource. A moderate impact means that the environmental effects are sufficient to alter noticeably, but not destabilize, important attributes of the resource. A large impact means that the environmental effects would be clearly noticeable and would be sufficient to destabilize important attributes of the resource.

The 1996 GEIS has been effective in focusing the NRC's resources on important license renewal environmental impact issues and has increased the efficiency of the environmental review process. Currently, 73 nuclear units at 43 plant sites have received renewed operating licenses.

Revised GEIS

The revised GEIS (Vol. 1, ''Main Report,'' ADAMS Accession No. ML13106A241; Vol. 2, ''Public Comments,'' ADAMS Accession No. ML13106A242; and Vol. 3, ''Appendices,'' ADAMS Accession No. ML13106A244) is both an update and a re-evaluation of the potential environmental impacts arising from the renewal of an operating license for a nuclear power reactor for an additional 20 years. Lessons learned and knowledge gained during previous license renewal environmental reviews provided a significant source of new information for the revised GEIS. In addition, public comments received during previous license renewal environmental reviews were re-examined to validate existing environmental issues and identify new ones. In preparing the revised GEIS, the NRC considered the need to modify, add to, consolidate, or delete any of the 92 environmental issues evaluated in the 1996 GEIS.

In the proposed rule and draft revised GEIS, the NRC carried forward 78 environmental impact issues for detailed consideration. Fifty-eight of these issues were determined to be Category 1. Of the remaining 20 issues, 19 were determined to be Category 2 and one issue, ''Electromagnetic fields, chronic effects,'' remained uncategorized.[4] These issues were summarized in the July 31, 2009 (74 FR 38117), proposed rule.

Based on public comments received on the proposed rule and draft revised GEIS, a number of the environmental impact issues identified in the proposed rule were re-evaluated for detailed consideration in the final revised GEIS and are reflected in the changes made by the final rule. These changes are discussed in detail in Section VIII, ''Final Actions and Basis for Changes to Table B–1,'' of this document and are briefly summarized as follows:

(1) ''Air quality during refurbishment (nonattainment and maintenance areas)'' issue was changed from a Category 2 to a Category 1 issue and renamed, ''Air quality impacts (all plants).''

(2) ''Groundwater and soil contamination'' issue was changed from a Category 2 to a Category 1 issue and consolidated with the ''Groundwater use and quality'' issue into a single renamed Category 1 issue, ''Groundwater contamination and use (non-cooling system impacts).''

(3) ''Thermal impacts on aquatic organisms'' issue was changed to remove several Category 1 thermal impacts issues (these Category 1 issues were consolidated together with a Category 2 thermal impact issue in the proposed rule) to create a new separate combined Category 1 issue, ''Infrequently reported thermal impacts (all plants),'' which also includes the previously separate ''Stimulation of aquatic nuisance species (e.g., shipworms),'' Category 1 thermal impact issue.

(4) ''Impingement and entrainment of aquatic organisms'' issue was changed to remove a single impingement and entrainment Category 1 issue (consolidated with other impingement and entrainment issues in the proposed rule) to create a new, separate Category 1 issue, ''Entrainment of phytoplankton and zooplankton (all plants).''

In addition to the changes previously discussed, the NRC has made changes to the ''Onsite storage of spent nuclear fuel'' issue and the ''Offsite radiological impacts of spent nuclear fuel and high-level waste disposal'' issue as a result of the United States Court of Appeals decision in *New York* v. *NRC,* 681 F.3d 471 (D.C. Cir. 2012), which vacated the NRC's 2010 Waste Confidence Decision and Rule (75 FR 81032 and 81037; December 23, 2010). The Category 1 ''Onsite storage of spent nuclear fuel'' issue was revised to limit the period of time covered by the issue to the license renewal term. Similarly, the NRC revised the Category 1 issue, ''Offsite radiological impacts of spent nuclear fuel and high-level waste disposal'' by reclassifying the issue from a Category 1 issue with an impact level of small to an uncategorized issue with an impact level of uncertain. Section V of this document, ''Related Issues of Importance,'' provides further details on the NRC's revisions to these issues in response to the *New York* v. *NRC* decision.

Ultimately, 59 environmental impact issues were determined to be Category 1 and would not require additional plant-specific analysis unless new and significant information is identified during the license renewal environmental review. Of the remaining 19 issues, 17 were determined to be Category 2, one remained uncategorized with respect to determining the impact level (''Chronic effects of electromagnetic fields (EMFs)''), and one was reclassified from Category 1 to uncategorized (''Offsite radiological impacts of spent nuclear fuel and high-level waste disposal''). These 78 issues were evaluated in the revised GEIS and are summarized in the final rule. No environmental issues identified in Table B–1 and evaluated in the 1996 GEIS were eliminated, but certain issues were consolidated or grouped according to similarities.

Environmental issues in the revised GEIS are arranged by resource area. This perspective is a change from the 1996 GEIS in which environmental issues are arranged by power plant systems (e.g., cooling systems, transmission lines) and activities (e.g., refurbishment). The structure of the revised GEIS conforms to the NRC's standard format for EISs found in Appendix A to Subpart A of 10 CFR part 51, ''Format for Presentation of Material in Environmental Impact Statements.'' The environmental impacts of license renewal activities, including plant operations, maintenance, and

[4] ''Electromagnetic fields, chronic effects'' remains an uncategorized issue. Due to the lack of a scientific consensus on the impacts of chronic exposure to electromagnetic fields, the NRC has not categorized this issue and did not perform a plant-specific analysis. Once a scientific consensus is reached, the NRC will categorize the issue for license renewal.

refurbishment activities, along with replacement power alternatives, are addressed in each resource area. The revised GEIS evaluated environmental impact issues under the following resource areas: (1) Land use and visual resources, (2) air quality and noise, (3) geologic environment, (4) water resources (surface water resources and groundwater resources), (5) ecological resources (terrestrial resources, aquatic resources, special status species and habitats), (6) historic and cultural resources, (7) socioeconomics, (8) human health, (9) environmental justice, and (10) waste management and pollution prevention. The final rule revises Table B–1 to follow the organizational format of the revised GEIS.

In the 1996 GEIS, the NRC assumed that licensees would need to conduct major refurbishment activities to ensure the safe and economic operation of nuclear power plants beyond the current license term. Activities included replacement and repair of major components and systems, upgrades, and equipment. Replacement of many systems, structures, and components included steam generators and pressurizers for pressurized water reactors (PWRs) and recirculation piping systems for boiling water reactors (BWRs). It was assumed that many nuclear power plants would also undertake construction projects to replace or improve infrastructure. Such projects could include construction of new parking lots, roads, storage buildings, structures, and other facilities.

Licensee practice since publication of the 1996 GEIS has shown that many refurbishment activities have already taken place (e.g., steam generator and vessel head replacement). Most license renewal applicants have not identified any refurbishment activities associated with license renewal. Therefore, the revised GEIS assumes that impacts from refurbishment activities outside of license renewal have been accounted for in annual site evaluation reports, environmental operating reports, and radiological environmental monitoring program reports. Detailed analyses have not been performed for refurbishment actions in the revised GEIS. Instead, the impacts of typical activities during the license renewal term, including any refurbishment activities, are addressed for each resource area.

Environmental impacts of license renewal and the resources that could be affected are identified in the revised GEIS. The general analytical approach for identifying environmental impacts was to: (1) Describe the nuclear power plant activity that could result in an environmental impact, (2) identify the resource that may be affected, (3) evaluate past license renewal reviews and other available information, (4) assess the nature and magnitude of the environmental impact on the affected resource, (5) characterize the significance of the effects, and (6) determine whether the results of the analysis apply to all nuclear power plants (i.e., whether the impact issue is Category 1 or Category 2).

The revised GEIS, and therefore the final rule, retains the 1996 GEIS definitions of a Category 1 and Category 2 issue. While some Category 2 issues have been changed to Category 1, no Category 1 issue has been changed to Category 2. The final rule makes four major types of changes:

(1) *New Category 1 Issues:* New Category 1 issues are either new Category 1 issues (i.e., not previously evaluated in the 1996 GEIS and listed in Table B–1) or multiple Category 1 issues from the 1996 GEIS (and listed as multiple Category 1 issues in Table B–1 of the current rule) that have been consolidated into a single Category 1 issue in the revised GEIS and in Table B–1. An applicant for license renewal does not need to assess the potential environmental impacts from these issues in its environmental report. However, under 10 CFR 51.53(c)(3)(iv), the applicant is still responsible for reporting in the environmental report any ''new and significant information'' of which the applicant is aware. If the applicant is not aware of any new and significant information that changes the conclusion in the revised GEIS, the applicant must state this determination in the environmental report. The NRC has addressed the environmental impacts of these Category 1 issues generically for all plants in the revised GEIS.

(2) *New Category 2 Issues:* New Category 2 issues are either new Category 2 issues (i.e., not previously evaluated in the 1996 GEIS and listed in Table B–1) or multiple Category 2 issues from the 1996 GEIS (and listed as multiple Category 2 issues in Table B–1 of the current rule) that have been consolidated into a single Category 2 issue in the revised GEIS and in Table B–1. For each new Category 2 issue, an applicant must conduct a plant-specific assessment of the potential environmental impacts related to that issue and include it in its environmental report. The NRC will then analyze the potential environmental impacts related to that issue in the SEIS.

(3) *Existing Issue Category Changes from Category 2 to Category 1:* These are issues that were determined to be Category 2 in the 1996 GEIS and have been re-evaluated and determined to be Category 1 in the revised GEIS. Table B–1 has been amended by the final rule. An applicant is no longer required to conduct a plant-specific assessment of the environmental impacts associated with these issues in its environmental report. Similarly, the NRC is no longer required to analyze the potential environmental impacts related to that issue in the SEIS. However, consistent with the requirements of 10 CFR 51.53(c)(3)(iv), an applicant is still required to describe in its environmental report any ''new and significant information'' of which it is aware.

(4) Existing Issue Changes from Category 1 to Uncategorized: The ''Offsite radiological impacts of spent nuclear fuel and high-level waste disposal'' issue [5] was determined to be a Category 1 issue in the 1996 GEIS, but given the DC Circuit decision in *New York* v. *NRC,* the NRC reclassified the issue to uncategorized in the revised GEIS. Table B–1 has been amended by the final rule. Because the issue is uncategorized in this final rule, pending further action by the Commission, an applicant is not required to conduct a plant-specific assessment of the environmental impacts associated with this issue in its environmental report.

IV. Response to Public Comments

A. Overview

The public comment period for the proposed rule, draft revised GEIS, and draft guidance documents associated with this rulemaking, ended on January 12, 2010. The NRC received 32 document submissions containing comments from industry stakeholders, representatives of Federal and State agencies, and other interested parties. The NRC also received verbal comments at the six public meetings held during the public comment period. A detailed description of all public comments submitted on the proposed rule, draft revised GEIS, and draft guidance documents, and the NRC's responses to those comments, are contained in separate documents (*see* Section XII, ''Availability of Documents,'' of this document). The following section summarizes the major issues raised during the public comment period resulting in substantive changes to the rule and other issues raised for which no changes were made to the rule.

[5] The issue was named ''Offsite radiological impacts (spent fuel and high waste disposal)'' in the 1996 rule and GEIS.

B. Summary of Comments Resulting in Substantive Changes to the Rule

Several issues were raised during the public comment period that resulted in substantive changes to the proposed rule, which are briefly discussed in the following paragraphs.

Seismic issues. Many commenters wanted seismic issues to be included in the rule and pointed out the importance of reassessing seismic conditions in determining the safety of operating nuclear power plants. Industry commenters disagreed and argued that seismology should not be considered as part of the issue of ''Impacts of nuclear plants on geology and soils'' in the proposed rule because it is an ongoing safety issue that is being addressed at all plants.

NRC Response. The NRC agrees with the industry commenters that consideration of seismic conditions is an ongoing safety issue. Although seismic conditions at nuclear power plants were generically discussed in the revised GEIS as part of the geologic environment, seismology was not identified as a separate issue in the revised GEIS because the NRC considered historical earthquake data for each nuclear power plant when that plant was first licensed. The NRC requires all licensees to take seismic hazards into account in order to maintain safe operating conditions at all nuclear power plants. When new seismic hazard information becomes available, the NRC evaluates the new data and models to determine if any changes are needed at existing plants. This continuous oversight process, which includes seismic safety, remains separate from license renewal and takes place on an ongoing basis at all licensed nuclear facilities.

Sections 3.4 and 4.4.1 of the revised GEIS explain that geologic and seismic conditions were considered in the original design of nuclear power plants and are part of the license bases for operating plants. Seismic conditions are attributes of the geologic environment that are not affected by continued plant operations and refurbishment and are not expected to change appreciably during the license renewal term for all nuclear power plants. The findings relative to geologic and soil conditions were re-evaluated in the revised GEIS and as such, the issue has been renamed, ''Geology and soils,'' in Table B–1, and the findings have been revised for clarity.

Air quality impacts. Several commenters objected to the issue, ''Air quality (nonattainment and maintenance areas),'' being listed as a Category 2 issue in the proposed rule. These commenters argued that air quality impacts would be small even in worst-case situations, because licensees are required to operate within State air permit requirements.

NRC Response. The NRC agrees with the commenters. The final rule revises Table B–1 by reclassifying the issue as a Category 1 issue. Operating experience has shown that the potential impact from emergency generators and boilers on air quality would be small for all plants and, given the infrequency and short duration of maintenance testing, would not be an air quality concern even at plants located in or adjacent to nonattainment areas.

In addition, the analysis presented in the revised GEIS has shown that the worst-case emissions from cooling tower drift and particulate emissions at operating plants were also small. Air quality impacts from vehicle, equipment, and fugitive dust emissions associated with refurbishment would also be small for most plants but could be a cause for concern for plants located in or near air quality nonattainment or maintenance areas. However, the impacts are expected to be temporary and would cease once projects were completed. In addition, operating experience has shown that refurbishment activities have not required the large numbers of workers and extended durations conservatively predicted and analyzed in the 1996 GEIS, nor have such activities resulted in exceedances in the *de minimis* thresholds for criteria pollutants in nonattainment and maintenance areas. Consequently, the NRC agrees with these commenters' arguments that air quality impacts would be small for all plants and, therefore, a Category 1 issue.

Groundwater and soil contamination. Several commenters objected to the new Category 2 issue, ''Groundwater and soil contamination,'' in the proposed rule and asserted that contamination from industrial practices is addressed by the U.S. Environmental Protection Agency (EPA) and State regulations that monitor and address these impacts. Specifically, the use, storage, disposal, release, and/or cleanup of spilled or leaked solvents, hydrocarbons, and other potentially hazardous materials are governed by the Resource Conservation and Recovery Act (RCRA); Comprehensive Environmental Response, Compensation, and Liability Act; Toxic Substances Control Act; Federal Insecticide, Fungicide, and Rodenticide Act; and the Federal Water Pollution Control Act (also known as the Clean Water Act (CWA)).

NRC Response. While classified as a Category 2 issue in the proposed rule, further consideration of the ''Groundwater and soil contamination'' issue and public comments revealed that the potential impacts on groundwater and soil quality from common industrial practices (e.g., the use, handling, storage, and disposal of chemicals, petroleum products, waste, and hazardous material) can be addressed generically because industrial practices employed by nuclear power plants are not unique, but common to all industrial facilities. The NRC concludes that the overall impact of industrial practices on groundwater use and quality from past and current operations is small for all nuclear power plants and not expected to change appreciably during the license renewal term. The NRC agrees with the commenters to the extent that clarification was needed and that common industrial practices that can cause groundwater or soil contamination can be addressed generically as a Category 1 issue.

Further, the final rule combines the reclassified ''Groundwater and soil contamination'' issue with the Category 1 proposed rule issue, ''Groundwater use and quality,'' and renames the consolidated Category 1 issue as ''Groundwater contamination and use (non-cooling system impacts).'' These issues were consolidated because they both consider the impact of industrial activities associated with the continued operations of a nuclear power plant (not directly related to cooling system effects) on groundwater use and quality. Consolidating these issues also conforms to the resource-based approach used in the revised GEIS and serves to facilitate the license renewal environmental review process.

The finding column of Table B–1 for ''Impacts of refurbishment on groundwater use and quality'' prior to the final rule, as analyzed in the 1996 GEIS, indicated that impacts of continued operations and refurbishment on groundwater use and quality would be small, as extensive dewatering is not anticipated, and the application of best management practices for handling any materials produced or used during activities would reduce impacts. These findings were re-evaluated in the revised GEIS and are retained in the finding column of Table B–1 for the consolidated issue.

This new consolidated issue also considers the impacts on groundwater, soil, and subsoil from the industrial use of solvents, hydrocarbons, heavy metals, or other chemicals at nuclear power plant sites during the license renewal term, including the impacts resulting from the use of wastewater disposal ponds or lagoons (both lined or unlined). Industrial practices at all nuclear power plants have the potential to contaminate groundwater and soil, especially on sites with unlined wastewater and storm water lagoons. Contaminants have been found in groundwater and soil samples at some nuclear power plants during previous license renewal environmental reviews.

Any groundwater and soil contamination at operating nuclear power plants is subject to characterization and clean-up under EPA- and State-regulated remediation and monitoring programs. In addition, wastewater disposal ponds and lagoons are subject to discharge authorizations under the National Pollutant Discharge Elimination System (NPDES) and related State wastewater discharge permit programs. Each operating nuclear power plant must comply with these EPA and State regulatory requirements. As such, each site has an established program for handling chemicals, waste, and other hazardous materials. Moreover, nuclear power plant licensees are expected to employ best management practices, both in minimizing effluents and in remediation. Thus, this new consolidated issue, as set forth in the final revised GEIS and the final rule, is listed as a Category 1 issue.

C. Summary of Other Comments

Radionuclides in groundwater. Several commenters expressed opposition to the inclusion of a new Category 2 issue, ''Radionuclides released to groundwater,'' with an impact estimate of small to moderate in the proposed rule. Some commenters indicated that the issue category should be changed to Category 1; others suggested that the levels of significance should range to large. The argument for changing the issue to Category 1 was based on the voluntary industry-wide initiative, Nuclear Energy Institute (NEI) 07–07, ''Industry Ground Water Protection Initiative—Final Guidance Document'' (ADAMS Accession No. ML072610036), designed to protect groundwater.

NRC Response. This new, Category 2 issue evaluates the potential contamination and degradation of groundwater resources resulting from inadvertent discharges of radionuclides into groundwater from nuclear power plants. Within the past several years, there have been numerous events at power reactor sites that involved unknown, uncontrolled, and unmonitored releases of radionuclides into the groundwater. The number of these events and the high level of public controversy have made this an issue that the NRC believes needs a ''hard look,'' as required by NEPA.

As a voluntary action, NEI 07–07 cannot be enforced by the NRC. As such, no violations can be issued against a licensee who fails to comply with the guidance in NEI 07–07. Furthermore, the NRC cannot rely on a voluntary initiative as a basis to ensure that the nuclear power industry will monitor and have adequate information available for the NRC to determine whether the issue does or does not have an adverse impact on groundwater resources.

Regarding the magnitude of impact, the NRC bases its determination of small to moderate impact on a review of existing plants that have had inadvertent releases of radioactive liquids. Even though the NRC expects impacts for all plants to be within this range, a conclusion of large impact would not be precluded for a future license renewal review based on new and significant information, if the data supports such a conclusion. As reflected in the revised final GEIS and the final rule, ''Radionuclides released to groundwater,'' remains a Category 2 issue.

Radiation exposures to the public. Several commenters identified recent studies that claim an association between cancer risk and proximity to nuclear power facilities.

NRC Response. The NRC's regulatory limits for radiological protection are set to protect workers and the public from the harmful health effects (i.e., cancer and other biological impacts) of radiation to humans. The limits are based on the recommendations of scientific standards-setting organizations. These radiation standards reflect extensive scientific study by national and international organizations. The NRC actively participates in and monitors the work of these organizations to remain current on the latest trends in radiation protection. If the NRC determines that there is a need to revise its radiation protection regulations, it will initiate a separate rulemaking. The models recognized by the NRC for use by licensees to calculate dose incorporate conservative assumptions to ensure that workers and members of the public are adequately protected from radiation.

On April 7, 2010, the NRC announced that it asked the National Academy of Sciences (NAS) to perform a state-of-the-art study on cancer risk for populations surrounding nuclear power facilities (ADAMS Accession No. ML100970142). The NAS has a broad range of medical and scientific experts who can provide the best available analysis of the complex issues involved in discussing cancer risk and commercial nuclear power plants. The NAS is a nongovernmental organization chartered by the U.S. Congress to advise the nation on issues of science, technology, and medicine. Through the National Research Council and Institute of Medicine, it carries out studies independently of the Government, using processes designed to promote transparency, objectivity, and technical rigor. More information on its methods for performing studies is available at *http://www.nationalacademies.org/studycommitteprocess.pdf.*

The NAS study will update the 1990 U.S. National Institutes of Health National Cancer Institute (NCI) report, ''Cancer in Populations Living Near Nuclear Facilities'' (NCI 1990), which concluded there was no evidence that nuclear facilities may be linked causally with excess death from leukemia or from other cancers in populations living nearby.[6] The study's objectives are to: (1) Evaluate whether cancer risk is different for populations living near nuclear power facilities, (2) include cancer occurrence, (3) develop an approach to assess cancer risk in geographic areas that are smaller than the county level, and (4) evaluate the study results in the context of offsite doses from normal reactor operations. The study began in the summer of 2010 and is expected to be completed within 4 years. The final revised GEIS has added a discussion on the NRC's sponsorship of this follow-up to the 1990 NCI study.

Onsite storage of spent nuclear fuel, waste disposal, and Yucca Mountain. Several commenters expressed concern about the increasing volume of spent nuclear fuel at existing power plant sites and the availability of a geological repository at Yucca Mountain for future waste disposal.

NRC Response. The Commission is aware that geologic disposal, at Yucca Mountain or elsewhere, may not be available in the timeframe that was originally envisioned. As an alternative, the Commission has considered the storage of spent nuclear fuel on reactor sites where it is generated. The impacts associated with onsite storage of spent nuclear fuel at nuclear power plant sites during the license renewal term are discussed in Section 4.11.1.2 of the revised GEIS. The impacts associated with offsite radiological impacts from

[6] More information on this report is available at *http://www.cancer.gov/cancertopics/factsheet/Risk/nuclear-facilities.*

spent nuclear fuel and high-level waste disposal are discussed in Section 4.11.1.3 of the revised GEIS. In light of the DC Circuit's decision in *New York* v. *NRC,* 681 F.3d 471, the NRC has revised two Table B–1 issues, ''Onsite storage of spent nuclear fuel'' and ''Offsite radiological impacts of spent nuclear fuel and high-level waste disposal.'' Section V of this document, ''Related Issues of Importance,'' provides a discussion of the NRC's revisions to these two issues, as well as the actions the NRC has taken or will take in response to the *New York* v. *NRC* decision.

Postulated accidents. Numerous comments were received on the NRC's evaluation and classification of postulated accidents in the draft revised GEIS. One commenter disagreed with the GEIS' conclusion that environmental impact from design basis accidents (DBAs) is small. Also, several commenters disagreed with the GEIS conclusion that the environmental impact from severe accidents is small and further, that the evaluation is not adequate because of its use of probability-weighted risk assessments. Their position is that for severe accidents, the revised GEIS should also evaluate the consequences of reactor accidents and expand the evaluation to include spent fuel pool accidents and accidents due to age-related plant component degradation. In addition, some of the commenters stated that the NRC has gained enough information from the many plant licenses it has renewed to make a determination, on a generic basis, that the ''severe accidents'' issue should be reclassified as Category 1.

NRC Response.

Design Basis Accidents. The NRC does not agree that the GEIS' evaluation of DBAs is incorrect. The NRC evaluates and presents the potential consequences of DBAs in nuclear power plant licensing documents and considers them in the GEIS for license renewal.

In order to receive NRC approval for an initial operating license, an applicant must submit a final safety analysis report (FSAR) as part of its application. The FSAR presents the applicable design criteria and design information for the proposed reactor, as well as comprehensive data on the proposed site. The FSAR also discusses hypothetical reactor accident situations and addresses the safety features that prevent and mitigate those accidents. During the initial licensing process for a power reactor, the NRC reviews the FSAR to determine whether or not the plant design meets the NRC's regulations.

At initial licensing, the NRC also considered the environmental impact of DBAs at each operating nuclear power plant. The DBAs are those events that both the applicant and the NRC evaluate to ensure that the plant can withstand normal and abnormal transients (e.g., rapid changes in reactor power) without undue risk to the health and safety of the public. Although the NRC does not expect that all of these postulated events will occur during the life of the plant, the NRC evaluates them to establish the basis for the preventive and mitigative safety systems of the facility. The acceptance criteria for DBAs are described in 10 CFR part 50, ''Domestic Licensing of Production and Utilization Facilities,'' and 10 CFR part 100, ''Reactor Site Criteria.'' Compliance with these regulations provides reasonable assurance of adequate protection of public health and safety.

During operations, the NRC requires each power plant licensee to maintain acceptable design and performance criteria in accordance with the NRC's regulations, including during any license renewal period. Therefore, the calculated releases from DBAs will remain within the NRC's regulatory limits.

The 1996 GEIS, in Section 5.2, discusses the impacts of potential accidents. It contains a discussion of plant accidents and consequences. This discussion addresses general characteristics of design basis (and severe) accidents, characteristics of fission products, meteorological considerations, possible exposure pathways, potential adverse health effects, avoiding adverse health effects, accident experience and observed impacts, and emergency preparedness. The revised GEIS reexamined the information from the 1996 GEIS and concluded that it is still valid. Because the information on DBAs is valid and has not changed, the revised GEIS does not repeat the information from the 1996 GEIS.

Severe Accidents. The NRC does not agree with the comments that the revised GEIS evaluation is inadequate regarding the impacts from severe accidents because it uses probability-weighted risk assessments. Severe accidents (i.e., beyond design basis accidents) are those that could result in substantial damage to the reactor core, whether or not there are serious off-site consequences. The 1996 GEIS estimated and considered the potential impacts on human health and economic factors from full-power severe reactor accidents initiated by internal events at different types of nuclear facilities located in different types of settings. That evaluation included modeling the release of radioactive materials into the environment and modeling the pathways (i.e., exposure to the radioactive plume, inhalation of radioactivity, consumption of contaminated food) through which members of the public could potentially be exposed to doses of radiation. Based on the calculated doses, the GEIS reported the consequences (i.e., potential early and latent fatalities) from such accidents. In developing a potential impact level, however, the NRC took into account the very low probability of such events, as well as their potential consequences, and concluded that the likely impact from individual nuclear power plants is small.

In the revised GEIS, the NRC expanded the scope of the severe accident evaluations and used more recent technical information that included both internal and external event core-damage frequency, as well as improved severe accident source terms, spent fuel pool accidents, low power and reactor shutdown events, new radiation risk-coefficients from the National Academy of Sciences, ''Health Risks from Exposure to Low Levels of Ionizing Radiation: Biological Effects of Ionizing Radiation (BEIR) VII'' report,[7] and risk impacts of reactor power uprates and higher fuel burn-up levels. As a result, the revised GEIS considers updated information in determining the potential consequences of a reactor accident. Considering this updated information and that severe reactor accidents remain unlikely, the revised GEIS concludes that the environmental impacts of a severe accident remain small.

The NRC notes, however, that the GEIS is not the primary vehicle the NRC uses to address and regulate risks from severe accidents. The NRC's regulations and regulatory practices employ safety standards in the design, construction, and operation of nuclear power plants as well as risk models to ensure the public is adequately protected on an ongoing basis. The NRC's ongoing oversight addresses the public's risk from nuclear power plant accidents, accounts for the effects of proposed changes that may be made as part of power plant operations, and considers new information about the facility or its environment when necessary.

[7] The BEIR VII report can be accessed at *http://search.nap.edu/napsearch.php?term=beir+vii.* The NRC staff reviewed this report in SECY–05–0202, ''Staff Review of the National Academies Study of the Health Risks from Exposure to Low Levels of Ionizing Radiation (BEIR VII),'' dated October 29, 2005 (ADAMS Accession No. ML052640532).

Although the NRC has determined that impacts from severe accidents are small for all facilities, the NRC continues to maintain that severe accidents cannot be a Category 1 issue because plant-specific mitigation measures vary greatly based on plant designs, safety systems, fuel type, operating procedures, local environment, population, and siting characteristics. Thus, severe accidents remain a Category 2 issue. Accordingly, the NRC has not changed the requirements in 10 CFR 51.53(c)(3)(ii)(L) that an applicant's environmental report must contain a discussion that considers alternatives to mitigate severe accidents if the NRC has not previously considered this issue in an environmental impact statement or environmental assessment for the facility.

Spent Fuel Pool Accidents. The 1996 GEIS included a quantitative analysis of a severe accident involving a reactor operating at full power. A qualitative evaluation of SFP accidents is presented in Appendix E of the revised GEIS. Based on this evaluation, the revised GEIS concludes that the environmental impacts from accidents involving SFPs are comparable to those from the reactor accidents at full power that were evaluated in the 1996 GEIS and as such, SFP accidents do not warrant separate evaluation. Based on the continued validity of conclusions from the 1996 GEIS, as affirmed by the Commission (*see* following paragraph), the revised GEIS does not contain a quantitative evaluation of SFP accidents.

The issue of an accident involving the spent fuel pool was specifically addressed by the NRC in its denial of two petitions for rulemaking (PRM): PRM–51–10 and PRM–51–12, submitted by the Attorney General of the Commonwealth of Massachusetts in 2006 and the Attorney General of California in 2007, respectively.[8] The petitioners requested that the NRC initiate a rulemaking concerning the environmental impacts of the high density storage of spent nuclear fuel in SFPs. The petitioners asserted that ''new and significant information'' shows that the NRC incorrectly characterized the environmental impacts of high-density spent fuel storage as ''insignificant'' in the 1996 GEIS for the renewal of nuclear power plant licenses. Specifically, the petitioners asserted that spent fuel stored in high-density SFPs is more vulnerable to a zirconium fire than the NRC concluded in its NEPA analysis. The NRC denied the two petitions, and the NRC denial was upheld by the United States Court of Appeals.

Aging-related Degradation. Issues related to age-related plant component degradation are addressed in the NRC's safety evaluation of the plant's license renewal application. The regulations covering the safety review for license renewal are in 10 CFR part 54, ''Requirements for Renewal of Operating Licenses for Nuclear Power Plants.''

The 1996 GEIS discusses the potential effects of age on the physical plant and notes that such deterioration could result in an increased likelihood of component or structure failure that could increase the rate of plant accidents. The GEIS notes that the NRC requires an applicant for license renewal to address the issue of age-related degradation by identifying, in an integrated plant assessment process, those passive, long-lived structures and components that are susceptible to age-related degradation and whose functions are necessary to ensure that the facility's current licensing basis is maintained. The GEIS found that the safety evaluation performed by the NRC as part of the license renewal process provides reasonable assurance that age-related degradation is managed and adequate protection of the health and safety of the public is maintained during the license renewal period. Therefore, the 1996 GEIS concluded, ''. . . the probability of any radioactive releases from accidents will not increase over the license renewal period.'' Based on nuclear power plants' continued compliance with 10 CFR part 54 to manage age-related degradation, the revised GEIS did not alter or revise this conclusion from the 1996 GEIS.

Greenhouse gas emissions and climate change. Several commenters discussed the need to include a discussion of the effects of climate change on plant operations and the effect of continued operations during the license renewal period on environmental resources affected by climate change.

NRC Response. The NRC acknowledges these concerns. The NRC has begun to evaluate the effects of greenhouse gas (GHG) emissions and its implications for global climate change in its environmental reviews for both new reactor and license renewal applications. Changes in climate have the potential to affect air and water resources, ecological resources, and human health, and should be taken into account when evaluating cumulative impacts over the license renewal term.

Subsequent to the publication of the proposed rule and during the public comment period, the Commission issued a memorandum and order concerning two combined operating license applications for new reactor units at the Tennessee Valley Authority Bellefonte site in Alabama and the Duke Energy Carolinas Lee site in South Carolina (CLI–09–21). The memorandum and order stated:

> because the Staff is currently addressing the emerging issues surrounding greenhouse gas emissions in environmental reviews required for the licensing of nuclear facilities, we believe it is prudent to provide the following guidance to the Staff. We expect the Staff to include consideration of carbon dioxide and other greenhouse gas emissions in its environmental reviews for major licensing actions under the National Environmental Policy Act. The Staff's analysis for reactor applications should encompass emissions from the uranium fuel cycle as well as from construction and operation of the facility to be licensed. The Staff should ensure that these issues are addressed consistently in agency NEPA evaluations and, as appropriate, update Staff guidance documents to address greenhouse gas emissions.[9]

Presently, insufficient data exists to support an impact level on a generic basis. The NRC only has direct emission data for a handful of facilities. Although some states have varying reporting requirements, GHG emissions reporting nationwide is in its infancy. The EPA promulgated its GHG emissions reporting rule on October 30, 2009 (74 FR 56260). In accordance with this rule, the first industry reporting date was March 31, 2011.[10] Moreover, the 25,000 annual metric ton reporting threshold EPA established in the final rule of October 30, 2009, is not an indication of what EPA considers to be a significant (or insignificant) level of GHG emissions on a scientific basis, but a threshold chosen by EPA for policy evaluation purposes.[11]

In order to comply with the Commission's direction in CLI–09–21 and in response to the comments received, a new section, ''Greenhouse Gas Emissions and Climate Change'' (Chapter 4, Section 4.12.3), summarizing the potential cumulative

[8] These PRMs were denied in the same **Federal Register** notice (73 FR 46204; August 8, 2008).

[9] In the matter of Duke Energy Carolinas, LLC (Combined License Application for William States Lee III Nuclear Station, Units 1 and 2); In the matter of Tennessee Valley Authority (Bellefonte Nuclear Power Plant, Units 3 and 4), CLI–09–21 (NRC November 3, 2009).

[10] 74 FR at 56267: October 30, 2009, codified at 40 CFR 98.3(b) (''The annual GHG report must be submitted no later than March 31 of each calendar year for GHG emissions in the previous calendar year'').

[11] The EPA concluded for policy evaluation purposes, that the 25,000 metric ton threshold more effectively targets large industrial emitters and suppliers, covers approximately 85 percent of the U.S. emissions, and minimizes the burden on smaller facilities (74 FR 56264; October 30, 2009).

impacts of GHG emissions and global climate change, has been added to the final revised GEIS. The NRC will also include within each SEIS a plant-specific analysis of any impacts caused by GHG emissions over the course of the license renewal term as well as any impacts caused by potential climate change upon the affected resources during the license renewal term. The final rule was not revised to include any reference to GHG emissions or climate change.

Recent advances in alternative energy technologies. Several commenters asserted that much of the information describing alternative energy technologies did not reflect the state-of-the-science. In some cases, commenters noted facts and events that occurred after the publication date of the draft revised GEIS.

NRC Response. The NRC has updated the final revised GEIS to incorporate the latest information on replacement power alternatives, but it is inevitable that rapidly evolving technologies will outpace the information presented in the final revised GEIS. Incorporation of this information is more appropriately made in the context of plant-specific license renewal reviews, rather than in the evaluations contained in the revised GEIS. As with renewable energy technologies, energy policies are evolving rapidly. While the NRC acknowledges that legislation, technological advancements, and public policy can underlie a fundamental paradigm shift in energy portfolios, the NRC cannot make decisions based on anticipated or speculative changes. Instead, the NRC considers the status of replacement power alternatives and energy policies when conducting plant-specific reviews. The final revised GEIS has been updated to clarify the NRC's approach to conducting replacement power alternative evaluations.

Emergency preparedness and security. Several commenters expressed concern with emergency preparedness, evacuation, and safety and security at nuclear power plants. Commenters stated that these topics were not addressed in the proposed rule and not adequately covered in the revised GEIS and should be included in the scope of the plant-specific SEISs.

NRC Response. Emergency preparedness and planning are part of the current licensing basis for each holder of a 10 CFR part 50 operating license and are outside the regulatory scope of license renewal. Before a plant is licensed to operate, the NRC must have ''reasonable assurance that adequate protective measures can and will be taken in the event of a radiological emergency'' (10 CFR 50.47). The Commission's regulatory scheme provides continuing assurance that emergency planning for every operating nuclear power plant is adequate. The Commission has determined that there is no need for a special review of emergency planning issues in the context of an environmental review for license renewal because the ongoing decisions and findings concerning emergency preparedness at nuclear power plants address concerns as they arise.

The Commission considered the need for a review of emergency planning issues in the context of license renewal during its rulemaking proceedings on 10 CFR part 54, which included public notice and comment. As discussed in the Statement of Considerations for the 10 CFR part 54 rulemaking (56 FR 64966; December 13, 1991), the programs for emergency preparedness at nuclear power facilities apply to all nuclear power facility licensees and require the specified levels of protection from each licensee regardless of plant design, construction, or license date. The NRC requirements related to emergency planning are in the regulations at 10 CFR 50.47 and Appendix E to 10 CFR part 50, ''Emergency Planning and Preparedness for Production and Utilization Facilities.'' These requirements apply to all holders of operating licenses and will continue to apply to facilities with renewed licenses. Through its standards and required exercises, the Commission reviews existing emergency preparedness plans throughout the life of any facility, keeping up with changing demographics and other site-related factors.

Further, the NRC actively reviews its regulatory framework to ensure that the regulations are current and effective. The agency began a major review of its emergency preparedness framework in 2005, including a comprehensive review of the emergency preparedness regulations and guidance, the issuance of generic communications regarding the integration of emergency preparedness and security, and outreach efforts to interested persons to discuss emergency preparedness issues. These activities informed a rulemaking effort to enhance the NRC's emergency preparedness regulations and guidance. This effort culminated in a final rule, which was published in the **Federal Register** on November 23, 2011 (76 FR 72560).

Security issues are not tied to a license renewal action but are treated on an ongoing basis as a part of the current (and renewed) operating license. If issues related to security are discovered at a nuclear power plant, they are addressed immediately, and any necessary changes are reviewed and incorporated under the current operating license. For example, after the terrorist attacks of September 11, 2001, the NRC issued security-related orders and guidance to nuclear power plant licensees. These orders and guidance included interim measures for emergency planning. Nuclear industry groups and Federal, State, and local government agencies assisted in the prompt implementation of these measures and participated in drills and exercises to test these new planning elements. The NRC reviewed licensees' commitments to address these requirements and verified their implementation through inspections to ensure public health and safety.

In summary, the issue of security is not unique to nuclear power plants requesting license renewal. The NRC routinely assesses threats and other information provided by other Federal agencies and sources. The NRC also ensures that licensees meet their security requirements through its ongoing regulatory process (routine inspections) as a current and generic regulatory issue that affects all nuclear power plants. Therefore, as discussed in the Statement of Considerations for the 10 CFR part 54 rulemaking (56 FR 64966), the Commission determined that there is no need for an evaluation of security issues in the context of a license renewal review.

V. Related Issues of Importance

This section addresses five issues of related importance to the final rule: (1) Consideration of the recent events at the Fukushima Dai-ichi Nuclear Power Plant, (2) removal of those parts of the final rule that refer to and rely upon the NRC's Waste Confidence Decision and Rule, (3) a description of the final rule's effective and compliance dates, (4) clarification of the term ''best management practices,'' and (5) deletion of the proposed definition of the term ''historic properties.''

A. Fukushima Events

On March 11, 2011, a massive earthquake off the east coast of Honshu, Japan produced a devastating tsunami that struck the coastal town of Fukushima. The six-unit Fukushima Dai-ichi Nuclear Power Plant was directly impacted by these events. The resulting damage caused the failure of several of the units' safety systems needed to maintain cooling water flow to the reactors. As a result of the loss of cooling, the fuel overheated, and there was a partial meltdown of the fuel contained in several of the reactors. Damage to the systems and structures containing reactor fuel resulted in the release of radioactive material to the surrounding environment.

In response to the earthquake, tsunami, and resulting reactor accidents at the Fukushima Dai-ichi Nuclear Power Plant (hereafter referred to as the ''Fukushima events''), the Commission directed the NRC staff to convene an agency task force of senior leaders and experts to conduct a methodical and systematic review of the relevant NRC regulatory requirements, programs, and processes, including their implementation, and to recommend whether the agency should make near-term improvements to its regulatory system. As part of the short-term review, the task force concluded that, while improvements are expected to be made as a result of the lessons learned from the Fukushima events, the continued operation of nuclear power plants and licensing activities for new plants do not pose an imminent risk to public health and safety.[12]

During the time that the task force was conducting its review, groups of individuals and non-governmental organizations petitioned the Commission to suspend all licensing decisions in order to conduct a separate, generic NEPA analysis to determine whether the Fukushima events constituted ''new and significant information'' under NEPA that must be analyzed as part of environmental reviews. The Commission found the request premature and noted, ''[i]n short, we do not know today the full implications of the [Fukushima] events for U.S. facilities.'' [13] However, the Commission found that if ''new and significant information comes to light that requires consideration as part of the ongoing preparation of application-specific NEPA documents, the agency will assess the significance of that information, as appropriate.'' [14] The Federal courts of appeal and the Commission have interpreted NEPA such that an EIS must be updated to include new information only when that new information provides ''a seriously different picture of the environmental impact of the proposed project from what was previously envisioned.'' [15]

In the context of the revised GEIS and this rulemaking, the Fukushima events are considered a severe accident (i.e., a type of accident that may challenge a plant's safety systems at a level much higher than expected) and more specifically, a severe accident initiated by an event external to the plant. The 1996 GEIS concluded that risks from severe accidents initiated by external events (such as an earthquake) could have potentially high consequences but found that external events are adequately addressed through a consideration of a severe accident initiated by an internal event (such as a loss of cooling water). Therefore, an applicant for license renewal need only analyze the environmental impacts from an internal event in order to adequately characterize the environmental impacts from either type of event. The revised GEIS examined more recent and up-to-date information regarding external events and concluded that the analysis in the 1996 GEIS remains valid. The Fukushima events are not considered in the revised GEIS because the analysis in the revised GEIS was completed prior to the Fukushima events.

The NRC's evaluation of the consequences of the Fukushima events is ongoing. As such, the NRC will continue to evaluate the need to make improvements to existing regulatory requirements based on the task force report and additional studies and analyses of the Fukushima events as more information is learned. To the extent that any revisions are made to the NRC's regulatory requirements, they would be made applicable to nuclear power reactors regardless of whether or not they have a renewed license. Therefore, no additional analyses have been performed in the revised GEIS as a result of the Fukushima events. In the event that the NRC identifies information from the Fukushima events that constitutes new and significant information with respect to the environmental impacts of license renewal, the NRC will discuss that information in its site-specific SEISs to the GEIS, as it does with all such new and significant information.

B. Removal of References to the Waste Confidence Decision and Rule

The Waste Confidence Decision and Rule represented the Commission's generic determination that spent nuclear fuel can continue to be stored safely and without significant environmental impacts for a period of time after the end of the licensed life for operation of a nuclear power plant.[16] This generic determination meant that the NRC did not need to consider the storage of spent nuclear fuel after the end of a reactor's licensed life for operation in the NEPA documents that support its reactor and spent-fuel storage license application reviews.

On December 23, 2010, the Commission published a revision of the Waste Confidence Decision and Rule to reflect information gained from experience in the storage of spent nuclear fuel and the increased uncertainty in the siting and construction of a permanent geologic repository for the disposal of spent nuclear fuel and high-level waste.[17] In response to the 2010 Waste Confidence Decision and Rule, the states of New York, New Jersey, Connecticut, and Vermont, along with several other parties, challenged the Commission's NEPA analysis in the decision, which provided the regulatory basis for the rule. On June 8, 2012, the United States Court of Appeals, District of Columbia Circuit, in *New York* v. *NRC,* 681 F.3d 471 (D.C. Cir. 2012), vacated the NRC's Waste Confidence Decision and Rule, after finding that it did not comply with NEPA.

The court concluded that the Waste Confidence Decision and Rule is a major federal action necessitating either an EIS or an environmental assessment that results in a ''finding of no significant impact.'' In vacating the 2010 decision and rule, the court identified three specific deficiencies in the analysis:

1. As to the Commission's conclusion that permanent disposal will be available ''when necessary,'' the court held that the Commission did not evaluate the environmental effects of failing to secure permanent disposal;

2. As to the storage of spent fuel on-site at nuclear plants after the expiration

[12] Recommendations for Enhancing Reactor Safety in the 21st Century, The Near-Term Task Force Review of Insights from the Fukushima Dai-ichi Accident'' (July 12, 2011) (ADAMS Accession No. ML111861807).

[15] *Id.* at 31 (quoting *Hydro Resources, Inc.* (2929 Coors Road, Suite 101, Albuquerque, NM 87120), CLI–99–22, 50 NRC 3, 14 (1999) (citing *Marsh* v. *Oregon Natural Resources Council,* 490 U.S. 360, 373 (1989))). The Commission also noted that it can modify a facility's operating license outside of a renewal proceeding and made clear that ''it will use the information from these activities to impose any requirement it deems necessary, irrespective of whether a plant is applying for or has been granted a renewed operating license.'' *Id.* at 26–27.

[16] The NRC first adopted the Waste Confidence Decision and Rule in 1984. The NRC amended the decision and rule in 1990, reviewed them in 1999, and amended them again in 2010. 49 FR 34694 (August 31, 1984); 55 FR 38474 (September 18, 1990); 64 FR 68005 (December 6, 1999); and 75 FR 81032 and 81037 (December 23, 2010). The NRC made a minor amendment to the rule in 2007 to clarify that it applies to combined licenses. 72 FR 49509 (August 28, 2007). The Waste Confidence Decision and Rule are codified in the NRC regulation 10 CFR 51.23.

[17] 75 FR 81032 and 81037.

of a plant's operating license, the court concluded that the Commission failed to properly examine the risk of spent fuel pool leaks in a forward-looking fashion; and

3. Also related to the post-license storage of spent fuel, the court concluded that the Commission failed to properly examine the consequences of spent fuel pool fires.

In response to the court's ruling, the Commission issued CLI–12–16 on August 7, 2012 (ADAMS Accession No. ML12220A212), in which the Commission determined that it would not issue licenses that rely upon the Waste Confidence Decision and Rule until the issues identified in the court's decision are appropriately addressed by the Commission. CLI–12–16 provided, however, that the decision not to issue licenses only applied to final license issuance; all licensing reviews and proceedings should continue to move forward. In SRM–COMSECY–12–0016, ''Approach for Addressing Policy Issues Resulting from Court Decision to Vacate Waste Confidence Decision and Rule,'' dated September 6, 2012 (ADAMS Accession No. 12250A032), the Commission directed the NRC staff to proceed with a rulemaking that includes the development of a generic EIS to support a revised Waste Confidence Decision and Rule and to publish both the EIS and the revised decision and rule in the **Federal Register** within 24 months. The Commission indicated that both the EIS and the revised Waste Confidence Decision and Rule should build on the information already documented in various NRC studies and reports, including the existing environmental assessment that the NRC developed as part of the 2010 Waste Confidence Decision and Rule. The Commission directed that any additional analyses should focus on the three deficiencies identified in the court's decision. The Commission also directed that the NRC staff provide ample opportunity for public comment on both the draft EIS and the proposed Waste Confidence Decision and Rule.

In accordance with CLI–12–16, the NRC will not approve any site-specific license renewal applications until the deficiencies identified in the court's decision have been resolved. Two Table B–1 license renewal issues that rely, wholly or in part, upon the Waste Confidence Decision and Rule are the ''Onsite storage of spent nuclear fuel'' and ''Offsite radiological impacts of spent nuclear fuel and high-level waste disposal.'' Both of these issues were classified as Category 1 in the 10 CFR part 51 rule that was promulgated in 1996; the 2009 proposed rule continued the Category 1 classification for both of these issues. As part of the NRC's response to the *New York* v. *NRC* decision, this final rule revises these two issues accordingly. Specifically, this final rule revises the Category 1 ''Onsite storage of spent nuclear fuel'' issue to narrow the period of onsite storage to the license renewal term. In both the 1996 rule [18] and the 2009 proposed rule, the NRC relied upon the Waste Confidence Decision and Rule to make a generic finding that spent nuclear fuel could be stored safely onsite with no more than a small environmental impact for the term of the extended license (from approval of the license renewal application to the expiration of the operating license) plus a 30-year period following the permanent shutdown of the power reactor and expiration of the operating license.[19]

The Waste Confidence Decision and Rule provided the basis for the 30-year period following the permanent shutdown of the reactor and expiration of the operating license. The 2010 Waste Confidence Decision and Rule extended this post-reactor shutdown onsite storage period from 30 years to 60 years. Given the *New York* v. *NRC* decision, and pending the issuance of a generic EIS and revised Waste Confidence Decision and Rule (as directed by SRM–COMSECY–12–0016), the final rule excludes from this issue the period of onsite storage of spent nuclear fuel following the permanent shutdown of the power reactor and expiration of the operating license. As revised by this final rule, this issue now covers the onsite storage of spent fuel for the term of the extended license only.

Similarly, this final rule revises the Category 1 issue ''Offsite radiological impacts of spent nuclear fuel and high level waste disposal.'' [20] In both the 1996 rule and the 2009 proposed rule, this issue pertained to the long-term disposal of spent nuclear fuel and high-level waste, including possible disposal in a deep geologic repository. Although the Waste Confidence Decision and Rule did not assess the impacts associated with disposal of spent nuclear fuel and high-level waste in a repository, it did reflect the Commission's confidence, at the time, in the technical feasibility of a repository and when that repository could have been expected to become available. Without the analysis in the Waste Confidence Decision, the NRC cannot assess how long the spent fuel will need to be stored onsite. Therefore, the final rule reclassifies this issue from a Category 1 issue with no assigned impact level to an uncategorized issue with an impact level of uncertain.

Upon issuance of the generic EIS and revised Waste Confidence Rule, the NRC will make any necessary conforming amendments to this rule. As referenced previously, the Commission will not approve any license renewal application for an operating nuclear power plant until the issues identified in the court's decision are appropriately addressed by the Commission.

C. Effective and Compliance Dates for Final Rule

The amendments made by the final rule shall be effective 30 days after the final rule's publication in the **Federal Register**. License renewal applicants are not required to comply with the amended rule until 1 year after the final rule's publication in the **Federal Register**. The Commission has decided on a 1-year compliance date given the long lead time required for preparation of license renewal applicant environmental reports.

D. Best Management Practices

''Best management practices'' is a term used to describe a type, method, or treatment technique for preventing pollution or reducing the quantities of pollutants released to the environment. The term, as used herein, includes the physical components used to control or minimize pollution (e.g., filters, barriers, mechanical devices, and retention ponds), as well as operational or procedural practices (e.g., minimizing use of a pollutant, spill control, and operator training). Best management practices are used in a variety of industrial sectors. In the nuclear power reactor sector, as in other industrial sectors, best management practices offer flexibility to achieve a balance between protecting the environment and the efficiency and economic limitations associated with the operations of a given plant. Both in the 1996 GEIS and in the revised GEIS, several issues have been determined to be a Category 1 issue with an impact level of small based upon the assumption that the license renewal applicant employs and will continue to employ best management practices

[18] The issue was named ''On-site spent fuel'' in the 1996 rule.

[19] Prior to the December 23, 2010, final rule, 10 CFR 51.23(a) read: ''The Commission has made a generic determination that, if necessary, spent fuel generated in any reactor can be stored safely and without significant environmental impacts for at least 30 years beyond the licensed life for operation (which may include the term of a revised or renewed license) of that reactor at its spent fuel storage basin or at either onsite or offsite independent spent fuel storage installations.''

[20] The issue was named ''Offsite radiological impacts (spent fuel and high level waste disposal)'' in the 1996 rule.

during the license renewal term. The NRC's regulatory experience has shown that licensees employ such best management practices.

The NRC's jurisdiction is limited to radiological health and safety and common defense and security. Therefore, the NRC does not generally impose a requirement that its licensees adopt those best management practices that concern non-radiological pollutants. The NRC nuclear power plant licensees, however, are subject to a host of regulatory requirements that are monitored and enforced by other Federal agencies (e.g., the EPA) or State or local regulatory agencies. The NRC-licensed nuclear power plants must obtain a variety of permits from these other agencies before they can operate (e.g., under the CWA, a licensee must obtain a NPDES permit from the EPA or, if the EPA has delegated its CWA authority to a particular State, from the appropriate agency of that State). These permits typically require that the licensee adopt and adhere to best management practices.

Therefore, an assumption underlying the revised GEIS is that NRC licensees will use best management practices to comply with other Federal, State, and local government requirements to prevent or reduce the quantities of non-radiological pollutants released to the environment. This description of best management practices is not a regulatory or policy change by the NRC because the use of best management practices by nuclear power plant licensees was also an underlying assumption of the 1996 GEIS. Rather, the NRC seeks to make transparent its basis for determining that certain issues are Category 1 issues with a small level of impact.

E. Definition of ''Historic Properties''

The proposed rule would have amended 10 CFR part 51 by adding a definition of the term ''historic properties'' to 10 CFR 51.14(a). Upon further consideration, the NRC determined that adding the definition was unnecessary. The NRC's license renewal determination to renew or not renew a nuclear power plant operating license is considered an undertaking as defined by Section 106 of the National Historic Preservation Act (NHPA) and its implementing regulations in 36 CFR part 800. The regulations define the term ''historic property'' in 36 CFR 800.16(l)(1). The NRC uses the term ''historic property'' or ''historic properties'' in the same context as set forth in 36 CFR 800.16(l)(1).

VI. Revisions to 10 CFR 51.53

The final rule revises 10 CFR 51.53 to conform to those changes made by the final rule to Table B–1. Because some Category 2 issues have been reclassified as Category 1 issues, license renewal applicants no longer need to assess these issues and, therefore, the final rule removes the requirements for applicants to provide information on these issues in their environmental reports. The final rule also adds new requirements to 10 CFR 51.53 for the new Category 2 issues for which applicants are now required to provide information in their environmental reports. The following describes each revision.

A. Reclassifying Category 2 Issues as Category 1 Issues

Section 51.53(c)(3)(ii)(F). The final rule removes and reserves 10 CFR 51.53(c)(3)(ii)(F) because the final rule reclassifies the Category 2 issue, ''Air quality during refurbishment (nonattainment and maintenance areas),'' to Category 1 and renames the issue, ''Air quality impacts (all plants).'' The removed regulatory language required the applicant to assess anticipated vehicle exhaust emissions at the time of refurbishment for plants located in or near a nonattainment or maintenance area, as those terms are defined under the Clean Air Act.

The final rule reclassifies this issue as Category 1 based upon public comments received on the proposed rule [21] and a subsequent re-evaluation of the data in the draft revised GEIS, which showed that air quality impacts from refurbishment have not resulted in exceedances in the *de minimis* thresholds for criteria pollutants in nonattainment and maintenance areas due to construction vehicle, equipment, and fugitive dust emissions. Significant air quality impacts are no longer anticipated from future license renewals. Therefore, applicants no longer need to assess the impacts on air quality of continued operations and refurbishment associated with license renewal in their environmental reports.

Section IV, ''Response to Public Comments,'' of this document provides a summary of the comments received on this issue, and Section VIII, ''Final Actions and Basis for Changes to Table B–1,'' of this document discusses this issue in more detail under Issue 5, ''Air quality impacts (all plants).''

Section 51.53(c)(3)(ii)(I). The final rule removes and reserves 10 CFR 51.53(c)(3)(ii)(I) because several Category 2 socioeconomic issues are reclassified as Category 1. The removed regulatory language required the applicant to assess the impacts of the proposed license renewal on housing availability, land use, and public schools (impacts from refurbishment activities only) within the vicinity of the plant. Additionally, the removed regulatory language required the applicant to assess the impact of population increases attributable to the proposed project on the public water supply. Specifically, the final rule reclassifies the following 1996 GEIS Category 2 socioeconomic issues: Housing impacts; [22] Public services: public utilities; [23] Public services, education (refurbishment); [24] Offsite land use (refurbishment); and Offsite land use (license renewal term).[25]

The final rule reclassifies these issues as Category 1 because significant changes in housing availability, land use, and increased population demand attributable to the proposed refurbishment project on the public water supply have not occurred at relicensed nuclear power plants. Therefore, impacts to these resources are no longer anticipated for future license renewals. In addition, refurbishment activities (such as steam generator and vessel head replacement) have not required the large numbers of workers and the months of time that were conservatively analyzed in the 1996 GEIS. As such, significant impacts on housing availability, land use, public schools, and the public water supply are no longer anticipated from continued operations during the license renewal term and refurbishment associated with license renewal.

Section 51.53(c)(3)(ii)(J). The final rule removes and reserves 10 CFR 51.53(c)(3)(ii)(J) because the Category 2 issue, ''Public services, transportation,'' is reclassified as Category 1 (the final rule also renames the issue, ''Transportation''). The removed

[21] The proposed rule renamed the ''Air quality during refurbishment (nonattainment and maintenance areas)'' issue as ''Air quality (nonattainment and maintenance areas)'' and retained the Category 2 classification.

[22] The final rule renames this issue as ''Population and housing'' (*see* Issue (55) under Section VIII, ''Final Actions and Basis for Changes to Table B–1,'' of this document).

[23] The final rule merges this issue into the consolidated issue, ''Community services and education'' (*see* Issue (54) under Section VIII of this document).

[24] The final rule merges this issue into the consolidated issue, ''Community services and education'' (*see* Issue (54) under Section VIII of this document).

[25] The final rule merges ''Offsite land use (refurbishment)'' and ''Offsite land use (license renewal term) into the consolidated issue, ''Offsite land use'' (*see* Issue (2) under Section VIII of this document).

regulatory language required the applicant to assess the impact of highway traffic generated by the proposed project on the level of service of local highways during periods of license renewal refurbishment activities and during the term of the renewed license. Therefore, applicants no longer need to assess the impacts on local traffic volumes of continued operations and refurbishment associated with license renewal in their environmental reports.

The issue was reclassified to Category 1 because refurbishment activities (such as steam generator and vessel head replacement) have not required the large numbers of workers and the months of time that was conservatively analyzed in the 1996 GEIS. As such, significant transportation impacts are not anticipated from future refurbishment activities. Section VIII, ''Final Actions and Basis for Changes to Table B–1,'' of this document discusses this issue in more detail under Issue 56, ''Transportation.''

Section 51.53(c)(3)(ii)(O). The proposed rule added a new paragraph 10 CFR 51.53(c)(3)(ii)(O) to address ''Groundwater and soil contamination'' as a Category 2 issue. However, based upon public comments received on the proposed rule [26] and further evaluation by the NRC, it was determined that this issue is properly classified as Category 1. Therefore, the proposed paragraph was not adopted by the final rule.[27]

B. Adding New Category 2 Issues

Section 51.53(c)(3)(ii)(N). The final rule adds a new paragraph 10 CFR 51.53(c)(3)(ii)(N) [28] to address ''Minority and low-income populations'' as a Category 2 issue. This new Category 2 issue is listed under the resource area ''Environmental Justice'' in the revised Table B–1. It addresses the effects of nuclear power plant operations and refurbishment associated with license renewal on minority populations and low-income populations living in the vicinity of the plant. This issue was listed in the original Table B–1 but was not evaluated in the 1996 GEIS. The finding in the original Table B–1 stated that ''[t]he need for and the content of an analysis of environmental justice will be addressed in plant specific reviews.'' This issue was not classified as either a Category 1 or 2 issue in the 1996 GEIS because guidance for implementing Executive Order (E.O.) 12898, dated February 16, 1994 (59 FR 7629), which initiated the Federal government's environmental justice program, was not available before the completion of the 1996 GEIS.

In August 2004, the Commission issued a policy statement on implementation of E.O. 12898: ''NRC's Policy Statement on the Treatment of Environmental Justice Matters in NRC Regulatory and Licensing Actions'' (69 FR 52040). As stated therein, ''the NRC is committed to the general goals of E.O. 12898, [and] it will strive to meet those goals through its normal and traditional NEPA review process.'' By making this a Category 2 issue, the final rule requires license renewal applicants to identify, in their environmental reports, minority and low-income populations and communities residing in the vicinity of the nuclear power plant. The NRC will then assess the information provided by the applicant in the NRC's plant-specific environmental review.

Section 51.53(c)(3)(ii)(O). The final rule adds a new paragraph 10 CFR 51.53(c)(3)(ii)(O) [29] to address ''Cumulative impacts'' as a Category 2 issue. This new Category 2 issue was added to Table B–1 to evaluate the potential cumulative impacts of continued operations during the license renewal term and refurbishment associated with license renewal at nuclear power plants. The NRC did not address cumulative impacts in the 1996 GEIS but has been evaluating these impacts in plant-specific supplements to the GEIS. The Council on Environmental Quality (CEQ) in 40 CFR 1508.7 defines cumulative impacts as ''the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions.'' [30] The NRC considers potential cumulative impacts on the environment resulting from the incremental impact of license renewal when added to other past, present, and reasonably foreseeable future actions.

The final rule change requires license renewal applicants to provide information about other past, present, and reasonably foreseeable future actions occurring in the vicinity of the nuclear power plant that may result in a cumulative impact. An example of the type of information to be provided includes data on the construction and operation of other power plants and other industrial commercial facilities in the vicinity of the nuclear power plant. Section VIII, ''Final Actions and Basis for Changes to Table B–1,'' of this document discusses this issue in more detail under Issue 73, ''Cumulative impacts.''

Section 51.53(c)(3)(ii)(P). The final rule adds a new paragraph 10 CFR 51.53(c)(3)(ii)(P) [31] to address ''Radionuclides released to groundwater'' as a Category 2 issue. This new Category 2 issue has been added to Table B–1 to evaluate the potential combined impact of inadvertent discharges of radioactive liquids from all plant systems into groundwater. The issue is relevant to license renewal because all commercial nuclear power plants have spent fuel pools, liquid storage tanks, and piping that contain and transport radioactive liquids. Over time, these systems and piping have a potential to degrade and release radioactive liquids that could migrate into the groundwater. The NRC has investigated several cases where radioactive liquids have been inadvertently released into the groundwater in an uncontrolled manner. In accordance with NRC requirements, residual activity from these inadvertent releases is subject to characterization and evaluation of the potential hazard. For this new Category 2 issue, the license renewal applicant is required to provide information on radioactive liquids released to groundwater.

In the final rule, the NRC modified the language of the proposed rule to specify that only ''documented'' releases need to be included in the applicant's environmental report. The NRC provides specific guidance on what constitutes a documented release in Regulatory Guide 4.2, Supplement 1, Revision 1, ''Preparation of Environmental Reports for Nuclear

[26] Section IV, ''Response to Public Comments,'' of this document provides a summary of the comments received on this issue.

[27] The final rule merges this issue into the consolidated issue, ''Groundwater contamination and use (non-cooling system impacts)'' (*see* Issue (20) under Section VIII of this document).

[28] The final rule adopts the proposed rule language.

[29] The proposed rule added this paragraph as 10 CFR 51.53(c)(3)(ii)(P). The final rule redesignates it as 10 CFR 51.53(c)(3)(ii)(O) because paragraph 10 CFR 51.53(c)(3)(ii)(O) of the proposed rule, which concerned ''Groundwater and soil contamination'' (*see* discussion in Section VI, ''A. Reclassifying Category 2 Issues as Category 1 Issues,'' of this document) was not adopted by the final rule.

[30] The NRC's regulations in 10 CFR part 51 incorporate the CEQ definition of cumulative impacts (10 CFR 51.14(b)).

[31] The proposed rule added this paragraph as 10 CFR 51.53(c)(3)(ii)(Q). The final rule redesignates it as paragraph 10 CFR 51.53(c)(3)(ii)(P) because the paragraph added as 10 CFR 51.53(c)(3)(ii)(O) by the proposed rule, which concerned groundwater and soil contamination caused by non-radionuclide, industrial contaminants, was not adopted by the final rule (*see* discussion in Section VI, ''A. Reclassifying Category 2 Issues as Category 1 Issues,'' of this document).

Power Plant License Renewal Applications.''

Section IV, ''Response to Public Comments,'' of this document provides a summary of the comments received on this issue, and Section VIII, ''Final Actions and Basis for Changes to Table B–1,'' of this document discusses this issue in more detail under Issue 27, ''Radionuclides released to groundwater.''

VII. Response to Specific Request for Voluntary Information

In Section VII of the Statement of Considerations for the July 31, 2009 (74 FR 38129–38130), proposed rule, the NRC requested voluntary information from industry about refurbishment activities and employment trends at nuclear power plants. Information on refurbishment would have been used to evaluate the significance of impacts from this type of activity. Information on employment trends would have been used to assess the significance of socioeconomic effects of ongoing plant operations on local economies.

The NRC received no response to these requests. The NRC interprets this lack of response on these issues to mean that information on major refurbishment and replacement activities and employment trends is either unavailable or insufficient to assist the NRC in re-evaluating the significance of refurbishment-related environmental impacts and socioeconomic effects of ongoing plant operations on local economies. Although no information was received regarding refurbishment activities and employment trends at nuclear power plants, the NRC believes that it has sufficient information based on lessons learned and knowledge gained from completed license renewal environmental reviews to substantiate the conclusions made in the final rule and GEIS.

VIII. Final Actions and Basis for Changes to Table B–1

The final rule revises Table B–1 to reflect the changes made in the revised GEIS. The revised GEIS is being made available with the final rule and provides a summary change table (in Appendix B) comparing the 92 environmental issues in the 1996 GEIS with the 78 environmental issues in the revised GEIS.

Land Use

(1) Onsite Land Use: ''Onsite land use'' remains a Category 1 issue. The final rule amends Table B–1 by making minor clarifying changes to the finding column entry for this issue. Specifically, the final rule replaces the sentence ''Projected onsite land use changes required during refurbishment and the renewal period would be a small fraction of any nuclear power plant site and would involve land that is controlled by the applicant,'' with ''Changes in onsite land use from continued operations and refurbishment associated with license renewal would be a small fraction of the nuclear power plant site and would involve only land that is controlled by the licensee.''

(2) Offsite Land Use: The final rule amends Table B–1 by consolidating two Category 2 issues, ''Offsite land use (refurbishment),'' with an impact level range small to moderate, and ''Offsite land use (license renewal term),'' with an impact level range small to large, and reclassifying the consolidated issue as a Category 1 issue, with an impact level of small, and naming the consolidated issue, ''Offsite land use.'' The final rule also creates a new Category 1 issue, ''Tax revenues'' (Issue 53), which concerns the impact of license renewal on state and local tax revenues, thereby removing tax revenues from the 1996 GEIS ''Offsite land use (license renewal term)'' issue. The final rule amends Table B–1 by removing the entries for ''Offsite land use (refurbishment)'' and ''Offsite land use (license renewal term),'' and by adding an entry for ''Offsite land use.'' The finding column entry of ''Offsite land use'' states ''[o]ffsite land use would not be affected by continued operations and refurbishment associated with license renewal.''

The Table B–1 finding column entry for the ''Offsite land use (refurbishment)'' issue indicated that impacts may be of moderate significance at plants in low population areas. Similarly, the finding column entry for the ''Offsite land use (license renewal term)'' issue indicates that significant changes (moderate to large) in land use may be associated with population and tax revenue changes resulting from license renewal. As described in the 1996 GEIS, environmental impacts are considered to be small if refurbishment activities were to occur at plants located in high population areas and if population and tax revenues would not change.

As reflected in the revised GEIS, significant impacts on offsite land use are not anticipated. Previous plant-specific license renewal reviews conducted by the NRC have shown no substantial increases in the number of workers during the license renewal term and that refurbishment activities (such as steam generator and vessel head replacement) have not required the large numbers of workers and the months of time that was conservatively estimated in the 1996 GEIS. These reviews support a finding that offsite land use impacts during the license renewal term would be small for all nuclear power plants.

(3) Offsite Land Use in Transmission Line Right-of-Ways (ROWs): The final rule amends Table B–1 by renaming the ''Power line right of way'' issue as ''Offsite land use in transmission line right-of-ways (ROWs).'' It remains a Category 1 issue with an impact level of small. The final rule amends the Table B–1 finding column entry for this issue by replacing the statement,

> Ongoing use of power line right of ways would continue with no change in restrictions. The effects of these restrictions are of small significance.

with the following:

> Use of transmission line ROWs from continued operations and refurbishment associated with license renewal would continue with no change in land use restrictions.

The final rule further amends Table B–1 by appending a footnote to the issue column entry for ''Offsite land use in transmission line right-of-ways (ROWs),'' concerning the extent to which transmission lines and their associated ROWs have been analyzed in the revised GEIS. The footnote states,

> This issue applies only to the in-scope portion of electric power transmission lines which are defined as transmission lines that connect the nuclear power plant to the substation where electricity is fed into the regional power distribution system and transmission lines that supply power to the nuclear plant from the grid.

As stated in the revised GEIS, the final environmental statements (essentially, the equivalent of environmental impact statements) prepared for the original construction of the various nuclear power plants (the construction permits) and for the initial operating licenses evaluated the impacts of those transmission lines built to connect the nuclear power plant to the regional electrical grid. Since the original construction of those lines, regional expansion of the electrical distribution grid has resulted in incorporation of those lines originating at the power plant substations. In most cases, the transmission lines originating at the power plant substations are no longer owned or managed by the nuclear power plant licensees. These lines would remain in place and be energized regardless of whether the subject nuclear power plant license was renewed or not. For this reason, those transmission lines that would not be impacted by a license renewal decision (i.e., those lines that would not be dismantled or otherwise decommissioned as a result of a plant terminating operations because its operating license had not been renewed) are considered beyond the scope of, and as such are not analyzed in, the revised GEIS.

Visual Resources

(4) Aesthetic Impacts: The final rule amends Table B–1 by consolidating three Category 1 issues, ''Aesthetic impacts (refurbishment),'' ''Aesthetic impacts (license renewal term),'' and ''Aesthetic impacts of transmission lines (license renewal term),'' each with an impact level of small, into one new Category 1 issue, ''Aesthetic impacts.'' The new consolidated issue also has an impact level of small. The 1996 GEIS concluded that renewal of operating licenses and the refurbishment activities would have no significant aesthetic impact during the license renewal term. Impacts are considered to be small if the visual appearance of plant and transmission line structures would not change. Previous license renewal reviews conducted by the NRC show that the appearance of nuclear power plants and transmission line structures do not change significantly over time or because of refurbishment activities. Therefore, because aesthetic impacts are not anticipated and the three issues are similar, they have been consolidated to facilitate the environmental review process. The final rule amends Table B–1 by removing the entries for ''Aesthetic impacts (refurbishment),'' ''Aesthetic impacts (license renewal term),'' and ''Aesthetic impacts of transmission lines (license renewal term),'' and adding an entry for ''Aesthetic impacts.'' The finding column entry for the new combined entry states ''[n]o important changes to the visual appearance of plant structures or transmission lines are expected from continued operations and refurbishment associated with license renewal.''

Air Quality

(5) Air Quality Impacts (All Plants): The final rule amends Table B–1 by renaming the ''Air quality during refurbishment (nonattainment and maintenance areas)'' issue as ''Air quality impacts (all plants).'' The final rule reflects the revised GEIS's expansion of the issue to include air emission impacts from emergency diesel generators, boilers, and particulate emissions from cooling towers. Based on public comments received on the proposed rule and the re-evaluation of information as described in the revised GEIS, the final rule further amends Table B–1 by revising this Category 2 issue, with an impact level range small to large, to a Category 1 issue with an impact level of small.[32] The final rule further amends Table B–1 by revising the finding column entry for this issue to state,

> Air quality impacts from continued operations and refurbishment associated with license renewal are expected to be small at all plants. Emissions resulting from refurbishment activities at locations in or near air quality nonattainment or maintenance areas would be short-lived and would cease after these refurbishment activities are completed. Operating experience has shown that the scale of refurbishment activities has not resulted in exceedance of the *de minimis* thresholds for criteria pollutants, and best management practices including fugitive dust controls and the imposition of permit conditions in State and local air emissions permits would ensure conformance with applicable State or Tribal Implementation Plans.
>
> Emissions from emergency diesel generators and fire pumps and routine operations of boilers used for space heating would not be a concern, even for plants located in or adjacent to nonattainment areas. Impacts from cooling tower particulate emissions even under the worst-case situations have been small.

Operating experience has shown that air quality impacts from these emission sources (including particulate emissions from cooling towers at operating plants) have been small at all nuclear power plants, including those plants located in or adjacent to nonattainment areas.

In addition, air quality impacts during refurbishment have also been small. These types of emissions could be a cause for concern if they occur at plants located in or near air quality nonattainment or maintenance areas. However, these impacts have been temporary and would cease once these activities were completed. Operating experience has also shown that refurbishment activities have not required the large numbers of workers and the months of time that was conservatively predicted and analyzed in the 1996 GEIS, nor have such activities resulted in exceedances in the *de minimis* thresholds for criteria pollutants in nonattainment and maintenance areas.

Implementation of best management practices, including fugitive dust controls as required by the imposition of conditions in State and local air emissions permits, would ensure conformance with applicable State or Tribal Implementation Plans, in accordance with EPA's revised General Conformity Regulations (75 FR 17254; April 5, 2010). On the basis of these considerations, the NRC has concluded that the air quality impact of continued nuclear power plant operations and refurbishment associated with license renewal would be small for all plants.

(6) Air Quality Effects of Transmission Lines: The final rule amends Table B–1 by appending a footnote to the issue column entry for ''Air quality effects of transmission lines,'' concerning the extent to which transmission lines and their associated right of ways have been analyzed under the revised GEIS. This footnote is the same one that was added to Issue 3, ''Offsite land use in transmission line right-of-ways (ROWs).'' See the description of the changes made by the final rule to Issue 3 for further explanation of this amendment.

Noise

(7) Noise Impacts: The final rule amends Table B–1 by renaming the issue ''Noise'' as ''Noise impacts.'' The issue remains a Category 1 issue with an impact level of small. The final rule further amends Table B–1 by making minor clarifying changes to the finding column entry for this issue. Specifically, the final rule replaces the sentence ''Noise has not been found to be a problem at operating plants and is not expected to be a problem at any plant during the license renewal term,'' with ''Noise levels would remain below regulatory guidelines for offsite receptors during continued operations and refurbishment associated with license renewal.''

Geologic Environment

(8) Geology and Soils: The final rule amends Table B–1 by adding a new Category 1 issue, ''Geology and soils.'' This issue has an impact level of small. The finding column entry for this issue states,

> The effect of geologic and soil conditions on plant operations and the impact of continued operations and refurbishment activities on geology and soils would be small for all nuclear power plants and would not change appreciably during the license renewal term.

This issue was not evaluated in the 1996 GEIS, as described in the proposed rule.[33] This new Category 1 issue considers geology and soils from the perspective of those resource conditions or attributes that can be affected by

[32] Under the proposed rule, the issue had been proposed to be renamed ''Air quality (nonattainment and maintenance areas);'' it would have remained a Category 2 issue with an impact level range of small to large (74 FR 38121, 38134; July 31, 2009).

[33] The proposed rule named the issue ''Impacts of nuclear plants on geology and soils.'' Under the proposed rule, the issue was also a Category 1 issue, with an impact level of small (74 FR 38121, 38134; July 31, 2009).

continued operations during the renewal term. The final rule does not require the license renewal applicant to assess this issue in its environmental report unless the applicant is aware of new and significant information about geologic and soil conditions and associated impacts at or near the nuclear power plant site that could change the conclusion in the GEIS.

An understanding of geologic and soil conditions has been well established at all nuclear power plants and associated transmission lines during the current licensing term, and these conditions are expected to remain unchanged during the 20-year license renewal term for each plant. The impact of these conditions on plant operations and the impact of continued power plant operations and refurbishment activities on geology and soils are small for all nuclear power plants and not expected to change appreciably during the license renewal term. Operating experience shows that any impacts to geologic and soil strata would be limited to soil disturbance from construction activities associated with routine infrastructure renovation and maintenance projects during continued plant operations. Implementing best management practices would reduce soil erosion and subsequent impacts on surface water quality. Information in plant-specific SEISs prepared to date and reference documents have not identified these impacts as being significant.

Surface Water Resources

(9) Surface Water Use and Quality (Non-Cooling System Impacts): The final rule amends Table B–1 by consolidating two Category 1 issues, ''Impacts of refurbishment on surface water quality'' and ''Impacts of refurbishment on surface water use,'' both with an impact level of small, and names the consolidated issue, ''Surface water use and quality (non-cooling system impacts).'' These two issues were consolidated because the impacts of refurbishment on both surface water use and quality are negligible and the effects are closely related. The consolidated issue has also been expanded to include the impacts of continued operations. The consolidated issue is a Category 1 issue with an impact level of small.

The final rule amends Table B–1 by removing the entries for ''Impacts of refurbishment on surface water quality'' and ''Impacts of refurbishment on surface water use'' and adding an entry for ''Surface water use and quality (non-cooling system impacts).'' The finding column entry for the new consolidated issue states,

> Impacts are expected to be small if best management practices are employed to control soil erosion and spills. Surface water use associated with continued operations and refurbishment associated with license renewal would not increase significantly or would be reduced if refurbishment occurs during a plant outage.

The NRC expects licensees to use best management practices during the license renewal term for both continuing operations and refurbishment activities. Use of best management practices will minimize soil erosion. In addition, implementation of spill prevention and control plans will reduce the likelihood of any liquid chemical spills. If refurbishment activities take place during a plant outage, with the reactor shutdown, the overall water use by the facility will be reduced. Based on this conclusion, the impact on surface water use and quality during the license renewal term will continue to be small for all plants.

(10) Altered Current Patterns at Intake and Discharge Structures, (11) Altered Salinity Gradients, (12) Altered Thermal Stratification of Lakes, and (13) Scouring Caused by Discharged Cooling Water: These four issues remain Category 1 issues, each with an impact level of small. The final rule amends Table B–1 by making minor clarifying changes to the finding column entries for each of these issues.

The final rule amends the ''Altered current patterns at intake and discharge structures'' finding column entry by replacing the statement,

> Altered current patterns have not been found to be a problem at operating nuclear power plants and are not expected to be a problem during the license renewal term.

with the following:

> Altered current patterns would be limited to the area in the vicinity of the intake and discharge structures. These impacts have been small at operating nuclear power plants.

The final rule amends the ''Altered salinity gradients'' finding column entry by replacing the statement,

> Salinity gradients have not been found to be a problem at operating nuclear power plants and are not expected to be a problem during the license renewal term.

with the following:

> Effects on salinity gradients would be limited to the area in the vicinity of the intake and discharge structures. These impacts have been small at operating nuclear power plants.

The final rule amends the ''Altered thermal stratification of lakes'' finding column entry by replacing the statement,

> Generally, lake stratification has not been found to be a problem at operating nuclear power plants and is not expected to be a problem during the license renewal term.

with the following:

> Effects on thermal stratification would be limited to the area in the vicinity of the intake and discharge structures. These impacts have been small at operating nuclear power plants.

The final rule amends the ''Scouring caused by discharged cooling water'' finding column entry by replacing the statement,

> Scouring has not been found to be a problem at most operating nuclear power plants and has caused only localized effects at a few plants. It is not expected to be a problem during the license renewal term.

with the following:

> Scouring effects would be limited to the area in the vicinity of the intake and discharge structures. These impacts have been small at operating nuclear power plants.

These changes reflect the findings of environmental reviews conducted since the publication of the 1996 GEIS, which show that the effects of these four issues are localized in the vicinity of the plant's intake and discharge structures.

(14) Discharge of Metals in Cooling System Effluent: The final rule amends Table B–1 by renaming ''Discharge of other metals in waste water'' as ''Discharge of metals in cooling system effluent.'' It remains a Category 1 issue with an impact level of small. The final rule also makes minor clarifying changes to the finding column entry for this issue. Specifically, the final rule amends the finding column entry by replacing the statement,

> These discharges have not been found to be a problem at operating nuclear power plants with cooling-tower-based heat dissipation systems and have been satisfactorily mitigated at other plants. They are not expected to be a problem during the license renewal term.

with the following:

> Discharges of metals have not been found to be a problem at operating nuclear power plants with cooling-tower-based heat dissipation systems and have been satisfactorily mitigated at other plants. Discharges are monitored and controlled as part of the National Pollutant Discharge Elimination System (NPDES) permit process.

(15) Discharge of Biocides, Sanitary Wastes, and Minor Chemical Spills: The final rule amends Table B–1 by consolidating two Category 1 issues, ''Discharge of chlorine or other biocides'' and ''Discharge of sanitary wastes and minor chemical spills,'' both with an impact level of small, and naming the consolidated issue ''Discharge of biocides, sanitary wastes,

and minor chemical spills.'' The consolidated issue is a Category 1 issue with an impact level of small. Specifically, the final rule amends Table B–1 by removing the entries for ''Discharge of chlorine or other biocides'' and ''Discharge of sanitary wastes and minor chemical spills'' and adding an entry for ''Discharge of biocides, sanitary wastes, and minor chemical spills.'' The finding column entry for the new consolidated issue states,

The effects of these discharges are regulated by Federal and State environmental agencies. Discharges are monitored and controlled as part of the NPDES permit process. These impacts have been small at operating nuclear power plants.

(16) *Surface Water Use Conflicts (Plants with Once-Through Cooling Systems):* ''Water use conflicts (plants with once-through cooling systems)'' remains a Category 1 issue with an impact level of small. The final rule amends Table B–1 by adding the word ''Surface'' to the title of this issue.

(17) *Surface Water Use Conflicts (Plants with Cooling Ponds or Cooling Towers Using Makeup Water from a River):* The final rule amends Table B–1 by adding the term ''surface'' and removing the terms ''small'' and ''low flow'' from the title and the associated numerical definition contained in 10 CFR 51.53(c)(3)(ii)(A) for low flow rivers from this and other related river flow issues. This issue remains a Category 2 issue with an impact range of small to moderate. The final rule also amends the finding column entry by replacing the statement,

The issue has been a concern at nuclear power plants with cooling ponds and at plants with cooling towers. Impacts on instream and riparian communities near these plants could be of moderate significance in some situations. See § 51.53(c)(3)(ii)(A).

with the following:

Impacts could be of small or moderate significance, depending on makeup water requirements, water availability, and competing water demands.

The 1996 GEIS distinguished between surface water use impacts during low flow conditions on ''small'' versus ''large'' rivers. Any river, regardless of size, can experience low flow conditions of varying severity during periods of drought and changing conditions in the affected watersheds such as upstream diversions and use of river water. Similarly, the NRC has determined that the use of the term ''low flow'' in categorizing river flow is of little value considering that plants that withdraw makeup water from a river can experience low flow conditions and would be required to conduct a plant-specific assessment of water use conflicts.

(18) *Effects of Dredging on Surface Water Quality:* The final rule amends Table B–1 by adding a new Category 1 issue, ''Effects of dredging on surface water quality,'' which evaluates the impacts of dredging to maintain intake and discharge structures at nuclear power plant facilities. This issue has an impact level of small. The finding column entry for this issue states,

Dredging to remove accumulated sediments in the vicinity of intake and discharge structures and to maintain barge shipping has not been found to be a problem for surface water quality. Dredging is performed under permit from the U.S. Army Corps of Engineers, and possibly, from other State or local agencies.

The impact of dredging on surface water quality was not considered in the 1996 GEIS and was not listed in Table B–1 prior to this final rule. Most plants have intake and discharge structures that must be maintained by periodic dredging of sediment accumulated in or on the structures. The NRC has found that dredging, while temporarily increasing turbidity in the source water body, generally has little long-term effect on water quality. In addition to maintaining intake and discharge structures, dredging is often done to keep barge slips and channels open to service the plant. Dredged material is most often disposed on property owned by the applicant and usually contains no hazardous materials. Dredging must be performed under a permit issued by the U.S. Army Corps of Engineers (the Corps) and consequently, each dredging action would be subject to a site-specific environmental review conducted by the Corps. Temporary impacts of dredging are measurable in general water quality terms, but the impacts have been shown to be small.

(19) *Temperature Effects on Sediment Transport Capacity:* There are no changes to this issue, and it remains a Category 1 issue with an impact level of small.

Groundwater Resources

(20) *Groundwater Contamination and Use (Non-Cooling System Impacts):* The final rule amends Table B–1 by expanding the scope of ''Impacts of refurbishment on groundwater use and quality'' issue to include the effects of continued nuclear power plant operations during the license renewal term. This Category 1 issue, with an impact level of small, was renamed ''Groundwater use and quality'' in the proposed rule.

The final rule also amends Table B–1 by changing the proposed rule's new Category 2 issue ''Groundwater and soil contamination,'' with an impact range of small to moderate (see 74 FR 38122, 38135), to Category 1, with an impact level of small. This issue was then consolidated with the ''Groundwater use and quality'' issue and renamed ''Groundwater contamination and use (non-cooling system impacts).'' These issues were consolidated because they consider the impact of industrial activities associated with the continued operations of a nuclear power plant (not directly related to cooling system effects) and refurbishment on groundwater use and quality. The final rule further amends Table B–1 by replacing the finding column entry, which states,

Extensive dewatering during the original construction on some sites will not be repeated during refurbishment on any sites. Any plant wastes produced during refurbishment will be handled in the same manner as in current operating practices and are not expected to be a problem during the license renewal term.

with the following:

Extensive dewatering is not anticipated from continued operations and refurbishment associated with license renewal. Industrial practices involving the use of solvents, hydrocarbons, heavy metals, or other chemicals, and/or the use of wastewater ponds or lagoons have the potential to contaminate site groundwater, soil, and subsoil. Contamination is subject to State or Environmental Protection Agency regulated cleanup and monitoring programs. The application of best management practices for handling any materials produced or used during these activities would reduce impacts.

The consolidated Category 1 issue considers the impacts from groundwater use and the impacts on groundwater, soil, and subsoil from the industrial use of solvents, hydrocarbons, heavy metals, or other chemicals at nuclear power plant sites from continued operation during the license renewal term and refurbishment. The consolidated issue also includes the use of wastewater disposal ponds or lagoons and non-radionuclide, industrial contaminants released inadvertently or as effluents into the environment. Industrial practices at all nuclear power plants have the potential to contaminate groundwater and soil, especially on sites with unlined wastewater and storm water ponds or lagoons. Any contamination of this type is subject to characterization and clean-up under EPA or State regulated remediation and monitoring programs.

Non-radionuclide contaminants have been found in groundwater and soil samples at some nuclear power plants during previous license renewal environmental reviews. Release of these contaminants into groundwater and soil degrades the quality of these resources, even if applicable groundwater quality standards are not exceeded. However, each site has its own program for handling chemicals, waste, and other hazardous materials in accordance with Federal and State regulations and is expected to employ best management practices. The use of wastewater disposal ponds or lagoons, whether lined or unlined, may increase the potential for groundwater and soil contamination. However, they are subject to discharge authorizations under NPDES and related State wastewater discharge permit programs.

The finding column of Table B–1 for ''Groundwater use and quality'' prior to this final rule, as analyzed in the 1996 GEIS, indicated that impacts of continued operations and refurbishment on groundwater use and quality would be small, as extensive dewatering is not anticipated. This finding was re-evaluated in the revised GEIS and is retained in Table B–1.

While the proposed rule's ''Groundwater and soil contamination'' issue was identified as a Category 2 issue, further consideration of the ''Groundwater and soil contamination'' issue and public comments revealed that the potential impacts on groundwater and soil quality from common industrial practices can be addressed generically, as these practices are common to all industrial facilities and are not unique to nuclear power plants. Moreover, as supported by the analysis in the revised GEIS, the NRC concludes that the overall impact of industrial practices on groundwater use and quality from past and current operations is small for all nuclear power plants and not expected to change appreciably during the license renewal term.

(21) *Groundwater Use Conflicts (Plants that Withdraw Less Than 100 Gallons per Minute [gpm]):* The final rule amends Table B–1 by renaming the ''Ground-water use conflicts (potable and service water; plants that use <100 gpm)'' issue as ''Groundwater use conflicts (plants that withdraw less than 100 gallons per minute [gpm]).'' It remains a Category 1 issue with an impact level of small. The final rule further amends Table B–1 by making minor clarifying changes to the finding column entry for this issue. Specifically, the final rule replaces the entry statement ''Plants using less than 100 gpm are not expected to cause any ground-water conflicts,'' with ''Plants that withdraw less than 100 gpm are not expected to cause any groundwater use conflicts.''

(22) *Groundwater Use Conflicts (Plants that Withdraw More Than 100 Gallons per Minute [gpm]):* The final rule amends Table B–1 by consolidating two Category 2 issues, ''Groundwater use conflicts (potable and service water, and dewatering; plants that use >100 gpm)'' and ''Ground-water use conflicts (Ranney wells),'' each with an impact level range of small to large, and names the consolidated issue, ''Groundwater use conflicts (plants that withdraw more than 100 gallons per minute [gpm]).'' Because Ranney wells produce significantly more than 100 gpm, the Ranney wells issue was consolidated with the general issue of groundwater use conflicts for plants using more than 100 gpm of groundwater. The consolidated issue is a Category 2 issue, with an impact level range of small to large. The final rule further amends Table B–1 by removing the entries for ''Groundwater use conflicts (potable and service water, and dewatering; plants that use >100 gpm)'' and ''Ground-water use conflicts (Ranney wells)'' and adding an entry for ''Groundwater use conflicts (plants that withdraw more than 100 gallons per minute [gpm]).'' The finding column entry for the new consolidated issue states ''Plants that withdraw more than 100 gpm could cause groundwater use conflicts with nearby groundwater users.''

(23) *Groundwater Use Conflicts (Plants with Closed-Cycle Cooling Systems that Withdraw Makeup Water from a River):* The final rule amends Table B–1 by renaming ''Ground-water use conflicts (plants using cooling towers withdrawing makeup water from a small river)'' as ''Groundwater use conflicts (plants with closed-cycle cooling systems that withdraw makeup water from a river).'' It remains a Category 2 issue, with an impact level range of small to large. The final rule further amends Table B–1 by replacing the finding column entry, which states,

> Water use conflicts may result from surface water withdrawals from small water bodies during low flow conditions which may affect aquifer recharge, especially if other ground-water or upstream surface water users come on line before the time of license renewal. See § 51.53(c)(3)(ii)(A).

with the following:

> Water use conflicts could result from water withdrawals from rivers during low-flow conditions, which may affect aquifer recharge. The significance of impacts would depend on makeup water requirements, water availability, and competing water demands.

The 1996 GEIS distinguished between surface water use impacts during low flow conditions on ''small'' versus ''large'' rivers. Any river, regardless of size, can experience low flow conditions of varying severity during periods of drought and changing conditions in the affected watersheds such as upstream diversions and use of river water. The NRC has thus determined that the use of the term ''small river'' or ''small water bodies'' is of little value considering that plants that withdraw makeup water from a river can experience low-flow conditions and would be required to conduct a plant-specific assessment of water use conflicts.

(24) *Groundwater Quality Degradation Resulting from Water Withdrawals:* The final rule amends Table B–1 by consolidating two Category 1 issues, ''Ground-water quality degradation (Ranney wells)'' and ''Ground-water quality degradation (saltwater intrusion),'' each with an impact level of small, and names the consolidated issue, ''Groundwater quality degradation resulting from water withdrawals.'' The consolidated issue remains a Category 1 issue, with an impact level of small. The final rule further amends Table B–1 by removing the entries for ''Ground-water quality degradation (Ranney wells)'' and ''Ground-water quality degradation (saltwater intrusion)'' and, by adding an entry for ''Groundwater quality degradation resulting from water withdrawals.'' The finding column entry for the consolidated issue states ''Groundwater withdrawals at operating nuclear power plants would not contribute significantly to groundwater quality degradation.'' The two issues were consolidated as they both consider the possibility of groundwater quality becoming degraded as a result of plant operations drawing water of potentially lower quality into the aquifer.

(25) Groundwater Quality Degradation (Plants with Cooling Ponds in Salt Marshes): The final rule amends Table B–1 by revising the title of the issue ''Ground-water quality degradation (cooling ponds in salt marshes)'' to ''Groundwater quality degradation (plants with cooling ponds in salt marshes).'' The issue remains a Category 1 issue, with an impact level of small. The final rule further amends Table B–1 by replacing the finding column entry, which states,

> Sites with closed-cycle ponds may degrade ground-water quality. Because water in salt marshes is brackish, this is not a concern for plants located in salt marshes.

with the following:

Sites with closed-cycle cooling ponds could degrade groundwater quality. However, groundwater in salt marshes is naturally brackish and thus, not potable. Consequently, the human use of such groundwater is limited to industrial purposes.

The final rule change to the finding column entry reflects the NRC's response to a public comment on the proposed rule by: (1) Deleting the term ''plants'' to eliminate any confusion that the NRC might have meant marsh ''plants'' rather than ''nuclear power plants;'' and (2) clarifying that the focus of this issue is on the degradation of groundwater quality for human use. Brackish groundwater has limited human use, thus, any impacts on groundwater quality caused by continued operations and refurbishment associated with license renewal are not significant.

(26) Groundwater Quality Degradation (Plants with Cooling Ponds at Inland Sites): The final rule amends Table B–1 by revising the title of the issue ''Ground-water quality degradation (cooling ponds at inland sites)'' to ''Groundwater quality degradation (plants with cooling ponds at inland sites).'' The issue remains a Category 2 issue, with an impact level range of small to large. The final rule further amends Table B–1 by replacing the finding column entry, which states,

Sites with closed-cycle cooling ponds may degrade ground-water quality. For plants located inland, the quality of the ground water in the vicinity of the ponds must be shown to be adequate to allow continuation of current uses. See § 51.53(c)(3)(ii)(D).

with the following:

Inland sites with closed-cycle cooling ponds could degrade groundwater quality. The significance of the impact would depend on cooling pond water quality, site hydrogeologic conditions (including the interaction of surface water and groundwater), and the location, depth, and pump rate of water wells.

(27) *Radionuclides Released to Groundwater:* The final rule amends Table B–1 by adding a new Category 2 issue, ''Radionuclides released to groundwater,'' with an impact level range of small to moderate, to evaluate the potential impact of discharges of radionuclides from plant systems into groundwater. The finding column entry for this issue states,

Leaks of radioactive liquids from plant components and pipes have occurred at numerous plants. Groundwater protection programs have been established at all operating nuclear power plants to minimize the potential impact from any inadvertent releases. The magnitude of impacts would depend on site-specific characteristics.

This new Category 2 issue has been added to evaluate the potential impact to groundwater quality from the discharge of radionuclides from plant systems, piping, and tanks. This issue was added because within the past several years there have been events at nuclear power reactor sites that involved unknown, uncontrolled, and unmonitored releases of radioactive liquids into the groundwater. The issue is relevant to license renewal because this experience has shown that components and piping at nuclear power plants have the potential to leak radioactive material into the groundwater and degrade its quality. While the NRC's regulations in 10 CFR part 20 and in 10 CFR part 50 limit the amount of radioactive material released (i.e., from routine and inadvertent sources) from a nuclear power plant into the environment, the regulations are focused on protecting the public, not the quality of the groundwater. Therefore, as required by NEPA, the NRC must consider the potential impacts to the groundwater from radioactive liquids released into groundwater.

The majority of the inadvertent radioactive liquid release events involved tritium, which is a radioactive isotope of hydrogen. However, in some of the events, radioactive isotopes of cesium and strontium have also been released. Non-routine releases of radioactive liquids into the groundwater have occurred from plant systems and buried piping.

In 2006, the NRC's Executive Director for Operations chartered a task force to conduct a lessons-learned review of these incidents. On September 1, 2006, the Task Force issued its report: ''Liquid Radioactive Release Lessons Learned Task Force Report'' (ADAMS Accession No. ML062650312). A significant conclusion of the report dealt with the potential health impacts to the public from the inadvertent releases. Although there were numerous events where radioactive liquids were released to the groundwater in an unplanned, uncontrolled, and unmonitored fashion, based on the data available, the task force did not identify any instances where public health and safety was adversely impacted. However, the task force did not evaluate the impact of the releases to groundwater quality. The task force also identified that under the existing regulatory requirements, the potential exists for radioactive liquid releases from leaking systems to not be detected for a period of time and, therefore, the contaminants could migrate into groundwater.

In response to these groundwater events, NEI, which represents the nuclear industry, in 2007 committed to the NRC to develop a voluntary initiative for each nuclear power plant to have a site-specific groundwater protection program. NEI provided guidance to the nuclear industry (NEI 07–07, ADAMS Accession No. ML072610036) on the development and implementation of a groundwater protection program. The program covers the assessment of plant systems and components, site hydrogeology, and methods to detect leaks to determine the needs for each site-specific program. To monitor the actions of the nuclear industry, the NRC routinely inspects nuclear power plant licensees to verify continued implementation of the Groundwater Protection Initiative programs, to review records of identified leakage and spill events, to assess whether the source of the leak or spill was identified and mitigated, and to review any remediation actions taken for effectiveness.

On the basis of the information and experience with these groundwater events and the evaluation in the revised GEIS, the NRC concludes that the impact to groundwater quality from the release of radionuclides is dependent on site-specific variables and could be small or moderate, depending on the magnitude of the leak, radionuclides involved, and the response time of plant personnel to identify and stop the leak in a timely fashion. Therefore, ''Radionuclides released to groundwater'' is a Category 2 issue and, as such, a site-specific evaluation in the environmental report is needed for each application for license renewal. Similarly, the NRC will analyze this issue in the SEIS for each license renewal action.

Terrestrial Resources

(28) *Effects on Terrestrial Resources (Non-Cooling System Impacts):* The final rule amends Table B–1 by renaming the ''Refurbishment impacts'' issue as ''Effects on terrestrial resources (non-cooling system impacts).'' It remains a Category 2 issue, with an impact level range of small to large.[34] The issue, as set forth in the 1996 GEIS, addressed only the impacts upon terrestrial resources resulting from any refurbishment activities during the license renewal term. The analysis in the revised GEIS builds on the analysis in the 1996 GEIS to include the environmental impacts resulting from continued plant operations during the license renewal term. The final rule

[34] The proposed rule named the issue, ''Impacts of continued plant operations on terrestrial ecosystems'' (74 FR 38123, 38136; July 31, 2009).

further amends Table B–1 by replacing the finding column entry, which states,

Refurbishment impacts are insignificant if no loss of important plant and animal habitat occurs. However, it cannot be known whether important plant and animal communities may be affected until the specific proposal is presented with the license renewal application. See § 51.53(c)(3)(ii)(E).

with the following:

Impacts resulting from continued operations and refurbishment associated with license renewal may affect terrestrial communities. Application of best management practices would reduce the potential for impacts. The magnitude of impacts would depend on the nature of the activity, the status of the resources that could be affected, and the effectiveness of mitigation.

(29) *Exposure of Terrestrial Organisms to Radionuclides:* The final rule amends Table B–1 by adding a new Category 1 issue, ''Exposure of terrestrial organisms to radionuclides.'' The new issue has been determined to have an impact level of small. The finding column entry for this issue states,

Doses to terrestrial organisms from continued operations and refurbishment associated with license renewal are expected to be well below exposure guidelines developed to protect these organisms.

This new issue evaluates the potential impact of radionuclides on terrestrial organisms resulting from continued operations of a nuclear power plant during the license renewal term and refurbishment associated with license renewal. This issue was not evaluated in the 1996 GEIS. Subsequent to the publication of the 1996 GEIS, however, members of the public and various Federal and State agencies commented on the need to evaluate the potential impact of radionuclides on terrestrial organisms during plant-specific license renewal reviews.

The revised GEIS evaluates the potential impact of radionuclides on terrestrial biota at nuclear power plants from continued operations during the license renewal term. For the evaluation, site-specific radionuclide concentrations in environmental media (e.g., water, air, milk, crops, food products, sediment, and fish and other aquatic biota) were obtained from publicly available Radiological Environmental Monitoring Program (REMP) annual reports from 15 nuclear power plants. The REMP is conducted at every NRC licensed nuclear power plant to assess the environmental impacts from plant operations. This is done by collecting samples of environmental media from areas surrounding the plant for analysis to measure the amount of radioactivity, if any, in the samples. The media samples reflect the radiation exposure pathways to the public from radioactive effluents released by the nuclear power plant and from background radiation (i.e., cosmic sources, naturally-occurring radioactive material, including radon and global fallout). These 15 plants were selected to represent sites that reported a range of radionuclide concentrations in the sample media and included both boiling water reactors and pressurized water reactors. Site-specific radionuclide concentrations in water and sediments, as reported in the plant's REMP reports, were used in the calculations. The calculated radiation dose rates to terrestrial biota, based on exposure to radioactivity in the environmental media, were compared against radiation-safety guidelines issued by the U.S. Department of Energy (DOE), the International Atomic Energy Agency (IAEA), the National Council of Radiation Protection and Measurements (NCRP), and the International Commission on Radiological Protection (ICRP). The NRC concluded that the impacts of radionuclides on terrestrial biota from past and current normal operations are small for all nuclear power plants and should not change appreciably during the license renewal term.

(30) *Cooling System Impacts on Terrestrial Resources (Plants with Once-Through Cooling Systems or Cooling Ponds):* The final rule amends Table B–1 by renaming the ''Cooling pond impacts on terrestrial resources'' issue as ''Cooling system impacts on terrestrial resources (plants with once-through cooling systems or cooling ponds).'' It remains a Category 1 issue, with an impact level of small. The analysis in the revised GEIS expands the scope of this issue to include plants with once-through cooling systems. This analysis concludes that the impacts on terrestrial resources from once-through cooling systems, as well as from cooling ponds, is of small significance at all plants. The final rule further amends Table B–1 by replacing the finding column entry, which states,

Impacts of cooling ponds on terrestrial ecological resources are considered to be of small significance at all sites.

with the following:

No adverse effects to terrestrial plants or animals have been reported as a result of increased water temperatures, fogging, humidity, or reduced habitat quality. Due to the low concentrations of contaminants in cooling system effluents, uptake and accumulation of contaminants in the tissues of wildlife exposed to the contaminated water or aquatic food sources are not expected to be significant issues.

(31) *Cooling Tower Impacts on Vegetation (Plants with Cooling Towers):* The final rule amends Table B–1 by consolidating two Category 1 issues, ''Cooling tower impacts on crops and ornamental vegetation'' and ''Cooling tower impacts on native plants,'' both issues having an impact level of small, and names the consolidated issue, ''Cooling tower impacts on vegetation (plants with cooling towers).'' The consolidated issue is a Category 1 issue with an impact level of small. The two issues were consolidated to conform to the resource-based approach used in the revised GEIS. With the recent trend of replacing lawns with native vegetation, some ornamental plants and crops are native plants, and the original separation into two issues is unnecessary and cumbersome. The final rule further amends Table B–1 by removing the entries for ''Cooling tower impacts on crops and ornamental vegetation'' and ''Cooling tower impacts on native plants,'' and by adding an entry for ''Cooling tower impacts on vegetation (plants with cooling towers).'' The finding column entry for the new consolidated issue states,

Impacts from salt drift, icing, fogging, or increased humidity associated with cooling tower operation have the potential to affect adjacent vegetation, but these impacts have been small at operating nuclear power plants and are not expected to change over the license renewal term.

(32) *Bird Collisions with Plant Structures and Transmission Lines:* The final rule amends Table B–1 by consolidating two Category 1 issues, ''Bird collisions with cooling towers'' and ''Bird collision with power lines,'' both issues having an impact level of small. The final rule also expands the scope of the consolidated issue to address collisions with all plant structures and names the issue, ''Bird collisions with plant structures and transmission lines.'' The consolidated issue is a Category 1 issue with an impact level of small. The two issues were consolidated to conform to the resource-based approach used in the revised GEIS. The final rule further amends Table B–1 by removing the entries for ''Bird collisions with cooling towers'' and ''Bird collision with power lines,'' and by adding an entry for ''Bird collisions with plant structures and transmission lines.'' The finding column entry for the new consolidated issue states,

Bird collisions with cooling towers and other plant structures and transmission lines occur at rates that are unlikely to affect local or migratory populations and the rates are not expected to change.

The final rule further amends Table B–1 by appending a footnote to the issue column entry for ''Bird collisions with plant structures and transmission lines,'' concerning the extent to which transmission lines and their associated right of ways have been analyzed under the revised GEIS. This footnote is the same one that was added to Issue 3, ''Offsite land use in transmission line right-of-ways (ROWs).'' See the description of the changes made by the final rule to Issue 3 for further explanation of this amendment.

(33) *Water Use Conflicts with Terrestrial Resources (Plants with Cooling Ponds or Cooling Towers Using Makeup Water from a River):* The final rule amends Table B–1 by adding a new Category 2 issue, ''Water use conflicts with terrestrial resources (plants with cooling ponds or cooling towers using makeup water from a river),'' to evaluate water use conflict impacts with terrestrial resources in riparian communities. The 1996 GEIS already addresses the resource aspects of this issue, and 10 CFR 51.53(c)(3)(ii)(A) requires a plant-specific analysis of the impacts of surface water withdrawals from rivers for cooling pond or cooling tower makeup on riparian ecological communities. However, this stand-alone issue was created to clearly separate out the related aspects and potential impacts on terrestrial, riparian communities associated with surface water withdrawals from a river for consumptive cooling water uses. The new issue has an impact level range of small to moderate. The finding column entry for this issue states,

Impacts on terrestrial resources in riparian communities affected by water use conflicts could be of moderate significance.

As described in the revised GEIS, such impacts could occur when water that supports these resources is diminished because of decreased availability due to droughts; increased water demand for agricultural, municipal, or industrial usage; or a combination of these factors. The potential range of impact levels at plants, subject to license renewal, with cooling ponds or cooling towers using makeup water from a river cannot be generically determined. The NRC has also removed the term ''low flow'' from the title of this issue, as set forth in the proposed rule, and other related river flow issues in the final rule as previously discussed in this section (*see* Issue 17, ''Surface Water Use Conflicts (Plants with Cooling Ponds or Cooling Towers Using Makeup Water from a River)'').

(34) *Transmission Line Right-of-Way (ROW) Management Impacts on Terrestrial Resources:* The final rule amends Table B–1 by consolidating two Category 1 issues, ''Power line right-of-way management (cutting and herbicide application)'' and ''Floodplains and wetland on power line right-of-way,'' each with an impact level of small, and names the consolidated issue, ''Transmission line right-of-way (ROW) management impacts on terrestrial resources.'' The consolidated issue is a Category 1 issue, with an impact level of small. The two issues were consolidated to conform to the resource-based approach used in the revised GEIS. The final rule further amends Table B–1 by removing the entries for ''Power line right-of-way management (cutting and herbicide application)'' and ''Floodplains and wetland on power line right-of-way,'' and, by adding an entry for ''Transmission line right-of-way (ROW) management impacts on terrestrial resources.'' The finding column entry for the consolidated issue states,

Continued ROW management during the license renewal term is expected to keep terrestrial communities in their current condition. Application of best management practices would reduce the potential for impacts.

The final rule further amends Table B–1 by appending a footnote to the issue column entry for ''Transmission line right-of-way (ROW) management impacts on terrestrial resources,'' concerning the extent to which transmission lines and their associated rights of way have been analyzed under the revised GEIS. This footnote is the same one that was added to Issue 3, ''Offsite land use in transmission line right-of-ways (ROWs).'' See the description of the changes made by the final rule to Issue 3 for further explanation of this amendment.

(35) Electromagnetic Fields on Flora and Fauna (Plants, Agricultural Crops, Honeybees, Wildlife, Livestock): There are no changes to this issue, and it remains a Category 1 issue with a small level of impact. The final rule amends Table B–1 by appending a footnote to the issue column entry for ''Electromagnetic Fields on Flora and Fauna (Plants, Agricultural Crops, Honeybees, Wildlife, Livestock),'' concerning the extent to which transmission lines and their associated rights of way have been analyzed under the revised GEIS. This footnote is the same one that was added to Issue 3, ''Offsite land use in transmission line right-of-ways (ROWs).'' See the description of the changes made by the final rule to Issue 3 for further explanation of this amendment.

Aquatic Resources

(36) *Impingement and Entrainment of Aquatic Organisms (Plants with Once-Through Cooling Systems or Cooling Ponds):* The final rule amends Table B–1 by consolidating two Category 2 issues, ''Entrainment of fish and shellfish in early life stages (for plants with once-through cooling and cooling pond heat dissipation systems)'' and ''Impingement of fish and shellfish (for plants with once-through cooling and cooling pond heat dissipation systems),'' both with impact level ranges of small to large, and names the consolidated issue, ''Impingement and entrainment of aquatic organisms (plants with once-through cooling systems or cooling ponds).'' The consolidated issue is a Category 2 issue with an impact level range of small to large. The final rule further amends Table B–1 by removing the entries for ''Entrainment of fish and shellfish in early life stages (for plants with once-through cooling and cooling pond heat dissipation systems)'' and ''Impingement of fish and shellfish (for plants with once-through cooling and cooling pond heat dissipation systems),'' and, by adding an entry for ''Impingement and entrainment of aquatic organisms (plants with once-through cooling systems or cooling ponds).'' The finding column entry for the consolidated issue states,

The impacts of impingement and entrainment are small at many plants, but may be moderate or even large at a few plants with once-through and cooling-pond cooling systems, depending on cooling system withdrawal rates and volumes and the aquatic resources at the site.

For the revised GEIS, these issues were consolidated to facilitate the review process in keeping with the resource-based approach and to allow for a more complete analysis of the environmental impact. Nuclear power plants typically conduct separate sampling programs to estimate the numbers of organisms entrained and impinged, which explains the original separation of these issues. However, it is the consolidated effects of entrainment and impingement that reflect the total impact of the cooling system intake on the resource. Environmental conditions are different at each nuclear power plant site, and impacts cannot be determined generically.

(37) *Impingement and Entrainment of Aquatic Organisms (Plants with Cooling Towers):* The final rule amends Table B–1 by consolidating two Category 1 issues, ''Entrainment of fish and shellfish in early life stages (for plants with cooling tower-based heat dissipation systems)'' and ''Impingement of fish and shellfish (for plants with cooling tower-based heat dissipation systems),'' both with impact levels of small, and names the consolidated issue, ''Impingement and entrainment of aquatic organisms (plants with cooling towers).'' The consolidated issue is a Category 1 issue with an impact level of small. The final rule further amends Table B–1 by removing the entries for ''Entrainment of fish and shellfish in early life stages (for plants with cooling tower-based heat dissipation systems)'' and ''Impingement of fish and shellfish (for plants with cooling tower-based heat dissipation systems),'' and by adding an entry for ''Impingement and entrainment of aquatic organisms (plants with cooling towers).'' The finding column entry for the consolidated issue states,

> Impingement and entrainment rates are lower at plants that use closed-cycle cooling with cooling towers because the rates and volumes of water withdrawal needed for makeup are minimized.

The two issues have been consolidated given their similar nature and to facilitate the environmental review process consistent with the resource-based approach in the revised GEIS.

(38) Entrainment of phytoplankton and zooplankton (all plants): There are no changes to this issue, and it remains a Category 1 issue with an impact level of small. The proposed rule had consolidated two Category 2 issues, ''Entrainment of fish and shellfish in early life stages (for plants with once-through cooling and cooling pond heat dissipation systems)'' and ''Impingement of fish and shellfish (for plants with once-through cooling and cooling pond heat dissipation systems)'' with the Category 1 issue, ''Entrainment of phytoplankton and zooplankton (for all plants)'' (74 FR 38124, 38136; July 31, 2009). Under the proposed rule, the consolidated issue would have been a Category 2 issue, with an impact range of small to large. Subsequent to the publication of the proposed rule, the NRC determined that such consolidation would have the effect of making ''Entrainment of phytoplankton and zooplankton (all plants),'' which is an issue generic to all plants (Category 1), a site-specific issue (Category 2). As there is no basis to support making the ''Entrainment of phytoplankton and zooplankton (all plants)'' a site-specific issue, the NRC determined not to adopt the proposed rule change. Instead, only the two Category 2 issues were consolidated (*see* Issue 36), and this issue remains separate.

(39) *Thermal Impacts on Aquatic Organisms (Plants with Once-Through Cooling Systems or Cooling Ponds):* The final rule amends Table B–1 by renaming the issue, ''Heat shock (for plants with once-through and cooling pond heat dissipation systems)'' as ''Thermal Impacts on Aquatic Organisms (plants with once-through cooling systems or cooling ponds).'' It remains a Category 2 issue with an impact level range of small to large. The final rule further amends Table B–1 by replacing the finding column entry for this issue, which states,

> Because of continuing concerns about heat shock and the possible need to modify thermal discharges in response to changing environmental conditions, the impacts may be of moderate or large significance at some plants. See § 51.53(c)(3)(ii)(B).

with the following:

> Most of the effects associated with thermal discharges are localized and are not expected to affect overall stability of populations or resources. The magnitude of impacts, however, would depend on site-specific thermal plume characteristics and the nature of aquatic resources in the area.

Environmental conditions are different at each nuclear power plant site, and thermal impacts associated with once-through and cooling pond heat dissipation systems cannot be determined generically. The proposed rule had consolidated the Category 2 issue, ''Heat shock (for plants with once-through and cooling pond heat dissipation systems)'' with four Category 1 issues, ''Cold shock (for all plants),'' ''Thermal plume barrier to migrating fish (for all plants),'' ''Distribution of aquatic organisms (for all plants),'' and ''Premature emergence of aquatic insects (for all plants)'' (74 FR 38124, 38136; July 31, 2009). These issues were proposed for consolidation to facilitate the environmental review process because they are all caused by thermal effects. The final rule consolidates these four Category 1 issues with another Category 1 issue, ''Stimulation of nuisance organisms (e.g., shipworms),'' as Issue 41, ''Infrequently reported thermal impacts (all plants),'' as described later in this section.

(40) *Thermal Impacts on Aquatic Organisms (Plants with Cooling Towers):* The final rule amends Table B–1 by renaming the issue ''Heat shock (for plants with cooling-tower-based heat dissipation systems)'' as ''Thermal Impacts on Aquatic Organisms (Plants with Cooling Towers).'' It remains a Category 1 issue with an impact level of small. The final rule further amends Table B–1 by replacing the finding column entry for this issue, which states, ''Heat shock has not been found to be a problem at operating nuclear power plants with this type of cooling system and is not expected to be a problem during the license renewal term,'' with the following, ''Thermal effects associated with plants that use cooling towers are expected to be small because of the reduced amount of heated discharge.''

The proposed rule had consolidated the Category 1 issue, ''Heat shock (for plants with cooling-tower-based heat dissipation systems)'' with four other Category 1 issues, ''Cold shock (for all plants),'' ''Thermal plume barrier to migrating fish (for all plants),'' ''Distribution of aquatic organisms (for all plants),'' and ''Premature emergence of aquatic insects (for all plants)'' (74 FR 38124, 38136). These issues were proposed for consolidation to facilitate the environmental review process because they are all caused by thermal effects. The final rule consolidates these four Category 1 issues with another Category 1 issue, ''Stimulation of nuisance organisms (e.g., shipworms),'' as Issue 41, ''Infrequently reported thermal impacts (all plants),'' as described in the following paragraphs.

(41) *Infrequently Reported Thermal Impacts (All Plants):* The final rule amends Table B–1 by consolidating five Category 1 issues, ''Cold shock (for all plants),'' ''Thermal plume barrier to migrating fish (for all plants),'' ''Distribution of aquatic organisms (for all plants),'' ''Premature emergence of aquatic insects (for all plants),'' and ''Stimulation of Nuisance Organisms (e.g., Shipworms),'' each with an impact level of small, and names the consolidated issue, ''Infrequently reported thermal impacts (all plants).'' The consolidated issue is a Category 1 issue, with an impact level of small. The final rule further amends Table B–1 by removing the entries for ''Cold shock (for all plants),'' ''Thermal plume barrier to migrating fish (for all plants),'' ''Distribution of aquatic organisms (for all plants),'' ''Premature emergence of aquatic insects (for all plants),'' and ''Stimulation of Nuisance Organisms (e.g., Shipworms),'' and, by adding an entry for ''Infrequently reported thermal impacts (all plants).'' The finding column entry for the new consolidated issue states,

Continued operations during the license renewal term are expected to have small thermal impacts with respect to the following:

Cold shock has been satisfactorily mitigated at operating nuclear plants with once-through cooling systems, has not endangered fish populations or been found to be a problem at operating nuclear power plants with cooling towers or cooling ponds, and is not expected to be a problem.

Thermal plumes have not been found to be a problem at operating nuclear power plants and are not expected to be a problem.

Thermal discharge may have localized effects but is not expected to affect the larger geographical distribution of aquatic organisms.

Premature emergence has been found to be a localized effect at some operating nuclear power plants but has not been a problem and is not expected to be a problem.

Stimulation of nuisance organisms has been satisfactorily mitigated at the single nuclear power plant with a once-through cooling system where previously it was a problem. It has not been found to be a problem at operating nuclear power plants with cooling towers or cooling ponds and is not expected to be a problem.

The five issues are consolidated to facilitate the environmental review process because they are all caused by thermal effects resulting from operation of a plant's cooling system. Previous license renewal reviews conducted by the NRC have shown that the previously described thermal issues have not been a problem at operating nuclear power plants and would not change during the license renewal term, and so no future impacts are anticipated.

(42) *Effects of Cooling Water Discharge on Dissolved Oxygen, Gas Supersaturation, and Eutrophication:* The final rule amends Table B–1 by consolidating three Category 1 issues, ''Eutrophication,'' ''Gas supersaturation (gas bubble disease),'' and ''Low dissolved oxygen in the discharge,'' each with an impact level of small, and names the consolidated issue, ''Effects of cooling water discharge on dissolved oxygen, gas supersaturation, and eutrophication.'' The consolidated issue is a Category 1 issue, with an impact level of small. The three issues are consolidated given their similar nature and to facilitate the environmental review process. The final rule further amends Table B–1 by removing the entries for ''Eutrophication,'' ''Gas supersaturation (gas bubble disease),'' and ''Low dissolved oxygen in the discharge,'' and, by adding an entry for ''Effects of cooling water discharge on dissolved oxygen, gas supersaturation, and eutrophication.'' The finding column entry for the new consolidated issue states,

Gas supersaturation was a concern at a small number of operating nuclear power plants with once-through cooling systems but has been mitigated. Low dissolved oxygen was a concern at one nuclear power plant with a once-through cooling system but has been mitigated. Eutrophication (nutrient loading) and resulting effects on chemical and biological oxygen demands have not been found to be a problem at operating nuclear power plants.

(43) *Effects of Non-Radiological Contaminants on Aquatic Organisms:* The final rule amends Table B–1 by renaming the issue ''Accumulation of contaminants in sediments or biota'' as ''Effects of non-radiological contaminants on aquatic organisms.'' The renamed issue remains a Category 1 issue with an impact level of small. The final rule further amends Table B–1 by replacing the finding column entry, which states,

Accumulation of contaminants has been a concern at a few nuclear power plants but has been satisfactorily mitigated by replacing copper alloy condenser tubes with those of another metal. It is not expected to be a problem during the license renewal term.

with the following:

Best management practices and discharge limitations of NPDES permits are expected to minimize the potential for impacts to aquatic resources during continued operations and refurbishment associated with license renewal. Accumulation of metal contaminants has been a concern at a few nuclear power plants, but has been satisfactorily mitigated by replacing copper alloy condenser tubes with those of another metal.

(44) *Exposure of Aquatic Organisms to Radionuclides:* The final rule amends Table B–1 by adding a new Category 1 issue, ''Exposure of Aquatic Organisms to Radionuclides,'' with an impact level of small. The finding column entry for this issue states,

Doses to aquatic organisms are expected to be well below exposure guidelines developed to protect these aquatic organisms.

The issue has been added to evaluate the potential impact of radionuclide discharges upon aquatic organisms, based on comments from members of the public and Federal and State agencies raised during the license renewal process for various plants.

The revised GEIS evaluates the potential impact of radionuclides on aquatic organisms at nuclear power plants from continued operations during the license renewal term. For the evaluation, site-specific radionuclide concentrations in environmental media (e.g., water, air, milk, crops, food products, sediment, and fish and other aquatic biota) were obtained from publicly available REMP annual reports from 15 nuclear power plants. The REMP is conducted at every NRC licensed nuclear power plant to assess the environmental impacts from plant operations. This is done by collecting samples of environmental media from areas surrounding the plant for analysis to measure the amount of radioactivity, if any, in the samples. The media samples reflect the radiation exposure pathways to the public from radioactive effluents released by the nuclear power plant and from background radiation (i.e., cosmic sources, naturally-occurring radioactive material, including radon and global fallout). These 15 plants were selected to represent sites that reported a range of radionuclide concentrations in the sample media and included both boiling water reactors and pressurized water reactors. Site-specific radionuclide concentrations in water and sediments, as reported in the plant's REMP reports, were used in the calculations. The calculated radiation dose rates to aquatic organisms, based on exposure to radioactivity in the environmental media, were compared against radiation-safety guidelines issued by DOE, IAEA, NCRP, and ICRP. The NRC concluded that the impacts of radionuclides on aquatic organisms from past and current normal operations are small for all nuclear power plants and should not change appreciably during the license renewal term.

(45) *Effects of Dredging on Aquatic Organisms:* The final rule amends Table B–1 by adding a new Category 1 issue, ''Effects of dredging on aquatic organisms,'' with an impact level of small, to evaluate the impacts of dredging on aquatic organisms. The finding column entry for this issue states,

Dredging at nuclear power plants is expected to occur infrequently, would be of relatively short duration, and would affect relatively small areas. Dredging is performed under permit from the U.S. Army Corps of Engineers, and possibly, from other State or local agencies.

Licensees conduct dredging to maintain intake and discharge structures at nuclear power plant facilities and in some cases, to maintain barge slips. Dredging may disturb or remove benthic communities. In general, maintenance dredging for nuclear power plant operations occur infrequently, is of relatively short duration, and affects relatively small areas. Dredging is performed under a permit issued by the U.S. Army Corps of Engineers and consequently, each dredging action is subject to a site-specific environmental review conducted by the Corps. Dredging activities may also require permits from various State or local agencies.

(46) *Water Use Conflicts with Aquatic Resources (Plants with Cooling Ponds or Cooling Towers using Makeup Water from a River):* The final rule amends Table B–1 by adding a new Category 2 issue, ''Water use conflicts with aquatic resources (plants with cooling ponds or cooling towers using makeup water from a river),'' with an impact level range of small to moderate, to evaluate water use conflicts with aquatic resources in stream communities. The 1996 GEIS already addresses the resource aspects of this issue, and 10 CFR 51.53(c)(3)(ii)(A) requires a plant-specific analysis of the impacts of surface water withdrawals from rivers for cooling pond or cooling tower makeup on stream (i.e., aquatic) ecological communities. However, this stand-alone issue was created to clearly separate out the related aspects and potential impacts on aquatic communities associated with surface water withdrawals from a river for consumptive cooling water uses.

The finding column entry for this issue states,

Impacts on aquatic resources in stream communities affected by water use conflicts could be of moderate significance in some situations.

Such impacts could occur when water that supports these resources is diminished because of decreased availability due to droughts; increased water demand for agricultural, municipal, or industrial usage; or a combination of these factors. The potential range of impact levels at plants, subject to license renewal, with cooling ponds or cooling towers using makeup water from a river cannot be generically determined. The NRC has also removed the term ''low flow'' from the title of this issue, as set forth in the proposed rule, and other related river flow issues in the final rule as previously discussed in this section (*see* Issue 17, ''Surface Water Use Conflicts (Plants with Cooling Ponds or Cooling Towers Using Makeup Water from a River)'').

(47) *Effects on Aquatic Resources (Non-Cooling System Impacts):* The final rule amends Table B–1 by renaming the ''Refurbishment'' issue as ''Effects on aquatic resources (non-cooling system impacts).'' [35] It remains a Category 1 issue with an impact level of small. The final rule further amends Table B–1 by replacing the finding column entry, which states,

During plant shutdown and refurbishment there will be negligible effects on aquatic biota because of a reduction of entrainment and impingement of organisms or a reduced release of chemicals.

with the following:

Licensee application of appropriate mitigation measures is expected to result in no more than small changes to aquatic communities from their current condition.

(48) *Impacts of Transmission Line Right-of-Way (ROW) Management on Aquatic Resources:* The final rule amends Table B–1 by adding a new Category 1 issue, ''Impacts of transmission line right-of-way (ROW) management on aquatic resources,'' with an impact level of small, to evaluate the impact of transmission line ROW management on aquatic resources during the license renewal term. The finding column entry for this issue states,

Licensee application of best management practices to ROW maintenance is expected to result in no more than small impacts to aquatic resources.

Impacts on aquatic resources from transmission line ROW maintenance could occur as a result of the direct disturbance of aquatic habitats, soil erosion, changes in water quality (from sedimentation and thermal effects), or inadvertent releases of chemical contaminants from herbicide use. As described in the revised GEIS, the NRC expects any impact on aquatic resources resulting from transmission line ROW maintenance to be small, short term, and localized for all plants because of licensee application of best management practices.

The final rule further amends Table B–1 by appending a footnote to the issue column entry for ''Impacts of Transmission Line Right-of-Way (ROW) Management on Aquatic Resources,'' concerning the extent to which transmission lines and their associated ROW have been analyzed under the revised GEIS. This footnote is the same one that was added to Issue 3, ''Offsite land use in transmission line right-of-ways (ROWs).'' See the description of the changes made by the final rule to Issue 3 for further explanation of this amendment.

(49) Losses from Predation, Parasitism, and Disease Among Organisms Exposed to Sublethal Stresses: There are no changes to this issue, and it remains a Category 1 issue, with an impact level of small.

Special Status Species and Habitats

(50) *Threatened, Endangered, and Protected Species and Essential Fish Habitat:* The final rule amends Table B–1 by renaming the issue ''Threatened or endangered species'' as ''Threatened, endangered, and protected species and essential fish habitat.'' The final rule expands the scope of the issue to include essential fish habitats protected under the Magnuson-Stevens Fishery Conservation and Management Act (MSA). The renamed and expanded issue is a Category 2 issue. The final rule further amends Table B–1 by replacing the finding column entry, which states,

Generally, plant refurbishment and continued operations are not expected to adversely affect threatened or endangered species. However, consultation with appropriate agencies would be needed at the time of license renewal to determine whether threatened or endangered species are present and whether they would be adversely affected. See § 51.53(c)(3)(ii)(E).

with the following:

The magnitude of impacts on threatened, endangered, and protected species, critical habitat, and essential fish habitat would depend on the occurrence of listed species and habitats and the effects of power plant systems on them. Consultation with appropriate agencies would be needed to determine whether special status species or habitats are present and whether they would be adversely affected by continued operations and refurbishment associated with license renewal.

The final rule also amends Table B–1 by removing the words ''SMALL, MODERATE, or LARGE'' from the finding column entry because the Endangered Species Act (ESA) requires other findings.[36] In complying with the ESA, the NRC determines whether the effects of continued nuclear power plant operations and refurbishment (1) would have no effect, (2) are not likely to adversely affect, (3) are likely to adversely affect, or (4) are likely to jeopardize the listed species or adversely modify the designated critical habitat of Federally listed species populations or their critical habitat during the license renewal term. For listed species where the NRC has found that its action is ''likely to adversely affect'' the species or habitat, the NRC may further characterize the effects as ''is [or is not] likely to jeopardize listed species or adversely modify designated critical habitat.''

Similarly, the MSA also requires other findings. In complying with the MSA, the NRC determines whether the effects

[35] The proposed rule had renamed this issue ''Refurbishment impacts on aquatic resources.'' (74 FR 38125, 38136; July 31, 2009).

[36] The proposed rule did not reflect this change (74 FR 38125, 38137; July 31, 2009).

of continued nuclear power plant operations and refurbishment associated with license renewal would have: (1) No adverse impact, (2) minimal adverse impact, or (3) substantial adverse impact to the essential habitat of federally managed fish populations during the license renewal term. Therefore, the NRC believes that reporting its ESA and MSA findings instead of the ''SMALL, MODERATE, or LARGE'' significance levels of impact will clarify the results.

Historic and Cultural Resources

(51) *Historic and Cultural Resources:* The final rule amends Table B–1 by renaming the issue ''Historic and archaeological resources'' as ''Historic and cultural resources.'' It remains a Category 2 issue. The final rule further amends Table B–1 by replacing the finding column entry, which states,

> Generally, plant refurbishment and continued operations are expected to have no more than small adverse impacts on historic and archaeological resources. However, the National Historic Preservation Act requires the Federal agency to consult with the State Historic Preservation Officer to determine whether there are properties present that require protection. See § 51.53(c)(3)(ii)(K).

with the following:

> Continued operations and refurbishment associated with license renewal are expected to have no more than small impacts on historic and cultural resources located onsite and in the transmission line ROW because most impacts could be mitigated by avoiding those resources. The National Historic Preservation Act (NHPA) requires the Federal agency to consult with the State Historic Preservation Officer (SHPO) and appropriate Native American Tribes to determine the potential effects on historic properties and mitigation, if necessary.

The final rule further amends Table B–1 by removing the words ''SMALL, MODERATE, or LARGE'' from the finding column entry [37] because the National Historic Preservation Act (NHPA) requires the NRC to determine whether historic properties are present on or near the project site, and if so, whether the license renewal decision would result in any adverse effect upon such properties. Thus, the NRC in its plant-specific environmental review makes the following determinations: no historic properties present; historic properties are present, but not adversely affected; or there is an adverse effect.

If continued operations and refurbishment associated with license renewal result in any adverse effects, the NHPA Section 106 process requires consultation with the requisite State Historic Preservation Officer (SHPO) and if appropriate, the requisite Tribal Historic Preservation Officer. The license renewal applicant is typically an active participant in such consultation, and the applicant may agree to commit to carrying out the appropriate mitigation measures. If an agreement is reached, the parties will execute a Memorandum of Agreement. Therefore, the NRC believes that reporting its NHPA findings in the plant-specific SEIS, instead of the ''SMALL, MODERATE, or LARGE'' significance levels of impact, will clarify the results.

Socioeconomics

(52) *Employment and Income, Recreation and Tourism:* The final rule amends Table B–1 by adding a new Category 1 issue, ''Employment and income, recreation and tourism,'' which includes the ''tourism and recreation'' portion of a current Table B–1 Category 1 issue, ''Public services: public safety, social services, and tourism and recreation.'' The issue has an impact level of small. The final rule consolidates the tourism and recreation portion with the new generic analysis to cover employment and income given the similar nature of these issues and to facilitate the environmental review process. The revised GEIS provides an analysis of this consolidated issue and concludes that the impacts are generic to all plants undergoing license renewal. The finding column entry for this issue states,

> Although most nuclear plants have large numbers of employees with higher than average wages and salaries, employment, income, recreation, and tourism impacts from continued operations and refurbishment associated with license renewal are expected to be small.

(53) *Tax Revenues:* The impact of changes to tax revenues was discussed in the 1996 GEIS, but was not listed in Table B–1. The final rule amends Table B–1 by adding a new Category 1 issue, ''Tax revenues,'' to evaluate the impacts of license renewal on tax revenues. The issue has an impact level of small. The finding column entry for this issue states,

> Nuclear plants provide tax revenue to local jurisdictions in the form of property tax payments, payments in lieu of tax (PILOT), or tax payments on energy production. The amount of tax revenue paid during the license renewal term as a result of continued operations and refurbishment associated with license renewal is not expected to change.

Refurbishment activities, such as steam generator and vessel head replacement, have not had a noticeable effect on the value of nuclear power plants, thus changes in tax revenues are not anticipated from future refurbishment activities. Refurbishment activities involve the one-for-one replacement of existing components and are generally not considered a taxable improvement. Also, new property tax assessments; proprietary payments in lieu of tax stipulations, settlements, and agreements; and State tax laws are continually changing the amounts paid to taxing jurisdictions by nuclear power plant owners, and these occur independent of license renewal and refurbishment activities.

(54) *Community Services and Education:* The final rule amends Table B–1 by reclassifying two Category 2 issues, ''Public services: public utilities,'' with an impact level range of small to moderate, and ''Public services, education (refurbishment),'' with an impact level range of small to large, as Category 1 issues. The final rule consolidates these two issues with the Category 1 issue, ''Public services, education (license renewal term),'' which has an impact level of small, and the ''Public safety and social service'' portion of the Category 1 issue, ''Public services: public safety, social services, and tourism and recreation,'' which also has an impact level of small.[38] The final rule names the consolidated issue, ''Community services and education,'' and classifies it as a Category 1 issue with an impact level of small. The final rule further amends Table B–1 by removing the entries for ''Public services: public utilities,'' ''Public services, education (refurbishment),'' ''Public services, education (license renewal term),'' and ''Public services: public safety, social services, and tourism and recreation,'' and by adding the entry for ''Community services and education.'' The finding column entry for the ''Community services and education'' issue states,

> Changes resulting from continued operations and refurbishment associated with license renewal to local community and educational services would be small. With little or no change in employment at the licensee's plant, value of the power plant, payments on energy production, and PILOT payments expected during the license renewal term, community and educational services would not be affected by continued power plant operations.

The four issues are consolidated because all public services are equally affected by changes in plant operations and refurbishment associated with

[37] The proposed rule did not reflect this change (74 FR 38125, 38137; July 31, 2009).

[38] The ''tourism and recreation'' portion of the ''Public services: public safety, social services, and tourism and recreation'' issue was consolidated with the new generic analysis concerning employment and income to form the consolidated Category 1 issue, ''Employment and income, recreation and tourism'' (see Issue 52).

license renewal. Any changes in the number of workers at a nuclear power plant will affect demand for public services from local communities. Nevertheless, past environmental reviews conducted by the NRC since the issuance of the 1996 GEIS have shown that the number of workers at relicensed nuclear power plants has not changed significantly because of license renewal. Thus, no significant impacts on community services are anticipated from future license renewals. In addition, refurbishment activities, such as steam generator and vessel head replacement, have not required the large numbers of workers and the months of time that was conservatively analyzed in the 1996 GEIS, and as such, significant impacts on community services are no longer anticipated. Combining the four issues also facilitates the environmental review process.

(55) *Population and Housing:* The final rule amends Table B–1 by renaming the Category 2 issue, ''Housing impacts,'' with an impact level range of small to large, to ''Population and housing.'' The final rule reclassifies this issue as a Category 1 issue with an impact level of small. As described in the revised GEIS, the availability and value of housing are directly affected by changes in population. The final rule further amends Table B–1 by removing the entry for ''Housing impacts,'' and by adding an entry for ''Population and housing.'' The finding column entry for this issue states,

Changes resulting from continued operations and refurbishment associated with license renewal to regional population and housing availability and value would be small. With little or no change in employment at the licensee's plant expected during the license renewal term, population and housing availability and values would not be affected by continued power plant operations.

As described in the revised GEIS, the NRC has determined that the impacts of continued operations and refurbishment activities on population and housing during the license renewal term would be small. Moreover, any impacts are not dependent on the socioeconomic setting of the nuclear power plant and are generic to all plants.

(56) *Transportation:* The final rule amends Table B–1 by reclassifying the Category 2 issue, ''Public services, Transportation,'' with an impact level range of small to large, as a Category 1 issue with an impact level of small, and renaming it ''Transportation.'' The final rule further amends Table B–1 by replacing the finding column entry, which states,

Transportation impacts (level of service) of highway traffic generated during plant refurbishment and during the term of the renewed license are generally expected to be of small significance. However, the increase in traffic associated with additional workers and the local road and traffic control conditions may lead to impacts of moderate or large significance at some sites. See § 51.53(c)(3)(ii)(J).

with the following:

Changes resulting from continued operations and refurbishment associated with license renewal to traffic volumes would be small.

As described in the revised GEIS, the NRC has determined that the numbers of workers have not changed significantly due to license renewal, so transportation impacts from continued operations and refurbishment associated with license renewal are no longer expected to be significant.

Human Health

(57) *Radiation Exposures to the Public:* The final rule amends Table B–1 by consolidating two Category 1 issues, ''Radiation exposures to the public during refurbishment'' and ''Radiation exposure to public (license renewal term)'' and names the consolidated issue, ''Radiation exposures to the public.'' The consolidated issue is a Category 1 issue with an impact level of small. These issues are consolidated given their similar nature and to facilitate the environmental review process. The final rule amends Table B–1 by removing the entries for ''Radiation exposures to the public during refurbishment'' and ''Radiation exposure to public (license renewal term)'' and by adding an entry for ''Radiation exposures to the public.'' The finding column entry for this consolidated issue states,

Radiation doses to the public from continued operations and refurbishment associated with license renewal are expected to continue at current levels, and would be well below regulatory limits.

(58) *Radiation Exposures to Plant Workers:* The final rule amends Table B–1 by consolidating two Category 1 issues, ''Occupational radiation exposures during refurbishment'' and ''Occupational radiation exposures (license renewal term)'' and names the consolidated issue, ''Radiation exposures to plant workers.'' The consolidated issue is a Category 1 issue with an impact level of small. These issues are consolidated given their similar nature and to facilitate the environmental review process. The final rule amends Table B–1 by removing the entries ''Occupational radiation exposures during refurbishment'' and ''Occupational radiation exposures (license renewal term)'' and by adding an entry for ''Radiation exposures to plant workers.'' The finding column entry for the combined issue states,

Occupational doses from continued operations and refurbishment associated with license renewal are expected to be within the range of doses experienced during the current license term and would continue to be well below regulatory limits.

(59) *Human Health Impact from Chemicals:* The final rule amends Table B–1 by adding a new Category 1 issue, ''Human health impact from chemicals,'' to evaluate the potential impacts to plant workers and members of the public from exposure to chemicals. The new issue has an impact level of small. The finding column entry for this issue states,

Chemical hazards to plant workers resulting from continued operations and refurbishment associated with license renewal are expected to be minimized by the licensee implementing good industrial hygiene practices as required by permits and Federal and State regulations. Chemical releases to the environment and the potential for impacts to the public are expected to be minimized by adherence to discharge limitations of NPDES and other permits.

The evaluation addresses the potential impact of chemicals on human health resulting from normal operations of a nuclear power plant during the license renewal term. Impacts of chemical exposure to human health are considered to be small if the use of chemicals within the plant is in accordance with industrial safety guides and discharges of chemicals to water bodies are within effluent limitations designed to ensure protection of water quality and aquatic life.

The disposal of hazardous chemicals used at nuclear power plants by licensees is subject to the RCRA and the CWA (which requires licensees to hold an NPDES permit). Adherence by the licensee to these statutory requirements should minimize adverse impacts to the environment, workers, and the public. It is anticipated that all plants would continue to operate in compliance with all applicable permits and that no mitigation measures beyond those implemented during the current license term would be warranted as a result of license renewal.

A review of the documents, as referenced in the revised GEIS, operating monitoring reports, and consultations with utilities and regulatory agencies that were performed for the 1996 GEIS, indicated that the effects of the discharge of chlorine and other biocides on water quality have been of small significance for all power plants. Small quantities of biocides are readily dissipated and/or are chemically altered in the body of water receiving them, so significant cumulative impacts to water quality would not be expected. The NRC expects no major changes in the operation of plant cooling systems during the license renewal term, so no changes are anticipated in the effects of biocide discharges on the quality of the receiving waters. The EPA and the States regulate discharges of sanitary wastes and heavy metals through NPDES permits. The NRC considers discharges that do not violate the permit limits to be of small significance. The effects of minor chemical discharges and spills on water quality are also expected to be of small significance during the license renewal term, and the appropriate regulating agencies would require the licensee to mitigate these discharges and spills as needed.

(60) *Microbiological Hazards to the Public (Plants with Cooling Ponds or Canals or Cooling Towers that Discharge to a River):* The final rule amends Table B–1 by renaming the ''Microbiological organisms (public health) (plants using lakes or canals, or cooling towers or cooling ponds that discharge to a small river)'' issue as ''Microbiological hazards to the public (plants with cooling ponds or canals or cooling towers that discharge to a river).'' The issue remains a Category 2 issue, with an impact level range of small to large. The final rule further amends Table B–1 by replacing the finding column entry, which states,

These organisms are not expected to be a problem at most operating plants except possibly at plants using cooling ponds, lakes, or canals that discharge to small rivers. Without site-specific data, it is not possible to predict the effects generically. See § 51.53(c)(3)(ii)(G).

with the following:

These organisms are not expected to be a problem at most operating plants except possibly at plants using cooling ponds, lakes, or canals, or that discharge into rivers. Impacts would depend on site-specific characteristics.

(61) *Microbiological Hazards to Plant Workers:* The final rule amends Table B–1 by renaming the ''Microbiological organisms (occupational health)'' issue as ''Microbiological hazards to plant workers.'' It remains a Category 1 issue with an impact level of small. The final rule amends Table B–1 by adding the phrase ''as required by permits and Federal and State regulations'' to the end of the finding column entry.

(62) *Chronic Effects of Electromagnetic Fields (EMFs):* The final rule amends Table B–1 by renaming the ''Electromagnetic fields, chronic effects'' issue as ''Chronic effects of electromagnetic fields (EMFs).'' It remains an uncategorized issue with an impact level of uncertain because there is no national scientific consensus on the potential impacts from chronic exposure to EMFs. The final rule further amends Table B–1 by replacing the finding column entry, which states,

Biological and physical studies of 60-Hz electromagnetic fields have not found consistent evidence linking harmful effects with field exposures. However, research is continuing in this area and a consensus scientific view has not been reached.

with the following:

Studies of 60-Hz EMFs have not uncovered consistent evidence linking harmful effects with field exposures. EMFs are unlike other agents that have a toxic effect (e.g., toxic chemicals and ionizing radiation) in that dramatic acute effects cannot be forced and longer-term effects, if real, are subtle. Because the state of the science is currently inadequate, no generic conclusion on human health impacts is possible.

Although there is no conclusion as to the impact level, and this issue is not considered to be a Category 1 issue in the sense that a generic conclusion on the impact level has not been reached, this issue will be treated uniformly in plant-specific SEISs by essentially providing the discussion appearing in this issue's finding column entry in Table B–1 until a national scientific consensus has been reached.

The final rule further amends Table B–1 by appending a footnote to the issue column entry for ''Chronic Effects of Electromagnetic Fields (EMFs),'' concerning the extent to which transmission lines and their associated right of ways have been analyzed under the revised GEIS. This footnote is the same one that was added to Issue 3, ''Offsite land use in transmission line right-of-ways (ROWs).'' See the description of the changes made by the final rule to Issue 3 for further explanation of this amendment. In addition, the final rule retains the footnote that was appended to issue column entry but renumbers that footnote from ''5'' to ''6'' and retains the footnote that was appended to category column entry but renumbers that footnote from ''4'' to ''5.''

(63) *Physical Occupational Hazards:* The final rule amends Table B–1 by adding a new Category 1 issue, ''Physical occupational hazards,'' to evaluate the potential impact of physical occupational hazards on human health resulting from normal nuclear power plant operations during the license renewal term. The issue has an impact level of small. The finding column entry for this issue states,

Occupational safety and health hazards are generic to all types of electrical generating stations, including nuclear power plants, and are of small significance if the workers adhere to safety standards and use protective equipment as required by Federal and State regulations.

Through a Memorandum of Understanding (53 FR 43950; October 31, 1988) between the NRC and the Occupational Safety and Health Administration (OSHA), plant conditions that result in an occupational risk, but do not affect the safety of licensed radioactive materials, are under the statutory authority of OSHA rather than the NRC. Nevertheless, the impact of physical occupational hazards on human health has been raised by the public, as well as Federal and State agencies during the license renewal process. As such, this issue has been added to allow for a more complete analysis of the human health impact of continued power plant operation during the license renewal term. Occupational hazards can be minimized by licensees when workers adhere to safety standards and use appropriate protective equipment, although fatalities and injuries from accidents can still occur. Data for occupational injuries in 2005 obtained from the U.S. Bureau of Labor Statistics indicate that the rate of fatal injuries in the utility sector is less than the rate for many sectors (e.g., construction, transportation and warehousing, agriculture, forestry, fishing and hunting, wholesale trade, and mining) and that the incidence rate for nonfatal occupational injuries and illnesses is the least for electric power generation, followed by electric power transmission control and distribution. It is expected that over the license renewal term, licensees would ensure that their workers continue to adhere to safety standards and use protective equipment, so adverse occupational impacts would be of small significance at all sites.

(64) *Electric Shock Hazards:* The final rule amends Table B–1 by renaming the ''Electromagnetic fields, acute effects (electric shock)'' issue as ''Electric shock hazards.'' It remains a Category 2 issue with an impact level range of small to large. The final rule further amends Table B–1 by replacing the finding column entry, which states,

Electrical shock resulting from direct access to energized conductors or from induced charges in metallic structures have not been found to be a problem at most operating plants and generally are not expected to be a problem during the license renewal term. However, site-specific review is required to determine the significance of the electric shock potential at the site. See § 51.53(c)(3)(ii)(H).

with the following:

Electrical shock potential is of small significance for transmission lines that are operated in adherence with the National Electrical Safety Code (NESC). Without a review of conformance with NESC criteria of each nuclear power plant's in-scope transmission lines, it is not possible to generically determine the significance of the electrical shock potential.

The final rule's change to the finding column entry reflects the analysis in the revised GEIS concerning the potential of electrical shock from transmission lines. The final rule further amends Table B–1 by appending a footnote to the issue column entry for ''Electric shock hazards,'' concerning the extent to which transmission lines and their associated right of ways have been analyzed under the revised GEIS. This footnote is the same one that was added to Issue 3, ''Offsite land use in transmission line right-of-ways (ROWs).'' See the description of the changes made by the final rule to Issue 3 for further explanation of this amendment.

Postulated Accidents

(65) *Design-Basis Accidents and (66) Severe Accidents:* ''Design-basis accidents,'' and ''Severe accidents,'' with impact levels of small, remain Category 1 and 2 issues, respectively. The final rule amends Table B–1 by making minor clarifying changes to the finding column entries for both of these issues.

Environmental Justice

(67) *Minority and Low-Income Populations:* The final rule amends Table B–1 by adding a new Category 2 issue, ''Minority and low-income populations,'' to evaluate the impacts of continued operations and any refurbishment activities during the license renewal term on minority and low-income populations living in the vicinity of the plant. This issue was listed in Table B–1, prior to this final rule, but was not evaluated in the 1996 GEIS. In that table the finding column entry for this issue states, ''[t]he need for and the content of an analysis of environmental justice will be addressed in plant-specific reviews.''

Executive Order 12898 (59 FR 7629; February 16, 1994) initiated the Federal government's environmental justice program. The NRC's ''Policy Statement on the Treatment of Environmental Justice Matters in NRC Regulatory and Licensing Actions'' (69 FR 52040; August 24, 2004) states, ''the NRC is committed to the general goals of E.O. 12898, [and] it will strive to meet those goals through its normal and traditional NEPA review process.'' Guidance for implementing E.O. 12898 was not available prior to the completion of the 1996 GEIS. By making this a Category 2 issue, the final rule requires license renewal applicants to identify, in their environmental reports, minority and low-income populations and communities residing in the vicinity of the nuclear power plant.

The final rule amends Table B–1 by replacing the finding column entry, which states,

The need for and the content of an analysis of environmental justice will be addressed in plant-specific reviews.

with the following:

Impacts to minority and low-income populations and subsistence consumption resulting from continued operations and refurbishment associated with license renewal will be addressed in plant-specific reviews. See NRC Policy Statement on the Treatment of Environmental Justice Matters in NRC Regulatory and Licensing Actions (69 FR 52040; August 24, 2004).

The final rule does not adopt the proposed rule's impact range of small to moderate for this issue as E.O. 12898 requires a determination of whether human health and environmental effects of continued operations during the license renewal term and refurbishment associated with license renewal on minority and low-income populations would be disproportionately high and adverse. This determination will be made by the NRC in each plant-specific SEIS.

The final rule removes the footnote from the category column entry for this issue and removes footnote ''6'' from Table B–1 as footnote ''6'' is no longer necessary.

Waste Management

(68) *Low-Level Waste Storage and Disposal:* This issue remains a Category 1 issue with an impact level of small. The final rule amends Table B–1 by replacing the finding column entry, which states,

The comprehensive regulatory controls that are in place and the low public doses being achieved at reactors ensure that the radiological impacts to the environment will remain small during the term of a renewed license. The maximum additional on-site land that may be required for low-level waste storage during the term of a renewed license and associated impacts will be small. Nonradiological impacts on air and water will be negligible. The radiological and nonradiological environmental impacts of long-term disposal of low-level waste from any individual plant at licensed sites are small. In addition, the Commission concludes that there is reasonable assurance that sufficient low-level waste disposal capacity will be made available when needed for facilities to be decommissioned consistent with NRC decommissioning requirements.

with the following:

The comprehensive regulatory controls that are in place and the low public doses being achieved at reactors ensure that the radiological impacts to the environment would remain small during the license renewal term.

(69) *Onsite Storage of Spent Nuclear Fuel:* The final rule amends Table B–1 by renaming the ''Onsite spent fuel'' issue as ''Onsite storage of spent nuclear fuel.'' It remains a Category 1 issue with an impact level of small. As described in Section V, ''Related Issues of Importance,'' of this document, the final rule revises the finding column entry for this issue to reflect the D.C. Circuit's decision in *New York* v. *NRC* and the NRC's planned response thereto. Specifically, the final rule reduces the period of time covered by this issue from the period of extended license (from approval of the license renewal application to the expiration of the operating license) plus 30 years after the permanent shutdown of the reactor and expiration of the operating license to the period of extended license only. The final rule amends Table B–1 by replacing the finding column entry, which states,

The expected increase in the volume of spent fuel from an additional 20 years of operation can be safely accommodated on site with small environmental effects through dry or pool storage at all plants if a permanent repository or monitored retrievable storage is not available.

with the following:

The expected increase in the volume of spent fuel from an additional 20 years of operation can be safely accommodated onsite during the license renewal term with small environmental effects through dry or pool storage at all plants.

(70) *Offsite Radiological Impacts of Spent Nuclear Fuel and High-Level Waste Disposal:* The final rule amends Table B–1 by renaming the ''Offsite radiological impacts (spent fuel and high level waste disposal)'' issue as ''Offsite radiological impacts of spent nuclear fuel and high-level waste disposal.'' As described in Section V ''Related Issues of Importance,'' of this document, the final rule revises the finding column entry for this issue to reflect the D.C. Circuit's decision in *New York* v. *NRC* and the NRC's planned response thereto. Specifically, the final rule reclassifies this issue from Category

1, with no impact level assigned, to an uncategorized issue with an impact level of uncertain. The final rule removes the description in the finding column entry and replaces it with the following: ''Uncertain impact. The generic conclusion on offsite radiological impacts of spent nuclear fuel and high-level waste is not being finalized pending the completion of a generic environmental impact statement on waste confidence.'' Upon issuance of the generic EIS and revised Waste Confidence Rule, the NRC will make any necessary confirming amendments to this rule.

(71) *Mixed-Waste Storage and Disposal:* This issue remains a Category 1 issue with an impact level of small. The final rule amends Table B–1 by replacing the finding column entry for this issue, which states,

The comprehensive regulatory controls and the facilities and procedures that are in place ensure proper handling and storage, as well as negligible doses and exposure to toxic materials for the public and the environment at all plants. License renewal will not increase the small, continuing risk to human health and the environment posed by mixed waste at all plants. The radiological and nonradiological environmental impacts of long-term disposal of mixed waste from any individual plant at licensed sites are small. In addition, the Commission concludes that there is reasonable assurance that sufficient mixed waste disposal capacity will be made available when needed for facilities to be decommissioned consistent with NRC decommissioning requirements.

with the following:

The comprehensive regulatory controls and the facilities and procedures that are in place ensure proper handling and storage, as well as negligible doses and exposure to toxic materials for the public and the environment at all plants. License renewal would not increase the small, continuing risk to human health and the environment posed by mixed waste at all plants. The radiological and nonradiological environmental impacts of long-term disposal of mixed waste from any individual plant at licensed sites are small.

(72) *Nonradioactive Waste Storage and Disposal:* The final rule amends Table B–1 by renaming the issue ''Nonradiological waste'' as ''Nonradiological waste storage and disposal.'' It remains a Category 1 issue, with an impact level of small. The final rule further amends Table B–1 by replacing the finding column entry, which states,

No changes to generating systems are anticipated for license renewal. Facilities and procedures are in place to ensure continued proper handling and disposal at all sites.

with the following:

No changes to systems that generate nonradioactive waste are anticipated during the license renewal term. Facilities and procedures are in place to ensure continued proper handling, storage, and disposal, as well as negligible exposure to toxic materials for the public and the environment at all plants.

Cumulative Impacts

(73) *Cumulative Impacts:* The final rule amends Table B–1 by adding a new Category 2 issue, ''Cumulative impacts,'' to evaluate the potential cumulative impacts of license renewal. The term ''cumulative impacts'' is defined in 10 CFR 51.14(b) by reference to the CEQ regulations, 40 CFR 1508.7, as ''the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions.''

For the purposes of analysis, past actions are considered to be when the nuclear power plant was licensed and constructed, present actions are related to current plant operations, and future actions are those that are reasonably foreseeable through the end of plant operations including the license renewal term. The geographic area over which past, present, and future actions are assessed depends on the affected resource.

The final rule requires license renewal applicants to identify other past, present, and reasonably foreseeable future actions, such as the construction and operation of other power plants and other industrial and commercial facilities in the vicinity of the nuclear power plant. The finding column entry for this issue states,

Cumulative impacts of continued operations and refurbishment associated with license renewal must be considered on a plant-specific basis. Impacts would depend on regional resource characteristics, the resource-specific impacts of license renewal, and the cumulative significance of other factors affecting the resource.

Uranium Fuel Cycle

(74) *Offsite Radiological Impacts—Individual Impacts from Other than the Disposal of Spent Fuel and High-Level Waste:* The final rule amends Table B–1 by renaming the ''Offsite radiological impacts (individual effects from other than the disposal of spent fuel and high level waste)'' issue as ''Offsite radiological impacts—individual impacts from other than the disposal of spent fuel and high-level waste.'' This issue remains a Category 1 issue with an impact level of small. The final rule further amends Table B–1 by replacing the finding column entry, which states,

Off-site impacts of the uranium fuel cycle have been considered by the Commission in Table S–3 of this part. Based on information in the GEIS, impacts on individuals from radioactive gaseous and liquid releases including radon-222 and technetium-99 are small.

with the following:

The impacts to the public from radiological exposures have been considered by the Commission in Table S–3 of this part. Based on information in the GEIS, impacts to individuals from radioactive gaseous and liquid releases, including radon-222 and technetium-99, would remain at or below the NRC's regulatory limits.

(75) *Offsite Radiological Impacts—Collective Impacts from Other than the Disposal of Spent Fuel and High-Level Waste:* The final rule amends Table B–1 by renaming the ''Offsite radiological impacts (collective effects)'' issue as ''Offsite radiological impacts—collective impacts from other than the disposal of spent fuel and high-level waste.'' It remains a Category 1 issue with no impact level assigned. The final rule further amends Table B–1 by replacing the finding column entry, which states,

The 100 year environmental dose commitment to the U.S. population from the fuel cycle, high level waste and spent fuel disposal excepted, is calculated to be about 14,800 person rem, or 12 cancer fatalities, for each additional 20-year power reactor operating term. Much of this, especially the contribution of radon releases from mines and tailing piles, consists of tiny doses summed over large populations. This same dose calculation can theoretically be extended to include many tiny doses over additional thousands of years as well as doses outside the U.S. The result of such a calculation would be thousands of cancer fatalities from the fuel cycle, but this result assumes that even tiny doses have some statistical adverse health effect which will not ever be mitigated (for example no cancer cure in the next thousand years), and that these doses projected over thousands of years are meaningful. However, these assumptions are questionable. In particular, science cannot rule out the possibility that there will be no cancer fatalities from these tiny doses. For perspective, the doses are very small fractions of regulatory limits, and even smaller fractions of natural background exposure to the same populations.

Nevertheless, despite all the uncertainty, some judgment as to the regulatory NEPA implications of these matters should be made and it makes no sense to repeat the same judgment in every case. Even taking the uncertainties into account, the Commission concludes that these impacts are acceptable in that these impacts would not be sufficiently large to require the NEPA conclusion, for any plant, that the option of extended operation under 10 CFR Part 54 should be eliminated. Accordingly, while the Commission has not assigned a single level of significance for the collective effects of the fuel cycle, this issue is considered Category 1.

with the following:

There are no regulatory limits applicable to collective doses to the general public from fuel-cycle facilities. The practice of estimating health effects on the basis of collective doses may not be meaningful. All fuel-cycle facilities are designed and operated to meet the applicable regulatory limits and standards. The Commission concludes that the collective impacts are acceptable.

The Commission concludes that the impacts would not be sufficiently large to require the NEPA conclusion, for any plant, that the option of extended operation under 10 CFR Part 54 should be eliminated. Accordingly, while the Commission has not assigned a single level of significance for the collective impacts of the uranium fuel cycle, this issue is considered Category 1.

(76) *Nonradiological Impacts of the Uranium Fuel Cycle:* The final rule amends Table B–1 by making minor clarifying changes to the finding column entry for this issue. This issue remains a Category 1 issue with an impact level of small.

(77) *Transportation:* This issue remains a Category 1 issue with an impact level of small. The final rule amends Table B–1 by replacing the finding column entry for this issue, which states,

The impacts of transporting spent fuel enriched up to 5 percent uranium-235 with average burnup for the peak rod to current levels approved by NRC up to 62,000 MWd/MTU and the cumulative impacts of transporting high-level waste to a single repository, such as Yucca Mountain, Nevada are found to be consistent with the impact values contained in 10 CFR 51.52(c), Summary Table S–4—Environmental Impact of Transportation of Fuel and Waste to and from One Light-Water-Cooled Nuclear Power Reactor. If fuel enrichment or burnup conditions are not met, the applicant must submit an assessment of the implications for the environmental impact values reported in § 51.52.

with the following:

The impacts of transporting materials to and from uranium-fuel-cycle facilities on workers, the public, and the environment are expected to be small.

Termination of Nuclear Power Plant Operations and Decommissioning

(78) *Termination of Plant Operations and Decommissioning:* The final rule amends Table B–1 by consolidating a new Category 1 issue, ''Termination of nuclear power plant operations'' with six other Category 1 issues related to the decommissioning of a nuclear power plant: ''Radiation doses,'' ''Waste management,'' ''Air quality,'' ''Water quality,'' ''Ecological resources,'' and ''Socioeconomic impacts,'' each with an impact level of small. The final rule names the consolidated issue, ''Termination of plant operations and decommissioning.'' The consolidated issue is a Category 1 issue with an impact level of small.

The final rule further amends Table B–1 by removing the entries for ''Radiation doses,'' ''Waste management,'' ''Air quality,'' ''Water quality,'' ''Ecological resources,'' and ''Socioeconomic impacts,'' and, by adding an entry for ''Termination of plant operations and decommissioning.'' The finding column entry for the consolidated issue states,

License renewal is expected to have a negligible effect on the impacts of terminating operations and decommissioning on all resources.

The 1996 GEIS analysis indicates that the six decommissioning issues are expected to be small at all nuclear power plant sites. The new issue addresses the impacts from terminating nuclear power plant operations and plant decommissioning. Termination of nuclear power plant operations results in the cessation of many routine plant operations as well as a significant reduction in the plant's workforce. It is assumed that termination of plant operations would not lead to the immediate decommissioning and dismantlement of the reactor or other power plant infrastructure.

The final rule consolidates the six decommissioning issues and the termination of nuclear power plant operations issue into one Category 1 issue to facilitate the environmental review process. For further information about the environmental effects of decommissioning, see the ''2002 Generic Environmental Impact Statement on Decommissioning of Nuclear Facilities: Regarding the Decommissioning of Nuclear Power Reactors,'' NUREG–0586.

IX. Section-by-Section Analysis

The following section-by-section analysis discusses the sections in 10 CFR part 51 that are being amended as a result of the final rule.

Section 51.53(c)(2)

The NRC is clarifying the required contents of the license renewal environmental report, which applicants must submit in accordance with 10 CFR 54.23, ''Contents of application—environmental information,'' by revising the second sentence in this subparagraph to read, ''This report must describe in detail the affected environment around the plant, the modifications directly affecting the environment or any plant effluents, and any planned refurbishment activities.''

Sections 51.53(c)(3)(ii)(A), (B), (C), and (E)

For those applicants seeking an initial license renewal and holding either an operating license, construction permit, or combined license as of June 30, 1995, the environmental report shall include the information required in 10 CFR 51.53(c)(2) but is not required to contain assessments of the environmental impacts of certain license renewal issues identified as Category 1 (generically analyzed) issues in Appendix B to Subpart A of 10 CFR part 51. The environmental report must contain analyses of the environmental impacts of the proposed action, including the impacts of refurbishment activities, if any, associated with license renewal and the impacts of operation during the renewal term, for those issues identified as Category 2 (plant-specific analysis required) issues in Appendix B to Subpart A of 10 CFR part 51 and must include consideration of alternatives for reducing adverse impacts of Category 2 issues. In addition, the environmental report must contain any new and significant information regarding the environmental impacts of license renewal of which the applicant is aware. The required analyses are listed in 10 CFR 51.53(c)(3)(ii)(A)–(P).

The final rule language for 10 CFR 51.53(c)(3)(ii)(A), (B), (C), (E), (F), (G), (I), (J), (K), and (N) consists of changes to conform to the final changes in Table B–1, which in turn, reflects the revised GEIS. The modified paragraphs more accurately reflect the specific information needed in the environmental report that will help the NRC conduct the environmental review of the proposed action.

Section 51.53(c)(3)(ii)(A) is revised to incorporate the findings of the revised GEIS and to require applicants to provide information in their environmental reports regarding water use conflicts encompassing water availability and competing water demands, and related impacts on stream (aquatic) and riparian (terrestrial) communities. The numerical definition for a low flow river has also been deleted requiring that applicants withdrawing makeup water for cooling towers or cooling ponds from any river provide a plant-specific assessment of water use conflicts in their environmental reports.

Section 51.53(c)(3)(ii)(B) is revised to replace ''heat shock'' with ''thermal changes'' to reflect the final changes in

Table B–1 as described earlier in this document under ''Aquatic Resources'' environmental impact Issue 39, ''Thermal impacts on aquatic organisms (plants with once-through cooling systems or cooling ponds).''

Section 51.53(c)(3)(ii)(C) is revised to delete the reference to ''Ranney wells'' to conform to the final changes made in the revised Table B–1.

Section 51.53(c)(3)(ii)(E) is revised to expressly include nuclear power plant continued operations within the scope of the impacts to be assessed by license renewal applicants. The paragraph is further revised to expand the scope of the provision to include all Federal wildlife protection laws and essential fish habitat under the MSA.

Section 51.53(c)(3)(ii)(F)

The final rule removes and reserves 10 CFR 51.53(c)(3)(ii)(F) because the final rule changes the Category 2 issue, ''Air quality during refurbishment (nonattainment and maintenance areas),'' to Category 1, ''Air quality impacts (all plants).''

Section 51.53(c)(3)(ii)(G)

The final rule language for 10 CFR 51.53(c)(3)(ii)(G) is revised to delete the numerical definition for a low flow river to conform to the final changes made in the revised Table B–1.

Section 51.53(c)(3)(ii)(I)

The final rule removes and reserves 10 CFR 51.53(c)(3)(ii)(I) because several Category 2 socioeconomic issues are reclassified as Category 1.

Section 51.53(c)(3)(ii)(J)

The final rule removes and reserves 10 CFR 51.53(c)(3)(ii)(J) because the final rule changes the Category 2 issue, ''Public services, Transportation,'' to Category 1, ''Transportation.''

Section 51.53(c)(3)(ii)(K)

The final rule language for 10 CFR 51.53(c)(3)(ii)(K) is revised to more accurately reflect the specific information needed in the environmental report that will help the NRC conduct the environmental review of the proposed action.

Section 51.53(c)(3)(ii)(N)

The final rule adds a new paragraph 10 CFR 51.53 (c)(3)(ii)(N) to require license renewal applicants to provide information on the general demographic composition of minority and low-income populations and communities (by race and ethnicity) residing in the immediate vicinity of the plant that could be affected by the renewal of the plant's operating license, including any planned refurbishment activities, and ongoing and future plant operations.

Section 51.53(c)(3)(ii)(O)

The final rule adds a new paragraph 10 CFR 51.53 (c)(3)(ii)(O) to require license renewal applicants to provide information about other past, present, and reasonably foreseeable future actions occurring in the vicinity of the nuclear power plant that may result in a cumulative effect.

Section 51.53(c)(3)(ii)(P)

The final rule adds a new paragraph 10 CFR 51.53 (c)(3)(ii)(P) to require the license renewal applicant to assess the impact of any documented inadvertent releases of radionuclides to groundwater. The assessment must include a description of any groundwater protection program used for the surveillance of piping and components containing radioactive liquids for which a pathway to groundwater may exist. The assessment must also include a description of any past inadvertent releases, including the projected impact to the environment (e.g., aquifers, rivers, lakes, ponds) during the license renewal term.

Section 51.71(d)

The final rule language for 10 CFR 51.71(d) is revised to make minor conforming changes to clarify the readability and to include the analysis of cumulative impacts. Cumulative impacts were not addressed in the 1996 GEIS, but are currently being evaluated by the NRC in plant-specific supplements to the GEIS. The NRC is modifying this paragraph to more accurately reflect the cumulative impacts analysis conducted for environmental reviews of the proposed action.

Section 51.95(c)

The final rule language revisions to the introductory text of 10 CFR 51.95(c) are administrative in nature and replace the reference to the 1996 GEIS for license renewal of nuclear power plants with a reference to the revised GEIS.

Section 51.95(c)(4)

The final rule removes the terms ''resolved Category 2 issues'' and ''open Category 2 issues'' from the second sentence of 10 CFR 51.95(c)(4), makes other clarifying changes to enhance the readability of the sentence, corrects a typographical error, and removes otherwise ambiguous or unnecessary language. The terms ''resolved Category 2 issues'' and ''open Category 2 issues'' are not defined nor used in 10 CFR part 51. In addition, the revised GEIS does not contain these terms nor does the NRC use these terms in SEISs. The only instance in past NRC practice in which an ''open'' or ''resolved'' Category 2 issue arises is for the Category 2 ''Severe accidents'' issue. The ''Severe accidents'' issue requires the preparation of a severe accident mitigation alternatives (SAMA) analysis as a prerequisite to license renewal. If a license renewal applicant had not yet performed a SAMA analysis for a given plant, then the issue would remain ''open'' pending the completion of a SAMA analysis. Some licensees, however, have already performed a SAMA analysis at some point. Thus, if a license renewal applicant had performed a SAMA analysis for a particular plant, then the issue would be considered ''resolved,'' and there would be no need to repeat a SAMA analysis as part of a license renewal application. As the finding column entry for ''Severe accidents'' already provides for a previously prepared SAMA analysis, and the ''open'' or ''resolved'' terminology is not used in connection with any other GEIS issue, there is no need to retain this language in the second sentence of 10 CFR 51.95(c)(4).

Table B–1

The final rule revises Table B–1 to follow the organizational format of the revised GEIS. Environmental issues in Table B–1 are arranged by resource area. The environmental impacts of license renewal activities, including plant operations and refurbishment along with replacement power alternatives, are addressed in each resource area. Table B–1 organizes environmental impact issues under the following resource areas: (1) Land use; (2) visual resources; (3) air quality; (4) noise; (5) geologic environment; (6) surface water resources; (7) groundwater resources; (8) terrestrial resources; (9) aquatic resources; (10) special status species and habitats; (11) historic and cultural resources; (12) socioeconomics; (13) human health; (14) postulated accidents; (15) environmental justice; (16) waste management; (17) cumulative impacts; (18) uranium fuel cycle; and (19) termination of nuclear power plant operations and decommissioning. Discussions of the environmental impact issues in each resource area and classification of issues into Category 1 or Category 2 are provided in Section VIII, ''Final Actions and Basis for Changes to Table B–1'' of this document. Additional changes to Table B–1 in the final rule were discussed previously in applicable resource areas in Section VIII. Footnote 1 was updated to reference the revised GEIS. A minor edit was made to footnote 2, clause (3), to improve clarity. Footnote 4 was added to define the in-scope electric transmission lines. Consequently, the previous footnotes 4 and 5 were renumbered as footnotes 5 and 6, respectively. The previous footnote 6 was deleted, as it is no longer needed.

X. Guidance Documents

In the Rules and Regulations section of this issue of the **Federal Register**, the NRC is providing notice of the availability of three additional documents related to this final rule: (1) A revised GEIS, NUREG–1437, ''Generic Environmental Impact statement for License Renewal of Nuclear Plants,'' Vol. 1, ''Main Report'' (ADAMS Accession No. ML13106A241); Vol. 2, ''Public Comments'' (ADAMS Accession No. ML13106A242); and Vol. 3, ''Appendices'' (ADAMS Acession No. ML13106A244); (2) Revision 1 of Environmental Standard Review Plan (ESRP), NUREG–1555, Supplement 1, ''Standard Review Plans for Environmental Reviews for Nuclear Power Plants, Supplement 1: Operating License Renewal'' (ADAMS Acession No. ML13106A246); and (3) Revision 1 of Regulatory Guide 4.2, Supplement 1, ''Preparation of Environmental Reports for Nuclear Power Plant License Renewal Applications'' (ADAMS Acession No. ML13067A354).

The revised GEIS is intended to improve the efficiency of the license renewal process by (1) Providing an evaluation of the types of environmental impacts that may occur from renewing commercial nuclear power plant operating licenses, (2) identifying and assessing impacts that are expected to be generic (the same or similar) at all nuclear power plants (or plants with specific plant or site characteristics), and (3) defining the number and scope of environmental impact issues that need to be addressed in plant-specific supplemental EISs. The content of the revised GEIS is discussed further in Section III, ''Discussion,'' of this document.

Revision 1 of RG 4.2, Supplement 1, provides general procedures for the preparation of environmental reports, which are submitted as part of the license renewal application for a nuclear power plant in accordance with 10 CFR part 54. More specifically, this revised RG explains the criteria for addressing Category 2 issues in the environmental report as required by the revisions to 10 CFR part 51 under the final rule.

The revised ESRP provides guidance to the NRC staff on how to conduct a license renewal environmental review. The ESRP parallels the format in RG 4.2. The primary purpose of the ESRP is to ensure that these reviews focus on those environmental concerns associated with license renewal as described in 10 CFR part 51.

XI. Agreement State Compatibility

Under the ''Policy Statement on Adequacy and Compatibility of Agreement States Programs,'' approved by the Commission on June 20, 1997, and published in the **Federal Register** (62 FR 46517), this rule is classified as compatibility category ''NRC.'' Agreement State Compatibility is not required for Category ''NRC'' regulations. The NRC program elements in this category are those that relate directly to areas of regulation reserved to the NRC by the Atomic Energy Act of 1954, as amended, or the provisions of Title 10 of the CFR. Although an Agreement State may not adopt program elements reserved to the NRC, it may wish to inform its licensees of certain requirements via a mechanism that is consistent with the particular State's administrative procedure laws. Category ''NRC'' regulations do not confer regulatory authority on the State.

XII. Availability of Documents

The NRC is making the documents identified in the following table available to interested persons through one or more of the methods provided in the **ADDRESSES** section of this document.

XIII. Voluntary Consensus Standards

The National Technology Transfer and Advancement Act of 1995, Public Law 104–113, requires that Federal agencies use technical standards that are developed or adopted by voluntary consensus standards bodies unless using such a standard is inconsistent with applicable law or is otherwise impractical. This final rulemaking, which amends various provisions of 10 CFR part 51, does not constitute the establishment of a standard that contains generally applicable requirements.

XIV. Environmental Impact—Categorical Exclusion

The NRC has determined that the promulgation of this final rule is a type of procedural action that meets the criteria of the categorical exclusion set forth in 10 CFR 51.22(c)(3)(i) and (iii). Therefore, neither an environmental impact statement nor an environmental assessment has been prepared for this final rule.

XV. Paperwork Reduction Act Statement

This final rule contains new or amended information collection requirements that are subject to the Paperwork Reduction Act of 1995 (44 U.S.C. 3501, *et seq.*). These requirements were approved by the Office of Management and Budget (OMB), control number 3150–0021.

The burden to the public for these information collections is estimated to be reduced by an average of 311.15 hours per response, including the time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing the information collection. Send comments on any aspect of these information collections, including suggestions for reducing the burden, to the Information Services Branch (T–5 F53), U.S. Nuclear Regulatory Commission, Washington, DC 20555–0001, or by email to *INFOCOLLECTS.RESOURCE@NRC.GOV;* and to the Desk Officer, Office of Information and Regulatory Affairs, NEOB–10202, (3150–0021), Office of Management and Budget, Washington, DC 20503, or by email to *Chad_S._Whiteman@omb.eop.gov.*

Public Protection Notification

The NRC may not conduct or sponsor, and a person is not required to respond to, a request for information or an information collection requirement unless the requesting document displays a currently valid OMB control number.

XVI. Plain Writing

The Plain Writing Act of 2010 (Pub. L. 111–274) requires Federal agencies to write documents in a clear, concise, well-organized manner that also follows other best practices appropriate to the subject or field and the intended audience. The NRC has attempted to use plain language in promulgating this rule consistent with the Federal Plain Writing Act guidelines.

XVII. Regulatory Analysis

The NRC has prepared a regulatory analysis of this regulation. The analysis examines the costs and benefits of the alternatives considered by the NRC. Availability of the regulatory analysis is provided in Section XII, ''Availability of Documents,'' of this document.

XVIII. Regulatory Flexibility Act Certification

In accordance with the Regulatory Flexibility Act (5 U.S.C. 605(b)), the NRC certifies that this rule does not have a significant economic impact on a substantial number of small entities. The final rule affects only nuclear power plant licensees filing license renewal applications. The companies that own these plants do not fall within the scope of the definition of ''small entities'' set forth in the Regulatory Flexibility Act or the size standards established by the NRC (10 CFR 2.810).

XIX. Backfitting and Issue Finality

Issuance of this final rule does not constitute ''backfitting'' as defined in 10 CFR 50.109(a)(1) of the Backfit Rule and is not otherwise inconsistent with the applicable issue finality provisions in 10 CFR part 52. The final rule does not meet the definition of a backfit in 10 CFR 50.109(a)(1) because the document is not a ''modification of or addition to systems, structures, components, or design of a facility; or the design approval or manufacturing license for a facility; or the procedures or organization required to design, construct or operate a facility.'' For these reasons, issuance of this final rule does not constitute ''backfitting'' within the meaning of the definition of ''backfitting'' in 10 CFR 50.109(a)(1). Similarly, the issuance of the this final rule does not constitute an action inconsistent with any of the issue finality provisions in 10 CFR part 52.

XX. Congressional Review Act

In accordance with the Congressional Review Act of 1996, the NRC has determined that this action is not a major rule and has verified this determination with the Office of Information and Regulatory Affairs of the OMB.

List of Subjects in 10 CFR Part 51

Administrative practice and procedure, Environmental impact statement, Nuclear materials, Nuclear power plants and reactors, Reporting and recordkeeping requirements.

For the reasons set out in the preamble and under the authority of the Atomic Energy Act of 1954, as amended; the Energy Reorganization Act of 1974, as amended; and 5 U.S.C. 552 and 553; the NRC amends 10 CFR part 51 as follows:

Part 51—Environmental Protection Regulations for Domestic Licensing and Related Regulatory Functions

■ 1. The authority citation for part 51 is revised to read as follows:

Authority: Atomic Energy Act sec. 161, 1701 (42 U.S.C. 2201, 2297f); Energy Reorganization Act secs. 201, 202, 211 (42 U.S.C. 5841, 5842, 5851); Government Paperwork Elimination Act sec. 1704 (44 U.S.C. 3504 note). Subpart A also issued under National Environmental Policy Act secs. 102, 104, 105 (42 U.S.C. 4332, 4334, 4335); Pub. L. 95 604, Title II, 92 Stat. 3033 3041; Atomic Energy Act sec. 193 (42 U.S.C. 2243). Sections 51.20, 51.30, 51.60, 51.80. and 51.97 also issued under Nuclear Waste Policy Act secs. 135, 141, 148 (42 U.S.C. 10155, 10161, 10168). Section 51.22 also issued under Atomic Energy Act sec. 274 (42 U.S.C. 2021) and under Nuclear Waste Policy Act sec. 121 (42 U.S.C. 10141). Sections 51.43, 51.67, and 51.109 also issued under Nuclear Waste Policy Act sec. 114(f) (42 U.S.C. 10134(f)).

■ 2. Amend § 51.53 by:
■ a. Revising the second sentence of paragraph (c)(2);
■ b. Revising the first sentence of paragraph (c)(3)(ii)(A);
■ c. Revising the second sentence of paragraph (c)(3)(ii)(B);
■ d. Revising paragraph (c)(3)(ii)(C);
■ e. Revising paragraph (c)(3)(ii)(E);
■ f. Removing and reserving paragraph (c)(3)(ii)(F);
■ g. Revising paragraph (c)(3)(ii)(G);
■ h. Removing and reserving paragraphs (c)(3)(ii)(I) and (J);
■ i. Revising paragraph (c)(3)(ii)(K); and
■ j. Adding paragraphs (c)(3)(ii)(N), (O), and (P).

The revisions and additions read as follows:

§ 51.53 Postconstruction environmental reports.

* * * * *

(c) * * *

(2) * * * This report must describe in detail the affected environment around the plant, the modifications directly affecting the environment or any plant effluents, and any planned refurbishment activities. * * *

(3) * * *

(ii) * * *

(A) If the applicant's plant utilizes cooling towers or cooling ponds and withdraws makeup water from a river, an assessment of the impact of the proposed action on water availability and competing water demands, the flow of the river, and related impacts on stream (aquatic) and riparian (terrestrial) ecological communities must be provided. * * *

(B) * * * If the applicant cannot provide these documents, it shall assess the impact of the proposed action on fish and shellfish resources resulting from thermal changes and impingement and entrainment.

(C) If the applicant's plant pumps more than 100 gallons (total onsite) of groundwater per minute, an assessment of the impact of the proposed action on groundwater must be provided.

* * * * *

(E) All license renewal applicants shall assess the impact of refurbishment, continued operations, and other license-renewal-related construction activities on important plant and animal habitats. Additionally, the applicant shall assess the impact of the proposed action on threatened or endangered species in accordance with Federal laws protecting wildlife, including but not limited to, the Endangered Species Act, and essential fish habitat in accordance with the Magnuson-Stevens Fishery Conservation and Management Act.

* * * * *

(G) If the applicant's plant uses a cooling pond, lake, or canal or discharges into a river, an assessment of the impact of the proposed action on public health from thermophilic organisms in the affected water must be provided.

* * * * *

(K) All applicants shall identify any potentially affected historic or archaeological properties and assess whether any of these properties will be affected by future plant operations and any planned refurbishment activities in accordance with the National Historic Preservation Act.

* * * * *

(N) Applicants shall provide information on the general demographic composition of minority and low-income populations and communities (by race and ethnicity) residing in the immediate vicinity of the plant that could be affected by the renewal of the plant's operating license, including any planned refurbishment activities, and ongoing and future plant operations.

(O) Applicants shall provide information about other past, present, and reasonably foreseeable future actions occurring in the vicinity of the nuclear plant that may result in a cumulative effect.

(P) An applicant shall assess the impact of any documented inadvertent releases of radionuclides into groundwater. The applicant shall include in its assessment a description of any groundwater protection program used for the surveillance of piping and components containing radioactive liquids for which a pathway to groundwater may exist. The assessment must also include a description of any past inadvertent releases and the projected impact to the environment (e.g., aquifers, rivers, lakes, ponds, ocean) during the license renewal term.

■ 3. In § 51.71, revise paragraph (d) to read as follows:

§ 51.71 Draft environmental impact statement—contents.

* * * * *

(d) *Analysis.* Unless excepted in this paragraph or § 51.75, the draft environmental impact statement will include a preliminary analysis that considers and weighs the environmental effects, including any cumulative effects, of the proposed action; the environmental impacts of alternatives to the proposed action; and alternatives available for reducing or avoiding adverse environmental effects. Additionally, the draft environmental impact statement will include a consideration of the economic, technical, and other benefits and costs of the proposed action and alternatives. The draft environmental impact statement will indicate what other interests and considerations of Federal policy, including factors not related to environmental quality, if applicable, are relevant to the consideration of environmental effects of the proposed action identified under paragraph (a) of this section. The draft supplemental environmental impact statement prepared at the license renewal stage under § 51.95(c) need not discuss the economic or technical benefits and costs of either the proposed action or alternatives except if benefits and costs are either essential for a determination regarding the inclusion of an alternative in the range of alternatives considered or relevant to mitigation. In addition, the supplemental environmental impact statement prepared at the license renewal stage need not discuss other issues not related to the environmental effects of the proposed action and associated alternatives. The draft supplemental environmental impact statement for license renewal prepared under § 51.95(c) will rely on conclusions as amplified by the supporting information in the GEIS for issues designated as Category 1 in appendix B to subpart A of this part. The draft supplemental environmental impact statement must contain an analysis of those issues identified as Category 2 in appendix B to subpart A of this part that are open for the proposed action. The analysis for all draft environmental impact statements will, to the fullest extent practicable, quantify the various factors considered. To the extent that there are important qualitative considerations or factors that cannot be quantified, these considerations or factors will be discussed in qualitative terms. Consideration will be given to compliance with environmental quality standards and requirements that have been imposed by Federal, State, regional, and local agencies having responsibility for environmental protection, including applicable zoning and land-use regulations and water pollution limitations or requirements issued or imposed under the Federal Water Pollution Control Act. The environmental impact of the proposed action will be considered in the analysis with respect to matters covered by environmental quality standards and requirements irrespective of whether a certification or license from the appropriate authority has been obtained. While satisfaction of Commission standards and criteria pertaining to radiological effects will be necessary to meet the licensing requirements of the Atomic Energy Act, the analysis will, for the purposes of NEPA, consider the radiological effects of the proposed action and alternatives.

* * * * *

Compliance with the environmental quality standards and requirements of the Federal Water Pollution Control Act (imposed by EPA or designated permitting states) is not a substitute for, and does not negate the requirement for NRC to weigh all environmental effects of the proposed action, including the degradation, if any, of water quality, and to consider alternatives to the proposed action that are available for reducing adverse effects. Where an environmental assessment of aquatic impact from plant discharges is available from the permitting authority, the NRC will consider the assessment in its determination of the magnitude of environmental impacts for striking an overall cost-benefit balance at the construction permit and operating license and early site permit and combined license stages, and in its determination of whether the adverse environmental impacts of license renewal are so great that preserving the option of license renewal for energy planning decision-makers would be unreasonable at the license renewal stage. When no such assessment of aquatic impacts is available from the permitting authority, NRC will establish on its own, or in conjunction with the permitting authority and other agencies having relevant expertise, the magnitude of potential impacts for striking an overall cost-benefit balance for the facility at the construction permit and operating license and early site permit and combined license stages, and in its determination of whether the adverse environmental impacts of license renewal are so great that preserving the option of license renewal for energy planning decision-makers would be unreasonable at the license renewal stage.

* * * * *

■ 4. Amend § 51.95 by revising paragraph (c) introductory text and the second sentence of paragraph (c)(4) to read as follows:

§ 51.95 Postconstruction environmental impact statements.

* * * * *

(c) *Operating license renewal stage.* In connection with the renewal of an operating license or combined license for a nuclear power plant under 10 CFR parts 52 or 54 of this chapter, the Commission shall prepare an environmental impact statement, which is a supplement to the Commission's NUREG–1437, ''Generic Environmental Impact Statement for License Renewal of Nuclear Plants'' (June 2013), which is available in the NRC's Public Document Room, 11555 Rockville Pike, Rockville, Maryland 20852.

* * * * *

(4) * * * In order to make recommendations and reach a final decision on the proposed action, the NRC staff, adjudicatory officers, and Commission shall integrate the conclusions in the generic environmental impact statement for issues designated as Category 1 with information developed for those Category 2 issues applicable to the plant under § 51.53(c)(3)(ii) and any new and significant information. * * *

* * * * *

■ 5. In appendix B to subpart A of part 51, Table B–1 is revised to read as follows:

Appendix B to Subpart A—Environmental Effect of Renewing the Operating License of a Nuclear Power Plant

* * * * *

TABLE B–1—SUMMARY OF FINDINGS ON NEPA ISSUES FOR LICENSE RENEWAL OF NUCLEAR POWER PLANTS [1]

Issue	Category [2]	Finding [3]
Land Use		
Onsite land use	1	SMALL. Changes in onsite land use from continued operations and refurbishment associated with license renewal would be a small fraction of the nuclear power plant site and would involve only land that is controlled by the licensee.
Offsite land use	1	SMALL. Offsite land use would not be affected by continued operations and refurbishment associated with license renewal.
Offsite land use in transmission line right-of-ways (ROWs) [4].	1	SMALL. Use of transmission line ROWs from continued operations and refurbishment associated with license renewal would continue with no change in land use restrictions.
Visual Resources		
Aesthetic impacts	1	SMALL. No important changes to the visual appearance of plant structures or transmission lines are expected from continued operations and refurbishment associated with license renewal.
Air Quality		
Air quality impacts (all plants)	1	SMALL. Air quality impacts from continued operations and refurbishment associated with license renewal are expected to be small at all plants. Emissions resulting from refurbishment activities at locations in or near air quality nonattainment or maintenance areas would be short-lived and would cease after these refurbishment activities are completed. Operating experience has shown that the scale of refurbishment activities has not resulted in exceedance of the *de minimis* thresholds for criteria pollutants, and best management practices including fugitive dust controls and the imposition of permit conditions in State and local air emissions permits would ensure conformance with applicable State or Tribal Implementation Plans. Emissions from emergency diesel generators and fire pumps and routine operations of boilers used for space heating would not be a concern, even for plants located in or adjacent to nonattainment areas. Impacts from cooling tower particulate emissions even under the worst-case situations have been small.
Air quality effects of transmission lines [4]	1	SMALL. Production of ozone and oxides of nitrogen is insignificant and does not contribute measurably to ambient levels of these gases.
Noise		
Noise impacts	1	SMALL. Noise levels would remain below regulatory guidelines for offsite receptors during continued operations and refurbishment associated with license renewal.
Geologic Environment		
Geology and soils	1	SMALL. The effect of geologic and soil conditions on plant operations and the impact of continued operations and refurbishment activities on geology and soils would be small for all nuclear power plants and would not change appreciably during the license renewal term.
Surface Water Resources		
Surface water use and quality (non-cooling system impacts).	1	SMALL. Impacts are expected to be small if best management practices are employed to control soil erosion and spills. Surface water use associated with continued operations and refurbishment associated with license renewal would not increase significantly or would be reduced if refurbishment occurs during a plant outage.
Altered current patterns at intake and discharge structures.	1	SMALL. Altered current patterns would be limited to the area in the vicinity of the intake and discharge structures. These impacts have been small at operating nuclear power plants.
Altered salinity gradients	1	SMALL. Effects on salinity gradients would be limited to the area in the vicinity of the intake and discharge structures. These impacts have been small at operating nuclear power plants.
Altered thermal stratification of lakes	1	SMALL. Effects on thermal stratification would be limited to the area in the vicinity of the intake and discharge structures. These impacts have been small at operating nuclear power plants.
Scouring caused by discharged cooling water.	1	SMALL. Scouring effects would be limited to the area in the vicinity of the intake and discharge structures. These impacts have been small at operating nuclear power plants.
Discharge of metals in cooling system effluent.	1	SMALL. Discharges of metals have not been found to be a problem at operating nuclear power plants with cooling-tower-based heat dissipation systems and have been satisfactorily mitigated at other plants. Discharges are monitored and controlled as part of the National Pollutant Discharge Elimination System (NPDES) permit process.

TABLE B–1—SUMMARY OF FINDINGS ON NEPA ISSUES FOR LICENSE RENEWAL OF NUCLEAR POWER PLANTS [1]—Continued

Issue	Category [2]	Finding [3]
Discharge of biocides, sanitary wastes, and minor chemical spills.	1	SMALL. The effects of these discharges are regulated by Federal and State environmental agencies. Discharges are monitored and controlled as part of the NPDES permit process. These impacts have been small at operating nuclear power plants.
Surface water use conflicts (plants with once-through cooling systems).	1	SMALL. These conflicts have not been found to be a problem at operating nuclear power plants with once-through heat dissipation systems.
Surface water use conflicts (plants with cooling ponds or cooling towers using makeup water from a river).	2	SMALL or MODERATE. Impacts could be of small or moderate significance, depending on makeup water requirements, water availability, and competing water demands.
Effects of dredging on surface water quality.	1	SMALL. Dredging to remove accumulated sediments in the vicinity of intake and discharge structures and to maintain barge shipping has not been found to be a problem for surface water quality. Dredging is performed under permit from the U.S. Army Corps of Engineers, and possibly, from other State or local agencies.
Temperature effects on sediment transport capacity.	1	SMALL. These effects have not been found to be a problem at operating nuclear power plants and are not expected to be a problem.
Groundwater Resources		
Groundwater contamination and use (non-cooling system impacts).	1	SMALL. Extensive dewatering is not anticipated from continued operations and refurbishment associated with license renewal. Industrial practices involving the use of solvents, hydrocarbons, heavy metals, or other chemicals, and/or the use of wastewater ponds or lagoons have the potential to contaminate site groundwater, soil, and subsoil. Contamination is subject to State or Environmental Protection Agency regulated cleanup and monitoring programs. The application of best management practices for handling any materials produced or used during these activities would reduce impacts.
Groundwater use conflicts (plants that withdraw less than 100 gallons per minute [gpm]).	1	SMALL. Plants that withdraw less than 100 gpm are not expected to cause any groundwater use conflicts.
Groundwater use conflicts (plants that withdraw more than 100 gallons per minute [gpm]).	2	SMALL, MODERATE, or LARGE. Plants that withdraw more than 100 gpm could cause groundwater use conflicts with nearby groundwater users.
Groundwater use conflicts (plants with closed-cycle cooling systems that withdraw makeup water from a river).	2	SMALL, MODERATE, or LARGE. Water use conflicts could result from water withdrawals from rivers during low-flow conditions, which may affect aquifer recharge. The significance of impacts would depend on makeup water requirements, water availability, and competing water demands.
Groundwater quality degradation resulting from water withdrawals.	1	SMALL. Groundwater withdrawals at operating nuclear power plants would not contribute significantly to groundwater quality degradation.
Groundwater quality degradation (plants with cooling ponds in salt marshes).	1	SMALL. Sites with closed-cycle cooling ponds could degrade groundwater quality. However, groundwater in salt marshes is naturally brackish and thus, not potable. Consequently, the human use of such groundwater is limited to industrial purposes.
Groundwater quality degradation (plants with cooling ponds at inland sites).	2	SMALL, MODERATE, or LARGE. Inland sites with closed-cycle cooling ponds could degrade groundwater quality. The significance of the impact would depend on cooling pond water quality, site hydrogeologic conditions (including the interaction of surface water and groundwater), and the location, depth, and pump rate of water wells.
Radionuclides released to groundwater	2	SMALL or MODERATE. Leaks of radioactive liquids from plant components and pipes have occurred at numerous plants. Groundwater protection programs have been established at all operating nuclear power plants to minimize the potential impact from any inadvertent releases. The magnitude of impacts would depend on site-specific characteristics.
Terrestrial Resources		
Effects on terrestrial resources (non-cooling system impacts).	2	SMALL, MODERATE, or LARGE. Impacts resulting from continued operations and refurbishment associated with license renewal may affect terrestrial communities. Application of best management practices would reduce the potential for impacts. The magnitude of impacts would depend on the nature of the activity, the status of the resources that could be affected, and the effectiveness of mitigation.
Exposure of terrestrial organisms to radionuclides.	1	SMALL. Doses to terrestrial organisms from continued operations and refurbishment associated with license renewal are expected to be well below exposure guidelines developed to protect these organisms.
Cooling system impacts on terrestrial resources (plants with once-through cooling systems or cooling ponds).	1	SMALL. No adverse effects to terrestrial plants or animals have been reported as a result of increased water temperatures, fogging, humidity, or reduced habitat quality. Due to the low concentrations of contaminants in cooling system effluents, uptake and accumulation of contaminants in the tissues of wildlife exposed to the contaminated water or aquatic food sources are not expected to be significant issues.

TABLE B–1—SUMMARY OF FINDINGS ON NEPA ISSUES FOR LICENSE RENEWAL OF NUCLEAR POWER PLANTS [1]—Continued

Issue	Category [2]	Finding [3]
Cooling tower impacts on vegetation (plants with cooling towers).	1	SMALL. Impacts from salt drift, icing, fogging, or increased humidity associated with cooling tower operation have the potential to affect adjacent vegetation, but these impacts have been small at operating nuclear power plants and are not expected to change over the license renewal term.
Bird collisions with plant structures and transmission lines [4].	1	SMALL. Bird collisions with cooling towers and other plant structures and transmission lines occur at rates that are unlikely to affect local or migratory populations and the rates are not expected to change.
Water use conflicts with terrestrial resources (plants with cooling ponds or cooling towers using makeup water from a river).	2	SMALL or MODERATE. Impacts on terrestrial resources in riparian communities affected by water use conflicts could be of moderate significance.
Transmission line right-of-way (ROW) management impacts on terrestrial resources [4].	1	SMALL. Continued ROW management during the license renewal term is expected to keep terrestrial communities in their current condition. Application of best management practices would reduce the potential for impacts.
Electromagnetic fields on flora and fauna (plants, agricultural crops, honeybees, wildlife, livestock) [4].	1	SMALL. No significant impacts of electromagnetic fields on terrestrial flora and fauna have been identified. Such effects are not expected to be a problem during the license renewal term.
Aquatic Resources		
Impingement and entrainment of aquatic organisms (plants with once-through cooling systems or cooling ponds).	2	SMALL, MODERATE, or LARGE. The impacts of impingement and entrainment are small at many plants but may be moderate or even large at a few plants with once-through and cooling-pond cooling systems, depending on cooling system withdrawal rates and volumes and the aquatic resources at the site.
Impingement and entrainment of aquatic organisms (plants with cooling towers).	1	SMALL. Impingement and entrainment rates are lower at plants that use closed-cycle cooling with cooling towers because the rates and volumes of water withdrawal needed for makeup are minimized.
Entrainment of phytoplankton and zooplankton (all plants).	1	SMALL. Entrainment of phytoplankton and zooplankton has not been found to be a problem at operating nuclear power plants and is not expected to be a problem during the license renewal term.
Thermal impacts on aquatic organisms (plants with once-through cooling systems or cooling ponds).	2	SMALL, MODERATE, or LARGE. Most of the effects associated with thermal discharges are localized and are not expected to affect overall stability of populations or resources. The magnitude of impacts, however, would depend on site-specific thermal plume characteristics and the nature of aquatic resources in the area.
Thermal impacts on aquatic organisms (plants with cooling towers).	1	SMALL. Thermal effects associated with plants that use cooling towers are expected to be small because of the reduced amount of heated discharge.
Infrequently reported thermal impacts (all plants).	1	SMALL. Continued operations during the license renewal term are expected to have small thermal impacts with respect to the following: Cold shock has been satisfactorily mitigated at operating nuclear plants with once-through cooling systems, has not endangered fish populations or been found to be a problem at operating nuclear power plants with cooling towers or cooling ponds, and is not expected to be a problem. Thermal plumes have not been found to be a problem at operating nuclear power plants and are not expected to be a problem. Thermal discharge may have localized effects but is not expected to affect the larger geographical distribution of aquatic organisms. Premature emergence has been found to be a localized effect at some operating nuclear power plants but has not been a problem and is not expected to be a problem. Stimulation of nuisance organisms has been satisfactorily mitigated at the single nuclear power plant with a once-through cooling system where previously it was a problem. It has not been found to be a problem at operating nuclear power plants with cooling towers or cooling ponds and is not expected to be a problem.
Effects of cooling water discharge on dissolved oxygen, gas supersaturation, and eutrophication.	1	SMALL. Gas supersaturation was a concern at a small number of operating nuclear power plants with once-through cooling systems but has been mitigated. Low dissolved oxygen was a concern at one nuclear power plant with a once-through cooling system but has been mitigated. Eutrophication (nutrient loading) and resulting effects on chemical and biological oxygen demands have not been found to be a problem at operating nuclear power plants.
Effects of non-radiological contaminants on aquatic organisms.	1	SMALL. Best management practices and discharge limitations of NPDES permits are expected to minimize the potential for impacts to aquatic resources during continued operations and refurbishment associated with license renewal. Accumulation of metal contaminants has been a concern at a few nuclear power plants but has been satisfactorily mitigated by replacing copper alloy condenser tubes with those of another metal.
Exposure of aquatic organisms to radionuclides.	1	SMALL. Doses to aquatic organisms are expected to be well below exposure guidelines developed to protect these aquatic organisms.

TABLE B–1—SUMMARY OF FINDINGS ON NEPA ISSUES FOR LICENSE RENEWAL OF NUCLEAR POWER PLANTS [1]—Continued

Issue	Category [2]	Finding [3]
Effects of dredging on aquatic organisms	1	SMALL. Dredging at nuclear power plants is expected to occur infrequently, would be of relatively short duration, and would affect relatively small areas. Dredging is performed under permit from the U.S. Army Corps of Engineers, and possibly, from other State or local agencies.
Water use conflicts with aquatic resources (plants with cooling ponds or cooling towers using makeup water from a river).	2	SMALL or MODERATE. Impacts on aquatic resources in stream communities affected by water use conflicts could be of moderate significance in some situations.
Effects on aquatic resources (non-cooling system impacts).	1	SMALL. Licensee application of appropriate mitigation measures is expected to result in no more than small changes to aquatic communities from their current condition.
Impacts of transmission line right-of-way (ROW) management on aquatic resources [4].	1	SMALL. Licensee application of best management practices to ROW maintenance is expected to result in no more than small impacts to aquatic resources.
Losses from predation, parasitism, and disease among organisms exposed to sublethal stresses.	1	SMALL. These types of losses have not been found to be a problem at operating nuclear power plants and are not expected to be a problem during the license renewal term.
Special Status Species and Habitats		
Threatened, endangered, and protected species and essential fish habitat.	2	The magnitude of impacts on threatened, endangered, and protected species, critical habitat, and essential fish habitat would depend on the occurrence of listed species and habitats and the effects of power plant systems on them. Consultation with appropriate agencies would be needed to determine whether special status species or habitats are present and whether they would be adversely affected by continued operations and refurbishment associated with license renewal.
Historic and Cultural Resources		
Historic and cultural resources [4]	2	Continued operations and refurbishment associated with license renewal are expected to have no more than small impacts on historic and cultural resources located onsite and in the transmission line ROW because most impacts could be mitigated by avoiding those resources. The National Historic Preservation Act (NHPA) requires the Federal agency to consult with the State Historic Preservation Officer (SHPO) and appropriate Native American Tribes to determine the potential effects on historic properties and mitigation, if necessary.
Socioeconomics		
Employment and income, recreation and tourism.	1	SMALL. Although most nuclear plants have large numbers of employees with higher than average wages and salaries, employment, income, recreation, and tourism impacts from continued operations and refurbishment associated with license renewal are expected to be small.
Tax revenues	1	SMALL. Nuclear plants provide tax revenue to local jurisdictions in the form of property tax payments, payments in lieu of tax (PILOT), or tax payments on energy production. The amount of tax revenue paid during the license renewal term as a result of continued operations and refurbishment associated with license renewal is not expected to change.
Community services and education	1	SMALL. Changes resulting from continued operations and refurbishment associated with license renewal to local community and educational services would be small. With little or no change in employment at the licensee's plant, value of the power plant, payments on energy production, and PILOT payments expected during the license renewal term, community and educational services would not be affected by continued power plant operations.
Population and housing	1	SMALL. Changes resulting from continued operations and refurbishment associated with license renewal to regional population and housing availability and value would be small. With little or no change in employment at the licensee's plant expected during the license renewal term, population and housing availability and values would not be affected by continued power plant operations.
Transportation	1	SMALL. Changes resulting from continued operations and refurbishment associated with license renewal to traffic volumes would be small.
Human Health		
Radiation exposures to the public	1	SMALL. Radiation doses to the public from continued operations and refurbishment associated with license renewal are expected to continue at current levels, and would be well below regulatory limits.
Radiation exposures to plant workers	1	SMALL. Occupational doses from continued operations and refurbishment associated with license renewal are expected to be within the range of doses experienced during the current license term, and would continue to be well below regulatory limits.

TABLE B–1—SUMMARY OF FINDINGS ON NEPA ISSUES FOR LICENSE RENEWAL OF NUCLEAR POWER PLANTS [1]—Continued

Issue	Category [2]	Finding [3]
Human health impact from chemicals	1	SMALL. Chemical hazards to plant workers resulting from continued operations and refurbishment associated with license renewal are expected to be minimized by the licensee implementing good industrial hygiene practices as required by permits and Federal and State regulations. Chemical releases to the environment and the potential for impacts to the public are expected to be minimized by adherence to discharge limitations of NPDES and other permits.
Microbiological hazards to the public (plants with cooling ponds or canals or cooling towers that discharge to a river).	2	SMALL, MODERATE, or LARGE. These organisms are not expected to be a problem at most operating plants except possibly at plants using cooling ponds, lakes, or canals, or that discharge into rivers. Impacts would depend on site-specific characteristics.
Microbiological hazards to plant workers	1	SMALL. Occupational health impacts are expected to be controlled by continued application of accepted industrial hygiene practices to minimize worker exposures as required by permits and Federal and State regulations.
Chronic effects of electromagnetic fields (EMFs) [4,6].	N/A [5]	Uncertain impact. Studies of 60-Hz EMFs have not uncovered consistent evidence linking harmful effects with field exposures. EMFs are unlike other agents that have a toxic effect (e.g., toxic chemicals and ionizing radiation) in that dramatic acute effects cannot be forced and longer-term effects, if real, are subtle. Because the state of the science is currently inadequate, no generic conclusion on human health impacts is possible.
Physical occupational hazards	1	SMALL. Occupational safety and health hazards are generic to all types of electrical generating stations, including nuclear power plants, and are of small significance if the workers adhere to safety standards and use protective equipment as required by Federal and State regulations.
Electric shock hazards [4]	2	SMALL, MODERATE, or LARGE. Electrical shock potential is of small significance for transmission lines that are operated in adherence with the National Electrical Safety Code (NESC). Without a review of conformance with NESC criteria of each nuclear power plant's in-scope transmission lines, it is not possible to determine the significance of the electrical shock potential.
		Postulated Accidents
Design-basis accidents	1	SMALL. The NRC staff has concluded that the environmental impacts of design-basis accidents are of small significance for all plants.
Severe accidents	2	SMALL. The probability-weighted consequences of atmospheric releases, fallout onto open bodies of water, releases to groundwater, and societal and economic impacts from severe accidents are small for all plants. However, alternatives to mitigate severe accidents must be considered for all plants that have not considered such alternatives.
		Environmental Justice
Minority and low-income populations	2	Impacts to minority and low-income populations and subsistence consumption resulting from continued operations and refurbishment associated with license renewal will be addressed in plant-specific reviews. See NRC Policy Statement on the Treatment of Environmental Justice Matters in NRC Regulatory and Licensing Actions (69 FR 52040; August 24, 2004).
		Waste Management
Low-level waste storage and disposal	1	SMALL. The comprehensive regulatory controls that are in place and the low public doses being achieved at reactors ensure that the radiological impacts to the environment would remain small during the license renewal term.
Onsite storage of spent nuclear fuel	1	SMALL. The expected increase in the volume of spent fuel from an additional 20 years of operation can be safely accommodated onsite during the license renewal term with small environmental effects through dry or pool storage at all plants.
Offsite radiological impacts of spent nuclear fuel and high-level waste disposal.	N/A [5]	Uncertain impact. The generic conclusion on offsite radiological impacts of spent nuclear fuel and high-level waste is not being finalized pending the completion of a generic environmental impact statement on waste confidence.[7]
Mixed-waste storage and disposal	1	SMALL. The comprehensive regulatory controls and the facilities and procedures that are in place ensure proper handling and storage, as well as negligible doses and exposure to toxic materials for the public and the environment at all plants. License renewal would not increase the small, continuing risk to human health and the environment posed by mixed waste at all plants. The radiological and nonradiological environmental impacts of long-term disposal of mixed waste from any individual plant at licensed sites are small.
Nonradioactive waste storage and disposal	1	SMALL. No changes to systems that generate nonradioactive waste are anticipated during the license renewal term. Facilities and procedures are in place to ensure continued proper handling, storage, and disposal, as well as negligible exposure to toxic materials for the public and the environment at all plants.

TABLE B–1—SUMMARY OF FINDINGS ON NEPA ISSUES FOR LICENSE RENEWAL OF NUCLEAR POWER PLANTS [1]—Continued

Issue	Category [2]	Finding [3]
Cumulative Impacts		
Cumulative impacts	2	Cumulative impacts of continued operations and refurbishment associated with license renewal must be considered on a plant-specific basis. Impacts would depend on regional resource characteristics, the resource-specific impacts of license renewal, and the cumulative significance of other factors affecting the resource.
Uranium Fuel Cycle		
Offsite radiological impacts—individual impacts from other than the disposal of spent fuel and high-level waste.	1	SMALL. The impacts to the public from radiological exposures have been considered by the Commission in Table S–3 of this part. Based on information in the GEIS, impacts to individuals from radioactive gaseous and liquid releases, including radon-222 and technetium-99, would remain at or below the NRC's regulatory limits.
Offsite radiological impacts—collective impacts from other than the disposal of spent fuel and high-level waste.	1	There are no regulatory limits applicable to collective doses to the general public from fuel-cycle facilities. The practice of estimating health effects on the basis of collective doses may not be meaningful. All fuel-cycle facilities are designed and operated to meet the applicable regulatory limits and standards. The Commission concludes that the collective impacts are acceptable. The Commission concludes that the impacts would not be sufficiently large to require the NEPA conclusion, for any plant, that the option of extended operation under 10 CFR part 54 should be eliminated. Accordingly, while the Commission has not assigned a single level of significance for the collective impacts of the uranium fuel cycle, this issue is considered Category 1.
Nonradiological impacts of the uranium fuel cycle.	1	SMALL. The nonradiological impacts of the uranium fuel cycle resulting from the renewal of an operating license for any plant would be small.
Transportation	1	SMALL. The impacts of transporting materials to and from uranium-fuel-cycle facilities on workers, the public, and the environment are expected to be small.
Termination of Nuclear Power Plant Operations and Decommissioning		
Termination of plant operations and decommissioning.	1	SMALL. License renewal is expected to have a negligible effect on the impacts of terminating operations and decommissioning on all resources.

[1] Data supporting this table are contained in NUREG–1437, Revision 1, ''Generic Environmental Impact Statement for License Renewal of Nuclear Plants'' (June 2013).

[2] The numerical entries in this column are based on the following category definitions:

Category 1: For the issue, the analysis reported in the Generic Environmental Impact Statement has shown:

(1) The environmental impacts associated with the issue have been determined to apply either to all plants or, for some issues, to plants having a specific type of cooling system or other specified plant or site characteristic;

(2) A single significance level (i.e., small, moderate, or large) has been assigned to the impacts (except for Offsite radiological impacts—collective impacts from other than the disposal of spent fuel and high-level waste); and

(3) Mitigation of adverse impacts associated with the issue has been considered in the analysis, and it has been determined that additional plant-specific mitigation measures are not likely to be sufficiently beneficial to warrant implementation.

The generic analysis of the issue may be adopted in each plant-specific review.

Category 2: For the issue, the analysis reported in the Generic Environmental Impact Statement has shown that one or more of the criteria of Category 1 cannot be met, and therefore additional plant-specific review is required.

[3] The impact findings in this column are based on the definitions of three significance levels. Unless the significance level is identified as beneficial, the impact is adverse, or in the case of ''small,'' may be negligible. The definitions of significance follow:

SMALL—For the issue, environmental effects are not detectable or are so minor that they will neither destabilize nor noticeably alter any important attribute of the resource. For the purposes of assessing radiological impacts, the Commission has concluded that those impacts that do not exceed permissible levels in the Commission's regulations are considered small as the term is used in this table.

MODERATE—For the issue, environmental effects are sufficient to alter noticeably, but not to destabilize, important attributes of the resource.

LARGE—For the issue, environmental effects are clearly noticeable and are sufficient to destabilize important attributes of the resource.

For issues where probability is a key consideration (i.e., accident consequences), probability was a factor in determining significance.

[4] This issue applies only to the in-scope portion of electric power transmission lines, which are defined as transmission lines that connect the nuclear power plant to the substation where electricity is fed into the regional power distribution system and transmission lines that supply power to the nuclear plant from the grid.

[5] NA (not applicable). The categorization and impact finding definitions do not apply to these issues.

[6] If, in the future, the Commission finds that, contrary to current indications, a consensus has been reached by appropriate Federal health agencies that there are adverse health effects from electromagnetic fields, the Commission will require applicants to submit plant-specific reviews of these health effects as part of their license renewal applications. Until such time, applicants for license renewal are not required to submit information on this issue.

[7] As a result of the decision of United States Court of Appeals in *New York* v. *NRC,* 681 F.3d 471 (DC Cir. 2012), the NRC cannot rely upon its Waste Confidence Decision and Rule until it has taken those actions that will address the deficiencies identified by the D.C. Circuit. Although the Waste Confidence Decision and Rule did not assess the impacts associated with disposal of spent nuclear fuel and high-level waste in a repository, it did reflect the Commission's confidence, at the time, in the technical feasibility of a repository and when that repository could have been expected to become available. Without the analysis in the Waste Confidence Decision and Rule regarding the technical feasibility and availability of a repository, the NRC cannot assess how long the spent fuel will need to be stored onsite.

TECHNICAL MEMORANDUM

From: Peter F. Andersen and James L. Ross, Tetra Tech

To: Rory Rahming, Florida Power & Light Company

Date: May 9, 2014

Subject: Evaluation of Required Floridan Water for Salinity Reduction in the Cooling Canal System

---

Introduction

This technical memorandum describes the water and salt balance modeling of the proposed salinity reduction in the Florida Power & Light (FPL) Cooling Canal System (CCS), located at the Turkey Point Nuclear Power Plant. The modeling was conducted to provide an assessment of the volume of Floridan water that would be required to add to the CCS in order to reduce the hypersalinity of CCS water to salt concentrations commensurate with seawater.

Two spreadsheet-based water and salt balance models were employed for this analysis: 1) a steady state balance model based on long-term average flows to/from the CCS, and 2) a transient balance model calibrated to 22 months of hydrologic and water quality data collected as a part of FPL comprehensive pre-uprate monitoring (Ecology and Environment, 2012). These models were collectively used to provide estimates of the amount of Floridan water required to achieve the desired CCS salinity reductions and the corresponding changes to canal stage within the CCS.

Background

The CCS is a constructed surface water body that receives heated water from Turkey Point Nuclear Units 3 and 4. As the heated water travels southward along the discharge canals and northward back to the plant along return canals, it is cooled by evaporation and mixing with inflowing water from the Biscayne Aquifer. Due to the evaporative process, which is facilitated by the elevated temperature of the water, a portion of the water from the CCS is lost to the atmosphere, leaving dissolved solids behind in the CCS and producing hypersaline conditions in the CCS. Hypersaline water exhibits salinities greater than that of seawater, which has a salinity of approximately 35 g/L. Salinity in the CCS has ranged between 42 and 69 g/L over the past 10 years.

In order to mitigate the contribution of hypersaline water to the underlying Biscayne Aquifer, FPL has evaluated remedial alternatives to reduce the salinity of water in the CCS to seawater levels. In the course of that evaluation, an inspection of 22 months of pre-uprate monitoring data revealed a correlation between daily rainfall on the CCS and CCS salinity, where rainfall events were generally followed by short term reductions in CCS salinity. The visual comparison between daily precipitation and daily averaged CCS salinities in Figure 1 illustrates this relationship. Two phenomena are evident in this figure: 1) CCS salinities generally reduce during rainy months (June through September); 2) significant rainfall events produce notable reductions in CCS salinity. The latter phenomenon is effectively illustrated by a large (> 7 inches) rainfall event in late-September 2010 that induced an approximate 10 g/L drop in the average CCS salinity.

Because precipitation events are simply freshwater inflows to the CCS, they effectively dilute the water and reduce salinity. Based on the effectiveness of these freshwater inflows in reducing salinity, a remedial alternative was proposed wherein low salinity water would be added to the CCS on a sustained basis. The Floridan Aquifer was identified as the source of added water due to the low salinity and long term availability of groundwater.

Balance Modeling

In order to evaluate the effectiveness of reducing CCS salinity with added Floridan water, as well as the associated volume of water that would be needed, two balance models were employed. First, a simple, uncalibrated water and salt balance model of the CCS was developed. This balance model is based on a conceptual understanding of the inflows to and outflows from the CCS; it was employed as a screening model to provide a broad assessment of the efficacy of the proposed remedial alternative.

Subsequent to analysis with the steady state balance model, a transient water and salt balance model of the CCS system was configured to provide estimates of impacts to the CCS caused by the remedial alternative, including canal stage changes, changes in salinity, and time required to reduce salinity to the desired concentration. This transient model, which has been accepted by South Florida Water Management District, is calibrated to 22 months of CCS hydrologic and water quality data, such that it effectively replicates historical responses of the CCS to changes in inflows and outflow; as such, this transient model is capable of evaluating a wide range of climatic and operational conditions.

Steady State Balance Model

In order to determine the volume of Floridan water required to reduce CCS salinity to approximately 35 g/L, a steady state water and salt balance model of the CCS was developed. This balance model was based on a conceptual model of CCS equilibrium where inflows to the CCS are equal to and offset by outflows from the CCS, such that the volume of water in the CCS is invariant. The components of inflow are:

- Inflow from Nuclear Units 3 and 4,
- Precipitation,
- Seepage of groundwater, and
- Blowdown from other nuclear units.

Outflows from the CCS are comprised of:

- Outflow to nuclear Units 3 and 4 (assumed equal to the inflow from these units),
- Evaporation, and
- Seepage to groundwater.

Based on measurements and estimates of many of the flow components and associated salinities, the steady state water and salt balance effectively defines equilibrium flows into and out of the CCS, as well as the resulting salinity of the water within the CCS (Table 1a).

An additional inflow component was considered in the balance model with an assumed concentration of approximate 2 g/L, based on recent measurements of Floridan water. Using the balance model, the volume of the additional inflow was adjusted until the equilibrium concentration of CCS water reached approximately 35 g/L; the minimum additional inflow was derived to be 14 million gallons per day (mgd), which reduced the CCS salinity to 34.4 g/L (Table 1b).

Transient Balance Model

As a necessary component of FPL's pre-uprate monitoring, a transient water and salt balance model was constructed for the CCS and calibrated to 22-months of hydrologic and salinity data from September 2010 through May 2012 (Ecology and Environment, 2012). Though the model considers the same CCS inflows and outflows as the steady state model, it calculates these inflows and outflows on a daily basis using 15-minute water level, salinity, and meteorological data measured throughout the Biscayne Aquifer, Biscayne Bay, the CCS, and nearby canals. The model uses these daily inflows and outflows to effectively simulate daily changes in CCS water and salt storage. The quality of the model is illustrated by the accurate simulation of daily changes in average CCS water levels and salinity between over the 22-month period (Figure 1). It should be noted that the model correctly simulates the reduction in salinity resulting from the addition of precipitation. The ability to match the response of salinity to addition of a known quantity and quality of water provides confidence that the model is capable of predicting a similar cause and response situation with the addition of Floridan water.

Transiently modeling the impacts of the proposed remedial alternative was a two-step process, wherein two predictive versions of the transient balance model were configured. The first model configuration, called the *unconstrained* model, predicted water levels in the CCS considering the addition of 14 mgd of Floridan water. This model was used to determine the increase in canal stage that would likely result from the added inflow: an average of 0.25 ft due to the Floridan-based inflow. Salinity changes were not assessed with this model due to the compounding error associated with predicting both hydrologic and water quality data.

The second model configuration, referred to as the *constrained* model, added the calculated 0.25 ft stage increase to the 22 months of observed CCS stages, and predicted the change in CCS salinity likely to result from the contribution of low salinity (2 g/L) Floridan water to the CCS. This model predicted a 41.3% reduction in CCS salinity from 60 g/L to approximately 35 g/L within 1 year of the initiation of the remedial action (Figure 2). Figure 2 also suggests that the quantity of added Floridan water could be optimally managed to obtain CCS salinities that are close to seawater. Note that less than 14 mgd may be required during the wet season while more may be required during the dry season when less precipitation is being added naturally.

The estimated flow of water for salinity reduction (14 mgd) appears low relative to the volume of the CCS (approximately 4.2×10^9 gallons); the key to remedial success, however, is the significantly low salinity in the Floridan relative to the salinity observed in the CCS. This difference between Floridan and CCS salinities may become less pronounced over time as the quality of the Floridan aquifer will likely vary and may degrade with continued stress on the aquifer. As such, two additional evaluations were performed with the transient model in order to determine the requisite increases in Floridan-based inflows to the CCS should the associated salinity increase by 50% (3 g/L) and 100% (4 g/L). Based on these analyses, it was determined that:

- If Floridan water were to degrade to 3 g/L, 14.5 mgd would be required to reduce the CCS salinity to 35.2 g/L; and
- If Floridan water were to degrade to 4 g/L, 15 mgd would be required to reduce the CCS salinity to 35.3 g/L.

As in the base remediation scenario, the relative difference between the CCS and the Floridan aquifer groundwater is critical to successful salinity reduction.

Summary

Changes in salinity in the CCS appear to be strongly correlated to precipitation: large precipitation events are followed by appreciable reductions in the salinity of the CCS. This observation led to exploration of the effect of adding on a continuous basis a source of water with a much lower salinity than the CCS. A simple steady state water balance and a more complex transient water balance were used in this evaluation. In order to abate the hypersaline conditions within the CCS, water and salt balance modeling determined that an average 14 mgd of Floridan water with a salinity of 2 g/L would need to be added to the CCS. Both models estimated that the addition of the Floridan water would reduce CCS concentrations to approximately 35 g/L. The transient model indicates that reduction of CCS salinity to that of seawater will take less than one year using an average addition of 14 mgd. Sensitivity analysis on the salinity of the added water indicates that the required quantities to reduce CCS concentration to approximately 35 g/L are 14.5 and 15 mgd for assumed Floridan aquifer salinities of 3 and 4 g/L, respectively. The transient model also indicates that the added water will raise the average stage in the CCS by 0.25 ft. This rise is accounted for in the water balance that is used for computations of CCS salinity and water budget components.

BEFORE THE STATE OF FLORIDA
DEPARTMENT OF ENVIRONMENTAL PROTECTION

STATE OF FLORIDA DEPARTMENT OF ENVIRONMENTAL PROTECTION	)	IN THE OFFICE OF THE SOUTHEAST DISTRICT
v.	)	
	)	OGC FILE NO. 16-0241
FLORIDA POWER & LIGHT COMPANY,	)	

CONSENT ORDER

This Consent Order ("Order") is entered into between the State of Florida Department of Environmental Protection ("Department") and Florida Power & Light Company ("Respondent" or "FPL") to reach settlement of certain matters at issue between the Department and Respondent.

The Department finds:

1. The Department is the administrative agency of the State of Florida having the power and duty to protect Florida's air and water resources and to administer and enforce the provisions of Chapter 403, Florida Statutes ("F.S."), and the rules promulgated and authorized in Title 62, Florida Administrative Code ("F.A.C."). The Department has jurisdiction over the matters addressed in this Order.

2. FPL is a "person" as defined under Section 403.031(5), F.S.

3. FPL owns and operates a cooling canal system ("CCS"), an approximately 5,900-acre network of unlined canals at Turkey Point Power Plant. FPL began construction of the CCS in 1972. Turkey Point originally obtained cooling water for the facility by drawing surface water from an intake channel connected to Biscayne Bay, and discharging that water, after it had been heated, into Biscayne Bay and Card Sound through a series of discharge canals. In 1971, FPL entered into a Final Judgment with the U.S. Department of Justice that required the permitting, construction, operation, and maintenance of a closed-loop cooling canal configuration with limitations on makeup and blowdown water.

4. FPL is the permittee and operates the CCS under National Pollutant Discharge Elimination System/Industrial Wastewater Permit Number FL0001562 (the "Permit"). This Permit is issued pursuant to the federal NPDES program and Florida industrial wastewater permitting program. The Permit authorizes wastewater discharges from the generating units through two internal outfalls into the CCS. The Permit does not authorize direct discharges to surface waters of the state. The Permit authorizes discharges from the CCS into Class G-III groundwater which is part of the surficial aquifer system. Condition IV.1 of the Permit provides that discharges to groundwater shall not cause a violation of the minimum criteria for ground water specified in Rules 62-520.400, F.A.C. and 62-520.430, F.A.C. Rule 62-520.400, F.A.C., provides that discharges to ground water shall not impair the reasonable and beneficial use of adjacent waters, either ground or surface.

5. Turkey Point Power Plant Units 3 through 5 are licensed under the Florida Power Plant Siting Act, Chapter 403, Part II, F.S. Those units operate in accordance with the conditions of certification in their license, PA 03-45. Condition of Certification X requires FPL to execute a 5th Supplemental Agreement with the South Florida Water Management District ("SFWMD") and to revise FPL's monitoring obligations, which resulted in the Turkey Point Plant Groundwater, Surface Water and Ecological Monitoring Plan, as amended, ("2009 Monitoring Plan") incorporated as Exhibit A to the Fifth Supplemental Agreement between the South Florida Water Management District and FPL entered on October 16, 2009.

6. Historical data show that, when the CCS was constructed in the 1970's, saline water had already intruded inland along the coast due to many factors such as freshwater withdrawals, drought, drainage and flood control structures, and other human activities. To date, the relative contributions of the different factors toward westward movement of the saltwater interface have not been fully identified.

7. FPL provided information on action they have already taken on several fronts to address the broader regional risks and the many causes of saltwater intrusion. In 2010, FPL installed a gated culvert approximately 3.8 miles inland of Biscayne Bay in the Card Sound Road Canal to eliminate an unrestricted inland conveyance of saltwater from the bay. Also, in 2014, FPL installed a broad, fix crested weir in the S-20 Discharge Canal to prevent the historic migration of bay saltwater up to the S-20 Canal.

8. The phrase "hypersaline water/plume" as used in this Order means water that exceeds 19,000 mg/L chlorides. The term "saltwater interface" ("SWI") as used in this Order means the intersection of class G-II and G-III groundwaters.

9. The CCS includes an approximately 18 foot deep interceptor ditch along the western edge of the CCS. As approved and constructed, the interceptor ditch system has been effective at restricting the westward movement of the saline water from the CCS in the upper portion of the aquifer but has not restricted the westward movement of saline waters into the deeper portions of the aquifer. Saline water from the CCS has moved, at depth, westward of the L-31E Canal in excess of those amounts that would have occurred without the existence of the CCS.

10. The Department issued an Administrative Order (OGC No. 14-0741) to FPL related to the CCS at Turkey Point on December 23, 2014 and made final by an Order of the Department issued on April 21, 2016. The Administrative Order requires FPL to reduce the salinity in the CCS. This Consent Order supersedes all of the requirements of that Administrative Order.

11. FPL conducted or implemented dredging, vegetation control, water stage management, and chemical additives to the CCS to maintain the thermal efficiency of the system and to control salinity and temperature.

12. Elevated salinity levels in the CCS cause, or at a minimum contribute to, the hypersaline discharges into the groundwater. Reducing the CCS surface water salinity from an elevated base salinity condition will require certain measures such as a greater

addition of relatively fresher water, removal of salt mass from the CCS, and management of CCS inflows and outflows. Ambient weather factors, such as precipitation amounts, temperatures, and regional water levels can also affect CCS salinity levels.

13. On October 7, 2015, FPL entered into a Consent Agreement with Miami-Dade County to resolve a Notice of Violation from the County dated October 2, 2015. Pursuant to paragraph 17 of the Consent Agreement, the objective is for FPL to demonstrate a statistically valid reduction in the salt mass and volumetric extent of the hypersaline water (as represented by chloride concentrations above 19,000 mg/L) in groundwater west and north of FPL's property without creating adverse environmental impacts. A further objective of the Consent Agreement is to reduce the rate of and, as an ultimate goal, arrest migration of hypersaline groundwater.

14. On April 25, 2016, the Department issued a Notice of Violation (OGC File No.: 16-0241) ("NOV") to FPL stating that the CCS is the major contributing cause to the continuing westward movement of the saline water interface, and that the discharge of hypersaline water contributes to saltwater intrusion. In the NOV, the Department found that saltwater intrusion into the area west of the CCS is impairing the reasonable and beneficial use of adjacent G-II groundwater in that area. FPL has operated the CCS under regulatory approvals, and the Department has not previously issued FPL either a Warning Letter or a Notice of Violation concerning FPL's operation of the CCS.

15. On April 25, 2016, the Department issued a Warning Letter, #WL 16-000151W13SED, to FPL concerning sampling events that indicated that ground water

originating from beneath the CCS is reaching tidal surface waters connected to Biscayne Bay in artificial deep channels immediately adjacent to the CCS. The Warning Letter requested that FPL provide facts to assist in determining whether any violations of Florida law have occurred.

16. The NOV directed FPL to enter into consultations to develop a consent order to, at a minimum, remediate the CCS contribution to the hypersaline plume, reduce the size of the hypersaline plume, and prevent future harm to waters of the State. FPL entered into consultations with the Department as required by the Orders for Corrective action in the NOV. The consultations resulted in resolutions to address the violations alleged in the NOV and issues raised in the Warning Letter, as memorialized in this Order.

17. On May 16, 2016, FPL submitted to the Department the nutrient monitoring results from certain surface water monitoring stations in deep channels adjacent to the CCS for total nitrogen, total phosphorous, TKN, and chlorophyll a. The Department reviewed the information by FPL and determined that no exceedances of surface water quality standards were detected in Biscayne Bay monitoring. This Order is intended to minimize the potential for future exceedances.

18. This Order and FPL's compliance with the requirements set forth in this Order address issues identified in the Department's Warning Letter, Administrative Order and NOV.

Respondent and the Department mutually agree and it is

ORDERED:

19. The first objective of this Order is for FPL to cease discharges from the CCS that impair the reasonable and beneficial use of the adjacent G-II ground waters to the west of the CCS in violation of Condition IV.1 of the Permit and Rule 62-520.400, F.A.C. FPL shall accomplish this first objective by undertaking freshening activities as authorized in the Turkey Point site certification, by eliminating the CCS contribution to the hypersaline plume, by maintaining the average annual salinity of the CCS at or below 34 Practical Salinity Units ("PSU"), by halting the westward migration of hypersaline water from the CCS, and by reducing the westward extent of the hypersaline plume to the L-31E within 10 years, thereby removing its influence on the saltwater interface, without creating adverse environmental impacts. The second objective of this Order is for FPL to prevent releases of groundwater from the CCS to surface waters connected to Biscayne Bay that result in exceedances of surface water quality standards in Biscayne Bay. FPL shall accomplish this second objective primarily by undertaking restoration projects in the Turtle Point Canal and Barge Basin area. The third objective of this Order is for FPL to provide mitigation for impacts related to the historic operation of the CCS, including but not limited to the hypersaline plume and its influence on the saltwater interface.

20. To achieve the first objective of this Order, FPL shall:

a. Achieve a CCS average annual salinity of at or below 34 PSU ("threshold") at the completion of the fourth year of freshening activities, which are authorized by the Turkey Point site certification modification. If FPL fails to reach an annual average salinity of at or below 34 PSU by the end of the fourth year of freshening activities, within 30 days of failing to reach the required threshold, FPL shall submit a plan to the Department detailing additional measures, and a timeframe, that FPL will implement to achieve the threshold. Subsequent to attaining the threshold in the manner set forth above, if FPL fails more than once in a 3 year period to maintain an average annual salinity of at or below 34 PSU, FPL shall submit, within 60 days of reporting the average annual salinity, a plan containing additional measures that FPL shall implement to achieve the threshold salinity level.

b. Submit a thermal efficiency plan within 180 days of the effective date of the Order that shall include a detailed description for the CCS to achieve a minimum of 70 percent thermal efficiency. This efficiency plan shall address water stage management, vegetation control, dredging, chemical additives to the CCS for facility operation, and upset recovery. FPL shall implement the efficiency plan within 90 days of being instructed to do so by the Department.

c. Implement a remediation project that shall include a recovery well system that will halt the westward migration of hypersaline water from the CCS within 3 years and reduce the westward extent of the hypersaline plume to the L-31E canal within 10 years without adverse environmental impacts.

i. Within 30 days of the effective date of this Order, provide the Department with available detailed plans for this remediation project, including supporting data, that are designed to halt the westward migration of the hypersaline plume within 3 years of commencement of the remediation project and retract the hypersaline plume to the L-31E canal within 10 years of the commencement of the remediation project. Location, volume and movement of the hypersaline plume shall be determined by Continuous Surface Electromagnetic Mapping ("CSEM") technology as detailed below.

ii. Apply for appropriate regulatory approvals within 90 days of the effective date of this Order and begin construction of this remediation project within 30 days after receipt of all necessary regulatory approvals. FPL shall advise the Department of any modifications to the submitted plans that result from regulatory reviews. FPL shall commence the operation of this remediation project upon completion of construction. FPL shall provide the Department with written notice of the date FPL commenced operation of this remediation project.

iii. For determining compliance, the westward migration of the hypersaline plume shall be deemed halted if the third CSEM survey shows no net increase in hypersaline water volume and no net westward movement in the leading edge of the hypersaline plume.

iv. To ensure overall remediation objectives are attained in a timely manner, if the second CSEM survey indicates that the net westward migration of the hypersaline plume is not being halted, then, within 180 days of the second CSEM survey, FPL shall develop and submit for approval to the Department a plan with specific actions to achieve the objectives of the remediation project. If the third CSEM survey still indicates the net westward migration of the hypersaline plume has not halted, FPL shall implement the approved additional measures within 30 days after submittal of the third CSEM report to the Department.

v. At the conclusion of the fifth year of operation of the remediation project, FPL shall evaluate and report to the Department, within 60 days, the effectiveness of the system in retracting the hypersaline plume to the L-31E canal within 10 years. If this report shows the remediation project will not retract the hypersaline plume to the L-31E canal within 10 years due to adverse environmental impacts of remedial measures or other technical issues, FPL shall provide an alternate plan for Department review and approval. FPL shall begin implementing the alternate plan within 30 days of receipt of notice that the alternate plan has been approved.

21. To achieve the second objective of this Order, FPL shall:

a. Complete Barge Basin and Turtle Point Canal restoration projects within 2 years of receiving the final regulatory approval. Within 60 days of the effective date of this Order, FPL shall provide the Department with a detailed plan and design of the restoration projects to prevent releases of groundwater from the CCS to surface waters connected to Biscayne Bay that result in exceedances of surface water quality standards in Biscayne Bay. Not more than 90 days after the effective date of this Order, FPL shall prepare and submit permit applications to relevant regulatory agencies (including the Department, the United States Army Corp of Engineers, and Miami-Dade County, as necessary) to address the restoration of the Turtle Point Canal and Barge Basin. Project success shall be based on full project completion and monitoring results of surface water sampling sites TPBBSW-4, TPBBSW-10, and TPBBSW-7T.

b. Within 90 days of the effective date of this Order, submit a detailed report outlining the potential sources of the nutrients found in the CCS, including chemical products used for plant operations. The report shall include a plan for minimizing nutrient levels in the CCS, which shall be implemented within 90 days after being instructed to do so by the Department.

c. Within 120 days of the effective date of this Order, conduct a thorough inspection of the CCS periphery including all dams, dikes, berms, and appurtenant structures using sound engineering judgment and best practices. FPL shall submit a detailed report to the Department of the inspection results, including underlying data. The inspection must be conducted by an independent qualified Florida licensed professional engineer. The term qualified means having successfully completed the Mine Safety and Health Administration Qualification for Impoundment Inspection course in addition to the Annual Retraining for Impoundment Qualification, or equivalent qualifications. The engineer shall also review available documentation and include in the report any actions necessary to ensure the integrity of the CCS. If the inspection identifies a material breach or structural defect in a peripheral levee of the CCS, FPL shall, within

60 days, submit a detailed description of the plan to address any material breaches or structural defects. FPL shall implement the plans to address any material breaches or structural defects within 60 days of the report mandated under this paragraph.

22. If FPL seeks renewal of the Combined License for either Unit 3 or 4 from the Nuclear Regulatory Commission, FPL shall provide the Department any information provided to the NRC detailing the future operating viability, including environmental and natural resource impacts, of the CCS and any potential alternative cooling technologies during the second renewal period.

23. To achieve the third objective of this Order, FPL shall undertake the following:

a. Complete an analysis, within 2 years from the effective date of this Order, with input from the Department and other agencies as selected by the Department, using the variable density three dimensional groundwater model developed under the Miami-Dade County Consent Agreement, that seeks to allocate relative contributions of other entities or factors to the movement of the SWI.

b. Enter into an agreement within 1 year with SFWMD, if SFWMD requests, to convey to SFWMD, FPL property interests in essential properties within the Biscayne Bay Coastal Wetlands Phase I project to facilitate the Comprehensive Everglades Restoration Plan in exchange for payment based on a jointly approved appraisal process or other mutually agreeable considerations. (See Attachment A).

c. Deposit $1.5 million into a Florida Department of Financial Services escrow account in accordance with an escrow agreement signed by FPL, the Department and the Florida Department of Financial Services. The escrow account shall be used to finance projects in the Turkey Point region that support mitigation of saltwater intrusion.

d. Conduct grab sampling within 90 days of the effective date of this Order, to improve trend analysis in Biscayne Bay and Card Sound surface waters, every two months, taking both top and bottom samples, for two years from the effective date of this Order at six sites as shown in Attachment B. The parameters sampled shall be: temperature, conductivity, pH, dissolved oxygen, turbidity, salinity, tritium, ammonia, nitrate + nitrite, total Kjedahl nitrogen, orthophosphate, total phosphorus, chlorophyll-*a*, total depth, and Secchi disk depth.

MONITORING REQUIREMENTS

24. Quality assurance and quality control for all monitoring requirements under this Order shall be achieved by compliance with the Quality Assurance Project Plan under the 2009 Monitoring Plan.

25. FPL shall timely apply for all regulatory approvals necessary for compliance with the monitoring requirements in this Order.

26. FPL shall continue to implement the monitoring program for the CCS, the 2009 Monitoring Plan, until such time as a monitoring plan is enacted pursuant to Section 403.087, F.S.

27. In addition to the monitoring requirements contained in the 2009 Monitoring Plan, FPL shall, within 90 days of the effective date of this Order, request or apply for regulatory approval to:

a. Obtain monitoring data from the USGS for the following wells for inclusion in the monitoring database: G-3946-S, G-3946-D, G-3900, G-3976, G-3966, and G-3699.

b. Install and monitor, consistent with the parameters and frequency set forth in the 2009 Monitoring Plan, a new 3 well cluster at G-3164. Construction shall commence within 180 days of FPL's receipt of all necessary regulatory approvals for the installation of the wells.

c. Replace and monitor, consistent with the parameters and frequency set forth in the 2009 Monitoring Plan well TPGW-8S. Construction shall commence within 180 days of FPL's receipt of all regulatory approvals necessary for compliance with this requirement.

d. Install and monitor, consistent with the parameters and frequency set forth in the 2009 Monitoring Plan a new deep well (to be designated as TPGW-20) located at the City of Homestead baseball complex, east of Kingman Road (SW 152nd Ave.) near the western parking area. Construction shall commence within 180 days of FPL's receipt of all regulatory approvals necessary for compliance with this requirement. The deep well will have a screened interval open to the deep high flow interval identified in the same manner as those described in the 2009 Monitoring Plan.

28. FPL shall expand the 2009 Monitoring Plan database to include all additional water monitoring data related to this Order required by all other governmental agencies and entities, including but not limited to the SFWMD, Nuclear Regulatory Commission, Miami-Dade County and the Florida Department of Health, as well as all monitoring data that is required in this Order.

29. In addition to the other monitoring requirements in this Order and for purposes of monitoring progress toward achievement of the hypersaline plume retraction, including determining whether the westward migration of the hypersaline plume has been halted and determining the rate of decline of saline levels in the CCS surface waters over time, the following monitoring requirements shall be met:

a. FPL shall conduct and report to the Department a baseline CSEM survey of the hypersaline plume after freshening activities are in operation but before the complete recovery well system begins operation. This will be the "Baseline Survey."

b. FPL shall conduct a CSEM survey within 30 days after the first year of recovery well operations and report the results to the Department.

c. FPL shall conduct a CSEM survey within 30 days after the second year of recovery well operations and report the results to the Department. This survey shall be the second CSEM survey.

d. FPL shall conduct a CSEM survey within 30 days after the third year of recovery well operations and report the results to the Department. This survey shall be the third CSEM survey.

e. FPL shall conduct and report to the Department subsequent CSEM surveys of the hypersaline plume 2 years after the third CSEM survey and every 2 years thereafter.

f. FPL shall monitor average weekly mass removal of salt as represented by total dissolved solids ("TDS"), by monitoring flow rate and weekly average TDS of the full extraction system, beginning at the time of commencement of the hypersaline plume remediation project operation.

g. FPL shall monitor average weekly chloride concentration of extracted water for the full extraction system, beginning at the time of commencement of the hypersaline plume remediation project operation.

h. FPL shall monitor average daily volume of hypersaline water extraction for the full extraction system, from beginning at the time of commencement of the Plume Extraction operation.

i. FPL shall maintain records of the operation of each extraction well (pump operation parameters such as: pump status, RPM, flow rate; water quality parameters such as salinity and TDS) and make such records available for review by the Department upon request, with reasonable notice.

j. FPL shall, when monitoring the salinity levels in the CCS, utilize all available monitoring resources in the CCS to obtain the average annual salinity rate. Specific monitoring points may not be excluded from the calculation unless such exclusion is allowed by the Department based upon a scientific reason. For the purposes of determining average annual salinities for the CCS, FPL shall use qualified hourly data (pursuant to the approved 2009 Monitoring Plan QAPP) from each of the CCS monitoring sites TPSWCCS-1, 2, 3, 4, 5, 6, and 7 collected beginning at 00:00 through 23:59 each day. The qualified hourly data for the day will be summed and divided by the number of qualified hourly values for the station that day. Stations with fewer than 12 qualified hourly data values in a given day shall not be used in the calculation of the CCS daily average. The daily averages for all qualified stations (up to seven per day) for a given day will be summed and divided by the number of qualified stations for that day to produce a qualified CCS daily average salinity value. The average annual salinity is calculated by summing the qualified CCS daily average salinity values from June 1st through May 31st and dividing the value by the number of days in the year.

k. FPL shall monitor TPBBSW7T consistent with the parameters and frequency in the 2009 Monitoring Plan.

30. FPL will take reasonable actions to select appropriate laboratories with sufficient capacity to avoid delay in receiving results due to backlogs. If such delay occurs, FPL will make reasonable efforts to resolve those delays.

REPORTING REQUIREMENTS

31. The Annual Monitoring Report required by the 2009 Monitoring Plan shall be expanded to include:

a. All additional water monitoring data required under this Order.

b. All additional water monitoring data related to this Order required by all other governmental agencies or entities, including but not limited to the SFWMD, Nuclear Regulatory Commission, Miami-Dade County, and the Florida Department of Health, as well as all monitoring data that is required in this Order.

c. A reporting of the average annual salinity of the CCS waters.

32. FPL shall provide a report to the Department at the conclusion of the year-long control elevation project described in paragraph 17 of the Miami-Dade Consent Agreement detailing the results of the year-long raise in control elevations in the Everglades Mitigation Bank.

33. FPL shall provide the Department a copy of all reports/summaries/reviews required under any other agreements with any other agency, such as the reports/ summaries/ reviews required by the Miami-Dade Consent Agreement.

NOTICES

34. FPL shall allow all authorized representatives of the Department access to the Facility at reasonable times for the purpose of determining compliance with the terms of this Order and the rules and statutes administered by the Department.

35. This Order supersedes all the requirements of the Administrative Order related to the CCS at Turkey Point. Upon execution of this Order, the DEP Administrative Order (OGC No. 14-0741) is hereby rescinded.

36. If any event, including administrative or judicial challenges by third parties unaffiliated with FPL, occurs which causes delay or the reasonable likelihood of delay in complying with the requirements of this Order, FPL shall have the burden of proving the delay was or will be caused by circumstances beyond the reasonable control of FPL and could not have been or cannot be overcome by FPL's due diligence. Neither economic circumstances nor the failure of a contractor, subcontractor, materialman, or other agent (collectively referred to as "contractor") to whom responsibility for performance is delegated to meet contractually imposed deadlines shall be considered circumstances beyond the control of FPL (unless the cause of the contractor's late performance was also beyond the contractor's control). Failure of regulatory agencies to issue required permits consistent with this Order shall be considered a circumstance beyond the control of FPL if FPL acted with due diligence in the permit application process. Upon occurrence of an event causing delay, or upon becoming aware of a potential for delay, FPL shall notify the Department within 2 working days and shall, within seven calendar days notify the Department in writing of (a) the anticipated length and cause of the delay, (b) the measures taken or to be taken to prevent or minimize the delay, and (c) the timetable by which FPL intends to implement these measures. If the parties can agree that the delay or anticipated delay has been or will be caused by circumstances beyond the reasonable control of FPL, the time for performance hereunder shall be extended. The agreement to extend compliance must identify the provision or provisions extended, the new compliance date or dates, and the additional measures FPL must take to avoid or

minimize the delay, if any. Failure of FPL to comply with the notice requirements of this paragraph in a timely manner constitutes a waiver of FPL's right to request an extension of time for compliance for those circumstances.

37. The Department, for and in consideration of the complete and timely performance by FPL of all the obligations agreed to in this Order, hereby conditionally waives its right to seek judicial imposition of damages, civil penalties, or injunctive relief for the violations described in the Notice of Violation and above up to the date of the filing of this Order. This waiver is conditioned upon FPL's complete compliance with all of the terms of this Order.

38. This Order is a settlement of the Department's civil and administrative authority arising under Florida law to resolve the matters addressed herein. This Order is not a settlement of any criminal liabilities which may arise under Florida law, nor is it a settlement of any violation which may be prosecuted criminally or civilly under federal law. Entry of this Order does not relieve FPL of the need to comply with applicable federal, state, or local laws, rules, or ordinances.

39. The Department hereby expressly reserves the right to initiate appropriate legal action to address any violations of statutes or rules administered by the Department that are not specifically resolved by this Order.

40. FPL is fully aware that a violation of the terms of this Order may subject FPL to judicial imposition of damages, civil penalties up to $10,000.00 per day per violation, and criminal penalties.

41. FPL acknowledges and waives its right to an administrative hearing pursuant to sections 120.569 and 120.57, F.S., on the terms of this Order. FPL also acknowledges and waives its right to appeal the terms of this Order pursuant to section 120.68, F.S.

42. Electronic signatures or other versions of the parties' signatures, such as .pdf or facsimile, shall be valid and have the same force and effect as originals. No modifications of the terms of this Order will be effective until reduced to writing, executed by both FPL and the Department, and filed with the clerk of the Department.

43. The terms and conditions set forth in this Order may be enforced in a court of competent jurisdiction pursuant to sections 120.69 and 403.121, F.S. Failure to comply with the terms of this Order constitutes a violation of section 403.161(l)(b), F.S.

44. This Order is a final order of the Department pursuant to section 120.52(7), F.S., and it is final and effective on the date filed with the Clerk of the Department unless a Petition for Administrative Hearing is filed in accordance with Chapter 120, F.S.

45. When FPL demonstrates to the Department that it has fulfilled the requirements of this Order, the Department shall notify FPL in writing that all requirements of this Order are terminated except for the requirement to maintain the average annual salinity of the CCS at or below 34 PSU until an average annual salinity of the CCS is designated in a Department permit issued subsequent to the effective date of this Order.

46. Upon the timely filing of a petition, this Order will not be effective until further order of the Department.

47. FPL shall publish the following notice in a newspaper of daily circulation in Miami-Dade County, Florida. The notice shall be published one time only within 30 days of the effective date of the Order. FPL shall provide a certified copy of the published notice to the Department within 10 days of publication.

STATE OF FLORIDA DEPARTMENT OF ENVIRONMENTAL PROTECTION

NOTICE OF CONSENT ORDER

The Department of Environmental Protection ("Department") gives notice of agency action of entering into a Consent Order with FPL pursuant to section 120.57(4), F.S. The Consent Order addresses the westward migration of hypersaline water from the Turkey Point Facility and potential releases to deep channels on the eastern and southern side of the Facility. The Consent Order is available for public inspection during normal business hours, 8:00 a.m. to 5:00 p.m., Monday through Friday, except legal holidays, at the Department of Environmental Protection Office of General Counsel, 3900 Commonwealth Boulevard, Tallahassee, Florida 32399-3000.

Persons who are not parties to this Consent Order, but whose substantial interests are affected by it, have a right to petition for an administrative hearing under sections 120.569 and 120.57, F.S. Because the administrative hearing process is designed to formulate final agency action, the filing of a petition concerning this Consent Order means that the Department's final action may be different from the position it has taken in the Consent Order.

The petition for administrative hearing must contain all of the following information:

a) The OGC Number assigned to this Consent Order;

b) The name, address, and telephone number of each petitioner; the name, address, and telephone number of the petitioner's representative, if any, which shall be the address for service purposes during the course of the proceeding;

c) An explanation of how the petitioner's substantial interests will be affected by the Consent Order;

d) A statement of when and how the petitioner received notice of the Consent Order;

e) Either a statement of all material facts disputed by the petitioner or a statement that the petitioner does not dispute any material facts;

f) A statement of the specific facts the petitioner contends warrant reversal or modification of the Consent Order;

g) A statement of the rules or statutes the petitioner contends require reversal or modification of the Consent Order; and

h) A statement of the relief sought by the petitioner, stating precisely the action petitioner wishes the Department to take with respect to the Consent Order.

The petition must be filed (received) at the Department's Office of General Counsel, 3900 Commonwealth Boulevard, MS# 35, Tallahassee, Florida 32399-3000 within 21 days of receipt of this notice. A copy of the petition must also be mailed at the time of filing Division of Water Resource Management, Industrial Wastewater Program at 2600 Blair Stone Road, Mail Station 3545, Tallahassee, Florida 32399-2400. Failure to file a petition within the 21-day period constitutes a person's waiver of the right to request an administrative hearing and to participate as a party to this proceeding under sections 120.569 and 120.57, F.S. Before the deadline for filing a petition, a person whose substantial interests are affected by this Consent Order may choose to pursue mediation as an alternative remedy under section 120.573, F.S. Choosing mediation will not adversely affect such person's right to request an administrative hearing if mediation does not result in a settlement. Additional information about mediation is provided in section 120.573, F.S. and Rule 62- 110.106(12), Florida Administrative Code.

FOR THE RESPONDENT:

Randall R. LaBauve
Vice-President, Environmental Services
Florida Power & Light Company
700 Universe Boulevard
Juno Beach, FL 33408

DONE AND ORDERED this 20th day of June, 2016, in Tallahassee, Florda.

August 2016

Prepared for
Nuclear Regulatory Commission

Pacific Northwest National Laboratory
Richland, Washington 99352

Summary

Researchers at Pacific Northwest National Laboratory served as members of a U.S. Nuclear Regulatory Commission review team for the Florida Power & Light Company's application for two combined construction permits and operating licenses (combined licenses or COLs) for two proposed new reactor units—Turkey Point Units 6 and 7. The review team evaluated the environmental impacts of the proposed action based on the October 29, 2014 revision of the COL application, including the Environmental Report, responses to requests for additional information, and supplemental information. As part of this effort, team members tasked with assessing the environmental effects of proposed construction and operation of Units 6 and 7 at the Turkey Point site reviewed two separate modeling studies that analyzed the interaction between surface water and groundwater that would be altered by the operation of radial collector wells (RCWs) at the site. To further confirm their understanding of the groundwater hydrodynamics and to consider whether certain actions, proposed after the two earlier modeling studies were completed, would alter the earlier conclusions documented by the review team in their draft environmental impact statement (EIS; NRC 2015), a third modeling analysis was performed. The third modeling analysis is discussed in this report.

The simulations were conducted using the water-salt-energy mode of the STOMP (Subsurface Transport Over Multiple Phases) simulator (White and Oostrom 2006). The applicable governing equations are the component mass-conservation equation for water and salt, and the energy conservation equation. The simulator allows for the consideration of density-driven flow and temperature effects caused by the seepage of warm hypersaline water from the unlined cooling-canal system (CCS) into the saline Biscayne aquifer. The model configuration was based on an earlier cross-sectional model published by Hughes et al. (2010). The two-dimensional (2D) model is 46 km long and extends 35 m vertically. The three-dimensional (3D) model that represents an extension of the 2D model is 2 km wide.

The initial conditions for both the 2D and 3D simulations are obtained using a steady-state simulation with a Biscayne Bay hydraulic head of 0.2 m and a west boundary head of 1.05 m. The long-term (10,000 year) simulations yielded a typical salt intrusion front, extending below the CCS. For the subsequent hypersaline water infiltration simulations, the same boundary conditions as proposed by Hughes et al. (2010) were used for hydraulic heads and temperature.

The main observations from the 2D simulations are as follows:

- CCS operation with warm 70 g/L hypersaline water leads to development of a large subsurface plume.
- Reducing the CCS salt concentration leads to a stable displacement of hypersaline water from the CCS subsurface.
- Increasing the hydraulic head in L-31E Canal limits westward migration of the hypersaline plume.
- Increasing the west boundary hydraulic head (indicative of increased recharge) results in a compression of the hypersaline plume at the west side of the CCS.
- Decreasing the west boundary hydraulic head (indicative of reduced recharge) has the opposite effect, leading to additional migration of the hypersaline plume in the western direction.
- During sea level rise, infiltrating saltwater from the Biscayne Bay pushes the hypersaline water toward the CCS subsurface. Over time, the interface between hypersaline water originating from the CCS and seawater becomes sharper and more vertical.

The main observations from the 3D simulations are as follows:

- Periodic extraction using the RCW system leads to fluctuating salt concentrations in the wells.
- During pumping, the concentrations initially increase because of advective transport of hypersaline water through the Upper Higher Flow Zone; the concentrations then decrease because of the influence of extracted Biscayne Bay saltwater.
- Between pumping episodes, the concentrations slightly increase due to diffusion of hypersaline water eastward; the well salt concentrations do not change significantly from year to year.
- RCW pumping increases the concentration gradients between the hypersaline plume below the CCS and Biscayne Bay saltwater in the upper parts of the aquifer and removes some of the hypersaline water from the Fort Thompson formation; the extracted volumes originate largely from the Biscayne Bay (>95 %); pumping rate reduction (up to 10% of maximum) and duration reduction (50 %) do not considerably influence well concentrations. This result indicates that the proposed RCW operation with 86,400 gal/min withdrawal rate over 60 days per year completely dominates flow and transport adjacent to the RCWs because reasonable variations in the rate and duration do not considerably influence well concentrations.
- Boundary condition modifications (i.e., L-31E Canal head and west boundary head increases) applied to the west of the CCS do not influence RCW extraction behavior.
- Seawater rise in Biscayne Bay leads to decreasing RCW saltwater concentration over time because the increasing Biscayne Bay hydraulic head displaces hypersaline water toward the CCS subsurface.
- Operation of remediation wells in the Lower Higher Flow Zone below the Interceptor Ditch does not influence extracted RCW salt concentrations.
- Salt concentrations in the remediation wells are predicted to increase to CCS levels within a year.
- Freshening of the CCS surface water results in reduced RCW salt concentrations with relatively minor (<1 g/L) fluctuations.

There is no question that some perturbations of the baseline boundary conditions result in significantly altered environmental baselines. However, while the operation of the RCWs would change the incremental impacts of the RCWs on the salinity distribution of the aquifer, the alterations would remain at levels that may only be detectable within the immediate vicinity of the RCWs. While the numerical model analysis suggest the slight westward movement of hypersalinity assumed in the conceptual model from the operation of the RCWs, it does not demonstrate any plausible upward impelling force above the RCWs that would result in hypersalinity moving into the Bay as a result of the RCWs. As the review team has acknowledged in the EIS, when the water surface elevation in the cooling canals exceeds that in the Bay, the water will follow the gradient of the impelling force into the Bay and may contribute to salinity in the Bay. Both of the above effects also apply for other tracers, including nutrients and tritium.

Although the primary focus of the review reported here is on the incremental effects of the RCWs on the Biscayne Bay, the review team also acknowledges the cumulative impacts of other changes, including those from sea level rise and possible future regulatory actions. While the scenarios considered in this analysis tended to be bounding for sea level rise and possible regulatory actions, they also provide a basis for assessing the cumulative impacts. The review team has no jurisdiction over the proposed regulatory actions considered and assumes that mitigation actions proposed by state and county agencies would improve the baseline environment. As long as the incremental effect of the RCWs remains minor, the cumulative effects would also remain minor.

The minor localized alterations in salinity distribution suggest that the operation of the RCWs is unlikely to interfere with any of the proposed mitigation actions.

Acknowledgments

The authors acknowledge the valuable comments and suggestions in scoping, performing, and documenting the analysis provided by Eric Stabenau and Kevin Kotun, South Florida Natural Resource Center, National Park Service; Dan Barnhurst, New Reactor Office, Nuclear Regulatory Commission; and Paul Thorne, Pacific Northwest National Laboratory.

1.0 Introduction

Pacific Northwest National Laboratory researchers served as members of a U.S. Nuclear Regulatory Commission review team for the Florida Power & Light Company's (FPL's) 2009 application for two combined construction permits and operating licenses (combined licenses or COLs) for two proposed new reactor units—Turkey Point Units 6 and 7. The review team evaluated the environmental impacts of the proposed action based on the October 29, 2014 revision of the COL application (FPL 2014a), including the Environmental Report (ER) (FPL 2014b), responses to requests for additional information, and supplemental information. As part of this effort, team members tasked with assessing the environmental effects of proposed construction and operation of Units 6 and 7 at the Turkey Point site reviewed two separate modeling studies that analyzed how the interaction between surface water and groundwater would be altered by the operation of proposed radial collector wells (RCWs) at the site. The team performed a third modeling analysis to further confirm their understanding of the groundwater hydrodynamics and to consider whether certain actions, proposed after the two earlier modeling studies were completed, would alter the earlier conclusions documented by the review team in the draft environmental impact statement (EIS, NRC 2015). This third modeling analysis is the subject of this report. The two earlier analyses are discussed in Appendix G.2.1 and G.2.2 of the draft EIS (NRC 2015).

1.1 Purpose and Scope

2D and 3D models of the subsurface of the Turkey Point cooling-canal system (CCS, also referred to as the IWF) were developed to assess the behavior of hypersaline saltwater emanating from the CCS. The 2D simulations were conducted to investigate the effects of CCS salinity, L-31E Canal head, Interceptor Ditch head, boundary conditions, and sea level rise. The 3D model was developed to evaluate potential impacts of RCW pumping on the movement of water between the CCS, the underlying Biscayne aquifer, and the Biscayne Bay. Numeric modeling and site potentiometric surface and boundary conditions were essential elements of the assessment.

1.1.1 Numerical Modeling

Numerical models are computer codes used to analyze the response of complex physical systems. Numerical models employ mathematical representations of physical processes to transform a specific set of initial conditions, boundary conditions, and process parameters into a time series of state variables at specific locations and times. Numerical models provide reliable enforcement of irrefutable principles such as conservation of mass for complex heterogeneous domains. By consistently applying assumptions that are explicitly codified in the model and its inputs, a clearer understanding of the complex systems behavior can be achieved. Systematic perturbation of assumptions about initial conditions, boundary conditions, and model parameter provide a basis for assessing the sensitivity of assumptions and uncertainty in the overall assessment.

Numerical modeling is often a necessary element of National Environmental Policy Act assessments that involve complex physical systems such as aquifers. However, numerical models rarely are sufficient as the sole basis of an assessment. The conceptual understanding that provides the framework for the model has limitations. It is the responsibility of the analyst looking at the model results to understand the implications of these limitations on the assessment.

Multiple distinct models can be used in multiple roles to assist on the same assessment. In the Turkey Point hydrologic modeling assessment described herein three distinct models were used in three distinct ways. Numerical models with different spatial scales and resolutions, models including different process representations, and models with different goals give the analyst a stronger basis for making an assessment. It should be noted that numerical models are never perfect representations of any system and that a prudent analyst will also consider the role of monitoring and mitigation in making an impact determination in case the actual system does not fit within the assessment envelope considered. Models help the analyst determine whether monitoring is likely to detect such outliers in a timely manner. Models also help the analyst determine if the proposed mitigation will be effective.

1.1.2 Site Potentiometric Surface and Boundary Conditions

The impelling force that drives subsurface water movement is defined by the potentiometric surface—the level to which fresh water in a confined aquifer would rise were it completely pierced with wells. The potentiometric surface of the Biscayne aquifer beneath the Turkey Point site is complicated by the presence of freshwater, seawater, and hypersaline water. While these fluids are not immiscible, their density differences help to maintain an interface between them. The density differences influence the shape of the potentiometric surface. Water moves from higher potentiometric head toward lower potentiometric head proportionally to the viscosity of the fluid and intrinsic permeability of the subsurface matrix material. The potentiometric surface will shift as the water transports and the boundary conditions change.

The RCW system for Turkey Point is described in Chapter 3 of the EIS (NRC, in progress). RCWs behave more like tile drainage systems than like conventional wells. In a conventional well, all the water must move laterally into a small cross-sectional area causing significant drawdowns at the well where a RCW moves the volume vertically through a much larger cross-sectional area. For instance, the nominal increase in cross-sectional area of a conventional 6 in. well screened over 100 ft relative to the surface area of a RCW with 100 ft radial arms is a 400 factor increase. This results in smaller perturbations in the potentiometric surface and emphasizes vertical water motion over lateral water motion. RCWs are placed at shallow depths beneath surface waterbodies that effectively provide an unconstrained source of water or a boundary condition unaffected by withdrawal from the RCWs. Differences on stratigraphy and hydraulic conductivity also influence the potentiometric surface around RCWs.

A variety of boundary conditions exist at the Turkey Point site, including potentiometric boundary conditions and salinity boundary conditions. Biscayne Bay represents both a specified potentiometric boundary condition and a specified salinity boundary condition to the upper surface of the conceptual model. The Bay potentiometric boundary condition varies in response to tides, storm surge, and sea level rise. The industrial wastewater facility (IWF) cooling canals, Interceptor Ditch, and L-31 Canal also represent potentiometric and salinity boundary conditions on the upper surface of the conceptual model. These boundary conditions may also vary over time and space.

The western vertical boundary is also represented by a specified potentiometric and salinity boundary condition. Wet periods cause this boundary condition to rise and dry periods cause this boundary to fall.

Two types of wells, the RCWs and remediation wells, also represent specified flux sink boundary conditions. The RCWs are the focus of this assessment. As discussed in Section 2.3, the remediation wells are proposed to abate the westward migration of the hypersaline plume. The exact design of this proposed remediation system is not known at this time.

All of the boundary conditions experience differing degrees of normal variability. For instance, a significant rainfall event will increase the potentiometric head in the western boundary, decrease the salinity in the cooling canals, increase the head in the cooling canals, increase head in the L-31 Canal, increase recharge, and decrease salinity in Biscayne Bay. Also, boundary conditions are linked to varying degrees. For instance, an increase in the Bay water surface elevation can influence the elevation of water in the cooling canals. Including these linkages and time-varying boundary conditions can make it more difficult for the analyst to understand the results because of too many confounding factors. One of the benefits of numerical models is that they allow selective and limited interactions of boundary conditions to reduce the confounding issues in interpreting the model results.

The spatial distribution of the salinity at the initiation of operation is the dominant initial condition. The location of the hypersaline plume and the freshwater-seawater interface are initial conditions. As discussed in Section 2.3, a variety of regulatory actions related to the IWF may alter the initial conditions before the proposed Units 6 and 7 would ever require operation of the RCWs. The initial conditions developed through a sequence of processes that occurred in the past. Prior to operation of the RCWs and the IWF a freshwater-saltwater interface formed based on patterns of freshwater flow from the aquifer to the ocean. As inland water demands and recharge patterns changed the saltwater interface moved farther inland. During this period, the IWF was constructed and the denser hypersaline water that occurred at times moved downward under the unlined cooling canals and displaced the less dense water below, thereby resulting in a hypersaline plume that extends all the way down to the base of the aquifer.

The hypersaline groundwater plume formed beneath the cooling-canal system that was used for Turkey Point Units 1, 2, 3, 4, and 5. The proposed Units 6 and 7 would rely primarily on reclaimed water from a regional wastewater treatment plant and discharge blowdown into a very deep formation called the Boulder Zone. Therefore, the review team determined that under normal operation the cooling system impact of Units 6 and 7 on the shallow subsurface aquifer and cooling canals would be de minimis. However, the proposed design for Units 6 and 7 also includes an RCW system as a backup in case of a loss of access to reclaimed water. The RCWs are designed to encourage downward movement of water from Biscayne Bay into a set of shallow laterals. However, the review team determined that even a very shallow depression in the potentiometric head in the aquifer around the RCW will result in some lateral movement in the groundwater.

1.2 Report Contents and Organization

The ensuing sections of this report contain brief descriptions of the site being modeled, the simulator used to model site behaviors, the 2D and 3D model configurations, the associated parameter values, and how the initial and bounding conditions were derived for the simulations. Section 7.0 provides a tabulated overview of the simulations by case number and title as a lead into the presentation of the 2D and 3D simulation results in Sections 8.9 and 9.0. A discussion of the results is provided in Section 10.0. Conclusions of the overall assessment are provided in Section 11.0.

2.0 Site Description

The 2D model configuration was based on an earlier cross-sectional model published by Hughes et al. (2010). The 2D model (Figure 2.1) has a length of 46 km and a vertical extent of 35 m. The 3D model represents an extension of the 2D model and has a width of 2 km. Both models extend approximately 15.5 km farther offshore than shown in Figure 2.1, allowing for the evaluation of Biscayne Bay effects. The models represents part of the Turkey Point power plant large CCS overlying a permeable limestone aquifer. At its maximum extent (south of the 2D model cross section), the CCS has 40 canals, 32 of which transport warm water toward the south (i.e., discharge canals), and 8 of which return water to the plant (i.e., return canals). In the model cross section used by Hughes et al. (2010) and for this modeling effort, 22 discharge and 8 return canals are intersected by the cross section used. The 60 m wide canals are separated by 27 m wide berms. The cooling water salinity is considerably higher than the natural salt concentrations in groundwater in the aquifer, which likely leads to unstable density-dependent convection. The cooling water temperatures are also higher than those of the aquifer water, which potentially reduces the density effects. A more detailed description of the CCS can be found in Section 2.3 of the Turkey Point Units 6 and 7 EIS (NRC 2016). Water exchange between the CCS and groundwater occurs because the canals are unlined. An Interceptor Ditch (Figure 2.1), located west of the CCS, is used to create an artificial groundwater gradient that inhibits shallow flow of the hypersaline water from the CCS to the west. Another prominent feature is the L-31E Canal, located just west of the Interceptor Ditch. The subsurface of the model area consists of an unconfined surficial aquifer characterized by the presence of two relatively thin very high-permeability zones (Cunningham et al. 2006) with hydraulic conductivities larger than 1,000 m/day.

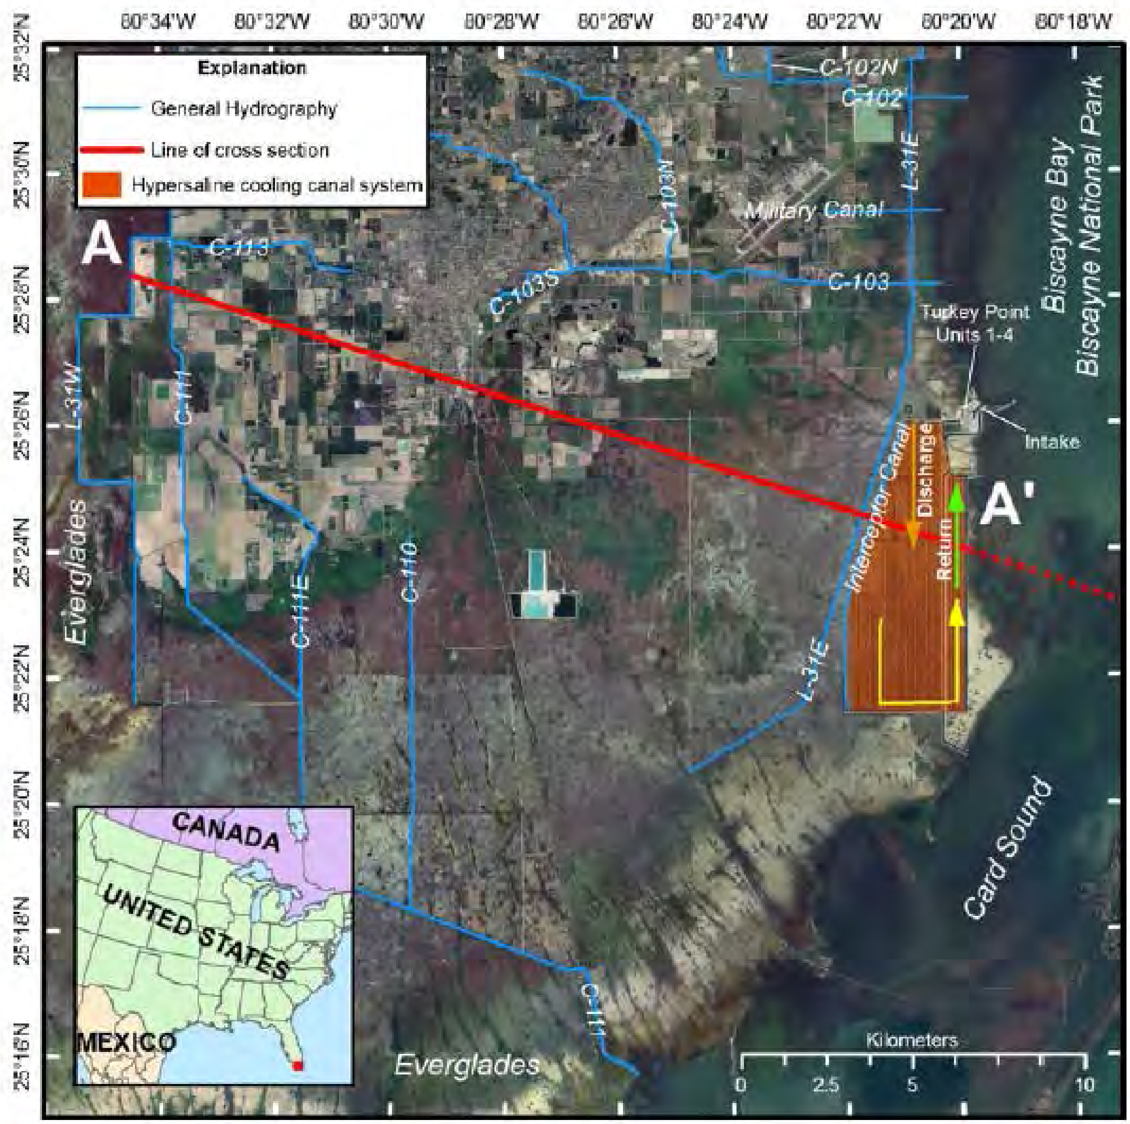

Figure 2.1. Cross-sectional model of the Turkey Point CCS (after Hughes et al. 2010). Note that the model extends approximately 15,500 m farther offshore than shown in the figure. The general hypersaline CCS flow direction is indicated with arrows.

3.0 Numerical Simulator

The simulations were conducted using the water-salt-energy mode of the STOMP (Subsurface Transport Over Multiple Phases) simulator (White and Oostrom 2006). The applicable governing equations are the component mass-conservation equation for water and salt, and the energy conservation equation. The simulator allows for the consideration of density-driven flow and temperature effects caused by the seepage of warm hypersaline water from the unlined canals of the CCS into the saline Biscayne aquifer. The governing partial differential equations are discretized with the integrated-volume finite difference method by integrating over a control volume. Using Euler backward time differencing, which yields a fully implicit scheme, a series of nonlinear algebraic expressions is derived. The algebraic forms of the nonlinear governing equations are solved with a multi-variable, residual-based Newton-Raphson iterative technique, in which the Jacobian coefficient matrix is composed of the partial derivatives of the governing equations with respect to the primary variables.

4.0 Model Configuration and Discretization

The layered configuration of the Biscayne aquifer and assignment of hydraulic properties to the layers were based on work performed by FPL and documented in the Final Safety Analysis Report and reports related to the power uprate for FPL Units 3 and 4. Figure 4.1 shows the geologic layering of the current model, including the thin Upper Higher Flow Zone (UHFZ) and the Lower Higher Flow Zone (LHFZ) of the Miami Limestone. Other units are the remainder of the Miami Limestone, the Key Largo, and the Fort Thompson formations. The model includes 22 discharge canals and 8 return canals, consistent with the cross section shown in Figure 4.1. The easternmost discharge canal is the Grand Canal, which is approximately 4 m deeper than the adjacent canals. The hydraulic conductivities assigned to the model layers are shown in Table 5.2 (see Section 5.0). For the 3D model, the same stratigraphy was used throughout the computational domain. In the current model configuration, the two "higher flow zones" were defined to be 1 m thick based on borehole data, rather than the 3 m thickness used by Hughes et al. (2010).

The 3D model configuration is shown in Figure 4.2. The model has a total width of 2 km, although the numerical model only comprises the right half of the total domain using the center line as a line of symmetry. The 3D model incorporates three RCWs, located 1,500, 1,700, and 1,900 m into the Biscayne Bay. Each RCW has a horizontal length of 150 m in the right half of the computational domain and all RCW laterals are installed in the UHFZ. The RCWs are assumed to operate continuously or for 60 days per year at a maximum pumping rate of 86,400 gal/min. The model also has the option to use up to 10 vertical remediation wells with open intervals located below the Interceptor Ditch in the LHFZ). FPL plans to install and operate these wells along the western side of the CCS to remove hypersaline water and limit its migration to the west. The extracted water will be pumped at a maximum combined rate of 12,000,000 gal/day. The 2D domain was discretized into 876 × 45 grid cells for a total of 39,420 nodes. Considerable refinement of the model grid was applied below the CCS. For the 1 km width of the 3D model, 72 grid cells were used, resulting in a total of 2,838,420 nodes.

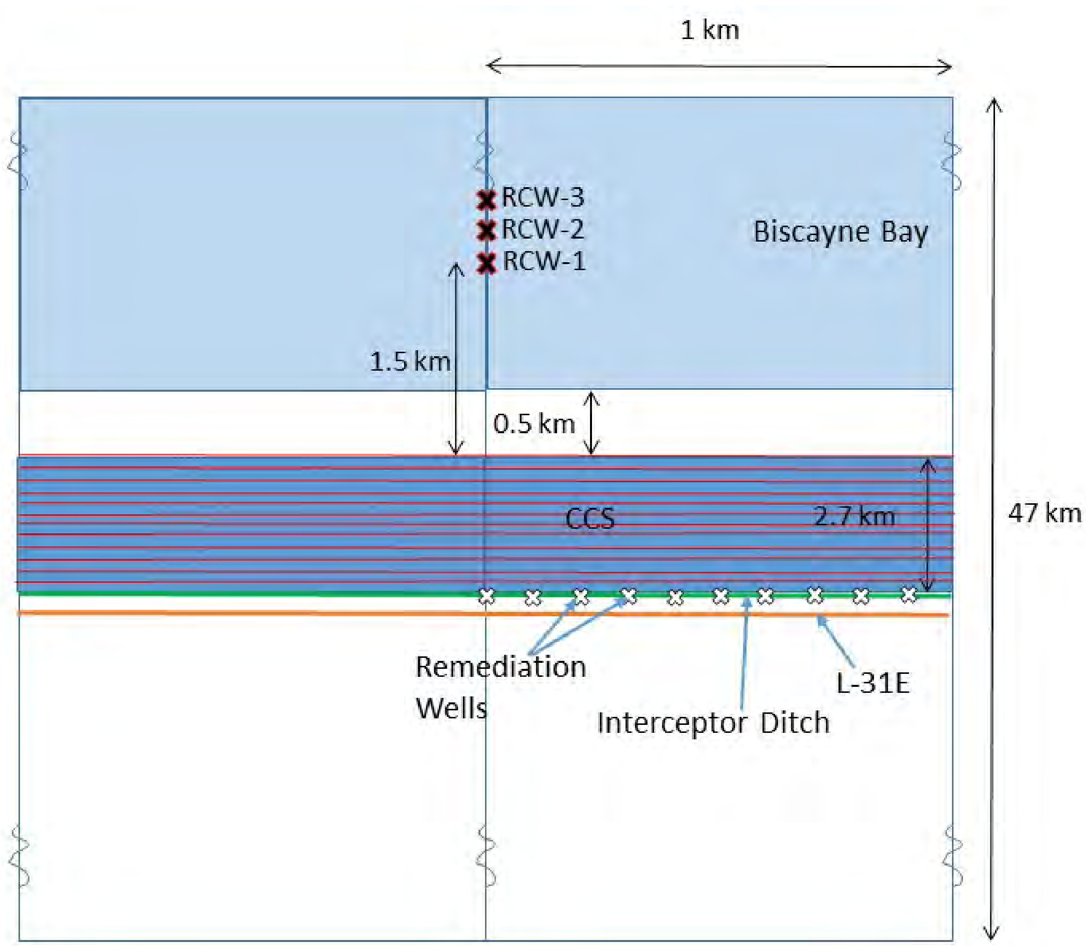

Figure 4.2. Top View of the Symmetrical 3D Model

5.0 Parameter Values

The fluid and aquifer properties are summarized in Table 5.1. The density-concentration relationships were obtained from Millero and Huang (2009). The hydraulic conductivities of the layers are listed in Table 5.2.

Table 5.1. Model Parameter Values

Model Parameter	Value
Reference Temperature (°C)	20
Land Surface Temperature (°C)	24.4
Seawater Temperature (°C)	26.2
Cooling-Canal System Temperature (°C)	35.6
Longitudinal Dispersivity (m)	1
Transverse Dispersivity (m)	0.1
Molecular Diffusion Coefficient Salt (m^2/s)	1.477e-09
Porosity	0.2
Particle Density (kg/m^3)	2650
Specific Heat Fluid (J/(kg°C))	4.183
Specific Heat Sediment (J/(kg°C))	835.0
Thermal Conductivity Fluid (J/(m°Cs))	0.61
Thermal Conductivity Sediment (J/(m°Cs))	3.59
Seawater Concentration (g/L)	35.0
Cooling-Canal Salt Concentration (g/L)	70.0

Table 5.2. Hydraulic Conductivity of the Model Layers (FPL 2015)

Layer Name	Horizontal Hydraulic Conductivity (cm/s)	Vertical Hydraulic Conductivity (cm/s)
Muck	0.0044	0.00044
Miami Limestone	0.088	0.00590
Upper High Flow Zone	30.0	3.700
Key Largo	5.90	0.740
Fort Thompson	0.33	0.033
Lower High Flow Zone	1.70	0.170

6.0 Initial and Boundary Conditions

The initial conditions for both the 2D and 3D simulations were obtained using a steady-state simulation with a Biscayne Bay hydraulic head of 0.2 m and a west boundary head of 1.05 m. The long-term (10,000 year) simulations yielded a typical salt intrusion front, extending below the CCS. For the subsequent hypersaline water infiltration simulations, the same boundary conditions as those proposed by Hughes et al. (2010) were used (Table 6.1) for hydraulic heads and temperature. Between the L-31E Canal and the west boundary, a no-flux boundary was established for the model surface without the consideration of spatial and temporal variations in local recharge. Instead, regional groundwater flow was assumed to enter solely from the west boundary.

Table 6.1. Overview of Imposed Boundary Condition for Hydraulic Head, Temperature, and Salt Concentration.

Feature	Hydraulic Head (m)	Temperature (°C)	Salt Concentration (g/L)
West Boundary	1.05	24.4	0
L-31E Canal	0.48	24.4	0
Interceptor Ditch	0.43	24.4	0
Discharge Canals	0.39	35.6	70
Return Canals	0.09	34.2	70
Biscayne Bay	0.20	28.2	35

7.0 Overview of the 2D and 3D Simulations

Overviews of the conducted 2D and 3D simulations are provided in Table 7.1 and Table 7.2, respectively. The 2D and 3D Base Case simulations involve a 25-year infiltration event of 70 g/L hypersaline water. Each sensitivity simulation has a duration of 40 years.

Table 7.1. Overview of 2D Sensitivity Simulations

Name	Variation with Base Case	Results Figures	Comments
2D-1	0 g/L salt concentration in CCS	8,4, 8.5, 8.6	Representative of freshwater.
2D-2	34 g/L salt concentration in CCS	8.7, 8.8, 8.9	Seawater concentration. Consistent with proposed freshening targets mentioned in Section 2.3 of the EIS.
2D-3	90 g/L salt concentration in CCS	8.10, 8.11, 8.12	Extreme hypersaline. No freshening.
2D-4	Head in CCS doubled	8.13, 8.14, 8.15	Potentiometric head increase in CCS. Increase consistent with freshening.
2D-5	Seawater rise in Biscayne Bay of 0.5 m over 40 years	8.16, 8.17, 8.18	Plausible sea level rise.
2D-6	Seawater rise in Biscayne Bay of 1.5 m over 40 years	8.19, 8.20, 8.21	Plausible sea level rise.
2D-7	Head in L-31E Canal increased by 0.5 m	8.22, 8.23, 8.24	Shallow hydraulic control of westward migration proposed by Miami-Dade County Department of Environmental Resources Management.
2D-8	Head at west boundary increased by 1.0 m	8.25, 8.6, 8.27	Rehydration of inland including Model Lands.
2D-9	Head at west boundary decreased by 1.0 m	8.28, 8.29, 8.30	Drought of inland and Model Lands.

Table 7.2. Overview of 3D Simulations

Name	Description	Results Figures
3D Base Case	86,400 gal/min divided evenly over three wells (RCW-1, RCW-2, and RCW-3). Wells operate 60 days per calendar year. Total system operation time 20 years. CCS operating with 70 g/L salt concentration.	9.1, 9.3
3D-1	As Base Case but no pumping	9.2, 9.3
Pumping Scenarios		
3D-2	As Base Case but with half the extraction rate (43,200 gal/min)	9.4
3D-3	As Base Case but with one-tenth of the extraction rate (8,640 gal/min)	9.5
3D-4	As Base Case but with 30 days per year of operation	9.6
3D-5	As Base Case but only two operational cycles during the first two years and no pumping afterwards	9.7
3D-6	As Base Case but with continuous pumping	9.8
Variations in Boundary Condition Scenarios		
3D-7	As Base Case but with 0.5 m elevated head in L-31E Canal	9.9, 9.10, 9.11
3D-8	As 3D-7 but without pumping	9.10b, 9.11
3D-9	As Base Case but with 1 m increased head at west boundary	9.12, 9.13a, 9.14
3D-10	As 3D-9 but without pumping	9.13b, 9.14
3D-11	As Base Case but with 1 m decreased head at west boundary	9.15, 9.16a, 9.17
3D-12	As 3D-11 but without pumping	9.16b, 9.17
3D-13	As Base Case but with 1.5 m sea level rise over 40 years	9.18, 9.19a, 9.20
3D-14	As 3D-13 but without pumping	9.19b, 9.20
3D-15	As Base Case but with 0.5 m sea level rise over 40 years	9.21, 9.22a, 9.23
3D-16	As 3D-15 but without pumping	9.22b, 9.23
Consideration on Remedial Pumping West of CCS		
3D-17	As Base Case but with 4 remediation wells continuously operating at 12,000,000 gal/day	9.24, 9.25
Scenarios after Aquifer Refreshing		
3D-18	Pumping after refreshing with 34 g/L salt water from CCS for 25 years. 86,400 gal/min divided evenly over three wells (RCW-1, RCW-2, and RCW-3). Total system time 20 years. CCS operating with 34 g/L salt concentration.	9.26
3D-19	As 3D-18 but without pumping.	9.27
3D-20	As 3D-18 but with 1.5 m sea level rise over 40 years	9.28
3D-21	As 3D-18 but with 1 m decreased head at west boundary, 1m increased head in CCS, and 1.5 m sea level rise over 40 years	9.29
3D-22	Initial conditions with pristine aquifer. CCS operating for 20 years with 34 g/L salt concentration. Pumping as in 3D-18.	9.30

EXECUTIVE SUMMARY

This environmental impact statement (EIS) presents the results of a U.S. Nuclear Regulatory Commission (NRC) environmental review of an application for a combined construction permit and operating license (combined license or COL) for two new nuclear reactor units at a proposed Turkey Point site in Miami-Dade County, Florida. The U.S. Army Corps of Engineers (USACE) participated in the preparation of the EIS as a cooperating agency and as a member of the review team, which consisted of the NRC staff, its contractor staff, and the USACE staff. The National Park Service (NPS) participated in the environmental review as a cooperating agency by providing special expertise for the areas in and around the adjacent national parks (Biscayne and Everglades National Parks). The NPS does not have a request to take any specific regulatory actions related to the proposed COLs before it. Due to this unique set of circumstances, all impact determinations made in this EIS should not be attributed to NPS, but only to the NRC and USACE (also referred to as the review team). The NPS's participation in connection with this EIS does not imply NPS concurrence.

Background

On June 30, 2009, the Florida Power & Light Company (FPL) submitted an application to the NRC for a combined construction permit and operating license (combined license or COL) for Turkey Point Units 6 and 7.

Upon acceptance of FPL's application, the NRC review team began the environmental review process by publishing a Notice of Intent to prepare an EIS and conduct scoping in the *Federal Register* on June 15, 2010. As part of this environmental review, the review team did the following:

- conducted public scoping meetings on July 15, 2010 in Homestead, Florida
- conducted a site visit of the proposed Units 6 and 7 plant area on the Turkey Point site in June 2010
- conducted visits to alternative sites in July 2010
- reviewed FPL's Environmental Report (ER)
- consulted with Tribal Nations and other agencies such as the U.S. Fish and Wildlife Service (FWS), Advisory Council on Historic Preservation, Florida Fish and Wildlife Conservation Commission, National Marine Fisheries Service, Miami-Dade Office of Historic and Archaeological Resources, and Florida Division of Historical Resources
- conducted the review following guidance set forth in NUREG-1555:
  - "Standard Review Plans for Environmental Reviews for Nuclear Power Plants
  - Supplement 1: Operating License Renewal"
- considered public comments received during the 60-day scoping process from June 15, 2010 to August 16, 2010

- conducted public meetings on the draft EIS on April 22, 2015, in Miami, Florida, and on April 23, 2015, in Homestead, Florida
- considered public comments received during the comment periods for the draft EIS, which extended from March 5 to May 22 and from May 28 to July 17, 2016.

Proposed Action

FPL initiated the proposed Federal action by submitting an application for Turkey Point Units 6 and 7 to the NRC. The NRC's Federal action is issuance of COLs for two Westinghouse AP1000 reactors at the Turkey Point site near Homestead, Florida.

The USACE is a cooperating agency in preparation of this EIS. The USACE's Federal action is its decision of whether to issue, deny, or issue with modifications a Department of Army (DA) permit pursuant to Section 404 of the Clean Water Act and Section 10 of the Rivers and Harbors Act of 1899 to authorize certain construction activities potentially affecting waters of the United States.(1)

Purpose and Need for Action

The purpose of the proposed NRC action, issuance of the COL, is to provide for additional baseload electric generating capacity for use in the FPL service territory.

The USACE determines both a basic and an overall project purpose pursuant to the Clean Water Act Section 404(b)(1) Guidelines, 33 CFR § 230.10. The basic purpose is to meet the public's need for electric energy. The overall purpose is to meet the public's need for reliable increased electrical baseload generating capacity in FPL's service territory.

Affected Environment

The Turkey Point site is located in southeast Miami-Dade County, Florida, near Homestead (Figure ES-1). Turkey Point Units 6 and 7 would be located on the same site as the existing Turkey Point site, which has five other power plants, including two nuclear power reactors. Turkey Point would be located 25 mi south of Miami and 4.5 and 8 mi east of Homestead and Florida City, respectively. The primary source of cooling water would be reclaimed wastewater and the alternative source would be saltwater supplied from radial collector wells beneath Biscayne Bay. The ultimate heat sink for Turkey Point Units 6 and 7 would be the atmosphere, using three mechanical draft cooling towers per reactor.

(1) Waters of the United States" is used to include both "waters of the United States" as defined by 33 CFR Part 328 (TN1683) defining the extent of USACE geographic jurisdiction pursuant to Section 404 of the Clean Water Act and "navigable waters of the United States" as defined by 33 CFR Part 329 (TN4770) defining the extent of USACE geographic jurisdiction pursuant to Section 10 of the Rivers and Harbors Act of 1899 (33 U.S.C. § 403) (TN4768).

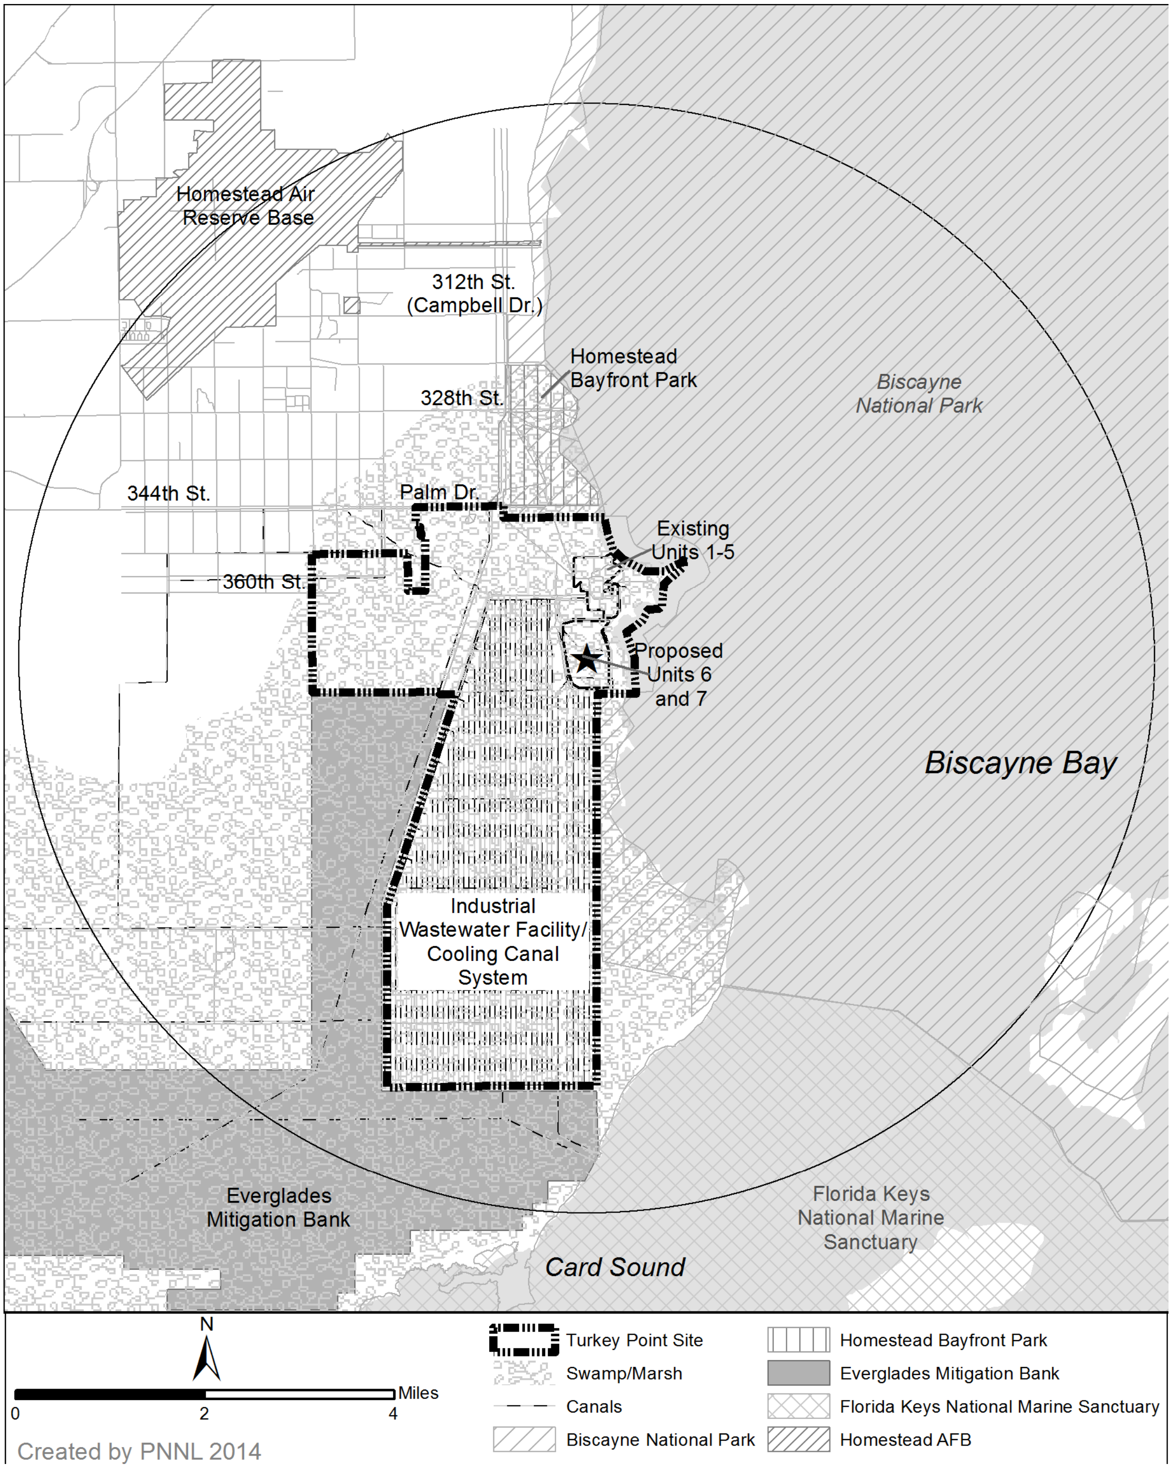

Figure ES-1. The Turkey Point Site and Affected Environment

Evaluation of Environmental Impacts

This EIS evaluates the potential environmental impacts of the construction and operation of the two new nuclear plants proposed for the Turkey Point site related to the following resource areas:

- land use
- air quality
- aquatic ecology
- terrestrial ecology
- surface and groundwater
- waste (radiological and nonradiological)
- human health (radiological and nonradiological)
- socioeconomics
- environmental justice
- cultural resources
- fuel cycle, decommissioning, and transportation

SMALL: Environmental effects are not detectable or are so minor that they will neither destabilize nor noticeably alter any important attribute of the resource.

MODERATE: Environmental effects are sufficient to alter noticeably, but not to destabilize, important attributes of the resource.

LARGE: Environmental effects are clearly noticeable and are sufficient to destabilize important attributes of the resource.

The impacts are designated as SMALL, MODERATE, or LARGE. The incremental impacts related to the construction and operations activities requiring NRC authorization are described and characterized, as are the cumulative impacts resulting from the proposed action when the effects are added to, or interact with, other past, present, and reasonably foreseeable future effects on the same resources. A summary of the construction and operation impacts are outlined in Table ES-1. Table ES-2 summarizes the review team's assessment of cumulative impacts. The review team's detailed analysis which supports the impact assessment of the proposed new units can be found in Chapters 4, 5, and 7, respectively.

Table ES-1. Environmental Impact Levels of the Proposed Turkey Point Units 6 and 7

Resource Category	Preconstruction and Construction	Operation
Land Use	MODERATE (NRC authorized construction impact level is SMALL)	MODERATE
Water-Related		
Water Use – Surface Water	SMALL	SMALL
Water Use – Groundwater Use	SMALL	SMALL
Water Quality – Surface Water	SMALL	SMALL
Water Quality – Groundwater	SMALL	SMALL
Ecology		
Terrestrial Ecosystems	MODERATE (NRC authorized construction impact level is SMALL)	MODERATE
Aquatic Ecosystems	SMALL to MODERATE	SMALL
Socioeconomic		
Physical Impacts	SMALL (adverse) to MODERATE (beneficial)	SMALL (adverse) to MODERATE (beneficial)
Demography	SMALL	SMALL
Economic Impacts on the Community	SMALL	SMALL and beneficial
Infrastructure and Community Services	SMALL to MODERATE	SMALL to MODERATE
Environmental Justice	NONE[a]	NONE[a]
Historic and Cultural Resources	MODERATE (NRC authorized construction impact level is SMALL)	SMALL
Air Quality	SMALL	SMALL
Nonradiological Health	SMALL	SMALL
Nonradiological Waste	SMALL	SMALL
Radiological Health	SMALL	SMALL
Postulated Accidents	n/a	SMALL
Fuel Cycle, Transportation, and Decommissioning	n/a	SMALL

(a) A determination of “NONE” for Environmental Justice analyses does not mean there are no adverse impacts to minority or low-income populations from the proposed project. Instead, an indication of “NONE” means that while there are adverse impacts, those impacts do not affect minority or low-income populations in any disproportionate manner, relative to the general population.

Table ES-2. Cumulative Impacts on Environmental Resources, Including the Impacts of Proposed Turkey Point Units 6 and 7

Resource Category	Impact Level
Land Use	MODERATE
Water-Related	
Water Use – Surface Water	SMALL
Water Use – Groundwater Use	SMALL
Water Quality – Surface Water	MODERATE
Water Quality – Groundwater	SMALL
Ecology	
Terrestrial Ecosystems	MODERATE to LARGE
Aquatic Ecosystems	MODERATE
Socioeconomic	
Physical Impacts	SMALL adverse to MODERATE beneficial
Demography	SMALL
Economic Impacts on the Community	SMALL and beneficial
Infrastructure and Community Services	SMALL to MODERATE
Environmental Justice	NONE[a]
Historic and Cultural Resources	MODERATE
Air Quality	SMALL to MODERATE for criteria pollutants and MODERATE for GHGs
Nonradiological Health	SMALL
Nonradiological Waste	SMALL
Radiological Health	SMALL
Postulated Accidents	SMALL
Fuel Cycle, Transportation, and Decommissioning	SMALL

(a) A determination of "NONE" for Environmental Justice analyses does not mean there are no adverse impacts to minority or low-income populations from the proposed project. Instead, an indication of "NONE" means that while there are adverse impacts, those impacts do not affect minority or low-income populations in any disproportionate manner, relative to the general population.

Alternatives

The review team considered the environmental impacts associated with alternatives to issuing a COL for the two new nuclear units proposed by FPL for the Turkey Point site. These alternatives included a no-action alternative (i.e., not issuing the COL) and alternative energy sources, siting locations, and system designs.

The no-action alternative would result in the COL not being granted or the USACE not issuing its permit. Upon such a denial, construction and operation of new units at the Turkey Point site would not occur and the predicted environmental impacts would not take place. If no other facility would be built or strategy implemented to take its place, the benefits of the additional electrical capacity and electricity generation to be provided would also not occur and the need for baseload power would not be met.

Based on the NRC staff's review of energy alternatives, the NRC staff concluded that, from an environmental perspective, none of the viable alternatives is environmentally preferable to building a new baseload nuclear power generation plant at the Turkey Point site. The NRC staff eliminated several energy sources (e.g., wind, solar, geothermal, and biomass) from full consideration because they are not currently capable of meeting the need of this project. None of the viable baseload alternatives (natural gas, coal, or a combination of alternatives) was environmentally preferable to the proposed Turkey Point units.

After comparing the cumulative effects of a new nuclear power plant at the proposed site against those at the alternative sites, the NRC staff concluded that none of the alternative sites would be environmentally preferable to the proposed site for building and operating a new nuclear power plant (Table ES-3). The four alternatives sites selected were as follows (Figure ES-2):

- Glades
- Martin
- Okeechobee 2
- St. Lucie.

Table ES-3. Comparison of Cumulative Impacts at the Turkey Point and Alternative Sites

Resource Category	Turkey Point Site[(a)]	Glades[(b)]	Martin[(b)]	Okeechobee 2[(b)]	St. Lucie[(b)]
Land Use	MODERATE	MODERATE	MODERATE	MODERATE	MODERATE
Water-Related					
Surface-water use	SMALL	MODERATE	MODERATE	MODERATE	SMALL
Groundwater use	SMALL	SMALL	SMALL	SMALL	SMALL
Surface-water quality	MODERATE	MODERATE	MODERATE	MODERATE	MODERATE
Groundwater quality	SMALL	SMALL	SMALL	SMALL	SMALL
Ecology					
Terrestrial and wetland ecosystems	MODERATE to LARGE	MODERATE	MODERATE	MODERATE	MODERATE
Aquatic ecosystems	MODERATE	MODERATE	MODERATE	MODERATE	SMALL to MODERATE
Socioeconomics					
Physical impacts	SMALL adverse except for MODERATE beneficial impacts on road quality	MODERATE adverse to SMALL beneficial impacts on road quality	MODERATE adverse to MODERATE beneficial impacts on road quality	MODERATE adverse to SMALL beneficial impacts on road quality	LARGE adverse to MODERATE beneficial impacts on road quality
Demography	SMALL	SMALL	SMALL	SMALL	SMALL, except for LARGE residential displacement impacts
Economic impacts on the community	SMALL and beneficial	SMALL and beneficial, except for LARGE and beneficial property tax revenues for Glades County and School District	SMALL and beneficial, except for MODERATE and beneficial property tax revenues for Martin County and School District	SMALL and beneficial, except for LARGE and beneficial property tax revenues for Okeechobee County and School District	SMALL and beneficial

Table ES-3. (contd)

Resource Category	Turkey Point Site[(a)]	Glades[(b)]	Martin[(b)]	Okeechobee 2[(b)]	St. Lucie[(b)]
Infrastructure and community services	SMALL except for MODERATE adverse impacts on traffic	SMALL except for MODERATE adverse impacts on traffic	SMALL except for MODERATE adverse impacts on traffic	SMALL except for MODERATE adverse impacts on traffic	SMALL except for MODERATE adverse impacts on traffic
Environmental Justice	None[(c)]	None[(c)]	None[(c)]	None[(c)]	None[(c)]
Historic and Cultural Resources	MODERATE	MODERATE	SMALL	MODERATE	SMALL
Air Quality					
Criteria pollutants	SMALL to MODERATE	SMALL	SMALL to MODERATE	SMALL to MODERATE	SMALL to MODERATE
Greenhouse gas emissions	MODERATE	MODERATE	MODERATE	MODERATE	MODERATE
Nonradiological Health	SMALL	SMALL	SMALL	SMALL	SMALL
Radiological Health	SMALL	SMALL	SMALL	SMALL	SMALL
Postulated Accidents	SMALL	SMALL	SMALL	SMALL	SMALL

(a) Cumulative impact determinations taken from EIS Table 7-3.
(b) Cumulative impact determinations taken from EIS Table 9-28.
(c) A determination of "NONE" for Environmental Justice analyses does not mean there are no adverse impacts on minority or low-income populations from the proposed project. Instead, an indication of "NONE" means that while there are adverse impacts, those impacts do not affect minority or low-income populations in any disproportionate manner, relative to the general population.

Table ES-3 provides a summary of the cumulative impacts for the proposed and alternative sites. The NRC staff concluded that all of the sites were generally comparable, and it would be difficult to state that one site is preferable to another from an environmental perspective. In such a case, the proposed site prevails because none of the alternatives is environmentally preferable to the proposed site.

Table ES-4 provides a summary of the EIS-derived impacts for a new nuclear power plant in comparison with the energy alternatives. The NRC staff concluded that none of the viable energy alternatives is preferable to construction of a new baseload nuclear power-generating plant located within FPL's region of interest.

The NRC staff considered various alternative systems designs, including seven alternative heat-dissipation systems and multiple alternative intake, discharge, and water-supply systems. The review team identified no alternatives that were environmentally preferable to the proposed Turkey Point Units 6 and 7 systems design.

Figure ES-2. Location of Sites Considered as Alternatives to the Turkey Point Site

Table ES-4. Summary of Environmental Impacts[(a)] of Construction and Operation of New Nuclear, Coal-Fired, and Natural-Gas–Fired Generating Units and a Combination of Alternatives

Impact Category	Nuclear	Coal[(b)]	Natural Gas[(b)]	Combination of Alternatives[(b)]
Land Use	MODERATE	MODERATE	MODERATE	MODERATE
Air Quality	SMALL	MODERATE	SMALL to MODERATE	SMALL to MODERATE
Water Use and Quality	SMALL	SMALL	SMALL	SMALL
Ecology	MODERATE	MODERATE	MODERATE	MODERATE
Waste Management	SMALL	MODERATE	SMALL	SMALL
Socioeconomics	MODERATE Beneficial to MODERATE Adverse	MODERATE Beneficial to MODERATE Adverse	MODERATE Beneficial to SMALL Adverse	MODERATE Beneficial to MODERATE Adverse
Human Health	SMALL	SMALL	SMALL	SMALL
Historic and Cultural Resources	MODERATE	MODERATE	MODERATE	MODERATE
Environmental Justice	NONE[(b)]	NONE[(b)]	NONE[(b)]	NONE[(b)]

(a) Impact levels for all alternatives are for construction and operation but do not reflect cumulative impacts. Thus, the nuclear impacts identified here may differ from those used to compare the proposed site to the alternative sites, which reflect cumulative impacts.
(b) Impacts taken from EIS Table 9-4. These conclusions for energy alternatives should be compared to NRC-authorized activities reflected in Chapters 4, 5, and Sections 6.1, and 6.2.
(c) A determination of "NONE" for Environmental Justice analyses does not mean there are no adverse impacts to minority or low-income populations from the proposed project. Instead, an indication of "NONE" means that while there are adverse impacts, those impacts do not affect minority or low-income populations in any disproportionate manner, relative to the general population.

Benefits and Costs

The NRC staff compiled and compared the pertinent analytical conclusions reached in the EIS. It gathered all of the expected impacts from building and operating proposed Turkey Point Units 6 and 7 and aggregated them into two final categories: (1) expected environmental costs and (2) expected benefits to be derived from approval of the proposed action. Although the analysis in Section 10.6 is conceptually similar to a purely economic benefit-cost analysis, which determines the net present dollar value of a given project, the purpose of the section is to identify potential societal benefits of the proposed activities and compare them to the potential internal (i.e., private) and external (i.e., societal) costs of the proposed activities. In general, the purpose is to inform the COL process by gathering and reviewing information that demonstrates the likelihood that the benefits of the proposed activities outweigh the aggregate costs.

On the basis of the assessments in this EIS, the building and operation of proposed Turkey Point Units 6 and 7, with mitigation measures identified by the review team, would accrue benefits that most likely would outweigh the economic, environmental, and social costs. For the NRC-proposed action (i.e., NRC-authorized construction and operation), the accrued benefits would also outweigh the costs of preconstruction, construction, and operation of proposed Turkey Point Units 6 and 7.

Public Involvement

A 60-day scoping period was held from June 15, 2010, to August 16, 2010. On July 15, 2010, the NRC held two public scoping meetings in Homestead, Florida. The review team received many oral comments during the public meetings and 32 e-mails and 10 letters throughout the rest of the scoping period on numerous topics including energy alternatives, terrestrial ecology, ground and surface water, and socioeconomics. The review team's response to the in-scope public comments can be found in Appendix D. The Scoping Summary Report (Agencywide Documents Access and Management System (ADAMS) Accession No. ML103130609) contains all of the comments, even those considered out-of-scope (e.g., security, safety issues).

During the initial 75-day comment period on the draft EIS, which began on March 6, 2015, the review team held public meetings in Miami, Florida, on April 22, 2015, and in Homestead, Florida, on April 23, 2015. During the course of the comment period, the NRC received requests from members of the public, a Tribal government, and Federal agencies to extend the comment period. In response to these requests, the NRC reopened the comment period on the draft EIS on May 28, 2015, until July 17, 2015, allowing additional time for public comments. In total, approximately 68 people provided oral comments at the public meetings held in April, and the NRC received approximately 11,300 pieces of correspondence during the original and reopened comment period.

Recommendation

The NRC's recommendation to the Commission related to the environmental aspects of the proposed action is that the COL should be issued.

This recommendation is based on the following:

- the application, including the ER, submitted by FPL
- consultation with Federal, State, Tribes, and local agencies
- site audits and alternative sites audits
- consideration of public comments received during the environmental review
- the review team's independent review and assessment summarized in this EIS.

The NRC's determination is independent of the USACE's determination of whether to issue, deny, or issue with modifications the DA permit application for the Turkey Point Units 6 and 7. The USACE will conclude its Clean Water Act Section 404(b)(1) Guidelines and public interest analyses in its Record of Decision.

5.0 OPERATIONAL IMPACTS AT THE TURKEY POINT SITE

This chapter examines environmental issues associated with the operation of proposed Units 6 and 7 at the Turkey Point Nuclear Power Plant (Turkey Point) site for an initial 40-year period as described by Florida Power & Light Company (FPL). As part of its application for combined construction permits and operating licenses (COLs), FPL submitted an Environmental Report (ER) that discussed the environmental impacts of plant operation (FPL 2014-TN4058). The U.S. Nuclear Regulatory Commission (NRC) staff, its contractor staff, and U.S. Army Corps of Engineers (USACE) staff (hereafter referred to as the "review team") independently evaluated information presented in FPL's ER (FPL 2014-TN4058) and supplemental documents, FPL responses to NRC Requests for Additional Information (RAIs), FPL's Site Certification Application (SCA) submitted to the Florida Department of Environmental Protection (FDEP) (FPL 2010-TN272), the FDEP review of the proposed project (State of Florida 2014-TN3637), USACE permitting documentation, as well as other government and independent sources.

This chapter is divided into 13 sections. Sections 5.1 through 5.11 discuss the potential operational impacts on land use, water, terrestrial and aquatic ecosystems, socioeconomics, environmental justice, historic and cultural resources, meteorology and air quality, nonradiological health, radiological health, nonradioactive waste, and postulated accidents. Section 5.12 discusses measures and controls that would limit the adverse impacts of station operation during the 40-year operating period. In accordance with Title 10 of the *Code of Federal Regulations* Part 51 (10 CFR Part 51) (TN250), impacts have been analyzed and a significance level of potential adverse impacts (i.e., SMALL, MODERATE, or LARGE) has been assigned by the review team to each impact category. In the area of socioeconomics related to taxes, the impacts may be considered beneficial and are stated as such, as appropriate. The review team's determination of significance levels is based on the assumption that the mitigation measures identified in the ER or activities planned by various State and County governments, such as infrastructure upgrades, as discussed throughout this chapter, are implemented. Failure to implement these upgrades might result in a change in significance level. Possible mitigation of adverse impacts is also presented, where appropriate. A summary of these impacts is presented in Section 5.13.

5.1 Land-Use Impacts

This section provides information about the land-use impacts associated with operation of proposed Units 6 and 7. Section 5.1.1 discusses land-use impacts at the site and in the vicinity. Section 5.1.2 discusses land-use impacts at offsite transmission line corridors and associated offsite facilities. Section 5.1.3 summarizes the land-use impacts.

5.1.1 The Site and Vicinity

The sections below address land-use impacts from operation of Units 6 and 7 facilities on the Turkey Point site and vicinity.

5.1.1.1 Onsite Land-Use Impacts

Permanent facilities in the 218 ac plant area would include the Units 6 and 7 power blocks, cooling towers and makeup-water reservoir, Clear Sky substation, and associated infrastructure (FPL 2014-TN4058). Outside of the plant area but still on the Turkey Point site, permanent facilities would include the FPL reclaimed water-treatment facility (RWTF), reclaimed water pipelines, radial collector wells (RCWs) and pipelines, nuclear administration and training buildings, parking areas, laydown areas, expanded equipment barge-unloading area, security buildings, heavy-haul road improvements, transmission infrastructure, sanitary-waste pipelines, potable-water supply pipelines, access road improvements, and the spoils areas. Table 4-1 lists each element of the proposed project and the land that would be dedicated to each. As noted in Section 4.1.1.1, the review team is assuming for purposes of analysis that all of the land dedicated to the project would be permanently dedicated.

Because the land dedicated to the project would remain occupied by plant-related facilities throughout the operational life of Units 6 and 7, the review team expects that the land dedicated to the project would not be available for unrelated land uses over that time. However, below-grade facilities such as pipelines may have only limited permanent land-use impacts, because they are underground and, in most places, the land at grade could be used for certain other unrelated uses (e.g., parking or storage). This is discussed in more detail below for specific facilities. FPL states that former construction laydown areas would be permanently dedicated to the project over its operational life and may be used during operations (FPL 2014-TN4058). The review team therefore assumes that these areas would not be available for non-project-related land uses throughout the operational life of Units 6 and 7.

Because the Units 6 and 7 facilities would be built mostly in previously undeveloped lands away from other concentrated areas of development, the review team expects that operation of the Units 6 and 7 and associated facilities would not affect or interfere with other land uses on the site or in the vicinity. Units 6 and 7 would be situated near other power-generation facilities (Units 1 through 5). Therefore, operation of the proposed new units would not represent a substantial change in land-use characteristics. While some land uses in the vicinity could be sensitive to the specific effects of the operation of a nuclear power plant, those effects are addressed in other sections of this environmental impact statement (EIS) related to aesthetics, recreation, and traffic (all in Section 5.4); salt deposition and fogging from cooling-tower operation (Section 5.7); and ecology (Section 5.3). These effects do not however suggest a potential for substantial land-use inconsistencies. As described in Section 2.2, land in the vicinity is predominantly wetlands and forestland (FPL 2014-TN4058) and includes several environmentally protected areas designated by the Miami-Dade County Comprehensive Development Master Plan (Miami-Dade County 2012-TN1150), as well as several areas of public land. The review team's evaluation of potential ecological impacts (Section 5.3) does not suggest any serious land-use conflicts with environmentally protected areas. Agricultural land composes approximately 4.5 percent (approximately 2,858 ac) of the land within the vicinity (Table 2-3). The review team expects because the proposed new facilities would be sufficiently isolated from these agricultural lands that would prevent substantial conflicts with nearby agricultural use.

Zoning and Consistency with Land-Use Plans

As addressed in Section 4.1, the Miami-Dade County Comprehensive Development Master Plan (Miami-Dade County 2012-TN1150) land-use designation for the location of proposed Units 6 and 7 is *Environmental Protection, Subarea F*. Electrical generation and transmission facilities are among the land uses described as being consistent with this designation.

The 218 ac plant area and most of the surrounding land on the Turkey Point site is zoned as GU (Interim District), with the exception of the land occupied by existing Turkey Point Units 1 through 5 and the area north of the plant area, which are zoned as IU-3 (Industrial, Unlimited Manufacturing District) areas. The GU zoning district allows for nuclear reactors, provided that approval by Miami-Dade County of an *Unusual Use* for the site is obtained. FPL applied for *Unusual Use* approval for Units 6 and 7 from Miami-Dade County, which was granted in Resolution No. Z-56-07 (Miami-Dade County 2007-TN1085) by the Miami-Dade Board of County Commissioners in December 2007. No additional changes to land use within the Turkey Point site are proposed or required for operation of Units 6 and 7.

Mineral Resources

As stated in Section 2.2, there are no known oil or gas wells or any sand or rock mining located within the Turkey Point site boundary. Thus, the review team finds that operation of the proposed project would cause no impacts on oil, gas, or mineral resources.

Prime and Unique Farmland

There is no prime or unique farmland, or farmland of State or local importance, as defined in the Farmland Protection Policy Act (7 U.S.C. § 4201 et seq.) (TN708) on the Turkey Point site (USDA 2012-TN1314). No impacts on special status farmland are therefore expected. Operational activities on the site are not expected to affect agricultural operations.

Coastal Zone Consistency

The Florida Coastal Management Act (Fla. Stat. 28-380-TN1147) authorizes the Coastal Zone Management Section of the FDEP to certify consistency with the Florida Coastal Management Program for all Federal licenses, permits, activities, and projects, when such activities affect land or water use. The Site Certification issued by the State of Florida on May 19, 2014 constitutes the State's concurrence that the licensed activity or use is consistent with the Federally approved program under the Florida Coastal Management Act.

Comprehensive Everglades Restoration Plan

Operating the Units 6 and 7 facilities after they are built is not expected to substantially interfere with the objectives or implementation of the CERP.

5.1.1.2 Pipelines

Land that would be used for the below-ground reclaimed water pipelines is identified in Figure 2-5 (FPL 2014-TN4058). Maintenance access by Miami-Dade County or FPL during operations would be accomplished on public roads or through access agreements with adjacent landowners. Because the pipelines would be easily accessible from roadways, maintenance and repair activities are not likely to interfere with adjacent land uses. Once built, the RCW caissons and pumping station would require periodic maintenance. Because these facilities would be located below ground, land uses of the offsite land area or Biscayne Bay would not be substantially affected. Impacts on other resources are addressed in other chapters of this EIS.

5.1.1.3 Access Roadways

As described in Section 3.3, the proposed project includes road improvements for operational access. The proposed improvements include widening three existing roadways and upgrading existing unpaved roads to establish new paved roadways (FPL 2014-TN4058).

FPL has indicated that roadway improvements installed during development of proposed Units 6 and 7 may not be needed for operations and could be removed to accommodate future land-use demands, although this is not specifically proposed (FPL 2014-TN4058). If roadway improvements were to be removed by FPL, FPL states that it would remove previous building materials, maintain historical hydrology, and regrade to previous contours (FPL 2014-TN4058).

5.1.2 Transmission Line Corridors and Associated Offsite Areas

5.1.2.1 Transmission Line Corridors

The following subsection addresses operations within the transmission line corridors and at substations.

The land proposed for use as transmission line corridors for proposed Units 6 and 7 is described in Section 2.2.2.

FPL has indicated that it would acquire land or easements as necessary to establish the proposed transmission line rights-of-way and would restrict incompatible uses in the rights-of-way during operation of the transmission lines (FPL 2014-TN4058). FPL requires that land uses in rights-of-way be compatible with the safe and reliable transmission of electricity. In areas that are in active agricultural cultivation, FPL typically allows farmers to grow feed for livestock and tree crops within the transmission line rights-of-way, subject to height limitations for vegetation and operation (FPL 2014-TN4058). FPL's standard rights-of-way vegetation management and line-maintenance programs would be followed to maintain the rights-of-way and transmission lines (FPL 2014-TN4058). These programs include requirements for use of herbicide application according to Federal, State, and local regulations. In addition, FPL states that environmental Best Management Practices (BMPs) would be used to reduce soil erosion and sedimentation, and that vegetation management in forested wetlands would comply with Fla. Stat. 29-403.814-TN1259, General Permits.

Local communities have raised concerns about the visual impacts and potential indirect blight impacts as a result of FPL's proposed location of the transmission lines (State of Florida 2012-TN1248; State of Florida 2011-TN1260; State of Florida 2011-TN1261). In addition, the National Park Service (NPS) has expressed concerns about aesthetics and land-use effects of locating transmission lines near the Everglades National Park (NRC 2010-TN516).

During scoping for this EIS, local agencies expressed concerns about potential interference with local agency radio operations. While effects are largely dependent on tower height and signal frequency, because all radio frequencies in the FM range are higher than the frequency emitted by the lines and because the effect would diminish very quickly with distance, interference would be unlikely to occur (Exponent 2012-TN3710).

5.1.2.2 Substations

As described in Section 4.1, FPL has stated that building and/or expansion of several substations would meet applicable environmental regulatory requirements for their development and operation. Thus, the review team finds that operation of the proposed expanded substations (the Turkey Point, Levee, Davis, and Pennsuco substations) would be compatible with existing land uses near the substations (power generation, tree nurseries, and rock quarries).

5.1.3 Summary of Land-Use Impacts

The effects on land-use resulting from operation of proposed Turkey Point Units 6 and 7 would be minimal because the land to be used for operations is land that has been previously disturbed to build the new facilities. Operation and maintenance of permanent site-access roadways and pipelines would be compatible with the current land uses and would not affect any existing or planned land uses.

Operation and maintenance of transmission lines would also be generally compatible with the current land uses and would not affect any existing or planned land uses. However, Miami-Dade County and cities within the county have raised issues related to the aesthetic compatibility of parts of the proposed new transmission lines with some urban areas. In addition, NPS has raised compatibility questions regarding where parts of the proposed transmission lines would be situated close to or adjacent to Everglades National Park.

Based on information provided by FPL and the review team's independent review, the review team concludes that the land-use impacts associated with operation of Units 6 and 7 would be MODERATE. The MODERATE conclusion primarily reflects the compatibility of portions of the transmission lines with adjacent land uses.

5.2 Water-Related Impacts

This section discusses water-related impacts on the surrounding environment from operation of proposed Turkey Point Units 6 and 7. Details of the operational modes and cooling-water systems associated with operation of the proposed units are discussed in Section 3.2.2.2.

Managing water resources requires understanding and balancing the tradeoffs between various, often conflicting, designated uses. At the site of the proposed Turkey Point Units 6 and 7, FDEP designates Biscayne National Park as an Outstanding Florida Water, meaning there is to be no degradation of its water quality (FDEP 62-302.400(14) and FDEP 62-302.700(9)(a)1) (Fla. Admin. Code 62-302-TN776). The canals in the area (constructed before November 28, 1975) are evaluated based on the limited aquatic life support and habitat limits of these waters (FDEP 62-302.400(4) [TN776]). The designated uses include navigation, recreation, visual aesthetics, fisheries, and consumptive water uses. The responsibility for any work in, over, or under navigable waters of the United States is delegated to the USACE. The FDEP is responsible for protecting and restoring the quality of Florida water, air, and land resources, and the Florida Department of Community Affairs is responsible for determining that projects are consistent with Florida's Coastal Management Program (FDEP 2012-TN1544).

Water-use and water-quality impacts involved with operation of a nuclear plant are similar to the impacts associated with the operation of any large thermoelectric power-generation facility. Accordingly, FPL must obtain the same water-related permits and certifications as any other large industrial facility. These include the following:

- Clean Water Act (CWA) (33 U.S.C. § 1251 et seq.) (TN662) - Section 401 is at 33 U.S.C. § 1341 (TN4764) Certification. This certification is issued by the FDEP as part of Florida's Power Plant Siting Act Certification (Fla. Stat. 29-403.501 2011-TN1068) and ensures that the project does not conflict with State water-quality standards. This certification is required before the NRC can issue a COL to FPL. Florida issued the final Order of Certification on May 19, 2014 (State of Florida 2014-TN3637). If a Department of the Army permit is issued, the 401 Water Quality Certification would be required in addition to a Coastal Zone Consistency Determination both of which are provided by the State of Florida.
- Department of the Army Permit. Authorization from the USACE would be required under CWA Section 404 (33 U.S.C. § 1344) (TN1019) for the discharge of dredge or fill material into waters of the United States associated with the site-preparation activities and construction of the nuclear power plant and its associated components. Authorization would also be required under Section 10 of the Rivers and Harbors Act of 1899 (33 U.S.C. § 403) (TN4768) for the construction of structures or work in, under, or over navigable waters of the United States associated with the construction of the nuclear power plant and its associated components. The USACE will conclude its Clean Water Act Section 404(b)(1) Guidelines and public interest analysis for this permit decision in its Record of Decision. Furthermore, Section 14 of the Rivers and Harbors Act (33 U.S.C. § 408) (TN4769) requires authorization for any components of the project that would in any way impair the usefulness of a USACE Civil Works Project; a separate 408 review will be conducted to ensure the will be no inconsistency with the intended use that was authorized by Congress.
- Clean Water Act (33 U.S.C. § 1251 et seq.) (TN662) - Section 402 is at 33 U.S.C. § 1342 (TN4765) National Pollutant Discharge Elimination System (NPDES) permit. This permit would regulate limits of pollutants in liquid discharges to surface water. The U.S. Environmental Protection Agency (EPA) has delegated the authority for administering the NPDES program in Florida to the FDEP. The NPDES permits are part of Power Plant Siting Act certification. A stormwater pollution prevention plan (SWPPP) for construction would also be required.
- Water-use permit. Consumptive use of surface water or groundwater would require a permit from the FDEP or the water-management district.
- Groundwater well drilling and operating permits. Construction of water wells would require a permit from the South Florida Water Management District (SFWMD).
- FDEP Class I Industrial Waste Underground Injection Control Permits (Fla. Admin. Code 62-528-TN556). Underground Injection Control (UIC) wells are required to be constructed,

maintained, and operated so that the injected fluid remains in the injection zone, and the unapproved interchange of water between aquifers is prohibited. Class I injection wells are monitored so that if migration of injection fluids were to occur it would be detected before reaching the underground source of drinking water (USDW).

5.2.1 Hydrological Alterations

The staff assessed the following potential hydrological alterations associated with the operation of Units 6 and 7 and the resulting effects on the environment:

- Operation of RCWs under Biscayne Bay for use as a backup supply of cooling water that would remove water from Biscayne Bay, the industrial wastewater facility (IWF), and the Biscayne aquifer.
- Use of potable and service water for the proposed units that would be obtained from the existing Miami-Dade Water and Sewer Department (MDWASD) water supply, which comes from the Biscayne aquifer in Miami-Dade County.
- Injection of station blowdown water and other liquid waste streams into the Boulder Zone—a cavernous, high-permeability South Florida geologic horizon located at depths of approximately 2,900 to 3,500 ft in the Lower Floridan aquifer.
- Deposition of drift from Units 6 and 7 cooling towers, including associated salt and chemical contaminants, onto nearby aquatic and terrestrial systems. With the use of reclaimed water as the cooling-tower water supply, chemical contaminants could be present in the cooling-tower water and drift. With the use of the Biscayne Bay as a backup supply of water (via the RCWs), salt deposition could occur on terrestrial and aquatic systems.
- Stormwater runoff from buildings, pavement, and RWTFs, and accompanying changes in the quality of runoff water from the spoils disposal area.

The following water resources are of primary interest for the review of hydrologic alterations:

- Biscayne Bay;
- Biscayne aquifer;
- Boulder Zone;
- IWF (cooling canals); and
- water resources on offsite/adjacent areas.

In the summer of 2014, the IWF experienced elevated temperatures, elevated salinities, elevated algae, and decreased water-surface elevations (see Section 2.3.1.1, Industrial Wastewater Facility). As discussed in Section 2.3.1.1, in response to these changes water was pumped into the canals from the Biscayne aquifer, Upper Floridan aquifer (also called the UFA), and the L-31E Canal. Continued actions are planned and the review team considered the consequence of the possible changes for the future affected environment.

The staff determined the only plausible change to the draft EIS impact assessment would be from the operation of the RCW. The review team identified no plausible significant changes in impacts from the operation of Units 6 and 7 under reclaimed water operation because the operation does not withdraw water from the Upper Floridan aquifer, the Biscayne aquifer, or

Biscayne Bay. As discussed Section 3.1, the AP1000 reactor design does not rely on either the reclaimed water supply or the RCWs to shut down safely.

Neither the conditions observed in the IWF in the summer of 2014 nor the subsequent response by FPL changed the review team's understanding of the current affected environment. However, future plans (see Section 2.3.1.1, Industrial Wastewater Facility) would change the affected environment in ways that were not explicitly discussed in the draft EIS. For instance, continued freshening of the cooling canals with water from wells in the Upper Floridan aquifer and the Biscayne aquifer, and withdrawals from the L-31E Canal may result in a sustained higher water-surface elevation and lower salinity in the IWF than observed during 2014 through 2015. In addition, efforts to retract the hypersaline plume to beneath FPL's property boundary would alter water pressures in the Biscayne aquifer and result in a general reduction of the salinity of groundwater in the Biscayne aquifer on the Turkey Point site.

Neither the exact design of systems for implementing either of the above actions nor their efficacy is fully known. Therefore, the review team considered a broad range of future conditions to determine if they might change the minimal incremental impact of the operation of the RCWs discussed in the EIS. The review team evaluated the hydrological alterations and their potential effects on the above-mentioned resources as discussed below.

5.2.1.1 Biscayne Bay

Hydrological alterations that may affect Biscayne Bay due to the operation of proposed Turkey Point Units 6 and 7 include (1) RCW operation, (2) drift deposition, and (3) stormwater runoff.

Effect of Radial Collector Well

To evaluate the effect of RCW pumping on salinity in Biscayne Bay, the U.S. Geological Survey (USGS), in conjunction with NRC conducted a numerical modeling study of the Biscayne Bay-Biscayne aquifer system (NRC 2014-TN3078; Appendix G). The model used for this study is a three-dimensional surface and groundwater model and was derived from a previously developed and calibrated model of the Biscayne aquifer and Biscayne Bay (Lohmann et al. 2012-TN1429). The NRC contracted with the USGS to modify the model to include the proposed RCWs, the IWF, and a dewatering well used during the building of proposed Units 6 and 7. The model incorporates tidal exchange with the Atlantic Ocean and freshwater inflows from canals and groundwater. The model was calibrated to groundwater heads, canal base flows, and the location of the saltwater-freshwater interface, salinity, and temperature in Biscayne Bay. The calibration period covered a 9-year simulation period from 1996 through 2004. The USGS prepared an administrative report (NRC 2014-TN3078) that documents the modeling analysis, which includes the effects of operating the RCW pumping on the surface and groundwater system. The review team summarized this administrative report, which is provided in Appendix G of this EIS.

The base case and all scenario model runs were made for a simulation period from 1996 through 2004 (the calibration period), during which time the effects of RCW pumping were examined via the differences in results for piezometric head and salinity. The base case was derived from the calibrated model with the addition of the cooling canals of the IWF and the wells used for dewatering of the plant area during building. The two dewatering wells were set to pump for a 6-month period (June 2001 through December 2001 of the simulation period) with a maximum pumping rate of 98,320 m^3/d) (9,128 gpm). The scenarios were derived from the base case with the addition of the RCWs. The USGS analysis (NRC 2014-TN3078) examined several RCW pumping scenarios, but the review team used the continuous-pumping scenario for its examination because it provided the most conservative analysis of the effects of the RCW operations. Continuous pumping is the most conservative scenario because it allows no time for the groundwater system to recover from RCW pumping.

Much of the assessment of RCW pumping used by the review team was based on the salinity time-series analyses provided by the USGS analysis of model results (NRC 2014-TN3078). However, the review team conducted additional analyses of the model results, which included examination of salinity time series at locations in Biscayne Bay in addition to those examined by the USGS (NRC 2014-TN3078). These additional locations were close to and north of Turkey Point (Appendix G, Figure G-5). The review team was also interested in examining the spatial distribution of salinity and salinity differences in Biscayne Bay produced by RCW pumping. The review team selected two dates that had either a relatively large salinity increase or a relatively large salinity decrease between the continuous-pumping scenario and the base case. The relatively large salinity increase occurred on 10/3/2003, while the relatively large salinity decrease occurred on 10/25/2004. The plot of the time series of salinity differences shown in Figure G-9 in Appendix G indicates these dates.

The review team's examination of salinity time series indicated that the salinity difference between the continuous pumping scenario and the base case was mostly within ±1 psu, with only transient increases to near 2 psu (Appendix G, Figure G-9). The review team examined the spatial distribution results on the date of a large increase (10/3/2003) and found the largest increases were less than about +2.3 psu. Also, the salinity increases greater than +1 psu occurred in a relatively small area (14.4 km^2 [5.57 mi^2]) located north of Turkey Point (Appendix G, Figure G-8); the maximum salinity within this area was about 30.8 psu. The review team examined the spatial distribution results on a date of a large salinity decrease and found salinity decreases less than -1 psu occurred in an area that was 24.2 km^2 (9.33 mi^2) in size located north of Turkey Point (Appendix G, Figure G-10); the maximum salinity within this area was about 31.8 psu. Overall, these results show that the temporal and spatial variation of salinity with continuous RCW pumping was minimal. The review team notes that the actual duration of pumping will not be continuous. As required by the FDEP Conditions of Certification (COCs; State of Florida 2014-TN3637), operation of the radial wells is to be limited to 60 days or less per year. This short duration of pumping will allow time for the groundwater system to recover after any pumping from the RCW and will limit the entrainment of saltwater and reduce alterations of salinity patterns within Biscayne Bay. Therefore, the effect on Biscayne Bay salinity of any permitted pumping would be much reduced from the already minimal salinity change found by the review team in the USGS modeling analyses for a continuous-pumping scenario. The NRC staff is aware that on April 20, 2016, a Florida court, (State of Florida 2016-TN4781) remanded the Conditions of Certification to the Florida Siting Board insofar as the COCs relate to proposed transmission lines and associated mitigation measures in the East Everglades. The remand, however, did not require reconsideration of the COCs related to operation of the RCWs. Accordingly, the original COC limiting RCW operation to 60 days per year remains undisturbed. Even if the COCs related to RCW operation are revisited, the review team considers it reasonable to expect that Conditions of Certification similar to or no less effective than those originally issued in regard to RCW operation will be in place before construction and operation of the proposed units begins.

Effect of Drift Deposition

While using treated reclaimed water as the source for makeup water, FPL would operate the cooling system to achieve four cycles of concentration (FPL 2014-TN4058). While using the RCWs (Biscayne Bay saltwater) as the source for makeup water, the system would operate at 1.5 cycles of concentration. Any residual contaminants in the treated reclaimed water and the chemical constituents of saltwater could be concentrated in the cooling-water system due to evaporative losses during cooling, although any individual contaminant could also have losses due to volatilization and environmental decay, thereby decreasing the concentration.

Small droplets of water (drift) and salt particles would be emitted from the cooling towers during operation. For the Turkey Point Units 6 and 7 combined drift rate from the circulating-water system and service-water system towers the expected maximum drift rate would be approximately 8 gpm (Table 3-6). As a result, salt along with any potential contaminants in the cooling water could be deposited on the area surrounding the cooling towers. When using treated reclaimed water for makeup water, priority pollutants and contaminants of emerging concern (CECs) could be contained in the drift. When using the RCWs, priority pollutants contained in seawater could occur in drift. Section 2.3.3.1 lists concentrations of contaminants that were detected in Biscayne Bay.

The review team has conducted analyses to estimate drift deposition of chemical contaminants on aquatic and terrestrial habitats. Four general categories of chemical constituents are included in the drift-deposition analysis: general water chemistry (e.g., total dissolved solids [TDS]), metals (e.g., copper), volatile organic compounds (VOCs; e.g., 1,4-dichlorobenzene), and CECs (e.g., 4-nonylphenol). The constituent TDS concentration increases in the cooling water by evaporation due to operation of the cooling towers. The high concentration of TDS in the cooling water results in drift with a high concentration of TDS. Evaporation of the water in the drift results in salt particles, which are deposited in the area surrounding the cooling towers. The other constituents (metals, VOCs, and CECs) are assumed to be carried with the drift particles in the same ratio as in the source water.

The EPA (2012-TN1018) identifies CECs as previously undetected chemicals in water or chemicals that are detected at concentrations different than expected, and for which human health and environmental risks are unknown or poorly known.

The estimated drift-deposition rates are used for determining aquatic and terrestrial ecological effects. The specific habitats examined include the cooling canals of the IWF, nearshore Biscayne Bay, and terrestrial areas west of the proposed Units 6 and 7 cooling towers. The potential concern for the cooling canals, while not a water body regulated for water quality, is related to the potential impact on the Federally protected crocodiles, which nest on the cooling-canal berms at several locations at the IWF. For Biscayne Bay, the concern relates to the designation by FDEP of Biscayne National Park as an Outstanding Florida Water (FDEP 2010-TN156).

The review team independently estimated drift deposition with the use of makeup water from reclaimed water and from Biscayne Bay water. Drift deposition is determined by the flow rate through the cooling towers and TDS concentration of the cooling water—higher TDS concentration produces higher deposition rates. The review team used the CALPUFF model to independently compute drift-deposition rates from the cooling towers. Using the total drift deposition of salt computed from CALPUFF for both reclaimed wastewater and Biscayne Bay marine water, the review team estimated the salt deposition and the associated drift deposition for representative chemical contaminants. The review team assumed that the ratio of contaminant concentration to TDS concentration was the same in the cooling-tower water as it was in the makeup water supplied by Miami-Dade County to FPL, including an adjustment for cycles of concentration. This conservative approach assumes no loss of contaminants via removal at FPL's RWTF, biodegradation, or volatilization. This conservative approach provides the worst case of loading via drift deposition from the cooling towers. It includes the assumption of increased concentration with increased cycles of concentration.

The TDS for makeup water derived from the reclaimed water source is expected to be 680 mg/L, which the review team calculated from Miami-Dade wastewater TDS concentrations and then assumed four cycles of concentration for estimating the drift concentrations. For saltwater, the makeup-water TDS concentration used was approximately 34,300 mg/L (FPL 2012-TN263) with a drift concentration assuming 1.5 cycles of concentration. The review team assumed there was no alteration of salinity from treatment.

To evaluate the potential effects of cooling-tower deposition on the aquatic resources of Biscayne Bay, the review team first performed a screening-level assessment to identify chemicals and constituents likely to occur at ecologically relevant concentrations in both reclaimed water and Biscayne Bay seawater obtained from the RCW system. As stated above, four general categories of chemical constituents were included in the initial screen: general water chemistry (e.g., TDS), metals (e.g., copper), organic compounds (e.g., 1,4-Dichlorobenzene, phenanthrene), and CECs) commonly found in pharmaceuticals, personal care products, and other consumer products. Likely concentrations in reclaimed water and Biscayne Bay seawater were obtained from technical data provided by FPL (2012-TN263), a study by Lietz and Meyer (2006-TN1005) on CECs from the Miami-Dade South District Wastewater Treatment Plant (SDWWTP), and information available in a 2011 study by the Biscayne Bay Coastal Wetlands Rehydration Pilot Project (Miami-Dade County 2011-TN1006). Detected concentrations of general water chemistry parameters (Section 2.3.3.1), organic compounds, and metals were compared to existing EPA freshwater and marine water-quality criteria, which are readily available for many compounds and believed to be protective of aquatic life. Compounds exceeding established water-quality criteria were retained in the screening-level assessment for fate and effects modeling. For chemicals lacking established water-quality criteria, such as many CECs, detected concentrations in reclaimed or Biscayne Bay water were compared to toxicological benchmarks available on EPA's ECOTOX (Ecotoxicology) Database (EPA 2012-TN1525). Chemicals present at >1/10 of a benchmark were retained in the screen and included in fate and effects modeling, as described in Section 5.3.2. Table 5-1 presents the review team's estimated drift-deposition rates for these compounds for three separate areas: the cooling canals of the IWF, adjacent areas west of the IWF, and Biscayne Bay. Compounds included for fate and effects analysis in the cooling canals included nine CECs and one metal. Constituents identified in Biscayne Bay seawater at levels above EPA criteria included only chlorides and sulfides. Areas west of the IWF were examined only for deposition rate and are considered in terrestrial ecology sections (Section 5.3.1).

Table 5-1. Estimated Annual Average Deposition Rates from Cooling-Tower Drift

Constituent Concentrations			Review Team-Estimated Annual Average Drift-Deposition Rates		
Constituent	**Category**	**Concentration (μg/L)**	**Cooling Canals (g/m^2-yr)**	**Western Areas/Model Lands (g/m^2-yr)**	**Biscayne Bay (g/m^2-yr)**
Reclaimed Water					
TDS	Wastewater	680,000[(a)]	0.34	0.18	0.082
1,4-Dichlorobenzene	Insect repellant	1.3[(a)]	6.6×10^{-7}	3.4×10^{-7}	1.6×10^{-7}
3 Beta-coprostanol	Human digestion	2[(b)]	1.0×10^{-6}	5.2×10^{-7}	2.4×10^{-7}
4-Nonylphenol	Detergent metabolite	4[(b)]	2.0×10^{-6}	1.0×10^{-6}	4.8×10^{-7}
Acetyl-hexamethyl-tetrahydro-naphthalene (AHTN)	Polycyclic musk (e.g., tonalide)	4[(b)]	2.0×10^{-6}	1.0×10^{-6}	4.8×10^{-7}

The salt-deposition rates over the nearshore of Biscayne Bay are lower with the use of reclaimed water (0.0069 $g/m^2/mo$) than with the use of marine waters for Biscayne Bay obtained from the RCWs (0.1292 $g/m^2/mo$). With the use of either the reclaimed water or RCWs, the deposition rates of potentially associated chemical contaminants are extremely low. Only TDS, chloride, and sulfide have deposition rates greater than 10^{-6} $g/m^2/mo$, and chloride and sulfide naturally occur in marine waters.

The review team considered the impact of contaminant drift deposition on Biscayne Bay by first examining the volumetric tidal exchange in the nearshore region of the Turkey Point site. The review team used the tidal elevation data from the Virginia Key station (NOAA 2012-TN1321) to compute the tidal range and volume change over the drift-deposition area in the CALPUFF model. (Because other National Oceanographic and Atmospheric Administration stations within Biscayne Bay had only limited historic data, they were not used.) The review team computed the average depth in this region to be 1.24 m and the median tidal range to be about 0.6 m. Using this tidal range and the computed volume in the nearshore region potentially affected by drift deposition, the review team calculated a median volumetric tidal exchange of 48 percent of the total nearshore volume. This means that almost half the volume is exchanged with each turn of the tide. Consequently, with the extremely low contaminant-deposition rates (Table 5-1) and high tidal exchange rate, contaminant concentrations from drift deposition in the water column would be too small to detect.

Effect of Stormwater Runoff

The site hydrology prior to construction is discussed in Section 2.3.1.1. Modifications to the land surface made during preconstruction and construction activities would alter the site hydrology, and these alterations would remain during plant operations. As discussed in Section 4.2.1.4, stormwater runoff from spoils areas, and nuclear administration and training buildings areas would be managed with environmental controls and directed to the IWF. Stormwater runoff from the RWTF area, except for the equipment area runoff, would be routed to stormwater management basins before being released to its surrounding wetland area. As discussed in Section 3.2.2.1, no direct stormwater discharges would be made to Biscayne Bay. Therefore, during operations, no noticeable effect of stormwater runoff in the hydrologic conditions of the Biscayne Bay is expected.

5.2.1.2 Biscayne Aquifer

Hydrological alterations affecting Biscayne aquifer that would be associated with the operation of Turkey Point Units 6 and 7 are the RCWs removing water from the aquifer beneath Biscayne Bay, and the additional demand for MDSWD-supplied potable water to meet the need for process and potable water. Removal of water by the RCWs is expected to (1) increase the velocity of water movement from the bay into the bed of the bay, (2) reduce aquifer hydraulic head within the aquifer under the bay, (3) influence aquifer hydraulic gradients in the vicinity of the hypersaline plume, and (4) change the water chemistry in sediments between the bay floor and the radial well laterals by increasing the flow of oxygenated water. These alterations to the groundwater flow system are described below.

Changes in the Velocity of Water Movement into the Bed of Biscayne Bay from Operation of the Radial Collector Wells

Water pumped by the RCWs will be drawn downward through the sediment and rock formations underlying Biscayne Bay and laterally through the more permeable zone where the well laterals are installed. The review team calculated that the vertical velocity of saltwater approaching the bay bottom would average 0.0003 ft/min (0.000152 cm/sec) or about 0.4 ft/d if all of the pumped water flowed homogeneously into the bay bottom within a polygon encircling the RCW laterals at the expected maximum flow rate of 86,400 gpm (327 m^3/min) (FPL 2014-TN4058). This assumption is conservative in that a large portion of the water is expected to move into the aquifer through the bay floor outside of the polygon and then move laterally through the aquifer to the wells. The review team estimated that the average vertical permeability of the aquifer confining layer is about 0.7 ft/d compared to 10,000 ft/d for the highly permeable portion of the aquifer (see Section 2.3 of the EIS). However, the approach velocity will vary laterally across the bay floor because of variations in the vertical permeability of the sediment and limestone that lie between the bay bottom and the permeable layer of the aquifer where the radial collector laterals will be placed. The review team analyzed a possible worst-case scenario for approach velocity by assuming that an enhanced vertical permeability flow path exists near the RCW laterals with a permeability of 1,000 ft/d, which is 1,428 times higher than the average vertical permeability. This results in a calculated maximum approach velocity of 0.43 ft/min at the enhanced vertical permeability feature. In reality, water pumped by the RCWs would likely infiltrate the bay bottom over a much larger area resulting in lower velocities.

Changes in Aquifer Hydraulic Head from Operation of the Radial Collector Wells

The RCWs installed under Biscayne Bay would pump saline groundwater from the Biscayne aquifer at a depth between 25 and 40 ft beneath the bay floor (Section 3.2.2). The review team determined that this pumping would reduce hydraulic head in the Biscayne aquifer resulting in flow of water from the overlying bay and from relatively permeable sediment layers that compose the Biscayne aquifer. Impacts on the inland portion of Biscayne aquifer are determined by the volume of water captured by the RCWs that comes from the inland portion of the aquifer compared to the volume that comes from the bay. Removing relatively large volumes of water from the inland aquifer could lower the water table in the inland portion of the aquifer, affecting existing water-supply wells and increasing saltwater intrusion to the Biscayne aquifer.

In regard to the Biscayne aquifer, saltwater from the sea has already intruded into the groundwater in the Biscayne aquifer in the vicinity of the Turkey Point site, which has resulted in elevated salinity in that groundwater. This saltwater intrusion from the sea is unrelated to operations at Turkey Point. Because of its elevated salinity, groundwater from the Biscayne aquifer in the vicinity of the Turkey Point site cannot be used as a drinking water source without treatment. Seepage of saline water from the IWF cooling canals associated with the existing Turkey Point Units 3 and 4 has also resulted in locally higher groundwater salinity near the cooling canals. Analyses from the USGS groundwater-surface water model presented in the EIS show that in the absence of remediation of the IWF hypersaline plume, increases in groundwater salinity may occur inland from Turkey Point because of movement of the existing hypersaline plume regardless of whether or not the proposed units are built and operated. The model-predicted increase in groundwater salinity is not caused by RCW pumping or other activities related to the proposed units. The model-predicted increase in groundwater salinity also does not reach the location of drinking water wells.

The review team determined that RCW drawdown effects are unlikely in the inland areas west and south of the IWF because the IWF cooling canals, the interceptor ditch, and the L-31E canal create hydraulic barriers that isolate the inland Biscayne aquifer from the RCWs. Effects on saltwater intrusion and inland wells in the Biscayne aquifer would also be reduced by the limitations on use of the RCWs, which is expected to be limited to 60 days per year, or less (FPL 2012-TN1262; State of Florida 2014-TN3637). The review team evaluated information about the reliability of the components of the reclaimed water system and determined that the RCW supply system would be called into use infrequently and for durations much shorter than 60 days. The NRC review team determined that there is a large volume of treated municipal wastewater that can be used for cooling the proposed plants without affecting the ability to meet demands for fresh water. Miami Dade Water and Sewer Department is required to direct 60 percent of the wastewater flows to reuse by 2025 and to cease using ocean outfalls by 2025 under the Florida State Ocean Outfall Legislation Compliance Plan (Miami Dade County 2013-TN4786). Therefore, the NRC staff concluded that the reclaimed water supply is reliable. The review team further determined that the primary reclaimed water source is reliable because of the reliability of the proposed reclaimed water-treatment facility and associated pipelines. Further, the review team also considered alternative sources of cooling water in EIS Section 9.4.2, none of which are environmentally preferable to the proposed sources of cooling water. In view of the high reliability of the reclaimed wastewater source and the availability of the RCW system as a backup, there is no need to consider additional backup sources of cooling water. If the RCWs are needed for a backup supply of water, the maximum pumping rate would be 86,400 gpm (327 m^3/min) (FPL 2014-TN4058). The minimum volume expected to be pumped per year for RCW maintenance and testing purposes would be a total of 40,000 gal (151.4 m^3).

The RCWs are designed so that nearly all the water comes from Biscayne Bay rather than from the inland aquifer because of the location of the RCW laterals a relatively short distance beneath the bay. However, the review team determined that the volume of water that would be removed from the inland aquifer is difficult to predict with certainty because it depends on several hydrogeologic features and parameters that are incompletely quantified. Water flowing to the RCWs from the bay must move through the bay floor or through permeable layers of the limestone bedrock exposed to seawater, either in the bay or at the continental shelf. As described in Section 2.3 the bottom of the bay consists of either sandy material, exposed rock, or a sandy muck. Areas of sand or sandy muck are usually signified by the presence of seagrass. However, the review team has observed that silty sediments are present in some areas of the Biscayne Bay floor near the proposed RCW location. These silty sediments could impede the downward flow of water from the bay to the laterals.

FPL used a local-scale groundwater flow model of the Biscayne aquifer to simulate the effects of construction dewatering and operational cooling-water withdrawals from proposed RCWs in sediments beneath Biscayne Bay. Results and details of the model configuration and calibration were provided in FPL's groundwater model report (FPL 2011-TN1440).

As described in Section 5.2.1.1, the USGS (2012-TN1441) also performed numerical modeling analysis of RCW operation to confirm the effect of RCW pumping on the Biscayne aquifer and Biscayne Bay. A detailed description of the USGS model is provided in Appendix G of this EIS. The review team used results from both of these models in its assessment of groundwater impacts at the Turkey Point site. However, neither of the models was the sole basis of the review team's assessment because such models are only an approximation of the real physical system.

According to FPL's groundwater modeling (FPL 2014-TN4069), the RCWs would draw produced water from Biscayne Bay (approximately 98 percent), the IWF cooling canals (approximately 2 percent), and the inland portions of the Biscayne aquifer (less than 0.3 percent) (FPL 2014-TN4058).

The USGS model also showed that nearly all of the water produced by the RCWs would come from Biscayne Bay with minor, seasonally variable, amounts of water coming from the inland portion of the Biscayne aquifer, from the IWF, and from nearby freshwater canals. The USGS model had a larger domain and included the effects of variable density fluid and changes in water levels at freshwater canals, which were ignored in the FPL model. However, the USGS model had a coarser discretization than the FPL model. Although the scale and discretization of the USGS model was not appropriate for providing accurate estimates of water volumes captured by the RCWs from different sources, it did provide information about potential RCW effects on salinity in the Biscayne aquifer and Biscayne Bay. For the continuous pumping scenario, the operation of the RCWs decreased aquifer salinity in an area centered northwest of Turkey Point. This was caused by the replacement of hypersaline water from the IWF with fresher water from the aquifer, adjacent canals, or Biscayne Bay. As described in Appendix G, the USGS model predicted increasing aquifer salinity in a ring around the IWF from continued migration of the IWF hypersaline plume. Predicted increases were near 40 psu in areas west of the IWF. The increase was predicted for scenarios both with and without RCW pumping and is not related to construction or operation of the proposed units.

If the RCWs are used as a backup supply of cooling water, the proportion of water flowing into the RCWs from the Biscayne aquifer is expected to be small, with over 95 percent of the water flowing into the RCWs coming from the overlying Biscayne Bay. This estimate is supported by separate groundwater modeling efforts performed by FPL and by the USGS, as described above. The modeling provided evidence that pumping of the RCWs as a backup water supply for 60 days per year or less would be unlikely to cause a significant increase in salinity within the bed of Biscayne Bay or within the bay itself compared to the variability that occurs under current conditions. The models also indicated that pumping the RCWs for 60 days per year or less is unlikely to cause a noticeable change in the existing extent of saltwater intrusion or to noticeably lower groundwater levels to such an extent that it would affect other users of the Biscayne aquifer. The review team recognizes that complete knowledge of the hydrologic system associated with the RCWs is not now available, and that uncertainties therefore remain in the impact analysis. Further, future operational and environmental conditions are not known with certainty. A vast number of future scenarios are plausible. The sources of uncertainty in the RCW analysis include: heterogeneity in subsurface parameters, lack of experience with RCW systems in carbonate strata, and uncertainty in the potential need for using the backup water supply. Uncertainties in the future site environment include: freshening of IWF cooling canals, remediation of the subsurface hypersaline plume, and the magnitude and rate of future sea level rise. In view of these uncertainties, the review team has taken care to avoid relying too heavily on numerical models, and has concludes that even the general conservatism adopted in the analysis does not ensure that the analysis is bounding of all future conditions. Accordingly, the review team does not rely solely on the output of any numerical model.

Numerical models are numerical representations of complex processes occurring in three dimensions over time. The appropriate role of a numerical model is to test assumptions of the behavior of complex systems. While running a numerical model numerous times with different parameters cannot compensate for all uncertainties, the models employed here have been tested and benchmarked within the conditions that limit their application. In this assessment the review team used models to test possible consequences of changes in the affected environment and uncertainty in some subsurface parameters within the capability of the models employed. This information was combined with the geography of the RCW field (such as the relatively short distance from the laterals to the bottom of Biscayne Bay relative to the distance from the laterals to the Homestead well fields) and the COC requirement of a monitoring program with mitigation options. The review team determined that the proposed monitoring of RCW construction and operation that is included is sufficient to detect unexpected behavior in a timely manner. While all possible mitigation measures have not yet been spelled out, in accordance with the COCs, the review team considers the ultimate mitigation of ceasing operation of the RCWs as ensuring prevention of any impacts in a timely manner. “When harm occurs, or is imminent, SFWMD will require Licensee to modify withdrawal rates or mitigate the harm” (FDEP COCs Page 61).

All groundwater models are subject to uncertainty caused by model assumptions and limited characterization data. Therefore, results from both the USGS model and the FPL groundwater model were only used qualitatively by the review team to understand potential impacts. The model results combined with the available characterization data supporting the leaky character of the Biscayne aquifer, and give confidence that the fraction of fresh groundwater that would be captured by the RCWs is small compared to the fraction that would come from saltwater in the bay. The review team estimated that the worst-case volume of groundwater removed from the Biscayne aquifer could reasonably be as high as 4,500 gpm during RCW operation. This represents 5 percent of the water produced by the RCWs and is conservatively 166 times greater than the fraction estimated by the base-case FPL groundwater model.

The review team determined that the proposed monitoring of RCW construction and operation is sufficient to detect unexpected behavior in a timely manner. While all possible mitigations are not detailed in the Conditions of Certification, the review team considers the ultimate mitigation of ceasing operation of the RCWs as ensuring prevention of any impacts in a timely manner. “When harm occurs, or is imminent, SFWMD will require [the] Licensee to modify withdrawal rates or mitigate the harm” (FDEP COCs Page 61). If reclaimed water is not available and the 60-day limitation on RCW pumping is exhausted, the plant can be safely shut down. Cooling the main condenser is not a safety function in the AP1000 design. Accordingly, there is no NRC requirement for a contingency plan to supply for emergency backup cooling water to the main condenser if reclaimed water is not available and the 60-day limitation on RCW pumping is exhausted. The plant can be safely shut down if water is not available from either source. Safety-related cooling water is stored onsite, and can be replenished from multiple sources. In a situation where the RCWs water may be needed, the EIS analyzes the case in which the RCWs would not operate more than 60 days per year as a bounding case. The case of continuous pumping was also analyzed as a sensitivity case. The primary source of cooling water, reclaimed wastewater from the Miami-Dade Water and Sewer Department, should be highly reliable, and therefore the availability of backup cooling water supplies need not be evaluated. Further, the review team also considered alternative sources of cooling water in EIS Section 9.4.2, none of which are environmentally preferable to the proposed sources of cooling water. In view of the high reliability of the reclaimed wastewater source and the availability of the RCW system as a backup, there is no need to consider additional backup sources of cooling water. Saline water from the RCWs beneath Biscayne Bay would only be used when reclaimed treated wastewater is not available in sufficient quantity or quality, and for a maximum of 60 days per year, as permitted under the Florida State Conditions of Certification. These limited periods of pumping of the RCWs will reduce the hydraulic head in the aquifer beneath Biscayne Bay near the wells and, therefore, will remove some water from the aquifer. However, the proportion of water flowing into the RCWs from the aquifer is expected to be small and over 95 percent of the water flowing into the RCWs is expected to be from the overlying Biscayne Bay. This estimate is supported by separate groundwater modeling efforts performed by FPL and by the USGS (Appendix G).

The models indicated that pumping the RCWs for 60 days per year or fewer is unlikely to cause a noticeable change in the existing extent of saltwater intrusion or to noticeably lower groundwater levels to such an extent that it would affect other users of the Biscayne aquifer. A vast number of future scenarios are plausible. The sources of uncertainty in the RCW analysis include heterogeneity in subsurface parameters, lack of experience with RCW systems in carbonate strata, and uncertainty in the potential need for using the backup water supply. Uncertainties in the future site environment include freshening of the IWF cooling canals, remediation of the subsurface hypersaline plume, and the magnitude and rate of future sea-level rise. In view of these uncertainties, the review team has taken care to avoid relying too heavily on numerical models, and concludes that even the general conservatism adopted in the analysis does not ensure that the analysis is bounding of all future conditions. Accordingly, the review team does not rely solely on the output of any numerical model.

Changes in the IWF Hypersaline Plume

If it becomes necessary to use the backup water supply, RCW pumping of saline groundwater from Biscayne aquifer beneath Biscayne Bay, could also affect movement of the hypersaline groundwater plume from the IWF cooling canals (described in Section 2.3.1.2). Under current conditions, most of the hypersaline water leaking from the cooling canals into the underlying groundwater system flows eastward beneath Biscayne Bay and likely mixes with bay water. The movement of this water in the subsurface is affected by tidal fluctuations that reverse the flow direction and by the complex mixing pattern of the ground waters with differing densities (Hughes et al. 2010-TN1545). Some hypersaline groundwater may move westward, although the interceptor ditch located on the west side of the IWF is operated to prevent inland movement of hypersaline groundwater (FPL 2014-TN4058). Pumping from the RCWs would increase the hydraulic gradient to the northwest. Both the FPL and USGS groundwater models (Appendix G) predict that some hypersaline water from the cooling canals would be drawn into the RCWs during extended periods of pumping. The increased gradient during RCW pumping would likely increase the flow velocity of hypersaline water eastward under Biscayne Bay and may change the area affected by the hypersaline plume.

After publication of the draft EIS, the review team performed additional groundwater modeling of the interaction between the planned RCWs, the existing hypersaline plume, and the cooling canals using a 2D cross-section model and a limited-extent 3D model. A more detailed description of this review team focused analysis is provided in Appendix G and in Oostrom and Vail (2016-TN4739). These models accounted for fluid density effects caused by salinity and temperature. The simulations were performed to better understand how the existing hypersaline plume may be affected by RCW pumping combined with remediation actions stipulated in a recent Consent Agreement between FPL and Miami-Dade County (Miami Dade County v. Florida Power & Light 2015-TN4505).

The modeling was useful in showing salinity changes that occur in the aquifer near the RCWs when the wells are operated. The results showed that when the wells are not operating hypersaline water from the cooling canals is present in the high-permeability zone where the well laterals are installed. This saline water would be drawn into the wells during the first few days of RCW pumping, resulting in increasing, then decreasing, salinity at the well. The salinity of the water produced by the operating RCW eventually would drop to about the concentration of the bay water. Water flowing down through the bed of the bay and into the RCWs would be expected to have about the same salinity as bay water. When RCW pumping ceases, water in the high-permeability zone would again increase in salinity because of the migration of water from the hypersaline plume into the high-permeability zone. This migration of hypersaline water into the high-permeability zone would occur regardless of the presence of the RCWs.

Predicted future change in sea level and its effect on interactions between the RCWs and the hypersaline plume were also simulated. The additional modeling confirmed that pumping of the RCWs would move hypersaline water toward the RCWs and would remove some groundwater captured by the RCWs from the hypersaline plume region of the Biscayne aquifer. The model also indicated that RCW pumping is not likely to reduce the effectiveness of hypersaline plume remediation actions specified in the Consent Agreement.

Changes in Groundwater Chemistry Caused by Movement of Bay Water into the Aquifer

Operation of the radial wells will induce water from Biscayne Bay to enter the material bottom at the top of the bay floor in the vicinity of the RCWs. The natural variability of the substrate will result in some preferential flow paths. The water chemistry along these flow paths may be altered as the well-oxygenated water from the Bay displaces the existing pore water. The substrate water quality is unknown and the nature of preferential flow paths is also currently unknown. However, previously in this section the review team has estimated the extent of the area possibly influenced by the RCW operation. Any increase in the density of preferential flow paths would reduce the area of influence and thereby reduce the extent of the changes in substrate water quality.

Changes in Hydraulic Heads and Saltwater Intrusion from Increased Demand on the MDWASD Potable-Water Supply

As described in Chapter 3 of this EIS, potable and service water for operation of the proposed units would be obtained from the MDWASD potable water-supply pipeline. Potable water from the MDWASD is almost entirely from the Biscayne aquifer in Miami-Dade County. Average increased demand for MDWASD potable water was estimated to be 1.5 Mgd based on normal use of 936 gpm with an occasional maximum use of 2,553 gpm for operating the proposed units (FPL 2014-TN4069). This represents less than 0.5 percent of the 349.5 Mgd that MDWASD is permitted to pump each year from the Biscayne aquifer (SFWMD 2012-TN1318). Any additional groundwater withdrawals required to meet Miami-Dade County needs will be managed under SFWMD policies to minimize impacts on the Biscayne aquifer. Therefore, the review team determined that the impact of this increased demand for potable water from MDWASD on Biscayne aquifer water levels and saltwater intrusion along the coast will be negligible.

5.2.1.3 Boulder Zone

Hydrologic alterations affecting the Boulder Zone of the Lower Floridan aquifer would result from the injection of up to 90 Mgd of blowdown water and other liquid waste streams from the proposed units. The injected water would include effluent from the sanitary waste-treatment plant, wastewater-retention basin, and liquid radwaste treatment system. The estimated injection rate is approximately 20 Mgd when only reclaimed water is used as a cooling-water source, as high as 90 Mgd when only saltwater from the RCWs is used, and between 20 Mgd and 90 Mgd if a combination of these water sources is used (FPL 2014-TN4058). However, the review team has determined that since reclaimed water will be the primary source injection rates higher than 20 Mgd will occur only on rare occasions and for short durations.

Composition of Injected Wastewater

Chemical constituents and concentrations in the injected water would vary depending on whether the source of cooling water is reclaimed water or saltwater from the RCWs. Chapter 3 provides details about the plant processes that affect the blowdown water composition and properties. Chemical constituents and concentrations expected to be present in water injected in the Boulder Zone are listed in Table 3-5 (Section 3.4.4.2) for both 100 percent reclaimed water as a cooling-water source and for 100 percent saltwater from the RCWs. FPL estimated these concentrations (FPL 2012-TN263) by adjusting the expected influent concentrations (reclaimed water or saltwater) based on the chemical changes expected to be caused by the RWTF, the circulating- and service-water systems, concentration in the cooling towers, and dilution to reduce radionuclide concentrations prior to discharge into the UIC wells. The concentrations for the reclaimed water case were estimated from analysis of composite effluent samples collected at the Miami-Dade SDWWTP from 2007 to 2011 and reported to the FDEP's UIC program. Concentrations for the saltwater case were based on analysis of samples collected from the production well during a pumping test conducted on Turkey Point from April 4 through May 5, 2009, from a monitoring well (MW-1 D2) on the Turkey Point site, and from a surface-water sampling location in Biscayne Bay (SP-1).

Upward migration of wastewater into an USDW, which has occurred at several Class I municipal disposal wells in Florida, was historically prohibited by Federal and State Underground Injection Control (UIC) regulations and the Safe Drinking Water Act (SDWA). Previously, facilities where migration into USDWs had occurred would have been forced to cease injecting and adopt an alternate wastewater disposal method. However, due to the severe local restrictions on wastewater disposal alternatives in Florida, the EPA revised the Federal UIC requirements for Florida to allow continued disposal well operations where migration had occurred, provided the injected wastewater is given "pretreatment, secondary treatment, and high-level disinfection prior to injection" in order to "provide an equivalent level of protection to USDWs as provided by the existing no-fluid-migration requirement of the Safe Drinking Water Act" (EPA 2005-TN4766). EPA considered this alternative to be "as effective as confinement of fluids in protecting USDWs from contaminants in wastewater" (EPA 2005-TN4766) and stated that after additional treatment, "the movement of fluids into the USDWs, whether known or suspected, should not endanger the USDWs because the quality of the wastewater has been treated to a level that is no longer a threat to USDWs" (EPA 2012-TN4782). EPA indicated that it understood that FDEP, which oversees the UIC program in Florida would propose state regulations that were equally or more stringent.

On April 29, 2004, FDEP and MDWASD entered into a Consent Order to address issues including fluid movement at the SDWWTP (Miami-Dade County 2014-TN4758). In accordance with the 2004 Consent Order, MDWASD was to treat wastewater at the SDWWTP to a higher than secondary treatment, including additional filtration and high-level disinfection (HLD) before disposal via injection wells. The impacts of migration of injected wastewater receiving advanced treatment from the SDWWTP was evaluated prior to implementation of this system using numerical modeling conducted by the USGS (Dausman et al. 2008-TN4757) and is discussed below. The HLD Facility at SDWWTP was completed in FY2013 (Miami-Dade County 2014-TN4758) and reclaimed water received by FPL from the SDWWTP and injected into the Boulder Zone will receive both filtration and high level disinfection as part of this advanced treatment. Additional sampling performed at the SDWWTP from 2013 to 2014 to determine seasonal variability of the concentrations of heptachlor, ethylbenzene, tetrachloroethylene and toluene, which are constituents in treated wastewater, also provide insight into the effect of this treatment on constituent concentrations. Concentrations for these constituents determined through this more recent sampling were below both EPA maximum contaminant levels and laboratory method detection limits, as indicated in the footnotes to Table 3-5 (NRC 2015-TN4773). These were lower than the values reported in Table 3-5 and may better represent the concentrations expected in reclaimed water that will be received by Turkey Point. The concentrations do not reflect the additional reduction which would occur due to treatment, volatilization, and dilution at the Turkey Point site before injection. In view of the above, the treatment that the reclaimed wastewater will receive at the SDWWTP will provide protection to the USDW even in the event of upwelling. Confinement of the wastewater below the USDW, which is discussed below, will provide an additional level of protection.

Evaluation of Confinement of Injected Wastewater in the Saline Lower Floridan Aquifer

The purpose of the evaluation of deep well injection presented in the FEIS is to determine the impacts to water resources that might reasonably occur if Units 6 and 7 are licensed. The responsibility to demonstrate that plant effluent injected in to the Boulder Zone will not impact overlying USDWs is that of FPL and is required as part of the FDEP UIC permit. To evaluate the impacts of deep well injection at the Turkey Point site, the review team 1) reviewed studies that characterized the confining ability of the MCU and the causes and extent of upwelling at other deep well injection sites, 2) compared hydrogeological conditions and parameters at the sites at which upwelling occurred to conditions and parameters at the proposed site, 3) evaluated numerical modeling of flow of injected wastewater presented by the applicant and performed confirmatory calculations, and 4) considered the injection well testing and groundwater monitoring requirements of the FDEP UIC program. As a result of this evaluation, the review team concluded that significant upwelling of injected wastewater is not likely at the Turkey Point site and that, if upwelling did occur it would not noticeably impact overlying USDW aquifers.

As described in Section 2.3.1.2, the Boulder Zone contains saline water and is regionally isolated from the overlying Upper Floridan aquifer by a thick section of low-permeability sediments of the middle confining unit (MCU). Information from an exploratory well constructed at the Turkey Point site identified highly porous and permeable rocks that form the upper portion of the Boulder Zone at a depth of 3,020 to 3,232 ft below the drill pad.

Almost all of the injected wastewater is expected to be from periods when Units 6 and 7 are using reclaimed water as a cooling-water source. Because the injected wastewater would have a lower TDS content and an elevated temperature compared to the native water in the Boulder Zone, the injected wastewater would have a lower density than that native water, resulting in buoyancy. Wastewater from periods when the plants are using water from the RCWs is expected to have a higher density than the native Boulder Zone water, resulting in negative buoyancy. These periods are expected to be rare and of short duration.

As described in Section 2.3.1.2 of this EIS, the naturally-occurring hydraulic gradient in the Boulder Zone is small and water flows slowly to the west. The natural gradient is very small compared to the pressure developed at the injection point into the Boulder Zone by the injection pumps, as discussed below. Accordingly, the injected reclaimed wastewater will be forced in all directions from the injection point into the Boulder Zone. In addition, when reclaimed wastewater is used, buoyant forces will dominate the small natural gradient due to the lower density warm injectate, resulting in an overall upward hydraulic gradient in the Boulder Zone. Upward flow of injected wastewater would nonetheless be inhibited by the more than 1,465 ft thick sequence of predominately low-permeability rocks that lie between the Boulder Zone and the USDW aquifer (FPL 2012-TN1577).

FPL performed an analysis of the pressure buildup by the injected wastewater (FPL 2014-TN3932). FPL calculated a maximum total pressure increase of 158 psi in the injection formation from the combined injection pressure of 12 injection wells plus buoyancy of the injectate based on a reclaimed water source. This is much lower than the calculated 1,235 psi minimum pressure that could create or open a fracture in the overlying confining zone (FPL 2013-TN3931).

Based on the above evaluation, the review team concluded that in general the matrix of the MCU would confine injected effluent and that incidences of upwelling at other sites have been coincident with features that provide vertical pathways for upward migration such as fractures or improperly completed wells. Site data indicates that substantial fracturing of the confining layers is not evident at the Turkey Point site and well construction related issues are not expected to create potential for upwelling at the Turkey Point site because of improved understanding of the confining zones within the MCU and improved construction techniques. However, studies of other injection sites indicate that if rapid vertical migration occurs, it is not likely to reach the Upper Floridan aquifer and that, if it did, it would not noticeably impact drinking water quality. This is discussed in greater detail in Sections 2.3.1.2 and 5.2.3.2 and within the following portions of this section.

Extent of Upwelling at Deep Well Injection Facilities

Maliva et al. (2007-TN1483) reports that of the more than 180 Class I UIC wells, "in the majority of injection well systems, no vertical movement of injected fluids has been detected in the monitoring zones." Seventeen sites have experienced migration, however upwelling into the USDW had occurred at 8 of those sites. Three of these sites are in southeast Florida and include the SDWWTP, which is north of the Turkey Point site. Previous reports indicated that injectate had migrated into the Upper Floridan aquifer (Starr et al. 2001-TN1251; 68 FR 23673 [TN3658]; EPA 2003-TN4759). However, more recent studies, such as Maliva et al (2007-TN1483) and Walsh and Price (2010-TN3656) have clarified that while migration has reached the USDW at some Class I injection facilities, no impact has been reported for the Upper Floridan aquifer in southeast Florida including at the SDWWTP. As discussed in Section 2.3.1.2, this is likely because the earlier studies referenced above considered the APPZ, where upwelling was detected, to be the lower part of the Upper Floridan aquifer. As a result of more recent characterization of the Floridan aquifer in south Florida (such as Reese and Richardson 2008-TN3436), it is now understood that the APPZ is separated from the Upper Floridan aquifer in south Florida by the upper confining unit of the MCU. Results from characterization at EW-1 indicate that the upper confining unit of the MCU may separate the APPZ from the Upper Floridan by approximately 250 ft.

Also, the base of the USDW is defined by the depth at which TDS exceeds 10,000 mg/L. The depth at which groundwater TDS exceeds 10,000 mg/L may occur beneath the base of the Upper Floridan Aquifer as it does at the SDWWTP. Therefore, upwelling into the USDW does not necessarily indicate that upwelling has reached the Upper Floridan aquifer. However, review of data from well EW-1 indicate that the base of the USDW and Upper Floridan aquifer occur around the same depth at the Turkey Point site.

Potential Causes of Upwelling of Injected Wastewater through the Middle Confining Unit

Many studies have been conducted to characterize the confining nature of the MCU and determine the causes of upwelling, where it has been observed. Studies have evaluated whether observed migration was caused by flow through the matrix of the MCU or through pathways provided by either natural geologic features or well-related problems. These studies generally conclude that the MCU matrix provides adequate confinement, that rapid flow results may result primarily from well-related issues, and that significant upwelling has not occurred at injection sites. These studies are summarized in the following paragraphs.

Starr et al. (2001-TN1251) reviewed "existing information that describes geology, hydrogeology, and geochemistry at the South District Wastewater Treatment Plant" to determine "the ability of the confining layer above the saline aquifer to prevent fluid migration into the overlying freshwater aquifer." The aquifers referred to are the Boulder Zone (the "saline aquifer") and the Upper Floridan aquifer (the "freshwater aquifer"). However, the Upper Floridan aquifer is brackish, not fresh, in the vicinity of the site. The Starr study expressed concern over the adequacy of the data set being evaluated and concluded that "the geologic data provided for review are not sufficient to demonstrate that the Middle Confining Unit is a competent, low hydraulic conductivity layer that is capable of preventing upward migrations of fluids from the

Boulder Zone into the overlying underground source of drinking water" or USDW. According to the report:

- "Although the confining layer above the Boulder Zone may in fact be competent, these data sets are not adequate to draw this conclusion."
- "A caveat to this interpretation is that the hydraulic characterization test methods employed may not adequately represent the less permeable hydrostratigraphic units, and hence the hydraulic data set may not adequately describe the actual site conditions."
- "…the geochemical data do not show a spatial pattern of contamination that is consistent with widespread upward migration of contaminated water through a highly permeable confining layer."

Rather than indicating a lack of confinement by the MCU, the study concludes that "the Middle Confining Unit and/or upper portion of the Lower Floridan Aquifer is a better confining unit than indicated" by the data that was provided for review. The study concluded that overall the spatial distribution of contaminants "suggests that isolated conduits, such as inadequately sealed wells or natural features, provide pathways for contaminated water to migrate upward from the Boulder Zone, but contaminants are not migrating upward through the Middle Confining Unit across a broad area."

This lack of observed migration across a broad area was also investigated by Maliva et. al. (2007-TN1483). Maliva, et al., studied vertical hydraulic conductivity data from core plugs from the MCU at 29 South Florida injection well sites (including the SDWWTP) and performed variable density solute-transport modeling. They observed that "matrix hydraulic conductivities of the limestone and dolostones that constitute the confining strata between the injection zone and the base of the USDW in South Florida are sufficiently low to retard significant vertical fluid movement" and that minimal vertical migration would occur through sections where vertical hydraulic conductivity was 10^{-6} cm/sec or less. As discussed in Section 2.3.1.2, intervals of dolomitic limestone and dolomite with hydraulic conductivities measured as low as 10^{-6} cm/sec occur within the MCU at well EW-1 at the Turkey Point site. As a result, these intervals at the Turkey Point site would be expected to prevent or limit vertical migration.

McNeill (2002-TN4571) recognized a thin "important low-permeability interval" which "appears to act as a competent confining unit" between the Boulder Zone and Middle Confining Unit throughout southeastern Florida. He referred to this interval as the Dolomite Confining Unit and identified characteristics of the unit that were indicative of confinement. These included zones in which the data showed high core recovery and low hydraulic conductivity, and other confining characteristics as indicated by geophysical logs. The review team observed zones with similar confining characteristics at several depths within the MCU at well EW-1 at the Turkey Point site.

Several studies indicated that upwelling may result from natural features or well-related issues. Dausman et al. (2010-TN4760) agreed that MCU "heterogeneity cannot explain all the effluent migration" and indicated that upwelling at the SDWWTP can generally be attributed to "…flow through a channelized pathway caused by well construction." At the SDWWTP, McNeill (2002-TN4571) indicated that upwelling likely occurred because 10 of 17 injection wells were drilled through but completed above the Dolomite Confining Unit at the base of the MCU, effectively leaving an open hole and upward pathway through which injected effluent could migrate.

Lastly, Walsh and Price (2010-TN3656) evaluated well logs and water chemistry data at the SDWWTP and determined that while natural features could not be ruled out, enhanced vertical flow pathways that allowed upwelling likely resulted from issues related to well installation or failure because effluent appeared to bypass deeper monitored intervals before being detected at higher depths.

Even if the MCU matrix is generally confining and wells are installed properly, upwelling may still result from fracturing or other natural geologic features within the confining zone. Cunningham (2012-TN4576; Cunningham 2013-TN4573; Cunningham 2014-TN4051; Cunningham 2015-TN4574) evaluated injection sites for natural vertical high conductivity features (such as karst collapse structures) using seismic-reflection data. He stated that “if present at or near wastewater injection utilities, these features represent a plausible physical system for the upward migration of effluent injected into the Boulder Zone to overlying EPA-designated USDW in the upper part of the Floridan aquifer system.” In the most recent study, karst collapse features have been identified in the vicinity of the North and South District Wastewater Treatment Plants as well as locations beneath Biscayne Bay and have been found to extend from the MCU to above the Upper Floridan aquifer (Cunningham 2015-TN4574). These structures are beyond the zone of influence of the injection wells proposed at the Turkey Point site, as described below. At an injection well operated by the City of Sunrise in Broward County a collapse structure was implicated in the observed migration of injected wastewater from the Boulder Zone to the uppermost permeable zone within the Lower Floridan aquifer however migration of contaminants above the Lower Floridan aquifer was not observed at this site (Cunningham 2014-TN4051). Migration above the APPZ and into the Upper Floridan aquifer resulting from natural features has not been identified at any site in south Florida.

Deep seismic data has not been collected at the Turkey Point site. In the absence of seismic data, Cunningham (2015- TN4574) suggests that, “other evidence for karst collapse includes borehole log signatures that indicate highly fractured rock,” and that fractures would be indicated by “..high travel times measured on borehole sonic log data.” Walsh and Price (2010-TN3656) reported that at the SDWWTP “no fracturing of the confining strata had been reported.” Using geophysical (sonic) logs from injection sites in south Florida, Maliva et al (2007-TN1483) and McNeill (2002-TN4571) described signatures and travel times for fractured rock. Staff evaluated travel times and signatures on sonic logs obtained at well EW-1 at the Turkey Point site and found sections of the MCU to have log signatures and transit times consistent with unfractured rock. Dissolution rates for limestone and dolostone presented by Palmer (2016-TN4755) are low, indicating that if fractures in the MCU at the Turkey Point site are absent or poorly developed, such fractures are not likely to become conduits capable of upwelling over the life of the plant. In order for rapid flow of injected effluent to occur from the Boulder Zone through the MCU as a result of these natural features, they would have to occur within the zone of influence of an injection site and create a set of pathways that compromise the approximately1500 ft thick MCU. However, characterization data indicates that these features are not evident at the site and modeling suggests that the expected zone of influence of injected wastewater is not expected to extend far beyond the boundaries of the Turkey Point site, as described below.

The review team evaluated the potential for upwelling due to flow through a competent MCU matrix or pathways created by natural features or well-related issues. Review of hydrogeological parameters at the site indicate that the MCU would be expected to offer confinement absent the presence of conduits. Results of borehole characterization activities at exploratory well EW-1 (FPL 2012-TN1577) and DZMW-1 (MHC 2014-TN4052) indicated that there were thick sections of low permeability sediments between the Boulder Zone and the Upper Floridan aquifer at the proposed Turkey Point injection site. Monitoring results from the water-injection testing at these wells above these low permeability strata did not indicate pressure fluctuations indicative of lack of confinement due to matrix flow or flow through pathways caused by either improper well construction or natural features (FPL 2014-TN4052). Installation, testing and monitoring required by the FDEP UIC permit are designed to prevent upwelling resulting from improper well construction and detect upwelling associate with the wells if it occurs. The review team notes that the one injection well has been drilled and characterization of the thickness and competency of the MCU is also required at each subsequent well location by the UIC permit process. The UIC permit for each well may not be issued unless adequate confinement has been demonstrated by the well-specific characterization data. The review team believes that enhanced vertical flow through the confining units to the Upper Floridan aquifer is extremely unlikely, and if leakage associated with an injection well did occur it could be detected and mitigated as required by the FDEP UIC program.

Extent of Injected Wastewater Migration at the Turkey Point Site

In order to understand the fate of injected wastewater at the Turkey Point site the review team evaluated local and regional site studies and modeling of the SDWWTP site, modeling conducted at the Turkey Point site by FPL, and independent confirmatory modeling by the review team.

Dausman et al. (2008-TN4757) modeled migration of two plumes from the SDWWTP of wastewater injected into the Boulder zone: one comprised of secondarily treated wastewater and another of wastewater receiving HLD, which has since been implemented along with additional filtration at the SDWWTP site. The Dausman study concluded that over a projected 148-year injection period (from 1983 forward) the resulting plume would extend "…outward about 13 mi from the site in the MFA, just beneath the UFA." The MFA, or Middle Floridan aquifer, is another name for the APPZ. Modeling also indicates that the initial concentration of constituents in the plumes would be significantly reduced through dilution, to less than 5 percent of the original injected concentration by the end of the modeling timeframe.

This prediction of limited vertical and horizontal effluent migration is supported by modeling and analysis performed by FPL and independent confirmatory analysis performed by the review team. FPL provided information about modeling and analysis of several scenarios of potential upward migration of injectate (FPL 2013-TN3931) in support of the safety analysis of the proposed plants. The scenarios in the analysis focused on the fate and transport of radionuclides over a 61-year injection period followed by a 41-year period with no injection, and used conservative assumptions that would tend to maximize the upward migration of effluent. In each scenario, injected wastewater was predicted to expand radially around the point of injection since injection rates would exert a stronger influence on flow than the negligible flow rates naturally occurring within the Boulder Zone. Injected wastewater was not predicted to extend more than around 4 mi beyond the point of injection over the modeled timeframe. This is bounded by the transport distance of 13 mi predicted by Dausman et al. (2008-TN4757). The extent of migration resulting from injection at Turkey Point would be expected to be less because injection rates would be around 20 percent of those at the SDWWTP and the injection period would be less than half that which was modeled by Dausman et al. (60 years vs 148 years).

One scenario evaluated by FPL determined that, in the absence of well-developed pathways, upward movement of injectate would be limited to approximately 300 ft into the MCU. The primary confinement portion of the MCU above the injection zone is 985 ft thick (FPL 2012-TN1577) and is overlain by an additional 480 ft thickness of moderate- to low-permeability layers of rock below the Upper Floridan aquifer. The staff performed a separate confirmatory analysis (Appendix G) and found that upward migration of injectate from the Boulder Zone would likely be less than 300 ft. These estimates of limited upward migration are supported by the conclusions from the studies of matrix flow through the MCU discussed earlier in this section.

FPL's safety analysis also considered a scenario in which a pathway through the MCU exists. In this scenario, a hypothetical water-supply well located 2.2 mi from the reclaimed wastewater injection site was drilled into the USDW aquifer and an instantaneous bypass/failure of the MCU occurred at the water supply well. The 2.2 mi distance is based on the nearest privately owned parcel of land. The FPL analysis showed that the transit time through the Boulder Zone from the injection well to beneath the offsite location would be at least 10 years, and the maximum radionuclide concentrations for tritium would not occur until year 21 (FPL 2013-TN3931). This analysis was conservative in that it did not account for transit time through the MCU and did not account for dilution of effluent within the Boulder Zone or Upper Floridan aquifer. It assumed that 100 percent of the water pumped by the water-supply well would be from the Boulder Zone with no dilution in the Avon Park Permeable Zone (APPZ) or the Upper Floridan aquifer. The review team performed a separate confirmatory analysis of this scenario (Appendix G), which predicted concentrations of radionuclides at the hypothetical well that were similar to those calculated by FPL. The assumptions of vertical migration in this scenario were made to determine a bounding dose. The conditions and parameters in this scenario have not been observed at operating injection sites and are not reasonably foreseeable based on the hydrogeology at the Turkey Point site.

FPL also considered impacts at the nearest user of brackish Upper Floridan aquifer groundwater, which is the Ocean Reef Club located on Key Largo 7.7 mi from the injection site. This scenario conservatively assumed that water from the existing irrigation supply well is used for drinking and other domestic purposes and there is a failure of confinement between the Boulder Zone and the Upper Floridan aquifer at the location of the water-supply well. FPL's radiological safety analysis at the Ocean Reef Club showed that radionuclide levels in the Upper Floridan aquifer would remain at inconsequential levels throughout the 100-year analysis period. This is expected since the wastewater is not predicted to travel this far beyond the injection well. Estimates of potential doses resulting from each of these scenarios are discussed in Section 5.9 of this EIS. While this evaluation considered the transport of radionuclides, predictions related to flow direction and horizontal extent would also apply to non-radiological constituents in the injected water.

The review team evaluated the impacts of this and other scenarios (direct injection into the Upper Floridan aquifer, upward migration through the MCU and rapid migration through preferential pathways through the MCU) using results from published risk assessments and modeling studies as well as expected constituent concentration data from reclaimed water at the Turkey Point site. The results are set forth in Section 5.2.3.2.

Another controlling factor on the direction of flow of injected wastewater was determined to be the structure of the confining layers that overly the Boulder Zone. McNeill (2002-TN4571) evaluated the structure and extent of a unit he called the Dolomite Confining Unit, which occurs at the base of the MCU in southeast Florida. McNeill indicated that while there is local variability in the bottom depth of the Dolomite Confining Unit, the overall dip of the unit is to the southwest. This implies that as distance beyond the injection well increases, flow of buoyant injected effluent may be more influenced by the structure of the base of the confining unit rather than injection pressure. As a result, any migration within the Boulder Zone beyond the site would move northeast toward (but beneath) the bay and away from areas in which the upper aquifers are used. As mixing, cooling and dilution occur, buoyancy of the injectate will decrease, causing it to eventually be subjected to the slow westward movement of the native water within the Boulder Zone (Meyer 1989-TN2255).

Finally, as described in Section 2.3.1.2 of the EIS, treated municipal wastewater injected into the Boulder Zone has migrated into relatively permeable zones within the MCU at the SDWWTP north of Turkey Point site, but has not reached the Upper Floridan aquifer. Studies have indicated that this migration could have resulted from well construction issues. Walsh and Price (2010-TN3656) presented a conceptual model that postulates the vertical migration through the lower portion of the MCU, below the APPZ, is fluid-density driven. Walsh and Price also determined that if migration into the APPZ occurred, “the transport mechanism appeared to be a horizontal flow with mixing of ambient waters” which would likely diminish the buoyant forces and reduce the impact above the APPZ. This conceptual model of horizontal flow in the APPZ overcoming the vertical flow component that dominated flow within the more confining MCU strata was also illustrated in a numerical modeling scenario by Maliva et al (2007-TN1483). This indicates that even where migration through the bottom portion of the MCU has occurred, upwelling to the upper MCU and the overlying Upper Floridan aquifer is not likely. This could partially explain why recent studies have indicated that upwelling to the Upper Floridan aquifer has not occurred at injection sites.

Based on the foregoing, the review team has determined it is reasonable to conclude that injected wastewater is not expected to migrate far beyond the site in the Boulder Zone, that upwelling to the Upper Floridan aquifer is not likely at the site, and that if significant upwelling through the MCU did occur, horizontal flow and mixing within the APPZ would likely prevent upwelling above the MCU. While not quantified by the review team, modeling near the site indicates that natural dilution of injected wastewater could significantly reduce the concentrations of constituents in wastewater. There are no users of groundwater within the Boulder Zone near the site, there are no users of groundwater within the Upper Floridan aquifer overlying the predicted extent of wastewater migration, and wastewater is not expected to migrate upward into the Upper Floridan aquifer.

Lastly, relative risk assessments of wastewater disposal methods in southeast Florida indicate that "distance has a major impact on risk" with the already low risk decreasing dramatically as distance from the injection well increases (Bloetscher et al. 2005-TN4756). The study considered scenarios that included breach of the MCU and determined that risk to receptors up to 5 mi from the injection well was minimal, which is similar to the migration distance indicated by site and regional modeling, as discussed above. Risk assessments that consider deep well injection are discussed in greater detail in Section 5.2.3.2.

5.2.1.4 Industrial Wastewater Facility (Cooling Canals)

Hydrological alterations affecting the IWF cooling canals, that would be associated with the operation of the proposed Turkey Point Units 6 and 7, may occur due to (1) drift deposition of contaminants on in the IWF (2) stormwater discharge to the IWF, (3) runoff from spoils piles, and (4), withdrawal of water from the IWF due to radial well operation.

Drift Deposition

The review team has conducted analyses to estimate drift deposition of chemical contaminants on aquatic and terrestrial habitats; these estimated depositions would be used for determining aquatic and terrestrial ecological effects. The methods of estimating drift deposition are discussed in the Biscayne Bay section above, and the estimated deposition rates are provided in Table 5-1, which includes the IWF cooling canals. Table 5-1 provides deposition rates with the use of reclaimed water as cooling-tower makeup water. The table includes concentrations in wastewater (or Biscayne Bay), ratios of constituent concentration to TDS concentration, and calculated deposition rates for each constituent to areas around the cooling towers.

The potential concern for the cooling canals, while not a water body regulated for water quality, is related to the potential impact on Federally protected crocodiles, which nest on the cooling-canal berms at several locations of the IWF. Most of the IWF is also designated critical habitat for the crocodile.

As noted in the section about Biscayne Bay, with the use of either the reclaimed water or RCWs, the deposition rates of potentially associated chemical contaminants is extremely low. Only TDS, chloride, and sulfide have deposition rates greater than 10^{-6} g/m^2/mo, and the IWF has concentrations of those that are greater than marine waters.

Using water and mass balance methods, the review team also calculated the equilibrium concentrations of contaminants within the cooling canals from drift deposition. To compute the mass balance, the review team first calculated a water balance using the cooling-canal storage information from the *Cooling Canal System Modeling Report* (Golder 2008-TN1072) and the FPL 2012 *Uprate Report* (FPL 2012-TN3439). The water balance data from FPL (2012-TN3439) was averaged by month and repeated over a 9-year period to provide inflows and outflows to the cooling canals for use in the mass balance calculations. Loading to the IWF and the flow balance of the IWF is discussed in Section 4.2.1.4. Figure 5-1 shows the review teams computed cooling-canal volumes for this period.

For the next step, the review team calculated the mass balance of each constituent in Table 5-1 using the hydrologic fluxes of the IWF to account for dilution of contaminant concentrations from drift deposition. For a conservative estimate, no loss of contaminants was assumed in the cooling canal from degradation or volatilization. Figure 5-2 provides an example of contaminant concentrations calculated from the mass balance of 1,4-dichlorobenzene, which is an insect repellent. Concentrations increase from the initial value of 0 µg/L and reach a dynamic equilibrium within approximately 4 years. The only input of contaminant is from cooling-tower drift, and the primary loss is via the seasonal inflows and outflows of groundwater, which produces the variation in volume shown in Figure 5-1. The maximum computed increase in concentration was 0.00070 µg/L. The same calculation was made for other potential contaminants deposited in the cooling canal from drift; the maximum concentrations attained are listed in Table 5-2. Comparison of the contaminant concentrations with detection limits indicates that all of the concentrations from this mass balance calculation are below current detection limits. Other chemical constituents with concentrations that were not measured in the reclaimed water, but which could have concentrations similar to those measured by MDWASD, would be expected to result in concentrations in the IWF as found above.

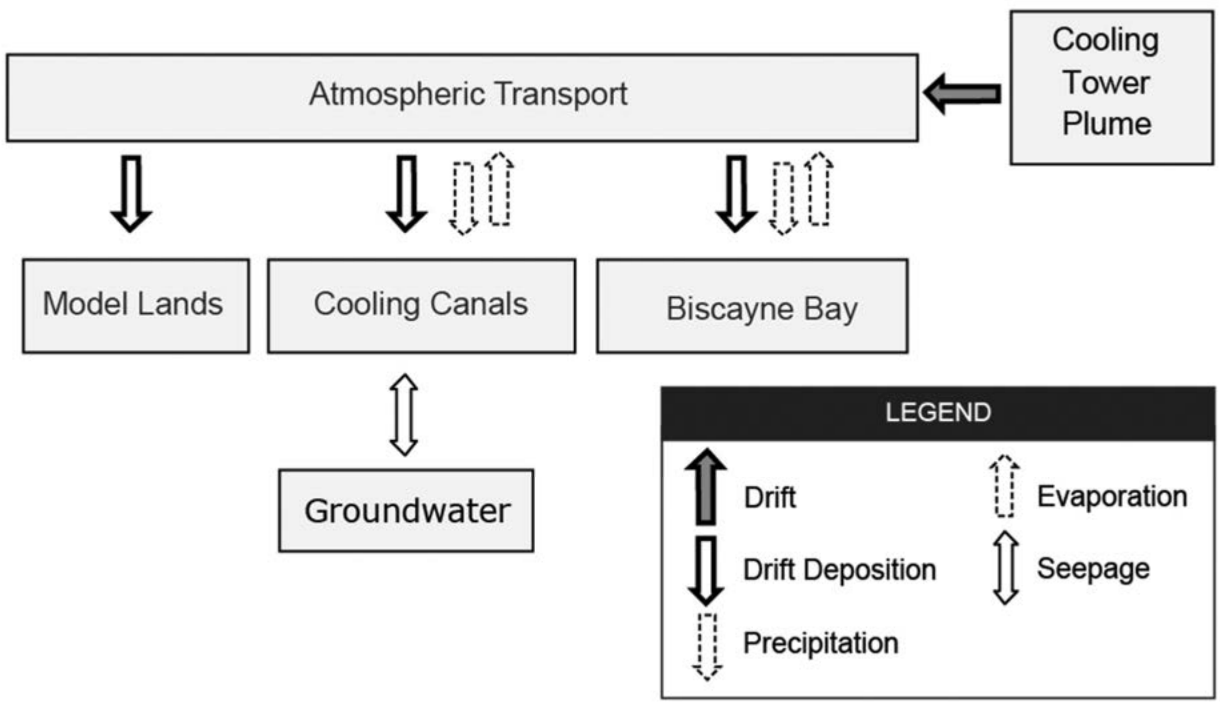

Figure 5-1. Schematic of Hydrologic and Mass Exchange Processes Considered in Estimating the Effects of Drift Deposition on the IWF Cooling Canals, Model Lands, and Biscayne Bay

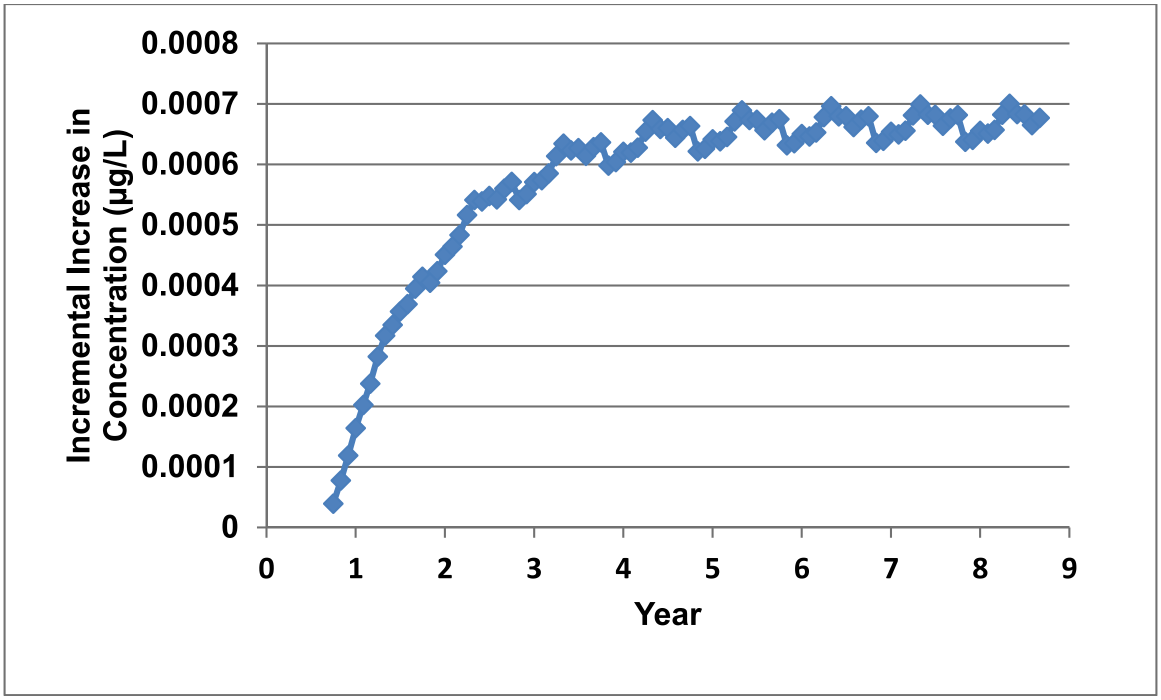

Figure 5-2. Concentrations of 1,4-Dichlorobenzene Based on Annual Average Drift Flux from the Cooling Towers over a 9-Year Period. ***Hydrologic conditions are those used to estimate the cooling-canal volumes shown in Table 5-2.***

G.3.1.3 Summary

The Biscayne aquifer transmissivity (T) and the vertical hydraulic conductivity (kv) of the confining zone above the Biscayne aquifer are important because they control the rates at which water will flow into the RCWs from the aquifer and the bay and impact the amount that is drawn from each potential source. The NRC staff's analyses resulted in K′/b′ values that vary from 0.23 to 0.53 d^{-1}, and average about 0.3 d^{-1}. If all the vertical resistance to flow is imposed by the muck layer, which averages in thickness (b') of 2 ft, then its vertical hydraulic conductivity is about 0.6 ft/d. This value is close to that determined by FPL (2009-TN1263).

The NRC staff found that values of T between about 800,000 and 1,000,000 ft^2/d are obtained from time-drawdown analysis of the APT using consistent r/B values, or from distance-drawdown analysis. Differences in the calculated T values arise because of uncertainty in steady-state drawdowns of only a few hundredths of a foot. Values from the staff's analysis are comparable with values determined by FPL (2009-TN1263), which states "The mean for the calculated T values using drawdown data is approximately 700,000 $feet^2$/day." Also, "The calculated T value using a distance-drawdown method is 800,000 ft^2/d." Thus, in spite of some inconsistency in analysis methods, results from the analysis prepared by FPL are similar to those determined in the NRC staff review.

G.3.2 Description of Groundwater Modeling Performed to Help Evaluate Effects of Excavation Dewatering and Radial Collector Well Operation on the Biscayne Aquifer

This appendix describes three separate modeling efforts performed to estimate the effects of radial collector well (RCW) pumping on the Biscayne aquifer, Biscayne Bay, and other portions of the hydrologic environment including nearby drainage canals and the cooling canals of the industrial wastewater facility (IWF). Two of these modeling efforts were performed before the NRC issued the draft environmental impact statement (EIS) in 2015, while the third was performed afterwards. The staff also used the two earlier studies to simulate the effects of dewatering the Units 6 and 7 plant excavations. To further confirm their understanding of the groundwater hydrodynamics and to consider whether certain actions proposed after the two earlier modeling studies were completed would alter the earlier conclusions documented in the draft EIS (EIS, NRC 2015-TN4444), the review team performed a third modeling analysis (Oostrom and Vail 2016-TN4739).

FPL conducted modeling (FPL 2014-TN4069) using a local-scale groundwater model of the Biscayne aquifer including the portion of the aquifer underlying Biscayne Bay near the Turkey Point site. The NRC commissioned the U.S. Geological Survey (USGS), to conduct additional modeling to help identify the potential effects of RCW pumping (NRC 2014-TN3078). As indicated above, after the Draft EIS was issued, the review team itself performed a third modeling analysis.

Each of these hydrologic models provides an estimation of the effects of building and operating the proposed plants, however these estimations are imperfect due to a number of uncertainties. Uncertainty in groundwater models has been described as arising from 1) uncertainty in model parameters, and 2) uncertainty in the definition of the conceptual model framework including the spatial and temporal variation in hydrologic variables (Neuman and Wierenga 2003-TN4090). Therefore, examining the results of the three modeling efforts provides a better understanding of the possible range of effects of building and operating Units 6 and 7.

The model used by the USGS model is a submodel of an existing regional-scale (Miami-Dade County) coupled surface-water/groundwater model originally created to evaluate then-recent hypersalinity events in Biscayne Bay, at the county scale, during 1996−2004 (NRC 2014-TN3078). The USGS model domain encompassed Biscayne Bay and included freshwater flows into Biscayne Bay through the offsite drainage canal system, exchange of groundwater between Biscayne aquifer and surface waterbodies including the Biscayne Bay, drainage canals, and the cooling canals of the IWF. It also included precipitation input to the bay, precipitation recharge to the Biscayne aquifer, evapotranspiration (ET) effects on bay salinity, and the effects of ET on recharge to the Biscayne aquifer. The USGS modified their existing model to include the cooling canals of the IWF, the proposed excavation dewatering wells, and four proposed RCW locations.

Both of the modeling efforts are approximations of the real physical system, and each has shortcomings that result in uncertainty in the modeling results. The FPL model assumes constant density fluid and does not represent the differences in density between fresh and saline water that can result in “density-driven” groundwater flow. The FPL model was strictly a groundwater model with surface-water features represented as boundary conditions. The FPL model area is much smaller than the USGS model and does not include as many offsite canals. However, the USGS model has much lower spatial resolution with 500 × 500 m cell size compared to FPL’s model which is variable and is refined to a 5 ft spacing in the area around the radial collector wells (FPL 2014-TN4069). Therefore, the USGS model’s representation of smaller-scale features is not as accurate as FPL’s model.

G.3.2.1 Summary of FPL Modeling

FPL performed groundwater modeling in support of its application for building and operating Units 6 and 7 at the Turkey Point site. The model was created using Visual MODFLOW, a commercial implementation of the USGS-developed MODFLOW 2000, and was a steady-state three-dimensional model that assumes constant density of the fluid being modeled. Measured heads applied in the model for non-seawater waterbodies (e.g., freshwater canals and hypersaline cooling canals) were corrected to equivalent seawater heads based on the fluid density ratio. The model and results are described in detail in Appendix CC of the FSAR (FPL 2014-TN4069). Therefore, only a brief summary and assessment are provided here.

The objectives of the model were to evaluate groundwater impacts of activities related to the building and operation of two new nuclear units by simulating groundwater flow in the Biscayne aquifer. The primary issues evaluated with the model were the following:

- expected rates of groundwater infiltration into excavations for the new reactor buildings
- origin of water pumped from the RCW, and
- sea water approach velocities to the bay floor during RCW pumping.

FPL calibrated the model by matching the groundwater level response to aquifer pumping tests performed at two wells (PW-7L and PW-7U) near the proposed plant locations and a well (PW-

1) near the proposed RCW on the Turkey Point peninsula. An additional aquifer test near the proposed plant locations (PW-6U) was simulated by the model as a "validation run."

FPL used the calibration process to estimate a variety of parameters which were included in their model. These included the horizontal hydraulic conductivity (Kh) and anisotropy (Kv/Kh; ratio of vertical (Kv) to horizontal (Kh) hydraulic conductivity) values for each of the 10 hydrogeologic units included in the model and the conductance values applied to head-dependent boundary conditions (cooling canals, regional canals, Biscayne Bay and model sides). The calibration parameters were varied manually until a model result was obtained that showed satisfactory agreement between simulated and observed pumping test drawdowns at monitored observation wells, as well as a reasonable match to understood directions and amounts of regional groundwater flow.

Model Results – Radial Collector Wells

Determining the environmental impacts of operating the proposed RCWs is the ultimate focus of the FPL groundwater model. The base case model results indicated that approximately 98 percent of water extracted from the RCWs originates in Biscayne Bay with most of the remainder coming from the cooling canals (industrial wastewater facility). Only 0.2 percent of the water produced was predicted by the base case model to come from the freshwater portion of the Biscayne aquifer. This is the water entering the model domain from head-dependent boundaries along the northwest corner of the model. With an assumed RCW continuous withdrawal of 120 Mgd, the predicted volume of water removed from the inland Biscayne aquifer was 0.36 Mgd or 250 gpm according to the base case FPL model. The worst-case sensitivity analysis conducted by FPL regarding extraction of water from the Biscayne aquifer was based on assuming values of vertical conductivity that were 50 percent of the values applied in the base case for all the model layers. This “worst-case” analysis predicted that 1.4 percent or 1,250 gpm would be continuously extracted from the Biscayne aquifer.

The model results indicated that the velocity of water moving downward from Biscayne Bay into the seabed is very low at less than 0.001 cm/s for all sensitivity cases.

The base case model predicted that 2.0 percent of the water extracted by the RCW would come from the industrial wastewater facility. A "worst" case of 3.2 percent of the extracted water coming from the industrial wastewater facility was predicted by cutting the vertical conductivity of all layers in half.

Assessment – Radial Collector Wells

The FPL model provides a reasonable, although uncertain, prediction of the impact of the RCWs on the Biscayne Bay and freshwater resources within the Biscayne aquifer. Parameter uncertainty in the FPL model prediction for the RCW water source is caused by several factors including the following:

- limited area of the pumping test observations used for calibration compared to the extent of the model
- large number of model parameters compared to the limited amount of calibration data

- limited data on the site-specific hydraulic properties of hydrogeologic units except at the pump test locations used in calibration
- lack of data on the hydraulic conductivity of the sediment at the bottom of Biscayne Bay.

Incomplete knowledge of the hydrogeologic system being modeled, the impacts of assuming constant density fluid, the assumption of a steady-state flow system, and problems related to discretization of the model into a cellular grid also cause conceptual model and structural uncertainty in the FPL model results.

One of the most significant uncertainties in the model is the hydraulic conductivity assigned to the sediment at the bottom of Biscayne Bay. The bay bottom was characterized as either "offshore sediment" or exposed "Miami limestone." Water entering the RCW from the bay must pass through one of these materials to enter the higher conductivity "upper high flow zone (UHFZ)" where the RCW are placed.

The NRC staff identified the following issues of potential concern with the FPL model setup:

- Specified heads for the "general head boundary conditions" at the northwest and southwest corners of the model were inconsistent. For the calibration simulations, the western boundary ends at the northwest corner with a specified head of 0.85 ft, while the northern boundary ends at that corner with a value of 0.65 ft. The western boundary ends at the southwest corner with a specified head of -0.2 ft, while the southern boundary ends at that corner with a value of -0.95 ft.
- The non-uniform lateral model discretization (row and column widths) exhibits moderately larger changes than the commonly accepted practice for finite-difference models. The accepted standard practice is for an increase in width between adjacent rows (or columns) to be 50 percent (width ratio of 1.5) or less, whereas the FPL model has increases of 100 percent.
- While the layer elevations mostly vary in a smooth fashion, there are places where adjacent cells of the same layer are offset vertically with no overlap, which differs from the accepted standard practice of 50 percent overlap. The lack of overlap is a result of the magnitude in elevation change over distance combined with the thinness of the layer.

However, the NRC staff expects that the impact of these issues is relatively minor in comparison to the uncertainty in the model parameter calibration.

FPL's base case model predicted that 2.0 percent of the water extracted by the RCW would come from the industrial wastewater facility. This prediction is also regarded as uncertain because of the parameter calibration uncertainty mentioned above and because of the potential effects of variable density fluid on the migration of the hypersaline plume. If the RCWs are operated continuously, then it is likely that the hypersaline water flow induced by the RCW from the industrial wastewater facility would be captured by the RCW. However, intermittent operation could result in an increase of hypersaline flow into the aquifer beneath the bay that could migrate into the bay when the RCW is not operating. The steady-state nature of the FPL model and the assumption of constant density fluids make the model inadequate for modeling this potential scenario.

The NRC staff performed limited runs of the FPL model to verify performance and check some additional sensitivity cases of interest. The main item of interest was the volume of water captured from the inland portion of the Biscayne aquifer along the northwestern corner of the model. A sensitivity case of 10X the base case offshore bay sediment hydraulic conductivity combined with 10X the base case Miami limestone sediment hydraulic conductivity and 10X lower general head boundary conductance was performed. The results showed that approximately 15 percent more water would be captured through the general head boundary along the northwestern corner of the model under these conditions.

Model Results – Inflow to the Power Block Excavations

The FPL model predicted that pumping rates of 96 gpm would be necessary for dewatering each of the excavations at Units 6 and 7. This is based on installation of essentially impermeable grout curtains at the sides of the excavations and grouting of the rock at the base of the excavation.

Assessment– Inflow to the Power Block Excavations

The model results for the dewatering calculations are also affected by model uncertainties discussed above. However, the NRC staff expects the impact of model uncertainty on these calculations to be less significant because of the smaller scale of the focus area. The permeability of the grouted base rock and side walls for the excavation are the primary parameters controlling inflow, and are easier to estimate than the large-scale hydrogeologic parameters that control the source of water captured by the RCW. Engineering controls are also feasible for mitigation of any adverse conditions that are encountered during the excavation activities.

Conclusions

The environmental impact of operating the proposed RCW system is the most important issue addressed by the groundwater model. The FPL model results indicate that continuous operation of the RCW results in extraction of a relatively small volume of water from the inland portion of the Biscayne aquifer and that the velocity of water moving downward from Biscayne Bay into the seabed is very low at less than 0.001 cm/s. The NRC staff's largest concern with the model is caused by uncertainty in the model parameters, especially in light of the limited area of calibration data and the large number of parameters that must be estimated. This may have a significant impact on the predicted volumes of water that would be extracted from the inland potion of Biscayne aquifer along the northwest corner of the model area and the amount captured from the industrial wastewater system. The NRC staff regards model estimates of inflow to the proposed excavations as more accurate than estimates of RCW captured water sources because of the knowledge of hydraulic parameters in that immediate area of the planned excavations.

G.3.2.2 Summary of USGS Modeling

The NRC commissioned the USGS to perform a numerical modeling study of the effects of the operation of a proposed RCW system at the Turkey Point site on surface and groundwater salinity. The resulting report (NRC 2014-TN3078) represents part of the review team's technical basis in its impact determination in this environmental impact statement (EIS).

Purpose of the Study

FPL proposes installing the RCWs at the Turkey Point site for use as a backup source of cooling water for proposed Units 6 and 7 in case of the loss of the normal water supply (reclaimed water from Miami-Dade County waste water treatment system). Neither the reclaimed water nor the water from the RCW system provides a safety-related function. The design of the RCW system and the flow from it are described in Chapter 3 of this EIS. Because of the potential during operation of the RCWs to alter the salinity of two sensitive and significant local water resources—the Biscayne Bay and the Biscayne aquifer—the review team commissioned the USGS independent modeling study. Salinity in Biscayne Bay is a concern because of the ongoing actions under the Comprehensive Everglades Restoration Plan (CERP) to restore freshwater flows to Biscayne Bay National Park (USACE/SFWMD 2011-TN1038). The Biscayne aquifer has been designated a sole-source aquifer by the U.S. Environmental Protection Agency and is critical to the region's freshwater supply.

Unique from other numerical modeling studies included in the review team's assessment, the USGS model explicitly considered density effects on the flow within and between the groundwater and the surface-water systems. The spatial and temporal patterns of salinity are primarily controlled by the flow of water. Therefore, an understanding of various processes resulting in flow is required for the review team to understand the plausible impacts of the RCW operation.

The commissioned study discussed herein relied on a numerical model developed and applied previously to this domain by USGS (NRC 2014-TN3078). This numerical model was used to simulate specific conditions that are understood to exist at the Turkey Point site and under boundary conditions consistent with the operation of the RCW system. The site conceptual model and the numerical model are discussed below.

Conceptual Model

The conceptual model of the region is consistent with a coastal freshwater-saltwater interface. Freshwater results from precipitation that infiltrates into the groundwater system and flows down gradient toward the ocean. As it approaches the seawater, the less dense freshwater tends to flow over the more dense seawater forming a saltwater wedge. The location of this saltwater wedge can move in response to increases and decreases in groundwater recharge from precipitation and also in response to groundwater pumping. Excess precipitation that does not enter the groundwater system through recharge can enter the ocean via sheet flow and channel flow. Several canals discharge freshwater during the wet season (summer to fall). However, along a portion of the area to the south of Turkey Point, the cooling canals prevent sheet flow from discharging to Card Sound and Biscayne Bay directly east of the cooling canals. The warm, hypersaline water in the unlined cooling canals also creates a plume of dense hypersaline groundwater under the cooling canals. Therefore, the site conceptual model reflects these conditions unique to the Turkey Point site. Further discussion of the hydrologic environment including the cooling canals can be found in Section 2.3 of this EIS.

The analysis considered the surface water (notably Biscayne Bay) to be vertically mixed (NRC 2014-TN3078). The review team considered this assumption and determined that because of the shallow depths of Biscayne Bay, particularly near Turkey Point, this assumption was not unreasonable for the examination of potential RCW impacts on salinity in Biscayne Bay. While localized areas of salinity stratification may develop, wind mixing is expected to keep Biscayne Bay well mixed. The analysis used two-dimensional circulation, which is driven in response to wind forcing and tidal elevation boundary conditions (NRC 2014-TN3078). The analysis also assumed that the tidal boundary had a typical seawater salinity of 35 practical salinity units (psu).

Given that one of the motivations for this study was to consider density-driven flow within the groundwater system, the conceptual model explicitly allows for multiple layers and for both vertical variations in hydrogeologic flow-related parameters and for salinity variations. The boundary conditions for the groundwater portion of the model are the freshwater piezometric heads at the boundary of the domain and the areal recharge rates over the extent of the land surface of the domain, which vary seasonally.

The conceptual model explicitly considers the surface-water/groundwater interface with exchange allowed in both directions depending on pressure gradients from upgradient freshwater inflows to groundwater, water-surface elevation differences along canals, well pumping, seepage of cooling canal waters to groundwater, and tidal head variation (NRC 2014-TN3078). For instance, marine waters of Biscayne Bay water can percolate into the bed, enter the groundwater system, and enter the RCWs, and freshwater can enter the Bay through groundwater discharge.

Evaporation of seawater results in increases of salinity. Poorly mixed shallow marine areas without sufficient freshwater inflow are likely to become hypersaline as a result of evaporation. The study included the effect of evaporation on salinity (NRC 2014-TN3078).

As described in Section 2.3 of this EIS, the groundwater underneath Biscayne Bay has salinity levels similar to the marine surface waters. Below the freshwater layer landward of Biscayne Bay, there is a wedge of saline water that intrudes inland. The freshwater underlying the land has a somewhat higher piezometric head than the groundwater underlying Biscayne Bay; hence, there is a flux of freshwater eastward toward Biscayne Bay. Seasonal rainfall patterns also influence the flux of freshwater with increased runoff and surface-water discharge to Biscayne Bay and increased infiltration into the surface layers of the groundwater. Additional components of the surface-water/groundwater system that exist at present include water-supply pumping around population centers, drainage ditches that intercept shallow groundwater, and the cooling canals at Turkey Point. Inland water-supply pumping withdraws freshwater from the groundwater, thereby reducing the piezometric head that drives the salinity wedge seaward. Drainage ditches intercept shallow groundwater and transport it for discharge to Biscayne Bay. These processes are included in the conceptual model.

Numerical Model

The USGS model is based on a previously developed regional-scale model (Lohmann et al. 2012-TN1429) that integrated surface-water and groundwater processes to study flows into and out of Biscayne Bay (Figure G-3). The original model's intent was to examine regional-scale processes that influence Biscayne Bay salinity.

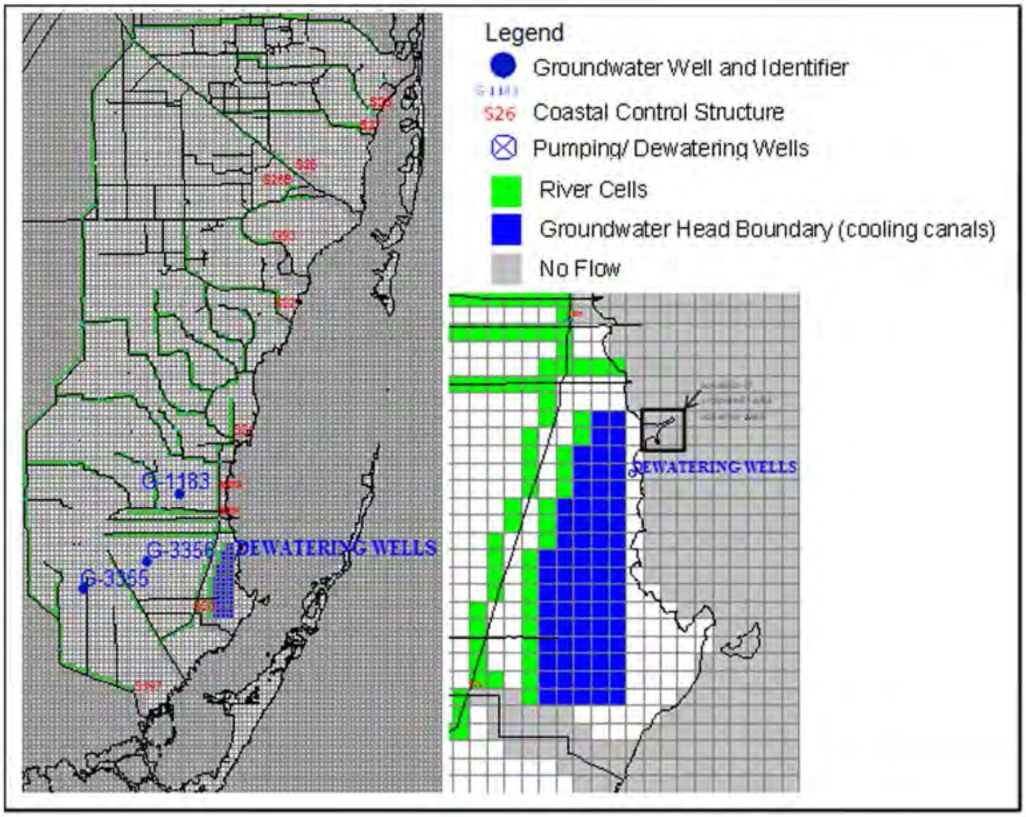

Figure G-3. USGS Model Domain and Grid Used for Salinity Analysis of RCW Pumping at Turkey Point. ***An inset of the grid in the vicinity of Turkey Point is included. (Taken from NRC 2014-TN3078, Figure 2)***

Both model studies (Lohmann et al. 2012-TN1429; NRC 2014-TN3078) covered the period January 1996 through December 2004, a duration of 9 years. This simulation period was chosen because the Lohmann et al. model was calibrated for this period. The canal inflows, precipitation, and meteorology applied in the NRC-commissioned study are the same as those used by Lohmann et al. (2012-TN1429). For the regional-scale analysis, the model used a 500 m by 500 m grid spacing to define the physical features of the model domain. The model uses 20 vertical layers that represent the whole aquifer, with one of those layers representing Biscayne Bay. The surface layer is 4 m thick, the second layer is 1.5 m thick, and the remaining layers are 2.75 m thick. The NRC commissioned study (NRC 2014-TN3078) updated the previously developed model to include (1) the cooling canals and (2) the representation of two temporary dewatering wells during the construction period at the proposed site for the Unit 6 and 7 reactors for the scenarios. Pumping from the dewatering wells was only included in the base case. The cooling canals were represented in the model by 70 cells for which the water-surface elevations were specified and the salinity was set to a constant 65 psu. The two dewatering wells were represented in the model in one cell and were set to pump for a 6-month period (June 2001 through December 2001). The inclusion of these two updates into the Lohmann et al. (2012-TN1429) model constituted the base case of the analysis.

For the evaluation of RCW pumping, the entire RCW system was represented in the model by four grid cells. When active, the total RCW pumping rate was set to 490,536 cubic meters per day (m^3/d) (90,000 gpm). Model inputs that were varied in the commissioned study were (1) the RCW withdrawal layer (layer 3 or layer 5) in the scenarios, (2) the distribution of RCW well intakes in model, (3) the RCW pumping period, and (4) vertical hydraulic conductivities and leakage of the subsurface layers (NRC 2014-TN3078). The commissioned report did not present results for all combinations of the varied inputs because the modeling results of some scenarios were not significantly different from the ones that were included in the report. The analyses ultimately included were for RCW groundwater extraction from layer 3 and for the well intakes distributed along the RCW intake pipes (NRC 2014-TN3078).

In regard to the RCW pumping periods, the commissioned study examined (1) continuous pumping (the most conservative pumping option), (2) 90-day pumping during the annual dry period, and (3) alternating periods of 30 days pumping and 90 days no pumping (NRC 2014-TN3078). Each of these pumping periods is longer than the 60 days mentioned in Section 5.2.1.2 of this EIS as the limit currently proposed by FDEP as the permit condition for operating the wells. Consequently, each pumping period analyzed by the commissioned study (NRC 2014-TN3078) is more conservative than the FDEP conditions would actually permit. Ultimately, the review team included only the continuous-pumping and 90-day-pumping scenarios, because they were the most conservative of the three pumping scenarios examined by USGS. Continuous pumping does not allow any time for system recovery as would occur with the alternating pumping and no-pumping scenarios.

In regard to vertical conductivities, the NRC (2014-TN3078) study examined (1) the values used in the previous study (Lohmann et al. 2012-TN1429), which were used in the base case, (2) decreased vertical conductivity in the subsurface layers plus decreased leakage between surface-water and groundwater layers, and (3) decreased vertical conductivity in all subsurface layers except layers 3, 4, and 5 (RCW extraction layers). The review team only included the first of these realizations because it was based on the calibrated model of the Biscayne Bay and aquifer system. Also, the review team expects that any reduction of vertical conductivity would decrease the effect of RCW pumping on Biscayne Bay salinity.

The commissioned study specified that initial conditions used to start the scenario analyses be the same as the final state of the base case in order to provide each of the scenarios with a common starting point. The specified initial conditions include heads, water levels, and salinity.

Results

The alterations on the salinity in the groundwater and in Biscayne Bay predicted by the USGS model are discussed in the following sections.

RCW Pumping Effects on Groundwater Salinity

At the end of the base case run, the predicted potentiometric surface showed a slight depression along the coast near Turkey Point that is the result of pumping the RCWs in the area that is included in the model (Figure G-4; NRC 2014-TN3078). Layers 2 and 3 were selected for plotting because they are just below Biscayne Bay and any canals, so that any groundwater effects from RCW pumping on Biscayne Bay will be transmitted through these two layers. For the continuous-RCW-pumping scenario, the USGS model predicted a cone of depression that surrounded the RCWs and extended laterally for several hundred meters (NRC 2014-TN3078).

The model predicted that the cone of depression for the continuous-pumping case would be present at the end of the simulation because there was no opportunity for recovery. For the 90-day-pumping case, the model predicted that the cone of depression would not be evident at the end of the simulation because the system would have fully recovered after 275 days of no pumping.

The effect on regional groundwater potentiometric head to the northwest and west of the RCWs and Turkey Point site was predicted to be minimal. Sensitivity tests with vertical conductivity predicted there could be slightly larger changes in potentiometric head, which were attributed to a slightly landward movement of higher density (higher salinity) groundwater (NRC 2014-TN3078). The review team notes that these ranges of potentiometric head were within the range of uncertainty and predictive error of the model.

The salinity results at the end of the simulations for layers 2 and 3 within the groundwater system are shown in Figure G-5 (NRC 2014-TN3078). The blue regions landward of the coast represent freshwater. The green regions are where the marine water was predicted to infiltrate into the first two groundwater layers. The red zones are the hypersaline (high density) plume originating from the cooling canals.

For the area north of the hypersaline plume Figure G-5 the model predicts that in the continuous-pumping case, salinity would decrease landward of Turkey Point in comparison with the base case, while in the 90-day-pumping case, there would be a smaller decrease in salinity. For the continuous-pumping case the model predicts an increase in salinity in layer 3 (Figure G-5) directly under Turkey Point (essentially in a single grid cell), and a decrease in salinity north of the hypersaline plume. For the 90-day-pumping scenario, a decrease in salinity north of the hypersaline plume was also predicted, though the decrease was smaller than for continuous pumping. The smaller change results from the 9 months of recovery per year that is modeled in the 90-day-pumping scenario.

The change in groundwater salinity predicted by the model was assessed by finding the greatest differences for each grid cell between a scenario and the base case (NRC 2014-TN3078). The results at the end of the simulations of the greatest salinity differences for the continuous-pumping and 90-day-pumping scenarios are shown in Figure G-6. Note that the maximum predicted salinity differences for each model grid cell would not necessarily occur in the same layer, but this analysis provided an overall trend of salinity change. The predicted penetration into the groundwater system of the hypersaline plume from the cooling canals produced the ring of high positive change that surrounds the Turkey Point facilities. The model predicted greater freshening of the groundwater under the continuous-pumping scenario than under the 90-day-pumping scenario. The freshening is shown by a negative change in salinity centered northwest of Turkey Point. The predicted change, with the inclusion of RCW pumping, likely results from the withdrawal of a portion of the hypersaline plume from the groundwater system. Because the model conserves mass, withdrawal of groundwater results in water being drawn from other sources to replace it, and the freshening in this region could be due to predicted inflow from either freshwater or marine waters.

Examination of the total volumetric exchange between surface waters and groundwater showed that for the base case the model predicted a tendency toward discharge from the aquifer to Biscayne Bay (Figure G-7), though the base case rates were small (<500 m^3/d). Landward of

Figure G-7. Total Leakage (m^3/d) at the End of the Simulation for the Base Case, Continuous RCW-Pumping, and 90 d/yr Pumping. (Taken from NRC 2014-TN3078, Figure 26 and Figure 27)

Biscayne Bay, the total volumetric exchange predicted for the base case tended toward recharge, as expected with the occurrence of precipitation and infiltration into the land. For the continuous-pumping case, the model predicted a tendency for high recharge (inflow) from Biscayne Bay into the aquifer, as expected with RCW pumping, with rates locally around 5,000 m^3/d. For the 90-day-pumping scenario, the results tended toward recharge but without the higher localized recharge rate predicted with continuous pumping.

RCW Pumping Effects on Biscayne Bay Salinity

To investigate the salinity response in Biscayne Bay to RCW pumping, the review team examined model output results at locations near Turkey Point (NRC 2014-TN3078) corresponding to the measurement stations reported in this EIS Table 2-9, as well as three additional stations further north and close to Turkey Point (Figure G-8). Only the continuous-pumping scenario was included in the examination of Biscayne Bay salinity because the USGS model predicted the largest effects on groundwater for this scenario and it provided an upper bound of salinity variation of all potential RCW-pumping scenarios.

Time series of salinity results and salinity differences for the seven stations are shown in Figure G-9. Generally, the model predicted that salinity would exhibit seasonal variation due to freshwater inflows from drainage canals into Biscayne Bay, while increases in salinity would result from evaporative losses. For both the base and continuous-pumping cases, the largest seasonal variations were predicted at the northernmost locations (station A and B), with the smallest seasonal variations around Turkey Point (station C). Model results for locations closest to the measurement stations exhibited an intermediate range of seasonal variation. The north-south differences in seasonal salinity variation was likely caused by the northern portion of the region receiving relatively larger inputs of freshwater inflows from canals during the wet season.

The review staff computed the summary statistics (Table G-22) for salinity time series for the stations shown in Figure G-9. As suggested by the variation seen in the time-series plots, the standard deviations were largest for the northernmost stations examined. The minimum and maximum salinities also varied by location, with the largest maximum and smallest minimum predicted for the northernmost stations. For the tidal boundary, the primary source of water for Biscayne Bay, the model had the salinity set to 35 psu (Lohmann et al. 2012-TN1429). In comparison with the measured stations (EIS Table 2-9), the maximum salinities from the NRC commissioned study were smaller than observed at the measured stations (NRC 2014-TN3078). However, the periods from which the data were available were not the same between the measured data (2005 onward) and model results (2004 and earlier), so that direct comparisons are not possible.

The review team finds that the salinity differences between the continuous-pumping and base cases varied between +2 psu to -2 psu, but with most variations between +1 psu and -1 psu (Figure G-9). The model predicted an anomalous increase within the first year (1996) because of the onset of pumping, but this was wiped out by the start of 1997. Variations beyond +2 psu and -2 psu were predicted to be of very short duration.

Source: NRC 2014-TN3078

To investigate the spatial distribution of salinity and salinity differences, the review team examined salinity at two different characteristic periods. One was selected that had positive salinity differences as shown in Figure G-9, and another was selected that had negative salinity differences as shown in Figure G-9. During both of these periods, the salinities along the nearshore north of Turkey Point were lower than those typically found for marine waters, being on the order of 20 psu compared to 35 psu specified at the model's tidal boundary with the Atlantic Ocean (Figure G-10 and Figure G-11). Examination of the salinity differences from the October 3, 2003 results showed a small increase in salinity in southern Biscayne Bay (Figure G-10), with only a small patch of nearshore water predicted to have a salinity increase on the order of +2 psu. In contrast, the results for the October 25, 2003 period showed a small decrease in salinity (Figure G-11), with a small patch of nearshore water predicted to have a salinity decrease on the order of -1.5 psu.

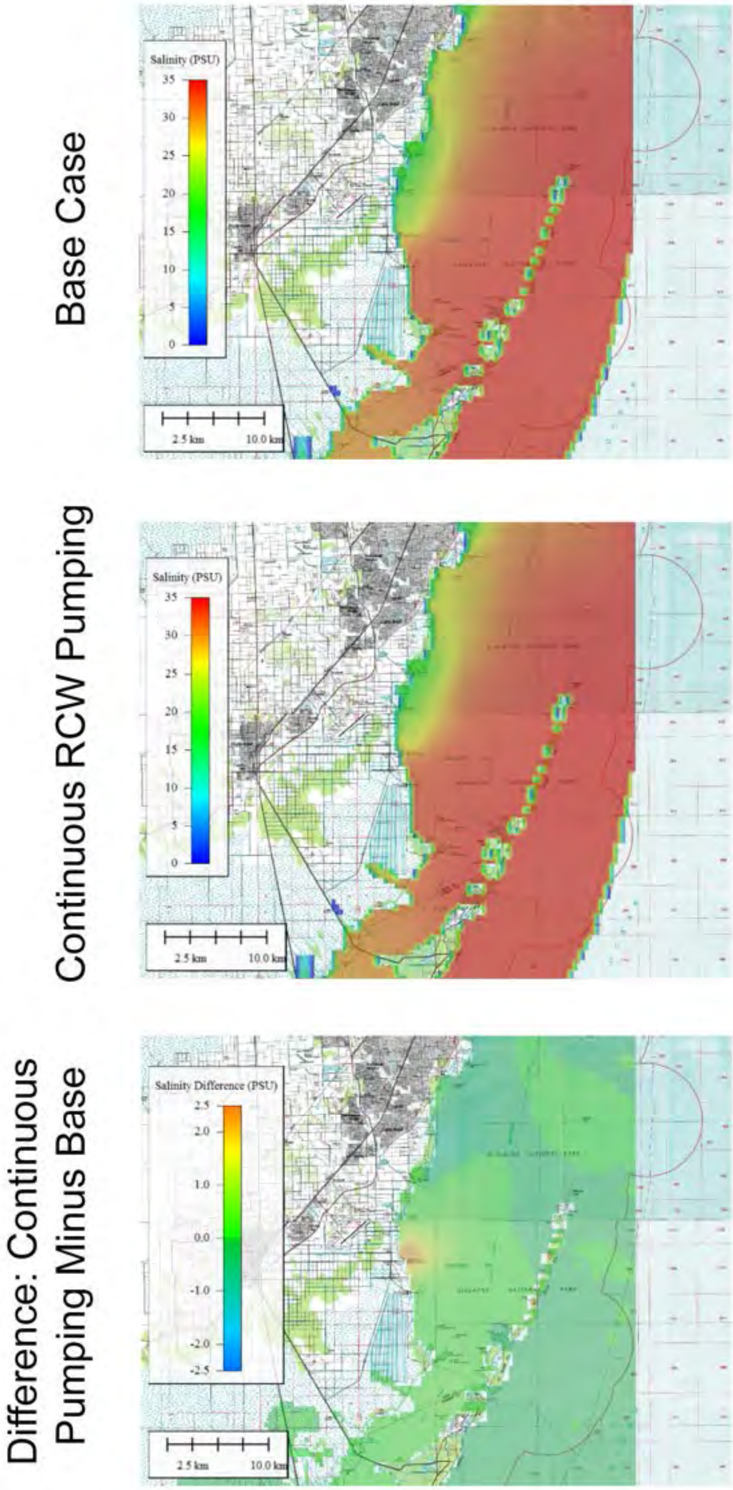

Figure G-10. Surface-Water Salinities at the Time with the Largest Difference North of Turkey Point between the Base Case and Continuous-Pumping Scenario on October 3, 2003. ***Units are psu (practical salinity units).***

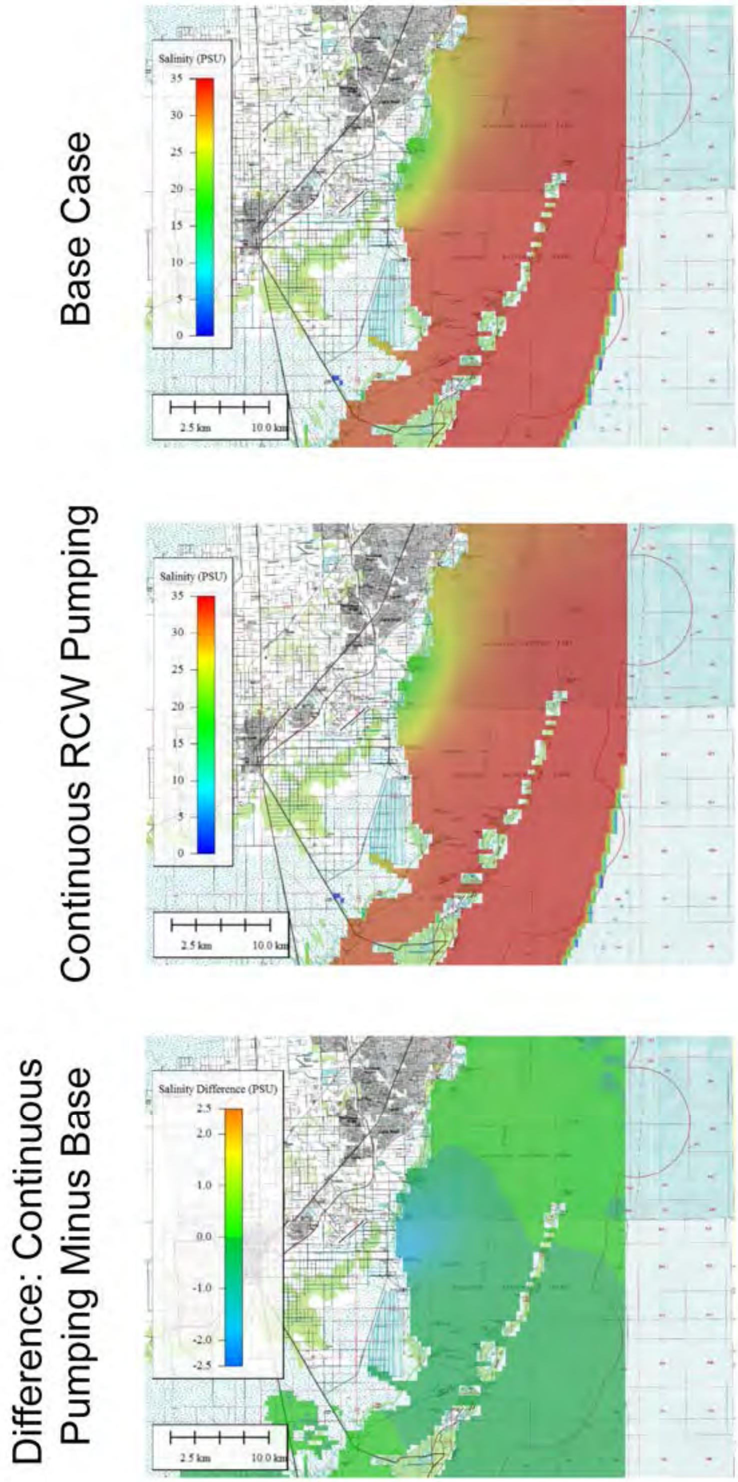

Figure G-11. Surface-Water Salinities at the Time with Largest Decreases North of Turkey Point between the Base Case and Continuous-Pumping Scenario on October 25, 2004. ***Units are psu (practical salinity units).***

G.3.2.3 Summary of Review Team Focused Modeling

To further confirm the review team's understanding of the groundwater hydrodynamics and to consider whether certain actions proposed after the two earlier modeling studies were completed would alter the earlier conclusions documented by the review team in their draft environmental impact statement (EIS, NRC 2015-TN4444), the review team performed a third modeling analysis. This third modeling analysis is discussed in this section and presented in detail by Oostrom and Vail (2016-TN4739).

The review team used the water-salt-energy mode of the STOMP (Subsurface Transport Over Multiple Phases) simulator to perform the simulations (White and Oostrom 2006-TN4808). The applicable governing equations are the component mass-conservation equation for water and salt and the energy conservation equation. The simulator allows for the consideration of density-driven flow and temperature effects caused by the seepage of warm hypersaline water from the unlined cooling-canal system (CCS) into the saline Biscayne aquifer. The review team based the model configuration on an earlier cross-sectional model published by Hughes et al. (2010-TN1545). The two-dimensional (2D) model is 46 km long and extends 35 m vertically. To facilitate simulation of the effects of radial collector well operation, the review team also developed a three-dimensional (3D) model, which represents a 2 km wide extension of the 2D model.

The review team performed a steady-state simulation with a Biscayne Bay hydraulic head of 0.2 m and a west boundary head of 1.05 m to obtain the initial conditions for both the 2D and 3D simulations. The long-term (10,000-year) simulations yielded a typical salt intrusion front, which extends below the CCS. For the subsequent hypersaline water infiltration simulations, the review team used the same boundary conditions as those proposed by Hughes et al. (2010-TN1545) for hydraulic heads and temperature.

The 2D simulations predict several main observations, as follows:

- CCS operation with warm 70 g/L hypersaline water leads to the development of a large subsurface plume.
- Reducing the CCS salt concentration leads to a stable displacement of hypersaline water from the CCS subsurface.
- Increasing the hydraulic head in the L-31E Canal limits westward migration of the hypersaline plume.
- Increasing the west boundary hydraulic head (indicative of increased recharge) results in a compression of the hypersaline plume at the west side of the CCS.
- Decreasing the west boundary hydraulic head (indicative of reduced recharge) has the opposite effect, and leads to additional migration of the hypersaline plume in the western direction.
- During sea-level rise, infiltrating saltwater from the Biscayne Bay pushes the hypersaline water toward the CCS subsurface. Over time, the interface between hypersaline water originating from the CCS and seawater becomes more sharply defined and more vertical.

The 3D simulations predict several main observations, as follows:

- Periodic extraction using the RCW system leads to fluctuating salt concentrations in the radial collector wells.
- During pumping, the salt concentrations initially increase because of advective transport of hypersaline water through the Upper Higher Flow Zone; the salt concentrations then decrease because of the influence of extracted Biscayne Bay saltwater.
- During intervals between periods of pump operation, salt concentrations slightly increase due to diffusion of hypersaline water eastward; the radial collector well salt concentrations do not change significantly from year to year.
- RCW pumping increases the concentration gradients between the hypersaline plume below the CCS and Biscayne Bay saltwater in the upper parts of the aquifer and removes some of the hypersaline water from the Fort Thompson formation; the extracted volumes originate largely from Biscayne Bay (>95 percent); pumping rate reduction (up to 10 percent of maximum) and duration reduction (50 percent) do not considerably influence collector well salt concentrations. This result indicates that the proposed RCW operation with a 86,400 gal/min withdrawal rate over 60 days per year would completely dominate flow and transport adjacent to the RCWs, because reasonable variations in the rate and duration do not considerably influence collector well salt concentrations.
- Boundary condition modifications (i.e., L-31E Canal head and west boundary head increases) applied to the west of the CCS do not influence RCW extraction behavior.
- Seawater rise in Biscayne Bay leads to decreasing RCW saltwater concentration over time because the increasing Biscayne Bay hydraulic head displaces hypersaline water toward the CCS subsurface.
- Operation of remediation wells in the Lower Higher Flow Zone below the Interceptor Ditch does not influence extracted RCW salt concentrations.
- Salt concentrations in the remediation wells are predicted to increase to CCS salt levels within a year of remediation pumping.
- Freshening of the CCS surface water results in reduced RCW salt concentrations with relatively minor (<1 g/L) fluctuations.

Without doubt, some perturbations of the baseline boundary conditions result in significantly altered environmental baselines. However, while the operation of the RCWs would change the incremental impacts of the RCWs on the salinity distribution of the Biscayne aquifer, the alterations would remain at levels that may only be detectable within the immediate vicinity of the RCWs. While the numerical model analysis predicts a slight westward movement of some hypersaline water as a result of the operation of the RCWs, there is no plausible upward impelling force above the RCWs that would result in hypersalinity moving into the Bay as a result of RCW operation. As the review team acknowledged in the EIS Section 2.3.1, when the water-surface elevation in the cooling canals exceeds that in the Bay, the water will follow the gradient of the impelling force into the Bay and may contribute to salinity in the Bay. Both of the above effects also apply for other dissolved constituents in the hypersaline plume, including nutrients and tritium.

Although the primary focus of the modeling reported here is on the incremental effects of the RCWs on the Biscayne Bay, the review team also acknowledges the cumulative impacts of other changes, including those from sea-level rise and possible future regulatory actions. While the scenarios considered in this analysis were designed to be bounding for sea-level rise and possible regulatory actions, they also provide a basis for assessing the cumulative impacts. NRC lacks authority to impose additional mitigation measures regarding surface water conditions subject to State regulation. However, additional mitigation actions proposed by state and county agencies would presumably improve the baseline environment. Because the modeling results predict that the incremental effect of the operation of the RCWs remains minor, the cumulative effects would also remain minor.

The review team's modeling predicts minor localized alterations in salinity distribution due to RCW operation, and these results suggest that the operation of the RCWs is unlikely to interfere with any of the mitigation measures proposed to address the conditions in the cooling canals or the underlying Biscayne aquifer.

G.3.3 Confirmatory Calculations of Potential Upward Migration of Injectate from the Boulder Zone of the Lower Floridan Aquifer

As described in Chapter 5 of the EIS, blowdown and other liquid wastes from the proposed plants would be injected into the Boulder Zone of the Lower Floridan aquifer. Use of reclaimed water as a makeup water source would result in injectate that is buoyant because of its lower density compared to the saline water in the Boulder Zone. FPL conducted performance assessment modeling of potential upward migration of injectate based on the reclaimed water source (FPL 2014-TN4069) in support of the safety and environmental analysis of the proposed plants. The analyses consisted of two main scenarios that were considered feasible:

- Normal Operation Scenario: Upward migration of contaminants through a competent middle confining unit (MCU) under expected hydrogeologic conditions. The normal operation scenario assumes that no system failures occur, e.g., no injection well failure or subsurface loss of confinement beyond the FPL property area.
- Off-Normal Operation and Inadvertent Intrusion Scenario: Bypass of the MCU at a location 2.2 mi from the wastewater injection site through a hypothetical high-conductivity channel or failed well (conduit), where a water-supply well is withdrawing water from the upper Floridan aquifer directly above the MCU conduit. The hypothetical water-supply well provides direct access to the upper Floridan aquifer, bypassing the intermediate confining unit and the Biscayne aquifer.

The FPL analyses were focused on the fate and transport of radionuclides in the injectate, but also demonstrate the potential movement of chemical species in the injectate. The FPL analyses were based on conservative assumptions that would tend to maximize the migration of effluent. The off-normal and inadvertent intrusion scenario "bounded" some other feasible scenarios such as bypass of the MCU at the injection site because it resulted in shorter travel times.

The review team performed a separate confirmatory analysis of these scenarios, which resulted in concentrations of radionuclides at receptor locations similar to those calculated by FPL. The confirmatory analyses were performed through spreadsheet calculations as described below.

G.3.3.1 *Normal Operations: Upward Migration through a Competent MCU Layer Scenario*

The confirmatory calculation was based on transport equations described by Post et al. (2007-TN4145) and used the parameters shown in Table G-23. The effective vertical hydraulic conductivity of the MCU was based on the harmonic mean of the values determined from testing of core samples from the MCU at the EW-1 exploratory well (FPL 2012-TN1577). The harmonic mean is the most appropriate hydraulic conductivity value for fluid flow perpendicular to a layered system (Freeze and Cherry 1979-TN3275). Lower porosity decreases travel time in the calculations, so a conservatively low porosity value of 0.2 was used. The core analysis results from EW-1 are shown in Table G-24.

Table G-23. Parameters and Results for the Confirmatory Analysis of Upward Migration through a Competent MCU Layer

Parameter	Value	Description
z1[(a)]	-2,900 ft	top of injection zone (referenced to sea level [positive upward])
z2[(b)]	-1,400 ft	bottom of USDW aquifer (referenced to sea level [positive upward])
ρ1[(c)]	62.230 lb_m/ft^3	water density at top of injection zone
ρ2[(d)]	62.792 lb_m/ft^3	water density at bottom of USDW aquifer
h1[(e)]	328.1 ft	piezometer head elevation at top of injection zone
h2[(f)]	188.6 ft	piezometer head elevation at bottom of USDW aquifer
Keff[(g)]	1.82E-07 ft/s	effective hydraulic conductivity
ρa	62.5 lb_m/ft^3	calculated average density over the migration interval
hf1	328.1 ft	fresh water head at top of injection zone
hf2	203.0 ft	fresh water head at bottom of USDW aquifer
Δhf	-125.1 ft	calculated freshwater head difference
Δz	1,500 ft	calculated elevation difference
Δhf/Δz	-0.0834	calculated fresh water gradient
(ρa-ρf)/ρf	0.0045	calculated density gradient
qz	1.24E-3 ft/d	calculated groundwater flux (positive upward)
Θeff[(h)]	0.2	effective porosity along flow path
tt	663 yr	calculated travel time from z1 to z2
Distance in 100 yr	226 ft	calculated vertical migration distance in 100 yr
Linear Velocity	0.00619 ft/d	calculated
C1	1	unit concentration of injectate at top of injection zone
t-half	12.3 yr	tritium half-life
C2	5.92E-17	calculated fraction of unit tritium concentration after 663 yr

Note: flux calculated based on Post et al. (2007-TN4145)
(a) FSAR Fig. 2.4.12-245
(b) FSAR Fig. 2.4.12-246
(c) minimum FSAR value assumed to be freshwater density = 62.2 lb_m/ft^3
(d) 10,000 mg/l TDS @ 20°C

G.3.3.2 Off-Normal Operation and Inadvertent Intrusion Scenario:

FPL's safety analysis (FPL 2014-TN4069) also considered a case with a hypothetical water-supply well being drilled into the upper Floridan (USDW) aquifer and a simultaneous bypass/failure of the MCU at the same location 2.2 mi from the wastewater injection site. The 2.2 mi distance is based on the nearest privately owned parcel. This scenario makes the off-normal operation assumption that there is a high-permeability connection through the MCU between the injection zone and the upper Floridan aquifer located 2.2 mi from Turkey Point wastewater injection site. This is combined with an inadvertent intrusion scenario that places a water-supply well in the upper Floridan aquifer directly above the conduit through the MCU. The FPL analysis showed that the transit time through the Boulder Zone from the Turkey Point injection wells to the offsite location 2.2 mi away would be 21 years (FPL 2014-TN4069). The staff's confirmatory calculation showed that at the expected injection rate of 12,460 gpm, and a conservatively low porosity of 0.2, the injectate plume would reach the hypothetical offsite location in 23.5 years.

The safety analysis was conservative in that it did not account for transit time through the MCU and it did not account for dilution of contaminants within the Upper Floridan aquifer. It assumed that 100 percent of the water pumped by the water-supply well would be from the Boulder Zone with no dilution in the APPZ or the Upper Floridan aquifer.

The staff performed a calculation of expected flux through the MCU and dilution in the Upper Floridan aquifer using the maximum MCU hydraulic conductivity from the range of values shown in Table G-24 for the area of the enhanced vertical flow pathway. This calculation assumed a pathway size of 0.3 m^2 to match the approximate size of a failed borehole seal. The results of the leakage calculations for this scenario were an upward velocity of 1,245 m/yr and eventual discharge of 54 gpd of injectate into the Upper Floridan aquifer. It was assumed that this volume of injectate would mix over a width of 10 m and 1 percent of the Upper Floridan aquifer depth before being brought to the surface through a water-supply well. This was based on an Upper Floridan aquifer transmissivity equal to the minimum of the range of values, which would minimize the calculated dilution factor. This very conservative mixing scenario results in a dilution factor of 0.93, meaning that 93 percent of the water from the well would be injectate. This calculation represents a conservative case in multiple ways, including the assumption that a water-supply well would be placed such that it would exclusively be pumping water from the assumed mixing zone directly above a high-conductivity conduit from the injection zone. An upward velocity of 262 ft/yr was estimated by Maliva et al. (2007-TN1483) for an enhanced vertical flow feature at an injection site in Palm Beach County compared to the 1,245 ft/yr upward velocity from this analysis.

Table G-25. Parameters and Results for the Confirmatory Analysis of Upward Migration Through a Conduit in the MCU and into the Upper Floridan Aquifer

Parameter	Value	Description
z1[(a)]	-2,900 ft	top of injection zone (referenced to sea level [positive upward])
z2[(b)]	-1,400 ft	bottom of USDW aquifer (referenced to sea level [positive upward])

G.4 SAMDA Sensitivity Evaluation and Supporting Documentation

G.4.1 Introduction

FPL performed a SAMDA evaluation and determined that none of the severe accident design alternatives (SAMDAs) can be justified to further reduce the risk of severe accidents. NRC's review of the FPL submittal is detailed in Section 5.11.3. The SAMDA evaluation by FPL and the confirmatory evaluation by NRC identified the self-actuating containment isolation valves design alternative as the only design alternative with a value comparable to the maximum attainable benefit for the Turkey Point site. The results of the FPL analysis indicate that the maximum attainable benefit if the total risk for the AP1000 at the Turkey Point site were reduced to zero would have a value of about $55,513. The cost of implementing the self-actuating containment isolation valves design alternative is estimated to be $33,000. Thus, this SAMDA would be potentially cost-beneficial. To evaluate the maximum benefit of implementing the self-actuating containment isolation for the risk that this SAMDA would actually affect the Containment Isolation severe accident release category of Table 5-18 would be eliminated by this SAMDA and its contribution would be added to the Intact Containment release category. This would result in a benefit associated with this SAMDA of approximately $994. As was

APPENDIX I

THE EFFECT OF CLIMATE CHANGE ON THE EVALUATION OF ENVIRONMENTAL IMPACTS

The review team has determined that it is reasonably foreseeable that climate change may substantially alter the affected environment described in Chapter 2 of this environmental impact statement (EIS). Climate change is a global phenomenon that the construction and operation of the proposed two-unit plant will not appreciably alter. However, climate change will provide a new environment that the operation of the proposed units will affect.

The objective of this appendix is to document the review team's consideration of the potential changes in impacts that may occur as a result of the new future environment. This appendix is not intended to be a comprehensive climate change assessment for the affected region. It documents the review team's qualitative determination of the likely changes in the impacts described in Chapter 5, if the environment is altered in a manner consistent with the predictions in current climate change literature.

The Nuclear Regulatory Commission staff documents the review of the safety of the plant in the Safety Evaluation Report (SER) expected to be published in November 2016 (NRC 2016-TN4619). If the NRC grants the FPL COL application, the staff will inspect and otherwise moniter plant construction and operation. This safety oversight process includes collection and analysis of information regarding changes in the severity or frequency of natural hazards, such as flooding from storm surge and sea level rise, as discussed in SECY-15-0137 (NRC 2015-TN4731). When warranted, the NRC can request licensee study and analysis of changing natural hazards, and can impose additional design or operation requirements to address those changing hazards.

In this appendix, the review team assessed the potential effects of climate change on its evaluation of the environmental impacts of the proposed action. The results of this assessment are presented below in three sections: (1) description of the assessment process, (2) potential climate change impacts in the region, and (3) assessment summary. The appendix also discusses the USACE's consideration of climate change in the context of the USACE Public Interest Review.

I.1 Description of the Assessment Process

As part of its National Environmental Policy Act (42 U.S.C. 4321 et seq.) (TN661) review, the U.S. Nuclear Regulatory Commission (NRC) staff analyzes greenhouse gas emissions and the potential effects of climate change for all resource areas in all new reactor licensing proceedings. In guidance dated August 1, 2016 on greenhouse gas emissions and climate change, the Council on Environmental Quality (CEQ) states "action agencies need not undertake new research or analysis of potential climate change impacts in the proposed action area, but may instead summarize and incorporate by reference the relevant scientific literature."

In this regard, this EIS incorporates by reference the U.S. Global Change Research Program report (GCRP 2014-TN3472; CEQ 2016-TN4732)."

In the first step of the NRC staff's process a master table was created identifying plausible nexuses between nuclear power station resource area issues related to operation and likely climate change impacts as identified in the most recent climate change impacts report issued by the GCRP (2014-TN3472). The interagency GCRP was established under the Global Change Research Act of 1990 (P.L. 101-606) (15 U.S.C. § 2921 et seq.) (TN3330) "to understand, assess, predict, and respond to human-induced and natural processes of global change" and is the authoritative U.S. government source on likely climate change impacts in the United States. The master table was used to develop a list of questions for each resource area to assist the NRC staff in addressing whether GCRP-identified climate change impacts were likely to increase, decrease, or leave unchanged the assessed impact of a proposed facility on the environment, or to identify areas where scientific uncertainty precludes a definitive assessment. The comprehensive master table and question list can be found in the NRC's Agencywide Documents Access and Management System (ADAMS), which is accessible from the NRC website at www.nrc.gov/reading-rm/adams.html (the Public Electronic Reading Room) under the following accession number ML5026A470 (NRC 2014-TN4149). A table, termed the site-specific resource table, and list of questions specific to the proposed site of Turkey Point Units 6 and 7 were then generated by removing non-relevant GCRP climate impacts and NRC resource area issues, and by using specific Southeast regional predictions identified by the GCRP. For example, the review team determined GCRP-identified direct impacts related to declining ice volume and extent were not relevant to the Turkey Point environment. The review team used the site-specific resource table and question list (NRC 2014-TN4150) in its assessment of the effects of climate change on relevant resource areas given in Section I.3. A combined construction permit and operating license (COL) is valid for 40 years (10 CFR 52.103) (TN251). In conducting its assessment, the NRC staff noted that if COLs are granted to the proposed facilities, baseline changes are more likely to be noticeable during operation (Chapter 5) than during preconstruction and construction (Chapter 4). The review team's efforts thus focused on assessing the potential effects of climate change on the resource area impact levels assigned in Chapter 5. While general scientific consensus exists that climate change is occurring and will continue to occur for the foreseeable future, significant uncertainty remains about the magnitude of the changes for specific regions and the precise magnitude and form of the impacts on the environment from climate change. The review team acknowledges this situation, explicitly noting in this appendix where uncertainty in future climate predictions and uncertainty in impacts may make it impossible at this time to conclude qualitatively the influence of climate change on a specific resource area or issue. The review team also acknowledges that the Southeast Florida Regional Climate Change Compact, which includes Miami-Dade County, has established a Regional Climate Action Plan that discusses goals to reduce greenhouse gas emissions and adapt to regional and local impacts of a changing climate. Some of the climate change impacts discussed in this appendix could be further reduced with the efforts of this Regional Compact.

I.2 Potential Climate Change Impacts in the Region

Climate change is a subject of national and international interest. The recent compilation of the state of knowledge in this area—GCRP's climate change impacts report (GCRP 2014-

TN3472)—has been considered in the preparation of this EIS. Most GCRP projections are expressed as a change expected for the later part of the 21st century (2071−2099) relative to average conditions existing in the later part of the 20th century (1970−1999). Projected changes are also dependent on future emissions of heat-trapping gases. The GCRP's climate change impacts report includes projections for wide-ranging scenarios where such emissions are rapidly reduced and where they continue to increase.

Florida Power & Light Company (FPL) has indicated that, if the COLs are granted, it expects to initiate commercial operations in the second quarter of 2027 and second quarter of 2028 for Units 6 and 7, respectively (FPL 2015-TN4502). The Atomic Energy Act (42 U.S.C. § 2011 et seq.) (TN663) and NRC regulations (10 CFR 52.103) (TN251) limit commercial power reactor licenses to an initial 40 years. If granted, under FPL's proposed schedule the COLs would be valid until 2067 and 2068. The NRC staff considers use of GCRP impacts report projections for the 2071−2099 period under a continued increasing emissions scenario to be a conservative proxy for likely future conditions encompassing the licensing action, and for assessing the effects of climate change on the resource area impact levels presented in this EIS. Unless otherwise stated, projected climate changes discussed in this section are taken from the impacts report (GCRP 2014-TN3472) and refer to changes for the 2071−2099 period relative to the 1970−1999 period under an increasing emissions scenario.

Projected changes in the climate for southeastern Florida include an increase in average surface air temperature of 5°F to 6°F. The number of days with maximum temperatures above 95°F is expected to increase, rising by 50 or more days per year for the 2041−2070 period relative to 1971−2000. The hottest and coldest days expected in a 20-year period at the end of this century (2081−2100) are both projected to be 6°F to 7°F warmer than those experienced at the turn of the last century (1986−2005); in other words, both the hottest and the coldest days will be warmer. Southeastern Florida is projected to experience no days with temperatures below 32°F during the 2070−2099 period; currently, the low-temperature extreme for the proposed Turkey Point site is 25°F (Section 2.9.1.2). Projected precipitation changes in southeastern Florida vary seasonally, increasing by 0 percent−10 percent in winter, decreasing by 0 percent−10 percent in spring, decreasing by 20 percent−30 percent in summer, and increasing by 10 percent−20 percent in fall. Extreme heavy precipitation events are expected to increase in both frequency and intensity; an event that now occurs once in 20 years is projected to occur 2 to 3 times as often by the end of the century. Heavy precipitation events are expected to have a 20 percent increase in the amount of precipitation falling. The climate change impacts report indicates that the number of tropical storms occurring around the globe will decrease, but those that occur will be stronger in force, yielding more Category 4 and 5 storms. Rainfall rates associated with tropical storms are expected to be greater, "…with projected increases of about 20 percent averaged near the center of hurricanes" (GCRP 2014-TN3472).

Sea level is projected to rise 1 to 4 ft globally by 2100 (GCRP 2014-TN3472). However, the review team acknowledges that, at the extreme high end, global sea level is predicted to rise by 8.2 ft by 2100 relative to 2000. Should this extreme high range of sea level rise occur, much of South Florida would be uninhabitable and millions of people would likely be displaced. Sea level rise, however, occurs gradually, so that adaptation is possible. As explained in the impacts report, the amount of sea-level rise experienced in any one location "depends on whether and how much the local land is sinking…or rising, and changes in offshore currents." In its report, the GCRP rates the vulnerability of the Turkey Point area to sea-level rise as "high" to "very high," and notes an "imminent threat of increased inland flooding during heavy rain events in low-lying coastal areas such as southeastern Florida, where just inches of sea level rise will impair the capacity of stormwater drainage systems to empty into the ocean." Sea-level rise also is expected to "…accelerate saltwater intrusion into freshwater supplies from rivers, streams, and groundwater sources near the coast" and agricultural areas around Miami-Dade County "…are at risk of increased inundation and future loss of cropland with a projected loss of 37,500 acres in Florida with a 27-inch sea level rise." Water demand in southeastern Florida is projected to increase by more than 50 percent by 2060, relative to 2005, based on combined changes in population, socioeconomic conditions, and climate. The GCRP cites the Southeast Florida Regional Compact as an "excellent example" of regional cooperative efforts among local, state, and federal agencies to develop "a comprehensive action plan" to adapt to impacts from climate change and sea-level rise.

The NRC staff also considered localized sea level rise associated with changes in regional ocean currents (Ezer et al. 2013-TN4734; Park and Sweet 2015-TN4733). The NRC staff determined that these localized changes were adequately bounded by the 1 to 4 ft sea level rise projected in the GCRP report.

The Southeast region currently contains "…existing power plant capacity to produce 32 percent of the nation's electricity," but also currently consumes 27 percent of the nation's total capacity, more than any other GCRP-defined region. Higher temperatures and increased use of air conditioning are projected to increase regional energy demand, "potentially stress[ing] electricity generating capacity, distribution infrastructure, and energy costs" (GCRP 2014-TN3472).

Other climate change impacts in the Southeast region identified in the GCRP report and relevant to the Turkey Point area include ecosystem exposure to risks from sea-level rise, particularly in tidal marshes, swamps, and wetlands; compromised protection of coastal lands and people against storm surge due to tidal wetland loss; effects on fisheries and fishery habitats due to wetland loss; spread of non-native plants; decreased crop production and livestock yield; increased formation of allergens and air pollutants, including ozone; and increases in harmful algal blooms and other surface-waterborne disease-causing agents. In addition, the GCRP indicates the potential for ocean warming leading to changes in local species composition, growth rates, spawning seasons, and/or migratory patterns; increased wildfire frequency, intensity, and size; effects on vector-borne and zoonotic (animal to human) disease transmission; increased insurance costs or unavailability of insurance coverage due to increased flooding incidents; stresses on society and infrastructure due to movement of people from vulnerable areas; effects of changes in energy costs on lower income households, the elderly, native tribes, and other vulnerable communities; and damage to transportation infrastructure.

I.3 Assessment Summary

This section summarizes the review team's assessment of the effects of climate change on relevant resource areas using the process outlined in Section I.1.

I.3.1 Land Use

I.3.1.1 Land-Use Summary

Climatological changes are not likely to influence, or lead to, any plant operational impacts on local/regional land-use classifications or economic development plans. Climate change could lead to changes in the distribution of land use in Miami-Dade County and sea-level rise could lead to the loss of some inhabitable land in the county. However, once the operational workforce is housed in the initial years of operation, operation of a reactor is not expected to alter land use. Therefore, there is little potential for interaction between land-use changes resulting from climate change and land-use changes caused by later operational years of the reactor.

I.3.1.2 Land-Use Conclusion

Climatological changes are not expected to affect the land-use operational impact level assigned in Chapter 5.

I.3.2 Hydrology

I.3.2.1 Summary

Climatological changes are not expected to affect the anticipated hydrologic alterations resulting from station operation, or influence (or lead to) plant operations impacts on other water uses and users. Sea-level rise will result in greater depth of Biscayne Bay near the Turkey Point site. Because of the current very shallow conditions of Biscayne Bay in this vicinity even a modest increase in sea level may help to improve circulation (reducing the hypersalinity of water entering the radial collector well system). Circulation is also controlled by flow conditions away from the site. The review team presumed that the cooling canals' water-surface elevation would likely also rise in response to the rise in sea level. This rise would increase the volume of water in the canals, but it is not expected to appreciably change the gradient between Biscayne Bay and the cooling canals. Therefore, no change in the interface between the canals and the Bay is expected.

Sea-level rise will also push the freshwater–seawater interface further inland. This will put further stresses on freshwater resources inland. However, because the proposed Units 6 and 7 would use reclaimed wastewater for most of its water needs, this would not alter the impact of the plant. Groundwater modeling analyses performed by the NRC staff explicitly considered the changes in impacts of operation of the radial collector wells that would occur with reduced inland recharge (e.g. drought) and increased sea level (see Appendix G.3). While saltwater intrusion is shown to move farther inland under both of these scenarios, the radial collector wells are shown to not have contributed to the saltwater intrusion.

Sea-level rise combined with more frequent Category 4 and 5 storms will increase the potential for damaging storm surge events at the Turkey Point site (Little et al. 2015-TN4729). The final SER discusses the safety of the proposed plants in regard to natural flooding hazards, including hazards from extreme hurricanes combined with other factors such as sea level rise. An extreme natural flood at the site, however, could damage features at the site, including the IWF for the existing units, piles of spoils from muck removal for the construction of the proposed units, and non-safety related structures built for the proposed units. While storm surge damage to these features would result in the release of sediment and nutrients to Biscayne Bay, such damage would not be localized to the Turkey Point site. The contribution of the Turkey Point site to the release of sediment and nutrients to Biscayne Bay as result of an extreme flood would likely be a small fraction of the total sediment and nutrient load that would enter the local waterways.

As discussed in Section I.2, precipitation amounts in South Florida are projected to shift in different directions in different seasons. Even if total precipitation increases, if the majority of this increase is in response to intense storms it would not result in a proportional increase in recharge to groundwater. The increase in temperature may also increase evapotranspiration, thereby further reducing recharge. The review team determined that overall recharge to the Biscayne Bay aquifer may be reduced as a result of climate change. However, because the proposed plant would use reclaimed wastewater for most of its water needs, this would not alter the plant's impact on the environment.

The review team could not determine whether an increase in temperature or changes in precipitation patterns would result in any change in the supply of wastewater for the plant's cooling system. A substantial increase in sea level rise, however, could impact the wastewater treatment plant that provides the primary source of cooling water for proposed Units 6 and 7. Given the abundance of wastewater in this region, the review team determined that a sufficient supply of wastewater would remain available regionally. In the event of substantial sea level rise, Miami Dade County may adapt some of its wastewater treatment infrastructure. Given the critical public health role of these facilities, the review team determined that such adaptations are reasonably foreseeable.

I.3.2.2 Conclusion

The review team identified no shift in the Chapter 5-assigned impacts on water use and water quality caused by the operation of the proposed plant due to a reasonably foreseeable alteration in the environmental baseline associated with climate change.

I.3.3 Terrestrial & Wetland Ecology

I.3.3.1 Summary

Climatological changes could affect the impact of plant operations from facility and landscape maintenance, noise, and traffic on terrestrial habitats and wildlife. In particular, climate change could increase stress on terrestrial habitats, especially the freshwater and brackish water wetlands comprising the Everglades, the mangrove wetlands adjoining Biscayne Bay, and the tree islands and remnant patches of pine rocklands that dot the surrounding landscape. Climate change could result in longer periods between precipitation events, drier conditions during some seasons, and more frequent wildfires that could facilitate introduction of new diseases and pests. Sea-level rise could stress mangrove forests due to inundation and could stress surviving wetland vegetation by introducing brackish water farther inland, while the expected tendency to armor fastlands could prevent concurrent establishment of more inland mangrove forests and other coastal wetlands. Climate change would place additional stress on the same habitats and wildlife affected by the operational impacts discussed in Section 5.3.1. Particularly noteworthy is that the stresses on wetlands and other terrestrial habitats caused by climate change could result in greater introduction of exotic species such as Melaleuca, Australian pine, and the Burmese python.

The expected climatological changes could exacerbate the effects of plant operations (discussed in Section 5.3.1) on terrestrial habitats, wetlands, and species. In particular, climate change could lead to drier conditions due to longer periods between precipitation events and wildfires. Climate change could reduce the extent of mangrove forests primarily due to coastal inundation and sawgrass in the Everglades primarily due to alteration of hydroperiod, stressing vegetation and wildlife. Increased introduction of exotic species could further reduce the ecological and hydrological function of wetlands and reduce the suitability of various upland and wetland habitats to threatened, endangered, and rare species.

The expected climatological changes could worsen the minor effects of plant and transmission line operations on birds, bats, and other wildlife due to collisions, electrocution, or electromagnetic radiation effects (discussed in Section 5.3.1). Climate change could substantially alter the hydroperiod of habitats traversed by the proposed corridors for the two transmission lines, including the eastern Everglades and remnant pine rockland patches. These changes could stress wildlife dependent on the affected habitats, including birds, bats, and other wildlife. Even though the effects on wildlife from collisions, electrocution, and electromagnetic radiation are typically minor (see Section 5.3.1), the stresses could be exacerbated when combined with the effects of climate change.

Although climate change could potentially interact synergistically with plant operations to raise impact levels on terrestrial wildlife from plant operations and influence the impact of the proposed units on terrestrial resources and wetlands, the ability to coordinate with other agencies should not be noticeably impeded. The importance of close coordination would, however, be greater.

The expected climatological changes could affect the overall impact of plant operations on regional standing stocks of important terrestrial species, including plant impacts on species' tolerance of environmental changes and their natural survival rates. The increased potential for substantial adverse effects on the sensitive wetland and upland habitats surrounding the Turkey Point site and proposed new offsite corridors would concurrently place increased stresses on species using those habitats, including important species. The increased stresses caused by climate change could reduce the tolerance of some important species to collisions, noise, and other plant operational impacts. Furthermore, many of the identified important species are species whose populations have already been severely lowered by recent decades of drainage and development, and thus are less capable of recovery from new stresses.

The stresses placed on terrestrial habitats by climate change could lead to a greater potential for introduction of disease organisms and invasive species. Climate change could stress those habitats by decreasing the hydroperiod and by inducing the introduction of exotic species adapted to warmer climates and seasonally drier habitats. The subject habitats have already been stressed by a history of introduction of numerous invasive species. Additional stresses to native vegetation can be expected to encourage the further establishment of invasive species.

I.3.3.2 Conclusion

Climate change could place multiple new stresses on wetlands and other terrestrial habitats, especially the hydrologically sensitive Everglades and Everglades National Park, the extensive mangrove forests bordering Biscayne Bay, including those within Biscayne National Park, and other unique ecological communities such as pine rocklands. Climate change would place additional stress on the same habitats and wildlife stressed by plant operations and could cause an increase in the impacts on terrestrial resources discussed in Section 5.3.1.

I.3.4 Aquatic Ecology

I.3.4.1 Summary

Climatological changes would have minimal influence on the impact of the operation of proposed Units 6 and 7 on aquatic resources using either reclaimed water or radial collector wells. A change in sea level would not influence the availability of reclaimed water, so an increase of cooling-water withdrawal by the radial wells is not expected. Sea-level rise will increase the depth of Biscayne Bay but it is not expected to affect the operation of the radial wells. Entrainment, entrapment, and impingement are highly unlikely due to the use of reclaimed water and RCW operation, and there is no evidence operation would directly affect aquatic resources. There is no evidence that proposed Units 6 and 7 would affect species tolerance or natural survival rates, or contribute to an increase in invasive or introduced species. Given the proposed cooling-system configurations, influence on the water quality of nearby receiving water would be negligible. Changes in baseline conditions due to climate change are not expected to alter this result. Climate change is not expected to noticeably impede the ability of agencies to coordinate on the protection of aquatic species. The importance of close coordination would, however, be greater.

I.3.4.2 Conclusion

The review team identified no shift in the Chapter 5-assigned impacts on aquatic ecology caused by the operation of the proposed plant due to a reasonably foreseeable alteration of baseline conditions associated with climate change.

I.3.5 Socioeconomics

As discussed in Section 5.4 and summarized in Section 10.2.2, within the area of socioeconomics the categories of physical impacts, demographic impacts, economic impacts, and impacts on infrastructure and community services are assessed separately, and individual category impact levels are assigned. These same categories are discussed here.

I.3.5.1 Summary

The review team determined that all of the expected physical impacts during operations (noise, air quality, buildings, roads, waterways, and aesthetics) would be SMALL and would warrant no mitigation. During the life of the proposed license the review team expects physical impacts on the listed categories would not be exacerbated by the effects of climate change and would remain at negligible levels.

The impacts on the demographic makeup of the area surrounding the proposed site would be SMALL and would not warrant mitigation. If the speculated climate change impacts were to occur during the life of the proposed license, the review team believes the demographic impact would be an out-migration of residents to other areas with higher elevations. Consequently, the operations-related impacts on the demographic makeup of the area would be reduced even further.

All economic impacts from operations of the proposed project would be beneficial and SMALL for Miami-Dade County, Homestead, and Florida City. In the event of climate change-induced sea-level rise, which is likely to occur gradually, the NRC requires licensees of nuclear power plants to implement corrective actions to mitigate conditions adverse to safety. The applicant would need to take measures to mitigate the effects of global climate change such that the proposed nuclear power plants would continue to be operated safely in accordance with 10 CFR Part 50 (TN249). Therefore, the review team anticipates the economic impacts of operations of the proposed project would continue unchanged.

There are four major subsections in the review team's assessment of the operations-related impacts on infrastructure and community services from the proposed project: traffic, recreation, housing, and public services.

- **Traffic**. The review team determined that the operations-related impacts of traffic would be moderate. While the long-term effects of global climate change would have a deleterious impact on the current level of infrastructure in the area, the review team believes it is not unreasonable to expect decision makers in the area to incrementally adapt to the climate change effects (e.g., sea-level rise) by incorporating mitigating measures that would prevent the deterioration of infrastructure services (e.g., raising the elevation of roads). Such adaptive measures would impose significant costs on local communities, the funds for which would either have to come from increased revenues (taxes and tolls) or be diverted from other expenses (maintenance, personnel, services). Consequently, the review team expects that if the physical changes predicted by the GCRP report (GCRP 2014-TN3472) were to occur, the traffic-related impacts on the local communities would increase.
- **Recreation**. The primary receptors of recreational impacts due to operations are accessibility and aesthetics. The review team expects that, like traffic, the long-term effects of climate change would significantly change the aesthetic appeal of local recreation areas and the public's access to Biscayne Bay and the Everglades. However, the NRC portion of the total impact would remain unchanged.
- **Housing**. The review team expects that any physical change in the environment from global climate change would occur at a rate slow enough that home owners in low-lying areas could either adapt their homes to the new conditions or to move out of the area. Consequently, the cumulative impact of global climate change on housing in the economic impact area would decline as the local population migrated away from the 50 mi region.

- **Public Services**. The review team expects that any physical change in the environment from global climate change would occur at a rate slow enough that local governments could adapt to whatever negative impacts may arise. Consequently, the review team determined the global climate change impacts on community services would decline as the population migrated away from the 50 mi region.

I.3.5.2 Conclusion

As indicated in Chapter 5, the review team identified no significant shifts in socioeconomic impacts of operational impacts as a result of possible climatological changes in the environmental baseline. Potential impacts on socioeconomics including infrastructure and community services as a result of climate change would continue to be addressed through regional and local governmental strategic adaptive plans.

I.3.6 Environmental Justice

I.3.6.1 Summary

Climate change could present challenges to minority and low-income communities, which the GCRP climate change impacts report refers to as "socially vulnerable populations," within the demographic region of the proposed project. The challenges include coping with climate change effects (e.g., sea-level rise), the capacity to adapt, and the ability to relocate. The review team believes it is not unreasonable to expect decision makers in the area to incrementally adapt to the climate change effects by implementing strategic adaptation plans and mitigating measures that would inform and assist minority and low-income communities. Therefore, the conclusions in Section 5.1.1 regarding environmental justice would remain unchanged.

I.3.6.2 Conclusion

Overall, the operational impact levels assigned to environmental justice in Chapter 5 did not change as a result of possible climatological changes in the environmental baseline. Potential impacts on environmental justice communities as a result of climate change would continue to be addressed through regional and local governmental strategic adaptive plans.

I.3.7 Historic and Cultural Resources

I.3.7.1 Summary

There are no known onsite historic and cultural resources at the Turkey Point site; therefore, there would be no shift in the impacts on historic and cultural resources caused by the operation and maintenance of the proposed plant due to a reasonably foreseeable alteration in the environmental baseline associated with climate change. It is not known whether the change in the environmental baseline would cause a shift in impacts of offsite facilities (e.g., transmission lines).

I.3.7.2 Conclusion

As previously discussed, the climatological changes would not affect the historic and cultural impact level assigned in Chapter 5 because of the lack of resources at the Turkey Point site. It is not known whether the change in the environmental baseline would affect offsite resources.

I.3.8 Meteorology

I.3.8.1 Summary

The expected climatological changes would largely be unlikely to affect cooling-system impacts from the operating plant on local weather. Projected temperature increases due to climate change may lead to an increase in fogging from the cooling tower. Changes in severe weather intensity or length of dry spells would be unlikely to change the current parameters.

I.3.8.2 Conclusion

Operational impacts from the cooling system on local weather are discussed in Section 5.7.2 and should not change as a result of reasonably foreseeable climate changes.

I.3.9 Air Quality

I.3.9.1 Summary

Climatological changes may affect the sources, types, and estimates of annual air emissions from the operating plant and transmission lines. For example, changes in climate such as sea-level rise and increased extreme weather events may lead to an increase in air emissions from emergency equipment, if additional emergency backup equipment is needed for the proposed plants and if testing of that equipment increases. Because of expected increases in temperature over the period of operation, the health impacts of operational air emissions may increase. In a higher temperature environment, the formation of ozone due to emissions of nitrogen oxides (NO_x) from the diesel generators and other equipment is likely to increase, thereby leading to an increase in health impacts.

I.3.9.2 Conclusion

Operational air-quality impacts are discussed in Section 5.7.1 and should not change as a result of reasonably foreseeable climate changes. It is unclear whether additional emergency equipment would actually be needed in a changing climate, or whether testing of that equipment would increase, causing an increase in air emissions. Any additional equipment would be subject to Clean Air Act (42 U.S.C. § 7401 et seq. (TN1141) Title V permitting requirements. Estimates of air emissions are likely to remain the same, with a possible increase in health impacts due to increased ozone formation from emergency equipment NO_x emissions in a higher temperature environment.

I.3.10 Nonradiological Health

I.3.10.1 Summary

It is not known how changes in climate will affect the presence of etiological agents associated with plant operations (receiving waters and cooling-tower operations). However, it is reasonable to expect that currently existing laws and regulations protecting workers and members of the public would continue, or would be adjusted as necessary, to be as protective as they are under current climate conditions.

Climatological changes are not likely to have an effect on noise produced by operating plants; therefore, there would be no change in the health impacts from noise discussed in Section 5.8.2.

It is not likely that climatological changes would affect potential health impacts from electromagnetic fields (EMFs) associated with plant operations because regulations protecting workers and members of the public from EMFs would likely be adjusted to avoid impacts.

It is not likely that climatological changes would affect occupational health risks for operational plants because regulations protecting workers would be adjusted to avoid impacts on workers.

As discussed in Section I.3.5.1, while the long-term effects of global climate change would have a deleterious impact on the current level of infrastructure in the area, the review team believes it is not unreasonable to expect decision makers in the area would incrementally adapt to the climate change effects (e.g., sea-level rise) by incorporating mitigating measures that would prevent the deterioration of infrastructure services (e.g., raising the elevation of roads, adjusting speed limits). The review team expects that if the physical changes predicted by the GCRP were to occur, such adaptive measures would limit potential health impacts from traffic-related accidents.

I.3.10.2 Conclusion

Overall, the expected climatological changes would not change the nonradiological health resource operational impact level assigned in Chapter 5. Potential impacts from noise, etiological agents, exposure to EMFs, and occupational injuries are and would continue to be regulated to be protective of human health. Although there is some uncertainty surrounding predicted climatological changes, it is likely that regulations governing occupational and public health would be adjusted accordingly if needed.

I.3.11 Radiological Impacts

I.3.11.1 Summary

The review team determined that the expected climatological changes would affect the possibility of exposure to radiation from the operating facility as follows:

- Existing low population exposures of humans from proposed Units 6 and 7 would remain low because the level of effluent releases and regulatory requirements should not significantly change over the time of the license.

- Existing low non-human biota exposures from proposed Units 6 and 7 should not change because the level of effluent releases and regulatory requirements should not significantly change over the time of the license.
- The level of effluent releases, regulatory requirements (including those for occupational doses), and existing low exposures should not significantly change over the time of the license.
- The level of the expected normal radioactive gaseous effluent releases would remain the same. Thus, monitoring activity should remain the same with the exception that the monitoring locations could change because of changes in the physical land and population distribution around the site. Normal radioactive liquid effluent releases should remain unchanged due to the use of deep-well injection.

I.3.11.2 Conclusion

The NRC staff identified no shift in the radiological impacts level caused by the operation of the proposed Units 6 and 7 due to reasonably foreseeable environmental alterations associated with climate change, because the level of effluent releases, regulatory requirements, and existing low population exposures should not significantly change over the time of the license.

I.3.12 Nonradioactive Waste

I.3.12.1 Summary

Sea-level rise and changes in land-use decisions may lead to changes in disposal options for nonradioactive waste and mixed wastes. However, solid, liquid, gaseous, hazardous, and mixed wastes generated during operation of the proposed Turkey Point Units 6 and 7 would still have to be handled, transported, stored, and disposed of according to County, State, and Federal regulations.

I.3.12.2 Conclusion

Because nonradioactive and mixed wastes would still be subject to applicable Federal, State, and local requirements, climatological changes are unlikely to influence the SMALL impact determination discussed in Section 5.10.4.

I.3.13 Accidents

I.3.13.1 Summary

Climatological changes are expected to affect the site-specific, 50th percentile atmospheric dilution factor (i.e., χ/Q) used to evaluate dose consequences from postulated design basis accidents (DBAs). The χ/Q around the site is dependent on local meteorological conditions (wind speed, direction and stability class). The expected variations for these parameters as a result of climate change may increase, likely leading to less stability, which would likely increase dispersion and decrease the corresponding radiological effects. However, the predominant wind direction could change such that higher χ/Qs could shift along the site boundary, low-population zone, and beyond to areas with higher population density, which would increase the impact. Therefore, the overall impact is unknown. Climatological changes might affect the average environmental risks of severe accidents because of changes in either severe accident probabilities or associated consequences. While the potential severity of storms and other natural phenomena might increase, nuclear power plants must be designed to withstand all creditable natural events at the site of concern.

As discussed in Section I.2, climate change in general and rising sea level are expected to be gradual. If the NRC grants the FPL COL application, the staff will inspect and otherwise moniter plant construction and operation. This safety oversight process includes collection and analysis of information regarding changes in the severity or frequency of natural hazards, such as flooding from storm surge and sea level rise, as discussed in SECY-15-0137 (NRC 2015-TN4731). When warranted, the NRC can request licensee study and analysis of changing natural hazards, and can impose additional design or operation requirements to address those changing hazards. In particular, the NRC can request information from a licensee under 10 CFR 50.54(f), and can determine whether or not a license should be modified based on the information provided in response the request. Such information could include the impact of climate change on plant operation, emergency preparedness, and the availability of nearby structures used for plant operation and safety. If the NRC determines that additional safety enhancements are necessary based on information obtained in accordance with 10 CFR 50.54(f), the NRC can require that such enhancements be implemented in a timely manner to assure adequate protection of the public within the current NRC regulatory process. The NRC staff generally expects that the low core damage frequencies (CDFs) for the AP1000 pressurized water reactor design are unlikely to change appreciably due to climate change. Therefore, even if consequences of severe accidents slightly change as a result of climate change, severe accident risk is likely to remain SMALL because CDFs are maintained low.

The effects of climatological changes on the severe accident mitigation alternative (SAMA) cost-benefit analysis of the proposed facility are uncertain. While the averted costs have components that are based on local land values and the cost of evacuation and cleanup, these are typically not the major contributors to the total averted costs. Rather, the cost of replacement power has a larger effect and it is uncertain whether climate change would have an effect that would change the SAMA cost-benefit analysis. However, because the smallest difference between a cost-beneficial severe accident mitigation design alternative that was not studied further for the AP1000 design at the Turkey Point site (see Section 5.11.3) and the averted cost is approximately $400,000 (7 percent discount rate), it is difficult to see how climate change would affect the probability-weighted consequences from severe accidents in a manner to cause a finding different from SMALL for SAMAs.

I.3.13.2 Conclusion

The impact level assigned in Chapter 5 should remain SMALL for next-generation nuclear power plants like the AP1000 reactor design. The overall risks for severe accidents are significantly lower than the current generation of nuclear power plants and any climate change effect would have to change the risks by at least two orders of magnitude to result in a change in the impact level assigned in Chapter 5.

I.3.14 Transportation of Radiological Materials

I.3.14.1 Summary

The number and type of radioactive material shipments, regulatory requirements, and existing low maximally exposed individual and population exposures and risks from accidents for these types of shipments should not significantly change over the time of the license as a result of climate change. Radiological doses are strong functions of the radiation dose rate emitted from the shipment, exposure distance, and exposure duration. None of these parameters would be directly or disproportionately influenced by the impacts of climate change. Transportation accidents risks are a function of weather conditions. However, climate change may increase dispersion conditions in some areas as a result of more frequent storms and severe weather, but may also reduce dispersion in areas where climate change may result in more mild average conditions. As a result, the changes in transportation impacts potentially caused by climate change are not expected to be significant, but there are substantial uncertainties about impacts on weather conditions in specific areas and demographic changes that could affect transportation impacts in the region of interest.

I.3.14.2 Conclusion

Impact levels are not expected to change as a result of the effects of climate change, but there are significant uncertainties associated with the impacts of climate change on local weather conditions and demographics.

I.3.15 Benefit-Cost

I.3.15.1 Summary

Climatological changes could affect the estimated operational benefits and costs of the proposed facility. Proposed Turkey Point Units 6 and 7 would continue to provide benefits in the form of electricity generation and economic impacts to the region such as tax impacts and other spending. To the extent that summer peak demand load increases, the benefit of a large baseload power station such as Units 6 and 7 could increase.

Operating costs include maintenance costs, fuel costs, and annualized capital costs. Future climate change impacts would not affect the already incurred capital costs. However, to the extent that climate change events require repair or prolonged shutdown of Units 6 and 7, maintenance costs could increase.

I.3.15.2 Conclusion

Although climate change could increase or decrease the benefits and costs of the project, the review team expects the accrued benefits of construction and operation of Units 6 and 7 would still outweigh the associated costs.

I.3.16 U.S. Army Corps of Engineers Public Interest Review

I.3.16.1 Summary

Pursuant to NEPA and the USACE public interest review at 33 CFR 320.4, the USACE considers the effects of climate change and sea level rise on the proposed project in order to determine whether the proposed project is contrary to the public interest. As set forth below, the USACE has determined that the NRC Advanced Safety Evaluation (ASE) dated July 14, 2016, on the Florida Power & Light (FPL) application to the NRC considers the effects of sea level rise on the proposed project (NRC 2016-TN4775).

As background, the NRC determined that the structures, systems, components, and design features of the AP1000 standard design comply with applicable NRC regulations and therefore provide adequate protection to the health and safety of the public. The NRC based its evaluation of the AP1000 design in part on assumed physical and environmental site features, such as maximum flood height compared to plant elevation, used to design the standard plant. The NRC calls these site features assumed for design “site parameters,” and they are specified in the Design Control Document (DCD) for the AP1000 standard design. In order for a company to obtain an NRC license to build and operate an AP1000 plant at an actual site, its application must show that the AP1000 design can handle the actual physical and environmental features of the proposed site, which the NRC calls “site characteristics.” To do this, the applicant compares the actual site characteristics to the site parameters postulated for design. If the site characteristics fall within the site parameters used to design the plant, then the standard AP1000 design protects the plant from the effects of the environment on the plant at that site, as required by NRC regulations. If a site characteristic does not fall within a site parameter, the applicant must provide engineering analysis to justify why the plant is nevertheless acceptable to build and operate on the proposed site.

For the proposed Turkey Point Units 6 and 7 reactors, the FPL application to the NRC included information to demonstrate that the actual Turkey Point site characteristics fall within the site parameters in the AP1000 DCD, except for four site parameters. For these four site parameters, FPL proposed departures from the AP1000 DCD, as allowed under NRC regulations. The four site parameters for which FPL proposed departures are population distribution exclusion area (site), the operating basis wind speed, maximum safety wet-bulb (non-coincident) air temperature value, and maximum normal wet-bulb (non-coincident) air temperature value. The NRC staff evaluation of the application in the ASE for Turkey Point Units 6 and 7 concludes that the applicant (1) justified the four proposed departures from the DCD site parameters and (2) demonstrated that the other characteristics of the Turkey Point site fall within (are bounded by) the site parameters specified in the AP1000 DCD (NRC 2016-TN4775).

In assessing whether the actual site characteristics fall within the postulated site parameters in the DCD, both the application and the NRC ASE consider the effects of sea-level rise. In particular, the NRC staff evaluations in the ASE Sections 2.3.1.4.7, “Climate Change,” 2.4.5.4.4, “Antecedent Water Level,” 2.4.5.4.5, “Analysis of Probable Maximum Storm Surge,” 2.4.5.4.6, “Wave Actions,” 2.4.6.4.3, “Source Generator Characteristics,” 2.4.6.4.5, “Tsunami Water Levels,” and 2.4.9.4.3, “Shoreline Changes” explicitly consider the effects of sea-level rise in connection with the NRC staff evaluation of the Turkey Point site characteristics. While the NRC staff did not explicitly consider sea level rise in its evaluation in ASE Section 2.4.12.4.12, “Site Characteristics for Subsurface Hydrostatic Loading,” the NRC staff determined that the actual groundwater level was at least twenty (20) feet below the maximum allowable groundwater level specified in the DCD for the AP1000 design, and that no further evaluation was warranted (NRC 2016-TN4775).

I.3.16.2 Conclusion

In view of the foregoing, the USACE has determined that the NRC staff has evaluated the effects of sea level rise on the proposed Turkey Point Units 6 and 7 in the context of its flooding evaluations in the ASE.

1.0 INTRODUCTION

1.1 Purpose of and Need for Action

The U.S. Nuclear Regulatory Commission (NRC) licenses the operation of domestic nuclear power plants in accordance with the Atomic Energy Act (AEA) of 1954, as amended, and NRC implementing regulations. Florida Power & Light Company (FPL) operates Turkey Point Nuclear Plant Units 3 and 4 (PTN) pursuant to NRC operating licenses (OLs) DPR-31 and DPR-41, respectively. Based on a license renewal application (LRA) submitted in 2000, the NRC issued renewed OLs in June of 2002, providing authorization to operate for an additional 20 years beyond the original 40-year licensed operating period. Currently, the renewed Unit 3 OL expires at midnight on July 19, 2032, and the renewed Unit 4 OL expires at midnight on April 10, 2033. PTN is located on Biscayne Bay in Miami-Dade County, Florida.

FPL has prepared this environmental report (ER) in conjunction with its application to the NRC for a subsequent renewal of the PTN OLs, as provided by the following NRC regulations:

- Title 10, Energy, Code of Federal Regulations (CFR), Part 54, Requirements for Renewal of Operating Licenses for Nuclear Power Plants, Section 54.23, Contents of Application—Environmental Information [10 CFR 54.23].

- Title 10, Energy, CFR, Part 51, Environmental Protection Requirements for Domestic Licensing and Related Regulatory Functions, Section 51.53, Postconstruction Environmental Reports, Subsection 51.53(c), Operating License Renewal Stage [10 CFR 51.53(c)].

The NRC has defined the purpose and need for the proposed action, renewal of the OLs for nuclear power plants such as PTN, as follows (NRC 2013a):

> The purpose and need for the proposed action (issuance of a renewed license) is to provide an option that allows for baseload power generation capability beyond the term of the current nuclear power plant operating license to meet future system generating needs. Such needs may be determined by other energy-planning decision-makers, such as State, utility, and, where authorized, Federal agencies (other than the NRC). Unless there are findings in the safety review required by the AEA or the National Environmental Policy Act (NEPA) environmental review that would lead the NRC to reject a LRA, the NRC does not have a role in the energy-planning decisions of whether a particular nuclear power plant should continue to operate.

The renewed OLs would allow an additional 20 years of operation for the PTN units beyond their current licensed operating periods. The subsequent renewed license for PTN Unit 3 would expire at midnight on July 19, 2052, and the subsequent renewed license for PTN Unit 4 would expire at midnight on April 10, 2053.

FPL has prepared Table 1.0-1 to verify conformance with regulatory requirements. Table 1.0-1 indicates the sections in the PTN subsequent license renewal (SLR) ER that respond to each requirement of 10 CFR 51.53(c).

Table 1.0-1
Environmental Report Responses to License Renewal Environmental Regulatory Requirements (Sheet 1 of 4)

Description	Requirement	ER Section(s)
Environmental Report—General Requirements [10 CFR 51.45]		
Description of the proposed action	10 CFR 51.45(b)	2.1
Statement of the purposes of the proposed action	10 CFR 51.45(b)	1.0
Description of the environment affected	10 CFR 51.45(b)	3.0
Impact of the proposed action on the environment	10 CFR 51.45(b)(1)	4.0
Adverse environmental effects which cannot be avoided should the proposal be implemented	10 CFR 51.45(b)(2)	6.3
Alternatives to the proposed action	10 CFR 51.45(b)(3)	2.6, 7.0, and 8.0
Relationship between local short-term uses of man's environment and the maintenance and enhancement of long-term productivity	10 CFR 51.45(b)(4)	6.5
Irreversible and irretrievable commitments of resources which would be involved in the proposed action should it be implemented	10 CFR 51.45(b)(5)	6.4
Analysis that considers and balances the environmental effects of the proposed action, the environmental impacts of alternatives to the proposed action, and alternatives available for reducing or avoiding adverse environmental effects	10 CFR 51.45(c)	2.6, 4.0, 7.0, and 8.0
Federal permits, licenses, approvals, and other entitlements which must be obtained in connection with the proposed action and description of the status of compliance with these requirements	10 CFR 51.45(d)	9.0
Status of compliance with applicable environmental quality standards and requirements which have been imposed by federal, state, regional, and local agencies having responsibility for environmental protection, including, but not limited to, applicable zoning and land-use regulations, and thermal and other water pollution limitations or requirements	10 CFR 51.45(d)	9.0

Table 1.0-1
Environmental Report Responses to License Renewal Environmental Regulatory Requirements (Sheet 2 of 4)

Description	Requirement	ER Section(s)
Alternatives in the report including a discussion of whether the alternatives will comply with such applicable environmental quality standards and requirements	10 CFR 51.45(d)	9.7
Information submitted pursuant to 10 CFR 51.45(b) through (d) and not confined to information supporting the proposed action but also including adverse information	10 CFR 51.45(e)	4.0 and 6.3
Operating License Renewal Stage [10 CFR 51.53(c)]		
Description of the proposed action including the applicant's plans to modify the facility or its administrative control procedures as described in accordance with §54.21. The report must describe in detail the affected environment around the plant, the modifications directly affecting the environment or any plant effluents, and any planned refurbishment activities.	10 CFR 51.53(c)(2)	2.1, 2.3, 2.4, 3.0, and 4.0
Analyses of the environmental impacts of the proposed action, including the impacts of refurbishment activities, if any, associated with license renewal and the impacts of operation during the renewal term, for applicable Category 2 issues, as discussed below	10 CFR 51.53(c)(3)(ii)	2.3 and 4.0
Surface Water Resources		
Surface water use conflicts (plants with cooling ponds or cooling towers using makeup water from a river)	10 CFR 51.53(c)(3)(ii)(A)	4.5.1
Groundwater Resources		
Groundwater use conflicts (plants with closed-cycle cooling systems that withdraw makeup water from a river)	10 CFR 51.53(c)(3)(ii)(A)	4.5.2
Groundwater use conflicts (plants that withdraw more than 100 gallons per minute)	10 CFR 51.53(c)(3)(ii)(C)	4.5.3
Groundwater quality degradation (plants with cooling ponds at inland sites)	10 CFR 51.53(c)(3)(ii)(D)	4.5.4
Radionuclides released to groundwater	10 CFR 51.53(c)(3)(ii)(P)	4.5.5

Table 1.0-1
Environmental Report Responses to License Renewal Environmental Regulatory Requirements (Sheet 3 of 4)

Description	Requirement	ER Section(s)
Aquatic Resources		
Impingement and entrainment of aquatic organisms (plants with once-through cooling systems or cooling ponds)	10 CFR 51.53(c)(3)(ii)(B)	4.6.1
Thermal impacts on aquatic organisms (plants with once-through cooling systems or cooling ponds)	10 CFR 51.53(c)(3)(ii)(B)	4.6.2
Water use conflicts with aquatic resources (plants with cooling ponds or cooling towers using makeup water from a river	10 CFR 51.53(c)(3)(ii)(A)	4.6.3
Terrestrial Resources		
Water use conflicts with terrestrial resources (plants with cooling ponds or cooling towers using makeup water from a river)	10 CFR 51.53(c)(3)(ii)(A)	4.6.4
Effects on terrestrial resources (non-cooling system impacts)	10 CFR 51.53(c)(3)(ii)(E)	4.6.5
Special Status Species and Habitats		
Threatened, endangered, and protected species, and essential fish habitat	10 CFR 51.53(c)(3)(ii)(E)	4.6.6
Historic and Cultural Resources		
Historic and cultural resources	10 CFR 51.53(c)(3)(ii)(K)	4.7
Human Health		
Microbiological hazards to the public (plants with cooling ponds or canals, or cooling towers that discharge to a river)	10 CFR 51.53(c)(3)(ii)(G)	4.9.1
Electric shock hazards	10 CFR 51.53(c)(3)(ii)(H)	4.9.2
Environmental Justice		
Minority and low-income populations	10 CFR 51.53(c)(3)(ii)(N)	3.11.2 and 4.10.1
Cumulative Impacts		
Cumulative impacts	10 CFR 51.53(c)(3)(ii)(O)	4.12

Table 1.0-1
Environmental Report Responses to License Renewal Environmental Regulatory Requirements (Sheet 4 of 4)

Description	Requirement	ER Section(s)
Severe Accident Mitigation Alternatives		
Severe accidents	10 CFR 51.53(c)(3)(ii)(L)	4.15
All Plants		
Consideration of alternatives for reducing adverse impacts for all Category 2 license renewal issues	10 CFR 51.53(c)(3)(iii)	4.0 and 6.2
New and significant information regarding the environmental impacts of license renewal of which the applicant is aware	10 CFR 51.53(c)(3)(iv)	4.0 and 5.0

1.2 Environmental Report Scope and Methodology

NRC regulations for domestic licensing of nuclear power plants require reviews of environmental impacts from renewing an OL. NRC regulation 10 CFR 51.53(c) requires that an applicant for license renewal submit with its application a separate document (Appendix E of the application) entitled, "Applicant's Environmental Report—Operating License Renewal Stage." In determining what information to include in the PTN SLR applicant's ER, FPL has relied on NRC regulations and the following supporting documents that provide additional insight into the regulatory requirements:

- NUREG-1437, *Generic Environmental Impact Statement for License Renewal of Nuclear Plants* (GEIS), Revision 1 (NRC 2013a), and referenced information specific to transportation (NRC 1999)
- NRC supplemental information in the *Federal Register* (78 FR 37282)
- *Regulatory Analysis for Amendments to Regulations for the Environmental Review for Renewal of Nuclear Power Plant Operating Licenses* (NRC 1996a)
- Regulatory Guide 4.2, Supplement 1, Revision 1, *Preparation of Environmental Reports for Nuclear Power Plant License Renewal Applications* (NRC 2013b)

1.3 Turkey Point Station Licensee and Ownership

FPL is a principal subsidiary of NextEra Energy Inc. (formerly FPL Group, Inc.), and the third-largest electric utility in the United States. FPL is a Juno Beach, Florida-based utility company serving approximately 4.9 million customer accounts or an estimated 10 million people across nearly half of the state of Florida. PTN is owned and operated by FPL, the licensee and applicant.

4.0 ENVIRONMENTAL CONSEQUENCES OF THE PROPOSED ACTION AND MITIGATING ACTIONS

> The report must contain a consideration of alternatives for reducing adverse impacts . . . for all Category 2 license renewal issues . . . . [10 CFR 51.53(c)(3)(iii)]
>
> The environmental report must include an analysis that considers . . . the environmental effects of the proposed action . . . and alternatives available for reducing or avoiding adverse environmental effects. [10 CFR 51.45(c)]
>
> The environmental report shall . . . discuss . . . the impact of the proposed action on the environment. Impacts shall be discussed in proportion to their significance. [10 CFR 51.45(b)(1)]
>
> The information submitted . . . should not be confined to information supporting the proposed action but should also include adverse information. [10 CFR 51.45(e)]

The NRC has identified and analyzed 78 environmental issues that it considers to be associated with nuclear power plant license renewal and has designated the issues as Category 1, Category 2, or not categorized (NRC 2013a). The NRC designated an issue as Category 1 if the following criteria were met:

- The environmental impacts associated with the issue have been determined to apply either to all plants or, for some issues, to plants having a specific type of cooling system or other specified plant or site characteristic.
- A single significance level (i.e., small, moderate, or large) has been assigned to the impacts that would occur at any plant, regardless of which plant is being evaluated (except for offsite radiological impacts—collective impacts from other than the disposal of spent fuel and high-level waste [HLW]).
- Mitigation of adverse impacts associated with the issue has been considered in the analysis, and it has been determined that additional plant-specific mitigation measures are likely to be not sufficiently beneficial to warrant implementation.

If the NRC concluded that one or more of the Category 1 criteria could not be met, the NRC designated the issue Category 2, which requires plant-specific analysis. The NRC designated one issue as not categorized (human health chronic effects of electromagnetic fields), signifying that the categorization and impact definitions do not apply to this issue. Until such time that this NA issue is categorized, applicants for license renewal are not required to submit information on this issue [10 CFR Part 51, Subpart A, Appendix B, Table B-1, Footnote 6]; therefore, this issue is not included in Tables 4.0-1, 4.0-2, or 4.0-3, nor is it addressed in Section 4.9. NRC rules do not require analyses of Category 1 issues that were resolved using generic findings [10 CFR Part 51, Subpart A, Appendix B, Table B-1] as described in the GEIS. Therefore, an applicant may reference the GEIS findings for Category 1 issues, absent new and significant information.

4.0.1 Category 1 License Renewal Issues

> The environmental report for the operating license renewal stage is not required to contain analyses of the environmental impacts of the license renewal issues identified as Category 1 issues in Appendix B to subpart A of this part. [10 CFR 51.53(c)(3)(i)]

> [A]bsent new and significant information, the analyses for certain impacts codified by this rulemaking need only be incorporated by reference in an applicant's environmental report for license renewal . . . . [61 FR 28483]

FPL has determined that, of the 60 Category 1 issues, 9 are not applicable to PTN. Table 4.0-1 lists these 9 issues and provides a brief explanation of why they are not applicable to the site. Table 4.0-2 lists the 51 Category 1 issues applicable to the site. FPL reviewed the NRC findings on these 51 Category 1 issues and identified no new and significant information that would invalidate the findings for the site (Chapter 5). The new and significant review did evaluate new information such as the findings of state and local agencies regarding the westward movement of hypersaline groundwater. Finding compliance with CAs and orders would result in insignificant impacts for the SLR term.Therefore, FPL adopts by reference the NRC findings for these Category 1 issues.

4.0.2 Category 2 License Renewal Issues

> The environmental report must contain analyses of the environmental impacts of the proposed action, including the impacts of refurbishment activities, if any, associated with license renewal and the impacts of operation during the renewal term, for those issues identified as Category 2 issues in Appendix B to subpart A of this part. [10 CFR 51.53(c)(3)(ii)]

> The report must contain a consideration of alternatives for reducing adverse impacts, as required by § 51.45(c), for all Category 2 license renewal issues . . . . [10 CFR 51.53(c)(3)(iii)]

The NRC designated 17 issues as Category 2. FPL has determined that, of the 17 issues shown in Table 4.0-3, five issues are not applicable to PTN because they apply to plants with natural setting features that do not exist at the facility, or the regulatory basis or requirement of the issue does not apply. Where the issue does not apply to the site, the section explains the basis.

For the 12 issues applicable to the site, the corresponding sections contain the required analyses. These analyses include conclusions regarding the significance of the impacts relative to renewal of the PTN OLs and, when applicable, discuss potential mitigation alternatives to the extent appropriate. With the exception of threatened and endangered species/EFH, historic and cultural resources, and environmental justice, FPL has identified the significance of the impacts associated with each issue as SMALL, MODERATE, or LARGE consistent with the criteria the NRC established in 10 CFR Part 51, Subpart A, Appendix B, Table B-1, Footnote 3, as follows:

> **SMALL**: Environmental effects are not detectable or are so minor that they will neither destabilize nor noticeably alter any important attribute of the resource. For the purposes of assessing radiological impacts, the Commission has concluded that those impacts that do not exceed permissible levels in the Commission's regulations are considered small.
>
> **MODERATE**: Environmental effects are sufficient to alter noticeably, but not to destabilize, important attributes of the resource.
>
> **LARGE**: Environmental effects are clearly noticeable and are sufficient to destabilize important attributes of the resource. For issues where probability is a key consideration (i.e., accident consequences), probability was a factor in determining significance.

Threatened and endangered species/EFH, historic and cultural resources, and environmental justice were not assigned a significance impact of SMALL, MODERATE, or LARGE in 10 CFR Part 51, Subpart A, Appendix B, Table B-1. Therefore consistent with NRC guidance, FPL identified the significance of the impacts for these three Category 2 issues as follows:

- For threatened and endangered species (ESA), the significance of the effects from license renewal can be characterized based on a determination of whether continued nuclear power plant operations, including refurbishment, (1) would have no effect on federally listed species; (2) are not likely to adversely affect federally listed species; (3) are likely to adversely affect federally listed species; or (4) are likely to jeopardize a federally listed species or adversely modify designated critical habitat. For EFH (MSA), the significance of effects from license renewal can be characterized based on a determination of whether continued nuclear power plant operations, including refurbishment, would have (1) no adverse impact; (2) minimal adverse impact; or (3) substantial adverse impact to the essential habitat of federally managed fish populations.

- For historic and cultural resources (NHPA), the significance of the effects from license renewal can be characterized based on a determination that (1) no historic properties are present (no effect); (2) historic properties are present but not adversely affected (no adverse effect); or (3) historic properties are adversely affected (adverse effect).

- For environmental justice, impacts would be based on disproportionately high and adverse human health and environmental effects on minority and low-income populations.

In accordance with NEPA practice, FPL considered ongoing and potential additional mitigation in proportion to the significance of the impact to be addressed (i.e., impacts that are small receive less mitigation consideration than impacts that are large).

4.0.3 Uncategorized License Renewal Issues

The NRC determined that its categorization and impact-finding definitions did not apply to chronic effects of electromagnetic fields. Because the categorization and impact finding definitions do not apply as noted in 10 CFR Part 51, Subpart A, Appendix B, Table B-1, Footnote 5, applicants are not currently required to submit information on this issue.

4.0.4 Format of Issues Reviewed

The review and analysis of the Category 1 and 2 issues identified in NRC Regulatory Guide 4.2, Supplement 1, Revision 1 (NRC 2013b), are discussed in the following sections. The format for the review of these issues is described below. Although Chapter 5 describes the process by which Category 1 issues have been evaluated for new and significant information, specific issues are also being listed in this chapter for consistency purposes with the recommended NRC Regulatory Guide 4.2, Supplement 1 format.

Issue: Title of the issue.

Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1: The findings for the issue from 10 CFR Part 51, Subpart A, Appendix B, Table B-1, Summary of Findings on NEPA Issues for License Renewal of Nuclear Power Plants.

Requirement: Restatement of the applicable 10 CFR 51.53 requirement.

Background: A background excerpt from the applicable section of the GEIS. The specific section of the GEIS is referenced for the convenience of the reader.

Analysis: An analysis of the environmental impact, taking into account information provided in the GEIS and 10 CFR Part 51, Subpart A, Appendix B, as well as current site-specific information. If an issue is not applicable, the analysis lists the explanation. The analysis section also provides a summary conclusion of the environmental impacts and identifies, as applicable, either ongoing or additional planned mitigation measures to reduce adverse impacts. For Category 1 issues listed in this chapter, an analysis is not required absent new and significant information.

Table 4.0-1
Category 1 Issues Not Applicable to PTN

Resource Issue	Comment
Land Use	
Offsite land use in transmission line ROWs	All in-scope transmission lines subject to the evaluation of environmental impacts for license renewal are located completely within the PTN site.
Surface Water Resources	
Altered current patterns at intake and discharge structures	PTN relies on cooling canals that are manmade features without natural currents that affect waters of the U.S.
Altered thermal stratification of lakes	PTN does not withdraw water from or discharge to a lake.
Surface water use conflicts (plants with once-through cooling systems)	PTN does not use a once-through cooling system.
Temperature effects on sediment transport capacity	PTN does not discharge to a natural water body that has sediment transport capacity.
Groundwater Resources	
Groundwater use conflicts (plants that withdraw less than 100 gallons per minute)	PTN withdraws groundwater at quantities greater than 100 gallons per minute.
Terrestrial Resources	
Cooling tower impacts on vegetation (plants with cooling towers)	PTN does not use cooling towers.
Aquatic Resources	
Impingement and entrainment of aquatic organisms (plants with cooling towers)	PTN does not use cooling towers.
Thermal impacts on aquatic organisms (plants with cooling towers)	PTN does not use cooling towers.

Table 4.0-2
Category 1 Issues Applicable to PTN (Sheet 1 of 3)

Resource Issue	Subcategory
Land Use	Onsite land uses
	Offsite land uses
Visual Resources	Aesthetic impacts
Air Quality	Air quality impacts (all plants)
	Air quality effects of transmission lines
Noise	Noise impacts
Geologic Environment	Geology and soils
Surface Water Resources	Surface water use and quality (non-cooling system impacts)
	Altered salinity gradients
	Scouring caused by discharged cooling water
	Discharge of metals in cooling system effluent
	Discharge of biocides, sanitary wastes, and minor chemical spills
	Effects of dredging
Groundwater Resources	Groundwater contamination and use (non-cooling system impacts)
	Groundwater quality degradation resulting from water withdrawals
	Groundwater quality degradation (plants with cooling ponds in salt marshes)
Terrestrial Resources	Exposure of terrestrial organisms to radionuclides
	Cooling system impacts on terrestrial resources (plants with once-through cooling systems or cooling ponds)
	Bird collisions with plant structures and transmission lines
	Transmission line ROW management impacts on terrestrial resources
	Electromagnetic fields on flora and fauna (plants, agricultural crops, honeybees, wildlife, livestock)

Category 2 Issues Applicability to PTN (Sheet 1 of 2)

Resource Issue	Applicability	ER Section
Surface Water Resources		
Surface water use conflicts (plants with cooling ponds or cooling towers using makeup water from a river)	Not applicable	4.5.1
Groundwater Resources		
Groundwater use conflicts (plants that withdraw more than 100 gallons per minute)	Applicable	4.5.3
Groundwater use conflicts (plants with closed-cycle cooling systems that withdraw makeup water from a river)	Not applicable	4.5.2
Groundwater quality degradation (plants with cooling ponds at inland sites)	Not applicable	4.5.4
Radionuclides released to groundwater	Applicable	4.5.5
Terrestrial Resources		
Effects on terrestrial resources (non-cooling system impacts)	Applicable	4.6.5
Water use conflicts with terrestrial resources (plants with cooling ponds or cooling towers using makeup water from a river)	Not applicable	4.6.4
Aquatic Resources		
Impingement and entrainment of aquatic organisms (plants with once-through cooling systems or cooling ponds)	Applicable	4.6.1
Thermal impacts on aquatic organisms (plants with once-through cooling systems or cooling ponds)	Applicable	4.6.2
Water use conflicts with aquatic resources (plants with cooling ponds or cooling towers using makeup water from a river)	Not applicable	4.6.3
Special Status Species and Habitats		
Threatened, endangered, and protected species and essential fish habitat	Applicable	4.6.6
Historic and Cultural Resources		
Historic and cultural resources	Applicable	4.7

Resource Issue	Applicability	ER Section
Human Health		
Microbiological hazards to the public (plants with cooling ponds or canals or cooling towers that discharge to a river)	Applicable	4.9.1
Electric shock hazards	Applicable	4.9.2
Postulated Accidents		
Severe accidents	Applicable	4.15
Environmental Justice		
Minority and low-income populations	Applicable	4.10.1
Cumulative Impacts		
Cumulative impacts	Applicable	4.12

4.1 Land Use and Visual Resources

The following sections address the land use issues applicable to PTN, providing background on the issues and the analyses regarding the SLR period.

4.1.1 Onsite Land Use

4.1.1.1 Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

SMALL. Changes in onsite land use from continued operations and refurbishment associated with license renewal would be a small fraction of the nuclear power plant site and would involve only land that is controlled by the licensee.

4.1.1.2 Requirement [10 CFR 51.53(c)(3)(iv)]

The ER must contain any new and significant information regarding the environmental impacts of license renewal of which the applicant is aware.

4.1.1.3 Background [GEIS Section 4.2.1.1]

Operational activities at a nuclear power plant during the license renewal term would be similar to those occurring during the current license term. Generally, onsite land use conditions would remain unchanged. However, additional spent nuclear fuel and LLRW generated during the license renewal term could require the construction of new or expansion of existing onsite storage facilities. Should additional storage facilities be required, this action would be addressed in separate license reviews conducted by the NRC. Refurbishment activities, such as steam generator and vessel head replacement, have not permanently changed onsite land use conditions.

4.1.1.4 Analysis

Onsite land use information is presented in Section 3.2.1. No license renewal-related refurbishment activities have been identified, as discussed in Section 2.3. In addition, no license renewal-related construction activities have been identified. Therefore, no changes in onsite land use during the SLR period are anticipated.

In the GEIS, the NRC determined that onsite land use impacts from continued plant operations over the license renewal term would be SMALL for all nuclear plants, and designated this as a Category 1 issue (NRC 2013a, Section 4.2.1.1). Based on FPL's review, no new and significant information was identified as it relates to onsite land use, and further analysis is not required.

4.1.2 Offsite Land Use

4.1.2.1 Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

SMALL. Offsite land use would not be affected by continued operations and refurbishment associated with license renewal.

4.1.2.2 Requirement [10 CFR 51.53(c)(3)(iv)]

The ER must contain any new and significant information regarding the environmental impacts of license renewal of which the applicant is aware.

4.1.2.3 Background [GEIS Section 4.2.1.1]

The impacts of continued plant operations during the license renewal term and refurbishment on offsite land use were evaluated separately in the 1996 GEIS. It was predicted that impacts associated with refurbishment and changes in population and tax revenue on offsite land use could range from SMALL to MODERATE. License renewal reviews, however, have shown no power plant-related population changes or significant tax revenue changes due to license renewal. Non-outage employment levels at nuclear power plants have remained relatively unchanged or have decreased. With no increase in the number of workers, there has been no increase in housing, infrastructure, or demand for services beyond what has already occurred. Operational activities during the license renewal term would be similar to those occurring during the current license term and would not affect offsite land use beyond what has already been affected.

For plants that have the potential to impact a coastal zone or coastal watershed, as defined by each state participating in the national Coastal Zone Management Program, applicants for license renewal must submit to the affected state a certification that the proposed license renewal is consistent with the state Coastal Zone Management Program. Applicants must coordinate with the state agency that manages the state Coastal Zone Management Program to obtain a determination that the proposed nuclear plant license renewal would be consistent with the state program.

4.1.2.4 Analysis

Offsite land use information is presented in Section 3.2.2. As discussed in Section 2.5, there are no plans to add workers to support plant operations during the SLR period and, as discussed in Section 2.3, no license renewal-related refurbishment activities have been identified. Therefore, no changes in offsite land use during the SLR period are anticipated.

In the GEIS, the NRC determined that offsite land use impacts from continued plant operations over the license renewal term would be SMALL for all nuclear plants, and designated this as a Category 1 issue (NRC 2013a, Section 4.2.1.1). Additionally, as detailed in Section 9.5.10, PTN has fulfilled the regulatory requirement to certify to the licensing agency that the proposed activity would be consistent with the state's federally approved coastal zone management program. Based on FPL's review, no new and significant information was identified as it relates to offsite land use, and further analysis is not required.

4.1.3 Offsite Land Use of Transmission Line Rights-of-Way

4.1.3.1 Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

SMALL. Use of transmission line ROWs from continued operations and refurbishment associated with license renewal would continue with no change in land use restrictions.

4.1.3.2 Requirement [10 CFR 51.53(c)(3)(iv)]

The ER must contain any new and significant information regarding the environmental impacts of license renewal of which the applicant is aware.

4.1.3.3 Background [GEIS Section 4.2.1.1]

Operational activities in offsite transmission line ROWs, within this scope of review, during the license renewal term, would be similar to those occurring during the current license term and would not affect offsite land use in transmission line ROWs beyond what has already been affected. Certain land-use activity in the ROW is usually restricted. Land cover is generally managed through a variety of maintenance procedures so that vegetation growth and building construction do not interfere with power line operation and access. Land use within ROWs are limited to activities that do not endanger power line operation; these include recreation, off-road vehicle use, grazing, agricultural cultivation, irrigation, roads, environmental conservation, and wildlife areas. Transmission lines do not preclude the use of the land for farming or environmental and recreational use. Transmission lines connecting nuclear power plants to the electrical grid are no different from transmission lines connecting any other power plant.

4.1.3.4 Analysis

As discussed in Section 2.2.5, in-scope transmission lines are located completely within PTN property (see Figure 2.2-4). Therefore, this issue is not applicable, and further analysis is not required.

4.1.4 Aesthetics Impacts

4.1.4.1 Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

SMALL. No important changes to the visual appearance of plant structures or transmission lines are expected from continued operations and refurbishment associated with license renewal.

4.1.4.2 Requirement [10 CFR 51.53(c)(3)(iv)]

The ER must contain any new and significant information regarding the environmental impacts of license renewal of which the applicant is aware.

4.1.4.3 Background [GEIS Section 4.2.1.2]

A case study performed for the 1996 GEIS found a limited number of situations where nuclear power plants had a negative effect on visual resources. Negative perceptions were based on aesthetic considerations (for instance, the plant is out of character or scale with the community or the viewshed), physical environmental concerns, safety and perceived risk issues, an anti-plant attitude, or an anti-nuclear orientation. It is believed that these negative perceptions would persist regardless of mitigation measures.

In addition, the visual appearance of transmission lines is not expected to change during the license renewal term. After the containment building and cooling towers, transmission line towers are probably the most frequently observed structure associated with nuclear power plants. Transmission lines from nuclear power plants are generally indistinguishable from those from other power plants. Because electrical transmission lines are common throughout the United States, they are generally perceived with less prejudice than the nuclear power plant itself. Also, the visual impact of transmission lines tends to wear off when viewed repeatedly.

4.1.4.4 Analysis

The visual appearance of the plant is presented in Section 3.2.3. As described in Section 2.2.5 and shown in Figure 2.2-4, the in-scope transmission lines do not contribute to the visual impacts of the site. As discussed in Section 3.2.3, Turkey Point is located in an unincorporated area in southeastern Miami-Dade County, Florida. There is sufficient vegetation to screen the existing units from roadways and recreational areas on land. The existing units are not visible from most areas within Biscayne National Park and Homestead Bayfront Park. The site is not visible beyond 6 miles from land. However, the site is visible for many miles from Biscayne Bay. At night, light from PTN is visible from several points in the vicinity. No refurbishment or construction activities have been identified that would change the aesthetics of the Turkey Point facility during the SLR term. Therefore, no changes in visual resources during the SLR period are anticipated.

In the GEIS, the NRC determined that aesthetic impacts from continued plant operations over the license renewal term would be SMALL for all nuclear plants, and designated this as a Category 1 issue (NRC 2013a, Section 4.2.1.2). Based on FPL's review, no new and significant information was identified as it relates to visual resources, and further analysis is not required.

4.2 Air Quality

The following sections address the air quality issues applicable to PTN, providing background on the issues and the analyses regarding the SLR period.

4.2.1 Air Quality Impacts (all plants)

4.2.1.1 Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

The NRC has made the following generic findings for all plants regarding air quality impacts from nuclear plants:

SMALL. Air quality impacts from continued operations and refurbishment associated with license renewal are expected to be small at all plants. Emissions resulting from refurbishment activities at locations in or near air quality nonattainment or maintenance areas would be short-lived and would cease after these refurbishment activities are completed. Operating experience has shown that the scale of refurbishment activities has not resulted in exceedance of the *de minimis* thresholds for criteria pollutants, and BMPs including fugitive dust controls and the imposition of permit conditions in state and local air emissions permits would ensure conformance with applicable state or tribal implementation plans.

Emissions from emergency diesel generators (EDGs) and fire pumps and routine operations of boilers used for space heating would not be a concern, even for plants located in or adjacent to nonattainment areas. Impacts from cooling tower particulate emissions even under the worst-case situations have been small.

4.2.1.2 Requirement [10 CFR 51.53(c)(3)(iv)]

The ER must contain any new and significant information regarding the environmental impacts of license renewal of which the applicant is aware.

4.2.1.3 Background [GEIS Section 4.3.1.1]

Impacts on air quality during normal plant operations can result from operations of fossil fuel-fired equipment needed for various plant functions. Each licensed plant typically employs EDGs for use as a backup power source. EDGs and fire pumps typically require state or local operating permits. These diesel generators are typically tested once a month with several test burns of various durations (e.g., 1 to several hours). In addition to these maintenance tests, longer-running endurance tests are also typically conducted at each plant. Each generator is typically tested for 24 hours on a staggered test schedule (e.g., once every refueling outage).

In addition to the EDGs, fossil fuel (i.e., diesel-, oil-, or natural gas-fired) boilers are used primarily for evaporator heating, plant space heating, and/or feed water purification. These units typically operate at a variable load on a continuous basis throughout the year unless end use is restricted to one application, such as space heating. The utility boilers at commercial plants are relatively small when compared with most industrial boilers and are typically regulated through state-level operating permits.

As discussed in Section 3.3 of the GEIS, cooling tower drift can increase downwind PM concentrations, impair visibility, ice roadways, cause drift deposition, and damage vegetation and painted surfaces. Thus, although there is the potential for some air quality impacts to occur as a result of equipment and cooling tower operations, even in the worst-case situation (Hope Creek), the impacts have been small, and licensees would be required to operate within state permit requirements.

In the 1996 GEIS, the NRC concluded that the impacts from plant refurbishment associated with license renewal on air quality could range from SMALL to LARGE, although these impacts were expected to be SMALL for most plants. However, findings from license renewal Supplemental Environmental Impact Statements (SEISs) published since the 1996 GEIS have shown that refurbishment activities, such as steam generator and vessel head replacement, have not required the large numbers of workers and months of time, as well as the degree of land disturbance that was conservatively estimated in the 1996 GEIS. Presumed air pollutant emissions, including levels of fugitive dust, have therefore not been realized.

4.2.1.4 Analysis

Air quality information is presented in Section 3.3.3. No license renewal-related refurbishment activities have been identified, as discussed in Section 2.3. As stated in the GEIS (NRC 2013a), BMPs, including fugitive dust controls and the imposition of permit conditions in FDEP air emissions permits, would ensure conformance with applicable state implementation plans.

As discussed in Section 3.3.3.1, Miami-Dade County is in attainment with the NAAQS for all criteria air pollutants. As discussed in Section 3.3.3.2, no future upgrade or replacement activities (e.g., diesel generators, diesel pumps) that would increase or decrease air emissions over the SLR period were identified as necessary for plant operations. As indicated in Section 3.3, a pump replacement is planned and the Title V permit would be amended as necessary.

The Turkey Point Title V facility is composed of two separate co-located power plants: the fossil plant (Unit 5) and the nuclear plant (Units 3 and 4). The non-nuclear operations of PTN are permitted by a Title V air emissions permit (Permit No. 0250003-021-AV). The operations of the fossil plant are addressed in a separate Title V permit. (FDEP 2014a) As discussed in Section 3.3.3.2 and Chapter 9, PTN and ancillary facilities have received a site certification in accordance with the Florida PPSA. This process provides a certification that encompasses all licenses and permits needed for affected Florida state, regional, and local agencies. The conditions of certification require FPL to comply with the provisions and limitations set forth in its Title V air operation permit (FDEP 2016a). The PTN air permit contains conditions established by the FDEP to protect Florida's ambient air quality standards and ensure impacts are maintained at acceptable levels. Appropriate permit conditions would regulate any future PTN activities that may increase air pollutants or threaten the attainment status of Miami-Dade County. Compliance with current and future air emissions regulatory requirements, applicable emissions control measures, and reporting requirements will ensure continued SMALL impact on ambient air quality.

In the GEIS, the NRC determined that air quality impacts from continued plant operations over the license renewal term would be SMALL for all nuclear plants, and designated this as a Category 1 issue (NRC 2013a, Section 4.3.1.1). Based on FPL's review, no new and significant information was identified as it relates to air quality, and further analysis is not required.

4.2.2 Air Quality Effects of Transmission Lines

4.2.2.1 Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

SMALL. Production of ozone and oxides of nitrogen is insignificant and does not contribute measurably to ambient levels of these gases.

4.2.2.2 Requirement [10 CFR 51.53(c)(3)(iv)]

The ER must contain any new and significant information regarding the environmental impacts of license renewal of which the applicant is aware.

4.2.2.3 Background [GEIS Section 4.3.1.1]

Small amounts of ozone and substantially smaller amounts of oxides of nitrogen are produced by transmission lines during corona, a phenomenon that occurs when air ionizes near isolated irregularities on the conductor surface such as abrasions, dust particles, raindrops, and insects. Several studies have quantified the amount of ozone generated and concluded that the amount produced by even the largest lines in operation (765 kV) is insignificant.

Ozone concentrations generated by transmission lines are therefore too low to cause any significant effects. The minute amounts of oxides of nitrogen produced are similarly insignificant. A finding of SMALL significance for transmission lines, within this scope of review is supported by the evidence that production of ozone and oxides of nitrogen are insignificant and does not measurably contribute to ambient levels of those gases.

4.2.2.4 Analysis

Based on the GEIS, it was determined through several studies that the amount of ozone generated by even the largest lines in operation (765 kV) would be insignificant (NRC 2013a, Section 4.3.1.1). As discussed in Section 2.2.5, Turkey Point's in-scope transmission lines are 230 kV. Therefore, the production of ozone and oxides of nitrogen would be *de minimis*.

In the GEIS, the NRC determined that air quality effects of transmission lines from continued plant operations over the license renewal term would be SMALL for all nuclear plants, and designated this as a Category 1 issue (NRC 2013a, Section 4.3.1.1). Based on FPL's review, no new and significant information was identified as it relates to air quality effects of transmission lines, and further analysis is not required.

4.3 Noise

The following sections address the noise issues applicable to PTN, providing background on the issues and the analyses regarding the SLR period.

4.3.1 Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

SMALL. Noise levels would remain below regulatory guidelines for offsite receptors during continued operations and refurbishment associated with license renewal.

4.3.2 Requirement [10 CFR 51.53(c)(3)(iv)]

The ER must contain any new and significant information regarding the environmental impacts of license renewal of which the applicant is aware.

4.3.3 Background [GEIS Section 4.3.1.2]

Major sources of noise at operating nuclear power plants are cooling towers, turbines, transformers, large pumps, and cooling water system motors. Nuclear plant operations have not changed appreciably with time, and no change in noise levels or noise-related impacts are expected during the license renewal term. Because no change is expected in the amount of noise generated during the license renewal term, the only issue of concern is the number of people now living close to the nuclear power plant who are exposed to operational noise.

Given the industrial nature of the power plant and the number of years of plant operation, noise from a nuclear plant is generally nothing more than a continuous minor nuisance. However, noise levels may sometimes exceed the 55 dBA level that the EPA uses as a threshold level to protect against excess noise during outdoor activities. However, according to the EPA, this threshold does "not constitute a standard, specification, or regulation," but was intended to provide a basis for state and local governments establishing noise standards. Nevertheless, noise levels at the site boundary are expected to remain well below regulatory standards for offsite residents.

Noise would also be generated by construction-related activities and equipment used during refurbishment. However, this noise would occur for relatively short periods of time (several weeks) and is not expected to be distinguishable from other operational noises at the site boundary nor create an adverse impact on nearby residents.

4.3.4 Analysis

Noise associated with plant operations is presented in Section 3.4. As discussed in Section 3.4, a noise monitoring survey which included noise from PTN was performed in June 2008 as part of the Turkey Point Units 6 and 7 COL application ER. The survey indicated that the baseline Ldn value is below the 65 dBA acceptance limit. Turkey Point Units 6 and 7 would be collocated with PTN; therefore, the noise study is also considered applicable to PTN.

No license renewal-related refurbishment activities have been identified, as discussed in Section 2.3. As discussed in Section 3.4, because Turkey Point is located in a rural area away from urban areas, it is unlikely that noise levels from Turkey Point would affect offsite residences. The nearest residence to PTN, as defined in the PTN AREOR, is located approximately 1.7 miles west-northwest of the PTN generating station area. These are identified as the FPL daycare center and shooting range near the entrance to PTN. The Homestead Bayfront Park complex is located 1.9 miles north of the plant and has occasional overnight recreational occupancy. (PTN 2017b) There are no applicable state or local environmental noise regulations for unincorporated areas of Miami-Dade County, where Turkey Point is located. As discussed in Section 3.4, there have been no noise complaints associated with Turkey Point's plant operations in the previous 5 years (2012–2016).

In the GEIS, the NRC determined that noise impacts from continued plant operations over the license renewal term would be SMALL for all nuclear plants, and designated this as a Category 1 issue (NRC 2013a, Section 4.3.1.2). Based on Turkey Point's review, no new and significant information was identified as it relates to noise, and further analysis is not required.

4.4 Geology and Soils

The following sections address the geology and soils issues applicable to PTN, providing background on the issues and the analyses regarding the SLR period.

4.4.1 Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

SMALL. The effect of geologic and soil conditions on plant operations and the impact of continued operations and refurbishment activities on geology and soils would be small for all nuclear power plants and would not change appreciably during the license renewal term.

4.4.2 Requirement [10 CFR 51.53(c)(3)(iv)]

The ER must contain any new and significant information regarding the environmental impacts of license renewal of which the applicant is aware.

4.4.3 Background [GEIS Section 4.4.1]

The impact of continued operations and refurbishment associated with license renewal on geologic and soil resources would consist of soil disturbance, including sediment and/or any associated bedrock, for projects, such as replacing or adding buildings, roads, parking lots, and below-ground and above-ground utility structures. Implementing BMPs would reduce soil erosion and subsequent impacts on surface water quality. These practices include, but are not limited to, minimizing the amount of disturbed land, stockpiling topsoil before ground disturbance, mulching and seeding in disturbed areas, covering loose materials with geotextiles, using silt fences to reduce sediment loading to surface water, using check dams to minimize the erosive power of drainages, and installing proper culvert outlets to direct flows in streams or drainages.

Detailed geotechnical analyses would be required to address the stability of excavations, foundation footings, and slope cuts for building construction, road creation, or other refurbishment-related construction projects. Depending on the plant location and design, riverbank or coastline protection might need to be upgraded, especially at water intake or discharge structures, if natural flows, such as storm surges, cause an increase in erosion. In addition, the FPPA [7 USC 4201 et seq.] requires federal agencies to take into account agency actions affecting the preservation of farmland, including prime and other important farmland soils, as described in Section 3.4 of the GEIS.

4.4.4 Analysis

Geology and soils information is presented in Section 3.5. Routine infrastructure, renovation, and maintenance projects would be expected during continued operation. As discussed in Section 3.5.3.2, stabilization measures are in place to prevent erosion and sedimentation impacts to the site and vicinity because PTN has been operational since the early 1970s.

In the GEIS, the NRC determined that geology and soil impacts from continued plant operations over the license renewal term would be SMALL for all nuclear plants, and designated this as a Category 1 issue (NRC 2013a, Section 4.4.1). Based on FPL's review, no new and significant information was identified as it relates to geology and soils, and further analysis is not required.

4.5 Water Resources

The following sections address the water resources issues applicable to PTN, providing background on the issues and the analyses regarding the SLR period.

4.5.1 Surface Water Use Conflicts (Plants with Cooling Ponds or Cooling Towers Using Makeup Water from a River)

4.5.1.1 Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

SMALL or MODERATE. Impacts could be of small or moderate significance, depending on makeup water requirements, water availability, and competing water demands.

4.5.1.2 Requirement [10 CFR 51.53(c)(3)(ii)(A)]

If the applicant's plant utilizes cooling towers or cooling ponds and withdraws makeup water from a river, an assessment of the impact of the proposed action on water availability and competing water demands, the flow of the river . . . must be provided.

4.5.1.3 Background [GEIS Section 4.5.1.1]

Nuclear power plant cooling systems may compete with other users relying on surface water resources, including downstream municipal, agricultural, or industrial users. Closed-cycle cooling is not completely closed, because the system discharges blowdown water to a surface water body and withdraws water for makeup of both the consumptive water loss due to evaporation and drift (for cooling towers) and blowdown discharge. For plants using cooling towers, the makeup water needed to replenish the consumptive loss of water to evaporation can be significant and is reported at 60 percent or more of the condenser flow rate. Cooling ponds will also require makeup water as a result of naturally occurring evaporation, evaporation of the warm effluent, and possible seepage to groundwater.

Consumptive use by plants with cooling ponds or cooling towers using makeup water from a river during the license renewal term is not expected to change unless power uprates, with associated increases in water use, are proposed. Such uprates would require an environmental assessment by the NRC. In the 1996 GEIS, application of this issue applied only to rivers with low flow so as to define the difference between plants located on "small" versus "large" rivers. However, any river, regardless of size, can experience low flow conditions of varying severity during periods of drought and changing conditions in the affected watershed such as upstream diversions and use of river water. NRC has subsequently determined that use of the term "low flow" in categorizing river flow is of little value considering that all rivers can experience low flow conditions.

Population growth around nuclear power plants has caused increased demand on municipal water systems, including systems that rely on surface water. Municipal intakes located downstream from a nuclear power plant could experience water shortages, especially in times of drought. Similarly, water demands upstream from a plant could impact the water availability at the plant's intake.

Water use conflicts associated with plants with cooling ponds or cooling towers using makeup water from a river with low flow were considered to vary among sites because of differing site-specific factors, such as makeup water requirements, water availability (especially in terms of varying river flow rates), changing or anticipated changes in population distributions, or changes in agricultural or industrial demands.

4.5.1.4 Analysis

As discussed in Section 2.2.3, Turkey Point utilizes a closed-cycle CCS for condenser cooling purposes, but does not withdraw makeup water from a river. PTN does not have a permit to use surface water for consumptive use nor have any plans for surface water consumptive use during the license renewal period. PTN uses approximately 690 gpm of water from the Miami-Dade public water supply system. Plant water use includes process (primary demineralizer water makeup), potable, and fire protection water. (FPL 2014a, Section 2.3.2.1.4.1) The use of municipal water for plant use will be significantly reduced by the end of 2017, when production from the Upper Floridan Aquifer will begin. Therefore, this issue is not applicable, and further analysis is not required.

4.5.2 Groundwater Use Conflicts (Plants with Closed-Cycle Cooling Systems that Withdraw Makeup Water from a River)

4.5.2.1 Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

SMALL, MODERATE, or LARGE. Water use conflicts could result from water withdrawals from rivers during low-flow conditions, which may affect aquifer recharge. The significance of impacts would depend on makeup water requirements, water availability, and competing water demands.

4.5.2.2 Requirement [10 CFR 51.53(c)(3)(ii)(A)]

If the applicant's plant utilizes cooling towers or cooling ponds and withdraws makeup water from a river, an assessment of the impact of the proposed action on water availability and competing water demands . . . must be provided. The applicant shall also provide an assessment of the impacts of the withdrawal of water from the river on alluvial aquifers during low flow.

4.5.2.3 Background [GEIS Section 4.5.1.2]

In the case of plants with cooling towers or cooling ponds that rely on a river for makeup of consumed (evaporated) cooling water, it is possible water withdrawals from the river could lead to groundwater use conflicts with other users. This situation could occur because of the interaction between groundwater and surface water, especially in the setting of an alluvial aquifer in a river valley. Consumptive use of the river water, if significant enough to lower the river's water level, would also influence water levels in the alluvial aquifer. Shallow wells of nearby groundwater users could therefore have reduced water availability or go dry. During times of drought, the effect would be occurring naturally, although withdrawals for makeup water would increase the effect.

4.5.2.4 Analysis

As discussed in Section 2.2.3, Turkey Point uses its closed-cycle cooling canals in the CCS for condenser cooling purposes, but does not withdraw makeup water from a river. Therefore, this issue is not applicable, and further analysis is not required.

4.5.3 Groundwater Use Conflicts (Plants that Withdraw more than 100 GPM)

4.5.3.1 Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

SMALL, MODERATE, or LARGE. Plants that withdraw more than 100 gpm could cause groundwater use conflicts with nearby groundwater users.

4.5.3.2 Requirement [10 CFR 51.53(c)(3)(ii)(C)]

If the applicant's plant pumps more than 100 gallons (total onsite) of groundwater per minute, an assessment of the impact of the proposed action on groundwater must be provided.

4.5.3.3 Background [GEIS Section 4.5.1.2]

A nuclear plant may have several wells, with combined pumping in excess of 100 gpm (378 liters per minute [L/min]). Overall site pumping rates of this magnitude have the potential to create conflicts with other local groundwater users if the cone of depression extends to the offsite well(s). Large offsite pumping rates for municipal, industrial, or agricultural purposes may, in turn, lower the water level at power plant wells. For any user, allocation is normally determined through a state-issued permit.

Groundwater use conflicts have not been observed at any nuclear power plants, and no significant change in water well systems is expected over the license renewal term. If a conflict did occur, it might be possible to resolve it if the power plant relocated its well or wellfield to a different part of the property. The siting of new wells would be determined through a hydrogeologic assessment.

4.5.3.4 Analysis

The FDEP (conditions of certification) allows a maximum Floridan Aquifer withdrawal total of 28.06 MGD:14.00 MGD for salinity reduction in the CCS and 14.06 MGD for Unit 5 cooling water and plant process water (FDEP 2016a). The SFWMD (Permit No. 13-06251-W) allows a maximum withdrawal of groundwater from the Biscayne Aquifer of 5,475 million gallons per year (15,000 gpd or 465 million gallons per month) for use in the capture of hypersaline water in the Biscayne Aquifer using the RWS (SFWMD 2017a). Therefore, the combined permitted groundwater maximum withdrawals from the Floridan Aquifer and Biscayne Aquifer Recovery System is 43.06 MGD. These Biscayne and Floridan Aquifer System withdrawals are permitted by FDEP and the SFWMD. During the permitting process, the impacts of the uses on existing land uses, pre-existing water rights, and the environment are fully evaluated and subject to public review and challenge prior to water rights being granted. In addition, in southern Florida, uses of seawater-quality water (dissolved chloride levels of 19,000 mg/L or above) do not require a permit. FPL maintains three such seawater wells constructed into the Biscayne Aquifer (Point Wells) for CCS freshening in the event of extreme salinity events. The combined capacity of these three wells is 45 MGD.

It is not anticipated that groundwater withdrawal increases above permitted quantities will be required during the license period; therefore, FPL concludes that impacts from groundwater withdrawals are SMALL and do not warrant additional mitigation measures.

4.5.4 Groundwater Quality Degradation (Plants with Cooling Ponds at Inland Sites)

4.5.4.1 Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

SMALL, MODERATE, or LARGE. Inland sites with closed-cycle cooling ponds could degrade groundwater quality. The significance of the impact would depend on cooling pond water quality, site hydrogeologic conditions (including the interaction of surface water and groundwater), and the location, depth, and pump rate of water wells.

4.5.4.2 Requirement [10 CFR 51.53(c)(3)(ii)(D)]

If the applicant's plant is located at an inland site and utilizes cooling ponds, an assessment of the impact of the proposed action on groundwater quality must be provided.

4.5.4.3 Background [GEIS Section 4.5.1.2]

Some nuclear power plants that rely on unlined cooling ponds are located at inland sites surrounded by farmland or forest or undeveloped open land. Degraded groundwater has the potential to flow radially from the ponds and reach offsite groundwater wells. The degree to which this occurs depends on the water quality of the cooling pond; site hydrogeologic conditions (including the interaction of surface water and groundwater); and the location, depth, and pump rate of water wells. Mitigation of significant problems stemming from this issue could include lining existing ponds, constructing new lined ponds, or installing subsurface flow barrier walls. Groundwater monitoring networks would be necessary to detect and evaluate groundwater quality degradation. The degradation of groundwater quality associated with cooling ponds has not been reported for any inland nuclear plant sites.

4.5.4.4 Analysis

As discussed in Section 2.2.3, Turkey Point utilizes a closed-loop cooling system with the CCS for condenser cooling purposes. Section 2.2.3 describes the CCS as composed of cooling canals that receive tidal inflow and outflow from the saline aquifer beneath Biscayne Bay. As shown in Section 3.1, Turkey Point's location is coastal rather than inland. Given that this issue is specific to inland sites and the cooling canals groundwater interface is to a marine aquifer, this issue is not applicable, and further analysis is not required. The issue was likewise considered not applicable in the first license renewal ER (FPL 2000b, Section 4.8). The GEIS also identifies Turkey Point's cooling canals as applicable to the Category 1 issue of cooling ponds located in salt marsh (NRC 2013a, Section 4.5.1.2).

4.5.5 Radionuclides Released to Groundwater

4.5.5.1 Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

SMALL or MODERATE. Leaks of radioactive liquids from plant components and pipes have occurred at numerous plants. Groundwater protection programs have been established at all operating nuclear power plants to minimize the potential impact from any inadvertent releases. The magnitude of impacts would depend on site-specific characteristics.

4.5.5.2 Requirement [10 CFR 51.53(c)(3)(ii)(P)]

An applicant shall assess the impact of any documented inadvertent releases of radionuclides into groundwater. The applicant shall include in its assessment a description of any groundwater protection program used for the surveillance of piping and components containing radioactive liquids for which a pathway to groundwater may exist. The assessment must also include a description of any past inadvertent releases and the projected impact to the environment (e.g., aquifers, rivers, lakes, ponds, ocean) during the license renewal term.

4.5.5.3 Background [GEIS Section 4.5.1.2]

The issue is relevant to license renewal because all commercial nuclear power plants routinely release radioactive gaseous and liquid materials into the environment. These radioactive releases are designed to be planned, monitored, documented, and released into the environment at designated discharge points. However, within the past several years, there have been numerous events at power reactor sites which involved unknown, uncontrolled, and unmonitored release of liquids containing radioactive material into the groundwater.

The majority of the inadvertent liquid release events involved tritium, which is a radioactive isotope of hydrogen. However, other radioactive isotopes, such as cesium and strontium, have also been inadvertently released into the groundwater. The types of events include leakage from spent fuel pools, buried piping, and failed pressure relief valves on an effluent discharge line.

In 2006, the NRC's Executive Director for Operations chartered a task force to conduct a lessons-learned review of these incidents. On September 1, 2006, the task force issued its report: Liquid Radioactive Release Lessons Learned Task Force Report.

The most significant conclusion dealt with the potential health impacts on the public from the inadvertent releases. Although there were numerous events where radioactive liquid was released to the groundwater in an unplanned, uncontrolled, and unmonitored fashion, based on the data available, the task force did not identify any instances where public health and safety was adversely impacted.

On the basis of the information and experience with these leaks, the NRC concludes that the impact to groundwater quality from the release of radionuclides could be SMALL or MODERATE, depending on the magnitude of the leak, radionuclides involved, hydrogeologic factors, the distance to receptors, and the response time of plant personnel to identify and stop the leak in a timely fashion.

4.5.5.4 Analysis

The Turkey Point groundwater protection program is discussed in Section 3.6.2.5. Table 3.6-2 presents well construction details for the Turkey Point groundwater monitoring wells, while Figures 3.6-10 and 3.6-11 show the location of the wells. Table 3.6-5 presents information on registered water wells within a 5-mile band around the FPL property boundary, while Figure 3.6-12 shows the locations of these registered wells.

As discussed in Section 3.6.4.2.1, tritium migrates with groundwater flow. As discussed in Section 3.6.4.2.1, radwaste releases are discharged to the IWW outfall 001 and mix with waters within the closed-loop IWW/CCS. Radwaste release administrative controls ensure the releases are consistent with the plant permits and do not present an environmental or public health risk. The cooling canals are in direct hydraulic connection to the underlying sediments and coral rock, and a near continuous exchange of surface water in the cooling canals and groundwater within the sediments exists by design. As discussed in Sections 3.6.4.2.1 and 3.6.4.2, groundwater beneath the CCS is saltwater, has been designated as a G-III non-potable groundwater by the FDEP, and is not used as a source of potable or irrigation supply. In addition, facility personnel are provided a municipal source of drinking water. Due to the administrative controls employed for discharges of radwaste, which ensure tritium levels are below public health safety levels, and the use of municipal water for human use, health risks due to human consumption are not credible. The IWW is not open to the public, thereby restricting access. Based on the groundwater and surface water data, none of the potential receptors identified are at a credible risk of exposure to concentrations of tritium. (FPL 2017b, Section 2.10.4)

As discussed in Section 3.6.4.2.1, nine minor unplanned releases of radioactive materials have occurred from 2012 to 2016. All releases have been remediated or monitored to ensure any released radionuclides have not migrated from the release site. Unplanned release events are entered into the CAP for evaluation, correction, and future prevention. For the four unplanned releases with the potential to reach groundwater (e.g., leaks onto soil), Table 3.6-6 presents groundwater monitoring results prior to and for the following year for the unplanned releases. The readings were below reportable levels and do not show a sustained trend. Thus, these unplanned releases would not influence groundwater quality during the SLR term. FPL would continue using its activities to identify unplanned releases, stop them, and enter them into CAP for evaluation, correction, and future prevention.

As discussed in Section 3.6.4.2, Turkey Point's groundwater monitoring program covers the existing quality of groundwater potentially affected by continued operations (as compared to the EPA primary drinking water standards), as well as the current and potential onsite and offsite uses and users of groundwater for drinking and other purposes. As discussed in Section 3.6.4.1.1, low-level liquid radioactive waste effluent from PTN is also discharged by procedurally controlled processes to the IWW facility (CCS). Groundwater tritium levels ranging from non-detectable to 5,500 pCi/L were detected in on-site well PTN-MW-5s in the first quarter of 2016, as shown in Table 4.5-1. This tritium concentration decreased to 480 pCi/L by the fourth quarter of 2016. (PTN 2017b) Since the groundwater monitoring program was initiated in 2010, no plant-related gamma isotopes or hard-to-detect radionuclides have been detected. Therefore, due to continued operations within the requirements of established operating procedures, permits, and site monitoring programs, FPL concludes that impacts from radionuclides to groundwater are SMALL and do not warrant additional mitigation measures beyond PTN's existing groundwater monitoring program and administrative controls.

Table 4.5-1
Turkey Point Groundwater Monitoring Results, Tritium Activity Concentration (pCi/L), 2016 (Sheet 1 of 2)

N/A = Not applicable, sampling not required for this quarter.

< MDC = Value less than 3.00E+02 pCi/L for tritium.

4.6 Ecological Resources

The following sections address the ecological resource issues applicable to PTN, providing background on the issues and the analyses regarding the SLR period.

4.6.1 Impingement and Entrainment of Aquatic Organisms (Plants with Once-Through Cooling Systems or Cooling Ponds)

4.6.1.1 Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

SMALL, MODERATE, or LARGE. The impacts of impingement and entrainment are small at many plants but may be moderate or even large at a few plants with once-through and cooling-pond cooling systems, depending on cooling system withdrawal rates and volumes and the aquatic resources at the site.

4.6.1.2 Requirement [10 CFR 51.53(c)(3)(ii)(B)]

If the applicant's plant utilizes once-through cooling or cooling pond heat dissipation systems, the applicant shall provide a copy of current Clean Water Act 316(b) determinations or equivalent state permits and supporting documentation. If the applicant cannot provide these documents, it shall assess the impact of the proposed action on fish and shellfish resources resulting from impingement and entrainment.

4.6.1.3 Background [GEIS Section 4.6.1.2]

Impingement occurs when organisms are held against the intake screen or netting placed within intake canals. Most impingement involves fish and shellfish. At some nuclear power plants, other vertebrate species may also be impinged on the traveling screens or on intake netting placed within intake canals.

Entrainment occurs when organisms pass through the intake screens and travel through the condenser cooling system. Aquatic organisms typically entrained include ichthyoplankton (fish eggs and larvae), larval stages of shellfish and other macroinvertebrates, zooplankton, and phytoplankton. Juveniles and adults of some species may also be entrained if they are small enough to pass through the intake screen openings, which are commonly 0.38 in. (1 cm) at the widest point.

The magnitude of the impact would depend on plant-specific characteristics of the cooling system (including location, intake velocities, screening technologies, and withdrawal rates) and characteristics of the aquatic resource (including population distribution, status, management objectives, and life history).

4.6.1.4 Analysis

As discussed in Section 2.2.3, PTN withdraws water from the CCS, which is not classified as waters of the U.S. by the EPA.

Entrainment of Fish and Shellfish in Early Life Stages

For plants with cooling ponds, including the Turkey Point CCS, entrainment of fish and shellfish in early life stages into cooling water systems associated with nuclear power plants is considered a Category 2 issue, requiring a site-specific assessment before license renewal. (NRC 2002a, Section 4.1.1)

The closed-loop, recirculating Turkey Point CCS neither withdraws nor discharges surface water to any surface water of the United States or the State of Florida. Therefore, impacts of entrainment on early life stages are limited to the CCS, and there are no impacts from entrainment of fish and shellfish in early life stages on biotic resources of Biscayne Bay, Card Sound, or other waters. (NRC 2002a, Section 4.1.1)

A species list or faunal survey for the fish and shellfish of the CCS is not available. Suitable spawning habitat for game species that favor ocean passes or open bays, such as the common snook and tarpon, is not present in the CCS. Table 3.7-1 details fish species historically documented as occurring in the CCS. As reported in the 2002 PTN EIS, game fish numbers in the CCS declined to very low numbers due to lack of spawning habitat. The 2002 EIS states that the predominant fish in the canals are killifish and other live-bearers. (NRC 2002a, Section 4.1.1) The absence of any hydrological connection between the CCS and adjacent waters prevents the establishment of new fish and shellfish populations in the CCS. Therefore, it is reasonable to conclude that killifish and live-bearers remain the dominant fish species in these waters.

Based on this review, the potential impacts of the cooling-water-intake system's entrainment of fish and shellfish in early life stages are SMALL, and mitigation is not warranted.

Impingement of Fish and Shellfish

For plants with once-through cooling systems, including the Turkey Point CCS, impacts of fish and shellfish on debris screens of cooling-water systems associated with nuclear power plants is considered a Category 2 issue, requiring a site-specific assessment before license renewal. (NRC 2002a, Section 4.1.2)

The closed-loop, recirculating Turkey Point CCS neither withdraws nor discharges surface water to the waters of the State. Therefore, impacts from impingement of fish and shellfish are limited to fish and shellfish in the cooling canals, and there are no impacts from impingement on fish and shellfish of Biscayne Bay, Card Sound, or other waters. (NRC 2002a, Section 4.1.2)

Impacts from impingement of fish and shellfish are limited to the populations of fish and shellfish residing in the CCS. A species list or faunal survey for the fish and shellfish of the CCS is not available.· Suitable spawning habitat for game species that favor ocean passes or open bays, such as the common snook and tarpon, is unlikely to occur in the CCS, although the 2002 PTN EIS reported that some gamefish spawning in the canals may still be occurring at that time. The 2002 EIS states that the dominant fish species in the CCS are killifish and other live-bearers (NRC 2002a, Section 4.1.2). The absence of any hydrological connection between the CCS and adjacent waters prevents the establishment of new fish and shellfish populations in the CCS. Therefore, it is unlikely that species not documented in the previous EIS are present in the CCS, and killifish and live-bearers likely remain the dominant fish species in these waters. The preferred habitat for killifish and other live-bearers are shallows and aquatic vegetation, and individuals are not widely ranging. It is unlikely that populations of such species would be greatly affected by impingement in the intakes of the nuclear plants. Any impacts on fish and shellfish populations within the CCS from impingement would not impact recreational or commercial fishing, because the cooling canals are closed to fishing or other resource-based uses. (NRC 2002a, Section 4.1.2)

Based on the available information relative to potential impacts of the cooling water intake system on the impingement of fish and shellfish, the potential impacts are SMALL, and mitigation is not warranted.

4.6.2 Thermal Impacts on Aquatic Organisms (Plants with Once-Through Cooling Systems or Cooling Ponds)

4.6.2.1 Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

SMALL, MODERATE, or LARGE. Most of the effects associated with thermal discharges are localized and are not expected to affect overall stability of populations or resources. The magnitude of impacts, however, would depend on site-specific thermal plume characteristics and the nature of aquatic resources in the area.

4.6.2.2 Requirement [10 CFR 51.53(c)(3)(ii)(B)]

If the applicant's plant utilizes once-through cooling or cooling pond heat dissipation systems, the applicant shall provide a copy of a 316(a) variance in accordance with 40 CFR Part 125, or equivalent state permits and supporting documentation. If the applicant cannot provide these documents, it shall assess the impact of the proposed action on fish and shellfish resources resulting from thermal changes

4.6.2.3 Background [GEIS Section 4.6.1.2]

Because characteristics of both the thermal discharges and the affected aquatic resources are specific to each site, NRC classified heat shock as a Category 2 issue that required a site-specific assessment for license renewal. The NRC found the potential for thermal discharge impacts to be greatest at plants with once-through cooling systems, primarily because of the higher discharge temperatures and larger thermal plume area compared to plants with cooling towers.

The impact level at any plant depends on the characteristics of its cooling system (including location and type of discharge structure, discharge velocity and volume, and three-dimensional characteristics of the thermal plume) and characteristics of the affected aquatic resources (including the species present and their physiology, habitat, population distribution, status, management objectives, and life history).

4.6.2.4 Analysis

PTN discharges to the CCS, which is not classified as waters of the U.S. by the EPA and is therefore not subject to CWA jurisdiction, and not subject to 316(a) regulations.

However, site conditions of certification require temperature monitoring in the canals and Biscayne Bay. The Fifth Supplemental Agreement requires monitoring of temperature in the canal system and adjacent surface and groundwater and ecological impacts from the canals. This information is reported annually, per the conditions of the Fifth Supplemental Agreement. (SFWMD 2009)

The 2002 LRA for PTN determined that use of the CCS would not result in thermal impacts to adjacent Waters of the U.S., including Biscayne Bay and Card Sound (NRC 2002a). However, the PTN uprate was anticipated to result in a temperature increase in the CCS. The Fifth Supplemental Agreement, authorizing the uprate, mandates temperature monitoring in the CCS and the adjacent Card Sound and Biscayne Bay, to ensure that there are no thermal impacts to waters of the U.S. A minimum of 2 years of monitoring was required prior to the uprate (SFWMD 2009). Pre-uprate monitoring data were collected prior to February 26, 2012; interim operating data were collected between February 26, 2012, and May 27, 2013; and post-uprate monitoring began after May 27, 2013.

Post-uprate monitoring did detect an increase in temperature in the CCS. The post-uprate temperatures near the plant discharge into the CCS and near the plant intake were 4.5ºC and 3.2ºC warmer, respectively, than the pre-uprate period. While pre- and post-uprate averages may not be directly comparable because they do not cover the same number of months, the post-uprate water temperatures were consistently warmer. The increase in CCS surface water temperatures during the post-uprate period cannot be explained by the uprate, because the total heat rejection rate to the CCS from Turkey Point Units 1, 2, 3, and 4, operating at full capacity prior to the uprate monitoring period, would have been higher than the post-uprate heat rejection rate to the CCS for Units 1, 3, and 4 operating at full capacity. Unit 2 was dedicated to operate in a synchronous condenser mode (i.e., not producing steam heat) in the beginning of 2011, thereby requiring no heat rejection from the CCS. FPL's observations have concluded that the temporal increase in average CCS temperature in 2014 (during the post-uprate monitoring period) was the result of a series of events that degraded CCS water quality and negatively affected the heat exchange capacity of the CCS, including the following: lower than average precipitation into the CCS during 2011 through early 2014; reduced circulation within the CCS; periods of degraded water quality in the CCS during 2012 and 2013 (increased salinity, turbidity, and algal concentration); and decreased CCS heat exchange efficiency from historical levels in 2013 and 2014, likely due to significant blockages and increased sediment levels principally in the northern segments of the CCS.

There continue to be no discernable effects of the CCS on Biscayne Bay surface water quality at monitoring stations located out in the bay. For most surface water stations around the CCS, there was no readily apparent change in the influence of CCS water via the groundwater pathway during the post-uprate period, as compared to the pre-uprate data. There were two locations in the surface water canal stations immediately adjacent to the southern end of the CCS (TPSWC-4, located in the S-20 Canal, and TPSWC-5, located in the Card Sound Canal) where there appeared to be some CCS water present/influence during the pre- and post-uprate monitoring periods. Regardless, water quality and tritium data collected during the pre- and post-uprate monitoring period at TPBBSW-4, located at the mouth of the S-20 Canal and Card Sound Canal in Biscayne Bay, did not show evidence of CCS water. This indicates influence immediately adjacent to the CCS but minimal, if any, influence in Biscayne Bay.

In conclusion, while temperature has increased in the CCS, this aquatic feature is not a water of the U.S. and is not subject to CWA 316(a) regulations. Ongoing field studies indicate that thermal dynamics in the CCS do not influence Biscayne Bay or Card Sound, and therefore, impacts are anticipated to be SMALL, and mitigation measures are not warranted.

4.6.3 Water Use Conflicts with Aquatic Resources (Plants with Cooling Ponds or Cooling Towers Using Makeup Water from a River)

4.6.3.1 Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

SMALL or MODERATE. Impacts on aquatic resources in stream communities affected by water use conflicts could be of moderate significance in some situations.

4.6.3.2 Requirement [10 CFR 51.53(c)(3)(ii)(A)]

If the applicant's plant utilizes cooling towers or cooling ponds and withdraws makeup water from a river, an assessment of the impact of the proposed action on water availability and competing water demands, the flow of the river, and related impacts on stream (aquatic) ecological communities must be provided.

4.6.3.3 Background [GEIS Section 4.6.1.2]

Increased temperatures and/or decreased rainfall would result in lower river flows, increased cooling pond evaporation, and lowered water levels in the Great Lakes or reservoirs. Regardless of overall climate change, droughts could result in problems with water supplies and allocations.

Because future agricultural, municipal, and industrial users would continue to share their demands for surface water with power plants, conflicts might arise if the availability of this resource decreased.

Water use conflicts with aquatic resources could occur when water to support these resources is diminished either because of decreased water availability due to droughts; increased demand for agricultural, municipal, or industrial usage; or due to a combination of such factors. Water use conflicts with biological resources in stream communities are a concern due to the duration of license renewal and potentially increasing demands on surface water.

4.6.3.4 Analysis

As discussed in Sections 2.2.3.2, 4.5.1.4, and 4.5.2.4, PTN does not obtain makeup water from a river. Therefore, this issue is not applicable, and further analysis is not required.

4.6.4 Water Use Conflicts with Terrestrial Resources (Plants with Cooling Ponds or Cooling Towers Using Makeup Water from a River)

4.6.4.1 Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

SMALL or MODERATE. Impacts on terrestrial resources in riparian communities affected by water use conflicts could be of moderate significance.

4.6.4.2 Requirement [10 CFR 51.53(c)(3)(ii)(A)]

If the applicant's plant utilizes cooling towers or cooling ponds and withdraws makeup water from a river, an assessment of the impact of the proposed action on water availability and competing water demands, the flow of the river, and related impacts on . . . riparian (terrestrial) ecological communities must be provided.

4.6.4.3 Background [GEIS Section 4.6.1.1]

Water use conflicts with terrestrial resources in riparian communities could occur when water that supports these resources is diminished either because of decreased availability due to droughts; increased water demand for agricultural, municipal, or industrial usage; or a combination of such factors. For future license renewals, the potential range of impact levels at plants with cooling ponds or cooling towers using makeup water from a river cannot be determined at this time.

4.6.4.4 Analysis

As discussed in Sections 2.2.3.2, 4.5.1.4, and 4.5.2.4, PTN does not obtain makeup water from a river. Therefore, this issue is not applicable, and further analysis is not required.

4.6.5 Effects on Terrestrial Resources (Non-Cooling System Impacts)

4.6.5.1 Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

SMALL, MODERATE, or LARGE. Impacts resulting from continued operations and refurbishment associated with license renewal may affect terrestrial communities. Application of BMPs would reduce the potential for impacts. The magnitude of impacts would depend on the nature of the activity, the status of the resources that could be affected, and the effectiveness of mitigation.

4.6.5.2 Requirement [10 CFR 51.53(c)(3)(ii)(E)]

All license renewal applicants shall assess the impact of refurbishment, continued operations, and other license-renewal-related construction activities on important plant and animal habitats.

4.6.5.3 Background [GEIS Section 4.6.1.1]

Continued operations and refurbishment activities could continue to affect onsite terrestrial resources during the license renewal term at all operating nuclear power plants. Factors that could potentially result in impacts include landscape maintenance activities, stormwater management, and elevated noise levels. These impacts would, for the most part, be similar to past and ongoing impacts.

The characteristics of terrestrial habitats and wildlife communities currently on nuclear power plant sites have generally developed in response to many years of typical operations and maintenance programs. While some may have reached a relatively stable condition, some habitats and populations of some species may have continued to change gradually over time. Operations and maintenance activities during the license renewal term are expected to be similar to current activities. Because the species and habitats present on the sites (i.e., weedy species and habitats they make up) are generally tolerant of disturbance, it is expected that continued operations during the license renewal term would maintain these habitats and wildlife communities in their current state, or maintain current trends of change.

Terrestrial habitats and wildlife could be affected by ground disturbance from refurbishment-related construction activities. Land disturbed during the construction of new ISFSIs would range from about 2.5 to 10 ac (1 to 4 ha). Other activities may include new parking areas for plant employees, access roads, buildings, and facilities. Temporary project support areas for equipment storage, worker parking, and material laydown areas could also result in the disturbance of habitat and wildlife.

Successful application of environmental review procedures, employed by the licensees at many of the operating nuclear plant sites, would result in the identification and avoidance of important terrestrial habitats. In addition, the application of BMPs to minimize the area affected; to control fugitive dust, runoff, and erosion from project sites; to reduce the spread of invasive nonnative plant species; and to reduce disturbance of wildlife in adjacent habitats could greatly reduce the impacts of continued operations and refurbishment activities.

4.6.5.4 Analysis

Refurbishment Activities

As discussed in Section 2.3, no license renewal-related refurbishment activities have been identified. Therefore, there would be no license renewal-related refurbishment impacts to important plant and animal habitats, and no further analysis is required.

Operational Activities

Terrestrial resources are described in Section 3.7.2. No license renewal-related construction activities or changes in operational practices have been identified that would involve disturbing habitats. FPL would continue to conduct ongoing plant operational and maintenance activities during the SLR period. However, these activities are expected to have minimal impacts on terrestrial resources because activities are anticipated to occur within previously disturbed habitats.

Operational and maintenance activities that FPL might undertake during the SLR term, such as maintenance and repair of plant infrastructure (e.g., roadways, piping installations, fencing, and other security infrastructure), would likely be confined to previously disturbed areas of the site. Furthermore, as discussed in Section 9.6, FPL has administrative controls in place at Turkey Point to ensure that operational changes or construction activities are reviewed, and the impacts minimized through implementation of BMPs, permit modifications, or acquisition of new permits as needed. In addition, regulatory programs that the site is currently subject to such as stormwater management, spill prevention, dredging, and herbicide usage further serve to minimize impacts to terrestrial resources.

In summary, adequate management programs and regulatory controls are in place to ensure that important plant and animal habitats are protected during the SLR period.

Therefore, FPL concludes the impacts to the terrestrial ecosystems from SLR are SMALL, and no additional mitigation measures beyond current management programs and existing regulatory controls are required.

4.6.6 Threatened, Endangered, and Protected Species, and Essential Fish Habitat

4.6.6.1 Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

The magnitude of impacts on threatened, endangered, and protected species, critical habitat, and EFH would depend on the occurrence of listed species and habitats and the effects of power plant systems on them. Consultation with appropriate agencies would be needed to determine whether special status species or habitats are present and whether they would be adversely affected by continued operations and refurbishment associated with license renewal.

4.6.6.2 Requirement [10 CFR 51.53(c)(3)(ii)(E)]

All license renewal applicants shall assess the impact of refurbishment, continued operations, and other license renewal-related construction activities on important plant and animal habitats. Additionally, the applicant shall assess the impact of the proposed action on threatened or endangered species in accordance with federal laws protecting wildlife, including but not limited to, the ESA, and EFH in accordance with the MSA.

4.6.6.3 Background [GEIS Section 4.6.1.3]

There are several federal acts that provide protection to certain species and habitats that are treated here under a single issue. The issue includes impacts to biological resources such as threatened and endangered species and their critical habitat under the ESA, EFH as protected under the MSA, and impacts to mammalian species protected under the Marine Mammal Protection Act.

Factors that could potentially result in impacts on listed terrestrial species include habitat disturbance . . . operation and maintenance of cooling systems, transmission line ROW maintenance, collisions with . . . and transmission lines, and exposure to radionuclides. The listed species on or in the vicinity of nuclear power plants also range widely, depending on numerous factors such as the plant location and habitat types present.

Potential impacts of continued operations and refurbishment activities on federally or state-listed threatened and endangered species, protected marine mammals, and EFH could occur during the license renewal term. Factors that could potentially result in impacts to these species and habitats include impacts of refurbishment, other ground-disturbing activities, release of contaminants, effects of cooling water discharge on dissolved oxygen, gas supersaturation, eutrophication, thermal discharges, entrainment, impingement, reduction in water levels due to the cooling system operations, dredging, radionuclides, and transmission line ROW maintenance.

4.6.6.4 Analysis

Refurbishment Activities

As discussed in Section 2.3, no license renewal-related refurbishment activities have been identified. Therefore, there would be no license renewal-related refurbishment impacts to threatened, endangered, and protected species, or EFH, and no further analysis is required.

Operational Activities

As discussed in Section 3.7.8.1, there are 52 federally listed species which are either threatened, endangered, or candidate species within Miami-Dade County. In addition, as discussed in Section 3.7.8.2, the FFWCC has designated 118 plant and animal species as state-listed threatened or endangered, in addition to those that are also listed as endangered or threatened under the federal ESA.

Federally Listed Species

As discussed in Section 3.7.8.1, of the 52 federally listed species, 21 are plant species. No clearing activities are anticipated to occur as the result of continued operations of PTN. Therefore, impacts to federally listed plant species will not be considered further. Further, PTN does not discharge cooling water to Biscayne Bay, Card Sound, or other waters of the U.S. Therefore, the 10 federally listed species inhabiting these waters, including shortnose sturgeon (*Acipenser brevirostrum*), Atlantic sturgeon (*Acipenser oxyrhynchus oxyrhynchus*), Nassau grouper (*Epinephelus striatus*), smalltooth sawfish (*Pristis pectinate*), loggerhead sea turtle (*Caretta caretta*), green sea turtle (*Chelonia mydas*), leatherback sea turtle (*Dermochelys coriacea*), hawksbill sea turtle (*Eretmochelys imbricate*), Kemp's ridley sea turtle (*Lepidochlys kempii*), and the Florida manatee (*Trichechus manatu*), are excluded from analysis. While federally listed as occurring in Miami-Dade County, habitat associations for 11 species are so restricted, or species occurrences are so rare, that these species are unlikely to occur on the Turkey Point property. These species are Florida leafwing (*Anaea troglodyta floridalis*), Miami tiger beetle (*Cicindelidia floridana*), Miami blue butterfly (*Cyclargus thomasi bethunebakeri*), Schaus' swallowtail (*Papilio aristodemus ponceanus*), Bartram's scrub-hairstreak (*Strymon acis bartrami*), Stock Island tree snail (*Orthalicus reses reses*), gopher tortoise (*Gopherus Polyphemus*), Cape Sable seaside sparrow (*Ammodramus maritimus mirabilis*), Audubon's crested caracara (*Polyborus plancus audubonii*), Kirtland's warbler (*Setophaga kirtlandi*), and Bachman's warbler (*Vermivora bachmani*). These species are not included in this analysis based on the low likelihood of occurrence on the Turkey Point property.

Habitat for nine federally listed species may occur on or adjacent to the Turkey Point property: American alligator (*Alligator mississippiensis*), American crocodile (*Crocodylus acutus*), eastern indigo snake (*Drymarchon corais couperi*), rufa red knot (*Calidris canutus*), piping plover (*Charadrius melodus*), wood stork (*Mycteria americana*), snail kite (*Rostrhamus sociabili*), Florida bonneted bat (*Eumops floridanus*), and Florida panther (*Puma concolor coryi*).

As a requirement of the SCA and Fifth Supplemental Agreement, crocodiles on the site are monitored under FPL's crocodile management plan, which is focused on the creation of an environment and the enhancement of crocodile nesting habitat as well as the monitoring the reproductive success, growth, and survival of hatchlings. PTN is one of three nesting locations in Florida. While the number of successful nests located at the site has decreased in recent years, the American crocodile population continues to remain in a much stronger position than before the Turkey Point CCS was established. Today, crocodiles continue to migrate in and out of the

CCS and call the system home. Despite the environmental changes taking place within the CCS, in 2016 the American crocodiles had eight successful nests, and 127 hatchlings were released at Turkey Point outside of the CCS. Therefore, operation of PTN has positively affected this species. No increase in traffic volume is anticipated to result from the continued operation of PTN, and continued operation of PTN will not result in a loss of habitat. This species is therefore not likely to be adversely affected by continued operation of PTN.

American alligators have the potential to occur on the Turkey Point site. However, while alligators are tolerant to low salinity levels, they are typically more prevalent in fresh and brackish water with salinity levels less than 35 ppt (Fujisaki et al. 2014). Salinity concentrations in the CCS are approximately twice that of Biscayne Bay. (FPL 2014a, Section 2.3.3.1.2) and, therefore, likely too high for the canals to be considered suitable habitat for alligators. Therefore, occurrences of American alligators on the Turkey Point property are unlikely, and the continued operation of PTN is unlikely to affect this species.

Eastern indigo snakes rely on a matrix of habitats to survive, and movement among habitats that contain roads increases the potential for vehicle collision mortality. Snakes in general are prone to collision mortality, because they use road surfaces for thermoregulation and their shape, coloration, and low profile make them difficult for automobile drivers to see. However, increased automobile traffic is not anticipated to occur as a result of continued operation of PTN; therefore, the likelihood of mortality resulting from vehicle collisions is low. (NRC 2016a, Section 5.3.1.3) Continued operation of PTN will not result in a loss of habitat. This species is therefore not likely to be adversely affected by continued operation of PTN.

Piping plovers and red knots are shorebirds that use open habitats, such as beaches and mudflats, during winter in southern Florida. Both are small birds not known to be exceptionally prone to collision mortality, so the likelihood of collision with tall structures associated with PTN is expected to be minimal, as is collision with vehicles. (NRC 2016a, Section 5.3.1.3) Collisions with in-scope transmission lines are not anticipated because in-scope transmission lines are located in areas with no ecological value to these species. Continued operation of PTN will not result in a loss of habitat. This species is therefore not likely to be adversely affected by continued operation of PTN.

Wood storks occur in a variety of wetlands and have been observed foraging in shallow portions of the CCS. Water within the system is hypersaline, and the prey wood storks consume are adapted to this environment. However, wood storks have not been observed in great numbers within the CCS, and it is not believed to be a major foraging area. Although juvenile wood storks are not particularly adept at flying, the likelihood of avian collision with tall structures is expected to be minimal. Collisions with in-scope transmission lines are not anticipated because in-scope transmission lines are located in areas with no ecological value to these species. Continued operation of PTN will not result in a loss of habitat. Therefore, the continued operation of PTN is not expected to noticeably affect the wood stork population growth in the region. (NRC 2016a, Section 5.3.1.3)

As discussed in Section 3.7.8.1, migratory movements or local flight patterns may result in the occurrence of the snail kite on the site. Habitat for this species may be located on portions of the Turkey Point site. However, activities on the Turkey Point site are conducted within compliance standards of the MBTA. When necessary, consultation with responsible agencies is conducted to maintain compliance with existing regulations. Compliance with all regulatory requirements associated with this species will continue to be an administrative control practiced by FPL for the life of the PTN facility. Adherence to these controls, as well as compliance with laws and regulations, will prevent impacts to this species. Collisions with in-scope transmission lines are not anticipated because in-scope transmission lines are located in areas with no ecological value to these species. Continued operation of PTN will not result in a loss of habitat. The continued operation of PTN is not likely to adversely affect this species.

The Florida bonneted bat may be present on the Turkey Point property. The Turkey Point site does not contain cavity-bearing, mature trees, or other man-made structures that would provide roosting habitat for the bat. FPL's compliance with federal, state, and local laws and regulations will prevent impacts to this species. Continued operation of the PTN facility is not likely to affect this species.

The USFWS recognizes much of Miami-Dade County and southern Florida as a Florida panther focus area. Although the focus area excludes the Turkey Point site, lands immediately adjacent the Turkey Point site to the south and west are contained within the focus area and are also considered to be within the panther's primary zone. Florida panthers are susceptible to vehicle collisions; one in five deaths of or major injuries to radio-collared panthers resulted from a collision with a vehicle. However, no increase in traffic volume is anticipated to result from the continued operation of PTN. Therefore, an increased risk of collision with this species is not anticipated. Continued operation of PTN will not result in a loss of habitat. (NRC 2016a, Section 5.3.1.3) The continued operation of PTN is not likely to adversely affect this species.

State-Listed Species

A total of 104 plant species are listed by the State of Florida as occurring in Miami-Dade County (Table 3.7-15). Many occur in habitats not found on the Turkey Point site. Some of these plants, such as Small's flax (*Linum carteri var. smallii*) and the Bahama ladder brake (*Pteris bahamaensis*) are known to occur in disturbed habitat, and the banded wild-pine (*Tillandsia flexuosa*) is an epiphyte that grows on a variety of other plants that occur in a wide range of habitats. The range of habitats the state-listed plants represent indicates that some of the species could occur within the plant area on the Turkey Point site, but the extent of their occurrence is undetermined. However, because continued operation of PTN do not involve clearing activities, state-listed plant species on the Turkey Point property are not likely to be impacted by continued operation of PTN (NRC 2016a, Section 5.3.1.3).

As discussed in Section 3.7.8.2, suitable habitat for a total of 10 state-listed species is likely to occur on the Turkey Point property. The following species are likely to occur on the Turkey Point property: Florida burrowing owl (*Athene cunicularia floridana*), little blue heron (*Egretta caerulea*), reddish egret (*Egretta rufescens*), tricolored heron (*Egretta tricolor*), southeastern American kestrel (*Falco sparverius paulus*), American oystercatcher (*Haematopus palliatus*), white-crowned pigeon (*Patagioenas leucocephala*), roseate spoonbill (*Platalea ajaja*), black skimmer (*Rynchops niger*), least tern (*Sternula antillarum*), southern mink, Southern Florida Pop (*Neovison vison* pop. 1).

One Florida burrowing owl was observed in 2010 within the Turkey Point site CCS. Florida burrowing owls are found in open upland habitat and cleared areas. Although berms among the canals of the CCS could be considered to be potential habitat because they are mostly non-vegetated and the deposition of fill raised them to upland elevations, the occurrence of a single burrowing owl does not necessarily indicate habitat suitable for Florida burrowing owls is present within the CCS. If these berms were, in fact, suitable for burrowing owls, one would expect more than a single observation. Therefore, continued operation of PTN is unlikely to affect this species, because occurrences of this species are rare. (NRC 2016a, Section 5.3.1.3)

Little blue heron, reddish egret, tricolored heron, and roseate spoonbill are all piscivorous wading birds. They all have been observed on the Turkey Point site in shallow wetland habitats. Operational noise may displace some individuals, but their occurrence within suitable habitats despite the current operation of existing plants indicates most adapt to increased noise, activity, and artificial light levels. Continued operation of PTN is not expected to affect populations of these species. (NRC 2016a, Section 5.3.1.3)

The American oystercatcher occurs on large open expanses and forages in shellfish beds. No known shellfish beds would be affected by the continued operation of PTN. Other operational effects, including noise and artificial lighting, are not expected to affect American oystercatchers. (NRC 2016a, Section 5.3.1.3)

As discussed in Section 3.7.8.2, migratory movements or local flight patterns may result in the occurrence of the southeastern American kestrel to the site. Habitat for this species may be located on portions of the Turkey Point site. However, activities on the Turkey Point site are evaluated to ensure compliance under the MBTA. When necessary, consultation with responsible agencies is conducted to maintain compliance with existing regulations. Compliance with all regulatory requirements associated with this species will continue to be an administrative control practiced by FPL for the life of the Turkey Point facility. Adherence to these controls, as well as compliance with laws and regulations, will prevent impacts to this species. The continued operation of PTN is not likely to impact this species.

White-crowned pigeons forage on fruit-bearing trees, especially poisonwood (*Metopium toxiferum*), located north and west of the CCS. Operational noise may displace some individuals, but their occurrence within suitable habitats despite the operation of existing plants indicates most adapt to increased noise, activity, and artificial light levels. Continued operation of PTN is not expected to affect populations of these species. (NRC 2016a, Section 5.3.1.3)

Black skimmers and least terns forage over open water. Least terns have been observed on the Turkey Point site, and dredge spoil may provide suitable nesting habitat for both species. Operational noise may displace skimmers and terns from dredge spoil within the CCS. (NRC 2016a, Section 5.3.1.3)

The Everglades mink may potentially use wetlands within the Turkey Point site. Little is known about the Everglades mink but, as with other species, operational noise may deter mink from using parts of the site nearby the facilities. Mink are primarily active at night. The effects of artificial lighting on mink are not known (NRC 2016a, Section 5.3.1.3). However, the effects of continued operation of PTN does not include refurbishment activities and, therefore, would not alter availability or suitability of wetland habitats for the Everglades mink.

FPL is not aware of any adverse impacts regarding threatened, endangered, and protected species attributable to the site. Maintenance activities necessary to support SLR likely would be limited to previously disturbed areas on site, and no additional land disturbance has been identified for the purpose of SLR. In addition, there are no plans to alter plant operations during the SLR term which would affect threatened, endangered, and protected species. FPL would be required to comply with all applicable federal, state, and local laws, regulations, and permitting requirements to minimize potential impacts on listed species. If operational impacts on state-listed wildlife cannot be avoided, FPL would be required to coordinate with the USFWS and the FFWCC on the need for appropriate mitigation.

As discussed in Section 9.6, FPL has administrative controls in place at Turkey Point to ensure that operational changes or construction activities are reviewed, and the impacts minimized through implementation of BMPs. In addition, regulatory programs, such as those discussed in Chapter 9 that the site is subject to further serve to minimize impacts to any threatened, endangered, and protected species.

In an effort to obtain an independent review, the USFWS and NMFS were also consulted. Based on this independent review, it was determined that there would be no effect on federally and state-listed threatened, endangered, and protected species or on designated critical habitat as a result of PTN SLR. In addition, NMFS concluded no designated EFH would be impacted by continued operation of PTN. Copies of the consultation letters to the USFWS and NMFS are included in Attachment B.

In summary, no license renewal-related refurbishment activities have been identified. As discussed above, the continued operation of PTN would have no adverse effect on any federally or state-listed species. Therefore, FPL concludes that SLR would have no effect on threatened, endangered, and protected species in the vicinity of Turkey Point, and mitigation measures beyond FPL current management programs and existing regulatory controls are not warranted.

4.7 Historic and Cultural Resources

The following sections address the historic and cultural resource issues applicable to PTN, providing background on the issues and the analyses regarding the SLR period.

4.7.1 Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

Continued operations and refurbishment associated with license renewal are expected to have no more than small impacts on historic and cultural resources located onsite and in the transmission line ROW because most impacts could be mitigated by avoiding those resources. The NHPA requires the federal agency to consult with the SHPO and appropriate Native American tribes to determine the potential effects on historic properties and mitigation, if necessary.

4.7.2 Requirement [10 CFR 51.53(c)(3)(ii)(K)]

All applicants shall identify any potentially affected historic or archaeological properties and assess whether any of these properties will be affected by future plant operations and any planned refurbishment activities in accordance with the NHPA.

4.7.3 Background [GEIS Section 4.7.1]

The NRC will identify historic and cultural resources within a defined APE. The license renewal APE is the area that may be impacted by land-disturbing or other operational activities associated with continued plant operations and maintenance during the license renewal term and/or refurbishment. The APE typically encompasses the nuclear power plant site, its immediate environs, including viewshed, and the transmission lines within this scope of review. The APE may extend beyond the nuclear plant site and transmission lines when these activities may affect historic and cultural resources.

Continued operations during the license renewal term and refurbishment activities at a nuclear power plant can affect historic and cultural resources through (1) ground-disturbing activities associated with plant operations and ongoing maintenance (e.g., construction of new parking lots or buildings), landscaping, agricultural or other use of plant property; (2) activities associated with transmission line maintenance (e.g., maintenance of access roads or removal of danger trees); and (3) changes to the appearance of nuclear power plants and transmission lines. Licensee renewal environmental reviews have shown that the appearance of nuclear power plants and transmission lines has not changed significantly over time; therefore additional viewshed impacts to historic and cultural resources are not anticipated.

4.7.4 Analysis

4.7.4.1 Refurbishment Activities

As discussed in Section 2.3, no license renewal-related refurbishment activities have been identified. Therefore, there would be no license renewal-related refurbishment impacts to historic and cultural resources, and no further analysis is required.

4.7.4.2 Operational Activities

As discussed in Section 3.7.2.2, Turkey Point property contains 7,996 acres of wetland, lake, and riverine waters (approximately 85 percent of the Turkey Point property). As discussed in Section 3.8.5, there have been seven previous cultural resource investigations conducted on the Turkey Point property. There are no recorded cultural resources on the 9,460-acre Turkey Point property, and there are no NRHP-listed resources within a 6-mile radius of Turkey Point.

As discussed in Section 3.8.6, although no license renewal-related ground-disturbing activities have been identified, FPL has administrative controls in place for management of cultural resources ahead of any future ground-disturbing activities at the plant. These consist of the 2016 conditions of certification and the Environmental Control Program for PTN. Therefore, no adverse effects are anticipated during the SLR term.

The area within a 2-mile radius of the site, especially along Biscayne Bay, may be archaeologically sensitive based on the location of archaeological sites in areas that have been surveyed for cultural resources (Table 3.8-1). However, adverse impacts would only occur to such sites as a result of soil-intrusive activities. Because FPL has no plans to conduct such soil-intrusive activities at any location outside of the Turkey Point property boundary under an SLR, no adverse effects to these archaeological sites would occur.

There are also no NRHP-listed aboveground historic properties within a 6-mile radius of PTN. As such, no potential adverse effects to any NRHP-listed properties, including viewshed, aesthetic, and noise impacts, as a result of the continued operation of PTN are expected. Two sites (Table 3.8-2) are eligible for the NRHP based on SHPO review, but based on the vegetation, topography, and distance, Turkey Point is not within the viewshed of these cultural resources. Due to no refurbishment activities being associated with the SLR, including construction and ground disturbances, no adverse effects to the NRHP-eligible resources are expected.

As discussed above, no license renewal-related refurbishment or construction activities have been identified. No offsite NRHP-listed historic properties will be adversely impacted as a result of continued operation of PTN, and there are no plans to alter operations, expand existing facilities, or disturb additional land for the purpose of SLR. As described in Section 3.8, the Florida SHPO/DHR, and Native American groups recognized as potential stakeholders, have been notified by FPL of the proposed action (Attachment C).

Therefore, FPL concludes that there will be no adverse effects as a result of continued operation of PTN during the SLR period, and additional mitigation measures beyond FPL's existing procedural administrative controls are not warranted.

4.8 Socioeconomics

The following sections address the socioeconomic issues applicable to PTN, providing background on the issues and the analyses regarding the SLR period.

4.8.1 Employment and Income, Recreation and Tourism

4.8.1.1 Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

SMALL. Although most nuclear plants have large numbers of employees with higher than average wages and salaries, employment, income, recreation, and tourism impacts from continued operations and refurbishment associated with license renewal are expected to be small.

4.8.1.2 Requirement [10 CFR 51.53(c)(3)(iv)]

The ER must contain any new and significant information regarding the environmental impacts of license renewal of which the applicant is aware.

4.8.1.3 Background [GEIS Section 4.8.1.1]

Employees receive income from the nuclear power plant in the form of wages, salaries, and benefits. Employees and their families, in turn, spend this income on goods and services within the community thereby creating additional opportunities for employment and income. In addition, people and businesses in the community receive income for the goods and services sold to the power plant. Payments for these goods and services create additional employment and income opportunities in the community. The measure of a communities' ability to support the operational demands of a power plant depends on the ability of the community to respond to changing socioeconomic conditions.

Some communities experience seasonal transient population growth due to local tourism and recreational activities. Income from tourism and recreational activities creates employment and income opportunities in the communities around nuclear power plants.

Nevertheless, the effects of nuclear power plant operations on employment, income, recreation, and tourism are ongoing and have become well established during the current license term for all nuclear power plants. The impacts from power plant operations during the license renewal term on employment and income in the region around each nuclear power plant are not expected to change from what is currently being experienced. In addition, tourism and recreational activities in the vicinity of nuclear plants are not expected to change as a result of license renewal.

4.8.1.4 Analysis

Information related to employment and income, and recreational facilities is presented in Sections 3.9.1 and 3.9.7. No license renewal-related refurbishment activities have been identified as discussed in Section 2.3. In addition, as discussed in Section 2.5, there are no plans to add workers to support plant operations during the SLR period. As previously discussed in Section 3.2.3, there is sufficient vegetation and distance to screen the existing units from most areas. As a result, the site does not visually impact most local areas that have a high degree of visitor or recreational use. Therefore, no changes in employment and income, and recreation and tourism during the SLR period are anticipated.

In the GEIS, the NRC determined that employment and income, and recreation and tourism impacts from continued plant operations over the license renewal term would be SMALL for all nuclear plants, and designated this as a Category 1 issue (NRC 2013a, Section 4.8.1.1). Based on FPL's review, no new and significant information was identified as it relates to employment and income, and recreation and tourism, and further analysis is not required.

4.8.2 Tax Revenues

4.8.2.1 Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

SMALL. Nuclear plants provide tax revenue to local jurisdictions in the form of property tax payments, payments in lieu of tax (PILOT), or tax payments on energy production. The amount of tax revenue paid during the license renewal term as a result of continued operations and refurbishment associated with license renewal is not expected to change.

4.8.2.2 Requirement [10 CFR 51.53(c)(3)(iv)]

The ER must contain any new and significant information regarding the environmental impacts of license renewal of which the applicant is aware.

4.8.2.3 Background [GEIS Section 4.8.1.2]

Nuclear power plants and the workers who operate them are an important source of tax revenue for many local governments and public school systems. Tax revenues from nuclear power plants mostly come from property tax payments or other forms of payments such as payments in lieu of (property) taxes, or PILOT payments, although taxes on energy production have also been collected from a number of nuclear power plants. County and municipal governments and public school districts receive tax revenue either directly or indirectly through state tax and revenue-sharing programs.

Counties and municipal governments in the vicinity of a nuclear power plant also receive tax revenue from sales taxes and fees from the power plant and its employees. Changes in the number of workers and the amount of taxes paid to county, municipal governments, and public schools can affect socioeconomic conditions in the counties and communities around the nuclear power plant.

A review of LRAs received by the NRC since the 1996 GEIS has shown that refurbishment activities, such as steam generator and vessel head replacement, have not had a noticeable effect on the assessed value of nuclear plants, thus changes in tax revenues are not anticipated from future refurbishment activities.

The primary impact of license renewal would be the continuation or change in the amount of taxes paid by nuclear power plant owners to local governments and public school systems. The impact of nuclear plant operations on tax revenues in local communities and the impact that the expenditure of tax revenues has on the region are not expected to change appreciably from the amount of taxes paid during the current license term. Tax payments during the license renewal term would be similar to those currently being paid by each nuclear plant.

4.8.2.4 Analysis

Information related to tax revenues is presented in Section 3.9.5. No license renewal-related refurbishment activities have been identified as discussed in Section 2.3. FPL's annual property taxes are expected to remain relatively constant through the SLR period.

In the GEIS, the NRC determined that tax revenue impacts from continued plant operations over the license renewal term would be SMALL for all nuclear plants, and designated this as a Category 1 issue (NRC 2013a, Section 4.8.1.2). Based on FPL's review, no new and significant information was identified as it relates to tax revenues, and further analysis is not required.

4.8.3 Community Services and Education

4.8.3.1 Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

SMALL. Changes resulting from continued operations and refurbishment associated with license renewal to local community and educational services would be small. With little or no change in employment at the licensee's plant, value of the power plant, payments on energy production, and PILOT payments expected during the license renewal term, community and educational services would not be affected by continued power plant operations.

4.8.3.2 Requirement [10 CFR 51.53(c)(3)(iv)]

The ER must contain any new and significant information regarding the environmental impacts of license renewal of which the applicant is aware.

4.8.3.3 Background [GEIS Section 4.8.1.3]

Any changes in the number of workers at a nuclear plant will affect the demand for public services from local communities. Environmental reviews conducted by NRC since the 1996 GEIS have shown, however, that the number of workers at relicensed nuclear plants has not changed significantly because of license renewal, so demand-related impacts on community services, including public utilities, are no longer anticipated from future license renewals.

In addition, refurbishment activities, such as steam generator and vessel head replacement, have not required the large numbers of workers and the months of time that were conservatively analyzed in the 1996 GEIS, so significant impacts on community services are no longer anticipated. Because of the relatively short duration of refurbishment-related activities, workers are not expected to bring families and school-age children with them; therefore, impacts from refurbishment on educational services are also no longer anticipated.

Taxes paid by nuclear power plant owners support a range of community services, including public water, safety, fire protection, health, and judicial, social, and educational services. In some communities, tax revenues from power plants can have a noticeable impact on the quality of services available to local residents. Although many of the community services paid for by tax revenues from power plants are used by plant workers and their families, the impact of nuclear plant operations on the availability and quality of community services and education is SMALL and is not expected to change as a result of license renewal.

4.8.3.4 Analysis

Information related to community services and education is presented in Section 3.9.4. No license renewal-related refurbishment activities have been identified as discussed in Section 2.3. In addition, as discussed in Section 2.5, there are no plans to add workers to support plant operations during the SLR period. As discussed in Section 4.8.2.4, FPL's annual property taxes are expected to remain relatively constant through the SLR period.

In the GEIS, the NRC determined that community services and education impacts from continued plant operations over the license renewal term would be SMALL for all nuclear plants, and designated this as a Category 1 issue (NRC 2013a, Section 4.8.1.3). Based on FPL's review, no new and significant information was identified as it relates to community services and education, and further analysis is not required.

4.8.4 Population and Housing

4.8.4.1 Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

SMALL. Changes resulting from continued operations and refurbishment associated with license renewal to regional population and housing availability and value would be small. With little or no change in employment at the licensee's plant expected during the license renewal term, population and housing availability and values would not be affected by continued power plant operations.

4.8.4.2 Requirement [10 CFR 51.53(c)(3)(iv)]

The ER must contain any new and significant information regarding the environmental impacts of license renewal of which the applicant is aware.

4.8.4.3 Background [GEIS Section 4.8.1.4]

Socioeconomic impact analyses of resources (e.g., housing) affected by changes in regional population are based on employment trends at nuclear power plants. Population growth from increased employment and spending at a nuclear power plant is important because it is one of the main drivers of socioeconomic impacts. As previously discussed, however, employment levels at nuclear power plants are expected to remain relatively constant with little or no population growth or increased demand for permanent housing during the license renewal term. The operational effects on population and housing values and availability in the vicinity of nuclear power plants are not expected to change from what is currently being experienced, and no demand-related impacts are expected during the license renewal term.

The increased number of workers at nuclear power plants during regularly scheduled plant refueling and maintenance outages does create a short-term increase in the demand for temporary (rental) housing units in the region around each plant. However, because of the short duration and the repeated nature of these scheduled outages and the general availability of rental housing units (including portable trailers) in the vicinity of nuclear power plants, employment-related housing impacts have had little or no long-term impact on the price and availability of rental housing. Refurbishment impacts would be similar to what is experienced during routine plant refueling and maintenance outages.

4.8.4.4 Analysis

Information related to population and housing is presented in Section 3.9.2. No license renewal-related refurbishment activities have been identified as discussed in Section 2.3. In addition, as discussed in Section 2.5, there are no plans to add workers to support plant operations during the SLR period.

In the GEIS, the NRC determined that population and housing impacts from continued plant operations over the license renewal term would be SMALL for all nuclear plants, and designated this as a Category 1 issue (NRC 2013a, Section 4.8.1.4). Based on FPL's review, no new and significant information was identified as it relates to population and housing, and further analysis is not required.

4.8.5 Transportation

4.8.5.1 Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

SMALL. Changes resulting from continued operations and refurbishment associated with license renewal to traffic volumes would be small.

4.8.5.2 Requirement [10 CFR 51.53(c)(3)(iv)]

The ER must contain any new and significant information regarding the environmental impacts of license renewal of which the applicant is aware.

4.8.5.3 Background [GEIS Section 4.8.1.5]

Transportation impacts depend on the size of the workforce, the capacity of the local road network, traffic patterns, and the availability of alternate commuting routes to and from the plant. Because most sites have only a single access road, there is often congestion on these roads during shift changes.

Transportation impacts are ongoing and have become well established during the current licensing term for all nuclear power plants. As previously discussed, it is unlikely that the number of permanent operations workers would increase at a nuclear power plant during the license renewal term. In addition, refurbishment activities, such as steam generator and vessel head replacement, have not required the numbers of workers and the months of time conservatively estimated in the 1996 GEIS. Consequently, employment at nuclear power plants during the license renewal term is expected to remain unchanged.

4.8.5.4 Analysis

Information related to transportation is presented in Section 3.9.6. No license renewal-related refurbishment activities have been identified as discussed in Section 2.3. As discussed in Section 2.5, there are no plans to add workers to support plant operations during the SLR period. In addition, as discussed in Section 3.9.6, roads in the immediate vicinity of the Turkey Point plant site are anticipated to operate at acceptable levels.

In the GEIS, the NRC determined that transportation impacts from continued plant operations over the license renewal term would be SMALL for all nuclear plants, and designated this as a Category 1 issue (NRC 2013a, Section 4.8.1.5). Based on FPL's review, no new and significant information was identified as it relates to transportation, and further analysis is not required.

4.9 Human Health

The following sections address the human health issues applicable to PTN, providing background on the issues and the analyses regarding the SLR period.

4.9.1 Microbiological Hazards to the Public (Plants with Cooling Ponds or Canals, or Cooling Towers that Discharge to a River)

4.9.1.1 Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

SMALL, MODERATE, or LARGE. These organisms are not expected to be a problem at most operating plants except possibly at plants using cooling ponds, lakes, or canals, or that discharge into rivers. Impacts would depend on site-specific characteristics.

4.9.1.2 Requirement [10 CFR 51.53(c)(3)(ii)(G)]

If the applicant's plant uses a cooling pond, lake, or canal or discharges into a river, an assessment of the impact of the proposed action on public health from thermophilic organisms in the affected water must be provided.

4.9.1.3 Background [GEIS Section 4.9.1.1.3]

N. fowleri, which is the pathogenic strain of the free-living amoebae *Naegleria* spp., appears to be the most likely microorganism that may pose a public health hazard resulting from nuclear power plant operations. Increased populations of *N. fowleri* may have significant adverse impacts.

Because *Naegleria* concentrations in fresh water can be enhanced by thermal effluents, nuclear power plants that use cooling lakes, canals, ponds, or rivers experiencing low-flow conditions may enhance the populations of naturally occurring thermophilic organisms.

Changes in microbial populations and in the public use of water bodies might occur after the OL is issued and the application for license renewal is filed. Other factors could also change, including the average temperature of the water, which could result from climate change that affected water levels and air temperature. Finally, the long-term presence of a power plant might change the natural dynamics of harmful microorganisms within a body of water.

4.9.1.4 Analysis

As discussed in Section 3.10, PTN discharges to the cooling canals, which are owner-controlled and closed to the public. The cooling canals do not discharge to surface waters, and thus the heated water does not have a pathway to enhance the naturally occurring thermophilic organisms within surface water accessible to the public. Also, as discussed in Section 3.10, the salinity concentration of the cooling canals anticipated for the SLR term is an annual average of 34 PSU, which is similar to ocean water and exceeds the freshwater conditions needed for the pathogen, *N. fowleri,* survival. PTN discharges to a 168-mile closed-loop CCS that occupies approximately 5,900 acres. The CCS receives heated effluent from the plant and distributes the flow into 32 feeder canals. The feeder canals discharge into a single collector canal that distributes the water into six return canals. (FPL 2000b, Section 3.1.2) As discussed in

Section 2.2.3.2, the Turkey Point NPDES permit authorizes discharges from the CCS into Class G-III groundwater, which is part of the surficial aquifer system. The permit does not authorize direct discharges to surface waters of the state.

While the cooling canals are closed to the public, FPL workers and contractors do perform work within the canals and thus could be exposed to *N. fowleri* or Legionella spp. The infection route for *N. fowleri* is water or water droplets being introduced into the nasal cavity, and for Legionella spp. the infection route is through inhalation. As discussed in Section 3.10, there are no water sprayers associated with the cooling canals, and work within the canals would be conducted under an occupational safety program.

Given the lack of an exposure pathway between the cooling canals and the public, the non-freshwater condition of the cooling canals, and the conditions and restrictions for the cooling canals minimizing exposure routes, the microbiological hazards to the public during the SLR term would be small, and no mitigation is warranted.

4.9.2 Electric Shock Hazards

4.9.2.1 Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

SMALL, MODERATE, or LARGE. Electrical shock potential is of small significance for transmission lines that are operated in adherence with the NESC. Without a review of conformance with NESC criteria of each nuclear power plant's in-scope transmission lines, it is not possible to determine the significance of the electrical shock potential.

4.9.2.2 Requirement [10 CFR 51.53(c)(3)(ii)(H)]

If the applicant's transmission lines that were constructed for the specific purpose of connecting the plant to the transmission system do not meet the recommendations of the NESC for preventing electric shock from induced currents, an assessment of the impact of the proposed action on the potential shock hazard from the transmission lines must be provided.

4.9.2.3 Background [GEIS Section 4.9.1.1.5]

Design criteria for nuclear power plants that limit hazards from steady-state currents are based on the NESC, adherence to which requires that utility companies design transmission lines so that the short-circuit current to ground produced from the largest anticipated vehicle or object is limited to less than 5 mA. With respect to shock safety issues and license renewal, three points must be made. First, in the licensing process for the earlier licensed nuclear plants, the issue of electrical shock safety was not addressed. Second, some plants that received OLs with a stated transmission line voltage may have chosen to upgrade the line voltage for reasons of efficiency, possibly without reanalysis of induction effects. Third, since the initial NEPA review for those utilities that evaluated potential shock situations under the provision of the NESC, land use may have changed, resulting in the need for a reevaluation of this issue. The electrical shock issue, which is generic to all types of electrical generating stations, including nuclear plants, is of SMALL significance for transmission lines that are operated in adherence with the NESC. Without a review of the conformance of each nuclear plant's transmission lines, within this scope of review with NESC criteria, it is not possible to determine the significance of the electrical shock potential generically.

4.9.2.4 Analysis

As depicted in Figure 2.2-4, all in-scope transmission lines are located completely within an owner-controlled area as discussed in Section 3.1.2. Thus, no induced shock hazards would exist for the general public, due to restricted site access.

As discussed in Section 3.10, the FPL analysis to support the initial LR remains applicable. The 2000 analysis considered the lines from the plant's main transformers to the switchyard, as well as those from the switchyard to the Davis, Flagami, Florida City, Levee, and Doral substations. It took into account the FDOT limits on vehicle size and utilized a hypothetical 53-foot long by 13.5-foot high by 8.5-feet wide tractor-trailer. It determined the minimum vertical roadbed clearance is 38.1 feet when ambient temperatures are 120°F. (FPL 2000b, Section 4.13.2; NRC 2002a, Section 4.2.1)

The EPRI guidance methodology was utilized to perform the calculation of maximum short-circuit current. Worst-case parameters (voltage, current, conductor position) were input to the EZEMF computer program to determine the maximum electrical field strength 1 meter above the road. The position of the tractor-trailer was perpendicular to the phase conductors and the maximum short-circuit current was calculated assuming the maximum electric field value was applied to the entire length of the truck. The resulting value of this calculation was 2.00 kV/m. The resulting maximum steady-state short circuit current was 1.60 mA rms. The lines connecting the plant to the switchyard are in compliance with the NESC requirements. Similar calculations were conducted for the lines leaving the switchyard, and they too were determined to be below the allowable 5 mA rms. (FPL 2000b, Section 4.13.2)

The PTN in-scope transmission lines meet the NESC requirements based upon the above analysis, and the potential impacts from electric shock would be SMALL, pursuant to 10 CFR 51.53(c)(3)(ii)(H). Therefore, mitigation is not warranted.

4.10 Environmental Justice

The following sections address the environmental justice issues applicable to PTN, providing background on the issues and the analyses regarding the SLR period.

4.10.1 Minority and Low-Income Populations

4.10.1.1 Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

Impacts to minority and low-income populations and subsistence consumption resulting from continued operations and refurbishment associated with license renewal will be addressed in plant-specific reviews. See NRC Policy Statement on the Treatment of Environmental Justice Matters in NRC Regulatory and Licensing Actions (69 FR 52040; August 24, 2004).

4.10.1.2 Requirement [10 CFR 51.53(c)(3)(ii)(N)]

Applicants shall provide information on the general demographic composition of minority and low-income populations and communities (by race and ethnicity) residing in the immediate vicinity of the plant that could be affected by the renewal of the plant's OL, including any planned refurbishment activities, and ongoing and future plant operations.

4.10.1.3 Background [GEIS Section 4.10.1]

Disproportionately high and adverse human health effects occur when the risk or rate of exposure to an environmental hazard for a minority or low-income population is significant and exceeds the risk or exposure rate for the general population or for another appropriate comparison group. Disproportionately high environmental effects refer to impacts or risk of impact on the natural or physical environment in a minority or low-income community that are significant and appreciably exceed the environmental impact on the larger community. Such effects may include biological, cultural, economic, or social impacts. Minority and low-income populations are subsets of the general public residing around the site and all are exposed to the same risks and hazards generated from operating a nuclear power plant.

Continued reactor operations and other activities associated with license renewal could have an impact on air, land, water, and ecological resources in the region around each nuclear power plant site, which might create human health and environmental effects on the general population. Depending on the proximity of minority and low-income populations in relation to each nuclear plant, the environmental impacts of license renewal could have a disproportionate effect on these populations.

The location and significance of environmental impacts may affect population groups that are particularly sensitive because of their resource dependencies or practices (e.g., subsistence agriculture, hunting, or fishing) that reflect the traditional or cultural practices of minority and low-income populations. The analysis of special pathway receptors can be an important part of the identification of resource dependencies or practices. Special pathways take into account the levels of contaminants in native vegetation, crops, soils and sediments, surface water, fish, and game animals on or near the power plant sites in order to assess the risk of radiological exposure through subsistence consumption of fish, native vegetation, surface water, sediment, and local produce; the absorption of contaminants in sediments through the skin; and the inhalation of airborne particulates.

4.10.1.4 Analysis

4.10.1.4.1 Refurbishment Activities

As discussed in Section 2.3, no license renewal-related refurbishment activities have been identified. Therefore, there would be no license renewal-related refurbishment impacts to minority and low-income populations, and no further analysis is applicable.

4.10.1.4.2 Operational Activities

The consideration of environmental justice is required to assure that federal programs and activities will not have disproportionately high and adverse human health or environmental effects on minority populations and low-income populations. FPL's analyses of the Category 2 issues defined in 10 CFR 51.53(c)(3)(ii) determined that environmental impacts from the continued operation of PTN during the SLR period would either be SMALL or non-adverse. Therefore, high or adverse impacts to the general human population would not occur.

As described in Section 3.10.3, FPL maintains a REMP. In this program, FPL monitors important radiological pathways and considers potential radiation exposure to plant and animal life in the environment surrounding Turkey Point. Monitoring during the period 2011–2016 verified the dose commitment to members of the public resulting from operations at PTN were well within the ALARA criteria established by 10 CFR Part 50, Appendix I, and no adverse trends in the radiological environment were identified. Therefore, no environmental pathways have been adversely impacted and are not anticipated to be impacted during the PTN SLR term.

Section 3.11.2 identifies the locations of minority and low-income populations as defined by NRR Office Instruction LIC-203. Section 3.11.3 describes the search for subsistence populations near Turkey Point, of which none were found. The figures accompanying Section 3.11.2 show the locations of minority and low-income populations within a 50-mile radius of Turkey Point (see Figure 3.11-1 through Figure 3.11-20). None of those locations, when considered in the context of impact pathways described in Chapter 4, are expected to be disproportionately impacted.

Therefore, no disproportionately high and adverse impacts or effects on members of the public, including minority and low-income populations, are anticipated as a result of PTN SLR.

4.11 Waste Management

The following sections address the waste management issues applicable to PTN, providing background on the issues and the analyses regarding the SLR period.

4.11.1 Low-Level Waste Storage and Disposal

4.11.1.1 Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

SMALL. The comprehensive regulatory controls that are in place and the low public doses being achieved at reactors ensure that the radiological impacts to the environment would remain small during the license renewal term.

4.11.1.2 Requirement [10 CFR 51.53(c)(3)(iv)]

The ER must contain any new and significant information regarding the environmental impacts of license renewal of which the applicant is aware.

4.11.1.3 Background [GEIS Section 4.11.1.1]

The NRC believes that the comprehensive regulatory controls that are in place and the low public doses being achieved at reactors ensure that the radiological impacts on the environment will remain SMALL during the term of a renewed license. The maximum additional onsite land that may be required for LLW storage during the term of a renewed license and associated impacts would be SMALL. Nonradiological impacts on air and water would be negligible. The radiological and nonradiological environmental impacts of long-term disposal of LLW from any individual plant at licensed sites are SMALL. In addition, the NRC concludes that there is reasonable assurance that sufficient LLW disposal capacity will be made available when needed for facilities to be decommissioned consistent with NRC decommissioning requirements.

4.11.1.4 Analysis

FPL would continue to manage and store LLW on site, as discussed in Section 2.2.6.3, in accordance with NRC regulations and dispose of LLW in NRC-licensed treatment and disposal facilities during the SLR period. As discussed above, there are comprehensive regulatory controls in place and FPL's compliance with these regulations and use of licensed treatment and disposal facilities would allow the impacts to remain SMALL during the SLR period. PTN's annual radiological environmental operating reports for years 2011–2016 indicated that doses to members of the public are well within ALARA criteria established by 10 CFR Part 50, Appendix I. Moreover, sampling by the DOH during those years also does not show adverse trends in levels of radiation and radioactive materials in publicly accessible areas. (PTN 2012b; PTN 2013b; PTN 2014c; PTN 2015b; PTN 2016b; PTN 2017b) No new and significant information has been identified for this issue; therefore, no further analysis is required. The issue was also considered in PTN's first license renewal's new and significant review, and no new and significant information was found at that time (FPL 2000b, Table 4.0-2).

4.11.2 Onsite Storage of Spent Nuclear Fuel

4.11.2.1 Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

During the license renewal term, SMALL. The expected increase in the volume of spent nuclear fuel from an additional 20 years of operation can be safely accommodated onsite during the license renewal term with small environmental impacts through dry or pool storage at all plants.

For the period after the licensed life for reactor operations, the impacts of onsite storage of spent nuclear fuel during the continued storage period are discussed in NUREG-2157 and as stated in § 51.23(b), shall be deemed incorporated into this issue.

4.11.2.2 Requirement [10 CFR 51.53(c)(3)(iv)]

The ER must contain any new and significant information regarding the environmental impacts of license renewal of which the applicant is aware.

4.11.2.3 Background [GEIS Section 4.11.1.2 and NUREG-2157 ES.12 and Table ES-3]

As discussed in Section 3.11.1.2 (GEIS), spent nuclear fuel is currently stored at reactor sites either in spent fuel pools or in ISFSIs. The storage of spent fuel in spent fuel pools was considered for each plant in the safety and environmental reviews at the construction permit and OL stage. This onsite storage of spent fuel and HLW is expected to continue into the foreseeable future.

Interim storage needs vary among plants, with older units likely to lose pool storage capacity sooner than newer ones. Given the uncertainties regarding the final disposition of spent fuel and HLW, it is expected that expanded spent fuel storage capacity will be needed at all nuclear power plants.

NUREG-2157, *Generic EIS for Continued Storage of Spent Nuclear Fuel*, concluded on a generic basis for all nuclear power plants that spent fuel can be stored onsite for 60 years following the license term with small environmental effects.

4.11.2.4 Analysis

The additional 20 years of spent nuclear fuel generated during the SLR term would be stored in the spent fuel pools until adequately cooled and then transferred to dry storage in an ISFSI. The ISFSI is licensed under the general license provided to power reactor licensees under 10 CFR 72.210. The NRC-licensed design and operation of each of these storage options ensures that the increased volume in onsite storage can be safely accommodated with small environmental effects. No new and significant information has been identified for this issue; therefore, no further analysis is required. The issue was also considered in PTN's first license renewal's new and significant review, and no new and significant information was found at that time (FPL 2000b, Table 4.0-2).

4.11.3 Offsite Radiological Impacts of Spent Nuclear Fuel and High-Level Waste Disposal

4.11.3.1 Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

For the HLW and spent-fuel disposal component of the fuel cycle, the EPA established a dose limit of 0.15 millisievert (mSv) (15 mrem) per year for the first 10,000 years and 1.0 mSv (100 mrem) per year between 10,000 years and 1 million years for offsite releases of radionuclides at the proposed repository at Yucca Mountain, Nevada.

NRC concluded that the impacts would not be sufficiently large to require the NEPA conclusion, for any plant, that the option of extended operation under 10 CFR Part 54 should be eliminated. Accordingly, while the Commission has not assigned a single level of significance for the impacts of spent fuel and HLW disposal, this issue is considered Category 1.

4.11.3.2 Requirement [10 CFR 51.53(c)(3)(iv)]

The ER must contain any new and significant information regarding the environmental impacts of license renewal of which the applicant is aware.

4.11.3.3 Background [GEIS Section 4.11.1.3]

As a result of the *New York v. NRC* decision, and pending the issuance of a generic EIS and revised Waste Confidence Decision and Rule, the NRC has revised the Category 1 issue, "Offsite radiological impacts of spent nuclear fuel and high-level waste disposal." This issue pertained to the long-term disposal of spent nuclear fuel and HLW, including possible disposal in a deep geologic repository. Although the Waste Confidence Decision and Rule did not assess the impacts associated with disposal of spent nuclear fuel and HLW in a repository, it did reflect the Commission's confidence, at the time, in the technical feasibility of a repository and when that repository could have been expected to become available. Without the analysis in the Waste Confidence Decision, the NRC cannot assess how long the spent fuel will need to be stored onsite. Therefore, the NRC reclassifies this GEIS issue from a Category 1 issue with no assigned impact level to an uncategorized issue with an impact level of uncertain. Moreover, the ultimate disposal of spent nuclear fuel in a potential future geologic repository is a separate and independent licensing action that is outside the regulatory scope of license renewal.

4.11.3.4 Analysis

As indicated in GEIS Section 4.11.3.3, NRC's GEIS analysis of the issue was tied to rulemaking for the Waste Confidence Decision, which was pending in 2013 when Revision 1 of the license renewal GEIS was issued. As part of NRC's NEPA actions associated with the Waste Confidence

Decision, NRC reviewed the environmental impacts of away-from-reactor storage and the technical feasibility of disposal in a geologic repository in NUREG-2157, GEIS for Continued Storage of Spent Nuclear Fuel (NRC 2014a). In the final Continued Storage of Nuclear Spent Fuel rulemaking, the listing and classification of license renewal issues found in 10 CFR Part 51, Subpart A, Appendix B, Table B-1 was revised to reclassify the impact determination for this issue as a Category 1 issue with no impact level assigned. This re-classification was upheld in May 2016 (81 FR 31532).

The NRC's August 2016 GEIS Supplement 57, prepared for LaSalle County Station, indicated that NRC is aware of no new and significant information on this issue (NRC 2016b, Section 4.13.1). Based on review of recent NRC documents and that PTN spent nuclear fuel will be disposed of offsite, FPL found no new and significant information, and further analysis is not required. Offsite radiological impacts of spent nuclear fuel and HLW disposal was also considered in PTN's first license renewal's new and significant review, and no new and significant information was found at that time (FPL 2000b, Table 4-2).

4.11.4 Mixed Waste Storage and Disposal

4.11.4.1 Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

SMALL. The comprehensive regulatory controls and the facilities and procedures that are in place ensure proper handling and storage, as well as negligible doses and exposure to toxic materials for the public and the environment at all plants. License renewal would not increase the small, continuing risk to human health and the environment posed by mixed waste at all plants. The radiological and nonradiological environmental impacts of long-term disposal of mixed waste from any individual plant at licensed sites are small.

4.11.4.2 Requirement [10 CFR 51.53(c)(3)(iv)]

The ER must contain any new and significant information regarding the environmental impacts of license renewal of which the applicant is aware.

4.11.4.3 Background [GEIS Section 4.11.1.4]

Mixed waste is regulated both by the EPA or the authorized state agency under RCRA and by the NRC or the agreement state agency under the Atomic Energy Act (AEA; Public Law 83-703). The waste is either treated onsite or sent offsite for treatment followed by disposal at a permitted landfill. The comprehensive regulatory controls and the facilities and procedures that are in place at nuclear power plants ensure that the mixed waste is properly handled and stored and that doses to and exposure to toxic materials by the public and the environment are negligible at all plants. License renewal will not increase the small but continuing risk to human health and the environment posed by mixed waste at all plants. The radiological and nonradiological environmental impacts from the long-term disposal of mixed waste at any individual plant at licensed sites are considered SMALL for all sites.

4.11.4.4 Analysis

FPL previously established its radiological waste programs and controls as described in Section 2.2.6 in accordance with NRC regulations. FPL has established oversight and controls for handling and storage of hazardous and mixed waste that implements the regulatory requirements for management, storage, inspections, and shipping. Review of PTN's recent annual radiological environmental operating reports indicated that doses to members of the public are well within ALARA criteria established by 10 CFR Part 50, Appendix I. Moreover, sampling by the DOH during those years also does not show adverse trends in levels of radiation and radioactive materials in publically accessible areas. (PTN 2012b; PTN 2013b; PTN 2014c; PTN 2015b; PTN 2016b; PTN 2017b). PTN has not received any violations for hazardous waste management in the past 5 years based on a review of its compliance history (EPA 2017d).

FPL would continue to store and dispose of mixed waste in accordance with NRC, EPA, and state regulations and dispose of the wastes in appropriately permitted treatment and disposal facilities during the SLR period. As indicated in the GEIS (NRC 2013a), continuation of existing systems and procedures to ensure proper storage and disposal would allow the impacts to be of small magnitude. No new and significant information has been identified for this issue; therefore, no further analysis is required. This issue was evaluated as a Category I issue in PTN's first license renewal's new and significant review and found to be bound by the GEIS conclusion of a SMALL impact (FPL 2000b, Table 4.0-2).

4.11.5 Nonradioactive Waste Storage and Disposal

4.11.5.1 Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

SMALL. No changes to systems that generate nonradioactive waste are anticipated during the license renewal term. Facilities and procedures are in place to ensure continued proper handling, storage, and disposal, as well as negligible exposure to toxic materials for the public and the environment at all plants.

4.11.5.2 Requirement [10 CFR 51.53(c)(3)(iv)]

The ER must contain any new and significant information regarding the environmental impacts of license renewal of which the applicant is aware.

4.11.5.3 Background [GEIS Section 4.11.1.5]

The management of hazardous wastes generated at all of these facilities, both onsite and offsite, is strictly regulated by the EPA or the responsible state agencies per the requirements of RCRA.

As does any industrial facility, nuclear power plants and the rest of the uranium fuel cycle facilities also generate nonradioactive nonhazardous waste. These wastes are managed by following good housekeeping practices and are generally disposed of in local landfills permitted under RCRA Subtitle D regulations.

In the 1996 GEIS, the impacts associated with managing nonradioactive wastes at uranium fuel cycle facilities, including nuclear power plants, were found to be SMALL. It was indicated that no changes to nonradioactive waste generation would be anticipated for license renewal, and that systems and procedures are in place to ensure continued proper handling and disposal of the wastes at all plants.

4.11.5.4 Analysis

Management of nonradioactive waste is discussed in Section 2.2.7. FPL has established oversight and controls for handling and storage of hazardous waste that implements the regulatory requirements for management, storage, inspections, and shipping. PTN has not received any violations for hazardous waste management in the past 5 years based on a review of its compliance history (EPA 2017d).

PTN's nonradiological, nonhazardous waste is disposed of by the Miami-Dade County Department of Solid Waste Management and is collected at the Turkey Point site by an approved solid waste collector (Section 2.2.7).

FPL would continue to store and dispose of hazardous and nonhazardous waste in accordance with EPA, state, and local regulations, and dispose of the wastes in appropriately permitted disposal facilities during the SLR period. As indicated in the GEIS (NRC 2013a), continuation of existing systems and procedures to ensure proper storage and disposal would allow the impacts to be of small magnitude. No new and significant information has been identified for this issue; therefore, no further analysis is required. This issue was evaluated as a Category I issue in PTN's first license renewal's new and significant review, and found to be bound by the GEIS conclusion of a SMALL impact (FPL 2000b, Table 4.0-2).

4.12 Cumulative Impacts

The following sections address the cumulative impacts applicable to PTN, providing background on the issues and the analyses regarding the SLR period.

Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

Cumulative impacts of continued operations and refurbishment associated with license renewal must be considered on a plant-specific basis. Impacts would depend on regional resource characteristics, the resource-specific impacts of license renewal, and the cumulative significance of other factors affecting the resource.

Requirement [10 CFR 51.53(c)(3)(ii)(O)]

Applicants shall provide information about other past, present, and reasonably foreseeable future actions occurring in the vicinity of the nuclear plant that may result in a cumulative effect.

Background [GEIS Section 4.13]

Actions to be considered in cumulative impact analyses include new and continuing activities, such as license renewal, that are conducted, regulated, or approved by a federal agency. The cumulative impacts analysis takes into account all actions, however minor, because impacts from individually minor actions may be significant when considered collectively over time. The goal of the analysis is to identify potentially significant impacts to improve decisions and move toward more sustainable development.

For some resource areas (e.g., water and aquatic resources), the contributions of ongoing actions within a region to cumulative impacts are regulated and monitored through a permitting process (e.g., NPDES) under state or federal authority. In these cases, it may be assumed that cumulative impacts are managed as long as these actions (facilities) are in compliance with their respective permits.

Analysis

The cumulative analysis involves determining if there is an overlapping of the anticipated impacts of the continued operation of PTN during the SLR period and past, present, and reasonably foreseeable future actions regardless of what agency (federal or non-federal) or person undertakes such actions. Past and present actions include all actions up to and including the time of the SLRA. Future actions are those that are "reasonably foreseeable" (i.e., they are ongoing and will continue into the future), are funded for future implementation, are included in firm, near-term plans, or generally have a high probability of being implemented. The affected environment sections for each resource area presented in Chapter 3 generally accounts for past and present actions. Future actions would be those anticipated for the time from the SLRA submittal through the 20 years of the SLR period.

The direct and indirect impact analyses presented in Chapter 4 address the incremental impacts of SLR renewal. Those analyses are considered along with reasonably foreseeable future actions that have the potential to combine with the impacts of the proposed action to determine cumulative impacts. Next, the assessment determines if any combined impacts would be significant. Significant cumulative impacts could stem from an impact that may be small by itself but could result in a moderate and/or large impact when considered in combination with the impacts of other actions on the affected resource. If a resource is regionally declining or imperiled, even a small individual impact could be important if it contributes to or accelerates the overall resource decline.

Section 3.1.4 describes other (non-PTN) projects at and in the vicinity of Turkey Point. At the Turkey Point site, FPL operates Turkey Point Units 1 and 2 in synchronous condenser mode to provide voltage support for the transmission system, and Unit 5, a combined-cycle unit (employing four natural gas turbines and one heat-recovery steam-powered generator). No major changes to operations or plans for future expansion of these units are anticipated. Section 3.1.4 also introduces Units 6 and 7, for which FPL is seeking a license from NRC. FPL has not made a decision to construct the units; however, for the purpose of assessing cumulative impacts to support the SLRA, the construction and operation of Units 6 and 7 is considered. There are no Turkey Point site projects anticipated, planned, or projected (other than construction and operation of Turkey Point 6 and 7 and continued operation of PTN and the continued operation of Units 1 and 2 in synchronous condenser mode and continued operation of Unit 5) during the SLR period. Another ongoing project locally and throughout the region is the CERP. These onsite projects and the CERP could result in cumulative impacts.

The overlap of construction of the units with the SLR period is not a matter of certainty. The earliest practical dates for bringing Turkey Point Units 6 and 7 in service are mid-2027 (Unit 6) and mid-2028 (Unit 7) (FPL 2017a). These earliest in-service dates for the units would mean that there would not be an overlap; however, it is reasonable to conservatively assume a site preparation and construction schedule for Units 6 and 7 that is delayed into the SLR period of PTN. Therefore, here and where appropriate, the impacts of construction as well as the impacts of operation of the proposed units is considered in the cumulative impacts analysis.

The NRC recently conducted a cumulative impacts assessment of the construction and operation of the proposed Turkey Point Units 6 and 7 in the EIS prepared for the COL for these proposed units (NRC 2016a). This cumulative impacts assessment considered the operation of PTN with the many past, present, and future projects in the area. The NRC developed a comprehensive list of projects and activities within a 50-mile radius and reviewed the potential for urban development as governed by state and local land use plans. This recent cumulative assessment is applicable to a cumulative impacts assessment for this SLRA for PTN and is the primary resource for this cumulative assessment.

The following sections address the potential for cumulative impacts by resource area.

4.12.1 Land Use and Visual Resources

PTN SLR is not anticipated to require land use changes, but would be a continuation of previously established land use for power generation. As described in Section 3.2.2, the areas surrounding Turkey Point are primarily water (i.e., Biscayne Bay) and wetlands. The large developed areas within a 6-mile vicinity are Homestead ARB and Homestead (Figure 3.2-2). The Adopted 2020–2030 Land Use Plan for Miami-Dade County, Florida (MDC 2016b) shows the lands surrounding Turkey Point as land designated as environmentally protected. The Miami-Dade County 2015−2025 Comprehensive Development Plan designated the unincorporated land in the immediate vicinity of the Turkey Point site as protected land, open land, parkland, or agricultural land (NRC 2016a, Section 7.1). Both the previous plan and the current plan indicate that land use in the vicinity of the Turkey Point site would not be expected to change.

The Units 6 and 7 EIS cumulative land use impacts analysis considered a 10-mile radius beyond the site proposed for the units, which is just south of the PTN location, as the geographic area of interest (NRC 2016a, Section 7.1). Projects considered in the cumulative impacts analysis included many ongoing projects including those on site and the conservation and remediation projects for the environmentally protected land surrounding Turkey Point (NRC 2016a, Table 7-1). In addition, the EIS considered freshening activities for improving water quality in the Turkey Point cooling canals and remediation of the hypersaline plume. The cumulative impact on land use would be MODERATE, with the incremental contribution of construction and operation of Units 6 and 7 being a significant contributor (EIS concluded that the construction and operation of Units 6 and 7 would be MODERATE).

Given that the proposed continued operation of PTN is not anticipated to require land use changes, the contribution of continued operation of PTN would be a small contributor to the overall moderate cumulative impact to land use.

The continued use of existing structures associated with PTN would not alter their visual impact. As discussed in Section 3.2.3, the containment structures are screened by vegetation on the landward side and clearly visible from Biscayne Bay. Proposed Units 6 and 7 would add to this viewscape, but because Units 6 and 7 would be built adjacent to existing units and from materials that are architecturally similar, the contrast with the existing landscape would be reduced; thus, the NRC concluded that the visual impact of Units 6 and 7 would be SMALL. Furthermore, the existing units lighting is visible at night from various locations landward and the addition of operational lighting at the proposed units was deemed to be minor.

The NRC also determined the visual impacts from construction of the units would also be SMALL (NRC 2016a, Sections 4.4.1.6, 4.12, 5.4.1.6, and 5.4.1.7). As mentioned above, the surrounding land is designated as environmentally protected and is thus not anticipated to undergo development. Therefore, the cumulative visual impacts would be those of the existing and proposed units. With the NRC previously determining the new units would have a SMALL visual impact, the combination of the existing units and the proposed units would have a cumulative small visual impacts.

4.12.2 Air Quality and Noise

4.12.2.1 Air Quality

As discussed in Section 3.3.3, Miami-Dade County where Turkey Point is located is in attainment of the NAAQSs. PTN air pollutant emissions are minor air emission sources and their minimal emissions stem from intermittent use and testing of EDGs and diesel pumps. The non-nuclear operations of PTN are permitted by a Title V air emissions permit (Permit No. 0250003-021-AV) (FDEP 2014a). The PTN air permit contains conditions established by the FDEP to protect

Florida's ambient air quality standards and ensure impacts are maintained at acceptable levels. As discussed in Section 2.3, no refurbishment or future upgrades or replacement activities have been identified; therefore, no increase or decrease of air emissions is expected over the SLR period. Section 4.2.1.4 concluded that the impact to air quality from the continued operation of PTN during the SLR term is anticipated to be small as generically determined by the NRC for all nuclear power plants.

The Units 6 and 7 EIS conducted an air quality cumulative impact analysis inclusive of the existing Turkey Point Units 1-5 (with Units 1 and 2 operating in synchronous condenser mode) and other past, present, and future projects (including other existing fossil fuel-fired power plants, planned and existing MSW incinerators, and power generation projects) (NRC 2016a, Table 7-1 and Section 7.6.1). The geographic area of interest was established as Miami-Dade County, and the county was in attainment for the NAAQSs at that time, as is the current condition. The NRC analysis concluded that cumulative air quality impacts due to criteria pollutants would SMALL to MODERATE. The NRC noted the following contributors to this conclusion to be the potential for growth and the contribution of criteria pollutant emissions from the three landfill gas power-generation projects.

Given the SLR for PTN does not include an increase in air emissions and the recent NRC cumulative analysis concluded SMALL to MODERATE impacts, the cumulative air quality impacts are anticipated to be small to moderate with the continued operation of PTN being only a minor contributor to the cumulative impact. In contrast, as presented in Section 7.2, replacement of PTN with a natural gas plant would be an addition of a major air emission source, resulting in a greater incremental contribution to air pollution.

4.12.2.2 Climate Change

The annual GHG emissions for the period 2012–2016 from PTN are presented in Table 3.3-10. The NRC estimated GHG emissions for the lifetime of a 1,000-MWe reactor at 10,500,000 MT carbon dioxide equivalent (CO_2e). This is equal to approximately 37.5 g CO_2e per kilowatt hour (CO_2e/kWh). (NRC 2013d) The contributions of PTN, which are less than 1,000 MWe each, for the 20 years of operation during the SLR term would be less than the estimate the NRC prepared for the 1,000-MWe reactor.

It is difficult to evaluate cumulative impacts of GHG emissions on a local level; the NRC evaluated GHG cumulative impacts on a global level in its guidance. GHG cumulative impacts on a global level indicate that national and worldwide cumulative impacts of GHG emissions are MODERATE, with or without the GHG estimated for the lifetime of a 1000-MWe reactor. (NRC 2013e)

NRC's EIS for proposed Units 6 and 7 also discussed cumulative impacts of GHG emissions on a global scale as well as on a national scale, concluding that the cumulative impact would be MODERATE based on EPA and U.S. Global Change Research Program reports. The EIS further concluded that the cumulative impacts would be MODERATE, whether or not the proposed units were constructed and operated. (NRC 2016a) The GHG contribution of PTN during the SLR period would be minor and would be less than the contribution from the construction of the proposed Units 6 and 7, which would require mobilization of hundreds of construction workers daily, and transport and manufacturing of building materials and components. Therefore, while the cumulative impact would be moderate, the contribution of continued operation of PTN would be negligible. Moreover, continued operation of PTN avoids millions of tons of carbon dioxide (CO_2) from alternative fossil-fuel generation, positively impacting the climate change factor of CO_2 concentrations.

4.12.2.3 Noise

PTN operations have a small impact on the noise environment as described in Section 4.3.4. As mentioned above, the surrounding land is designated as environmentally protected and is not anticipated to undergo development. Therefore, the cumulative noise impacts would be those of the existing and proposed units. The NRC determined the noise impacts from construction and operation of the proposed Units 6 and 7 would also be SMALL. Peak noise from construction of the proposed Units 6 and 7 was estimated to be below 65 dBA at the nearest residence, a level considered to be a small significance. (NRC 2016a, Sections 4.4.1.1, 4.12, and 5.4.1.1) With the NRC previously determining that even the peak construction noise of the proposed units would have a SMALL noise impact, the combination of the existing units, including continued operation of PTN, and the proposed units would have a cumulative small noise impact.

4.12.3 Geology and Soils

Impacts to geology and soils could result from ground-disturbing activities and stormwater runoff. Routine infrastructure, renovation, and maintenance projects would be expected during continued operation. Stormwater is routed to the cooling canals. As discussed in Section 3.5.3.2, stabilization measures are in place to prevent erosion and sedimentation impacts to the site and vicinity. Section 4.4.4 concluded that PTN's impact on geology and soils would be small. No new development attributable to PTN during the SLR period is anticipated, and any new development would be subject to state and local stormwater management requirements.

Stormwater runoff from the construction and operations period of the proposed Units 6 and 7 would be routed to the cooling canals and stormwater management basins before release to the surrounding wetland area. No direct stormwater discharges would be made to Biscayne Bay. SFWMD reviewed stormwater management and surmised that stormwater mitigation could be achieved through the planned BMPs, and impacts to offsite water resources would be minimal. (NRC 2016a, Sections 4.2.1.1 and 5.2.1.6)

As mentioned in Section 4.12.1, the land surrounding Turkey Point is designated as environmentally protected, indicating that little to no construction activities would be taking place adjacent to the Turkey Point boundary. Given ground disturbances at the PTN site and that the surrounding area would be subject to stormwater permitting and applicable BMPs, the cumulative impact to geology and soils would be small.

4.12.4 Water Resources

4.12.4.1 Surface Water

Surface water resource impacts would stem from alterations in hydrology, withdrawals, discharges, and stormwater. PTN does not withdraw water from surface water resources and the units' discharges, including stormwater, are to the closed-cycle cooling canals. There are no construction or refurbishment plans related to the proposed action, thus no alterations in hydrology are anticipated. The cooling canals, the groundwater wells associated with the cooling canals, and the cooling canals' interface with groundwater are discussed in Section 3.6. The compliance history associated with the cooling canals freshening and hypersaline recovery is presented in Section 3.6.1.4.5. The cooling canals' effect on surface water through the groundwater interface was studied in sampling events in 2010–2017. The results indicated that the groundwater pathway is having no discernable influence on Biscayne Bay (EEI 2017).

NRC's Units 6 and 7 EIS analyzed cumulative impacts to surface water quality in surface waters adjacent to the Turkey Point site. The EIS considered the contributing projects to be those of Turkey Point existing and proposed units, and historical point and non-point-source discharges have affected the water quality of streams and rivers near Turkey Point. The EIS considered that some water bodies near Turkey Point are listed as impaired (CWA 303[d]) and designation of the waters of Biscayne National Park as an Outstanding Florida Water. The EIS analysis determined that cumulative impacts would be MODERATE, with the proposed Units 6 and 7 contribution being of small significance. (NRC 2016a) Given that PTN do not discharge to surface waters and have stormwater controls in place, they likewise would have a contribution of small significance within the MODERATE cumulative impact.

4.12.4.2 Groundwater

PTN operations include groundwater withdrawals for process water and freshening of the cooling canals, recovery of hypersaline groundwater, underground injection of wastewater and, as discussed above, migration of water in the cooling canals of the IWW facility into groundwater. In addition, FPL has groundwater withdrawal wells located at Turkey Point (PW-1, PW-3, and PW-4) for process water for other operating units. All of these wells are discussed in Section 3.6.3.2. Section 4.5.3.4 discusses the impacts of groundwater withdrawals and concluded that the withdrawals are within permitted quantities.

The EIS prepared by NRC for Turkey Point Units 6 and 7 analyzed cumulative impacts to groundwater considering the groundwater withdrawals and injections of PTN and the other Turkey Point facilities and those from other projects and activities in the surrounding area (e.g., impacts of enhanced recharge to the Biscayne Aquifer from activities related to CERP and offsite wastewater-injection operations). The NRC determined the cumulative impacts to be SMALL given the hydrologic characteristics of the affected aquifers, fate and transport processes, and the monitoring and management programs required by the State. (NRC 2016a)

As indicated in Section 4.12 of NRC Regulatory Guide 4.2, Revision 1 (NRC 2013b), it may be assumed that cumulative impacts are managed as long as facility operations are in compliance with their respective permits. Given that FPL continues to comply with its permits for groundwater withdrawals and injection, the FDEP CO for freshening of the cooling canals, and the CA with Miami-Dade County for remediation of the hypersaline plume, cumulative impacts would be managed, and continued operation of PTN during the SLR period would be small.

4.12.4.3 Climate Change

Aside from GHG levels discussed in Section 4.12.2.2, other climate change indicators are trends in increasing air temperature, precipitation, and water temperature. The reliance of PTN on closed-cycle cooling using the cooling canals limits the opportunities for operation of the units to contribute to these factors due to the reuse of water and no discharge. Extensive studies were conducted by FPL to determine the effects, if any, of the CCS on surface water via the groundwater pathway. The results indicated that the groundwater pathway is having no discernable influence on Biscayne Bay. The results indicate that water temperature in Biscayne Bay is influenced by seasonal and meteorological conditions. The increase in cooling canals water temperatures during the post-uprate period do not correspond with commensurately higher air temperatures. As for precipitation, the results from 2010 through 2017 showed differences in rainfall between stations, as may be expected over the large area of sampling. However, there was no increasing trend in rainfall for the stations or relative trends among the stations (EEI 2017, Sections 2.2.2, 2.4.2, and 5.1).

So, while national and global trends may show warming trends, the available data indicate that the no-discharge, closed-loop cooling used by PTN would also be a small contributor to local and regional warming trends. Moreover, continued operation of PTN avoids millions of tons of CO_2 from alternative fossil-fuel generation, positively impacting the climate change factor of CO_2 concentrations.

4.12.5 Ecological Resources

4.12.5.1 Terrestrial

The affected environment for terrestrial ecological communities is described in Section 3.7 and represents the cumulative impact of past and present activities on site and in the surrounding area of environmental protected lands.

As discussed above, FPL conducted pre-and post-uprate studies during the period 2010–2017 to determine the influence of the cooling canals on the surrounding areas through migration of groundwater. The results indicate that the cooling canals do not have any ecological impact on the surrounding areas (PTN 2017, Executive Summary).

The cooling canals are the home to the threatened American crocodile. As discussed in Section 4.6.6.4, the cooling canals provide habitat for the species, and FPL has a management plan in place to support the population and minimize adverse impacts. Section 4.6.6.4 concludes that the continued operation of the site would have no adverse effects on any federally or state-listed species.

As discussed in Sections 3.7.8.1 and 4.6.6.4, habitat for federally and state-listed terrestrial species other than the American crocodile does occur on or immediately adjacent to the Turkey Point site. However, adherence to regulatory and permit requirements to avoid take of protected species and FPL administrative controls, such as those regarding response to avian collisions with transmission lines, will minimize or avoid impact to these species. FPL is not aware of any adverse impacts regarding threatened, endangered, and protected species attributable to the site. Maintenance activities necessary to support SLR likely would be limited to previously disturbed areas on site. Lands adjacent to the Turkey Point site are designated as environmentally protected and, therefore, development is not expected. Therefore, cumulative impacts on protected species would be small.

In its EIS for proposed Units 6 and 7, the NRC concluded that the overall cumulative impacts on terrestrial resources within a 50-mile radius from past, present, and reasonably foreseeable future actions would be MODERATE to LARGE, with particular consideration of the impacts of Units 6 and 7, habitat loss and degradation from past, ongoing, and anticipated regional land development; the sensitivity of terrestrial habitats in the region to hydrological changes; the number and distribution of federally and state-listed species present in the region; and the presence of two national parks and numerous other conservation lands in the area. The contribution of construction and operation of Units 6 and 7 were assessed by the NRC as a MODERATE contributor to this overall impact significance. (NRC 2016a, Section 7.3.1)

The USFWS biological opinion for federally listed species with regard to the construction and operation of the proposed Turkey Point Units 6 and 7 project concluded that the project as proposed is not likely to jeopardize the continued existence of the crocodile, indigo snake, snail kite, panther, red knot, or wood stork, and it will not adversely modify the critical habitat of the crocodile. The USFWS also concluded that the project was not likely to adversely affect the Florida bonneted bat, Bartram's scrub-hairstreak butterfly, Florida leafwing butterfly, Miami tiger beetle, and Schaus swallowtail butterfly, Beach jacquernontia, Carter's small-flowered flax, crenulate lead-plant, deltoid spurge, Florida brickell-bush, Garber's spurge, Small's milkpea tiny polygala, piping plover, and the West Indian manatee. (USFWS 2017e)

Given that continued operation of PTN does not include the construction of new facilities and that ongoing remediation activities associated with the cooling canals would be conducted in compliance with state and local requirements and monitoring would be conducted to ensure its effectiveness, the contribution to the overall cumulative impacts to terrestrial habitats including wetlands and terrestrial species communities would be small.

4.12.5.2 Aquatic

The aquatic ecological communities could be impacted through discharges to the surface waters and wetlands. PTN's cooling canals are closed loop and do not discharge to surface waters; however, the cooling canals are unlined so they have an interface with underlying groundwater. Stormwater is also routed to the cooling canals. As discussed above, pre- and post-uprate studies and continued monitoring were undertaken to determine any influence on the surrounding surface and groundwater due to seepage from the unlined cooling canals. The studies' data support the conclusion that the cooling canals do not have any ecological impact on the surrounding areas, and there is no evidence of cooling canal water in the surrounding marsh and mangroves areas from a groundwater pathway (EEI 2017, Executive Summary).

NRC's Units 6 and 7 EIS also conducted a cumulative impact assessment for impacts on aquatic ecological communities using a geographic area of interest of all the aquatic resources in southeastern Florida. The NRC determined the cumulative impact to be MODERATE, primarily based on past activities that altered the hydrology of the region. Other activities noted by the NRC were success or failure of existing and pending restoration CERP activities, continued urbanization in southern Florida, and the magnitude of hydrological alterations as a result of climate change. NRC's assessment determined that the proposed and existing Turkey Point units' contribution would be SMALL to the cumulative impacts. The NRC further indicated that their previous assessments of PTN operations indicated that their impact on aquatic communities were limited to those in the cooling canals. (NRC 2016a, Section 7.3.2)

Given that FPL will continue to manage the cooling canals in compliance with its IWW permit, continue to comply with the AO regarding improving water quality in the canals, and continue to implement its American crocodile management plan, the continued contribution of PTN to cumulative impacts during the SLR period would be small.

4.12.5.3 Climate Change

Terrestrial and aquatic species could be vulnerable to the air and water temperature warming trends and rising sea levels. As discussed in Sections 4.12.2.2 and 4.12.4.3, the cumulative impact of climate change on a national level was assessed previously to be MODERATE. Given PTN's no-discharge cooling system and data indicating that cooling water discharges are not indicated in local air, water temperature, and precipitation trends, the continued operation of the PTN would be a small contributor to climate change effects that impact vulnerable species.

4.12.6 Historic and Cultural Resources

As discussed in Sections 3.8.5 and 4.7.4.2, there have been seven previous cultural resource investigations conducted on the Turkey Point site. There are no recorded cultural resources on the Turkey Point site and there are no NRHP-listed resources within a 6-mile radius of Turkey Point. As discussed in Section 3.8.6, FPL has administrative controls in place for management of cultural resources ahead of any future ground-disturbing activities at the plant. These consist of the 2016 conditions of certification (FDEP 2016a) and the Environmental Control Program for PTN. Section 4.7.4.2 concluded that no adverse effects are anticipated during the PTN SLR term.

NRC's Units 6 and 7 EIS cumulative land use impacts analysis considered the direct and indirect APE determined for the construction and operation of proposed Units 6 and 7 as the geographic area of interest. The direct-effects APE is the area that may be physically affected by land-disturbing activities, and the indirect-effects APE is the area that may be visually and/or auditory affected. The Units 6 and 7 project includes construction of the units' onsite and offsite facilities, including transmission corridors. The indirect-effects APE applicable to the onsite portions is determined by the maximum distance from which the tallest structures associated with proposed Units 6 and 7 can be seen from offsite locations. In the case of the Turkey Point site, the indirect-effects APE was determined to be 0.5 miles from the facility. The NRC's cumulative impact assessment, which included consideration of the transmission corridor, was MODERATE; however, the NRC stated that incremental impacts associated with the onsite NRC-authorized activities for Units 6 and 7 would not significantly contribute to the cumulative impact, because no significant historic or cultural resources would be affected by these activities in the geographic area of interest. (NRC 2016a, Sections 2.7 and 7.5)

NRC's Units 6 and 7 EIS assessment and the Section 4.7.4.2 assessment indicates that there would not be an overlap of impacts resulting in cumulative impacts; therefore, cumulative impacts to cultural resources from this SLR are not anticipated.

4.12.7 Socioeconomics

The SLR does not include additional workers (Section 4.8.1.4) so the small adverse impacts that are the result of workers' impact on community services, education, and infrastructure, including transportation, would continue. As discussed in Section 4.5.1.4, the demand for municipal water for plant use is being reduced and this reduced usage would be applicable to the SLR term. Tax payments from the operating plant (Section 4.8.2.4) are anticipated to continue without significant change through the SLR period and the economic contributions of the plant's workers, thus the beneficial socioeconomic impacts would also continue. FPL also does not have currently have plans to expand or contract operations at the other existing units during the SLR period, so their contributions to the taxable value of Turkey Point is anticipated to continue. However, operational Units 6 and 7 would impact the Turkey Point site's taxable value. In addition, construction of the proposed units would impact socioeconomics through increased employment directly and indirectly by adding to the local economy and placing greater demand on community services and infrastructure.

NRC's Units 6 and 7 EIS considered the cumulative impacts of the proposed units, existing units, and other past, present, and future projects using Miami-Dade County as the geographic area of interest. The EIS determined the adverse cumulative impact to be SMALL with the exception of traffic in the vicinity of the proposed units, which would be MODERATE with the proposed units being the principal contributor to the traffic impact. (NRC 2016a)

Given that continued operation of PTN would allow employment levels and tax payments to be consistent with current levels, the cumulative impacts determined in the Units 6 and 7 EIS, considering construction and operation, remain applicable; therefore, cumulative socioeconomic impacts would be small with the exception of moderate traffic impacts in the vicinity of Turkey Point resulting from the addition of the proposed Units 6 and 7.

4.12.8 Human Health

Operating PTN for an additional 20-year period is not expected to cause an increase in annual radioactive effluent releases. The NRC concluded that the cumulative radiological impacts of operating the existing and proposed Turkey Point units and the influence of other manmade sources of radiation nearby would be SMALL (NRC 2016a, Section 7.8). The cumulative impact of the units and the proposed units along with any existing or proposed medical, industrial, and research facilities using radioactive materials in the region during the SLR period would be small, because all routine releases by the facilities and occupational exposure to their employees would be subject to federal and state regulations designed to ensure radioactive emissions and occupational exposure do not significantly impact human health.

4.12.9 Waste Management

As discussed in Section 4.11.1.4, the comprehensive regulatory controls in place for management of radiological waste, FPL's compliance with these regulations, and use of only licensed treatment and disposal facilities would allow the impacts to remain SMALL during the SLR term. There are no other operating nuclear power plants, fuel-cycle facilities, or radiological waste treatment and disposal facilities within a 50-mile radius of PTN. There are industrial, medical, and research facilities in the region that use radioactive materials.

NRC's Units 6 and 7 EIS analyzed the cumulative impacts of managing radioactive waste within a 50-mile radius of PTN and determined the cumulative impact to be SMALL (NRC 2016a, Section 7.8)

FPL would continue its programs of radioactive waste management and comply with waste management guidelines and discharge limits. Given that NRC, EPA, and state authorities would likely continue ensuring licensed facilities are available for waste treatment and disposal, and FPL's ongoing waste management practices, the cumulative impact of radioactive waste management would be small.

Section 4.11.5.4 concluded that continued operation of PTN would have a small impact on nonradioactive waste management facilities given FPL's program for waste management and the availability of treatment and disposal facilities. NRC's Units 6 and 7 EIS analyzed cumulative impacts of nonradioactive waste from the past, present, and future projects in the geographic area of interest of Miami-Dade County. The EIS concluded that cumulative impacts from nonradioactive waste management would be SMALL. (NRC 2016a, Section 7.9) FPL would continue its programs of waste management and comply with permits and waste management regulations. Given that facilities within Miami-Dade County are also required to comply with appropriate EPA and state requirements for the management of hazardous and nonhazardous waste, that state and local authorities would continue ensuring permitted facilities are available for waste treatment and disposal, and FPL's ongoing waste management practices, the cumulative impact of nonradioactive waste management would be small.

4.13 Impacts Common to all Alternatives: Uranium Fuel Cycle

The following sections address the fuel cycle issues applicable to PTN, providing background on the issues and the analyses regarding the SLR period.

4.13.1 Offsite Radiological Impacts—Individual Impacts from other than the Disposal of Spent Fuel and High-Level Waste

4.13.1.1 Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

SMALL. The impacts to the public from radiological exposures have been considered by the Commission in Table S-3 of this part. Based on information in the GEIS, impacts to individuals from radioactive gaseous and liquid releases, including radon-222 and technetium-99, would remain at or below the NRC's regulatory limits.

4.13.1.2 Requirement [10 CFR 51.53(c)(3)(iv)]

The ER must contain any new and significant information regarding the environmental impacts of license renewal of which the applicant is aware.

4.13.1.3 Background [GEIS Section 4.12.1.1]

The primary indicators of impact are the concentrations of radionuclides in the effluents from the fuel cycle facilities and the radiological doses received by a maximum exposed individual (MEI) on the site boundary or at some location away from the site boundary. The basis for establishing the significance of individual effects is the comparison of the releases in the effluents and the MEI doses with the permissible levels in applicable regulations. The analyses performed by the NRC in the preparation of Table S-3 and found in the 1996 GEIS indicate that as long as the facilities operate under a valid license issued by either the NRC or an agreement state, the individual effects will meet the applicable regulations. On the basis of these considerations, the NRC has concluded that the impacts on individuals from radioactive gaseous and liquid releases during the license renewal term would remain at or below the NRC's regulatory limits. Accordingly, the NRC concludes that offsite radiological impacts of the uranium fuel cycle (individual effects from sources other than the disposal of spent fuel and HLW) are SMALL.

4.13.1.4 Analysis

This issue concerns the direct individual impacts from facilities involved in supplying nuclear fuel to nuclear power plants. The issue was considered in FPL's new and significant review and no new and significant information was identified as it relates to offsite radiological impacts—individual impacts from other than the disposal of spent fuel and HLW; therefore, no further analysis is required. The issue was also considered in PTN's first license renewal's new and significant review, and no new and significant information was found at that time (FPL 2000b, Table 4.0-2).

4.13.2 Offsite Radiological Impacts—Collective Impacts from other than the Disposal of Spent Fuel and High-Level Waste

4.13.2.1 Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

There are no regulatory limits applicable to collective doses to the general public from fuel-cycle facilities. The practice of estimating health effects on the basis of collective doses may not be meaningful. All fuel-cycle facilities are designed and operated to meet the applicable regulatory limits and standards. The Commission concludes that the collective impacts are acceptable.

The Commission concludes that the impacts would not be sufficiently large to require the NEPA conclusion, for any plant, that the option of extended operation under 10 CFR Part 54 should be eliminated. Accordingly, while the Commission has not assigned a single level of significance for the collective impacts of the uranium fuel cycle, this issue is considered Category 1.

4.13.2.2 Requirement [10 CFR 51.53(c)(3)(iv)]

The ER must contain any new and significant information regarding the environmental impacts of license renewal of which the applicant is aware.

4.13.2.3 Background [GEIS Section 4.12.1.1]

There are no regulatory limits applicable to collective doses to the general public from fuel cycle facilities. All regulatory limits are based on individual doses. All fuel cycle facilities are designed and operated to meet the applicable regulatory limits.

As discussed in the 1996 GEIS, despite the lack of definitive data, some judgment as to the regulatory NEPA implications of these matters should be made and it makes no sense to repeat the same judgment in every case. The Commission concludes that these impacts are acceptable in that these impacts would not be sufficiently large to require the NEPA conclusion, for any plant, that the option of extended operation under 10 CFR Part 54 should be eliminated. Accordingly, while the Commission has not assigned a single level of significance for the collective effects of the fuel cycle, this issue was considered Category 1.

4.13.2.4 Analysis

This issue concerns the direct collective impacts from facilities involved in supplying nuclear fuel to nuclear power plants. The issue was considered in FPL's new and significant review and no new and significant information was identified as it relates to offsite radiological impacts—collective impacts from other than the disposal of spent fuel and HLW; therefore, no further analysis is required. The issue was also considered in PTN's first license renewal's new and significant review, and no new and significant information was found at that time (FPL 2000b, Table 4.0-2).

4.13.3 Nonradiological Impacts of the Uranium Fuel Cycle

4.13.3.1 Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

SMALL. The nonradiological impacts of the uranium fuel cycle resulting from the renewal of an OL for any plant would be small.

4.13.3.2 Requirement [10 CFR 51.53(c)(3)(iv)]

The ER must contain any new and significant information regarding the environmental impacts of license renewal of which the applicant is aware.

4.13.3.3 Background [GEIS Section 4.12.1.1]

Data on the nonradiological impacts of the fuel cycle are provided in Table S-3. These data cover land use, water use, fossil fuel use, and chemical effluents. The significance of the environmental impacts associated with these data was evaluated in the 1996 GEIS on the basis of several relative comparisons. It was noted that the impacts associated with uses of all of the above resources would be SMALL. Any impacts associated with nonradiological liquid releases from the fuel cycle facilities would also be SMALL. As a result, the aggregate nonradiological impact of the uranium fuel cycle resulting from the renewal of an OL for a plant would be SMALL, and it was considered a Category 1 issue in the 1996 GEIS.

4.13.3.4 Analysis

This issue concerns the direct nonradiological impacts from facilities involved in supplying nuclear fuel to nuclear power plants. The issue was considered in FPL's new and significant review, and no new and significant information was identified as it relates to nonradiological impacts of the uranium fuel cycle; therefore, no further analysis is required. The issue was also considered in PTN's first license renewal's new and significant review, and no new and significant information was found at that time (FPL 2000b, Table 4.0-2).

4.13.4 Transportation

4.13.4.1 Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

SMALL. The impacts of transporting materials to and from uranium-fuel-cycle facilities on workers, the public, and the environment are expected to be small.

4.13.4.2 Requirement [10 CFR 51.53(c)(3)(iv)]

The ER must contain any new and significant information regarding the environmental impacts of license renewal of which the applicant is aware.

4.13.4.3 Background [GEIS Section 4.12.1.1]

The impacts associated with transporting fresh fuel to one 1,000 MWe model light-water reactor and with transporting spent fuel and radioactive waste (LLW and mixed waste) from that light water reactor are provided in Table S-4 in 10 CFR 51.52. Similar to Table S-3, and as indicated in 10 CFR 51.52, every ER prepared for the construction permit stage of a commercial nuclear power plant must contain a statement concerning the transport of fuel and radioactive waste to and from the reactor. A similar statement is also required in LRAs. Table S-4 forms the basis of such a statement.

In 1999, the NRC issued an addendum to the 1996 GEIS in which the agency evaluated the applicability of Table S-4 to future license renewal proceedings, given that the spent fuel is likely to be shipped to a single repository (as opposed to several destinations, as originally assumed in the preparation of Table S-4) and given that shipments of spent fuel are likely to involve more highly enriched fresh fuel (more than 4 percent as assumed in Table S-4) and higher-burnup spent fuel (higher than 33,000 MWd/MTU as assumed in Table S-4). In the addendum, the NRC evaluated the impacts of transporting the spent fuel from reactor sites to the candidate repository at Yucca Mountain and the impacts of shipping more highly enriched fresh fuel and higher-burnup spent fuel. On the basis of the evaluations, the NRC concluded that the values given in Table S-4 would still be bounding, as long as the (1) enrichment of the fresh fuel was 5 percent or less, (2) burnup of the spent fuel was 62,000 MWd/MTU or less, and (3) higher-burnup spent fuel (higher than 33,000 MWd/MTU) was cooled for at least 5 years before being shipped offsite.

4.13.4.4 Analysis

The NRC did not revisit the radiological impact analysis of transporting spent nuclear fuel to away from reactor storage locations in the 2014 GEIS for Continued Storage of Spent Nuclear Fuel and again stated that the radiological impact analysis can be found in Table S-4 (NRC 2014a).

As stated above, the NRC considered the impacts of this issue to be SMALL provided three conditions were met. As discussed in Section 2.2.1, the fuel used at PTN is enriched to a maximum of 5.0 percent, and the equilibrium core maximum fuel discharge burnup rate is approximately 62,000 MWd/MTU. Furthermore, as discussed in Section 2.2.6.5, spent fuel is stored on site in each of the units' spent fuel pools prior to transfer to onsite dry storage. The environmental assessment for the EPU determined that spent fuel management was bounded by the impacts analyzed in Table S-4 (NRC 2012b). The issue was considered in FPL's new and significant review, and no new and significant information was identified as it relates to nonradiological impacts of the uranium fuel cycle; therefore, no further analysis is required. The issue was also considered in PTN's first license renewal's new and significant review, and no new and significant information was found at that time (FPL 2000b, Table 4.0-2).

4.14 Termination of Nuclear Power Plant Operations and Decommissioning

The following sections address the issue of license termination and decommissioning, providing background on the issue and an analysis of the issue as it applies to the SLR period.

4.14.1 Findings from 10 CFR Part 51, Subpart A, Appendix B, Table B-1

SMALL. License renewal is expected to have a negligible effect on the impacts of terminating operations and decommissioning on all resources.

4.14.2 Requirement [10 CFR 51.53(c)(3)(iv)]

The ER must contain any new and significant information regarding the environmental impacts of license renewal of which the applicant is aware.

4.14.3 Background [GEIS Sections 4.12.2 and 4.12.2.1]

The NRC evaluated the impacts of decommissioning nuclear plants in NUREG-0586, the *Generic Environmental Impact Statement for Decommissioning Nuclear Facilities: Supplement 1, Regarding the Decommissioning of Nuclear Power Reactors* (NRC 2002b).

This section describes and discusses the environmental consequences of terminating nuclear power plant operations and decommissioning, but the only impacts attributable to the proposed action (license renewal) are the effects of an additional 20 years of operations on the impacts of decommissioning. The majority of the impacts associated with plant operations would cease with reactor shutdown; however, some impacts would remain unchanged, while others would continue at reduced or altered levels. Some new impacts might also result directly from terminating nuclear power plant operations.

Terminating nuclear power plant operations would result in the cessation of actions necessary to maintain the reactor, as well as a significant reduction in the workforce. NRC presumes that terminating nuclear power plant operations would not immediately lead to the dismantlement of the reactor or other infrastructure, much of which would still be in use to support other units on site that continued to operate. Even for sites with just one unit, some facilities would remain in operation to ensure that the site was maintained in safe shutdown condition.

4.14.4 Analysis

Only the incremental increase in the impacts of termination of plant operations and decommissioning attributable to continued operation during the SLR term is within the scope of this issue. The additional operating years would generate additional spent nuclear fuel to be managed during the decommissioning period, as well as potentially greater volumes of radioactive waste or radioactive materials. The proposal to continue operation during an SLR term does not include construction of additional plant structures that would require decommissioning, and additional workers are not anticipated for the SLR term that would incrementally increase socioeconomic impacts of termination of plant operations. FPL would plan and conduct decommissioning activities in accordance with NRC-reviewed methods and evaluate anticipated environmental impacts to ensure they are bounded by previously issued environmental assessments or are SMALL. No new and significant information has been identified for this issue; therefore, no further analysis is required.

The decommissioning impacts component of this issue was considered in PTN's first license renewal's new and significant review, and no new and significant information was found at that time (FPL 2000b, Table 4.0-2). The GEIS (NRC 2013a) combined several Category 1 decommissioning issues in the 1996 GEIS and added consideration of termination of plant operations.

4.15 Severe Accident Mitigation Alternatives Analysis

The following sections address severe accident mitigation alternatives (SAMAs) analysis applicable to PTN, providing background on the issues and the analyses regarding the SLR period.

In 2000, FPL submitted an application for OL renewal, which was approved in 2002. The original 40-year OLs for PTN were thereby renewed for a period of 20 years. As part of the first license renewal process, a detailed evaluation of potential SAMAs was performed. Of the 169 potential SAMAs identified in the first license renewal, 93 were qualitatively screened from further evaluation (e.g., those that are only applicable to boiling water reactors), and a detailed cost-benefit analysis was performed on the 76 SAMAs that could not be screened (FPL 2000a). The cost-benefit analysis included development of a Level 3 probabilistic risk assessment (PRA) for PTN Unit 3, which was used to calculate conditional offsite population doses and offsite economic consequences for each of the PRA source term categories (STCs). The analysis was developed for Unit 3, and applicable to the license renewal for both units (FPL 2000a). By calculating the reduction in STC frequencies for each potential SAMA, the present value dollar benefit of each was determined, utilizing the guidance of NUREG/BR-0184 (NRC 1997). The benefit was then compared to a cost estimate for each to complete the cost-benefit comparison. The conclusion of the analysis was that none of the proposed SAMAs were cost beneficial to PTN.

As part of the SLRA process to renew the PTN OLs for another 20 years, the PTN PRA was again examined for insights. The purpose was to determine if there was any new and significant information regarding the SAMA analyses that were prepared to support issuance of the initial renewed OLs for PTN. Over the course of plant operation, changes are made to the plant design, operation, and maintenance practices. Periodic updates to the PTN PRA have ensured that the PRA includes the relevant changes and continues to reflect the current plant design and operation. PRA updates also include updates to the plant-specific initiating event and equipment data utilized, and improvements in state-of-the-art analysis of severe accidents. Therefore, the PRA provides valuable insights into the risk significance of the plant changes over time.

The analyses below follow the model approach in NEI 17-04 [Rev. 0] (NEI 2017c), which NEI has submitted for endorsement by the NRC staff for determining whether there is new and significant information regarding the SAMA analyses. For the PTN SLRA, the consideration of new and significant changes since the time of the first license renewal is consistent with the GEIS (NRC 2013a), Supplement 49 (NRC 2014b). Section 5.3.9 of GEIS Supplement 49 states the following:

New information is significant if it provides a seriously different picture of the impacts of the federal action under consideration. Thus, for mitigation alternatives such as SAMAs, new information is significant if it indicates that a mitigation alternative would substantially reduce an impact of the federal action on the environment. Consequently, with respect to SAMAs, new information may be significant if it indicated a given cost-beneficial SAMA would substantially reduce the impacts of a severe accident or the probability or consequences (risk) of a severe accident occurring.

The implication of this statement is that "significance" is not solely related to whether or not a SAMA is cost beneficial, but depends also on a SAMA's potential to significantly reduce risk to the public (NEI 2017c).

4.15.1 Category 1 Issue—Design-Basis Accidents

The following Category 1 issue related to postulated accidents was reviewed for new and significant information that could make the generic finding as described in the GEIS (NRC 2013a) inapplicable to PTN: Issue 65—Design-basis accidents.

The GEIS (NRC 2013a) concluded that because a licensee is required to maintain the plant within acceptable design and performance criteria, including during any license renewal term, impacts from design-basis accidents would not be affected by changes in plant environment because such impacts (1) are based on calculated radioactive releases that are not expected to change; (2) are not affected by plant environment because they are evaluated for the hypothetical maximally exposed individual; and (3) have been previously determined acceptable.

4.15.2 Category 2 Issue—Severe Accidents

The following Category 2 issue (requirement) related to severe accidents has been defined by the NRC in 10 CFR 51.53(c)(3)(ii)(L):

If the staff has not previously considered SAMAs for the applicant's plant in an EIS or related supplement or in an environmental assessment, a consideration of alternatives to mitigate severe accidents must be provided.

The NRC finding regarding severe accidents is stated in 10 CFR Part 51, Subpart A, Appendix B, Table B-1, as follows:

The probability-weighted consequences of atmospheric releases, fallout onto open bodies of water, releases to groundwater, and societal and economic impacts from severe accidents are small for all plants. However, alternatives to mitigate severe accidents must be considered for all plants that have not considered such alternatives.

The NRC has ruled that when a plant qualifies for the exception from the requirement to consider SAMAs in 10 CFR 51.53(c)(3)(ii)(L), the exception operates to designate this Category 2 issue as the "functional equivalent" of a Category 1 issue (NRC 2013f). Accordingly, using a review process similar to that used for other Category 1 issues, FPL reviewed this issue for new and significant information that would cause the following generic conclusions in the GEIS (NRC 2013a) concerning this issue to be inapplicable to PTN.

1. The probability-weighted consequences of atmospheric releases, fallout onto open bodies of water, releases to groundwater, and societal and economic impacts from severe accidents are small for all plants.

2. License renewal ERs for plants for which SAMAs have been previously considered need not consider SAMAs.

The subsections below describe the methodology and review for each conclusion.

4.15.3 Methodology for Evaluation of New and Significant SAMAs

4.15.3.1 PTN SLRA SAMA Stage 1 Evaluations—Screening

The evaluations of the PTN SLRA SAMAs are consistent with the NEI 17-04 methodology (NEI 2017c), which describes a three-stage process for determining whether there is any "new and significant" information relevant to a previous SAMA analysis. In Stage 1, the SLRA applicant uses PRA risk insights and/or risk model quantifications to estimate the percent reduction in the maximum benefit (MB) associated with (1) all unimplemented "Phase 2" SAMAs for the analyzed plant and (2) those SAMAs identified as potentially cost beneficial for other U.S. nuclear power plants and which are applicable to the analyzed plant. If one or more of those SAMAs are shown to reduce the MB by 50 percent or more, then the applicant must complete Stage 2 by developing updated averted cost-risk estimates for implementing those SAMAs. If the Stage 2 assessment confirms that one or more SAMAs reduce the MB by 50 percent or more, then the applicant must complete Stage 3 by performing a cost-benefit analysis for the "potentially significant" SAMAs identified in Stage 2. Applicants that are able to demonstrate through the Stage 1 screening process that there is no potentially significant new information are not required to perform the Stage 2 or Stage 3 evaluations. The application of the NEI 17-04 methodology to PTN is described in the following subsections.

4.15.3.1.1 Definitions of New and Significant Information

"New" information pertains to data used in a SAMA analysis that have changed or become available since the time the preceding SAMA analysis was performed.

There are some inputs to the SAMA analysis that are expected to change, or to potentially change, for all plants. These inputs include the following:

- Updated Level 3 PRA model consequence results, which may be impacted by multiple inputs, including, but not limited to, the following:
    - Population, as projected within a 50-mile radius of the plant.
    - Value of farm and non-farm wealth.
    - Core inventory (e.g., due to power uprate).
    - Evacuation timing and speed.
    - Level 3 PRA methodology updates.
- NUREG/BR-0058 (NRC 2004) cost-benefit methodology updates.

In addition, other changes that could be considered "new information" are dependent on plant activities or site-specific changes. These types of changes include the following:

- Identification of a new hazard (e.g., a fault that was not previously analyzed in the seismic analysis).
- Updated plant risk model (e.g., a fire PRA that replaces the individual plant examination of external events [IPEEE] analysis).
    - Impacts of plant changes that are included in the plant risk models will be reflected in the model results and do not need to be assessed separately.

- Non-modeled modifications/changes to the plant.
  - o Modifications determined to have no risk impact need not be included (e.g., replacement of the condenser vacuum pumps), unless they impact a specific input to SAMA (e.g., a new low-pressure turbine in the power conversion system that results in a greater net electrical output).

For risk model updates performed to reflect the latest PRA model state of the practice, it was noted that the actual physical plant risk may not have changed; however, because the best-estimate assessment or understanding of the risk (e.g., plant-specific risk profile) has changed, it was considered to be new information.

The NEI methodology (NEI 2017c) considers a potential SAMA to not be significant unless it reduces the MB, as defined in Section 4.5 of NEI 05-01 [Rev. A], by at least 50 percent. The Stage 1 quantitative screening process evaluates this using the criterion of no STC frequency being reduced by at least 50 percent. Because the MB is the sum total of the contribution of each STC, if no STC decreases by at least 50 percent, then the total MB reduction cannot exceed 50 percent. However, the approach of evaluating every STC is not necessary to ensure the MB reduction is less than 50 percent. In reality, many individual STCs have a frequency that is insignificant, and while an insignificant STC could in theory be reduced by more than 50 percent, its impact on MB would be negligible. Therefore, for this analysis, STC groups (large early release frequency [LERF]; small early release frequency [SERF], etc.) were examined as a whole for percentage reduction. If no STC group frequency was reduced by more than 50 percent, then also the MB would not be reduced by more than 50 percent. Therefore, that SAMA would not be considered potentially significant and would not be evaluated further in assessing the significance of new information.

The quantitative evaluations performed for this analysis use the PTN internal events model for full evaluation of Level 2 STC groups. However, the PTN internal flood and fire models are only capable of quantifying core damage frequency (CDF) and the LERF STC group. PTN does not have a seismic PRA. In 2014, a bounding seismic evaluation was performed for PTN using appropriate seismic hazard curves and a plant-level fragility curve. While the bounding seismic evaluation for PTN was sufficient to demonstrate that seismic risk at PTN is not significant, the nature of the analysis does not lend itself to the detailed evaluations performed for this SLRA.

For consideration of total STC group frequencies being reduced by more than 50 percent, detailed calculations are performed for the internal events STC group and for fire/flood LERF (CDF was also quantified). The fire/flood LERF and CDF calculations provide confidence that their impact from each SAMA is consistent with the internal events calculations, and that the MB would not be reduced by more than 50 percent for any of the SAMAs evaluated. Since PTN does not have a seismic PRA, its impact is considered represented by the internal events analyses. Because the Stage 1 analysis evaluates percentage (and not absolute value) reduction in MB, the percentage reduction in seismic would be consistent with internal events and fire. In terms of internal floods and external event consideration, the percentage reduction in total MB is comparable or conservatively represented by utilizing the internal events models. The flood and fire models utilize the logic from the Level 1 PRA event trees. Most fire and seismic significant contributors would utilize the sequence logic of loss of offsite power (LOOP) and/or station blackout (SBO) events. Therefore, the percentage reduction in MB achieved by each SAMA would be similar to that of the internal events LOOP and SBO analyses. While this would yield some change to the specific contribution on each STC group, the changes are not expected to be significant because of the use of the same supporting event tree logic.

It is also important to note that the FPL internal events model receives a significant contribution to LERF (and also MB) from interfacing systems loss-of-coolant accident (ISLOCA) (19 percent of total internal events MB). The external events analysis, however, does not have any contribution from ISLOCA initiating events. Since ISLOCA events have a significant contribution to the overall MB, this reduces the relative contribution from external events.

Regarding new information about changes in population near the PTN site and changes in methodology (e.g., dollar/person-rem estimates), there are some changes since the first PTN license renewal and SAMA analysis. However, compared to the greater than a factor of 20 decrease in the absolute value of internal events CDF at PTN, the other changes are small. Specifically, the PTN model used to evaluate the SAMA in the initial LRA had an internal events CDF of approximately 1.6E-5/year. The current model of record has a CDF of approximately 7.0E-7/year for each unit.

4.15.4 Analysis

4.15.4.1 Identification and Screening

The list of candidate SAMAs for the PTN SLRA was developed from plant-specific and industry sources. For the plant-specific portion, the first PTN license renewal SAMA evaluation was examined to identify all SAMAs that could not be qualitatively screened, and they were found not to be cost effective. Evaluating these items was appropriate for determining if there was any new and significant information for PTN and the PRA since the time of the first license renewal in regard to the potential plant improvements.

The GEIS (NRC 2013a) includes the SEISs that licensees were required to prepare to address potential environmental impacts and mitigation measures for 23 issues requiring plant-specific review. Potentially cost-beneficial SAMAs were identified by licensees as part of this review and are documented in these plant-specific supplements. As PTN has a large, dry pressurized water reactor containment, the scope of the search was limited to these designs.

The list of SAMAs collected was evaluated qualitatively to screen from further evaluation any SAMAs not applicable to PTN, or that already have been implemented at PTN. In addition, one other screening criterion was applied to eliminate SAMAs that have excessive implementation costs. Specifically, SAMAs were screened from further consideration if they were found to reduce the PTN MB by greater than 50 percent in the first PTN license renewal, but nonetheless were found not to be cost effective due to their high estimated costs of implementation in the first LRA and the related NRC SEIS.

The remaining SAMAs were then grouped based on similarities in mitigation equipment or risk-reduction benefits, and all were evaluated for the impact they would have on the PTN STC group frequencies, assuming those SAMAs were implemented at PTN. If any of the SAMAs were found to reduce at least one STC group frequency by at least 50 percent, then the SAMA would retained for a full Level 3 PRA evaluation of the reduction in MB.

4.15.4.2 Stage 1 Screening Evaluation

Industry internal event and external event SAMAs were collected for evaluation in the PTN SLRA. The total number of PTN-specific SAMAs considered was 76. The total number of industry SAMAs considered was 263. Qualitative screening of each from further analysis resulted in elimination of all external event SAMAs in the PTN SLRA. Qualitative screening of the internal events SAMAs, along with binning of similar SAMAs, reduced the total number of SAMAs requiring further evaluation to 13. The binning of SAMAs was performed in a manner that allowed bounding cases that completely addressed a plant risk contributor to be defined to estimate the maximum possible benefits for any of the grouped SAMAs. For example, all ISLOCA-related SAMAs could be represented by a single case in which all ISLOCA events are set to zero (i.e., the risk of an ISLOCA event was assumed to be completely eliminated by SAMA implementation). This bounding approach ensured a conservative analysis, while limiting the total number of cases requiring more detailed evaluation.

Table 4.15-1 presents the industry internal events SAMAs, combined with the PTN-specific SAMAs selected for quantitative screening analysis. "Quantitative screening" refers to the methodology described in preceding sections and was performed using the full internal events Level 2 PRA and the CDF/LERF portions of the fire and flood PRAs. Specifically, SAMAs are quantitatively screened if the bounding PTN-specific case yields a reduction of less than 50 percent in the frequency of each STC group.

The first column presents a number assigned to each SAMA for tracking purposes. The second column is a case identifier. The third column provides a summary description of each potential SAMA; the fourth column provides the results of the quantitative screening evaluation of the STC group frequencies, and the fifth column presents a summary assessment the screening. As presented in Section 4.15.4.1, the criterion for quantitative screening from further evaluation in the Stage 1 evaluation was that the SAMA does not reduce any STC group frequency by at least 50 percent.

After performing the qualitative and quantitative Stage 1 screening, all potential SAMAs were screened from further evaluation. Therefore, Stage 2 of the NEI methodology was not entered, and an update of the PTN Level 3 PRA was not required.

4.15.5 Conclusions

Based on the Phase 1 qualitative and quantitative screening results, all plant-specific and industry SAMAs were demonstrated to not be new and significant.

Therefore, it is concluded that there is no new and significant information that would alter the conclusions of the original SAMA analysis for PTN.

Table 4.15-1
Quantitative Screening of SAMAs that were not Qualitatively Screened (Sheet 1 of 9)

#	Case Name	Description of Bounding Case	Results				Notes
			Internal Events[a]	**Base Model Results**	**Case 1**	**% Change**	
1	HHSI-PMP	The case represents an additional high pressure safety injection pump with independent pump failures (fails to start, fails to run, pump in test and maintenance (T&M), failure to restore pump from T&M) and failures in high pressure safety injection discharge header and suction header.	CDF (ALLTOPS)	6.97E-07	5.76E-07	-17.36	All internal events STC group frequencies were reduced by less than 50 percent. Fire and flood CDF and LERF were reduced by less than 50 percent.

#	Case Name	Description of Bounding Case	Results				Notes
6	CISO	Set containment isolation failure to zero.	**Internal Events[(a)]**	**Base Model Results**	**Case 6**	**% Change**	All internal events STC group frequencies were reduced by less than 50 percent. Fire CDF and LERF were reduced by less than 50 percent. Reduction in internal flooding LERF was 71 percent. However, the absolute value of internal flooding LERF is only 2.40E-10/year, compared to the internal events and fire LERF that are several orders of magnitude larger and only show a reduction in the LERF group of 9.9 percent and 8.3 percent, respectively. Therefore, the flood contribution is negligible, and the total reduction of the LERF STC group for this case is well below 50 percent.

SERF–TOTAL: total frequency of small, early release containment failure end states

5.0 ASSESSMENT OF NEW AND SIGNIFICANT INFORMATION

> The environmental report must contain any new and significant information regarding the environmental impacts of license renewal of which the applicant is aware. [10 CFR 51.53(c)(3)(iv)]

The NRC has resolved most license renewal environmental issues generically and requires an applicant to analyze only those issues the NRC has not resolved generically. While NRC regulations do not require an applicant's ER to contain analyses of the impacts of those Category 1 environmental issues that have been generically resolved [10 CFR 51.53(c)(3)(i)], the regulations do require that an applicant identify any new and significant information of which the applicant is aware. [10 CFR 51.53(c)(3)(iv)]

5.1 New and Significant Information Discussion

The NRC provides guidance on new and significant information in Regulatory Guide 4.2, Supplement 1, Revision 1 (NRC 2013b). In this guidance, new and significant information is defined as follows:

1. Information that identifies a significant environmental impact issue that was not considered or addressed in the GEIS and, consequently, not codified in Table B-1, "Summary of Findings on NEPA Issues for License Renewal of Nuclear Plants," in Appendix B, "Environmental Effect of Renewing the Operating License of a Nuclear Power Plant," to Subpart A, "National Environmental Policy Act—Regulations Implementing Section 102(2)," of 10 CFR Part 51;

2. Information not considered in the assessment of impacts evaluated in the GEIS leading to a seriously different picture of the environmental consequences of the action than previously considered, such as an environmental impact finding different from that codified in Table B-1; or

3. Any new activity or aspect associated with the nuclear power plant that can act upon the environment in a manner or an intensity and/or scope (context) not previously recognized.

Based on available guidance and the definitions of SMALL, MODERATE, and LARGE impacts provided by NRC in 10 CFR Part 51, Appendix B, Table B-1, Footnote 3, FPL expects that any new information regarding Category 1 issues with moderate or large impacts would be significant. Section 4.0.2 presents the NRC definitions of SMALL, MODERATE, and LARGE impacts.

5.2 New and Significant Information Review Process

FPL's new and significant information assessment process outlined in the following discussion was designed to meet the guidance in the regulatory guide noted above.

FPL's process is collectively carried out through its ongoing environmental planning, assessment, monitoring, and compliance activities performed by corporate and PTN management and staff and ER-specific reviews. This team has collective knowledge of the license renewal process, the site, licensing and permitting, environmental issues, the first license renewal of PTN, the NEPA process, and nuclear industry activities. The team implemented the in-house process for reviewing and evaluating environmental issues that could potentially be new and significant information.

FPL's new and significant review included establishment of applicable and non-applicable Category 1 issues through the following:

- Review of the FPL first license renewal ER (FPL 2000a), the related NRC SEIS (NRC 2002a), and the GEIS Category 1 issues discussion (NRC 2013a).
- Review of recent publicly available information, or information held by the applicant, related to the resource area and each applicable Category 1 impact issue, as summarized in the appropriate section of Chapter 3.
- Identification and review of modifications to PTN since the most recent licensing environmental review and, if any, those anticipated during the proposed SLR operating period, including refurbishment. However, no license renewal-related refurbishment activities have been identified.
- Identification and assessment of potential changes in environmental interfaces since the most recent environmental review and those anticipated during the proposed license renewal period.

FPL applied an investigative process for purposely seeking new information related to the Category I environmental issues through the following:

- Environmental review team discussions with FPL subject matter experts on the Category 1 issues as they relate to the plant.
- Review of permits and reference materials listed in Table 9.1-1 and Chapter 1 related to regulatory compliance status of the plant, environmental issues at the plant, and the environmental resource areas related to Category 1 issues.
- Review of environmental monitoring and reporting required by regulations.

- Review of FPL environmental programs and procedures.
- Review of correspondence and permitting documentation related to oversight of Turkey Point facilities and operations by state and federal regulatory agencies (permanent activities that would bring significant issues to the plant's attention) for the agencies' roles in identifying site-specific environmental concerns.
- Review of previous LRAs for issues relevant to the PTN application.
- Review of previous licensing actions at the Turkey Point site, including but not limited to the PTN Units 3 and 4 EPU and the Turkey Point Units 6 and 7 COL application.
- Review of the environmental assessment for the 2014 UHS amendment and the related licensing board order.

In addition, FPL is made aware of and stays abreast of new and emerging environmental issues and concerns on an ongoing basis through the following:

- Review of other LRAs and nuclear industry publications and participation in nuclear industry organizations.
- Involvement in the recent Turkey Point Units 6 and 7 COL application and NRC reviews.
- Contact with state and federal agencies with regulatory jurisdiction over environmental regulation.
- Review of correspondence and permitting documentation and discussions related to oversight of PTN facilities and operations by state and federal regulatory agencies in their role in identifying site-specific environmental concerns.
- Development and periodic review of regulatory guidance procedures that address ongoing and emergent issues.

Information resulting from the information-seeking process was assessed to determine if it is new, applying the following considerations:

- Was the information included in or available for the GEIS analysis of the Category 1 issue?
- Was the information included in or available for the SEIS for PTN first license renewal?

The following considerations were applied to determine significance:

- Does the information identify an environmental issue not generically considered in the GEIS and consequently not codified in 10 CFR 51, Appendix B, Table B-1?
- Does the information present a seriously different picture of the environmental consequences of the action than previously considered, leading to an impact finding different (i.e., MODERATE or LARGE) from that included in the GEIS or codified in regulation?
- Does the information involve a new activity or aspect associated with the nuclear power plant that can act upon the environment in a manner or an intensity (MODERATE or LARGE impact) and/or scope (context) not previously recognized?

As a result of this review, FPL is aware of no new and significant information regarding the environmental impacts of license renewal associated with PTN. Therefore, the findings in NUREG-1437, Revision 1, for the applicable Category 1 issues are incorporated by reference.

New and significant review methodology and results for the SAMA evaluation are addressed separately in Section 4.15.

9.0 STATUS OF COMPLIANCE

The ER shall list all federal permits, licenses, approvals, and other entitlements which must be obtained in connection with the proposed action and shall describe the status of compliance with these requirements. The ER shall also include a discussion of the status of compliance with applicable environmental quality standards and requirements including, but not limited to, applicable zoning and land-use regulations, and thermal and other water pollution limitations or requirements which have been imposed by federal, state, regional, and local agencies having responsibility for environmental protection. [10 CFR 51.45(d)]

9.1 PTN Authorizations

Table 9.1-1 provides a summary of authorizations held by PTN for current plant operations. Authorizations in this context include any permits, licenses, approvals, or other entitlements that would continue to be in place, as appropriate, throughout the period of extended operation given their respective renewal schedules. Table 9.1-2 lists additional environmental authorizations and consultations related to the renewal of the PTN site. FPL routinely interacts with stakeholders and will notify the appropriate state and local agencies to inform them of the proposed action.

Table 9.1-1
Environmental Authorizations for Current PTN Operations (Sheet 1 of 7)

Agency	Authority	Requirement	Number	Expiration Date	Authorized Activity
CILLRWC	Omnibus Low-Level Radioactive Waste Interstate Compact Consent Act (1980; amended in 1985)	Authorization to export waste	None	Updated annually	Export of LLRW outside the region.
EPA & FDEP	Clean Water Act Section 401 [33 USC 1341]	Certification of state water quality standards	PA 03-45E	Final conditions of certification issued 3/29/2016	Discharges during license renewal term.
FAA	14 CFR Part 77 – Safe, Efficient Use, and Preservation of Navigable Airspace	FAA obstruction permit for Units 3 and 4	2009-ASO-4096-OE and 2009-ASO-4094-OE	N/A; pre-construction coordination	FAA obstruction permit for Units 3 and 4.
NRC	10 CFR 72	General license for storage of spent fuel at power reactor sites	General permit	N/A	Storage of power reactor spent fuel and other associated radioactive materials in an ISFSI.
NRC	Atomic Energy Act 10 CFR 50	Licensing of nuclear power plant	DPR-31	7/19/2032	Operation of Unit 3.
NRC	Atomic Energy Act 10 CFR 50	Licensing of nuclear power plant	DPR-41	4/10/2033	Operation of Unit 4.
US District Court	Clean Water Act	Consent decree	70-328-CA	N/A	IWW Construction, Operation, and Maintenance.

Table 9.1-1
Environmental Authorizations for Current PTN Operations (Sheet 2 of 7)

Agency	Authority	Requirement	Number	Expiration Date	Authorized Activity
USDOT	40 CFR 107 Subpart G	Registration	060911 551 091T	None	Hazardous materials shipments.
USACE & FDEP	Clean Water Act of 1976	Section 401/404 permit	Pending	Permit pending	Discharge of dredge and fill materials into waters of the U.S. (Turtle Point and Barge Terminal).
USACE & FDEP	Clean Water Act Section 401 [33 USC 1341]	Certification of State Water Quality Standards	FL0001562 (Section I.E. 15)	Under agency review	Discharges during license renewal term
USACE & FDEP	Resource Conservation and Recovery Act (RCRA) 42 USC 6901	Hazardous waste generator number	FLR000192922	N/A	Small Quantity Hazardous Waste Generator
USFWS	16 USC 1539(a)(1)(A) 50 CFR Parts 13, 17	Endangered species permit to take American crocodile during monitoring	TE092945-2	4/20/2018	Provides authorization to take (capture, examine, weigh, sex, collect tissue samples, mark, radio-tag, radio-track, relocate, release) endangered American crocodile individuals during population monitoring.

Table 9.1-1
Environmental Authorizations for Current PTN Operations (Sheet 3 of 7)

Agency	Authority	Requirement	Number	Expiration Date	Authorized Activity
USFWS	16 USC 703-712	Migratory bird special purpose utility permit	MB697722-0	3/31/2018	Authorizes utilities to collect, transport and temporarily possess migratory birds found dead on utility property, structures, and ROWs for avian mortality monitoring or disposal purposes.
USFWS	Biological Opinion	Effects of operation on the on the endangered American crocodile	41420-2006-FA-0478; 41420-2006-F-0125	Perpetual	Plan to minimize the potential adverse effects of ongoing operations of PTN to the American crocodile.
State of Florida Authorizations					
FDEP Siting Board	FS 403.501-.518	Power plant site certification	PA 03-45E	Final conditions of certification issued 3/29/2016	Construction and operation of a power plant with more than 75 MW of steam generated power and associated facilities.
SFWMD	Fifth Supplemental Agreement	Power plant site certification	N/A	N/A	Implementation of new monitoring plan that includes groundwater, surface water, and ecological monitoring in and around the Turkey Point CCS.

Environmental Authorizations for Current PTN Operations (Sheet 6 of 7)

Agency	Authority	Requirement	Number	Expiration Date	Authorized Activity
Tennessee Department of Environment and Conservation Division of Radiological Health	TDEC Rule 1200-2-10.32	Revision of existing Tennessee radioactive waste license for delivery		Annual authorization	Transport of radioactive waste into the State of Tennessee.
Local Authorizations					
MDC DERM	Section 24-18(A)17 Code of Miami-Dade County	Stratospheric ozone protection annual operations permit	APCF-001747-2017/2018	Annual renewal	Use of refrigerants R-12, R-22, R-502 for Robinair Recovery Units, Models 25200, 25200A, 25200B.
MDC DERM	40 CFR 403; Section 24-42.4 Code of Miami-Dade County	Domestic wastewater annual operating permit	DWO-000010-2017/2018	April 14, 2018 Annual renewal	Stabilization treatment facility.
MDC DERM	41 CFR 403; Section 24-42.4 Code of Miami-Dade County	Industrial waste annual operations permit	IW-000003-2017/2018	Annual renewal	Onsite disposal of Class III industrial solid waste consisting of earth and earth-like products, concrete, rock, bricks, and land clearing debris.
MDC DERM	42 CFR 403; Section 24-42.4 Code of Miami-Dade County	IW5 permit (or waiver)	IW-000016-2017/2018	Annual renewal	Hazardous materials or hazardous waste-, large user or generator.

Table 9.1-1
Environmental Authorizations for Current PTN Operations (Sheet 7 of 7)

Agency	Authority	Requirement	Number	Expiration Date	Authorized Activity
MDC DERM	43 CFR 403; Section 24-42.4 Code of Miami-Dade County	Operation of pollution control facility permit	IW5-006229-2017/2018	Annual renewal	Operation of fleet vehicle maintenance facility that generates waste oil, coolant, and used batteries with a solvent wash tank and served by septic tank.
MDC DERM	Chapter 24, Code of Miami-Dade County	Research permit on MDC DERM environmentally endangered lands	2011	6/17/2017	Authorization to conduct ecological monitoring on county-owned environmentally endangered lands.

CFR: Code of Federal Regulations
CILLRWC: Central Interstate Low-Level Radioactive Waste Commission
DOE: U.S. Department of Energy
FAA: Federal Aviation Administration
FAC: Florida Administrative Code
FDEP: Florida Department of Environmental Protection
FFWCC: Florida Fish and Wildlife Conservation Commission
FWS: U.S. Fish and Wildlife Service
MDC DERM: Miami-Dade County Department of Environmental Resources Management
NPS: National Park Service
NRC: U.S. Nuclear Regulatory Commission
SFWMD: South Florida Water Management District
USACE: U.S. Army Corps of Engineers
USDOT: U.S. Department of Transportation

Table 9.1-2
Environmental Authorizations and Consultations for PTN License Renewal

Agency	Authority	Requirement	Remarks
U.S. Nuclear Regulatory Commission	Atomic Energy Act [42 USC 2011 et seq.]	License renewal	Applicant for federal license must submit an ER in support of license renewal application.
U.S. Fish and Wildlife Service	Endangered Species Act Section 7 [16 USC 1636]	Consultation	Requires federal agency issuing a license to consult with the USFWS, and NMFS if applicable, regarding federally protected species.
National Marine Fisheries Service	Endangered Species Act Section 7 [16 USC 1636]	Consultation	Requires federal agency issuing a license to consult with the USFWS, and NMFS if applicable, regarding federally protected species.
Florida Department of State Historic Preservation Office	National Historic Preservation Act Section 106	Consultation	Requires federal agency issuing a license to consider cultural impacts and consult with SHPO and/or tribal historic preservation officer.
Miccosukee Tribe of Indians of Florida	National Historic Preservation Act Section 106	Consultation	Requires federal agency issuing a license to consider cultural impacts and consult with SHPO and/or tribal historic preservation officer.
Poarch Band of Creek Indians	National Historic Preservation Act Section 106	Consultation	Requires federal agency issuing a license to consider cultural impacts and consult with SHPO and/or tribal historic preservation officer.
Seminole Tribe of Florida	National Historic Preservation Act Section 106	Consultation	Requires federal agency issuing a license to consider cultural impacts and consult with SHPO and/or tribal historic preservation officer.
The Choctaw Nation of Oklahoma	National Historic Preservation Act Section 106	Consultation	Requires federal agency issuing a license to consider cultural impacts and consult with SHPO and/or tribal historic preservation officer.
Muscogee (Creek) Nation	National Historic Preservation Act Section 106	Consultation	Requires federal agency issuing a license to consider cultural impacts and consult with SHPO and/or tribal historic preservation officer.
Seminole Nation of Oklahoma	National Historic Preservation Act Section 106	Consultation	Requires federal agency issuing a license to consider cultural impacts and consult with SHPO and/or tribal historic preservation officer.

9.2 Status of Compliance

Turkey Point has established control measures in place to ensure compliance with the authorizations listed in Table 9.1-1, including monitoring, reporting, and operating within specified limits. Turkey Point environmental compliance coordinators are responsible for monitoring and ensuring that the site complies with its environmental permits and applicable regulations. Monitoring and sampling results associated with environmental programs are submitted to appropriate agencies, as specified in the permits and/or governing regulations.

9.2.1 Site Certification

The Florida PPSA, ss. 403.501-.518, F.S., is the state's centralized process for licensing large power plants. One license, a certification, replaces many of the local and state permits. Local governments and state agencies within whose jurisdiction the power plant is to be built participate in the process. However, additional state and local permits may be required that do not fall under the umbrella of site certification. Certification addresses permitting, land use and zoning, and property interests. A certification grants approval for the location of the power plant and its associated facilities such as a natural gas pipeline supplying the plant's fuel, rail lines for bringing coal to the site, and roadways and electrical transmission lines carrying power to the electrical grid, among others (FDEP 2017g).

Turkey Point Units 3 through 5 are licensed under the Florida PPSA, Chapter 403, Part II, F.S. Those units operate in accordance with the conditions of certification in their license, PA 03-45E. The Florida PPSA process provides a certification that encompasses many licenses and permits needed for affected Florida state, regional, and local agencies. It also includes any regulatory activity applicable under these agencies' regulations for PTN. COC X requires FPL to execute a fifth supplemental agreement with the SFWMD and to revise FPL's monitoring obligations, which resulted in the Turkey Point groundwater, surface water, and ecological monitoring plan, as amended (2009 monitoring plan) incorporated as Exhibit A to the fifth supplemental agreement between the SFWMD and FPL entered on October 16, 2009 (FDEP 2016b). On March 29, 2017, the State of Florida approved an amendment to the final conditions of certification to FPL authorizing the average daily withdrawal of the 28.06 MGD from the upper production zones of the Floridan Aquifer (FDEP 2016a). The final conditions of certification issued are binding and subject to the requirements listed in the Florida PPSA.

9.3 Notices of Violation

In April 2013, the SFWMD sent a letter to FPL indicating that the district had completed its technical analysis of data associated with implementation of the comprehensive pre-uprate monitoring report. The letter also provided notice to FPL to begin consultation with the SFWMD to identify measures to mitigate, abate, or remediate the movement of CCS saline water. Following the issuance of this letter, FPL began active consultation with the FDEP, SFWMD, and MDC DERM. The result of that consultation was an AO issued by the FDEP in December 2014 directing FPL to develop a salinity management plan to lower salinity in the CCS, among other requirements. (FDEP 2014b)

The AO was challenged by several parties, including MDC DERM. On October 2, 2015, MDC DERM issued an NOV to FPL for alleged violations of county water quality standards and criteria in groundwater. At the time the NOV was issued, FPL was working with MDC DERM to address its challenge to the AO. On October 7, 2015, MDC DERM entered into a CA (2015 CA) with FPL, which acknowledged FPL's plans to reduce salinity in the CCS, and required FPL to implement actions to intercept, capture, contain, and retract hypersaline groundwater west and north of the Turkey Point CCS boundary. It also required FPL to conduct additional monitoring and reporting. As a result, MDC DERM dropped its challenge to the AO. (MDC 2015)

The 2015 CA addresses MDC DERM's October 2015 NOV and defines actions that FPL must take. The principal specific objectives of the 2015 CA are for FPL: (1) to demonstrate a statistically valid reduction in salt mass and volumetric extent of the hypersaline water in groundwater west and north of FPL's property without creating adverse environmental impacts and (2) to reduce the rate of and arrest migration of hypersaline groundwater. Frequent meetings and correspondence between FPL and MDC DERM document the continued implementation of the CA. (MDC 2015)

The 2015 CA acknowledged the abatement activities that FPL was undertaking to lower the salinity of the CCS, thus reducing the movement of hypersaline water into the groundwater. The 2015 CA also recognized that factors beyond FPL's control may influence movement of groundwater in the surficial aquifer, and FPL must take into account such factors when developing and implementing remedial actions to minimize the timeframe for achieving compliance with the 2015 CA. FPL is moving forward with the implementation of the activities required by the 2015 CA. The 2015 CA also required FPL to consider alternative water sources to reduce chloride concentration, including, e.g., reclaimed water from Miami-Dade County. (MDC 2015)

The remaining challenges to the AO led to an administrative hearing in which the administrative law judge issued a recommended order to rescind or modify the AO. In response to that recommended order, the FDEP modified and issued the AO as a final AO on April 21, 2016. (FPL 2017c)

On April 25, 2016, the FDEP issued an NOV (the FDEP NOV) regarding the hypersaline groundwater to the west of the CCS and a warning letter identifying concerns related to water quality in deep artificial channels in four specific areas immediately adjacent to the east and south of the CCS. The FDEP NOV directed FPL to enter into consultations to develop a CO to develop corrective actions to reduce the CCS contribution to the hypersaline plume and to reduce the size of the hypersaline plume. On June 20, 2016, a CO (2016 CO) was executed between FPL and the FDEP. The 2016 CO and FPL's compliance with its requirements incorporate the issues and requirements identified in the final AO, as well as the FDEP NOV and the warning letter. As such, the 2016 CO supersedes all requirements of the final AO and rescinds the AO. (FDEP 2016b)

The primary objectives of the 2016 CO are to: (1) cease discharges from the CCS that impair the reasonable and beneficial use of the adjacent G-II groundwaters west of the CCS; (2) prevent releases of groundwater from the CCS to surface waters connected to Biscayne Bay that result in exceedances of surface water quality standards in Biscayne Bay by undertaking restoration projects at Turtle Point and Barge Basin; and (3) provide mitigation to address impacts due to historic operation of the CCS. To meet the first objective, the CO requires FPL to achieve an average annual salinity of 34 PSU by the end of the fourth year of freshening activities. If FPL is unable to meet this target, it must submit a plan to FDEP within 30 days with additional measures that it will implement to meet the target. FPL is moving forward with the implementation of the activities required by the 2016 CO activities including continued implementation of the nutrient management plan and thermal efficiency plan; complete construction of the RWS (Section 3.6.3.2.1) and commence full operation; initiate construction of Barge Basin and Turtle Point Canal restoration projects; and prepare and submit the annual monitoring reports. (FDEP 2016b)

On August 15, 2016, MDC DERM and FPL executed an addendum to the October 2015 CA (2016 CAA). The 2016 CAA requires FPL to take action to address MDC DERM's alleged violations of water quality standards and cleanup target levels relating to the exceedance of ammonia in deep remnant canals adjacent to the Turkey Point CCS. The 2016 CAA required FPL to prepare and submit a SAP to MDC DERM to allow for the identification of source(s) of the ammonia exceedances and the delineation of the vertical and horizontal extent of the subject ammonia exceedances in surface water. Additionally, the SAP was required to adequately address the ammonia exceedances to the surface waters surrounding the facility, including but not limited to, waters tidally connected to Biscayne Bay. (MDC 2016a)

Following MDC DERM approval, and FPL's implementation of the SAP, the 2016 CAA required FPL to prepare and submit a SAR addressing the requirements of the approved SAP, and further submit to MDC DERM a corrective action plan consisting of an environmental restoration plan to correct the exceedances of ammonia; details of proposed process modifications or changes in operational systems to manage and control the source(s) of ammonia to prevent future ammonia exceedances; and physical, structural, or hydraulic modifications to the area of the CCS to eliminate contributions of CCS water to surface water, including a timetable for implementation and completion of the corrective action plan. (MDC 2016a)

There have been no other federal (i.e., agencies other than the NRC), state, or local regulatory NOVs issued to the facility since the last license renewal.

9.4 Remediation Activities

Cooling Canal System

The actions FPL has taken over the last few years have resulted in improved conditions within the CCS. Most notably, FPL has observed improvements in thermal efficiency of the CCS as a direct result of sediment management activities. FPL has also been able to better control water salinity concentrations and algae that can result from significant drought conditions. (FPL 2017c)

Since operations of the underground injection well testing phase of the RWS began on September 28, 2016, as of June 30, 2017, approximately 3.7 BG of hypersaline groundwater from beneath the CCS have been extracted and disposed of in the naturally saline Boulder Zone formation located 3,200 feet below the surface. This amounts to approximately 890,000 tons of salts removed from the Biscayne Aquifer beneath the CCS. Construction of the ten RWS extraction wells began in June 2017 and the wells are expected to begin operations in early 2018. Groundwater models of the RWS indicate the westward migration of the hypersaline plume will be stopped in three years of operation, with retraction of the hypersaline plume north and west of the CCS beginning in 5 years. Retraction of the plume back to the FPL site boundary is projected in 10 years. (FPL 2017c)

As noted above, the extracted groundwater is disposed of in a deep injection well in the Boulder Zone under FDEP Permit No. 293962-002-UC. The FDEP has permitted FPL and others to discharge treated sewage and other wastes through injection wells into the Boulder Zone. The Boulder Zone is located in the Lower Floridan Aquifer and is overlaid by a confining layer that prevents upward migration of the water (see Section 3.6.2 for detailed description of the aquifers underlying PTN). The competency of the middle confining layer at the Turkey Point site was recently evaluated and confirmed by the NRC staff as part of the PTN Units 6 and 7 licensing proceeding (ASLB 2017; NRC 2016a, Section 5.2.13; NRC 2016d, Section 11.2.4).

FPL has determined that Upper Floridan Aquifer water wells are the best choice of water supply for meeting its CCS freshening objective. Operation of the 14 MGD Upper Floridan Aquifer freshening well system began on November 28, 2016. The brackish water from the Floridan wells (2.5 PSU compared to bay salinity at 34 PSU) is being used to help reduce the CCS salinity to an average annual level of 34 PSU, essentially equivalent to the salinity of the bay. The addition of this water was instrumental in minimizing the increase in salinity that ordinarily occurs during the dry season. Continued operation of the freshening wells during the wet season will further reduce CCS salinities, achieving progress towards the overall goal of 34 PSU. (FPL 2017c)

Deep Canal Ammonia

The SAP was submitted to the MDC DERM on September 14, 2016 and approved for implementation on December 21, 2016. The SAR was submitted on March 17, 2017 and concluded that the CCS is not the source of the measured elevated ammonia samples collected at some of the adjacent remnant canals connected to Biscayne Bay. (FPL 2017d)

The data collected during the SAR investigation indicate the presence of elevated ammonia values in excess of MDC DERM surface water standards is not the result of point or non-point source contamination attributable to the Turkey Point site. Rather, the report concluded the occurrence of elevated ammonia is the result of the conversion of organic nitrogen sourced from organic wetland soils, decomposition of wetland and aquatic plant material, atmospheric nitrogen fixation, and natural microbial processes in anoxic, stagnant surface and groundwater environments similar to numerous other such occurrences documented along the coastal Biscayne Bay region. Therefore, FPL concludes that additional assessment work associated with the 2016 CAA is not warranted based on the SAP results. There is no evidence of any sources of ammonia being caused by FPL that warrant a corrective action plan by FPL. (FPL 2017d)

9.5 Federal, State, and Local Regulatory Standards: Discussion of Compliance

This section contains information regarding environmental programs identified in the 2013 GEIS that may or may not be applicable to the site, and current status of compliance with each program.

9.5.1 Atomic Energy Act

9.5.1.1 Radioactive Waste

As discussed in Section 2.2.6, PTN utilizes liquid, gaseous, and solid radioactive waste-management systems to collect and treat radioactive materials produced from the plants' generation. As a generator of both LLRW and spent fuel, PTN is subject to and complies with provisions and requirements of the Low-Level Radioactive Waste Policy Amendment Act of 1985 and the Nuclear Waste Policy Act of 1982, as subsequently amended.

PTN also complies with permits issued by (1) the Central Interstate Low-Level Radioactive Waste Commission for exporting radioactive waste outside the region; (2) the Mississippi Emergency Management Agency for transportation of radioactive material into, within, or through the state of Mississippi; and (3) the Tennessee Department of Environment and Conservation for shipping radioactive material to a licensed disposal/processing facility within the state of Tennessee.

9.5.2 Clean Air Act

9.5.2.1 Air Permit

PTN has a permit to operate backup diesel generators, diesel generator engines, and one diesel pump (FDEP 2014a).

Operation of these air emission sources is maintained within the emissions, opacity, fuel sulfur content, and fuel usage (as applicable) limits established in the station air permit issued by the FDEP. As required by the air permit, reports are submitted annually and semiannually to the FDEP. Due to its co-location with the Turkey Point Fossil Plant, PTN is considered a Title V major emission source. PTN is in compliance with this permit.

9.5.2.2 Chemical Accident Prevention Provisions [40 CFR Part 68]

PTN is not required to have a risk management plan under 40 CFR Part 68 because the amount of regulated chemicals present on site does not exceed the threshold quantities specified in 40 CFR 68.130 (FDEP 2014a).

9.5.2.3 Stratospheric Ozone [40 CFR 82]

Under Title VI of the CAA, the EPA is responsible for several programs that protect the stratospheric ozone layer. Regulations promulgated by the EPA to protect the ozone layer are contained in 40 CFR Part 82. Refrigeration appliances and motor vehicle air conditioners are regulated under Sections 608 and 609 of the CAA, respectively. A number of service practices, refrigerant reclamation, technician certification, and other requirements are covered by these programs. PTN is in compliance with Section 608 of the CAA as amended in 1990 and the implementing regulations codified in these regulations. The program to manage stationary refrigeration appliances at PTN is described in the FPL administrative procedure "Title VI: Stratospheric Ozone Protection" (PTN 2017c).

Because motor vehicle air conditioners are not serviced on site, Section 609 of the CAA is not applicable.

9.5.2.4 Stratospheric Ozone [Section 24-18(A)17 of the Miami-Dade County Code]

Section 24-18(A)17 of the Miami-Dade County Code requires that a stratospheric ozone protection permit be obtained to ensure that individuals meet and maintain the required training and certification and that they utilize the required recovery and recycling equipment and approved practices to prevent venting of ozone-depleting compounds (ODCs) to the environment. A permit is required to:

- Purchase, sell, offer to sale, let, or allow the distribution of regulated ODCs as defined in 24-5 of Chapter 24, the Environmental Code of Miami-Dade County. Regulated ODCs include, but are not limited to, Freon (R-12 and R-22), halon, and various other compounds defined by the EPA as having ozone-depleting potential.

- Perform installation, evacuation, recharge, repair, salvage, and maintenance services on any appliance or system containing regulated ODCs. Examples of these appliances or systems include, but are not limited to, mobile (automotive and freight) and stationary (wall and central) air-conditioning units, refrigerators, freezers, and fire extinguishing systems.

- Handle, recover, or recycle regulated ODCs from any appliance or system.

PTN operates under MDC DERM stratospheric ozone protection permit number APCF-001747 (Table 9.1-1). PTN is in compliance under Section 24-18(A)17 of the Miami-Dade County Code and maintains fleet procedures to ensure compliance (PTN 2017c).

9.5.3 Clean Water Act

9.5.3.1 Section 10/404 Permitting

PTN is currently seeking authorization through the FDEP and USACE for fill activities in the Barge Basin and Turtle Point. The canal was previously dredged to approximately -20 to -28 feet NAVD88 during the original construction of the plant to allow once-through cooling water from Units 1 and 2 to be discharged to the bay. The construction of the CCS replaced the need for the original cooling water discharge. Cooling water is no longer discharged, and the remnant canal has been plugged. The remnant canal and the adjacent area of scour are proposed to be backfilled to improve water quality in Biscayne Bay (FPL 2016d). PTN will comply with all regulatory requirements imposed by the FDEP and USACE as they relate to performing activities in federal jurisdictional waters.

9.5.3.2 Water Quality (401) Certification

Federal CWA Section 401 requires that applicants for a federal license to conduct an activity that might result in a discharge into navigable waters provide the licensing agency with a certification from the state that the discharge will comply with applicable CWA requirements (33 USC 1341). FPL is applying to the NRC for a license (i.e., license renewal) to continue PTN operations. PTN discharges to the CCS, which is not considered waters of the U.S.

FPL received confirmation of 401 certification in a letter from the FDEP to the USACE dated March 9, 2012 (FDEP 2012). The operating agreement between the FDEP and participating agencies identifies the final order issued as part of the PPSA as the 401 certification for the authorized power plant. Therefore, PTN has fulfilled the regulatory requirement to provide certification by the state.

9.5.3.3 NPDES Permit

FPL operates the CCS (IWW facility) under NPDES/IWW permit number FL0001562. This permit is issued pursuant to the federal NPDES program and Florida IWW permitting program. The permit authorizes wastewater discharges from the generating units through two internal outfalls into the CCS. The permit does not authorize direct discharges to surface waters of the state. The permit authorizes discharges from the CCS into Class G-III groundwater, which is part of the surficial aquifer system. Condition IV.1 of the permit provides that discharges to groundwater shall not cause a violation of the minimum criteria for groundwater specified in Rules 62-520.400 FAC, 62-520.430 FAC, and 62-520.400 FAC provide that discharges to groundwater shall not impair the reasonable and beneficial use of adjacent waters, either ground or surface (FDEP 2005).

9.5.3.4 Stormwater Permit

Plant stormwater is recycled to the CCS (IWW facility), which is an FDEP-permitted wastewater treatment facility. PTN has no intake or direct discharge to surface waters and therefore is designated as a zero-discharge facility under the NPDES permit. The NPDES permit requires monitoring of water quality at the internal outfalls that handle facility wastewater. The state IWW/NPDES permit is incorporated into the conditions of certification (State of Florida 2016)

9.5.3.5 Sanitary Wastewaters

As previously discussed in Section 2.2.7, PTN is equipped with its own sewage treatment plant. Sanitary waste from showers, water closets, toilets, etc. is routed to county-approved onsite septic systems for the fossil and land management facilities. The nuclear units' domestic wastewater is routed to an onsite, county and state approved, contact stabilization sewage treatment plant. Sanitary wastewater from PTN is regulated by PTN's MDC DERM permit number DWO-00010-99 (DERM 2017).

FPL complies with monthly reporting requirements to the FDEP to ensure compliance with permit conditions.

9.5.3.6 Spill Prevention, Control, and Countermeasures

The EPA's Oil Pollution Prevention Rule became effective January 10, 1974, and was published under the authority of Section 311(j)(1)(C) of the Federal Water Pollution Control Act. The regulation has been published in 40 CFR Part 112, and facilities subject to the rule must prepare and implement an SPCC plan to prevent any discharge of oil into or upon navigable waters of the United States or adjoining shorelines. PTN is subject to this rule and has a written SPCC plan that identifies and describes the procedures, materials, equipment, and facilities that are utilized at the station to minimize the frequency and severity of oil spills to meet the requirements of this rule.

9.5.3.7 Reportable Spills [40 CFR Part 110]

PTN is subject to the reporting provisions of 40 CFR Part 110 as it relates to the discharge of oil in such quantities as may be harmful pursuant to Section 311(b)(4) of the Federal Water Pollution Control Act. Any discharges of oil in such quantities that may be harmful to the public health or welfare or the environment must be reported to the EPA's national response center. Based on a review of records over the previous 5 years (2012–2016), there have been no releases at PTN that have triggered this notification requirement.

9.5.3.8 Reportable Spills [FAC 62-780.110]

PTN is also subject to the reporting provisions of FAC 62-780.110, and under the conditions of certification Attachment 4. This reporting provision requires that any release of oil having the potential to significantly pollute surface or groundwaters and which are not confined to a building or similar structure reported to the FDEP, the coordinator of emergency services of the locality that could reasonably be expected to be impacted, and appropriate federal authorities. Based on a review of records over the previous 5 years (2011–2016), there have been no releases at PTN that have triggered this notification requirement .

9.5.3.9 Facility Response Plan

PTN is not subject to the facility response plan risk requirements described in 40 CFR 112.20 because the facility does not transfer oil over water to or from vessels and does not store oil in quantities greater than 1 million gallons.

9.5.4 Safe Drinking Water Act

9.5.4.1 Safe Drinking Water Act

As discussed in Section 2.2.3, potable water for PTN is obtained from the Miami-Dade Rex system, which is part of the county's public water supply system. This water is used for plant processes, potable water, and for the plant fire protection program.

A new replacement water treatment plant, which supplies pure water for steam-related use, was completed in 2017. The new plant has the ability to treat either potable water or Upper Floridan Aquifer well water (as does the Unit 5 treatment plant). Injection wells on the Turkey Point site are permitted through the FDEP and do not endanger drinking water sources. Compliance with these permits (Table 9.1-1) ensures compliance under the Safe Drinking Water Act.

9.5.5 Endangered Species Act

Potential impacts on federally and state-listed species were considered in FPL's review and analysis in Section 4.6.6, and it was concluded that none would likely be adversely affected as a result of SLR.

Section 7 of the ESA requires federal agencies to ensure that their actions are not likely to jeopardize the continued existence of species that are listed, or proposed for listing, as endangered or threatened. Depending on the action involved, the ESA requires consultation with the USFWS, and with the NMFS if marine or anadromous species could be affected. Although FPL has invited comment from the USFWS and NMFS (Attachment B), a more structured consultation process with these agencies may be initiated by the NRC per Section 7 of the ESA.

9.5.6 Migratory Bird Treaty Act

The MBTA makes it unlawful to pursue, hunt, take, capture, kill, or sell birds listed and grants protection to any bird parts including feathers, eggs, and nests. FPL maintains state and federal avian permits, included in Table 9.1-1.

9.5.7 Bald and Golden Eagle Protection Act

The BGPA prohibits the take, transport, sale, barter, trade, import and export, and possession of eagles, making it illegal for anyone to collect eagles and eagle parts, nests, or eggs without a USFWS permit. Bald eagles are known to use the Turkey Point site; therefore, consultation with the USFWS is conducted prior to new activities and maintenance activities to ensure compliance with the BGPA. There are currently no BGPA permitting requirements associated with PTN operations.

9.5.8 Magnuson-Stevens Fishery Conservation and Management Act

As discussed in Section 3.7.8.3, according to the 2009 EFH Final Amendment, potential EFH exists within the proposed project area for the following species:

- Adult and juvenile gray snapper (*Lutjanus griseus*)
- All life stages of dog snapper (*L. jocu*)
- Juvenile mutton snapper (*L. analis*)
- All life stages of bluestriped grunt (*Haemulon sciurus*)
- Adult white grunt (*H. plumieri*)

- Juvenile and adult spiny lobster (*Panulirus argus*)
- All life stages of pink shrimp (*Farfantepenaeus duorarum*)

FPL has invited comment from the NMFS. Attachment B includes a copy of FPL correspondence with the DNR regarding potential effects that PTN SLR might have on EFH and HAPCs.

9.5.9 Marine Mammal Protection Act

The Marine Mammal Protection Act prohibits, with certain exceptions, the "take" of marine mammals in U.S. waters and by U.S. citizens on the high seas, and the importation of marine mammals and marine mammal products into the United States. There are currently no Marine Mammal Protection Act permitting requirements associated with PTN operations.

9.5.10 Coastal Zone Management Act

The federal Coastal Zone Management Act [16 USC 1451 et seq.] imposes requirements on applicants for a federal license to conduct an activity that could affect a state's coastal zone. The act requires the applicant to certify to the licensing agency that the proposed activity would be consistent with the state's federally approved coastal zone management program [16 USC 1456(c)(3)(A)]. NOAA has promulgated implementing regulations indicating that the requirement is applicable to renewal of federal licenses for activities not previously reviewed by the state [15 CFR 930.51(b)(1)]. The regulation requires the license applicant to provide its certification to the federal licensing agency and a copy to the applicable state agency [15 CFR 930.57(a)].

The NRC's Office of Nuclear Reactor Regulation has issued guidance to its staff regarding compliance with the act. This guidance acknowledges that Florida has an approved coastal zone management program (NRC 2013c). The entire state of Florida is designated as a coastal zone; therefore, Turkey Point is located within the Florida coastal zone.

FPL received confirmation of coastal zone certification in a letter dated March 9, 2012, from the FDEP to the USACE (FDEP 2012). The operating agreement between the FDEP and participating agencies identifies the final order issued as part of the PPSA as the CZMA consistency for the authorized power plant. Therefore, PTN has fulfilled the regulatory requirement to certify to the licensing agency that the proposed activity would be consistent with the state's federally approved coastal zone management program.

9.5.11 National Historic Preservation Act

Potential impacts on historic properties were considered in FPL review and analysis in Section 4.7.4.2, and it was concluded that no eligible historic properties are present on the Turkey Point site. As previously discussed in Section 3.8.6, administrative controls are in place for management of cultural resources ahead of any future ground-disturbing activities at the plant. These controls ensure that existing or potentially existing cultural resources are adequately protected, and assist PTN in meeting state and federal expectations.

Section 106 of the NHPA (16 USC 470 et seq.) requires federal agencies having the authority to license any undertaking, prior to issuing the license, to take into account the effect of the undertaking on historic properties and to afford the Advisory Council on Historic Preservation an opportunity to comment on the undertaking. Council regulations provide for establishing an agreement with any SHPO to substitute state review for council review (35 CFR 800.7). Although not required of an applicant by federal law or NRC regulation, FPL has invited comment from the Florida SHPO. Attachment C includes a copy of FPL correspondence with the Florida SHPO regarding potential effects that PTN SLR might have on historic or cultural resources. In accordance with Section 101(d)(2) of the NHPA (P.L. 102-575), FPL has chosen to initiate consultation with SHPO-identified tribal historic preservation officers (THPOs), designated representatives of tribes with no THPO, and with Indian tribes that may attach religious and cultural significance to historic properties within Florida.

9.5.12 Resource Conservation and Recovery Act

9.5.12.1 Nonradioactive Wastes

As a generator of hazardous and nonhazardous wastes, PTN is subject to and complies with RCRA and specific FDEP regulations contained in the site certification conditions of certification. PTN is classified as a small quantity generator of hazardous wastes (EPA 2017d). As a generator of hazardous wastes, PTN also maintains a hazardous waste generator identification number (Table 9.1-1). PTN has not received any violations for hazardous waste management in the past 5 years based on a review of its compliance history (EPA 2017d).

For most hazardous waste records, the regulations require that records be retained for at least 3 years from the date the hazardous waste, for which the record pertains, is last shipped offsite. It is an FPL fleet procedure to maintain most records for 3 years in accordance with the FPL non-radiological environmental protection program administrative guidance.

9.5.12.2 Reportable Spills [40 CFR Part 262]

PTN is subject to the reporting provisions of 40 CFR 262.34(d)(5)(iv)(C) as it relates to a fire, explosion, or other release of hazardous waste which could threaten human health outside the facility boundary or when the facility has knowledge that a spill has reached surface water. Any such events must be reported to the EPA's national response center.

Based on a review of records over the previous 5 years (2012–2016), there have been no releases at PTN that have triggered this notification requirement (EPA 2017e).

9.5.12.3 Mixed Wastes

Radioactive materials are regulated by the NRC under the AEA of 1954, and hazardous wastes are regulated by the EPA under the RCRA of 1976. Management of radioactive waste at PTN is discussed in Section 2.2.6. FPL has developed guidance documents for managing its hazardous waste streams, including mixed wastes. In addition, FPL inspects its waste management areas for compliance. FPL's management of its waste streams is in compliance with applicable regulatory standards and has not resulted in any NOVs for the 2012–2016 timeframe (EPA 2017e). FPL would continue to store and dispose of hazardous and nonhazardous waste in accordance with EPA and state regulations and dispose of the wastes in appropriately permitted treatment and disposal facilities during the SLR term. As indicated in the 2013 GEIS, PTN will continue existing systems and procedures to ensure proper storage and disposal.

9.5.12.4 Underground Storage Tanks [FAC 62-761]

FPL no longer utilizes underground storage tanks at Turkey Point. The six tanks previously utilized on the site have been removed (FDEP 2015).

9.5.12.5 Reportable Spills [§Site Certification]

FPL no longer utilizes underground storage tanks at Turkey Point; therefore, PTN is not subject to reporting requirements for the release of regulated substances from underground storage tanks.

9.5.13 Pollution Prevention Act

In accordance with RCRA Section 3002(b) and 40 CFR 262.27, a small or large quantity generator must certify that a waste minimization program is in place to reduce the volume and toxicity of the waste generated to the degree determined to be economically practical. As previously discussed in Section 4.11.5.4, PTN is meeting this requirement as procedural measures are in place to minimize hazardous waste generated to the maximum extent practical.

9.5.14 Federal Insecticide, Fungicide, and Rodenticide Act

Commercially approved herbicides may be used to maintain linear facilities connecting the collector yard to the switch yard. Maintenance must be performed in accordance with the SCA and any state and federal regulations concerning the use of herbicides. FPL must notify the FDEP Southeast District of the Department of Siting Coordination Office of the type of herbicides to be used at least 60 days prior to their first use (FDEP 2016a).

9.5.15 Toxic Substances Control Act

The Toxic Substances Control Act of 1976 regulates PCBs [40 CFR Part 761] and asbestos [40 CFR Part 763], both of which may be present at PTN. FPL procedure 0-ENV-601 provides guidance for asbestos removal to ensure compliance with state and federal regulations. PTN is in compliance with the PCB and asbestos regulations applicable to the facility.

9.5.16 Hazardous Materials Transportation Act

Because PTN ships offsite the hazardous materials regulated by the USDOT, the facility is subject to and complies with the applicable requirements of the Hazardous Materials Transportation Act described in 49 CFR, including the requirement to possess a current hazardous materials certificate of registration (Table 9.1-1).

9.5.17 Emergency Planning and Community Right-to-Know Act

9.5.17.1 Section 312 Reporting [40 CFR Part 370]

PTN is subject to and complies with Section 312 of the Emergency Planning and Community Right-to-Know Act, which requires the submission of an emergency and hazardous chemical inventory report (Tier II) to the local emergency planning commission, the state emergency response commission, and the local fire department. This report, which typically includes, but is not limited to, chemicals such as ammonium hydroxide, boric acid, CO_2, diesel fuel, electrohydraulic fluid, ethylene glycol, gasoline, hydrazine, hydrogen, lube oils, Nalco products, nitrogen, sodium hydroxide, and sulfuric acid, is submitted to these agencies annually.

9.5.17.2 Section 313 Reporting [40 CFR Part 372]

Because PTN is located on the same property as Turkey Point Units 1, 2, and 5, and the facilities are owned by the same entity, the facilities are designated as one "complex." By default, this subjects PTN to the Section 313 Toxic Release Inventory reporting requirements. Although reporting under this requirement may not be applicable in certain calendar years given, PTN is in compliance with the Section 313 Toxic Release Inventory reporting requirements.

9.5.18 Comprehensive Environmental Response, Compensation, and Liability Act

PTN is subject to the hazardous substance release and reporting provisions of the Comprehensive Environmental Response, Compensation, and Liability Act of 1980, as subsequently amended. Any release of reportable quantities of listed hazardous substances to the environment requires a notification to the EPA's national response center, the FDEP, and subsequent written follow-up within 15 days of the release. Based on a review of records over the previous 5 years (2012–2016), no releases at PTN have triggered this notification requirement. PTN has not received any NOVs for hazardous waste management in the past 5 years based on a review of its compliance history (EPA 2017f).

9.5.19 Farmland Protection Policy Act

The FPPA only applies to federal programs. The term "federal program" under this act does not include federal permitting or licensing for activities on private or non-federal lands. Therefore, because license renewal is considered a federal licensing activity and PTN is located on non-federal lands, the FPPA is not applicable.

9.5.20 Federal Aviation Act

Coordination with the Federal Aviation Administration (FAA) is required when it becomes necessary to ensure that the highest structures associated with the project do not impair the safety of aviation. Submission of a letter of notification (with accompanying maps and project description) to the FAA would result in a written response from the FAA certifying that no hazard exists or recommending project changes and/or the installation of warning devices such as lighting. PTN was originally authorized under FAA permit numbers 2009-ASO-4093-OE and

2009-ASO-4094-OE. The Turkey Point property is currently authorized under FAA permit numbers 2015-ASO-11359-OE (Unit 6) and 2015-ASO-11360-OE (Unit 7) (Table 9.1-1). No license renewal-related construction activities have been identified; therefore, no new notifications to the FAA are required.

9.5.21 Occupational Safety and Health Act

OSHA governs the occupational safety and health of the construction workers and operations staff. PTN and its contractors comply with OSHA's substantive requirements, as these are incorporated in the sites occupational health and safety practices.

9.5.22 State Water Use Program

The SCA for PTN authorized the average daily withdrawal of 28.06 mgd from the upper production zones of the Floridan Aquifer. Pursuant to section 373.236(4), F.S., every 10 years from the date of certification issuance, PTN must submit a water use compliance report for review and approval by SFWMD (FDEP 2016a). PTN is in compliance with this reporting requirement.

9.5.23 Miami-Dade County Zoning Requirements

PTN is located in unincorporated Miami-Dade County, Florida. Miami-Dade County has adopted a CDMP to meet the requirements of the Local Government Comprehensive Planning and Land Development Regulation Act, Chapter 163, Part II, F.S. The CDMP was last revised in October 2006 (FPL 2008).

PTN has a future land use category of "institutions, utilities, and communications," according to the Miami-Dade County CDMP map. The CDMP map illustrates the locations of major institutional uses, communication facilities, and utilities of metropolitan significance. The Miami-Dade County CDMP land use element allows a full range of institutions, communications, and utilities in the "institutions, utilities, and communications" future land use category. PTN, as well as Turkey Point Units 1, 2, and 5, are an allowed use under this land use designation (FPL 2008).

The Miami-Dade County Land Development Code (Code) has been adopted to implement the policies and objectives of the Miami-Dade CDMP and to regulate land development within the unincorporated portions of Miami-Dade County. The Code incorporates a zoning map that depicts the zoning categories of lands lying within unincorporated Miami-Dade County. PTN is zoned as "industrial unlimited manufacturing district" (IU-3). The IU-3 zoning district allows "atomic reactors" (i.e., nuclear reactors) as a permitted use in the Code. The SLR project is an allowed use in the IU-3 district and does not represent a change or adjustment to the existing use status of PTN. The Miami-Dade County Department of Planning and Zoning has concurred with that conclusion (FPL 2008). PTN is in compliance with all zoning requirements.

9.6 Environmental Reviews

FPL has procedural controls in place to ensure that environmentally sensitive areas at Turkey Point, if present, are adequately protected during site operations and project planning. These controls, which encompass nonradiological environmental resource areas such as land use, air quality, surface water and groundwater, terrestrial and aquatic ecology, historic and cultural resources, and waste management and pollution prevention consist of the following:

- Appropriate local, state, and/or federal permits are obtained or modified as necessary.
- BMPs are implemented to protect wetlands, natural heritage areas, and sensitive ecosystems.
- Appropriate agencies are consulted on matters involving federally and state-listed threatened, endangered, and protected species, and that BMPs are implemented to minimize impacts to these species.
- Appropriate agencies are consulted on matters involving cultural resources and to ensure BMPs are implemented to minimize impact to this resource.

In summary, FPL's administrative controls ensure that appropriate local, state, and/or federal permits are obtained or modified as necessary, that cultural resources and threatened and endangered species are protected if present, and that other regulatory issues are adequately addressed as necessary.

9.7 Alternatives

The discussion of alternatives in the ER shall include a discussion of whether alternatives will comply with such applicable environmental quality standard and requirements [10 CFR 51.45 (d)].

The natural gas combined cycle plant, new nuclear, and combination of natural gas combined cycle, and solar PV combination alternative discussed in Section 7.2.1 would be constructed and operated to comply with all applicable environmental quality standards and requirements.

19304 Federal Register / Vol. 83, No. 85 / Wednesday, May 2, 2018 / Notices

evidence of a chilled environment at the Byron Station.

III. Conclusion

The NRC staff conducted inspections at the Byron Station and Braidwood Station that assessed the licensee's compliance with the regulations under 10 CFR part 50, Appendix B, Criterion III, ''Design Control,'' and Criterion XVI, ''Corrective Action,'' related to the adequacy of the AOR for the structural design of the MSIV house and the main steam tunnel, and took enforcement action as outlined in the inspection reports identified above. The NRC staff requested that the licensee evaluate the SCWE concerns expressed in the petition, and conducted an inspection that assessed the licensee's SCWE at Byron Station. Based on the licensee's voluntary response and the results of the inspection, the NRC staff did not identify challenges to the licensee's SCWE or evidence of a chilled environment at the Byron Station and, therefore, determined that issuance of a chilling effect letter was not warranted. Because these actions address the underlying concerns raised in requests 1, 2, 4, and 5 of the petition, the petition is granted in part.

As provided in 10 CFR 2.206(c), a copy of this director's decision will be filed with the Secretary of the Commission for review. As provided by this regulation, the decision will constitute the final action of the Commission 25 days after the date of the decision unless the Commission, on its own motion, institutes a review of the decision within that time.

Dated at Rockville, Maryland, this 24th day of April, 2018.

For the Nuclear Regulatory Commission.

Brian E. Holian,

Acting Director, Office of Nuclear Reactor Regulation.

[FR Doc. 2018–09210 Filed 5–1–18; 8:45 am]

BILLING CODE 7590–01–P

NUCLEAR REGULATORY COMMISSION

[Docket Nos. 50–250 and 50–251; NRC–2018–0074]

Florida Power & Light Company; Turkey Point Nuclear Generating, Unit Nos. 3 and 4

AGENCY: Nuclear Regulatory Commission.

ACTION: License renewal application; opportunity to request a hearing and to petition for leave to intervene.

SUMMARY: The U.S. Nuclear Regulatory Commission (NRC) is considering an application for the subsequent license renewal of Renewed Facility Operating License Nos. DPR–31 and DPR–41, which authorize Florida Power & Light Company (FPL or the applicant) to operate Turkey Point Nuclear Generating Unit Nos. 3 and 4 (Turkey Point). The renewed licenses would authorize the applicant to operate Turkey Point for an additional 20 years beyond the period specified in each of the current renewed licenses. The current renewed operating licenses for Turkey Point expire as follows: Unit No. 3 on July 19, 2032, and Unit No. 4 on April 10, 2033.

DATES: A request for a hearing or petition for leave to intervene must be filed July 2, 2018.

ADDRESSES: Please refer to Docket ID NRC–2018–0074 when contacting the NRC about the availability of information regarding this document. You may obtain publicly-available information related to this document using any of the following methods:

- *Federal Rulemaking website:* Go to *http://www.regulations.gov* and search for Docket ID NRC–2018–0074. Address questions about NRC dockets to Jennifer Borges; telephone: 301–287–9127; email: *Jennifer.Borges@nrc.gov.* For technical questions, contact the individual listed in the **FOR FURTHER INFORMATION CONTACT** section of this document.
- *NRC's Agencywide Documents Access and Management System (ADAMS):* You may obtain publicly-available documents online in the ADAMS Public Documents collection at *http://www.nrc.gov/reading-rm/adams.html.* To begin the search, select ''ADAMS Public Documents'' and then select ''Begin Web-based ADAMS Search.'' For problems with ADAMS, please contact the NRC's Public Document Room (PDR) reference staff at 1–800–397–4209, 301–415–4737, or by email to *pdr.resource@nrc.gov.* The ADAMS accession number for each document referenced (if it is available in ADAMS) is provided the first time that it is mentioned in this document.
- *NRC's PDR:* You may examine and purchase copies of public documents at the NRC's PDR, Room O1–F21, One White Flint North, 11555 Rockville Pike, Rockville, Maryland 20852.

FOR FURTHER INFORMATION CONTACT: Lois M. James, Office of Nuclear Reactor Regulation, U.S. Nuclear Regulatory Commission, Washington, DC 20555–0001; telephone: 301–415–3306, email: *Lois.James@nrc.gov.*

SUPPLEMENTARY INFORMATION:

I. Introduction

By letters dated January 30, 2018 (ADAMS Package Accession No. ML18037A812); February 9, 2018 (ADAMS Accession No. ML18044A653); February 16, 2018 (ADAMS Package Accession No. ML18053A123); March 1, 2018 (ADAMS Package Accession No. ML18072A224), and April 10, 2018 (ADAMS Package Accession No. ML18102A521 and Accession No. ML18113A132), the NRC received an application from FPL, filed pursuant to Section 103 of the Atomic Energy Act of 1954, as amended (the Act), and part 54 of title 10 of the *Code of Federal Regulations* (10 CFR), to renew the operating licenses for Turkey Point at 2,644 megawatt thermal each. The Turkey Point units are pressurized-water reactors designed by Westinghouse Electric Company and are located in Homestead, Miami-Dade County, Florida. A notice of receipt of the subsequent license renewal application (SLRA) was published in the **Federal Register** (FR) on April 18, 2018 (83 FR 17196).

The NRC staff has determined that FPL has submitted sufficient information in accordance with 10 CFR 54.19, 54.21, 54.22, 54.23, 51.45, and 51.53(c), to enable the staff to undertake a review of the application, and that the application is, therefore, acceptable for docketing. The current Docket Nos. 50–250 and 50–251 for Renewed Facility Operating License Nos. DPR–31 and DPR–41, respectively, will be retained. The determination to accept the SLRA for docketing does not constitute a determination that a subsequent renewed license should be issued, and does not preclude the NRC staff from requesting additional information as the review proceeds.

Before issuance of the requested subsequent renewed licenses, the NRC will have made the findings required by the Act, and the Commission's rules and regulations. In accordance with 10 CFR 54.29, the NRC may issue a subsequent renewed license on the basis of its review if it finds that actions have been identified and have been or will be taken with respect to: (1) Managing the effects of aging during the period of extended operation on the functionality of structures and components that have been identified as requiring aging management review; and (2) time-limited aging analyses that have been identified as requiring review, such that there is reasonable assurance that the activities authorized by the renewed licenses will continue to be conducted in accordance with the current licensing basis and that any changes made to the plant's current licensing basis will comply with the Act and the Commission's regulations.

Additionally, in accordance with 10 CFR 51.95(c), the NRC will prepare an environmental impact statement as a supplement to the Commission's NUREG–1437, ''Generic Environmental Impact Statement for License Renewal of Nuclear Power Plants,'' dated June 2013. In considering the SLRA, the Commission must find that the applicable requirements of subpart A of 10 CFR part 51 have been satisfied, and that any matters raised under 10 CFR 2.335 have been addressed. Pursuant to 10 CFR 51.26, and as part of the environmental scoping process, the staff intends to hold public scoping meetings. Detailed information regarding the environmental scoping meetings will be the subject of a separate **Federal Register** notice.

II. Opportunity To Request a Hearing and Petition for Leave To Intervene

Within 60 days after the date of publication of this notice, any persons (petitioner) whose interest may be affected by this action may file a request for a hearing and petition for leave to intervene (petition) with respect to the action. Petitions shall be filed in accordance with the Commission's ''Agency Rules of Practice and Procedure'' in 10 CFR part 2. Interested persons should consult a current copy of 10 CFR 2.309. The NRC's regulations are accessible electronically from the NRC Library on the NRC's website at *http://www.nrc.gov/reading-rm/doc-collections/cfr/.* Alternatively, a copy of the regulations is available at the NRC's Public Document Room, located at One White Flint North, Room O1–F21, 11555 Rockville Pike (First Floor), Rockville, Maryland 20852. If a petition is filed, the Commission or a presiding officer will rule on the petition and, if appropriate, a notice of hearing will be issued.

As required by 10 CFR 2.309, a petition should specifically explain the reasons why intervention should be permitted with particular reference to the following general requirements for standing: (1) The name, address, and telephone number of the petitioner; (2) the nature of the petitioner's right under the Act to be made a party to the proceeding; (3) the nature and extent of the petitioner's property, financial, or other interest in the proceeding; and (4) the possible effect of any decision or order which may be entered in the proceeding on the petitioner's interest.

In accordance with 10 CFR 2.309(f), the petition must also set forth the specific contentions which the petitioner seeks to have litigated in the proceeding. Each contention must consist of a specific statement of the issue of law or fact to be raised or controverted. In addition, the petitioner must provide a brief explanation of the bases for the contention and a concise statement of the alleged facts or expert opinion which support the contention and on which the petitioner intends to rely in proving the contention at the hearing. The petitioner must also provide references to the specific sources and documents on which the petitioner intends to rely to support its position on the issue. The petition must include sufficient information to show that a genuine dispute exists with the applicant or licensee on a material issue of law or fact. Contentions must be limited to matters within the scope of the proceeding. The contention must be one which, if proven, would entitle the petitioner to relief. A petitioner who fails to satisfy the requirements at 10 CFR 2.309(f) with respect to at least one contention will not be permitted to participate as a party.

Those permitted to intervene become parties to the proceeding, subject to any limitations in the order granting leave to intervene. Parties have the opportunity to participate fully in the conduct of the hearing with respect to resolution of that party's admitted contentions, including the opportunity to present evidence, consistent with the NRC's regulations, policies, and procedures.

Petitions must be filed no later than 60 days from the date of publication of this notice. Petitions and motions for leave to file new or amended contentions that are filed after the deadline will not be entertained absent a determination by the presiding officer that the filing demonstrates good cause by satisfying the three factors in 10 CFR 2.309(c)(1)(i) through (iii). The petition must be filed in accordance with the filing instructions in the ''Electronic Submissions (E-Filing)'' section of this document.

A State, local governmental body, Federally-recognized Indian Tribe, or agency thereof, may submit a petition to the Commission to participate as a party under 10 CFR 2.309(h)(1). The petition should state the nature and extent of the petitioner's interest in the proceeding. The petition should be submitted to the Commission no later than 60 days from the date of publication of this notice. The petition must be filed in accordance with the filing instructions in the ''Electronic Submission (E-Filing)'' section of this document, and should meet the requirements for petitions set forth in this section, except that under 10 CFR 2.309(h)(2) a State, local governmental body, or Federally-recognized Indian Tribe, or agency thereof does not need to address the standing requirements in 10 CFR 2.309(d) if the facility is located within its boundaries. Alternatively, a State, local governmental body, Federally-recognized Indian Tribe, or agency thereof may participate as a non-party under 10 CFR 2.315(c).

If a hearing is granted, any person who is not a party to the proceeding and is not affiliated with or represented by a party may, in the discretion of the presiding officer, be permitted to make a limited appearance pursuant to the provisions of 10 CFR 2.315(a). A person making a limited appearance may make an oral or written statement of his or her position on the issues but may not otherwise participate in the proceeding. A limited appearance may be made at any session of the hearing or at any prehearing conference, subject to the limits and conditions as may be imposed by the presiding officer. Details regarding the opportunity to make a limited appearance will be provided by the presiding officer if such sessions are scheduled.

III. Electronic Submissions (E-Filing)

All documents filed in NRC adjudicatory proceedings, including a request for hearing and petition for leave to intervene (petition), any motion or other document filed in the proceeding prior to the submission of a request for hearing or petition to intervene, and documents filed by interested governmental entities that request to participate under 10 CFR 2.315(c), must be filed in accordance with the NRC's E-Filing rule (72 FR 49139; August 28, 2007, as amended at 77 FR 46562, August 3, 2012). The E-Filing process requires participants to submit and serve all adjudicatory documents over the internet, or in some cases to mail copies on electronic storage media. Detailed guidance on making electronic submissions may be found in the Guidance for Electronic Submissions to the NRC and on the NRC's website at *http://www.nrc.gov/site-help/e-submittals.html.* Participants may not submit paper copies of their filings unless they seek an exemption in accordance with the procedures described below.

To comply with the procedural requirements of E-Filing, at least 10 days prior to the filing deadline, the participant should contact the Office of the Secretary by email at *hearing.docket@nrc.gov,* or by telephone at 301–415–1677, to request (1) a digital identification (ID) certificate, which allows the participant (or its counsel or representative) to digitally sign submissions and access the E-Filing system for any proceeding in which it is participating; and (2) advise the Secretary that the participant will be submitting a request or other adjudicatory document (even in instances in which the participant, or its counsel or representative, already holds an NRC-issued digital ID certificate). Based upon this information, the Secretary will establish an electronic docket for the hearing in this proceeding if the Secretary has not already established an electronic docket.

Information about applying for a digital ID certificate is available on the NRC's public website at *http://www.nrc.gov/site-help/e-submittals/getting-started.html.* Once a participant has obtained a digital ID certificate and a docket has been created, the participant can then submit adjudicatory documents. Submissions must be in Portable Document Format (PDF). Additional guidance on PDF submissions is available on the NRC's public website at *http://www.nrc.gov/site-help/electronic-sub-ref-mat.html.* A filing is considered complete at the time the document is submitted through the NRC's E-Filing system. To be timely, an electronic filing must be submitted to the E-Filing system no later than 11:59 p.m. Eastern Time on the due date. Upon receipt of a transmission, the E-Filing system time-stamps the document and sends the submitter an email notice confirming receipt of the document. The E-Filing system also distributes an email notice that provides access to the document to the NRC's Office of the General Counsel and any others who have advised the Office of the Secretary that they wish to participate in the proceeding, so that the filer need not serve the document on those participants separately. Therefore, applicants and other participants (or their counsel or representative) must apply for and receive a digital ID certificate before adjudicatory documents are filed so that they can obtain access to the documents via the E-Filing system.

A person filing electronically using the NRC's adjudicatory E-Filing system may seek assistance by contacting the NRC's Electronic Filing Help Desk through the ''Contact Us'' link located on the NRC's public website at *http://www.nrc.gov/site-help/e-submittals.html,* by email to *MSHD.Resource@nrc.gov,* or by a toll-free call at 1–866–672–7640. The NRC Electronic Filing Help Desk is available between 9 a.m. and 6 p.m., Eastern Time, Monday through Friday, excluding government holidays.

Participants who believe that they have a good cause for not submitting documents electronically must file an exemption request, in accordance with 10 CFR 2.302(g), with their initial paper filing stating why there is good cause for not filing electronically and requesting authorization to continue to submit documents in paper format. Such filings must be submitted by: (1) First class mail addressed to the Office of the Secretary of the Commission, U.S. Nuclear Regulatory Commission, Washington, DC 20555–0001, Attention: Rulemaking and Adjudications Staff; or (2) courier, express mail, or expedited delivery service to the Office of the Secretary, 11555 Rockville Pike, Rockville, Maryland 20852, Attention: Rulemaking and Adjudications Staff. Participants filing adjudicatory documents in this manner are responsible for serving the document on all other participants. Filing is considered complete by first-class mail as of the time of deposit in the mail, or by courier, express mail, or expedited delivery service upon depositing the document with the provider of the service. A presiding officer, having granted a request for exemption from using E-Filing, may require a participant or party to use E-Filing if the presiding officer subsequently determines that the reason for granting the exemption from use of E-Filing no longer exists.

Documents submitted in adjudicatory proceedings will appear in the NRC's electronic hearing docket which is available to the public at *https://adams.nrc.gov/ehd,* unless excluded pursuant to an order of the Commission or the presiding officer. If you do not have an NRC-issued digital ID certificate as described above, click cancel when the link requests certificates and you will be automatically directed to the NRC's electronic hearing dockets where you will be able to access any publicly available documents in a particular hearing docket. Participants are requested not to include personal privacy information, such as social security numbers, home addresses, or personal phone numbers in their filings, unless an NRC regulation or other law requires submission of such information. For example, in some instances, individuals provide home addresses in order to demonstrate proximity to a facility or site. With respect to copyrighted works, except for limited excerpts that serve the purpose of the adjudicatory filings and would constitute a Fair Use application, participants are requested not to include copyrighted materials in their submission.

Detailed information about the subsequent license renewal process can be found under the Nuclear Reactors icon at *http://www.nrc.gov/reactors/operating/licensing/renewal.html* on the NRC's website. Copies of the application to renew the operating licenses for Turkey Point are available for public inspection at the NRC's PDR, and at *https://www.nrc.gov/reactors/operating/licensing/renewal/subsequent-license-renewal.html,* the NRC's website while the application is under review. The application may be accessed in ADAMS through the NRC Library on the internet at *http://www.nrc.gov/reading-rm/adams.html* under ADAMS Accession No. ML18113A132. As stated above, persons who do not have access to ADAMS or who encounter problems in accessing the documents located in ADAMS may contact the NRC's PDR reference staff by telephone at 1–800–397–4209 or 301–415–4737, or by email to *pdr.resources@nrc.gov.*

The NRC staff has verified that a copy of the SLRA is also available for inspection near the site at the Homestead Branch Library, 700 North Homestead Boulevard, Homestead, Florida 33030; South Dade Regional Library, 10750 SW 211th Street, Miami, Florida 33189; Naranja Branch Library, 14850 SW 280 St., Homestead, Florida 33032; and Main Library, 101 West Flagler St., Miami, Florida 33130.

Dated at Rockville, Maryland, this 27th day of April 2018.

For the Nuclear Regulatory Commission.

Eric R. Oesterle,

Chief, License Renewal Project Branch, Division of Materials and License Renewal, Office of Nuclear Reactor Regulation.

[FR Doc. 2018–09279 Filed 5–1–18; 8:45 am]

BILLING CODE 7590–01–P

NUCLEAR REGULATORY COMMISSION

[Docket Nos. 52–029 and 52–030; NRC–2008–0558]

Duke Energy Florida, LLC; Levy Nuclear Plant, Units 1 and 2

AGENCY: Nuclear Regulatory Commission.

ACTION: Termination of licenses.

SUMMARY: The U.S. Nuclear Regulatory Commission (NRC) is terminating the Levy Nuclear Plant (LNP) Units 1 and 2 Combined Licenses (COLs) designated as NPF–99 and NPF–100 and their included licenses to manufacture, produce, transfer, receive, acquire, own, possess, or use byproduct material. By letter dated January 25, 2018, Duke Energy Florida, LLC (Duke) requested that the NRC terminate the LNP COLs. Construction was not initiated for LNP Units 1 and 2, and nuclear materials were never procured or possessed under these licenses. Consequently, the LNP site is approved for unrestricted use.

DATES: The termination was issued on April 26, 2018.

DECLARATION OF Anne Hemingway Feuer

I, Anne Hemingway Feuer, declare as follows:

1. I am a resident of Cutler Bay, Florida. I own a house at 18661 Belview Drive Lane and have resided at this house with my wife since May, 1991. We raised two daughters in this home, though currently only my husband Bill and I reside at 18661 Belview Drive.
2. I am currently a member of Friends of the Earth ("FoE"), and have been a member since 1979. As a resident of Florida's Miami-Dade county, I am particularly interested in and

support FoE's work related to Florida Power and Light Company (FPL) and their Turkey Point Power Plant ("Turkey Point") reactors.

3. Among its missions, FoE seeks to ensure that the public has an opportunity to influence the outcome of governmental and corporate decisions that affect the lives of many people, including myself.

4. My home is about 5 miles from Turkey Point. I am an RN Care Manager for AIDS Healthcare Foundation, gardener and a glass/clay artist in my spare time

5. I live with my husband Bill Feuer, who does Biostatistics for the University of Miami Bascom Palmer Eye Institute and enjoys playing guitar and creating music in his spare time. We both enjoy working from home at least half time on our computer based home offices. An accicident at Turkey Point would mean that we would no longer be able to enjoy fresh avocados, mangoes, carambolas, bananas, tomatoes and pineapples that grow in our yard as the prevailing wind blows straight off the ocean from Turkey Point. We would no longer be able to live where we do, as that same wind hits our home at 18661 Belview Drive, Cutler Bay.

6. I am concerned that the continued operation of Turkey Point for an additional 20 years beyond the term of its original license and the additional 20 year relicense renewal period will jeopardize the health and safety of my family and myself and the value of our property. I am also concerned that the operation of Turkey Point will have an adverse effect on the health of the environment in which I live.

7. My personal health and safety and my family's personal health and safety will be seriously affected in the event that Turkey Point is damaged by sea level rise, storm surge, hurricanes or other accidents, causing a radiation leak from the plant.

8. Turkey Point's operation without adequate assurance that its essential structures will continue to operate and that the plant can be safely shut down in the event of flooding or storm related power outages and damage poses a significant risk to my personal health and safety. I am particularly worried about the consequences that an accident at Turkey Point would cause for my daughter, as very young, developing children are at greater risk for radiation-related health problems than adults.

USCA Case #20-1026 Document #1832341 Filed: 03/06/2020 Page 42 of 53

9. The value of my home - a three-bedroom, two-bath house with surrounding green space and gardens - will be adversely affected in the event of an earthquake/hurricane and subsequent release or threatened release of radioactivity at Turkey Point. The value of our home offices and creative space and our assets will be adversely affected in the event of a flood or accident or threatened release of radioactivity from Turkey Point because the local community will not want to purchase property with mature fruit trees and a garden near such a potential calamity.

10. My husband and I love to walk and bike out at Black Point Marina, and down in Everglades National Park. We are concerned about reports of heightened tritium from Turkey Point in our local waters. Continued operation of the Turkey Point reactors will only increase these contamination problems and threaten my use and enjoyment of the environment near the reactors and an accident at Turkey Point would destroy my ability to continue recreational activities in this area. We enjoy eating local seafood at Golden Rule and Captain's Tavern, and would be very distressed if this was no longer an option due to radioactive contamination of local fish.

11. The whole of Miami-Dade County surrounding Turkey Point would be financially ruined following any disaster at the plant, not to mention that the health and safety of my family and neighbors would be in jeopardy. Tourism is the economic backbone of Miami-Dade County and would be severely impacted if not completely destroyed in the event of an accident at Turkey Point. Agriculture is another leading economic force in our county. The integrity of agricultural land would certainly be spoiled by an accident at Turkey Point.

12. As a member of 350.com and Urban Paradise Guild and Awake Miami/Labor and Community Alliance of South Florida since 2015, I've been involved in several efforts to protect and restore the coastal environment surrounding Turkey Point. I have supported Cleo Institute's work and Oceana's work to establish a Marine Sanctuary in Biscayne Bay, and I've been active in protesting contamination from Turkey Point.

13. The continued operation of Turkey Point for an additional 20 years without ensuring that the aging plant can withstand foreseeable accidents, natural disasters and climate change

(Page 44 of Total)

USCA Case #20-1026 Document #1832341 Filed: 03/06/2020 Page 43 of 59

impacts poses a significant risk to my personal health and safety, the health and safety of my family, the market value of my home and business, and my interest in using and protecting the environment around Turkey Point.

14. I authorize FoE to petition to intervene in this proceeding on my behalf. I authorize FoE to represent my interests in any hearing on the license renewal request.

15. I strongly support the petition to intervene filed by FoE with the Nuclear Regulatory Commission regarding Turkey Point.

I declare, under penalty of perjury, that the foregoing information is true, accurate, and correct. Executed on 29th June, in 2018..

DECLARATION OF Laura Bauman

I, Laura Bauman, declare as follows:

1. I am a resident of Key Largo, Florida. I own a house at 404 Thumper Thoroughfare and have resided at this house with my significant other since 2009. We are raising one daughter in this home. All three of us reside at the 404 Thumper Thoroughfare address.
2. I am currently a member of Friends of the Earth ("FoE"). As a resident of Florida's Monroe County, I am particularly interested in and support FoE's work related to Florida Power and Light Company (FPL) and their Turkey Point Power Plant ("Turkey Point") reactors.
3. Among its missions, FoE seeks to ensure that the public has an opportunity to influence the outcome of governmental and corporate decisions that affect the lives of many people, including myself.
4. My home is about 41 miles from Turkey Point. I am a wetland ecologist that works in the Everglades and Florida Bay. My significant other is a mooring buoy specialist that works on the coral reef tract in the Florida Keys National Marine Sanctuary. We both rely on the health and vitality of our local waters for employment.
5. An accident at Turkey Point would mean that my family could not live and work in Key Largo, temporarily or permanently depending on the severity of the contamination. My child could not attend school. We would be forced to evacuate.

6. I am concerned that the continued operation of Turkey Point for an additional 20 years beyond the term of its original license and the additional 20 year relicense renewal period will jeopardize the health and safety of my family and myself and the value of our property. I am also concerned that the operation of Turkey Point will have an adverse effect on the health of the environment in which I live.
7. My personal health and safety and my family's personal health and safety will be seriously affected in the event that Turkey Point is damaged by sea level rise, storm surge, hurricanes or other accidents, causing a radiation leak from the plant.
8. Turkey Point's operation without adequate assurance that its essential structures will continue to operate and that the plant can be safely shut down in the event of flooding or storm related power outages and damage poses a significant risk to my personal health and safety. I am particularly worried about the consequences that an accident at Turkey Point would cause for my daughter, as young, developing children are at greater risk for radiation-related health problems than adults.
9. The value of my home - a three-bedroom, two-bath house with surrounding green space- will be adversely affected in the event of an earthquake and subsequent release or threatened release of radioactivity at Turkey Point.
10. I have been an avid diver since 2000 and have regularly swum waters in the Florida Keys for almost 20 years. I am concerned about reports of heightened tritium from Turkey Point in our local waters, including our fragile drinking water that comes from the Biscayne aquifer. Continued operation of the Turkey Point reactors will only increase these contamination problems and threaten my use and enjoyment of the environment. An accident at Turkey Point would destroy my ability to continue recreational activities in this area, as well as threaten my drinking water supply.
11. Monroe County has a very real threat to be financially ruined following any disaster at the plant, not to mention that the health and safety of my family and neighbors would be in jeopardy. Tourism is the economic backbone of Monroe County and would be severely impacted if not completely destroyed in the event of an accident at Turkey Point.
12. The continued operation of Turkey Point for an additional 20 years without ensuring that the aging plant can withstand foreseeable accidents, natural disasters and climate change impacts poses a significant risk to my personal health and safety, the health and safety of

USCA Case #20-1026 Document #1832341 Filed: 03/06/2020 Page 47 of 59

my family, the market value of my home, and my interest in using and protecting the environment around Turkey Point.

13. I authorize FoE to petition to intervene in this proceeding on my behalf. I authorize FoE to represent my interests in any hearing on the license renewal request.
14. I strongly support the petition to intervene filed by FoE with the Nuclear Regulatory Commission regarding Turkey Point.

I declare, under penalty of perjury, that the foregoing information is true, accurate, and correct. Executed on July 30, in 2018.

DECLARATION OF VICKI MCGEE-ABSTEN

I, Vicki McGee-Absten, declare as follows:

1. I am a resident of Key Largo, Florida. I rent a house from my father at 980 Oleander Rd and have resided at this house with my two sons since 2013.
2. I am currently a member of Friends of the Earth ("FoE"). As a resident of Florida's Monroe County, I am particularly interested in and support FoE's work related to Florida Power and Light Company (FPL) and their Turkey Point Power Plant ("Turkey Point") reactors.
3. Among its missions, FoE seeks to ensure that the public has an opportunity to influence the outcome of governmental and corporate decisions that affect the lives of many people, including myself.
4. My home is about 35 miles from Turkey Point. I am a marine bioogist that works in the Florida Bay. As a biologist I rely on the health and vitality of our local waters for employment.
5. An accident at Turkey Point would mean that my family could not live and work in Key Largo, temporarily or permanently depending on the severity of the contamination. My children could not attend school. We would be forced to evacuate.
6. I am concerned that the continued operation of Turkey Point for an additional 20 years beyond the term of its original license and the additional 20 year relicense renewal period

will jeopardize the health and safety of my family and myself and the value of our property. I am also concerned that the operation of Turkey Point will have an adverse effect on the health of the environment in which I live.

7. My personal health and safety and my family's personal health and safety will be seriously affected in the event that Turkey Point is damaged by sea level rise, storm surge, hurricanes or other accidents, causing a radiation leak from the plant.
8. Turkey Point's operation without adequate assurance that its essential structures will continue to operate and that the plant can be safely shut down in the event of flooding or storm related power outages and damage poses a significant risk to my personal health and safety. I am particularly worried about the consequences that an accident at Turkey Point would cause for my daughter, as young, developing children are at greater risk for radiation-related health problems than adults.
9. The value of my home - a three-bedroom, two-bath house with surrounding green space- will be adversely affected in the event of an earthquake and subsequent release or threatened release of radioactivity at Turkey Point.
10. I am a native Floridian and have enjoyed the local waters my entire life (50 years) and have watched the reef deteriorate over my life time due to climate change, global warming coral bleaching and pollution run off. I am concerned about reports of heightened tritium from Turkey Point in our local waters, including our fragile drinking water that comes from the Biscayne aquifer. Continued operation of the Turkey Point reactors will only increase these contamination problems and threaten my use and enjoyment of the environment. An accident at Turkey Point would destroy my ability to continue recreational activities in this area, as well as threaten my drinking water supply.
11. Monroe County has a very real threat to be financially ruined following any disaster at the plant, not to mention that the health and safety of my family and neighbors would be in jeopardy. Tourism is the economic backbone of Monroe County and would be severely impacted if not completely destroyed in the event of an accident at Turkey Point.
12. The continued operation of Turkey Point for an additional 20 years without ensuring that the aging plant can withstand foreseeable accidents, natural disasters and climate change impacts poses a significant risk to my personal health and safety, the health and safety of my family, the market value of my home, and my interest in using and protecting the

environment around Turkey Point. South Florida needs to be at the fore front of global warming and sea level rise. Alternative energy sources especially in such environmentally sensitive areas are a must.

13. I authorize FoE to petition to intervene in this proceeding on my behalf. I authorize FoE to represent my interests in any hearing on the license renewal request.
14. I strongly support the petition to intervene filed by FoE with the Nuclear Regulatory Commission regarding Turkey Point.

I declare, under penalty of perjury, that the foregoing information is true, accurate, and correct. Executed on July 30, in 2018.

DECLARATION

I, Patricia J. Wynn, declare as follows:

1. I am a resident of Miami, Florida. I own a house at 11781 SW 91st Terrace and have resided at this house with my husband since 1982. Currently only my husband I reside at this address.
2. I am currently a member of Friends of the Earth ("FoE"), and have been a member since 2018. As a resident of Florida's Miami-Dade county, I am particularly interested in and support FoE's work related to Florida Power and Light Company (FPL) and their Turkey Point Power Plant ("Turkey Point") reactors.
3. Among its missions, FoE seeks to ensure that the public has an opportunity to influence the outcome of governmental and corporate decisions that affect the lives of many people, including myself.
4. My home is about 20 miles from Turkey Point. I am a real estate broker specializing in commercial property leasing and management. My husband is a web-site designer and musician.
5. I am concerned that the continued operation of Turkey Point for an additional 20 years beyond the term of its original license and the additional 20 year relicense renewal period will jeopardize the health and safety of ourselves as well as our neighbors, which would ultimately impact the value of our property. I am also concerned that the operation of

Turkey Point will have an adverse effect on the health of the environment in which we live.

6. My personal health and safety and that of my husband's will be seriously affected in the event that Turkey Point is damaged by sea level rise, storm surge, hurricanes or other accidents, causing a radiation leak from the plant.
7. Turkey Point's operation without adequate assurance that its essential structures will continue to operate and that the plant can be safely shut down in the event of flooding or storm related power outages and damage poses a significant risk to my personal health and safety. I am particularly worried about the consequences that an accident at Turkey Point would cause for young developing children, which are at greater risk for radiation-related health problems than adults.
8. The value of my home - a three-bedroom, three-bath townhome with surrounding green space, gardens and a shed - will be adversely affected in the event of an earthquake and subsequent release or threatened release of radioactivity at Turkey Point. The value of my business and my husband's will be adversely affected in the event of a flood or accident or threatened release of radioactivity from Turkey Point because the local market will have changed for the commercial real estate industry.
9. I have been an avid windsurfer since 1978 and have regularly windsurfed waters near Turkey Point since 1993, over 20 years. I am concerned about reports of heightened tritium from Turkey Point in our local waters. Continued operation of the Turkey Point reactors will only increase these contamination problems and threaten my use and enjoyment of the environment near the reactors and an accident at Turkey Point would destroy my ability to continue recreational activities in this area.
10. The whole of Miami-Dade County surrounding Turkey Point would be financially ruined following any disaster at the plant, not to mention that the health and safety of my family and neighbors would be in jeopardy. Tourism is the economic backbone of Miami-Dade County and would be severely impacted if not completely destroyed in the event of an accident at Turkey Point. Agriculture is another leading economic force in our county. The integrity of agricultural land would certainly be spoiled by an accident at Turkey Point.

11. The continued operation of Turkey Point for an additional 20 years without ensuring that the aging plant can withstand foreseeable accidents, natural disasters and climate change impacts poses a significant risk to my personal health and safety, the health and safety of my family, the market value of my home and business, and my interest in using and protecting the environment around Turkey Point.
12. I authorize FoE to petition to intervene in this proceeding on my behalf. I authorize FoE to represent my interests in any hearing on the license renewal request.
13. I strongly support the petition to intervene filed by FoE with the Nuclear Regulatory Commission regarding Turkey Point.

I declare, under penalty of perjury, that the foregoing information is true, accurate, and correct.

Executed on _July 31, 2018_, in _Miami-Dade County_.

DECLARATION OF JONATHAN LESTER FRIED

I, Jonathan Lester Fried, declare as follows:

1. I am a resident of Homestead, Florida. I own a house at 715 NW 9th Court and have resided at this house since 2002.
2. I am currently a member of Friends of the Earth ("FoE"), and have been a member since 2018. As a resident of Florida's Miami-Dade county, I am particularly interested in and support FoE's work related to Florida Power and Light Company (FPL) and their Turkey Point Power Plant ("Turkey Point") reactors.
3. Among its missions, FoE seeks to ensure that the public has an opportunity to influence the outcome of governmental and corporate decisions that affect the lives of many people, including myself.
4. My home is about 12 miles from Turkey Point. I am the executive director of WeCount!, Inc., a non-profit organization in Homestead. My workplace is about 11 miles from Turkey Point.
5. I am concerned that an accident at Turkey Point would mean the community where I reside and work would longer be able a viable place to live for myself and my friends and neighbors.
6. I am concerned that the continued operation of Turkey Point for an additional 20 years beyond the term of its original license and the additional 20 year relicense renewal period will jeopardize my health and safety, and that of my friends and neighbors. I am also

concerned that the operation of Turkey Point will have an adverse effect on the health of the environment in which I live.

7. My personal health and safety and that of my neighbors and friends will be seriously affected in the event that Turkey Point is damaged by sea level rise, storm surge, hurricanes or other accidents, causing a radiation leak from the plant.
8. Turkey Point's operation without adequate assurance that its essential structures will continue to operate and that the plant can be safely shut down in the event of flooding or storm related power outages and damage poses a significant risk to my personal health and safety.
9. The value of my home - a three-bedroom, two-bath house with surrounding green space, garden, and shed - will be adversely affected in the event of an earthquake and subsequent release or threatened release of radioactivity at Turkey Point.
10. One of the joys of living in South Miami-Dade County is the enjoyment of the beautiful natural environment. I am concerned about reports of heightened tritium from Turkey Point in our local waters. Continued operation of the Turkey Point reactors will only increase these contamination problems and threaten my use and enjoyment of the environment near the reactors and an accident at Turkey Point would destroy my ability to continue recreational activities in this area.
11. The whole of Miami-Dade County surrounding Turkey Point would be financially ruined following any disaster at the plant, not to mention that my health and safety, and that of my friends and neighbors would be in jeopardy. Tourism is the economic backbone of Miami-Dade County and would be severely impacted if not completely destroyed in the event of an accident at Turkey Point.
12. Agriculture is another leading economic force in our county. The integrity of agricultural land would certainly be spoiled by an accident at Turkey Point. Many of the members of the organization where I work are farm and plant nursery workers. Their livelihood would disappear in the event of an accident at Turkey Point.
13. The continued operation of Turkey Point for an additional 20 years without ensuring that the aging plant can withstand foreseeable accidents, natural disasters and climate change impacts poses a significant risk to my personal health and safety, the market value of my

home, my livelihood, and my interest in using and protecting the environment around Turkey Point.

14. I authorize FoE to petition to intervene in this proceeding on my behalf. I authorize FoE to represent my interests in any hearing on the license renewal request.
15. I strongly support the petition to intervene filed by FoE with the Nuclear Regulatory Commission regarding Turkey Point.

I declare, under penalty of perjury, that the foregoing information is true, accurate, and correct.
Executed on July 31, 2018, in Homestead, Florida.

FLORIDA POWER & LIGHT COMPANY Docket Nos. 50-250, 50-251

Turkey Point Nuclear Generating Station, Units 3 and 4)

DECLARATION OF PETER STOCKER

I, Peter Stocker, hereby declare as follows:

1. The facts set forth in this declaration are based on my personal knowledge.

2. I am the Vice President of Membership and Development of Friends of the Earth. I have served in that position since January 2017. Friends of the Earth is a tax exempt, nonprofit environmental advocacy organization founded in 1969. Friends of the Earth is headquartered and incorporated in the District of Columbia and has an office in Berkeley, California. I am also a member of Friends of the Earth.

3. I am familiar with the organization's mission, which is to defend the environment and create a more healthy and just world. One aspect of that mission is to engage in efforts to improve the environmental, health, and safety conditions at civil nuclear facilities licensed by the Nuclear Regulatory Commission and its predecessor agencies and oppose proposals to design and build new reactors subsidized with federal funds. To that end, Friends of the Earth utilizes its institutional resources, including legislative advocacy, litigation, and public outreach and education, to minimize the risks that nuclear facilities pose to its members and to the general public.

4. Friends of the Earth is a part of Friends of the Earth International, a federation of grassroots groups working in 74 countries on today's most urgent environmental and social issues. Friends of the Earth International is the world's largest grassroots environmental federation. In the United States, Friends of the Earth has more than 100,000 members in all 50 states, 4,800 of those members are in Florida. In addition to dues paying members, Friends of the Earth has 1.49 million online activist supporters across the country with 72,000 of them in Florida.

5. Friends of the Earth relies on sound science and uses the law to advocate innovative strategies to conserve natural resources and protect public health and the environment. Friends of the Earth is engaged in a number of efforts before the Nuclear Regulatory Commission (NRC) to improve operating nuclear facilities and oppose new proposals and in litigation to support these efforts. The instant petition and request for a hearing in the NRC proceeding regarding Turkey Point, is an integral part of our advocacy to address the environmental, health and safety impacts from Turkey Point.

I declare under penalty of perjury that the foregoing is true and correct to the best of my knowledge, information, and belief.

REQUEST FOR HEARING AND PETITION TO INTERVENE SUBMITTED BY FRIENDS OF THE EARTH, NATURAL RESOURCES DEFENSE COUNCIL, AND MIAMI WATERKEEPER

PRELIMINARY STATEMENT

Friends of the Earth, Inc. ("FOE"), Natural Resources Defense Council, Inc. ("NRDC"), and Miami Waterkeeper, Inc. ("Miami Waterkeeper") (collectively, "Petitioners") hereby submit this hearing request and petition to intervene in the Nuclear Regulatory Commission ("NRC") subsequent relicensing proceeding that will determine whether Turkey Point Nuclear Generation Station, Unit Nos. 3 and 4 ("Turkey Point"), will be licensed to operate until 2052 and 2053, respectively. Florida Power & Light Company ("Applicant" or "FPL") owns and operates Turkey Point. These units have operated since the early 1970s adjacent to the Florida Everglades, Biscayne Bay, and several population centers on South Florida's Atlantic coast.

STANDING

Friends of the Earth

FOE is a national non-profit environmental organization headquartered and incorporated in the District of Columbia with an office in Berkeley, California.[1] FOE has a nationwide membership of over 100,000 (including approximately 4,800 members in Florida) and 1.49 million online activists.[2] FOE seeks to defend the environment and create a more healthy and just world.[3] Since its inception in 1969, FOE has sought to improve the environmental, health, and safety conditions at civil nuclear facilities licensed by the NRC and its predecessor agencies.[4] To that end, FOE utilizes its institutional resources, including legislative advocacy, litigation, and public outreach and education, to minimize the risks that nuclear facilities pose to its members and to the general public.

Anne Hemingway Feuer is a member of FOE and lives in Cutler Bay, Florida, approximately five miles from Turkey Point.[5] Ms. Feuer and her husband frequently work from home and grow avocados, mangoes, carambolas, bananas, tomatoes and pineapples in their yard. Ms. Feuer and her husband enjoy walking and biking at Black Point Marina and in Everglades National Park, as well as eating local seafood. Ms. Feuer is concerned about the continued operation of Turkey Point for an additional 20 years without adequate analysis of Turkey Point's environmental impacts.[6] Prevailing winds blow off the ocean from Turkey Point toward Ms. Feuer's home. An accident at Turkey Point would personally and significantly affect Ms. Feuer

[1] Declaration of Peter Stocker (Attachment A) at ¶ 2.

[16] *Id.* at ¶ 5.

about the effects of tritium pollution on the local watershed, and specifically on her ability to recreate near Turkey Point and her access to clean drinking water.[17] The continued operation of Turkey Point for an additional 20 years without ensuring that the aging plant can withstand foreseeable accidents, natural disasters and climate change impacts poses a significant risk to Ms. McGee-Absten's and her family's personal health and safety, the market value of her home, and her interest in using and protecting the environment around Turkey Point.[18]

Patricia J. Wynn is a member of FOE and lives in Miami, Florida, approximately 20 miles from Turkey Point.[19] Ms. Wynn has been an avid windsurfer since 1978, and has regularly windsurfed waters near Turkey Point for over 20 years. Ms. Wynn is concerned about reports of heightened tritium pollution from Turkey Point.[20] She is concerned that continued operation of Turkey Point during the subsequent license renewal period will threaten her ability to safely recreate in the environment around Turkey Point.[21] An accident at Turkey Point would personally affect Ms. Wynn.[22]

Jonathan Lester Fried, a member of FOE, lives in Homestead, Florida, approximately 12 miles from Turkey Point.[23] Mr. Fried is executive director of WeCount!, Inc., a non-profit organization in Homestead.[24] Mr. Fried enjoys recreating in the waters near Turkey Point, and

[21] *Id.* at ¶ 9.
[22] *Id.* at ¶¶ 6-9, 11.
[23] Declaration of Jonathan Lester Fried (Attachment F) at ¶¶ 1, 4.
[24] *Id.* at ¶ 4.

an accident would adversely impact his ability to continue recreating there.[25] An accident at Turkey Point resulting in a radiation leak would harm Mr. Fried's personal health and safety.[26]

Natural Resources Defense Council

NRDC is a national non-profit environmental organization with offices in Washington, D.C., New York City, San Francisco, Chicago, Santa Monica, and Beijing.[27] NRDC has a nationwide membership of over 384,000 (plus hundreds of thousands of online activists), including 15,324 members in Florida, at least 1,746 members living within 50 miles of Turkey Point Units 3 and 4. Among its missions, NRDC seeks to maintain and enhance environmental quality, to safeguard the natural world for present and future generations, and to foster the fundamental right of all people to have a voice in the decisions that affect their environment. Since its inception in 1970, NRDC has sought to improve the environmental, health, and safety conditions at the nuclear facilities operated by the Department of Energy and the civil nuclear facilities licensed by the NRC and their predecessor agencies. To that end, NRDC utilizes its institutional resources, including legislative advocacy, litigation, and public outreach and education, to minimize the risks that nuclear facilities pose to its members and to the general public.

Dr. Philip Stoddard is a member of NRDC and has been since 1993.[28] Dr. Stoddard lives

---

[25] *Id.* at ¶¶ 7, 8, 10.
[26] *Id.* at ¶ 7.
[27] Declaration of Gina Trujillo (Attachment G) at ¶¶ 1–6.
[28] Declaration of Phillip Stoddard (Attachment H) at ¶ 2.

at 6820 SW 64th Court, South Miami, Florida, and has lived at that address for about fifteen years.[29] Dr. Stoddard's home is approximately 18 miles from Turkey Point Units 3 and 4. In his capacity as Mayor of the City of South Miami, Florida, Dr. Stoddard has toured Turkey Point Units 3 and 4 and has studied issues related to flooding, evacuation, environmental problems related to the cooling canal system, and other issues at Turkey Point Units 3 and 4.[30] Due to the location of Dr. Stoddard's home within the 50-mile emergency planning zone for the ingestion pathway, Dr. Stoddard is concerned that an accident at Turkey Point Units 3 and 4 would result in dangerous airborne levels of radioiodines and increased risk of radiation-induced thyroid cancers. He is concerned by the lack of a plan to distribute potassium iodide prophylaxis to the vulnerable population before airborne exposure to radioiodines.[31] Dr. Stoddard is personally familiar with FPL's "shelter-in-place" plan in the event of a radiation emergency. Dr. Stoddard is concerned that the plan, which calls for residents to stay in their homes and tape over door seams and A/C vents to prevent radiation exposure, is unreasonable and unworkable.[32]

Miami Waterkeeper

Miami Waterkeeper is a Florida non-profit organization with a mission to defend, protect, and preserve the aquatic integrity of South Florida's watershed and wildlife through citizen involvement and community action.[33] Miami Waterkeeper seeks to eliminate or mitigate threats

[29] *Id*. at ¶ 3.
[30] *Id.* at ¶¶ 5-6.
[31] *Id.* at ¶ 8.
[32] *Id.* at ¶ 7.
[33] Declaration of Rachel Silverstein, Ph.D (Attachment I) at ¶ 2.

to South Florida's coastal waters. Miami Waterkeeper works to ensure a clean and vibrant South Florida watershed and coastal culture for future generations. Miami Waterkeeper uses education, community outreach, and legal advocacy to protect South Florida's marine ecosystems, marine life, and coral reefs.[34] Miami Waterkeeper is a member of the Waterkeeper Alliance, an international organization uniting more than 190 Waterkeeper affiliates across the world. Miami Waterkeeper has approximately 100 members.

Rachel Silverstein, Ph.D lives approximately 30 miles from Turkey Point.[35] Dr. Silverstein is the Executive Director of Miami Waterkeeper, as well as a member of Miami Waterkeeper and the Waterkeeper Alliance, and a member of NRDC. Dr. Silverstein holds a Ph.D. in the Department of Marine Biology and Fisheries from the University of Miami's Rosenstiel School for Marine and Atmospheric Science.[36] In her role at Miami Waterkeeper, Dr. Silverstein patrols the bays, monitors and tests water quality, investigates pollution problems, enforces state and federal environmental laws and works with government officials and civic leaders to develop better environmental policy.[37] Dr. Silverstein enjoys boating in southern Biscayne Bay, as well as scuba diving, snorkeling, and camping in Biscayne National Park and the Florida Keys National Marine Sanctuary. Along with her family, Dr. Silverstein frequently visits Everglades National Park. Dr. Silverstein plans to continue visiting nearby national parks

---

[34] *Id.* at ¶ 2
[35] *Id.* at ¶ 8.
[36] *Id.* at ¶ 3.
[37] *Id.* at ¶ 3.

and marine sanctuaries, and enjoying viewing the unique wildlife that depend on sustained fresh water flow for their habitats and lifecycles.[38] As a resident of Miami-Dade County, Dr. Silverstein relies on the Biscayne Aquifer as a primary source of drinking water. Dr. Silverstein is concerned that the hypersaline plume emanating from Turkey Point's cooling canal system is contaminating the Biscayne Aquifer.[39] If an accident happened and a radiation release occurred, Dr. Silverstein's personal safety may be at risk.[40]

Daniel Parobok is a member of Miami Waterkeeper and lives 28 miles from Turkey Point.[41] Mr. Parobok works as a biologist in Monroe County, Florida. Mr. Parobok frequently uses and enjoys the waters of South Florida, including those of Biscayne National Park and the area near Turkey Point for recreational purposes, including boating and fishing for bonefish, permit, snapper, tarpon, sheepshead, snook, and redfish.[42] Mr. Parobok frequently boats and fishes in Biscayne Bay, Card Sound, Barnes Sound, and Florida Bay. Mr. Parobok enjoys viewing wildlife such as manatees, turtles, birds, dolphins, and crocodiles when he recreates in these areas.[43] In his professional capacity, Mr. Parobok regularly conducts listed species surveys for wildlife including turtles, cara caras, queen conch, woodstorks, scrub jays, red cockaded woodpeckers, everglades snail kites, sand skinks, and gopher tortoises.[44] Mr. Parobok is

[41] Declaration of Daniel Parobok (Attachment J) at ¶¶ 4, 7.
[42] *Id.* at ¶ 4.
[43] *Id.* at ¶ 5.
[44] *Id.* at ¶ 5.

concerned that Turkey Point's cooling canal system (sometimes referred to as the "CCS") is degrading the environment that he relies upon for recreational, aesthetic, and professional purposes.[45] Mr. Parobok also relies on the Biscayne Aquifer as a primary source of drinking water. He is concerned that the hypersaline plume from Turkey Point's cooling canal system will harm his source of drinking water.[46]

Legal standards

Under the AEA, the Commission must grant a hearing on a license application upon "the request of any person whose interest may be affected by the proceeding, and shall admit any such person as a party to such proceeding."[47] To that end, a petitioner must provide the Commission with information regarding "(1) the nature of the petitioner's right under the governing statutes to be made a party; (2) the nature of the petitioner's property, financial, or other interest in the proceeding; and (3) the possible effect of any decision or order on the petitioner's interest."[48] "The NRC generally uses judicial concepts of standing in interpreting this regulation."[49] Thus, a petitioner may intervene if it can specify facts showing "that (1) it has suffered or will suffer a distinct and palpable harm constituting injury-in-fact within the zone of interests arguably protected by the governing statutes, (2) the injury is fairly traceable to the

[45] *Id.* at ¶ 7.
[46] *Id.* at ¶ 6–7.
[47] 42 U.S.C. § 2239(a)(1)(A).
[48] *Entergy Nuclear Vermont Yankee, L.L.C., and Entergy Nuclear Operations, Inc.* (Vermont Yankee Nuclear Power Station), 60 N.R.C. 548, 552 (2004) (citing 10 C.F.R. § 2.309(d)(1)).
[49] *Entergy Nuclear Vermont Yankee*, 60 N.R.C. at 552.

action being challenged, and (3) the injury will likely be redressed by a favorable determination."[50] In determining whether a petitioner has met the requirements for establishing standing, the petition is to be construed "in favor of the petitioner."[51]

Member organizations such as FOE, NRDC, and Miami Waterkeeper may intervene on behalf of their members if they can "demonstrate that the licensing action will affect at least one of [their] members, . . . identify that member by name and address, and . . . show that [they are] authorized by that member to request a hearing on his or her behalf."[52] FOE, NRDC, and Miami Waterkeeper have each supplied declarations from one or more members who reside within 50 miles of Units 3 and 4. Each declaration describes the economic, aesthetic, and environmental interests they wish to safeguard and the harms that the relicensing of Units 3 and 4 without full compliance with the law will pose to those interests.[53] Each of the Member Declarants supports this Petition, and has authorized his or her respective organization to intervene in this proceeding and request a hearing on his or her behalf.[54]

Petitioners' experts discuss in their declarations the inadequacies in the applicant's analysis of potential adverse environmental consequences of renewing the operating licenses for Units 3 and 4, including inadequate analysis of sea level rise and its impacts on the plant and

---

[50] *Id.* at 552–53.
[51] *Id.* at 553 (citing *Institute of Technology* (Georgia Tech Research Reactor, Atlanta, Georgia), CLI-95-12, 42 N.R.C. 111, 115 (1995)).
[52] *Id.*
[53] *See generally* Attachments A - J.
[54] *Id.*

affected resources. These inadequacies impact Member Declarants' right to a complete and accurate assessment of the costs and benefits of the proposed action and alternatives to the proposed action.

As Member Declarants explain, they will suffer (or will be under threat of suffering) concrete and particularized injuries from the continued operations of Units 3 and 4 operations without adequate analysis of threatened environmental harms.[55] Petitioners' experts confirm the science behind these concerns: if Units 3 and 4 are not relicensed, the potential harms will not occur; and even if Units 3 and 4 are relicensed, the adverse environmental consequences caused by operations can be substantially mitigated if they are identified, analyzed and, based on that analysis, mitigated. Units 3 and 4 may not continue operations without a license from the Commission.[56] Accordingly, Turkey Point and the NRC will have caused these injuries if the proposed new operating license is issued as currently proposed. By granting Petitioners the relief they request and requiring that an adequate environmental analysis be performed, Member Declarants will obtain redress for their injuries. Even if the Applicant chooses to revise its ER to provide a legally sufficient analysis, Member Declarants will still have obtained redress: NEPA, in NRC's implementing regulations at 10 C.F.R. Parts 2 and 51, accords procedural rights to Member Declarants, whose concrete interests may be harmed by the project. By requiring FPL and the NRC staff to comply with these authorities' requirements, Member Declarants'

[55] Feuer Decl., at ¶¶ 6–8; Bauman Decl., at ¶¶ 6–8; McGee-Absten Decl., at ¶¶ 6–8; Wynn Decl., at ¶¶ 5–7; Fried Decl., at ¶¶ 7, 8, 10; Stoddard Decl., at ¶ 8; Silverstein Decl., at ¶¶ 7–9; Parobak Decl., at ¶ 7.

[56] 42 U.S.C. § 2133.

procedural rights will have been vindicated.[57]

Finally, Member Declarants have expressed concerns that fall within the zone of interests protected by NEPA and its implementing regulations.[58] Their concerns also fall within the zone of interests protected by the AEA and its implementing regulations.[59]

Member Declarants therefore have standing to intervene in their own right: they have met the requirements for injury-in-fact, causation, and redressability, and their concerns fall within the zone of interests protected by NEPA, the AEA, and their implementing regulations. They will be affected by Turkey Point's proposed relicensing and failure to provide a legally adequate environmental analysis, have provided their names and addresses, and have authorized their respective member organizations (Miami Waterkeeper, FOE, or NRDC) to intervene in this proceeding on their behalf. Thus, Petitioners have standing to pursue this action.[60]

NOTICE OF INTENT TO PARTICIPATE

Pursuant to 10 C.F.R. § 2.309 and the Notice of License Renewal Application; Opportunity to Request a Hearing and to Petition for Leave to Intervene, 83 Fed. Reg. 19,304 (May 2, 2018), Petitioners Friends of the Earth, Natural Resources Defense Council, and Miami Waterkeeper hereby submit contentions regarding FPL's application for subsequent renewal of its licenses to operate Turkey Point Units 3 and 4 for an additional 20 years, or until 2052 and 2053, respectively. As demonstrated below, these contentions should be admitted because they satisfy the NRC's admissibility requirements in 10 C.F.R. § 2.309.[61]

As noted above, at least one member of each Petitioner lives within 50 miles of the Turkey Point reactors, has authorized his or her respective member organization to represent his or her interests in environmental protection in this proceeding and, thus, pursuant to 10 C.F.R. § 2.309(d)(1), each Petitioner has standing for purposes of raising its concerns in this proceeding.

CONTENTIONS

Pursuant to 10 C.F.R. § 2.309, Petitioners set forth below the specific contentions they seek to litigate. Each contention challenges the sufficiency of the application under NRC regulations, as specified therein, as well as its compliance with NEPA. Petitioners acknowledge that, as a private entity, FPL is not directly bound by NEPA. However, pursuant to 10 C.F.R. § 2.309(f)(2), Petitioners have styled their NEPA contentions as against the ER.[62] Because an applicant's ER generally serves as the basis for the Commission's eventual Draft SEIS,

---

[61] By Order of the Commission dated June 29, 2018, the time for filing a Petition to Intervene by all parties was extended to August 1, 2018.
[62] 10 C.F.R. § 2.309(f)(2) ("On issues arising under the National Environmental Policy Act, the petitioner shall file contentions based on the applicant's environmental report.").

Petitioners raise these NEPA concerns at this time in order to preserve any objections they may have if the flaws that appear in the ER also appear in the Draft SEIS. In addition, if the Draft SEIS deviates from FPL's ER in a manner to which Petitioners object, they plan to submit amended or new contentions addressing these deviations pursuant to 10 C.F.R. § 2.309(f)(2).

Each of Petitioner's contentions is within the scope of this license renewal proceeding, which is described in Parts 51 and 54.[63] A license renewal application review typically implicates issues that fall into one of two broad areas: safety/aging management issues, and public health/environmental impacts. Petitioner's contentions are focused on environmental and public health impacts.

The scope of the environmental review is defined by 10 C.F.R. Part 51, the NRC's "Generic Environmental Impact Statement for License Renewal of Nuclear Plants," NUREG-1437 (May 1996) (the "GEIS"), and the initial hearing notice and order.[64] Some environmental issues that might otherwise be germane in a license renewal proceeding have been resolved generically for all plants and are normally, therefore, "beyond the scope of a license renewal hearing."[65] These "Category 1" issues are classified in 10 C.F.R. Part 51, Subpart A, Appendix B. Category 1 issues may be raised when a petitioner (1) demonstrates that there is new and significant information subsequent to the preparation of the GEIS regarding the environmental

---

[63] *See Florida Power & Light Co.*, CLI-01-17, 54 NRC 3, 6–13 (Jul. 19, 2001); Nuclear Power Plant License Renewal, 60 Fed. Reg. 22,461 (May 8, 1995).
[64] *See, e.g., Vermont Yankee*, 64 N.R.C. at 148–49.
[65] *Turkey Point*, 54 NRC at 15; see 10 C.F.R. § 51.53(c)(3)(i).

impacts of license renewal; (2) files a petition for a rulemaking with the NRC; or (3) seeks a waiver pursuant to 10 C.F.R. § 2.335.[66]

Each of Petitioner's contentions are "material" to the findings NRC must make.[67] A "material" issue is one that would make a difference in the outcome of the proceeding.[68] "This means that there should be some significant link between the claimed deficiency and either the health and safety of the public or the environment."[69]

Each of Petitioner's contentions also demonstrate sufficient information to show that a genuine dispute exists with the Applicant on a material issue of law or fact. NRC set forth factors relevant to determining if a genuine dispute exists when it adopted the current version of 10 C.F.R. § 2.309(f)(1):

> This will require the intervenor to read the pertinent portions of the license application, including the Safety Analysis Report and the Environmental Report, state the applicant's position and the petitioner's opposing view. Where the intervenor believes the application and supporting material do not address a relevant matter, it will be sufficient for the intervenor to explain why the application is deficient.[70]

As set forth in detail in the following contentions, Petitioners satisfy the admissibility standard with respect to each contention.

CONTENTION 1-E: THE ENVIRONMENTAL REPORT FAILS TO CONSIDER A REASONABLE RANGE OF ALTERNATIVES TO THE PROPOSED ACTION, AS REQUIRED BY NEPA AND NRC

---

[66] *Turkey Point*, 54 NRC at 10-12; see also 10 C.F.R. § 51.53(c)(3)(iv) (new and significant information).

IMPLEMENTING REGULATIONS.

1. **Statement of the issue of law or fact to be raised or controverted (10 C.F.R. § 2.309(f)(1)(i))**

The Environmental Report (§ 7.3) fails to comply with 10 C.F.R. §§ 51.45(c) and 51.53(c)(3)(iii)[71] because it fails to consider an alternative under which the existing cooling canal system would be replaced with cooling towers to reduce the well-documented adverse environmental effects related to the cooling canal system. The Environmental Report fails to include an accurate or complete analysis of "alternatives available for reducing or avoiding adverse environmental effects" and because it does not contain an adequate "consideration of alternatives for reducing adverse impacts . . . for all Category 2 license renewal issues."[72] The Environmental Report unlawfully fails to consider replacement of the canal cooling system with cooling towers as a reasonable alternative that would "reduc[e] or avoid[] adverse environmental effects" relating to numerous Category 2 issues (described below).[73]

---

[71] 10 C.F.R. § 51.53(c)(3) applies to applications for an "initial renewed license," and it is unclear whether the requirements of that subsection apply to an application for a subsequent license renewal, such as the one FPL seeks here. Even if the Commission determines that § 51.53(c)(3) does not apply, Petitioners hereby rely upon 10 C.F.R. § 51.53(c)(1) and (2), which provide:

> (1) Each applicant for renewal of a license to operate a nuclear power plant under part 54 of this chapter shall submit with its application a separate document entitled 'Applicant's Environmental Report—Operating License Renewal Stage.' (2) The report must contain a description of the proposed action, including the applicant's plans to modify the facility or its administrative control procedures as described in accordance with § 54.21 of this chapter. This report must describe in detail the affected environment around the plant, the modifications directly affecting the environment or any plant effluents, and any planned refurbishment activities. In addition, the applicant shall discuss in this report the environmental impacts of alternatives and any other matters described in § 51.45.

[72] 10 C.F.R. § 51.53(c)(3)(iii).

[73] 10 C.F.R. § 51.45(c); *see also* Turkey Point Nuclear Power Plant, Units 3 and 4, Applicant's Environmental Report Subsequent Operating License Renewal Stage, ADAMS Accession No. ML18037A836 (Jan. 2018), at 7-39

1. Brief explanation of basis for the contention (10 C.F.R. § 2.309(f)(1)(ii)); concise statement of the alleged facts or expert opinions supporting the contention (10 C.F.R. § 2.309(f)(1)(v)); and statement that a genuine dispute exists with the licensee on a material issue of law or fact (10 C.F.R. § 2.309(f)(1)(vi))

The Environmental Report violates NEPA's requirement that each NEPA document consider a range of reasonable alternatives.[74] NEPA requires a "discussion of alternatives" that "must '[r]igorously explore and objectively evaluate all reasonable alternatives.'"[75] The NRC's regulations implementing NEPA require that, FPL's "discussion of alternatives shall be sufficiently complete to aid the Commission in developing and exploring, pursuant to section 102(2)(E) of NEPA, 'appropriate alternatives to recommended courses of action in any proposal which involves unresolved conflicts concerning alternative uses of available resources.'"[76] An agency's consideration of reasonable alternatives is "the heart" of NEPA.[77] "The existence of a viable but unexamined alternative renders [a NEPA document] inadequate."[78]

The Environmental Report considered only two alternatives: (1) the preferred alternative (renew the operating licenses for Units 3 and 4) and (2) the no-action alternative (not renew the operating licenses and, instead, implement replacement power sources).[79] The Environmental

(hereinafter "ER")..

[74] *See* 42 U.S.C. § 4332(2)(C).

[75] *Union Neighbors United, Inc. v. Jewell*, 831 F.3d 564, 569 (D.C. Cir. 2016) (quoting 40 C.F.R. § 1502.14).

[76] 10 C.F.R. § 51.45(b)(3).

[77] *Union Neighbors United,* 831 F.3d at 575 (citing 40 C.F.R. § 1502.14). CEQ's regulations implementing NEPA apply to all federal agencies, including the NRC. *Union Neighbors United*, 831 F.3d at 569 n.1 (citing 40 C.F.R. § 1500.3).

[78] *Natural Res. Defense Council v. U.S. Forest Serv.*, 421 F.3d 797, 813 (9th Cir. 2005) (internal quotation marks omitted); *see also City of Grapevine v. Dep't of Transp.*, 17 F.3d 1502, 1506 (D.C. Cir. 1994) (agency must consider "all 'feasible' or 'reasonable' alternatives[.]").

[79] ER, at 7-1.

Report evaluated three replacement power sources within the no-action alternative:

1. Natural Gas-Fired Generation. Construct a 1,726-MWe natural gas combined-cycle plant utilizing closed-cycle cooling with mechanical draft cooling towers using reclaimed water as the source of cooling water make-up.[80]

2. New Nuclear Generation. Construct a new nuclear facility with a 1,668-MWe generating capacity utilizing closed-cycle cooling with a mechanical draft cooling tower. Cooling water make-up would be reclaimed water from the Miami-Dade Water and Sewer Department.[81]

3. Combination of Natural Gas-Fired Generation and Solar PV Facilities. Construct a 1,636-MWe natural gas combined-cycle plant utilizing closed-cycle cooling with mechanical draft cooling towers. Construct four 75-MWe solar photovoltaic facilities (no cooling system required).[82]

In the license renewal context, NRC's NEPA regulations require all environmental reports to include certain analyses of environmental impacts of alternatives to the proposed action (granting a license renewal). 10 C.F.R. § 51.53(c)(iii) provides that the environmental report "must contain a consideration of alternatives for reducing adverse impacts, as required by § 51.45(c), for all Category 2 license renewal issues." 10 C.F.R. § 51.45(c) provides that the environmental report "must include an analysis that considers and balances the environmental effects of the proposed action, the environmental impacts of alternatives to the proposed action, and *alternatives available for reducing or avoiding adverse environmental effects*."[83]

The Environmental Report (§ 7.3) fails to satisfy either 10 C.F.R. §§ 51.45(c) or 51.53(c)(3)(iii). The ER purports to satisfy NEPA's obligation to consider alternatives available for reducing adverse impacts in two short, conclusory paragraphs devoid of any substantive

[83] Emphasis added.

analysis. Section 7.3 of the Environmental Report (titled "Alternatives for Reducing Adverse Impacts") states:

> No additional alternatives were considered by FPL to reduce impacts, because . . . the continued operation of PTN does not result in significant adverse effects to the environment.[84]

The Environmental Report does not consider cooling towers as an alternative that would reduce adverse impacts related to the following Category 2 issues:

- Threatened, endangered, and protected species and essential fish habitat[85];
- Groundwater use conflicts (plants that withdraw more than 100 gallons per minute)[86]; and
- Radionuclides released to groundwater.[87]

Each of the above issues are Category 2 issues.[88]

a. *Replacing the existing cooling canal system with cooling towers is a reasonable alternative to granting the subsequent license renewal application.*

Replacing the existing cooling canal system with cooling towers is a reasonable and feasible alternative to granting the requested license renewal based on continued operation of the cooling canal system during the renewal term.[89] FPL itself has demonstrated that the siting and

[89] Declaration of Bill Powers (attached to Petition to Intervene by Southern Alliance for Clean Energy), submitted Aug. 1, 2018; *see generally* Expert Report of Bill Powers, P.E., Powers Engineering (hereinafter "Cooling Tower Feasibility Assessment") (Attachment K).

water supply aspects of cooling towers are feasible.

First, FPL chose cooling towers rather than the existing cooling canal system or another cooling system at Turkey Point Units 6 and 7, for which the NRC has granted combined construction permits and operating licenses. Both Units 6 and 7 would utilize closed-cycle wet-cooling towers using reclaimed water from the Miami-Dade Water and Sewer Department.[90] The EIS for Units 6 and 7 includes specific design elements of the cooling system, including: (a) a plan for piping reclaimed water from the Miami-Dade Water and Sewer Department South District Wastewater Treatment Plant to the cooling system for Units 6 and 7; (b) location of the water-treatment facility and related infrastructure; (c) storage of treated reclaimed water in a make-up water reservoir.[91]

Second, each of the three replacement power options under the no-action alternative considered in the Environmental Report incorporate closed-cycle cooling with mechanical draft cooling towers.[92] None of the replacement power options—not even the new nuclear generation option—would utilize the existing cooling canal system. In other words, under the alternative to shut down Units 3 and 4 and construct and operate a new nuclear plant, FPL has deemed construction of cooling towers as the best option, rather than utilization of the already

[92] ER, at 7-3, 7-22, 8-5.

constructed cooling canal system.

Third, Turkey Point Unit 5 (a natural gas combined-cycle unit that began operating in 2007) already utilizes mechanical-draft cooling towers that use make-up water drawn from the Upper Floridan Aquifer.[93] Thus, it is clear that the siting and water supply aspects of cooling towers are feasible.

Construction of cooling towers to replace the existing cooling canal system at Units 3 and 4 is feasible. Palisades Nuclear Plant, an 800-MW plant in Michigan, converted from a once-through cooling system to a closed-cycle wet cooling tower system after a significant period of operating utilizing the once-through system.[94] At least five other power plants have also converted to a closed-cycle system.[95]

The cost of replacing the cooling canal system with cooling towers is reasonable. The cost of the Palisades retrofit was approximately $99/kW in 2017 dollars.[96] The installed cost of cooling towers at Turkey Point Units 3 and 4, each of which has nearly the same capacity as Palisades (816 MW), would be approximately $81 million per unit for conventional inline mechanical draft cooling towers, or $162 million for both units.[97] This $160 million capital expense, amortized over only ten years at standard rates, equates to approximately $41 million

[97] *Id*.

annual cost for both units.[98] Given that the subsequent license renewal periods, if granted, would not expire until 2052 and 2053, FPL could expect a much longer amortization period and, therefore, a lower annual cost. This would equate to an increase of less than one percent of the energy charge component of an FPL residential customer's bill.[99]

b. *Replacing the cooling canal system with cooling towers would satisfy the proposed action's purpose and need.*

NEPA requires the agency (or here, FPL) to "discuss those alternatives that are reasonable and 'will bring about the ends' of the proposed action."[100] The Environmental Report here considered only two alternatives: (1) the proposed action (renew the operating licenses for Units 3 and 4) and (2) the no-action alternative (not renew the operating licenses and, instead, implement replacement power sources).[101] FPL determined that those two alternatives constituted a reasonable range of alternatives because the proposed action "is to renew the [operating licenses] for PTN, which would preserve the option for FPL to continue to operate PTN and provide reliable base-load power throughout the 20-year SLR period to meet future power generating needs."[102]

But the proposed action's purpose and need—to continue to provide baseload power—does not limit the range of reasonable alternatives to (1) grant the license renewal application as

---

[98] *Id.* at 15–16.
[99] *Id*. at 16.

[101] ER, at 7-1.
[102] ER, at 7-1.

filed or (2) deny the application.[103] Instead, NEPA requires FPL to consider any reasonable alternative that satisfies the project's purpose and need. Construction of cooling towers satisfies that test. For the reasons described above, retrofitting the plant to use cooling towers is technically and economically feasible. And installing cooling towers aligns with the proposed action's purpose and need by allowing Units 3 and 4 to continue to provide baseload power.

c. *Replacing the existing cooling canal system with cooling towers would reduce adverse impacts related to Category 2 issues.*

i. <u>Threatened, endangered, and protected species and essential fish habitat</u>

Continued operation of Units 3 and 4 during the subsequent license renewal term will result in harm to threatened, endangered, and protected species and essential fish habitat. Replacing the cooling canal system with cooling towers would reduce these adverse impacts. Subsequent to the uprate for Units 3 and 4, both temperature and salinity in the cooling canal have increased, resulting in decreased nesting and fewer American crocodiles, an endangered species, observed in the cooling canals.[104] In 2017, the FWS explained that:

> [T]here has been a reduction in the number of crocodile nests produced within the CCS. A total of 9 nests were observed in 2015 and 8 in 2016. The decrease in nesting in the CCS has occurred with a concomitant decrease in the number of crocodiles observed within the CCS…. In addition, the body condition of many of the crocodiles observed within the CCS has decreased (i.e., animals appear emaciated and much thinner than healthy animals of the same total length).

---

[103] *See* ER, at 1-1 (quoting NRC, "Generic Environmental Impact Statement for License Renewal of Nuclear Power Plants," NUREG-1437, Vols. 1 & 3, Rev. 1 (June 2013) (discussing purpose and need) (hereinafter "2013 GEIS Revision").

[104] *See* Biological Opinion for Combined License for Turkey Point Nuclear Plant, Units 6 and 7 (June 23, 2017), at 20, (hereinafter "2017 BiOp"); *see infra* Contention 5-E.

> Moreover, anecdotal evidence suggests that a majority of the fish and invertebrate species that used to provide prey for the crocodile in the waters of the CCS no longer occur or are greatly diminished in numbers… [These issues] are thought to be the result of the recent increase in water temperature and salinity, and decrease in water quality within the waters of CCS observed during the past few years, beginning in 2013… [The cause for the decrease in water quality conditions] include FPL's recent increase in power production from nuclear Units 3 and 4, [and] the discharge of vegetative cutting within the CCS.[105]

Thus, ceasing operation of the cooling canals as a heat sink and replacing them with cooling towers, while keeping the canals in place, would protect existing American crocodile habitat. With an adequate effort to freshen the canals,[106] and without the dangerously high temperatures of the recent past, the canals would continue to provide valuable critical habitat into the future.

Furthermore, the cooling canal system has driven the westward migration of a hypersaline plume, resulting in salination of freshwater wetlands that are habitat for a range threatened and endangered species, including the Florida panther, American crocodile, indigo snake, snail kite, red knot and wood stork.[107] Replacing the cooling canals with cooling towers would mitigate serious environmental impacts on threatened and endangered species.[108]

ii. Groundwater use conflicts

The Environmental Report recognizes that "[i]f the applicant's plant pumps more than 100 gallons (total onsite) of groundwater per minute, an assessment of the impact of the

[105] 2017 BiOp, at 20.
[106] Direct Testimony and Exhibits of Sorab Panday, Docket No. 20170007-EI (Aug. 23, 2017), at 35:7-14 (Attachment L) (hereinafter "Panday Tr.")
[107] 2017 BiOp, at 44.
[108] *See infra* Contention 5-E.

proposed action on groundwater must be provided."[109] The ER acknowledges that continued use of the cooling canal system will further stress the already strained groundwater resources below and near Turkey Point.[110] Given these impacts on groundwater use conflicts (a category 2 issue) and the ability of cooling towers to reduce these impacts, construction of cooling towers is a reasonable alternative.

Both state and local governments have found FPL to be violating the water quality laws and regulations that they enforce by contaminating the freshwater portions of the Biscayne Aquifer. As a result, the Applicant has been ordered, through a series of administrative enforcement efforts by the Florida Department of Environmental Protection (FDEP) and Miami-Dade County, to take remedial measures, including adding 15 MGD of mildly saline water from the Floridan Aquifer (2.5 PSU) into the cooling canals to dilute canal salinities. FPL's goal is to achieve an average concentration of 34 PSU in the canals by April 2020.

The Applicant has now proposed and begun testing a plan to construct a "recovery well system" to attempt to draw the plume back toward the cooling canal system.[111] This plan would require installation of a series of wells located near the interceptor ditch and screened near the base of the Biscayne Aquifer that would withdraw approximately 14 MGD of water from that part of the aquifer for disposal via reinjection into the Boulder Formation.[112] The recovery well

---

[109] ER, at 4-23.

[111] ER, at 3-109.
[112] ER, at 3-109, 9-12 – 9-13.

system would assert additional pressure on existing groundwater use conflicts by withdrawing even more groundwater from an already stressed Biscayne Aquifer. The plan, moreover, would not abate continued leaching of hypersaline water from the unlined canals in the cooling canal system into groundwater.[113]

Recent developments suggest the remedial measures FPL is taking to mitigate the adverse environmental impacts of operating the cooling canal system measures are not having the intended effects.[114] Even if they do work as designed, there will still be net addition of salt to the aquifer from cooling canal system, and 15 MGD of saline water (34 PSU) migrating into aquifer every day, with part of that migrating into freshwater at upper levels of the aquifer causing adverse environmental impacts (impacts to freshwater wetlands and other surface waters, and impacts to listed species that rely on those wetlands, and salination of a potable water aquifer). These impacts reduce the amount of groundwater available to users in South Florida, including the Florida Keys, thereby exacerbating groundwater use conflicts.

Neither the NRC nor the Applicant has considered any other alternatives to mitigate these impacts on groundwater use conflicts. Because the stress on groundwater resources originates from operation of the cooling canal system as the ultimate heat sink for Units 3 and 4, the ER should have considered closure of the cooling canal system and installation of mechanical draft

[113] Panday Tr., at 35:7-36:12

[114] For example, recent salinity measurements in the L-31 canal west of the interceptor ditch indicate that saline water from the plume has surfaced in and entered the L-31 canal, from which it can now enter adjacent freshwater wetlands, causing further adverse environmental impacts. As the County explains, "The water quality of the L-31 E was initially freshwater and salinities during the period of record have increased to over 29 PSU." Letter from Lee N. Heft, Director, Miami-Dade County Division of Environmental Resources Management to Lee Crandall and Timothy Rach, Florid Department of Environmental Protection (July 18, 2018), at 3 (Attachment M) (hereinafter "FDEP-DERM July 2018 Letter"). Over the past ten years, canal salinities have trended upward and the highest salinities (29 PSU) were recorded during the first quarter of 2018. DERM-FDEP July 2018 Letter, at 55, 56.

cooling towers instead. The cooling tower alternative is certain to remediate the impacts of continued operation. Under such an alternative, there would be no new addition of salt to the aquifer.

Decommissioning the cooling canal system and construction of cooling towers would result in no future risk to groundwater use. Proper implementation of a closed-cycle cooling system would ensure no further harm to groundwater. FPL's failure to consider a cooling-tower alternative violates the requirement to consider alternatives that would reduce adverse impacts for all Category 2 license renewal issues.[115]

The Applicant's failure to consider cooling towers as an alternative is even more egregious when considered in light of new and significant information regarding the impacts of the cooling canal system on groundwater use conflicts. The agency (or here, FPL) is required to follow the "rule of reason" in preparing a NEPA document, and this rule "governs . . . *which* alternatives the agency must discuss."[116] The rule of reason does not permit the Applicant to delineate the range of alternatives in a vacuum. Instead, "where changed circumstances affect the factors relevant to the development and evaluation of alternatives, the [agency] must account for such change in the alternatives it considers."[117] "[T]he concept of 'alternatives' is an evolving one, requiring the agency to explore more or fewer alternatives as they become better

---

[115] 10 C.F.R. §§ 51.53(c)(3)(iii) and 51.45(c).

known and understood."[118]

Rather than assessing this information and utilizing it to determine which alternatives to address and the extent to address them (as NEPA requires),[119] the Applicant relies on the naked assertion that the continued operation of Units 3 and 4—and, therefore, the cooling canal system —"does not result in significant adverse effects to the environment."[120] By any measure, this statement is false.[121] It is clear that continued operation of Units 3 and 4 will result in significant environmental effects relating to Category 2 issues. The Applicant should have considered new information regarding groundwater use impacts in delineating the range of alternatives.

iii. Radionuclides released to groundwater

Recent water sampling has found elevated tritium levels surrounding the cooling canal system.[122] Tritium is a radioactive type of hydrogen that is released with nuclear power plant wastewater.[123] The Applicant has documented nine releases of radioactive liquids into the environment.[124] As sea level rises and the cooling canal system is subject to more frequent inundation, the elevated levels of tritium found in the cooling canal system wastewater will spread into the environment. Conversion to a closed-cycle cooling system, such as cooling

[120] ER, at 7-39.
[121] An environmental impact statement will be prepared to analyze the environmental effects of the license renewal. 10 C.F.R. § 51.20(b)(2). An environmental impact statement is prepared only for "major federal actions *significantly* affecting the quality of the human environment." 42 U.S.C. 4332(2)(C) (emphasis added). The Applicant's statement in the Environmental Report that continued operation of Units 3 and 4 does not result in significant adverse environmental impacts is, therefore, contrary to the NRC's assessment, as well as the plain facts.
[122] Miami Herald, *FPL Nuclear Plant Canals Leaking Into Biscayne Bay, Study Confirms* (Updated May, 17, 2016), https://www.miamiherald.com/news/local/environment/article64667452.html.
[123] NRC, "Backgrounder on Tritium, Radiation Protection Limits, and Drinking Water Standards," https://www.nrc.gov/reading-rm/doc-collections/fact-sheets/tritium-radiation-fs.html.
[124] ER, at 4-26.

towers, would eliminate discharges of wastewater into the environment and, thus, eliminate risk of further release of tritium into the environment. The Applicant's failure to consider such an alternative violates 10 C.F.R. §§ 51.53(c)(3)(iii) and 51.45(c).

d. *Applicant's failure to discuss the reasons for eliminating a cooling-towers alternative from further study violates NEPA.*

The Applicant's failure to even state the reasons it did not evaluate cooling towers as alternative violates NEPA. NEPA requires an agency (or here, FPL) to "[r]igorously explore and objectively evaluate all reasonable alternatives, and for alternatives which were eliminated from the detailed study, briefly discuss the reasons for their having been eliminated."[125] The Applicant made no attempt in the Environmental Report to comply with this requirement. Instead, the company summarily concluded that, because the purpose of the proposed action was to continue to provide baseload power during the subsequent renewal term, the alternatives that required consideration were the preferred alternative (granting the subsequent license renewal application) and the no-action alternative (denying the application). That does not satisfy NEPA's "hard look" test.

4. The issue raised in the contention is within the scope of the proceeding (10 C.F.R. § 203.9(f)(1)(iii))

NRC regulations broadly divide the scope of a license renewal proceeding into (1) safety/aging management issues, and (2) environmental impacts. This contention concerns environmental impacts. The scope of the required environmental review is established by 10 C.F.R. Part 51 and the GEIS for license renewals.[126] This contention is within the scope of the

[125] 40 C.F.R. § 1502.14(a).
[126] *Entergy Nuclear Vermont Yankee, LLC* (Vermont Yankee), LBP-06-20, 64 N.R.C. 131, 148-49 (2006).

proceeding because it challenges the sufficiency of the environmental analysis in the Environmental Report and the GEIS.

5. **The issue raised in the contention is material to the findings the NRC must make to support relicensing (10 C.F.R. § 203.9(f)(1)(iv))**

An issue is "material" if "the resolution of the dispute would make a difference in the outcome of the licensing proceeding."[127] "This means that there must be some link between the claimed error or omission regarding the proposed licensing action and the NRC's role in protecting public health and safety or the environment."[128] The issue raised in this contention—The Applicant's failure to comply with NRC's regulations requiring consideration of alternatives—relates directly to the NRC's role in protecting public health and safety and the environment. NEPA imposes requirements on the NRC to ensure environmental protection. The failure to comply with these requirements is material to the findings NRC must make to support relicensing. Petitioners request a hearing and intervention to present evidence that mechanical draft cooling towers are an alternative to mitigate adverse impacts of continuing to operate Units 3 and 4.

<u>CONTENTION 2-E:</u> THE ENVIRONMENTAL REPORT FAILS TO ADEQUATELY CONSIDER THE CUMULATIVE IMPACTS OF CONTINUED OPERATION OF UNITS 3 AND 4.

1. **Statement of the issue of law or fact to be raised or controverted (10 C.F.R. § 2.309(f)(1)(i))**

Applicant's Environmental Report (§ 4.12) fails to comply with 10 C.F.R.

---

[127] *Vermont Yankee*, 64 N.R.C. at 149.
[128] *Id.*

§ 51.53(c)(3)(ii) because it does not address the "impacts of operation during the renewal term[] for those issues identified as Category 2 issues." Specifically, Applicant fails to adequately address cumulative impacts of the continued operation of Units 3 and 4 on water resources associated with reasonably foreseeable increases in sea levels rise and air temperature.[129] Applicant fails to address cumulative impacts on groundwater associated with its cooling canal system.[130]

2. Brief explanation of the basis for the contention (10 C.F.R. § 2.309(f)(1)(ii))

NRC's NEPA regulations require an applicant to include in its environmental report "analyses of the environmental impacts . . . associated with license renewal and the impacts of operation during the renewal term, for those issues identified as Category 2 issues in Appendix B to Subpart A of [Title 10, Part 51]."[131] These regulations specifically require an applicant to "provide information about other past, present, and reasonably foreseeable future actions occurring in the vicinity of the nuclear plant that may result in a cumulative effect."[132] This cumulative impacts analysis must account for climate change, including rising sea levels and a hotter climate.[133] A failure to take a hard look at cumulative impacts, including those from climate change, violates the NRC's NEPA regulations and thus NEPA.

Here, the Environmental Report does not address cumulative impacts from the reasonably foreseeable effects of climate change, including sea level rise and hotter temperatures.[134]

---

[129] *See* 10 CFR Pt. 51, Subpt. A, App. B.
[130] *See* ER, at 4-68 – 4-69.
[131] 10 C.F.R. § 51.53(c)(3)(ii).
[132] 10 C.F.R. § 51.53(c)(3)(O).
[133] *See* 2013 GEIS Revision, at 1-30 (noting that climate change impacts on affected resources will be treated on a plant-specific basis).
[134] ER at 4-62 – 4-74.

While NRC Guidance provides that an applicant's cumulative impacts analysis may, under limited circumstances, assume cumulative impacts are avoided through management, those circumstances are not present here. Specifically, NRC Guidance allows an applicant to assume cumulative impacts regulated and monitored by a permitting process are managed if, but only if, the facility is "in compliance with their respective permits."[135] The Guidance does not authorize applicants to assume cumulative impacts are managed following permit violations.

Here, Applicant's Environmental Report fails to address cumulative impacts on groundwater because it assumes such impacts associated with the hypersaline plume from the cooling canal system "would be managed" based on compliance with a Consent Order with the Florida Department of Environmental Protection and a Consent Agreement with Miami-Dade County.[136] NRC Guidance, however, does not authorize Applicant to assume cumulative impacts will be managed where, as here, the applicant actually *violated* its permit and is now required to mitigate future violations and remediate existing impacts to correct its violations.[137]

3. The issue raised in the contention is within the scope of the proceeding (10 C.F.R. § 2.309(f)(1)(iii))

The issue is within the scope of the proceeding because NRC's NEPA regulations require

[135] NRC Regulatory Guide 4.2, Rev. 1, Supp. 1, "Preparation of Environmental Reports for Nuclear Power Plant License Renewal Applications," (July 2009), at 49, *available at* https://www.nrc.gov/docs/ML1306/ML13067A354.pdf.

[136] ER, at 4-68.

[137] *See e.g.*, *State of Florida Dep't of Environmental Protection v. Florida Power & Light Co.,* OGC File No. 16-0241 (Fla. Dep. of Envt'l Prot. Jun. 20, 2016) (Consent Order), ¶ 19 (Ordering Applicant to "cease discharges from the [cooling canal system] that impair the reasonable and beneficial use of the adjacent G-II ground waters to the west of the [cooling canal system] in violation of Condition IV.1 of the Permit and Rule 62-520.400, F.A.C.").

a plant-specific assessment of cumulative impacts in the applicant's Environmental Report.[138] Additionally, the NRC recognizes that "impacts from individually minor actions may be significant when considered collectively over time."[139]

4. The issue raised in the contention is material to the findings the NRC must make to support the action that is involved in the proceeding (10 C.F.R. § 2.309(f)(1)(iv))

The issue raised is material to the findings NRC must make because the NRC is required to undertake a cumulative impacts analysis.[140] The issue is also material because a failure to take a hard look at cumulative impacts associated with the proposed project constitutes a violation of NEPA.

5. Concise statement of the alleged facts or expert opinions which support the petitioner's position on the issue and on which the petitioner intends to rely at hearing (10 C.F.R. § 2.309(f)(1)(v))

Global mean sea level in the area around Turkey Point has risen over the past century and is projected to continue rising at an accelerated rate throughout this century and beyond.[141] Relative to the year 2000, there is at least a 90 percent probability that global mean sea level will rise by 0.3–0.6 feet by 2030 and 0.5–1.2 feet by 2050.[142] By 2100, scientists predict that global mean sea level will rise by at least 1.0 foot and could rise more than 8 feet under certain

[138] Appendix B to Subpart A of Part 51–Environmental Effect of Renewing the Operating License of a Nuclear Power Plant, 10 CFR Pt. 51, Subpt. A, App. B
[139] ER, page 4-63 (referencing 2013 GEIS Revision, § 4.13).
[140] 10 CFR Pt. 51, Subpt. A, App. B
[141] Declaration of Dr. Robert Kopp ("Kopp Decl.") ¶ 12(i) (Attachment N) (referencing William V. Sweet et al., "*Sea Level Rise*," in CLIMATE SCIENCE SPECIAL REPORT: FOURTH NATIONAL CLIMATE ASSESSMENT, VOL. 1 333–363 (D.J. Wuebbles et al. eds., 2017).
[142] *Id.* ¶ 12(ii).

greenhouse gas emissions and Antarctic ice sheet stability scenarios.[143] Sea-level rise for the remainder of this century in south Florida, including around Turkey Point will be faster than the average over the last century in every reasonably foreseeable climate change scenario.[144]

Through 2060, there is between a 68 and 95 percent chance that average sea-level rise at the Key West tidal gauge, which reflects relative sea level at Turkey Point, will exceed 1 foot above the National Tidal Datum Epoch.[145] Through 2060, there is a 10 to 37 percent chance that average sea level rise will exceed 2 feet if today's rate of growth in emissions of greenhouse gases continues, leading to a near-doubling of carbon dioxide emissions between today and 2050, with continued growth thereafter.[146] By 2100, there is a 15 to 83 percent chance that average sea level will exceed 4 feet if today's rate of growth in emissions of greenhouse gases continues.[147]

Most experts believe hurricanes and tropical storms will become more intense as temperatures rise due to climate change.[148] Assuming storm characteristics do not change, sea level rise will increase the frequency and extent of extreme flooding associated with coastal storms, such as hurricanes.[149] For an intense storm with an appropriate track, extreme water levels well above the highest level observed historically at a particular site are well within the

[149] *Id*. ¶ 12(v).

range of possibility. [150]

The effect of sea level rise can be added to storm surge. Extreme high-water levels arise from the superimposition of tidal and storm influences on top of average sea level.[151] If the sea level rises by one foot, for example, the probability of storms increasing water levels to the height of 2.0 feet becomes 50% rather than 1%.[152] Even with drastic reductions in emissions of greenhouse gases and with a relatively stable Antarctic ice sheet, it is likely (greater than two chances in three) that sea-level rise will exceed 1 foot in south Florida by 2060.[153] If the Antarctic becomes unstable, as predicted by some, and greenhouse gas emissions continue to grow at today's rate, sea level rise in Florida is likely to exceed 4 feet by 2100, and there is a greater than 1-in-10 chance of exceeding 10 feet by 2100.[154] The annual average temperature of the contiguous United States is projected to rise throughout this century.[155] For the period 2021–2050, temperatures are projected to rise on average by 2.5°F for a lower scenario, which still makes this near-term average comparable to the hottest year in the historical record (2012).[156] Projected temperature increases in the Southeast for the 2036–2065 period range from 3.40°F to 4.30°F.[157] Projected changes in temperatures extremes for the Southeast region over 2036–2065

[157] *Id.* at 197, Table 6.4.

are projected to be 5.79°F for the warmest day of the year compared to the 1976–2005 period.[158] Change in the warmest 5-day, 1-in-10-year event for the same period is 11.09°F.[159] Extreme temperatures in the contiguous United States are projected to increase even more than average temperatures, with heat waves becoming more intense.[160]

The Applicant's current operating license limits allowable intake water temperature for Units 3 and 4 at 104°F.[161] In 2014 The Applicant requested and received from the NRC a modification to its license authorizing an increase of 4°F (from 100 to 104) for its cooling water intake.[162] FPL requested this modification to its license because "prolonged hot weather in the area has resulted in sustained elevated [Ultimate Heat Sink] temperatures . . . . High temperatures during the daytime with little cloud cover and low precipitation have resulted in elevated canal water temperatures at the Turkey Point site."[163] The average intake temperature of cooling water for Units 3 and 4 is 2.5°F above the average ambient air temperature.[164] The foreseeable increase in air temperature at Turkey Point during the subsequent license renewal period, absent mitigating measures, will cause intake water temperatures to exceed the 104°F limit in Applicant's operating license. An increase in air temperature during the subsequent license renewal period will increase the rate of evaporation from the cooling water canals,

[163] FP&L, Letter, "Request for Enforcement Discretion Regarding Technical Specification 3/4.7.4, Ultimate Heat Sink," ADAMS Accession No. ML14204A083 (July 21, 2014), encl. at 3.
[164] FP&L, Letter, "License Amendment Request No. 231, Application to Revise Technical Specification to Revise Ultimate Heat Sink Temperature Limit," ADAMS Accession No. ML14196A006 (July 10, 2014), encl. at 5.

thereby increasing salinity in the canals and cumulative impacts on groundwater. Additional mitigation measures or alternatives will be necessary to lower this increase in salinity.

6. A genuine dispute exists with the applicant on a material issue of law or fact (10 C.F.R. § 2.309(f)(1)(vi))

A genuine dispute exists with the Applicant's analysis of cumulative impacts on water resources. First, Applicant failed to consider cumulative impacts on water resources associated with reasonably foreseeable increases in sea level rise and hotter temperatures during the subsequent license renewal period. Second, Applicant erroneously assumes that cumulative impacts associated with the hypersaline plume emanating from the cooling canal system will be mitigated through a management program. NRC guidance, however, authorizes an applicant to make this assumption only when it complies with its permits. Here, Applicant *violated* its permits and has caused significant impacts on groundwater resources in the vicinity of Turkey Point.

a. *Section 4.12.4 Fails to Analyze Cumulative Impacts on Water Resources*

Applicant's approach to analyzing the cumulative impacts on water resources from climate change is woefully inadequate. The Environmental Report omits sea level rise from the list of "climate change indicators" when sea level rise will significantly impact Turkey Point.[165] Indeed, the reasonably foreseeable impacts from sea level rise during the current license renewal period have already required the company to implement mitigation measures to protect against flood events.[166] Applicant predicts a sea level rise of 0.39 feet *before* its current license expires

[165] ER, at 4-69 – 4-71.
[166] FP&L, Letter, "NEI 12-06, Revision 2, Appendix G, G.4.2, Mitigating Strategies Assessment (MSA) for FLEX Strategies report for the New Flood Hazard Information," ADAMS Accession No. ML17012A065 (Dec. 20, 2016).

in the early 2030s. Applicant cannot meaningfully address cumulative impacts from climate change without accounting for greater and more accelerated sea level rise during the subsequent license renewal period.

Applicant describes its cooling canal system as a "closed-cycle" system with no apparent "discernable influence on Biscayne Bay." However, reasonably foreseeable impacts from sea level rise will increase the risk of flooding at Turkey Point, including the potential for overtopping or breach of the canal system, leading to direct discharges of polluted canal water into surface water resources including Biscayne Bay.

Applicant also fails to analyze cumulative impacts on water resources associated with the reasonably foreseeable increase in air temperature. Higher air temperatures will increase the rate of evaporation in the cooling canal system leading to more saline conditions. Higher salinity in the cooling canals will, as has been shown, adversely impact groundwater resources.

b. *Applicant's Environmental Report (§ 4.12.4.2) Erroneously Assumes that Cumulative Impacts Associated with its Hypersaline Plume will be Managed.*

As a matter of law, Applicant may not rely on NRC Regulatory Guide 4.2, Revision 1 to assume that cumulative impacts from its plant will be eliminated through a management program.[167] The Guidance provides that applicants for a license renewal may assume cumulative impacts are managed under certain limited circumstances. For an applicant to benefit from this assumption, the cumulative impacts must be regulated and monitored by a permitting process and the facility must be "in compliance with their respective permits."[168]

[167] ER, at 4-86.
[168] NRC Regulatory Guidance 4.2, Rev. 1, Supp. 1, at 49.

Here, however, Applicant violated its permits and relevant regulations with respect to groundwater resources. For example, discharges from the cooling canal system have impaired "the reasonable and beneficial use of adjacent G-II ground waters to the west of the [Cooling Canal System] in violation of Condition IV.1 of [Applicant's] Permit and Rule 62-520.400, F.A.C."[169] Applicant seeks to turn the NRC guidance on its head by conflating permit compliance with remedial compliance. These are not the same. The former represents continual compliance with applicable permit conditions and regulations. The latter represents actual harm to the environment with new conditions and requirements, arrived through negotiations, seeking to correct past harm to the environment and mitigate future harm. NRC's NEPA regulations and guidance do not authorize Applicant to assume cumulative impacts will be managed when the facts demonstrate that impacts have not been managed through permit compliance.

<u>CONTENTION 3-E</u>: THE ENVIRONMENTAL REPORT FAILS TO CONSIDER NEW AND SIGNIFICANT INFORMATION REGARDING THE EFFECT OF SEA LEVEL ON CERTAIN CATEGORY 1 AND 2 ISSUES, IN VIOLATION OF 10 C.F.R. § 51.53(C)(3)(iv).

1. Statement of the issue of law or fact to be raised or controverted (10 C.F.R. § 2.309(f)(1)(i))

The Environmental Report (§§ 3 and 5) fails to comply with 10 C.F.R. § 51.53(c)(3)(iv) because it fails to analyze new and significant information regarding the effect of sea level rise on a number of Category 1 and 2 issues. Section 51.53(c)(3)(iv) requires an environmental

[169] *State of Florida Dep't of Environmental Protection v. Florida Power & Light Co*., OGC File No. 16-0241 (Fla. Dep. of Envt'l Prot. Jun. 20, 2016) (Consent Order) ¶ 19.

report submitted as part of a license renewal application to "contain any new and significant information regarding the environmental impacts of license renewal of which the applicant is aware." Neither the GEIS nor the Environmental Report contains any analysis of new and significant information regarding sea level rise relating to the following Category 1 or 2 issues:

- Surface water use conflicts (Category 2)
- Groundwater use conflicts (plants that withdraw more than 100 gallons per minute) (Category 2)
- Cumulative impacts (Category 2)
- Termination of plan operations and decommissioning (Category 1)

1. Brief explanation of the basis for the contention (10 C.F.R. § 2.309(f)(1)(ii)) and concise statement of the alleged facts or expert opinions supporting the contention (10 C.F.R. § 2.309(f)(1)(v))

NRC regulations require an environmental report to consider any "new and significant" information that may alter previous environmental conclusions.[170] "New and significant information" is defined as "[i]nformation not considered in the assessment of impacts evaluated in the GEIS leading to a seriously different picture of the environmental consequences of the action than previously considered."[171]

This obligation applies to both Category 1 and 2 issues.[172] "[E]ven where the GEIS has found that a particular impact applies generically (Category 1), the applicant must still provide

[170] 10 C.F.R. § 51.53(c)(3)(iv).
[171] ER, at 5-1 (citing NRC Regulatory Guide 4.2, Supp. 1, Rev. 1).
[172] *Massachusetts v. United States*, 522 F.3d 115, 120 (1st Cir. 2008).

additional analysis in its Environmental Report if new and significant information may bear on the applicability of the Category 1 finding at its particular plant."[173] This requirement is intended to ensure that "[w]hen the GEIS and SEIS are combined [or here, the GEIS and the Environmental Report], they cover all issues that NEPA requires be addressed in an EIS for a nuclear power plant license renewal proceeding."[174]

Here, the GEIS and the Environmental Report, when combined, do not "cover all issues that NEPA requires be addressed." Far from it: the GEIS expressly recognized that analysis of the effects of GHG emissions and climate change upon nuclear power plants could not be assessed generically.[175] The GEIS provided, therefore, that "each SEIS [will include] a plant-specific analysis of any impacts caused by GHG emissions over the course of the license renewal term *as well as any cumulative impacts caused by potential climate change upon the affected resources during the license renewal term*."[176]

The Environmental Report, however, fails to include an analysis of the effects of sea level rise in relation to numerous Category 1 and 2 issues. Beyond a brief mention that sea level rise will impact certain threatened, endangered, and sensitive species, the Environmental Report

---

[173] *In the Matter of Fla. Power & Light Co*. (Turkey Point Nuclear Generating Plant, Units 3 & 4), 54 N.R.C. 3, 11 (July 19, 2001).
[174] *Massachusetts*, 522 F.3d at 120.
[175] 2013 GEIS Revision, at 1-29 to 1-30.
[176] 2013 GEIS Revision, at 1-30 (emphasis added); *see also In the Matter of Duke Energy Carolinas, LLC* (Combined License Application for William States Lee III Nuclear Station, Units 1 & 2), 84 N.R.C. 180 (Dec. 15, 2016); *In the Matter of Tennessee Valley Auth.* (Bellefonte Nuclear Power Plant, Units 3 & 4) 2009 WL 3659545, at *3 (N.R.C. Nov. 3, 2009) ("We expect the Staff to include consideration of carbon dioxide and other greenhouse gas emissions in its environmental reviews for major licensing actions under the National Environmental Policy Act.").

does not discuss sea level rise *at all*.[177] Section 5 of the Environmental Report, "Assessment of New and Significant Information," contains only a summary of the process used by FPL to assess whether any new and significant information required analysis. The entirety of the FPL's analysis appears in one sentence: "As a result of this review, FPL is aware of no new and significant information regarding the environmental impacts of license renewal associated with PTN." [178] That conclusion fails to address information relating to sea level rise. This information is both new and significant.

The failure to address sea level rise is even more stark in light of Applicant's acknowledgement of future sea level rise at Turkey Point. In 2016, the company acknowledged that probable maximum storm surge exceeded the plant's design basis in several respects when "20 Year Sea Rise" was considered.[179] In the same document, FPL acknowledged that three "flood barrier segments" at Turkey Point "are not sufficient" to prevent flooding "when the projected 20 year sea-level rise of 0.39 inches is included."[180]

Moreover, the Final Environmental Impact Statement prepared for issuance of the combined construction permits and operating licenses for Turkey Point Units 6 and 7

---

[177] ER, at 3-181, 3-205, 3-210, 4-71.
[178] ER, at 5-4.
[179] FP&L, Letter, "NEI 12-06, Revision 2, Appendix G, G.4.2, Mitigating Strategies Assessment (MSA) for FLEX Strategies report for the New Flood Hazard Information," ADAMS Accession No. ML17012A065 (Dec. 20, 2016), encl. at 11, Table 2.2-3.
[180] *Id*. encl. at 16; *see also id.* ("In the longer term, sea level rise may result in wave run-up overtopping the north and south barriers in the turbine building."). Additionally, a projected 20-year sea level rise of 0.39 inches unreasonably low and not supported by any evidence. *See* Kopp Decl. at ¶ 30(a) and (d) (projecting a 68-95 percent chance that average sea level rise at Key West will exceed 1 foot by 2060 and, under a "High emissions scenario," projecting a 1.5-39 percent chance that average sea level rise will exceed 6 feet by 2100).

acknowledge that global sea level is projected to rise 1 to 4 feet by 2100, and that some projections predict 8.2 feet by 2100 relative to 2000.[181] The FEIS acknowledged that this scenario would mean that "much of South Florida would be uninhabitable and millions of people would likely be displaced."[182] The FEIS further acknowledged that:

- "Sea-level rise combined with more frequent Category 4 and 5 storms will increase the potential for damaging storm surge events at the Turkey Point site."[183]
- Sea level rise and storm surge would result in release of "sediment and nutrients" from the Turkey Point site.[184]
- "Sea-level rise could stress mangrove forests due to inundation and could stress surviving wetland vegetation by introducing brackish water farther inland," as well as also "place additional stress on the same habitats and wildlife affected by [Turkey Point's] operational impacts." [185]

Despite the above discussion of the effects of sea level rise in the Units 6 and 7 FEIS, the Environmental Report submitted with the Units 3 and 4 license renewal application fails to address the issue at all. This deficiency violates NEPA.

a. *Cumulative effects (Category 2)*

The Environmental Report's cumulative effects analysis (§ 4.12) fails entirely to discuss

[181] NRC, Final Report, "Environmental Impact Statement for Combined Licenses (COLs) for Turkey Point Nuclear Plant Units 6 and 7, Appendices A to K," ADAMS Accession No. ML16301A018 (Oct. 2016), App. I at I-3, *available at* https://www.nrc.gov/docs/ML1630/ML16301A018.pdf; *see also* Kopp Decl. at ¶¶ 38.
[182] *Id.*
[183] *Id.* at I-5.
[184] *Id.* at I-6
[185] *Id.* at I-6 to I-7. Because Units 6 and 7, if constructed, will be cooled by cooling towers rather than the existing cooling canal system, the FEIS for Units 6 and 7 did not address the effects of sea level rise in relation to the cooling canal system.

the sea level rise-related impacts upon affected resources. The GEIS recognized that "[c]hanges in climate have the potential to affect air and water resources, ecological resources, and human health, and should be taken into account when evaluating cumulative impacts over the license renewal term." [186] But the Environmental Report fails to address a primary localized effect of climate change: sea level rise. This failure violates the GEIS's assurance that each SEIS (or environmental report) will contain "a plant-specific analysis of any impacts caused by GHG emissions over the course of the license renewal term as well as any cumulative impacts caused by potential climate change upon the affected resources during the license renewal term."[187]

b. *Water resources (Surface water use conflicts (Category 2) and groundwater use conflicts (plants that withdraw more than 100 gallons per minute) (Category 2))*

The Environmental Report erroneously fails to account for the effect sea level rise will have on freshwater availability, ground water resources, and release of polluted cooling water into Biscayne Bay.[188] The Environmental Report's analysis of water resources impacts rests on the assumption that the cooling canal system is a "closed-loop" system and will not release of radionuclides or other pollution into the environment—an assumption that will no longer be valid once sea level rise has eliminated the "closed-loop" nature of the cooling canal system.[189]

---

[186] 2013 GEIS Revision, at 1-29.
[187] 2013 GEIS Revision, at 1-30; *see* Contention 3-E.
[188] *See* ER, at 4-20 – 4-29.
[189] E.g., ER, at 4-26. The cooling canal system is not "closed-loop." *See* ER at 3-114 ("The cooling canals by design are in direct hydraulic connection to the underlying surficial aquifer and are authorized to discharge to groundwater by the state of Florida IWW permit and the associated federal NPDES permit which is issued under delegation to the state of Florida[.]").

Climate change will result in sea level rise and more extreme and more frequent storm surges at Turkey Point.[190] Sea level rise will result in a frequent interchange of water from Biscayne Bay and the cooling canal system. These effects paint a "seriously different picture of the environmental consequences of the action than previously considered," and therefore must be considered.[191]

c. *Termination of plant operations and decommissioning (Category 1)*

Neither (1) the license renewal GEIS, (2) the GEIS prepared to analyze impacts related to plant decommissioning, nor (3) the Environmental Report addresses the effects of sea level rise on termination of plant operations and the decommissioning process.[192] Sea level rise will affect Applicant's ability to terminate plant operations and decommission the plant. If a subsequent license renewal is granted, Units 3 and 4 operating licenses will expire in the early 2050s, and the decommissioning process is expected to take 60 years to complete. This means that decommissioning will continue well past 2100, when sea level at Turkey Point could rise between four and ten feet.[193] NEPA requires either a GEIS or the Environmental Report to analyze this issue.[194] The failure to do so violates NEPA.

2. The issue raised in the contention is within the scope of the proceeding because it relates to Applicant's failure to consider new and significant information relating to Category 1 and 2 issues (10 C.F.R. § 203.9(f)(1)(iii))

---

[190] Kopp Decl. at ¶¶ 12(iv).
[191] ER, at 5-1.
[192] *See* 2013 GEIS Revision, at 4-10; NRC, Final Report, "Generic Environmental Impact Statement on Decommissioning of Nuclear Facilities, Vol. 1, Supp. 1 (NUREG-0586)," ADAMS Accession No. ML023500395 (Nov. 2002); ER, at 7-1.
[193] Kopp. Decl. at ¶¶ 40.
[194] *Massachusetts*, 522 F.3d at 120.

This issue is within the scope of the proceeding because NRC's NEPA regulations require the Environmental Report to include "any new and significant information regarding the environmental impacts of license renewal of which the applicant is aware."[195]

3. The issue raised in the contention is material to the findings the NRC must make to support relicensing (10 C.F.R. § 203.9(f)(1)(iv))

An issue is "material" if "the resolution of the dispute would make a difference in the outcome of the licensing proceeding."[196] "This means that there must be some link between the claimed error or omission regarding the proposed licensing action and the NRC's role in protecting public health and safety or the environment."[197] The issue raised in this contention—Applicant's failure to comply with NRC's regulations requiring consideration of all relevant information in its NEPA analysis—relates directly to the NRC's role in protecting public health and safety and the environment. NEPA imposes requirements on the NRC to ensure environmental protection. The failure to comply with these requirements is material to the findings NRC must make to support relicensing.

4. A genuine dispute of material fact or law exists regarding the Environmental Report's analysis (10 C.F.R. § 2.309(f)(1)(vi))

A genuine dispute of material fact or law exists regarding the sufficiency of the ER's analysis of new and significant information. The Applicant has concluded that it need not

---

[195] 10 C.F.R. § 51.53(c)(3)(iv).
[196] *Vermont Yankee*, 64 N.R.C. at 149.
[197] *Id.*

discuss any new and significant information regarding the environmental impacts of license renewal.[198] Petitioners contend to the contrary, that the ER's failure to analyze new and significant information regarding the effect of sea level rise on numerous category 1 and 2 issues is unlawful.[199]

CONTENTION 4-E: THE ENVIRONMENTAL REPORT FAILS TO DESCRIBE THE FORESEEABLE AFFECTED ENVIRONMENT DURING THE SUBSEQUENT LICENSE RENEWAL PERIOD.

1. Statement of the issue of law or fact to be raised or controverted (10 C.F.R. § 2.309(f)(1)(i))

Applicant's Environment Report (§ 3) erroneously fails to describe the reasonably foreseeable affected environment during the subsequent license renewal period (2032–2053) in violation of 10 C.F.R. § 51.53(c)(2). This failure renders Applicant's analyses of environmental impacts (§ 4), mitigating actions (§ 6), and alternatives analysis (§ 8) legally insufficient.[200]

2. Brief explanation of the basis for the contention (10 C.F.R. § 2.309(f)(1)(ii))

NEPA prohibits agencies from making decisions without first taking a "hard look" at the environmental consequences, requiring agencies to prepare an environmental impact statement (EIS).[201] The "heart" of the EIS is the agency's evaluation and analysis of alternatives to the proposed action.[202] This analysis turns on an accurate description of the areas "to be affected by

---

[198] ER at 5-4.
[199] *See* 54 Fed. Reg. at 33,170 ("Where the intervenor believes the application and supporting material do not address a relevant matter, it will be sufficient for the intervenor to explain why the application is deficient.").
[200] 42 U.S.C. § 4332(2)(A); 10 C.F.R. § 51.53(c)(3)(ii) and (iii).
[201] *Sierra Club v. Fed. Energy Regulatory Comm'n*, 867 F.3d 1357, 1367 (D.C. Cir. 2017).
[202] 10 C.F.R. Part 51, App. A, §§ 4, 5; *see also* 40 C.F.R. § 1502.14.

the proposed action."[203] Without an accurate description of the affected environment, an agency is unable to meaningfully "understand the effects of the alternatives."[204]

When the impacts occur is as important as where.[205] A description of the affected environment as it exists today is legally insufficient when the environment will undergo reasonably foreseeable and significant changes by the time the project commences and throughout its proposed lifetime. An agency's failure to consider this information in any meaningful or logical way violates NEPA.[206]

Here, Applicant omitted from its Environmental Report any description of reasonably foreseeable and significant aspects of the affected environment. The Environmental Report fails to discuss the changes in the surrounding environment and their effects on Turkey Point, including sea level rise, increased air temperature, increased surface water temperature, acidification, annual precipitation, drought, and increased storm intensity.[207] Thus, the Applicant

---

[203] 10 C.F.R. Part 51, App. A, § 6; *see also* 10 C.F.R. § 51.53(c)(2) (requiring a detailed description of the affected environment).

[204] 40 C.F.R. § 1502.15.

[205] 10 C.F.R. § 51.53(c)(3)(ii) (requiring analyses of "environmental impacts of the proposed action . . . *during the renewal term*.").

[206] *See AquAlliance v. U.S. Bureau of Reclamation*, 287 F. Supp. 3d 969, 1031–32 (E.D. Cal. 2018) (granting summary judgment to plaintiffs where agency failed to reconcile information on climate change impacts with ultimate conclusions about proposed action).

[207] Applicant admits elsewhere that sea level rise is reasonably foreseeable, relevant, and significant. *See e.g.* FP&L, Letter, "NEI 12-06, Revision 2, Appendix G, G.4.2, Mitigating Strategies Assessment (MSA) for FLEX Strategies report for the New Flood Hazard Information," ADAMS Accession No. ML17012A065 (Dec. 20, 2016), encl. at 16 (stating that various barrier segments at the plant are "adequate for the current sea-level; however, they are not sufficient when the projected 20 year sea-level rise of 0.39 inches is included and require modification to increase the height of the flood barrier."); *see also*, Attachment Q, Declaration of David Lochbaum, who provided an expert declaration upon which Petitioners rely and states: "[t]he license renewal rule, specifically 10 CFR 54.29, states that a renewed license may be issued if the Commission finds that "there is reasonable assurance that the activities authorized by the renewed license will continue to be conducted in accordance with the CLB" [current

provided no analysis of alternatives to avoid the effects of these changes. As a result, Applicant's Environmental Report violates 10 C.F.R. § 51.53(c)(2), 40 C.F.R. § 1202.15, and 42 U.S.C. § 4332(2)(C).

3. The issue raised in the contention is within the scope of the proceeding (10 C.F.R. § 2.309(f)(1)(iii))

NRC's NEPA regulations require an applicant for a license renewal to draft an Environmental Report.[208] The regulations specifically require a detailed description of the effected environment, which forms the basis of the applicant's, and later the NRC's, analyses of environmental impacts, mitigation measures, and alternatives.[209] Consequently, Applicant's failure to describe the affected environment during the relevant time frame is within the scope of this proceeding.

4. The issue raised in the contention is material to the findings the NRC must make to support the action involved in the proceeding (10 C.F.R. § 2.309(f)(1)(iv))

A contention is "material" to the NRC's duty to make environmental findings if the issue of law or fact it raises "is of possible significance to the result of the proceeding. This means that there should be some significant link between the claimed deficiency and either the health and safety of the public or the environment."[210]

The issue raised in this contention is material because Applicant's failure to describe the

licensing basis]. Because the flooding evaluations and assessments only went out to 2033, the expiration of the current operating licenses, and there is no evaluation or assessment concluding that reactor operation beyond 2033 will remain bound by those analyses, reasonable assurances needed to issue subsequent license renewals cannot be found." Att. Q at ¶ 41.

[208] 10 C.F.R. § 51.53(c).

[209] *Id*.

[210] *In re Entergy Nuclear Vt. Yankee L.L.C. & Entergy Nuclear Operations*, 60 N.R.C. 548, 556, 2004 NRC LEXIS 247, *16-17 (N.R.C. November 22, 2004).

reasonably foreseeable affected environment during the subsequent license renewal period taints the analyses of environmental impacts, mitigating actions, and alternatives. There are plainly real and significant differences, both in terms of safety and environmental impacts, between operating Units 3 and 4 in the affected environment described in Applicant's environmental report and one that is substantially hotter and prone to extreme flooding.

5. Concise statement of facts or expert opinions which support Petitioner's position and on which the Petitioner intends to rely at hearing (10 C.F.R. § 2.309(f)(1)(v))

Global mean sea level in the area around Turkey Point has risen over the past century and is projected to continue rising at an accelerated rate throughout this century and beyond.[211] Relative to the year 2000, there is at least a 90 percent probability that global mean sea level will rise by 0.3–0.6 feet by 2030 and 0.5–1.2 feet by 2050.[212] By 2100, scientists predict that global mean sea level will rise by at least 1.0 foot and could rise more than 8 feet under certain greenhouse gas emissions and Antarctic ice sheet stability scenarios.[213] Outside of Alaska, relative sea level rise along all U.S. coastlines will be greater than the global average rise.[214]

Sea-level rise for the remainder of this century in south Florida, including around Turkey Point will be faster than the average over the last century in every reasonably foreseeable climate change scenario.[215] Through 2060, there is between a 68 and 95 percent chance that average sea-

---

[211] Kopp Decl. ¶ 12(i) (referencing William V. Sweet et al., *Sea Level Rise*, in CLIMATE SCIENCE SPECIAL REPORT: FOURTH NATIONAL CLIMATE ASSESSMENT, VOL. 1 333–363 (D.J. Wuebbles et al. eds., 2017).
[212] *Id*. ¶ 12(ii).
[213] *Id*. ¶¶ 12(ii), 40.
[214] *Id*. ¶ 12(iii).
[215] *Id*. ¶ 13.

level rise at the Key West tidal gauge, which reflects relative sea level at Turkey Point, will exceed 1 foot above the National Tidal Datum Epoch.[216] Through 2060, there is a 10 to 37 percent chance that average sea level will exceed 2 feet with continuing unchecked fossil-fuel-based economic growth, leading to a near-doubling of carbon dioxide emissions between today and 2050, with continued growth thereafter.[217] By 2100, there is a 15 to 83 percent chance that average sea level will exceed 4 feet if the world's use of fossil fuels continues to grow unabated.[218]

Assuming storm characteristics do not change, sea level rise will increase the frequency and extent of extreme flooding associated with coastal storms, such as hurricanes.[219] Extreme high-water levels arise from the superimposition of tidal and storm influences on top of average sea level.[220] Most experts believe hurricanes and tropical storms will become more intense as temperatures rise due to climate change.[221]

For an intense storm with an appropriate track, extreme water levels well above the highest level observed historically at a particular site are well within the range of possibility.[222] The effect of sea level rise can be added to storm surge. If the sea level rises by one foot, for example, the probability of storms increasing water levels to the height of 2.0 feet becomes 50%

[222] *Id.* ¶ 33.

rather than 1%.[223]

Even if emissions are drastically curtailed, and the Antarctic Ice Sheet remains relatively stable, it is likely (greater than two chances in three) that sea-level rise will exceed 1 foot in south Florida by 2060.[224] If emissions around the world continue to grow unrestrained, and the Antarctic Ice Sheet becomes unstable, sea-level rise in Florida is likely to exceed 4 feet by 2100, and there is a greater than 1-in-10 chance of exceeding 10 feet by 2100.[225]

The annual average temperature of the contiguous United States is projected to rise throughout this century.[226] For the period 2021–2050, temperatures are projected to rise on average by 2.5°F for a lower scenario, which still makes this near-term average comparable to the hottest year in the historical record (2012).[227] Projected temperature changes in the Southeast for the 2036–2065 period range from 3.40°F to 4.30°F.[228] Projected changes in temperatures extremes for the Southeast region over 2036–2065 are projected to be 5.79°F for the warmest day of the year compared to the 1976–2005 period.[229] Change in the warmest 5-day, 1-in-10-year event for the same period is 11.09°F.[230] Extreme temperatures in the contiguous United States are projected to increase even more than average temperatures, with heat waves becoming

[230] *Id*.

more intense.[231] Oceans have absorbed about 93 percent of excess heat from global climate change, altering global and regional feedbacks.[232] Surface ocean temperatures have increased by an average of 1.3ºF (.70ºC) from 1900 to 2016.[233]

However, the Southeast region of the U.S. has experienced over .13ºC of surface temperature rise over the same period.[234] The Southeast region is projected to have 1.6 to 2.7ºC of sea surface temperature rise by 2080.[235] The residual heat that the ocean does not absorb causes land and sea ice to melt, which amplifies subsurface ocean warming and ice shelf melting due to increased thermal stratification, which reduces the ocean's ability to transport heat to deep waters.[236] Increased ocean stratification contributes to further ocean warming and mean sea level rise.[237]

Ocean surface waters have become 30 percent more acidic over the past 150 years.[238] Annually, oceans absorb more than a quarter of the CO_2 emitted into the atmosphere from human activities. Under higher emission scenarios, the average surface ocean acidity is projected to increase by 100 to 150 percent. Increased CO_2 in the ocean decreases the amount of carbonate ions available, affecting saturation states for calcium carbonate compounds, which many marine

species use to build shells or skeletons.[239]

Increased air temperatures, due to anthropogenic climate change, have created deficits in surface soil moisture, and surface soil moisture is *likely* to decrease as evaporation will outpace precipitation.[240] However, extreme precipitation events will increase in frequency and intensity throughout the contiguous U.S because of higher atmospheric water vapor concentrations due to increasing atmospheric temperatures.[241] Studies project that increased heavy precipitation will continue into the future; the number of extreme events will increase between 50 to 200 percent the historical average for every region, depending on emission scenario.[242]

Extreme precipitation events in the Southeast region are projected to increase by 9 percent in the lower emission scenario and 12 percent in the higher emission scenario by mid-century. Increased atmospheric water vapor concentration also causes increased precipitation within hurricanes by enhancing moisture convergence into the storm.[243] Hurricanes are responsible for the most extreme precipitation events, especially in southeastern U.S., and those events are predicted to be heavier in the future.[244] Numerical model simulations predict an increase in tropical cyclones (hurricanes and typhoons) in a warmer world, and the models show a general increase in the number of very intense storm events.[245] Temperature and precipitation

extremes are becoming more common, and some have become more frequent, intense, or have longer duration. These extremes have impacts on water quality and availability, agriculture, human health, infrastructure, and on iconic ecosystems and species.[246]

6. A genuine dispute exists over the Applicant's description of the affected environment (10 C.F.R. § 2.309(f)(1)(vi))

Petitioner contends that Applicant's Environment Report "fails to contain information on a relevant matter as required by law."[247] Petitioner identifies each such failure below and the supporting reasons for this belief, including various widely-accepted reports on climate change and expert opinions on the reasonably foreseeable affected environment. These failures create a genuine dispute on material issues of law and fact because, at a minimum, they render Applicant's analyses of environmental impacts of alternatives under consideration incomplete and incorrect in violation of NEPA.

c. *Section 3.3 of Applicant's Environmental Report Fails to Accurately Describe the Meteorology and Air Quality that Will Exist During the License Renewal Period*

The Environmental Report (§ 3.3) omits information about reasonably foreseeable increases in the ambient air temperature during the license renewal period.[248] Applicant's discussion of cumulative impacts from climate change omits this information as well.[249]

Increased temperatures can affect whether Units 3 and 4 are able to operate in the

---

[246] *Id.* at 18.
[247] 10 C.F.R. § 2.309(f)(1)(vi).
[248] *See e.g.,* FEIS for Units 6 and 7, at 2-212 ("The projected change in temperature by 2100, which encompasses the period of the licensing action in the southeastern United States is a regional average increase of between 4°F to 8°F in the annual average temperature.").
[249] ER, at 4-66, 4-69 (omitting information about reasonably foreseeable increases in sea level).

configuration described in the Environmental Report. Namely, higher temperatures affect the cooling canal system's heat exchange capacity either directly, by warming the water, or indirectly via degraded water quality.[250] Applicant will need to implement measures for reducing the temperature of water in the cooling canal system to reduce temperatures as they approach the current license limit of 104°F. If the plant cannot run as efficiently as predicted, or at all, if there are high temperatures in the cooling canal system, then the Environmental Report must account for the corresponding difference in power output when considering the purpose and need of the project and the analysis of alternatives.

d. *Section 3.6.1.3 of Applicant's Environmental Report Fails to Accurately Describe the Potential for Flooding During the License Renewal Period.*

Applicant's description of the affected environment's potential for flooding (§ 3.6.1.3) omits relevant information about reasonably foreseeable and significant sea level rise. For example, in the context of its flood hazard reevaluations (not discussed in the ER), Applicant determined that its design-basis flood barriers were "not sufficient when the projected 20 year [initial license renewal period] sea-level rise of 0.39 inches is included and require modification to increase the height of the flood barrier."[251] Though there is *no* dispute that mean sea levels will rise significantly in the reasonably foreseeable future, Applicant fails to discuss this issue or

---

[250] ER, at 4-33 (describing various issues that impacted the Cooling Canal System's heat exchange capacity).
[251] FP&L, Letter, "NEI 12-06, Revision 2, Appendix G, G.4.2, Mitigating Strategies Assessment (MSA) for FLEX Strategies report for the New Flood Hazard Information," ADAMS Accession No. ML17012A065 (Dec. 20, 2016), encl. at 16; *see also* Declaration of David Lochbaum (Attachment Q) ¶ 22.

capture this important aspect of the affected environment in its Environmental Report.[252]

Dr. Kopp, Petitioner's expert, opines that even under the best-case emissions scenario, there is greater than two chances in three that sea-level rise will exceed 1 foot in south Florida by 2060.[253] This will dramatically increase the rate of flooding:

> 1.0 feet of average sea-level rise turns the current 50% annual probability high-water level (1.0 feet above Mean Higher High Water) into the new average higher high-water level and the current 1% annual probability high-water level (2.0 feet above Mean Higher High Water) into the new 50% annual probability high-water level. 2.0 feet of average sea-level rise turns the current 1% annual probability high-water level into the new average higher high water level. The effects of this cannot be understated: at Key West, 3.0 feet of sea-level rise is sufficient to turn the highest water level experienced to a flood level expected to be exceeded, on average, half of the days of the year.[254]

Superimposed on higher sea levels, tidal and storm influences will lead to extreme high-water levels at Turkey Point.

If Units 3 and 4 are unable to achieve the stated 1,632 megawatts output due to flooding, then the Environmental Report must account for this diminished output in the discussion of the project's purpose and need as well as the analysis of alternatives.

e. *Section 3.6.2 of Applicant's Environmental Report Fails to Accurately Describe Groundwater Resources that Will Exist During the License Renewal Period.*

Applicant's Environmental Report fails to address the reasonably foreseeable condition

---

[252] *See id.*; Pacific Northwest National Laboratory, "Potential Impacts of Accelerated Climate Change, Annual Report of Work for NRC Agreement Number NRC-HQ-60-14-D-0025," ADAMS Accession No. ML16208A282 (May 2016). Applicant's discussion of cumulative impacts similarly omits information about reasonably foreseeable sea level rise. *See* ER, § 4.12.
[253] Kopp Decl. ¶ 38.
[254] Kopp Decl. ¶ 34.

of groundwater resources during the relevant time period, 2032–2053.[255] This failure is material to the NRC's decision. Applicants like FPL whose plants pump "more than 100 gallons (total onsite) of groundwater per minute" must assess the impact of the proposed action on groundwater resources.[256]

Applicants cannot, however, adequately assess groundwater impacts from the operation of the plant during the subsequent license renewal period without first accurately describing groundwater resources during the same period. Applicant states—without explanation—that it does not anticipate increasing groundwater withdrawals beyond currently permitted levels during the renewal period.[257] Because it does not anticipate increasing its groundwater withdrawals, Applicant concludes that environmental impacts from its future withdrawals will remain the same (allegedly small) and do not warrant additional mitigation measures.[258] Applicant's analysis of this issue fails to address, however, whether sufficient groundwater resources will be available during the license renewal period. In fact, it is highly probable that groundwater resources will be inadequate, putting Turkey Point's need for groundwater in conflict with the need for drinking water of the population of South Florida.

CONTENTION 5-E: THE ENVIRONMENTAL REPORT FAILS TO ADDRESS THE ADVERSE EFFECT OF OPERATING THE COOLING CANAL SYSTEM FOR AN ADDITIONAL 20 YEARS ON

[255] Applicant's Supplement to the Environment Report, similarly does not address the reasonably foreseeable future state of groundwater resources. FP&L, "Turkey Point Units 3 and 4 Subsequent License Renewal Application, Appendix E Environmental Report Supplemental Information," ADAMS Accession No. ML18102A521 (Apr. 10, 2018).

[256] 10 C.F.R. § 51.53(c)(3)(ii)(C); Applicant admits groundwater use conflicts are a relevant Category 2 issue in this proceeding. ER, at 4-9.

[257] ER at 4-23.

[258] *Id.*; FP&L, "Turkey Point Units 3 and 4 Subsequent License Renewal Application, Appendix E Environmental Report Supplemental Information," ADAMS Accession No. ML18102A521 (Apr. 10, 2018), encl. Attachment 1, at 4 (concluding Turkey Point groundwater withdrawals are small and do not warrant additional mitigation measures).

SURFACE WATERS, FRESHWATER WETLANDS, AND ENDANGERED SPECIES PRESENT IN THOSE WETLANDS

1. Statement of the issue of law or fact to be raised or controverted (10 C.F.R. § 2.309(f)(1)(i))

NRC regulations require the Environmental Report to consider the effects of Turkey Point's continued operation on surface waters, freshwater wetlands, and endangered species present in those wetlands.[259] But the ER gives no consideration to how the salinization of freshwater wetlands caused by the cooling canal system will impact threatened or endangered species, and otherwise harm important plant and animal habitats. This failure violates NEPA.

2. Brief explanation of the basis for the contention (10 C.F.R. § 2.309(f)(1)(ii)) and concise statement of facts or expert opinions which support Petitioners' position and on which Petitioners intend to rely at hearing (10 C.F.R. § 2.309(f)(1)(v))

Operation of the cooling canal system causes salt and other pollutants to migrate into the groundwater surrounding the cooling canals.[260] Heat from Units 3 and 4 causes evaporation of water in the cooling canals that concentrates salt, creating a hypersaline environment in the canals. The relatively denser saline water leaches out of the cooling canal system and into the aquifer, creating a "hypersaline plume." [261] This process and associated environmental impacts have been recognized by the NRC, the State of Florida, and Miami-Dade County.[262]

---

[259] 10 C.F.R. § 51.53(c)(3)(ii)(E) (ER must consider the "impact of refurbishment, continued operations, and other license renewal-related construction activities on important plant and animal habitats" and "on threatened or endangered species"); *see also id.* § 51.53(c)(3)(ii)(B) (ER must consider impacts on fish and shellfish resources resulting from thermal changes and impingement and entrainment).
[260] ER, at 3-82, 3-111.
[261] ER, at 3-111.
[262] *See infra* notes 114, 137.

Over the last four decades, the portion of the Biscayne Aquifer below the cooling canal system has become saturated with hypersaline water moving down into the aquifer and radially in all directions, including westward (*i.e.*, towards the Model Lands Basin, the wider Everglades, and drinking water wells screened in the Biscayne Aquifer), and eastward towards Biscayne Bay where the plume discharges to the surface water.[263]

Salt migrating out of the cooling canal system has formed a hypersaline plume and has moved the saltwater/freshwater interface westwards at all elevations in the Biscayne Aquifer.[264] Operation of the cooling canal system has driven the saltwater/freshwater interface at the base of the aquifer several miles westward into what was previously a potable portion of the aquifer.[265]

The cooling canal system is bounded to the west, southwest, south, and northwest by extensive freshwater wetlands that form part of the Everglades. The nearest wetland watershed unit is called the Model Lands Basin and consists primarily of publicly owned, undeveloped freshwater wetlands that are important habitat for plants and animals, including multiple endangered species.[266] Endangered species that depend on this wetland habitat include the Florida panther, American crocodile, indigo snake, snail kite, red knot and wood stork.[267] The Model Lands Basin also contains the company's Everglades Mitigation Bank.

Reg. 20059, 20062 (Apr. 3, 2012) ("Because the PTN canals are unlined, there is an exchange of water between the PTN canal system and local groundwater and Biscayne Bay" including a seasonal "flow of hypersaline water from the CCS toward the Everglades").
[264] Chin, David A, Ph.D., *The Cooling System at the FPL Turkey Point Power Station* at 12 (2015) (Attached hereto as Exhibit O).
[265] *Id*. at 12-13.
[266] ER, at 3-149.
[267] 2017 BiOp, at 44.

The discharge of saline groundwater from the cooling canal system is now degrading those wetlands. According to Miami-Dade County: "The FPL Turkey Point CCS, as well as FPL's Everglades Mitigation Bank are located in the extreme southeast region of the county, in an area that is experiencing significant westward migration of the salt intrusion front at the base of the Biscayne aquifer, and where historically fresh surface water canals have recently been documented with higher conductivity and chloride levels uncharacteristic of fresh water bodies."[268]

The County has also noted that "hydrologic impacts including salt intrusion and groundwater and surface water contamination have been documented on these lands."[269] Measurements recorded in County-owned wetlands west of the canal in April 2018 found that shallow groundwater in the area now exhibits conductivity of more than 5000 microSiemens (µmhos/cm).[270] These conductivity levels are dangerously high for a naturally freshwater environment.[271]

---

[268] DERM-FDEP July 2018 Letter, at 2.
[269] *Id.* at 4.
[270] *Id.* at 27, 59.
[271] *See* EPA, *Conductivity*, https://archive.epa.gov/water/archive/web/html/vms59.html (last visited July 27, 2018) ("Conductivity is a measure of the ability of water to pass an electrical current. Conductivity in water is affected by the presence of inorganic dissolved solids such as chloride, nitrate, sulfate, and phosphate anions (ions that carry a negative charge) or sodium, magnesium, calcium, iron, and aluminum cations (ions that carry a positive charge). . . . The conductivity of rivers in the United States generally ranges from 50 to 1500 µmhos/cm. Studies of inland fresh waters indicate that streams supporting good mixed fisheries have a range between 150 and 500 µhos/cm. Conductivity outside this range could indicate that the water is not suitable for certain species of fish or macroinvertebrates. Industrial waters can range as high as 10,000 µmhos/cm."); *see also* Ami L. Riscassi and Raymond W. Schaffranek, USGS, Flow Velocity, Water Temperature, And Conductivity In Shark River Slough, Everglades National Park, Florida: July 1999 – August 2001 (2002), available at https://pubs.usgs.gov/of/2003/ofr03348/ (Appendix C records specific conductance in the range of 300 to 500 µmhos/cm over two years of observations).

Further, recent salinity measurements in the L-31 canal west of the interceptor ditch indicate that saline water from the plume has surfaced in and entered the L-31 canal, from which it can now enter adjacent freshwater wetlands, causing further degradation of the wetlands.[272] As the County explains, "The water quality of the L-31 E was initially freshwater and salinities during the period of record have increased to over 29 PSU."[273] Over the past ten years, canal salinities have trended upward and the highest salinities (29 PSU) were recorded during the first quarter of 2018.[274] Some of this information thus post-dates Applicant's Environmental Report, and none of this information has been previously considered by the NRC.

Turkey Point discharges other pollutants from the cooling canal system to nearby surface waters via the Biscayne Aquifer. Specifically, violations of surface water ammonia standards have been observed in canals near Turkey Point.[275] In the ER, Applicant claims that ammonia detected in surface water is not the result of point or non-point source contamination attributable to Turkey Point.[276] Miami-Dade County, however, has offered evidence that Turkey Point is a key source of the ammonia and is responsible for the violations of water quality standards.[277] Ammonia can have direct and highly toxic effects on the aquatic environment,[278] yet the ER fails

---

[272] DERM-FDEP July 2018 Letter, at 3, 26, 51; NRC, "Environmental Impact Statement for Combined Licenses for Turkey Point Nuclear Plant Units 6 and 7," Appendix I at I-6 (describing harm to wetland vegetation caused by the advance of brackish water farther inland).
[273] DERM-FDEP July 2018 Letter, at 3.
[274] *Id.* at 55, 56.

to consider the impacts of ammonia discharges on threatened and endangered species and important habitat.[279]

3. The issue raised in the contention is within the scope of the proceeding (10 C.F.R. § 2.309(f)(1)(iii))

NRC regulations plainly require the ER to address the effects of Turkey Point's continued operations on surface waters, freshwater wetlands, and endangered species.[280] The effects on these resources of the Turkey Point's cooling canal system are therefore within the scope of this proceeding.

4. The issue raised in the contention is material to the findings the NRC must make to support the action involved in the proceeding (10 C.F.R. § 2.309(f)(1)(iv))

A contention is "material" to the NRC's duty to make environmental findings if the issue of law or fact it raises "is of possible significance to the result of the proceeding. This means that there should be some significant link between the claimed deficiency and either the health and safety of the public or the environment."[281]

There is a significant link between the issue raised in this contention—FPL's failure to assess the impacts of Turkey Point's operations on surface waters, freshwater wetlands, and threatened and endangered species—and "the health and safety of the public or the environment."[282] NRC regulations require the ER to include such an analysis. Each aspect of

---

52192 (Aug. 22, 2013)

[279] 10 C.F.R. § 51.53(c)(3)(ii)(E) and (B).

[280] *See, e.g.*, 10 C.F.R. § 51.53(c)(3)(ii)(E) (ER must consider "impact of refurbishment, continued operations, and other license renewal-related construction activities on important plant and animal habitats" and "on threatened or endangered species"); *id.* § 51.53(c)(3)(ii)(B) (ER must consider impacts on fish and shellfish resources resulting from thermal changes and impingement and entrainment).

[281] *In re Entergy Nuclear Vt. Yankee L.L.C. & Entergy Nuclear Operations*, 60 N.R.C. 548, 556–57, 2004 NRC LEXIS 247, *16-17 (N.R.C. November 22, 2004).

[282] *Id.*

the contention relates directly to an impact on the public health or the environment and, thus, is material to the findings the NRC must make to support relicensing.

5. A genuine dispute of material fact or law exists over the Environmental Report's analysis (10 C.F.R. § 2.309(f)(1)(vi))

Where the intervenor alleges that a license renewal application does not address a relevant matter, a genuine dispute of material fact or law exists if the intervenor explains why the application is deficient.[283] Petitioners meet this standard. Here, the Applicant has failed to give any consideration to the impacts that groundwater salinization caused by the Turkey Point cooling system could have on surface waters, freshwater wetlands and the plants and animals that live there, including threatened and endangered species. Applicant states that studies it conducted "to determine the influence of the cooling canals on the surrounding areas through migration of groundwater" demonstrate that "the cooling canals do not have any ecological impact on the surrounding areas."[284] Applicant's discussion of "Threatened, Endangered, and Protected Species, and Essential Fish Habitat" did not even consider the effects of salinization of freshwater wetlands west of Turkey Point.

Petitioners have cited authoritative government documents that establish that Applicant's analysis does not comply with NRC regulations.[285] These analyses plainly evidence saltwater intrusion into historically fresh surface water canals and wetlands.[286] Furthermore, there is a genuine dispute as to the impact of ammonia on nearby surface waters.

---

[283] 54 Fed. Reg. at 33,170.

INTRODUCTION

As may be permitted by the Atomic Safety and Licensing Board ("ASLB")[1], Southern Alliance for Clean Energy ("SACE"), Natural Resources Defense Council ("NRDC"), Friends of the Earth ("FoE"), and Miami Waterkeeper ("MWK") (hereinafter "Petitioners") hereby respond to Applicant's Surreply to New Arguments Raised in Reply Pleadings (Sept. 20, 2018) ("Surreply"). The Applicant, Florida Power & Light ("FPL"), asks the ASLB to disregard the plain language of 10 C.F.R. § 51.53(c)(3), which restricts the applicability of that regulation to "applicants seeking an *initial* renewed license." But FPL's arguments are without merit.

ARGUMENT

I. FPL'S INTERPRETATION OF 10 C.F.R. § 51.53(c)(3) VIOLATES BASIC PRINCIPLES OF STATUTORY INTERPRETATION.

FPL does not dispute that the plain language of the phrase "applicants seeking an initial renewed license" means applicants seeking a renewed license directly following an initial 40-year license term; nor does FPL deny that the phrase, if applied to FPL's subsequent license renewal application, would preclude FPL from relying on § 51.53(c)(3) to avail itself of the binding Category 1 exclusions in Table B-1 of Appendix A to 10 C.F.R. Part 51. Instead, FPL urges the ASLB to disregard the plain language of § 51.53(c)(3) and apply the Category 1 exceptions to FPL's subsequent license renewal application anyway. FPL's various arguments violate the bedrock principles guiding adjudicatory bodies in construing statutes and legislative rules. And FPL has failed to justify any exception to these principles.

---

[1] Petitioners have filed a motion for leave to file this response to FPL's Surreply. *See* Motion for Leave to Respond to Surreply (Oct. 1, 2018).

The paramount rule of construction is that when construing legislative text,[2] "we look first to its language, giving the words used their ordinary meaning." *Artis v. District of Columbia*, 138 S. Ct. 594, 603 (2018). "There is, of course, no more persuasive evidence of the purpose of a statute than the words by which the legislature undertook to give expression to its wishes." *United States v. Am. Trucking Assns., Inc.*, 310 U.S. 534, 543 (1940); *see also Puerto Rico v. Franklin Cal. Tax-Free Tr.*, 136 S. Ct. 1938, 1946 (2016) (Where a "statute's language is plain," resolution of a disputed issue "begins with the language of the statute itself, and that is also where the inquiry should end." (internal quotation marks omitted)). The Supreme Court has repeatedly made clear that the "plain meaning" of a legislative text is "conclusive, except in the 'rare cases'" in which such an interpretation would "produce a result *demonstrably at odds with the intentions of its drafters*." *Griffin v. Oceanic Contractors, Inc.*, 458 U.S. 564, 571 (1982) (emphasis added).

In violation of this principle, FPL urges the Board to go beyond the plain language of § 53(c)(3) and disregard *entirely* the clear, unambiguous language of the regulation. In essence, FPL contends that "initial renewed license" means "*any* type of renewed license, including initial or subsequent." But FPL's interpretation—in addition to violating the cardinal rule of legislative construction by ignoring the plain language of the regulation—would read the crucial limiting word "initial" out of the regulation. FPL's argument violates the cardinal rule of statutory construction that "effect must be given, if possible, to every word, clause and sentence." *United States v. Menasche*, 348 U.S. 528, 538–39 (1955); *see also Wrangler Laboratories, et. al.,*

[2] Canons of statutory construction apply with equal force to construction of regulations. *Nat'l Ass'n of Home* Builders *v. Defs. of Wildlife*, 551 U.S. 644, 668 (2007); *Long Island Care at Home, Ltd. v. Coke*, 551 U.S. 158, 170 (2007).

ALAB-951, 33 N.R.C. 505, 513–14 (1991) (quoting *Long Island Lighting Co.* (Shoreham Nuclear Power Station, Unit 1), ALAB-900, 28 N.R.C. 275, 288 (1988)).

FPL's proposed interpretation of § 51.53(c)(3) to apply to all license renewal applicants would also negate the meaning of other language in the regulation. In addition to being limited to "initial" license renewals, the benefit to applicants from § 51.53(c)(3) is also limited to applicants that "hold[] an operating license . . . as of June 30, 1995." To adopt FPL's argument that § 51.53(c)(3) must be applied to *all* subsequent license renewal applicants would require the ASLB to ignore this unambiguous language as well. But the ASLB may not construe the regulation "in a way that negates its plain text." *Honeycutt v. United States*, 137 S. Ct. 1626, 1635 n.2 (2017); *see also Nat'l Ass'n of Home Builders*, 551 U.S. at 668–69 (court cannot interpret a regulation to render part of it surplusage); *Gardebring v. Jenkins*, 485 U.S. 415, 430 (1988) (court should reject agency's interpretation of its own statute in favor of an alternative if that alternative "is compelled by the regulation's plain language").

II. FPL FAILS TO JUSTIFY ANY EXCEPTION TO THE PLAIN MEANING RULE.

FPL does not dispute the general applicability to NRC proceedings of the "plain meaning rule," *i.e.,* that "the starting point in construing a statute (or a regulation) is the language of the statute or regulation itself, and that if that language is plain and unambiguous, then it must be applied according to its terms."[3] But FPL claims this case falls under "one generally recognized exception," for circumstances where application of the plain meaning of a regulation would

---

[3] FPL Surreply at 4 and n.12 (citing *Northeast* Nuclear *Energy Co.* (Millstone Nuclear Power Station, Unit 3), CLI-01-10, 53 N.R.C. 353, 361 (2001); *Hydro Res., Inc.,* (P.O. Box 777, Crownpoint, New Mexico 87313), CLI-04-11, 63 N.R.C. 483, 491 (2004)).

"produce an 'absurd' or 'unintended' result."[4]

This exception, however, is "rarely applied, because the result produced by the plain meaning canon must be *truly absurd* before this principle trumps it. Otherwise, clearly expressed legislative decisions would be subject to the policy predilections of judges." *Merritt v. Dillard Paper Co.*, 120 F.3d 1181, 1188 (11th Cir. 1997) (emphasis added). It is not enough to rely on "broad [statutory] purposes" to justify ignoring specific language whose meaning is unambiguous. *Int'l Bhd. of Teamsters v. Interstate Commerce Com.*, 801 F.2d 1423, 1430 (D.C. Cir. 1986), *on reh'g,* 818 F.2d 87 (D.C. Cir. 1987) (rejecting the Interstate Commerce Commission's attempt to ignore unambiguous statutory language). The exception is even less appropriate to apply where, as here, a court is asked to violate another cardinal rule of statutory construction—that "effect must be given, if possible, to every word, clause and sentence." *Menasche*, 348 U.S. at 538–39. FPL utterly fails to justify an exception to the plain language rule here.

A. There Is Nothing Absurd, Let Alone *Truly* Absurd, About Giving § 51.53(C)(3) Its Plain and Ordinary Meaning.

Application of the plain meaning of § 51.53(c)(3) to exclude subsequent license renewal applicants yields a logical result, not an absurd result. There is nothing "absurd" or even illogical about requiring a subsequent license renewal applicant to analyze Category 1 environmental issues on a site-specific basis. The 1996 GEIS focused only on the environmental impacts of the first twenty years following the initial license term, and the 2013 Revision to the

[4] *Id.*

GEIS did nothing to expand on that temporal scope. Therefore, it would be *illogical* to apply the Category 1 exemptions to a second license renewal term whose environmental impact had never been analyzed in an EIS.[5]

1. The temporal scope of the 1996 GEIS is clearly limited to the 40-year initial license term plus one renewal term.

The limited temporal scope of the 1996 GEIS is clear. As a general matter, it states:

> This GElS examines how these plants and their interactions with the environment would change if such plants were allowed to operate (under the proposed license renewal regulation 10 CFR Part 54) *for a maximum of 20 years past the term of the original plant license of 40 years*.[6]

And the limited temporal scope of the 1996 GEIS' findings undergirding Table B-1 is repeated in specific environmental analyses. For instance, the Category 1 designation of "radiation exposures to the public" in Table B-1 is based on the conclusion that "[r]adiation doses to the public from continued operations and refurbishment associated with license renewal are expected to continue at current levels, and would be well below regulatory limits." This finding is based, in turn, on the environmental analysis in Section 2.6 of the 1996 GEIS, which assumes that the license to be renewed is the initial operating license. As stated in Section 2.6.2.2:

> The generic license renewal programs utilized in this evaluation were based on similar schedules for carrying out the selected aging management activities. Any major refurbishment work called for by the programs was assumed to start shortly after a renewed license had been granted. *In these example programs, this would occur in roughly year 30 of the original 40-year license term. This work was assumed to be completed over several successive outages, including one at the end of the 40th year of plant*

[5] To be clear, Petitioners *do not* challenge the content or conclusions of the GEIS.

[6] 1996 GEIS at 2-1 (emphasis added).

operation.[7]

NRC carried this temporal limit throughout the 1996 GEIS for a range of environmental impacts.[8] Thus, the 1996 GEIS analyzes the effects of adding a 20-year term to an original 40-year license term, and no more.[9]

2. The NRC did not expand the temporal scope of the License Renewal GEIS in the 2013 Revised GEIS.

The 2013 Revised License Renewal GEIS did not change this temporal scope. Instead, it simply re-evaluated and confirmed the previous findings. For instance, the 2013 Revised GEIS asserts that the 1996 GEIS' conclusions regarding the environmental impacts of refurbishment activities are "valid and conservative."[10] And the 2013 Revised GEIS concludes that "[d]uring the license renewal term, commercial nuclear power plants would continue to operate in the

---

[7] 1996 GEIS at 2-34 (emphasis added). *See also* Section 2.6.2.7, where the 1996 assumes that a renewed license would be "covering the balance of the original 40-year term, as well as the additional 20-year term." *Id.* at 2-36.

[8] *See, e.g., id.* at 7-1 – 7-17 (decommissioning); *id.* at 3-39 (radiation protection); *id.* at 4-59 (transmission lines); *id.* at 4-85 (public radiation doses). A 40-year term of reactor operation is assumed throughout as the "base case" or "baseline." *Id.* at 7-1, 7-10, 7-14, 4-85.

[9] Further confirmation of the NRC's intent to limit the temporal scope of the 1996 GEIS can be found in a clarifying amendment to the 1996 rule, promulgated later that year. Final Rule, Environmental Review for Renewal of Nuclear Power Plant Operating Licenses, 61 Fed. Reg. 66,537 (Dec. 18, 1996) (making "minor non-substantive changes" to Table B-1 and other provisions). In responding to comments, the NRC referred to "waste currently being generated during the initial license term of power reactors" (*id.* 66,538) and the "attribution of transportation impacts between the initial operating license and the renewed license." *Id.* at 66,539. This language confirms that the only two license terms that were evaluated in the 1996 GEIS or the 1996 rule were the initial license term and the first license renewal term.

[10] 2013 Revised GEIS at 2-3.

same manner as they had during the original license term."[11]

The temporal limitation of the 2013 Revised GEIS to 40 plus 20 years is also evident in the GEIS' discussion of specific types of environmental impacts. With respect to occupational radiation exposures, for example, the 2013 Revised GEIS states:

> During 2005, with occupational radiation protection programs in place, nuclear power plants maintained an annual average individual dose of 0.12 rem and 0.18 rem for PWRs and BWRs, respectively (Table 3.9-11), compared with an exposure limit of 5 rem. For all nuclear power plants combined, the occupational doses to individual workers are estimated to average 0.15 rem/yr (Table 3.9-4). At these dose levels, the average increase in fatal individual cancer risk to a worker is approximately 6 x 10-5/yr (using the ICRP risk coefficient of 4 x 10-4/rem from Table 3.9-20). *If the reactor operates for 60 years, the cumulative increase in fatal cancer to an individual worker is estimated to be 3.6 x 10-3 (a 50 percent increase over the baseline of 40 years of operations).* However, it is very unlikely that the same worker would be employed for all 60 years of plant operations.[12]

The 2013 Revised GEIS contains a similar analysis for public radiation doses. Once again, 40 years is the "baseline" for an environmental analysis that predicts environmental impacts over a subsequent 20-year renewal period:

> Although dose rates (mrem/yr) are not expected to change during license renewal, the cumulative dose (total mrem) would increase as a result of 20 more years of operations. If the reactor operates for 60 years, it is estimated that the increase in fatal cancer risk to the MEI would range from 6 x 10-7 to 4.6 x 10-4 (a 50 percent increase over the baseline of 40 years of operation). However, it is unlikely that the same person would be exposed to these doses for 60 years of plant operations.[13]

On the same topic of environmental impacts of radiation exposures to the public, the 2013

---

[11] *Id.*

[12] 2013 Revised GEIS at 4-138 – 4-139 (emphasis added).

[13] *Id.* at 4-145 (emphasis added).

Revised GEIS further states:

> Regulatory Guide 1.109 (NRC 1977) provides guidance for calculating the dose for significant release pathways. To account for the buildup of radioactive materials, buildup factors are included in the calculations. Initially, most of the calculations for the construction and operating stage permits used 15 years as the approximate midpoint of a facility's operating life. This value is now more often taken to be 20 years. The potential license renewal term is an additional 20 years; *thus, the effective midlife is 30 years.*[14]

Along the same lines, with respect to decommissioning, the 2013 Revised GEIS states:

> As discussed in the 1996 GEIS, the dose to the public from long-lived radionuclides after 40 years of plant operation is expected to be negligible, and the increase in quantities of long-lived radionuclides after an additional 20 years would result in a negligible dose (less than 0.1 person-rem). Accordingly, the NRC concluded that the contribution of license renewal to radiological impacts to the public from decontamination would be of SMALL significance at all nuclear plants.[15]

Throughout the 2013 Revised GEIS, the NRC refers to a time frame totaling 60 years, and a baseline of 40 years. *Nowhere* does the 2013 Revised GEIS refer to a time frame totaling 80 years or a baseline of 60 years.

There is nothing surprising, therefore, about a regulatory provision that would preclude a subsequent license renewal applicant from relying on the Category 1 finding in Table B-1. To the contrary, application of the plain meaning of § 51.53(c)(3) would yield a logical result, *i.e.*, to preclude a subsequent license renewal applicant from relying on environmental findings beyond the temporal scope of a second license renewal term. Thus, there is nothing "absurd" about applying the plain language of § 51.53(c)(3) to FPL's subsequent license renewal application.

---

[14] *Id*. at 4-144 (emphasis added).

[15] *Id*. at 4-217.

B. The Limitation Of § 51.53(C)(3) To "Applicants Seeking an Initial Renewed License" Is Not Inconsistent with NRC's Entire Regulatory Scheme for Implementation of NEPA in License Renewal Proceedings.

FPL contends that interpreting § 51.53(c)(3) to exclude subsequent license renewal applicants like FPL is inconsistent with the NRC's "entire regulatory scheme."[16] According to FPL, Petitioners' "plain language" interpretation of § 51.53(c)(3) contradicts NRC's regulations for preparing environmental impact statements, which contain no comparable prohibition against applying the Category 1 exclusions of Table B-1 to EISs for subsequent license renewal applicants:

> Section 51.71 governs the content of the Staff's draft (and ultimately final) supplemental environmental impact statement ("SEIS"). Section 51.71(d) provides that "[t]he draft [SEIS] for license renewal prepared under § 51.95(c) *will rely on conclusions as amplified by the supporting information in the GEIS for issues designated as Category 1* in appendix B to subpart A of this part." Section 51.95(c) provides, among other things, that the license renewal SEIS "shall address those issues as required by § 51.71," and "shall integrate the conclusions in the [GEIS] for issues designated as Category 1 with information developed for those Category 2 issues applicable to the plant under § 51.53(c)(3)(ii) and any new and significant information."[17]

But the failure of logic lies with FPL. In promulgating Table B-1, § 51.71, and § 51.95 in 1996, the NRC had no reason to state that the Category 1 exception applied only to initial license renewals, because neither the rule nor the underlying 1996 GEIS applied to anything *other than*

---

[16] FPL Surreply at 27 (citing Northeast *Nuclear Energy Co.* (Millstone Nuclear Power Station, Unit 3), CLI-01-10, 53 N.R.C. 353, 366 (2001); *U.S. Dep't of Energy* (High-Level Waste Repository), LBP-04-20, 60 N.R.C. 300, 335 (2004)).

[17] FPL Surreply at 8 (emphasis in original) (footnotes omitted).

initial license renewals (*i.e.*, 40 plus 20 years).[18] The NRC could not allow licensees to rely upon generic review of Category 1 issues beyond the initial license renewal term, because the agency never conducted a generic environmental analysis of impacts beyond the 60-year time frame to justify it. Thus, the NRC had no reason to state that Table B-1 would apply to subsequent license renewal applications (*i.e.*, 60 plus 20 years).[19] The NRC *did* have a reason to notify license applicants that § 51.53(c)(3) (and hence Table B-1) would only apply to the initial license renewal term, however. Having told licensees that "[n]o limit on the number of license renewals is specified" in NRC's Part 54 regulations,[20] the NRC reasonably clarified that the scope of its license renewal review under NEPA would be more limited in § 51.53(c)(3).

FPL suggests that Petitioners' textual argument fails because Table B-1 does not refer to "initial" renewed licenses, only renewed licenses:

> On this point, it bears emphasis that the preamble to Table B-1 refers to the Commission's assessment of "the environmental impacts associated with granting a renewed operating license for a nuclear power plant to a licensee who holds either an operating license or construction permit as of June 30, 1995." Unlike Section 51.53(c)(3), on which Petitioners' entire "plain language" argument hinges, Table B-1 does *not* refer to "initial" renewed licenses.[21]

But FPL stumbles over its own argument. The phrase "renewed operating license" in the

---

[18] *See* discussion above in Section II(A)(1).

[19] As discussed below in Section II(A)(2), these circumstances have not changed. The NRC's "update" to the 1996 GEIS in the 2013 Revised GEIS did not extend the temporal scope of the 1996 GEIS beyond the initial license renewal period.

[20] 1996 GEIS at 1-1.

[21] FPL Surreply at 8 (emphasis in original).

Table B-1 preamble cannot be read to govern *all* operating licenses because it expressly excludes *some* renewed licenses, *i.e.*, post-1995 licensees. The only reasonable and logical interpretation of this preamble when read in conjunction with § 51.53(c)(3) is that the preamble only applies to a pre-1995 licensee's "initial" license renewal application. No other construction would give effect to every word.[22] In any event, even assuming for purposes of argument that there were any inconsistency between § 51.53(c)(3) and the overarching purposes of NRC's regulations for NEPA review, such an inconsistency would not give the ASLB broad authority to effectively re-write the regulation. The "felt necessities of the [rulemaking] process inevitably produce more narrowly focused provisions which fail in full rigor to effectuate the overarching goal." *See Int'l Bhd. of Teamsters*, 801 F.2d at 1430 ("And the hard fact remains that it is not the judiciary's assigned task to sit as a modernday Council of Revision . . . and to *cy pres* statutory provisions that may not be in full keeping with the spirit that has more recently animated Congress.").

1. The History of the NRC's License Renewal Regulations Contains No Evidence of any Intent by the Commission to Alter or Disregard the Plain Meaning of § 51.53(c)(3).

FPL acknowledges that in the 1991 proposed rule, where the NRC first proposed to include the phrase "applicants seeking an initial renewed license" in 10 C.F.R. § 51.53(c)(3), that the NRC explicitly intended to limit the scope of license renewal environmental reviews to the

[22] FPL suggests, incorrectly, that Petitioner SACE argues that §§ 51.53(c)(2) and 51.53(c)(3) are "mutually exclusive." FPL Surreply at 7. But Petitioners only argue that § 51.53(c)(3) is limited to the initial license renewal application. Thus, while a pre-1995 licensee seeking an initial license renewal may rely on § 51.53(c)(3), a subsequent license renewal applicant may not.

first twenty-year renewal term after the initial forty-year term.[23] According to FPL, however, the NRC abandoned that intention as early as the final 1996 version of the rule, which "*omits*" any similar representations, *i.e.,* it does not use the phrase 'one renewal of the initial license' or 'up to 20 years beyond the expiration of the initial license.'"[24] Thus, according to FPL, the phrase "initial license renewal applicants," as used in § 51.53(c)(3), constitutes a "residual reference," *i.e.*, a meaningless historical artifact. But FPL does not cite a single word or phrase to show that the inclusion of this phrase in the regulation was a mistake. And in fact, the regulatory history of the NRC's regulations for NEPA review of license renewal applications contradicts FPL.

a. The regulatory history of NRC's NEPA rules and GEIS for license renewal contain no reference to the concept of subsequent license renewal.

Tellingly, FPL does not identify even a single reference to the concept of subsequent license renewal in the 1996 Final Rule, the 2009 proposed amendments to the 1996 Final Rule, or the 2013 Final Rule amending the 1996 rule. Nor does FPL point to a single reference to the concept of subsequent license renewal in the 1996 GEIS, the 2013 Revised GEIS, or the draft versions of those documents. And no such references can be found. In fact, the regulatory history of § 51.53(c)(3), the License Renewal GEIS, and the NRC's regulations for the implementation of NEPA in license renewal cases demonstrates unequivocally that the inclusion of the phrase "applicants seeking an initial renewed license" in past and current versions of

---

[23] Surreply at 6 (citing SACE reply at 4 and quoting Proposed Rule, Environmental Review for Renewal of Nuclear Power Plant Operating Licenses, 56 Fed. Reg. 47,016, 47,017 (Sept. 17, 1991)).

[24] Surreply at 6 (emphasis in original) (citing Final Rule, Environmental Review for Renewal of Nuclear Power Plant Operating Licenses 61 Fed. Reg. 28,467 (June 5, 1996)).

§ 51.53(c)(3) was indeed intentional; and that NRC never considered applying § 51.53(c)(3) or the generic Category 1 findings of Table B-1 to any license renewal term other than the first twenty-year renewal term following an initial 40-year license term.

b. The history of § 51.53(c)(3) contradicts FPL's argument.

FPL would have the ASLB disregard the inclusion of the phrase "applicants seeking an initial renewed license," as used in § 51.53(c)(3) as an oversight that the NRC should have corrected when it changed course after the 1991 proposed rule and decided to include multiple license renewal terms in the final 1996 rule. But the rulemaking history of § 51.53(c)(3) shows that the NRC repeatedly carried over that same phrase from the 1991 proposed rule into the 1996 final rule, the 2009 proposed amendments to the 1996 final rule, and the 2013 final amendments to the 1996 rule. *See* Final Rule, 61 Fed. Reg. at 28,487; Proposed Amended Rule, 74 Fed. Reg. 38,117, 38,128, 38,132 (July 31, 2009); and Final Amended Rule, 78 Fed. Reg. 37,312, 37,316 (June 20, 2013). It is absurd for FPL to characterize the inclusion of the phrase "applicants seeking an initial renewal term" in three separate rulemaking notices following the 1991 Proposed Rule as "residual."

i. <u>The 1996 Final Rule and 1996 GEIS specifically state that the NRC's generic environmental analysis for license renewal, including Category 1 designations, covers only the initial license renewal term.</u>

FPL's claim that the 1996 final rule contains no reference to a single license renewal term is incorrect.[25] The 1996 Final Rule directly references the NRC's assumption that its environmental review for license renewal covered only the first renewal term, with respect to decommissioning impacts:

---

[25] *See* FPL Surreply at 6.

> The analysis in the GEIS for license renewal examines the physical requirements and attendant effects of decommissioning after a 20-year license renewal compared with decommissioning at the end of 40 years of operation and finds little difference in effects.

Environmental Review for Renewal of Nuclear Power Plant Operating Licenses, 61 Fed. Reg. 28,467, 28,482 (June 5, 1996). Equally importantly, the 1996 Final Rule codifies and relies on the findings of the 1996 GEIS. *Id*. at 28,467 (stating that the rule is "based on the analyses conducted for and reported in NUREG–1437, ''Generic Environmental Impact Statement for License Renewal of Nuclear Plants'' (May 1996)). The GEIS, in turn, explicitly describes the "proposed action" addressed by its analysis as allowing nuclear power plants to operate "for a maximum of 20 years past the terms of their *original* 40-year operating licenses."[26] *See also* discussion above in Section II(A).

ii. The NRC did not expand the temporal scope of the 1996 GEIS when it prepared the 2013 Revised GEIS.

FPL argues that the 2013 Revised GEIS expands the scope of the environmental analysis

---

[26] 1996 GEIS at 2-28–29 (emphasis added). FPL argues that restricting the scope of the GEIS to the first license renewal term is illogical in light of the NRC's stated intention to update the GEIS every ten years after issuance of the 1996 GEIS. FPL Surreply at 6 (citing Table B-1). But there is nothing illogical or inconsistent about making such a plan for initial license renewal reviews. At the time the 1996 rule was promulgated, none of the licenses for more than 100 operating reactors had been renewed, and indeed all plans for license renewal were awaiting promulgation of regulations that would allow them to go forward. Thirteen years later (in 2009), about half (51) of reactor licenses had been renewed. Proposed Revisions to Environmental Review for Renewal of Nuclear Power Plant Operating Licenses, 74 Fed. Reg. 38,117, 38,119 (Jul. 31, 2009). Had the NRC stayed on schedule and actually revised its GEIS every ten years after 1996 as originally planned, the License Renewal GEIS would have been revised several times before all original operating licenses were renewed for an initial renewal term.

to include a second license renewal term.[27] As discussed above in Section II(A)(2), however, the 2013 Revised GEIS contains no evidence of such an expansion, and indeed is replete with statements showing that the NRC assumed the same time frame as the 1996 GEIS: the original 40-year term plus an additional 20 years. Throughout the 2013 Revised GEIS, the NRC refers to a time frame totaling 60 years, and a baseline of 40 years. *Nowhere* does the 2013 Revised GEIS refer to a time frame totaling 80 years or a baseline of 60 years.

Thus, the use of the term "current" in the 2013 Revised GEIS does not signify any change from the use of the same term in the 1996 GEIS to describe the original license term.[28]

C. FPL's Proposed Interpretation of § 51.53(c)(3) is Inconsistent with NRC's Regulatory Scheme for Preparation of EISs, Including the Scoping Process.

FPL argues that depriving subsequent license renewal applicants of Category 1 exclusions would "make no practical sense" in light of the Commission's goal of using the Category 1 designations to make the license renewal process more efficient.[29] But the NRC could not have subordinated its specific procedural regulations to a general goal of efficiency. And the record contains no evidence that the NRC used its scoping process to expand the scope of the 1996 GEIS in the 2013 Revised GEIS.

In the process of scoping an EIS, the NRC must, *inter alia,* "[d]efine the proposed action"

---

[27] FPL Surreply at 10–11.

[28] FPL makes much of the fact that the 2013 Revised GEIS uses the phrase "current license term," leaving open to interpretation whether the NRC meant that the agency was considering an addition to the original license term or to an already-renewed license term. FPL Surreply at 10. But the 1996 GEIS uses the phrases "current license term," "current license period," and "current license" throughout to refer to the original license term. *See, for example,* 2013 Revised GEIS at xxxvii-xliii, 1-2, 1-6, 2-36, 2-37, 2-48, 3-6, 3-50, 4-55, 4-123 – 4-127, 5-1, 5-97, 6-37.

[29] FPL Surreply at 9.

(10 C.F.R. § 51.29(a)(1)), "[d]etermine the scope of the statement" (10 C.F.R. § 51.29(a)(2)), and "identify the significant issues to be analyzed in depth." *Id.* As discussed above in Section II(A)(1), the record of the 1996 GEIS shows that the temporal scope of that GEIS was limited exclusively to the first license renewal term after the initial operating license term. FPL cannot point to a single word in either the scoping notice for the 2009 proposed amendments to the 1996 final rule or the 2009 draft revised GEIS that (a) re-defined the proposed action as extending reactor operating licenses for multiple 20-year terms, (b) stated that the scope of the 2013 Revised GEIS would cover multiple license renewal terms, or (c) identified or sought public comment on the significant issues that should be analyzed in the course of the expanded environmental review. Instead, the only action proposed by the NRC was to "update" the 1996 GEIS. Notice of Intent to Prepare an Environmental Impact Statement for the License Renewal of Nuclear Power Plants and to Conduct Scoping Process, 68 Fed. Reg. 33,209 (June 3, 2003).

FPL's inability to point to a scoping process that expanded the scope of the License Renewal GEIS fundamentally undermines any claim to a temporal expansion, because the scope of an EIS determines the scope of the federal action that may be taken under the authority of that EIS. *Duke Power Co. (Oconee/McGuire),* LBP-80-28, 12 N.R.C. 459, 473 (1980) (citing *Swain v. Brinegar,* 542 F.2d 364, 367 (7th Cir. 1976)). Here, the scope of the 1996 GEIS, as updated in the 2013 Revised GEIS, is limited to the first license renewal term after the original operating license term. Therefore, the NRC may not take the federal action of applying the Category 1 exclusions in Table B-1 to any license renewal applications other than initial license renewal applications. The NRC may still *refer* to the environmental findings of the 2013 Revised GEIS in a subsequent license renewal review, but NEPA prohibits the NRC from *codifying* those findings for purposes of a subsequent license renewal review.

III. INTERNAL NRC MEMORANDA AND POLICY STATEMENTS CANNOT SUBSTITUTE FOR NOTICE-AND-COMMENT RULEMAKING, SCOPING PROCESS, AND A NEW DRAFT GEIS FOR LICENSE RENEWALS.

As discussed above, a formal notice-and-comment rulemaking led to the original and still-current language in § 51.53(c)(3). That language is plain in limiting the scope of the regulation to initial license renewal applications. If FPL wishes to change that language, it must petition for a rulemaking and ask the NRC to prepare a new or revised License Renewal GEIS. No intervening memoranda, policy statements, or GEIS can change that. *See, e.g., Perez v. Mortg. Bankers Ass'n*, 135 S. Ct. 1199, 1206 (2015) ("agencies [must] use the same procedures when they amend or repeal a rule as they used to issue the rule in the first instance."). The "convenience" of avoiding notice-and-comment rulemaking "comes at a price: Interpretive rules 'do not have the force and effect of law and are not accorded that weight in the adjudicatory process.'" *Id.* at 1204 (internal citations omitted). This is black letter law.[30]

[30] FPL's argument that reference in SECY-12-0063 to the potential filing of subsequent license renewal applications overrides the scoping notice and summary report for the 2013 Revised GEIS -- which contain no reference whatsoever to the concept of subsequent license renewal or any license renewal term beyond the first twenty years -- is inconsistent with NRC regulations and case law interpreting NEPA. Surreply at 11 n.40 (citing SECY-12-0063, Final Rule: Revisions to Environmental Review for Renewal of Nuclear Power Plant Operating Licenses (Apr. 20, 2012) (ML110760033)). Accuracy in the initial scoping of an EIS is critical because a proposed federal action may not exceed the scope of its supporting EIS. *Duke Power Co.,* 12 N.R.C. at 473. Hence, the NRC must conduct a scoping process "as soon as practicable after publication of the notice of intent" and use it to "[d]efine the proposed action which is to be the subject of the statement or supplement." 10 C.F.R. §§ 51.29(a) and 51.29(a)(1). Public participation is also an important element of the scoping process, and therefore NRC regulations require that a broad range of affected parties, including individuals and organizations, government agencies, and Indian tribes, must be notified and invited to participate. 10 C.F.R. § 51.28. To disregard the content of the scoping notice for the 2013 Revised GEIS or the results of the scoping process would defeat the purpose of these regulations.

A. NRC Internal Memoranda Do Not Substitute for NEPA Compliance or Notice-and-Comment Rulemaking.

The only NRC documents that FPL can point to which actually mention subsequent license renewal in the context of the NRC's NEPA review are three NRC memoranda: SECY-12-0063; SECY-14-0016, Ongoing Staff Activities to Assess Regulatory Considerations for Power Reactor Subsequent License Renewal (Jan. 31, 2014) (ML14050A306), and SRM-SECY-14-0016 – Ongoing Staff Activities to Assess Regulatory Considerations for Power Reactor Subsequent License Renewal (Aug. 29, 2014) (ML14241A578) ("SRM-SECY-14-0016").[31] None of these internal NRC memoranda could substitute for the notice-and-comment rulemaking, scoping process, and new draft GEIS for license renewal that the NRC *must* undertake if it wishes to apply the Category 1 exclusions to subsequent license renewal applications. *See Perez*, 135 S. Ct. at 1206.

In any event, the internal memoranda do not come close to addressing the issue of whether the NRC is entitled to ignore the plain language of § 51.53(c)(3) or the temporal limitations of the 1996 GEIS as revised in 2013. They simply acknowledge that licensees will become eligible for a second license renewal term and that the NRC should establish guidance for the proceedings.

---

[31] FPL Surreply at 11–13.

B. Absent a New Rulemaking and NEPA Proceeding, FPL's Subsequent License Renewal Application is Governed by 10 C.F.R. §§ 51.53(c)(2) and 51.45(a).

Absent a new rulemaking and NEPA proceeding to expand the scope of the 1996 GEIS and 2013 Revised GEIS, FPL's subsequent license renewal application must be reviewed under §§ 51.53(c)(2) and 51.45(a), which do not provide for application of Category 1 exclusions.[32] If the NRC wishes to apply the Category 1 exemptions to subsequent license renewal applicants like FPL, it must first revise the 1996 GEIS and rule, and the 2013 Revised GEIS and amended rule, to comply with its own procedural requirements for implementation of NEPA and the Administrative Procedure Act. First, the NRC must issue a scoping notice for a new or revised GEIS, which clearly states the scope of the proposed GEIS and seeks public participation in determining the scope of the analysis and the issues that must be addressed "in depth." 10 C.F.R. §§ 50.28, 50.29(a)(1), and 50.29(a)(2).

Second, the NRC must prepare a draft GEIS and solicit public comment, as required by 10 C.F.R. Part 51. Compliance with these procedural requirements is essential to fulfill NEPA's twin purposes of ensuring sound environmental decisions and allowing the public to play a role in the decision-making process. *Robertson v. Methow Valley Citizens Council*, 490 U.S. 332, 348–49 (1989).

Finally, the NRC must comply with NEPA and the Administrative Procedure Act by publishing, for public comment, revised NEPA regulations which make the requirements of

---

[32] *See* SACE's Hearing Request at 5 and 29.

Table B-1 binding in subsequent license renewal proceedings. *New York v. N.R.C.,* 681 F.3d 471, 476 (D.C. Cir. 2012) (holding that regulations codifying NEPA findings constitute "major federal action" requiring an EIS or environmental assessment); *Union of Concerned Scientists v. N.R.C.,* 711 F.2d 370, 383 (D.C. Cir. 1983) (citing *Pickus v. U.S. Board of Parole,* 507 F.2d 1107, 1113 (D.C. Cir. 1974) (requiring notice-and-comment rulemaking for an NRC decision that "alters a binding norm.").[33]

CONCLUSION

For the foregoing reasons, Petitioners respectfully request that the ALSB determine that § 51.53(c)(3) only applies to pre-1995 applicants for an initial license renewal.

---

[33] FPL's argument that the reference in SECY-12-0063 to the potential filing of subsequent license renewal applications overrides the scoping notice and summary report for the 2013 Revised GEIS—which contain no reference whatsoever to the concept of subsequent license renewal or any license renewal term beyond the first twenty years—is inconsistent with NRC regulations and case law. Surreply at 11 n.40. Accuracy in the initial scoping of an EIS is critical because a proposed federal action may not exceed the scope of its supporting EIS. *Duke Power Co.,* 12 N.R.C. at 473 ("In making an evaluation of the environmental impact of a proposed action under NEPA, the scope of the environmental statement or appraisal must be at least as broad as the scope of the action being taken.")). Hence, the NRC must conduct a scoping process "as soon as practicable after publication of the notice of intent" and use it to "[d]efine the proposed action which is to be the subject of the statement or supplement." 10 C.F.R. §§ 51.29(a) and 51.29(a)(1). Public participation is also an important element of the scoping process, and therefore NRC regulations require that a broad range of affected parties, including individuals and organizations, government agencies, and Indian tribes, must be notified and invited to participate. 10 C.F.R. § 51.28. To disregard the content of the scoping notice for the 2013 Revised GEIS or the results of the scoping process would defeat the purpose of these regulations.

UNITED STATES OF AMERICA
NUCLEAR REGULATORY COMMISSION

ATOMIC SAFETY AND LICENSING BOARD

Before Administrative Judges:

E. Roy Hawkens, Chairman
Dr. Michael F. Kennedy
Dr. Sue H. Abreu

In the Matter of	Docket Nos. 50-250-SLR & 50-251-SLR
FLORIDA POWER & LIGHT COMPANY	ASLBP No. 18-957-01-SLR-BD01
(Turkey Point Nuclear Generating Units 3 and 4)	March 7, 2019

MEMORANDUM AND ORDER
(Granting the Hearing Requests of SACE and Joint Petitioners, Denying the Hearing Request of Albert Gomez, Granting Monroe County's Request to Participate as an Interested Governmental Participant, and Referring a Ruling to the Commission)

Pending before this Licensing Board are three hearing requests that challenge an application from Florida Power & Light Company (FPL) for a subsequent license renewal (i.e., a second twenty-year license renewal) for two nuclear power reactors, Turkey Point Units 3 and 4, located near Homestead, Florida. The hearing requests were filed by (1) Southern Alliance for Clean Energy (SACE); (2) Friends of the Earth, Inc., Natural Resources Defense Council, Inc., and Miami Waterkeeper, Inc. (collectively, Joint Petitioners); and (3) Albert Gomez. Additionally, Monroe County, Florida filed a request to participate in this proceeding as an interested governmental participant.

For the reasons discussed below, we conclude that (1) SACE has established standing and proffered two admissible contentions; (2) Joint Petitioners have established standing and proffered two admissible contentions; and (3) Mr. Gomez has failed to proffer an admissible contention. We therefore grant SACE's and Joint Petitioners' hearing requests, and we deny

Mr. Gomez's hearing request. We also grant Monroe County's request to participate as an interested governmental participant.

Additionally, pursuant to 10 C.F.R. § 2.323(f)(1), we refer to the Commission our ruling, infra Part III.A, that 10 C.F.R. § 51.53(c)(3) applies to the preparation of environmental reports (ERs) in subsequent license renewal proceedings. See infra note 46.[1]

I. PROCEDURAL BACKGROUND

On January 30, 2018, FPL submitted an application for a subsequent license renewal (SLR) for two nuclear power reactors, Turkey Point Units 3 and 4, located near Homestead, Florida. See Letter from Mano K. Nazar, President and Chief Nuclear Officer, FPL, to Document Control Desk, NRC (Jan. 30, 2018).[2] FPL submitted an ER with its application, as required.[3]

On May 2, 2018, the NRC issued a notice of opportunity to request a hearing and petition for leave to intervene, which provided members of the public sixty days from the date of publication to file a hearing request. See [FPL]; Turkey Point Nuclear Generating, Unit Nos. 3 and 4, 83 Fed. Reg. 19,304 (May 2, 2018). On June 29, 2018, in response to several requests to extend the filing deadline, the Commission granted a thirty-day extension, to and including August 1, 2018. See Commission Order (June 29, 2018) at 2 (unpublished).

---

[1] Appended to this Memorandum and Order is an opinion by Judge Abreu dissenting in part (with the majority's interpretation and application of section 51.53(c)(3)) and concurring in part (with those portions of the majority's decision that do not involve the interpretation or application of section 51.53(c)(3)).

[2] See [FPL], Turkey Point Nuclear Plant Units 3 and 4 [SLR] Application (rev. 1 Apr. 2018) [hereinafter SLRA]. The original licenses issued to FPL for Units 3 and 4 authorized forty years of operation, and the first renewal was for an additional twenty years of operation. The current licenses for the units will expire, respectively, on July 19, 2032 and April 10, 2033. Id. at 1-1.

[3] See [FPL] SLRA, App. E, Applicant's Environmental Report, Subsequent Operating License Renewal Stage, Turkey Point Nuclear Plant Units 3 and 4 (Jan. 2018) [hereinafter ER]. The purpose and content of an ER are discussed infra Part III.A.2.

On August 1, 2018, SACE filed a hearing request that proffered two multi-faceted environmental contentions,[4] and Joint Petitioners filed a hearing request that proffered five multi-faceted environmental contentions.[5] On August 2, 2018, Mr. Gomez, acting pro se, submitted a hearing request that proffered ten contentions consisting of safety and environmental challenges to FPL's application.[6]

FPL filed answers opposing all three hearing requests.[7] The NRC Staff filed an answer that (1) did not oppose granting SACE's hearing request and admitting, in part, both of SACE's environmental contentions;[8] and (2) did not oppose Joint Petitioners' hearing request and admitting, in part, two of Joint Petitioners' five environmental contentions.[9] In a separately filed answer, the NRC Staff opposed Mr. Gomez's hearing request.[10]

---

4 See [SACE's] Request for Hearing and Petition to Intervene (Aug. 1, 2018) [hereinafter SACE Pet.].

5 See Request for Hearing and Petition to Intervene Submitted by [Joint Petitioners] (Aug. 1, 2018) [hereinafter Joint Pet'rs Pet.].

6 See Proposed Petition to Intervene and for Hearing Under 10 C.F.R. § 2.206, for Docket ID # NRC-2018-0074 (Aug. 2, 2018) [hereinafter Gomez Pet.].

7 See Applicant's Answer Opposing [SACE's] Request for Hearing and Petition to Intervene (Aug. 27, 2018) [hereinafter FPL Answer to SACE Pet.]; Applicant's Answer Opposing Request for Hearing and Petition to Intervene Submitted by [Joint Petitioners] (Aug. 27, 2018) [hereinafter FPL Answer to Joint Pet'rs Pet.]; Applicant's Opposition to Albert Gomez's Petition to Intervene (Sept. 4, 2018) [hereinafter FPL Answer to Gomez Pet.].

8 See NRC Staff's Corrected Response to Petitions to Intervene and Requests for Hearing Filed by (1) [Joint Petitioners], and (2) [SACE] (Aug. 27, 2018) at 57–69 [hereinafter NRC Staff Answer to Joint Pet'rs Pet. and SACE Pet.].

9 See id. at 28–57.

10 See NRC Staff's Response to Petition to Intervene and Request for Hearing Filed by Albert Gomez (Sept. 4, 2018) [hereinafter NRC Staff Answer to Gomez Pet.].

On September 10, 2018, SACE and Joint Petitioners filed replies to FPL's and the NRC Staff's answers.[11] Mr. Gomez did not file a reply.

On September 20, 2018, FPL filed motions to strike certain portions of SACE's and Joint Petitioners' replies, or in the alternative, for leave to file an attached surreply.[12] Although SACE and Joint Petitioners opposed FPL's motions to strike, they did not oppose FPL's motion to file the surreply, and they requested permission to file an attached joint response to it.[13] On October 23, 2018, we (1) denied FPL's motions to strike, but granted its request to file the surreply; (2) granted the request of SACE and Joint Petitioners to file a joint response to FPL's surreply; and (3) authorized the NRC Staff to respond to these pleadings.[14] The NRC Staff filed a response on November 2, 2018.[15]

---

[11] See [SACE's] Reply to Oppositions by [FPL] and NRC Staff to SACE's Hearing Request (Sept. 10, 2018) [hereinafter SACE Reply]; Reply in Support of Request for Hearing and Petition to Intervene Submitted by [Joint Petitioners] (Sept. 10, 2018).

[12] See Applicant's Motion to Strike a Portion of the September 10, 2018 Reply Filed by [SACE] or, in the Alternative, for Leave to File a Surreply (Sept. 20, 2018); Applicant's Motion to Strike Portions of the September 10, 2018 Reply Filed by [Joint Petitioners] or, in the Alternative, for Leave to File a Surreply (Sept. 20, 2018); Applicant's Surreply to New Arguments Raised in Reply Pleadings (Sept. 20, 2018) [hereinafter FPL Surreply].

[13] See [SACE]'s Response to [FPL]'s Motion to Strike a Portion of SACE's September 10, 2018, Reply or, in the Alternative for Motion for Leave to File a Surreply (Oct. 1, 2018); [Joint Petitioners'] Answer in Opposition to Applicant's Motion to Strike Portions of the September 10, 2018 Reply Filed by Joint Petitioners or, in the Alternative, for Leave to File a Surreply (Oct. 1, 2018); Motion For Leave to Respond to Applicant's Surreply (Oct. 1, 2018); Petitioners' Response to Applicant's Surreply (Oct. 1, 2018) (corrected Oct. 4, 2018) [hereinafter Pet'rs Response to FPL Surreply].

[14] See Licensing Board Memorandum and Order (Denying FPL's Motion to Strike Portions of Replies, Granting FPL's Request to File a Surreply, Granting SACE and Joint Petitioners' Motion to File Response to Surreply, and Authorizing NRC Staff to File Response) (unpublished) (Oct. 23, 2018).

[15] See NRC Staff's Response to the Applicant's Surreply and the Petitioners' Response, Regarding the Applicability of 10 C.F.R. § 51.53(c)(3) to [SLR] Applications (Nov. 2, 2018) [hereinafter NRC Staff Response to FPL Surreply].

Meanwhile, on September 20, 2018, Monroe County, Florida filed a request to participate as an interested local governmental body pursuant to 10 C.F.R. § 2.315(c), seeking to participate on the two environmental contentions proffered by SACE.[16] The NRC Staff did not oppose Monroe County's participation, provided that the Board admitted the two contentions specified by the County.[17]

On December 4, 2018, this Board held an oral argument in Homestead, Florida to assess SACE's and Joint Petitioners' standing and the admissibility of their proffered contentions. See Official Transcript of Proceedings, [FPL] Turkey Point Units 3 & 4 at 11–259 (Dec. 4, 2018) [hereinafter Tr.].[18] Pursuant to the Board's direction at oral argument, see Tr. at 257, the NRC Staff filed a supplemental brief on December 18, 2018 regarding its position on a contention proffered by SACE and Joint Petitioners,[19] and on January 7, 2019, the other participants filed timely responses. See id. at 258–59.[20]

---

[16] See Monroe County, Florida's Request to Participate as Interested Governmental Participant (Sept. 20, 2018) [hereinafter Monroe County Request]. Section 2.315(c) permits a local governmental body that is not admitted as a party under section 2.309 an opportunity to participate in a hearing as an interested non-party.

[17] See NRC Staff's Response to Monroe County, Florida's Request to Participate as an Interested Governmental Entity at 7 (Oct. 1, 2018).

[18] Mr. Gomez's arguments on standing and contention admissibility were submitted on his written pleading. See Tr. at 15; Licensing Board Order (Providing Oral Argument Topics) at 2 n.3 (Nov. 14, 2018) (unpublished).

On December 21, 2018, this Board issued an order granting a joint motion requesting transcript corrections. See Licensing Board Order (Adopting Transcript Corrections) (Dec. 21, 2018) (unpublished).

[19] See NRC Staff's Clarification of its Views Regarding the Admissibility of Joint Petitioners' Contention 1-E and SACE Contention 2 (Alternative Cooling Systems) (Dec. 18, 2018).

[20] See Petitioners' Response to NRC Staff Clarification (Jan. 7, 2019); Applicant's Response to the NRC Staff's Clarification Regarding the Admissibility of Proposed Cooling Tower Contentions (Jan. 7, 2019).

II. LEGAL STANDARDS FOR STANDING AND CONTENTION ADMISSIBILITY

To participate in this proceeding as an intervenor, a petitioner must establish standing and proffer at least one admissible contention. See 10 C.F.R. § 2.309(a). We summarize the applicable legal standards below.

A. LEGAL STANDARDS GOVERNING STANDING

1. Individual Standing and the 50-Mile Proximity Presumption

In determining whether a petitioner has established standing, the Commission applies contemporaneous judicial concepts of standing that require a petitioner to "(1) allege an injury in fact that is (2) fairly traceable to the challenged action and (3) is likely to be redressed by a favorable decision." Fla. Power & Light Co. (Turkey Point Nuclear Generating Plant, Units 3 & 4), CLI-15-25, 82 NRC 389, 394 (2015).[21] However, in the context of certain reactor licensing proceedings (e.g., reactor construction permit proceedings and new reactor operating license proceedings), the Commission has expressly authorized the use of a "proximity presumption," which presumes that a petitioner has standing if he or she resides, or otherwise has frequent contacts, within approximately 50 miles of the facility in question. See PPL Bell Bend, LLC (Bell Bend Nuclear Power Plant), CLI-10-7, 71 NRC 133, 138–39 (2010); Calvert Cliffs 3 Nuclear Project, LLC (Calvert Cliffs Nuclear Power Plant, Unit 3), CLI-09-20, 70 NRC 911, 915–16

---

[21] Under section 189a of the Atomic Energy Act, the NRC is required to "grant a hearing upon the request of any person whose interest may be affected by the proceeding." 42 U.S.C. § 2239(a)(1)(A). Pursuant to the agency's regulation implementing general standing requirements, a petitioner's hearing request must state

(i) The name, address and telephone number of the requestor or petitioner;
(ii) The nature of the requestor's/petitioner's right under the [relevant statute] to be made a party to the proceeding;
(iii) The nature and extent of the requestor's/petitioner's property, financial or other interest in the proceeding; and
(iv) The possible effect of any decision or order that may be issued in the proceeding on the requestor's/petitioner's interest.

10 C.F.R. § 2.309(d)(1).

(2009). This presumption "rests on [the] finding . . . that persons living within the roughly 50-mile radius of [a] facility face a realistic threat of harm if a release from the facility of radioactive material were to occur." Calvert Cliffs, CLI-09-20, 70 NRC at 917 (internal quotation marks omitted).

Licensing boards routinely have applied the 50-mile proximity presumption in reactor license renewal proceedings, reasoning that a renewal "allows operation of a reactor over an additional period of time during which the reactor could be subject to the same equipment failures and personnel errors as during operations over the original period of the license." Exelon Generation Co. (Limerick Generating Station, Units 1 & 2), LBP-12-8, 75 NRC 539, 547, rev'd in part on other grounds, CLI-12-19, 76 NRC 377 (2012). The Commission implicitly endorsed this approach when it cited with approval a licensing board's application of the proximity presumption in a reactor license renewal proceeding. See Calvert Cliffs, CLI-09-20, 70 NRC at 915 n.15 (citing Fla. Power & Light Co. (Turkey Point Nuclear Generating Plant, Units 3 & 4), LBP-01-6, 53 NRC 138, 150, aff'd on other grounds, CLI-01-17, 54 NRC 3 (2001)).

We conclude that the 50-mile proximity presumption should apply in all reactor license renewal proceedings, including SLR proceedings. As the Commission explained in Calvert Cliffs, the 50-mile proximity presumption "is simply a shortcut for determining standing in certain cases." Calvert Cliffs, CLI-09-20, 70 NRC at 917. Applying this shortcut to reactor license renewal proceedings not only satisfies contemporaneous judicial concepts of standing, it provides clarity for litigants and licensing boards, thereby promoting efficiency in the adjudicatory process. See, e.g., Entergy Operations, Inc. (River Bend Station, Unit 1), LBP-18-1, 87 NRC 1, 7 n.4 (2018).

2. Representational Standing

An organization that seeks to intervene on behalf of one or more of its members must demonstrate representational standing. To do so, the organization must show that (1) at least one of its members would otherwise have standing to sue in his or her own right; (2) the member has authorized the organization to represent his or her interest; (3) the interests that the organization seeks to protect are germane to its purpose; and (4) neither the claim asserted nor the relief requested requires the member to participate in the adjudicatory proceeding. See Private Fuel Storage, L.L.C. (Indep. Spent Fuel Storage Installation), CLI-99-10, 49 NRC 318, 323 (1999).

B. LEGAL STANDARDS GOVERNING CONTENTION ADMISSIBILITY

A timely-filed contention is admissible if it satisfies the six-factor contention admissibility criteria in 10 C.F.R. § 2.309(f)(1), which requires a petitioner to

> (i) Provide a specific statement of the issue of law or fact to be raised or controverted . . . ;
> (ii) Provide a brief explanation of the basis for the contention;
> (iii) Demonstrate that the issue raised in the contention is within the scope of the proceeding;
> (iv) Demonstrate that the issue raised in the contention is material to the findings the NRC must make to support the action that is involved in the proceeding;
> (v) Provide a concise statement of the alleged facts or expert opinions which support the requestor's/petitioner's position on the issue . . . , together with references to the specific sources and documents on which the requestor/petitioner intends to rely to support its position on the issue; [and]
> (vi) . . . [P]rovide sufficient information to show that a genuine dispute exists with the applicant/licensee on a material issue of law or fact. This information must include references to specific portions of the application . . . that the petitioner disputes and the supporting reasons for each dispute.

10 C.F.R. § 2.309(f)(1)(i)–(vi). Additionally, pursuant to 10 C.F.R. § 2.335, a contention that challenges a Commission rule or regulation will be rejected unless the petitioner makes an appropriate prima facie showing supporting a rule waiver before the licensing board, which then must certify the waiver request to the Commission.

The Commission's contention-admissibility standard is "strict by design," Amergen Energy Co. (Oyster Creek Nuclear Generation Station), CLI-06-24, 64 NRC 111, 118 (2006) (quoting Dominion Nuclear Conn., Inc. (Millstone Nuclear Power Station, Units 2 & 3), CLI-01-24, 54 NRC 349, 358 (2001)), and failure to comply with any admissibility requirement "renders a contention inadmissible." Entergy Nuclear Operations, Inc. (Indian Point, Unit 2), CLI-16-5, 83 NRC 131, 136 (2016).

III. ANALYSIS

Because of its overarching significance to this and other SLR cases, we first examine a legal question relevant to the admissibility of contentions proffered by SACE and Joint Petitioners; namely, whether 10 C.F.R. § 51.53(c)(3) applies to an applicant's preparation of an ER in SLR proceedings. After resolving that issue in the affirmative, infra Part III.A, we then consider whether to grant the hearing requests of SACE, infra Part III.B, Joint Petitioners, infra Part III.C, and Mr. Gomez, infra Part III.D.

A. THE APPLICABILITY OF 10 C.F.R. § 51.53(c)(3) TO THE PREPARATION OF AN ER IN SLR PROCEEDINGS

Petitioners[22] proffer environmental contentions challenging the adequacy of FPL's ER. Before we address the admissibility of these contentions, we consider a legal issue of first impression raised by petitioners, the resolution of which will affect our contention admissibility analysis. Petitioners argue that 10 C.F.R. § 51.53(c)(3)—which provides, inter alia, that applicants for initial license renewals need not consider Category 1 issues in their ER[23]—does not apply to applicants who (like FPL) seek a subsequent license renewal.

To assist the reader in understanding the issue presented, we first discuss the statutory and regulatory scheme governing the NRC Staff's preparation of an environmental impact

---

22 When we use the term "petitioners," we are referring collectively to SACE and Joint Petitioners.

23 As explained infra Parts III.A.1 and III.A.2, Category 1 issues are those environmental issues with effects that (1) are generic to all existing nuclear power plants; (2) have been analyzed in the generic environmental impact statement (GEIS) and codified by notice and comment rulemaking in 10 C.F.R. Part 51; (3) are reviewed by the Commission on a 10-year cycle; and (4) need not be addressed by the NRC Staff on a site-specific basis in the draft supplemental environmental impact statement for license renewals.

statement (EIS) incident to its review of applications seeking the renewal of licenses to operate nuclear power plants.[24] We then analyze 10 C.F.R. § 51.53(c)(3) and its applicability to SLRs.

1. Statutory and Regulatory Background Governing the NRC Staff's Preparation of an EIS

In 10 C.F.R. Part 51, the NRC promulgated regulations implementing NEPA requirements. See 10 C.F.R. § 51.10. NEPA requires federal agencies to prepare an EIS for proposed major federal actions "significantly affecting the quality of the human environment," including a detailed discussion of "the environmental impact of the proposed action," "any adverse environmental effects which cannot be avoided should the proposal be implemented," and "alternatives to the proposed action." 42 U.S.C. § 4332(C)(i)–(iii).

NEPA's EIS requirement serves two purposes. "First, it places upon an agency the obligation to consider every significant aspect of the environmental impact of a proposed action." Balt. Gas & Elec. Co. v. Nat'l Res. Def. Council, Inc., 462 U.S. 87, 97 (1983) (quotation marks omitted). "Second, it ensures that the agency will inform the public that it has indeed considered environmental concerns in its decisionmaking process." Id. Although NEPA requires the agency to take a "hard look" at environmental consequences of major federal actions, id., it "seeks to guarantee process, not specific outcomes." Massachusetts v. NRC, 708 F.3d 63, 67 (1st Cir. 2013).

Pursuant to NRC regulations, the renewal of a license to operate a nuclear power plant constitutes a "major Federal action" triggering the NRC's obligation under NEPA to prepare an EIS. See 10 C.F.R. § 51.20(a), (b)(2).

[24] The NRC has codified two sets of regulations governing license renewal applications: (1) 10 C.F.R. Part 54, which focuses on safety-related issues such as equipment aging, see 10 C.F.R. § 54.4 (describing scope of renewal requirements in 10 C.F.R. Part 54); and (2) 10 C.F.R. Part 51, which focuses on the NRC's obligations under the National Environmental Policy Act (NEPA), see id. § 51.10 (explaining the purpose of Part 51 regulations). For purposes of this discussion, we deal only with NEPA and the environmental regulations in Part 51.

Preparing an EIS that considers all of the significant environmental issues relevant to the renewal of a nuclear power plant on a site-specific basis is a demanding and time-consuming task. See Massachusetts v. NRC, 522 F.3d 115, 119 (1st Cir. 2008). In 1991, in anticipation of a wave of applications for initial reactor license renewals, the NRC published a proposed rule[25] and a draft generic environmental impact statement (GEIS)[26] that were designed to inject efficiencies into the agency's environmental review portion of the license renewal process. Both documents embodied the results of a comprehensive study conducted by the NRC to determine those NEPA-related issues that could be addressed generically (that is, issues that applied to all plants) and those that needed to be determined on a plant-by-plant basis. The agency characterized the first group as Category 1 issues and the second as Category 2 issues. See Massachusetts, 522 F.3d at 119; Fla. Power & Light Co. (Turkey Point Nuclear Generating Plant, Units 3 & 4), CLI-01-17, 54 NRC 3, 11 (2001).[27]

In 1996, the NRC issued a final GEIS that analyzed Category 1 issues as to all nuclear power plants,[28] and it codified these findings in 10 C.F.R. Part 51. See Final Rule, Environmental Review for Renewal of Nuclear Power Plant Operating Licenses, 61 Fed. Reg. 28,467 (June 5, 1996) [hereinafter 1996 Final Rule]; 10 C.F.R. pt. 51, subpt. A, app. B (listing

---

25 Proposed Rule, Environmental Review for Renewal of Operating Licenses, 56 Fed. Reg. 47,016 (Sept. 17, 1991) [hereinafter 1991 Proposed Rule].

26 Draft [GEIS] for License Renewal of Nuclear Plants, NUREG-1437 (Aug. 1991).

27 For a more comprehensive definition of what constitutes a generic Category 1 issue, see Final Rule, Revisions to Environmental Review for Renewal of Nuclear Power Plant Operating Licenses, 78 Fed. Reg. 37,282, 37,283–84 n.2 (June 20, 2013) [hereinafter 2013 Final Rule]. The Supreme Court has upheld the NRC's authority to make generic determinations to meet its NEPA obligations. See Balt. Gas & Elec. Co., 462 U.S. at 101 (stating that the generic method is "clearly an appropriate method of conducting the hard look required by NEPA").

28 See Office of Nuclear Regulatory Research, NUREG-1437, [GEIS] for License Renewal of Nuclear Plants at 1-3 to 1-6 (May 1996).

"NEPA issues for license renewal of nuclear power plants" and assigning them to either Category 1 or Category 2); Massachusetts, 522 F.3d at 120.

As the Commission explained in the context of an initial license renewal application proceeding, there are several steps in the NRC Staff's preparation of an EIS. See Turkey Point, CLI-01-17, 54 NRC at 12. First, the Staff prepares a draft supplemental EIS (SEIS), which is a site-specific supplement to the GEIS addressing Category 2 issues, and then the Staff seeks public comments on that draft. See id. The final SEIS adopts all applicable Category 1 environmental impact findings from the GEIS, and it also "takes account of public comments, including plant-specific claims and new information on generic findings. Part 51 requires the final SEIS to weigh all of the expected environmental impacts of license renewal, both those for which there are generic findings and those described in plant-specific analyses." Id. (internal citation omitted).[29]

In sum, the governing regulations establish that for all nuclear plant license renewal applications, the SEIS must include a plant-specific analysis of all Category 2 issues, but that it need not discuss Category 1 issues because those issues have already been addressed

[29] Because Category 1 issues have been addressed and codified in Part 51, "they cannot be litigated in individual adjudications, such as license renewal proceedings for individual plants." Massachusetts, 522 F.3d at 120; see also 10 C.F.R. § 2.335. Instead, the NRC has provided the following avenues for reviewing, changing, or challenging GEIS findings regarding Category 1 issues: (1) the Commission reviews GEIS findings on a ten-year basis to ensure their continuing validity; (2) the NRC Staff can request that the Commission suspend a generic rule or that a particular adjudication be delayed until the GEIS and accompanying rule are amended; (3) the NRC Staff can request that a generic rule be suspended with respect to a particular plant; (4) a party to an adjudicatory proceeding can invoke 10 C.F.R. § 2.335 and request that an NRC rule (i.e., a GEIS finding for a Category 1 issue) be waived with respect to that proceeding; and (5) any member of the public can petition the agency for a rulemaking proceeding for the purpose of changing the GEIS findings. See Massachusetts, 522 F.3d at 120–21; Turkey Point, CLI-01-17, 54 NRC at 12, 23 n.14.

Category 2 issues, unlike Category 1 issues, can be litigated in NRC adjudicatory proceedings. As the United States Court of Appeals for the First Circuit stated, this "divergent treatment of generic and site-specific issues is reasonable and consistent with the purpose of promoting efficiency in handling license renewal decisions." Massachusetts, 522 F.3d at 120.

globally in the GEIS and codified in 10 C.F.R. Part 51. See 10 C.F.R. pt. 51, subpt. A, app. B; id. §§ 51.71(d), 51.95(c)(4). "When the GEIS and SEIS are combined, they cover all issues that NEPA requires be addressed in an EIS for a nuclear power plant license renewal proceeding." Massachusetts, 522 F.3d at 120.[30]

2. The Applicability of 10 C.F.R. § 51.53(c)(3) to SLR Proceedings

Although preparing an EIS that complies with NEPA is ultimately the NRC's responsibility, the process of creating an EIS begins with the license renewal applicant. See Massachusetts, 522 F.3d at 120. Pursuant to 10 C.F.R. §§ 51.45 and 51.53(c)(1), license renewal applicants must submit an ER, the purpose of which is "to aid the Commission in complying with section 102(2) of NEPA." 10 C.F.R. § 51.14.[31] The NRC Staff, in turn, reviews the ER and "draw[s] upon [it] to produce a draft [SEIS]." Massachusetts, 522 F.3d at 120.

As previously mentioned, this case raises the question of Commission intent regarding the scope of section 51.53(c)(3); more specifically, this case requires us to determine whether section 51.53(c)(3) may be construed as applying to an SLR applicant. The regulation states in pertinent part:

> (c) *Operating license renewal stage.* (1) Each applicant for renewal of a license to operate a nuclear power plant under part 54 of this chapter shall submit with its application a separate document entitled "Applicant's Environmental Report—Operating License Renewal Stage."
>
> (2) . . . This report must describe in detail the affected environment around the plant, the modifications directly affecting the environment or any plant

[30] SACE makes a passing argument in its brief that the NRC Staff may not rely on the GEIS for addressing Category 1 issues in preparing a draft EIS for SLR applications. See Pet'rs Response to FPL Surreply at 16; see also Tr. at 24. We disagree. Such an argument flies in the face of the 1996 regulatory language and structure, see 10 C.F.R. §§ 51.71(d), 51.95(c)(4); infra note 35 and accompanying text, as well as the plain language of the 2013 GEIS, which is a progeny of the 1996 regulations and which states that "[f]or [Category 1 issues] . . . no additional plant-specific analysis is required in future . . . SEISs unless new and significant information is identified." Office of Nuclear Reactor Regulation, Generic Environmental Impact Statement for License Renewal of Nuclear Plants, NUREG-1437, at 4-3 (Vol. 1, Rev. 1 June 2013) [hereinafter 2013 GEIS].

[31] Accord 10 C.F.R. § 51.41; see also id. § 51.45(c) ("The [ER] should contain sufficient data to aid the Commission in its development of an independent analysis [in the EIS].").

effluents, and any planned refurbishment activities. In addition, the applicant shall discuss in this report the environmental impacts of alternatives and any other matters described in § 51.45. . . .

(3) For those applicants seeking an initial renewed license and holding an operating license . . . as of June 30, 1995, the environmental report shall include the information required in paragraph (c)(2) of this section subject to the following conditions and considerations:

(i) The environmental report for the operating license renewal stage is not required to contain analyses of the environmental impacts of the license renewal issues identified as Category 1 issues in Appendix B to subpart A of this part.

(ii) The environmental report must contain analyses of the environmental impacts of the proposed action, including the impacts of refurbishment activities, if any, associated with license renewal and the impacts of operation during the renewal term, for those issues identified as Category 2 issues in Appendix B to subpart A of this part. . . .

* * *

(iii) The report must contain a consideration of alternatives for reducing adverse impacts, as required by § 51.45(c), for all Category 2 license renewal issues in Appendix B to subpart A of this part. No such consideration is required for Category 1 issues in Appendix B to subpart A of this part.

(iv) The environmental report must contain any new and significant information regarding the environmental impacts of license renewal of which the applicant is aware.

10 C.F.R. § 51.53(c) (emphasis added).

Section 51.53(c)(3) thus identifies a particular category of license renewal applicants (i.e., those seeking "an initial renewed license"), and it states that their ERs shall include the information required in section 51.53(c)(2) subject to certain "conditions and considerations," including the following: (1) the ER need not contain analyses of generic Category 1 issues but, instead, may reference and adopt the Commission's generic findings in 10 C.F.R. Part 51 and the GEIS, id. § 51.53(c)(3)(i); (2) the ER must provide a site-specific review of the non-generic Category 2 issues, id. § 51.53(c)(3)(ii); and (3) the ER must address any new and significant information regarding environmental impacts, of which the applicant is aware, that might render the Commission's generic Category 1 determinations incorrect in that proceeding. Id. § 51.53(c)(3)(iv); see also Turkey Point, CLI-01-17, 54 NRC at 3, 11.

In considering petitioners' assertion that section 51.53(c)(3) does not apply to SLRs, our starting point is the regulatory language. See Ne. Nuclear Energy Co. (Millstone Nuclear Power Station, Unit 3), CLI-01-10, 53 NRC 353, 361 (2001) ("[Regulatory] interpretation begins with the language and structure of the provision itself."). Although section 51.53(c)(3) directs applicants seeking an initial renewed license to prepare ERs in accordance with certain regulatory prescriptions, it (1) is silent as to SLR applicants; and (2) imposes no restrictions on the Commission's authority to allow SLR applicants to utilize these regulatory prescriptions when preparing ERs. Restated, the plain regulatory language does not answer the question presented, because it neither directs the Commission to apply section 51.53(c)(3) to SLR applicants, nor does it forbid the Commission from doing so. Given this regulatory silence, we must look beyond the plain language to discern the Commission's intent.

In our effort to ascertain Commission intent, we are guided by the Supreme Court's approach in Fed. Express Corp. v. Holowecki, 552 U.S. 389 (2008), where, in limning the scope of a regulatory provision in the face of regulatory silence, the Court conducted a holistic analysis that considered (1) the regulatory structure; (2) the agency's interpretative rules; and (3) administrative efficiency, logic, and practicality. In our judgment, a holistic analysis of section 51.53(c)(3) counsels emphatically against the restrictive interpretation urged by petitioners, and reveals, instead, that the Commission intended section 51.53(c)(3) to apply to all license renewal applications, including SLRs. Cf. Christensen v. Harris Cty., 529 U.S. 576, 583–88 (2000) (rejecting petitioners' invitation to put a restrictive gloss on a silent statutory provision when that gloss is not supported by the statutory or regulatory scheme).[32]

---

[32] In Shook v. D.C. Fin. Responsibility and Mgmt. Assistance Auth., 132 F.3d 775, 782 (D.C. Cir. 1998), the court of appeals recognized that "[s]ometimes Congress drafts statutory provisions that appear preclusive of other unmentioned possibilities . . . without meaning to exclude the unmentioned ones." Agencies are likewise susceptible of such drafting imprecision, and in such circumstances, a tribunal is obliged to give effect to agency intent in a manner that comports with the regulatory text, purpose, and structure.

At the outset, we observe that the regulatory history accompanying the 1991 proposed rule stated that the rule was intended to apply "to one renewal of the initial license for up to 20 years beyond the expiration of the initial license." See 1991 Proposed Rule, 56 Fed. Reg. at 47,017. Significantly, however, the proposed rule itself did not include the above restrictive phrase, and when the final rule was issued in 1996, neither it nor its regulatory history included this phrase. See 1996 Final Rule, 61 Fed. Reg. at 28,467. The omission of this phrase supports a conclusion that the Commission did not intend to limit section 51.53(c)(3) to initial license renewals. See Tr. at 62. This conclusion is buttressed by the regulatory structure, including Appendix B to Subpart A of Part 51—to which section 51.53(c)(3)(ii) refers and that codifies the GEIS's findings—that does not refer to "initial" renewals, but speaks more broadly about applying to "a renewed operating license for a nuclear power plant," and as "represent[ing] the analysis of the environmental impacts associated with renewal of any operating license . . . ." 10 C.F.R. pt. 51, subpt. A, app. B.[33]

---

[33] As discussed supra Part III.A.1, a singular purpose of the rule was to promote efficiency in the license renewal process for the wave of initial license renewal applications that was expected to arrive shortly after the rule's promulgation in 1996. FPL and the NRC Staff state that the NRC was, quite understandably, then focused on initial license renewals. See FPL Surreply at 5–6; Tr. at 37. In FPL's view, the word "initial" in section 51.53(c)(3) is properly viewed as a non-restrictive reference to the category of renewals the agency was then contemplating. See FPL Surreply at 6; Tr. at 38. They argue that this non-restrictive reference—although still operative—does not perforce indicate a Commission intent to limit section 51.53(c)(3) to initial license renewals. We agree.

Despite numerous regulatory revisions to section 51.53 since its initial issuance, we found nothing in the regulatory history indicating that the scope of section 51.53(c)(3)—in 1996 or thereafter—was intended to be restricted to initial license renewals, nor do petitioners identify any such history. See Final Rule, Environmental Review for Renewal of Nuclear Power Plant Operating Licenses, 61 Fed Reg. 66,537 (Dec. 18, 1996) (making minor clarifying and conforming changes and adding language to Table B-1 that had been omitted); Final Rule, Licenses, Certifications, and Approvals for Nuclear Power Plants, 72 Fed. Reg. 49,352 (Aug. 28, 2007) (modifying section 51.53(c)(3) to clarify its applicability to combined license applications); 2013 Final Rule, 78 Fed. Reg. at 37,282 ("[R]edefin[ing] the number and scope of the environmental impact issues that must be addressed by the NRC and applicants during license renewal environmental reviews"); Final Rule, Continued Storage of Spent Nuclear Fuel, 79 Fed. Reg. 56,238, 56,253 (Sept. 19, 2014) (amending section 51.53 "to improve readability and to clarify how the generic determination will be used in future NEPA documents for power

That the Commission did not intend to restrict section 51.53(c)(3) to initial license renewals is also consistent with an explicitly stated regulatory purpose, which is to promote efficiency in the environmental review process for license renewal applications.[34] Accepting petitioners' argument would result in an environmental review process where SLR applicants would be required to analyze Category 1 issues on a plant-specific basis, despite the fact that these generic issues have already been analyzed in the GEIS and codified in Appendix B to Subpart A of Part 51. In other words, accepting petitioners' cabined interpretation of section 51.53(c)(3) would compel SLR applicants to perform a time-consuming and unnecessary act, in derogation of the regulatory purpose. This we are unwilling to do. See Exxon Nuclear Co. (Nuclear Fuel Recovery and Recycling Center), ALAB-447, 6 NRC 873, 878 (1977) ("It is an elementary canon of construction that we 'cannot interpret federal statutes to negate their own stated purposes.'") (quoting N.Y. Dep't of Social Servs. v. Dublino, 413 U.S. 405, 419–20 (1973)).

Accepting petitioners' restricted interpretation of section 51.53(c)(3) is also incompatible with the purpose of an ER, which is designed to aid the NRC Staff in preparing a draft SEIS. See supra note 31. When the NRC Staff prepares a draft SEIS, unambiguous regulations require it to apply the GEIS to Category 1 issues.[35] Because an ER is "essentially the

---

reactors and ISFSIs"); Final Rule, Miscellaneous Corrections, 79 Fed. Reg. 66,598, 66,599 (Nov. 10, 2014) (correcting typographical errors in section 51.53(d)).

[34] See 1996 Final Rule, 61 Fed. Reg. at 28,467 (explaining that the Commission's intent behind 10 C.F.R. Part 51 is to "improve the efficiency of the process of environmental review for applicants seeking to renew an operating license").

[35] See 10 C.F.R. § 51.95(c)(4) (stating that the SEIS prepared by the NRC incident to the renewal of an operating license "shall integrate the conclusions in the [GEIS] for issues designated as Category 1 with information developed for those Category 2 issues applicable to the plant"); id. § 51.71(d) (stating that the draft SEIS "for license renewal prepared under § 51.95(c) will rely on conclusions as amplified by the supporting information in the GEIS for issues designated as Category 1 in appendix B to subpart A of this part"); id. pt. 51, subpt. A, app. B (identifying Category 1 issues applicable to "license renewal of nuclear power plants").

applicant's proposal" for the NRC Staff's supplemental SEIS,[36] it logically follows that an SLR applicant should, like an applicant for an initial renewal, prepare an ER in accordance with section 51.53(c)(3) and, accordingly, apply the GEIS to Category 1 issues rather than analyzing them on a plant-specific basis. Otherwise, its ER would contain an overwhelming amount of information that would be of no assistance to the NRC Staff in its preparation of the draft SEIS. Absent persuasive indicators to the contrary, we are unwilling to impute to the Commission an intent to have an SLR applicant prepare an ER that does not serve its regulatory purpose.

Accepting petitioners' argument would not only undermine the regulatory purpose, it would ignore an express regulatory mandate in section 51.95(c)(4). In license renewal proceedings, the NRC Staff is required to integrate into the draft SEIS "information developed for those Category 2 issues applicable to the plant under § 51.53(c)(3)(ii)." 10 C.F.R. § 51.95(c)(4) (emphasis added). In other words, section 51.95(c)(4), which applies broadly to all license renewal proceedings, see supra note 35, commands the NRC to consider the "information developed" by an SLR applicant "under § 51.53(c)(3)(ii)" in its preparation of the draft SEIS. In our view, this regulatory command is persuasive evidence that, contrary to petitioners' argument, the Commission did not intend to restrict section 51.53(c)(3) to initial license renewal applicants.

This conclusion is strengthened by the fact that Part 51 requires periodic reviews of the GEIS findings to ensure that the environmental analyses for Category 1 issues remain current. The regulation states in pertinent part: "On a 10-year cycle, the Commission intends to review the material in [Appendix B] and update it if necessary. A scoping notice must be published in the Federal Register indicating the results of the NRC's review and inviting public comments and proposals for other areas that should be updated." 10 C.F.R. pt. 51, subpt. A, app. B. This

---

36 See Final Rule, Rules of Practice for Domestic Licensing Proceedings—Procedural Changes in the Hearing Process, 54 Fed. Reg. 33,168, 33,172 (Aug. 11, 1989).

regulatory requirement for periodic reviews and updates of the GEIS would not be necessary unless the Commission contemplated that the NRC Staff, as well as all license renewal applicants, could rely on the generic findings in the GEIS instead of engaging in the wholly unnecessary process of considering Category 1 issues on a site-specific basis.

The most recent update of the GEIS occurred in June 2013. See 2013 GEIS.[37] The following extract from the final regulatory analysis for that update expressly considered SLR applications in its cost-benefit analysis, signifying that the Commission intended the 2013 GEIS and Appendix B to apply to SLRs:

> Some plants will become eligible for a second 20-year license extension after [fiscal year (FY)] 2013. While the NRC understands that the possibility exists for license holders to submit a second license renewal application, no letters of intent have been received as of the issuance date of this document. The NRC estimates receiving 3 applications per year from FY 2015 through FY 2022. The NRC estimates that a total of 30 license renewal applications (including applications for a second license renewal) will be received in the 10-year cycle following the effective date of the rule.

See SECY-12-0063, Final Rule: Revisions to Environmental Review for Renewal of Nuclear Power Plant Operating Licenses, encl. 2 at 25 (Apr. 20, 2012).[38] Nowhere in the regulatory

---

[37] Notably, the NRC's scoping report for the 2013 update to the GEIS stated that "[t]he NRC's current plan is to apply the revised GEIS to all license renewal applications submitted after the date [of] the Record of Decision for the revised GEIS is printed in the Federal Register." [EIS] Scoping Process Summary Report, Update of the [GEIS] for License Renewal of Nuclear Plants at 67 (May 2009) (emphasis added). This scoping summary report was referenced in the proposed rule to update Part 51. See Proposed Rule, Revisions to Environmental Review for Renewal of Nuclear Power Plant Operating Licenses, 74 Fed. Reg. 38,117, 38,119 (July 31, 2009) (describing the scoping process). For a full description of the reasons public comments were sought, see Notice of Intent to Prepare an [EIS] for the License Renewal of Nuclear Power Plants and to Conduct Scoping Process, 68 Fed. Reg. 33,209, 33,210 (June 3, 2003).

[38] We acknowledge that this SECY paper (which is a formal memorandum to the Commissioners from the Executive Director for Operations that seeks Commission approval for the specified Staff action) "lack[s] the force of law" and, accordingly, cannot serve to alter a regulation. Christensen, 529 U.S. at 587. Here, however, we seek to discern Commission intent regarding the scope of a silent regulation. In our judgment, this SECY paper, which was the basis for Commission action on the final rule, see SRM-SECY-12-0063, Final Rule: Revisions to Environmental Review for Renewal of Nuclear Power Plant Operating Licenses

history of the 2013 rulemaking (or, for that matter, in any of the post-1996 rulemakings, see supra note 33), was there any discussion of an intent to restrict the application of section 51.53(c)(3) to initial license renewals. Rather, it discussed license renewals in general, without differentiating between initial renewals and SLRs, giving rise to a persuasive inference that the Commission intended the updated GEIS—and therefore section 51.53(c)(3)—to apply to all applicants.

After completion of the 2013 rulemaking, the NRC Staff informed the Commission that, with regard to SLR applications, "[t]he staff does not recommend updating the environmental regulatory framework under 10 CFR Part 51 . . . , because environmental issues can be adequately addressed by the existing GEIS and through future GEIS revisions." SECY-14-0016, Ongoing Staff Activities to Assess Regulatory Considerations for Power Reactor [SLR], at 5 (Jan. 31, 2014). The Commission accepted that recommendation, which is further evidence of the Commission's intention to apply the 2013 GEIS and Appendix B—and, hence, section 51.53(c)(3)—to SLR applicants. See SRM-SECY-14-0016, Ongoing Staff Activities to Assess Regulatory Considerations for Power Reactor [SLR] (Aug. 29, 2014) (disapproving the NRC Staff's recommendation to initiate a rulemaking pursuant to Part 54, but refraining—consistent with the NRC Staff's recommendation—from updating the Part 51 regulatory framework for SLR applications).

(Dec. 6, 2012), provides insight into the Commission's view regarding the continuing applicability of the GEIS to license renewals and, hence, the applicability of section 51.53(c)(3) to SLR applications. In other words, as we have shown, when the regulations were issued in 1996, the regulatory purpose and structure reveal that the Commission did not intend section 51.53(c)(3) to be restrictive in its scope, and that intent has remained constant with the passage of time.

The 2013 GEIS itself discusses license renewals in general and non-restrictive terms, from which it may be inferred that SLR applicants may rely on the GEIS and Appendix B and, accordingly, need not consider Category 1 issues on a site-specific basis in their ER.[39]

Petitioners nevertheless assert that the agency intended the 1996 GEIS and the 2013 GEIS to be limited to initial license renewals. See Pet's Response to FPL Surreply at 5–8. But petitioners fail to identify any provision in the 1996 GEIS that compels us to accept their argument. And regarding the 2013 GEIS, petitioners' argument fails to account for the following language in the GEIS: (1) the "purpose and need for the proposed action (issuance of a renewed license) is to provide an option [to continue plant operations] beyond the term of the current . . . operating license," 2013 GEIS at 1-3; (2) the "decisions to be [] supported by the GEIS are whether or not to renew the operating licenses of . . . power plants for an additional 20 years," id. at 1-7; and (3) "[t]here are no specific limitations in the Atomic Energy Act or the NRC's regulations restricting the number of times a license may be renewed." Id. at S-1. The 2013 GEIS clearly indicates that it assesses "environmental consequences of renewing the licenses . . . and operating the plants for an additional 20 years beyond the current license term." Id. at S-4 (emphasis added). Additionally, the 2013 GEIS states that the proposed action

39 See, e.g., 2013 GEIS at 1-4 ("The GEIS serves to facilitate NRC's environmental review process by identifying and evaluating environmental impacts that are considered generic and common to all nuclear power plants. . . . Generic impacts will be reconsidered in SEISs only if there is new and significant information that would change the conclusions in the GEIS."); id. at 1-7 to1-8 ("The decisions to be [] supported by the GEIS are whether or not to renew the operating licenses of individual commercial nuclear power plants for an additional 20 years. The GEIS was developed to support these decisions and to serve as a basis from which future NEPA analyses for the license renewal of individual nuclear power plants would tier."); id. at 1-8 ("The GEIS provides the NRC decision-maker with important environmental information considered common to all nuclear power plants and allows greater focus to be placed on plant-specific (i.e., Category 2) issues."); id. at 1-17 ("The applicant is not required to assess the environmental impacts of Category 1 issues listed in Table B-1 unless the applicant is aware of new and significant information that would change the conclusions in the GEIS."); id. at 4-3 ("For [Category 1 issues], no additional plant-specific analysis is required in future supplemental EISs . . . unless new and significant information is identified.").

includes the activities associated with the "license renewal term," id. at 4-2, and this term is used throughout the GEIS in assessing the impacts of these activities, as well as in various impact findings codified in Table B-1. The 2013 GEIS defines the "license renewal term" as "[t]hat period of time past the original or current license term for which the renewed license is in force." Id. at 7-27 (emphasis added).

In short, the 2013 GEIS—which is an express regulatory product of the 1996 regulations—explicitly purports to assess the environmental impacts associated with a 20-year renewal period, regardless of whether this period follows the original license or a current renewed license. And the 2013 revisions to the Part 51 rules codify in Table B-1 the findings from the 2013 GEIS on the impacts associated with the "license renewal term."[40]

In our judgment, the Part 51 regulatory structure—commencing with the proposed 1991 regulations, and continuing to present (including the 2013 GEIS)—is compelling evidence that the Commission intended for all license renewal applicants to comply with the requirements of 10 C.F.R. § 51.53(c)(3) when preparing an ER. More specifically, consistent with section 51.53(c)(3), an SLR applicant "is not required to assess the environmental impacts of Category 1 issues listed in Table B-1 unless the applicant is aware of new and significant information that would change the conclusions in the GEIS." 2013 GEIS at 1-17.

---

[40] Despite the above regulatory language, petitioners argue that the 2013 GEIS should not apply to SLRs because it fails to adequately consider the environmental impacts associated with SLRs (i.e., with a plant life of 80 years) for, e.g., occupational radiation exposures, public radiation doses, and decommissioning. See Pet'rs Response to FPL Surreply at 7–8. In light of our conclusion above that the 2013 GEIS aims to assess the environmental impacts associated with SLRs, and because Part 51 commands the NRC Staff to use the GEIS in preparing the SEIS for a license renewal, see supra note 35, we summarily reject petitioners' argument, concluding that it is essentially an impermissible attempt to challenge Category 1 findings in an adjudicatory proceeding without having first sought a waiver. See 10 C.F.R. § 2.335(a).

NRC guidance documents support this conclusion.[41] For example, NRC Regulatory Guide 4.2 provides instructions for license renewal applicants for the "preparation of [ERs] that are submitted as part of an application for the renewal of a nuclear power plant operating license in accordance with [10 C.F.R. Part 54]." Preparation of Environmental Reports for Nuclear Power Plant License Renewal Applications, Regulatory Guide 4.2, at 1 (supp. 1, rev. 1 June 2013) [hereinafter Reg. Guide 4.2]. This Regulatory Guide does not distinguish between initial and subsequent license renewal applicants; rather, because it repeatedly refers broadly to "applicants" and "license renewal applicants," it is reasonably construed as applying to both categories of applicants. See, e.g., Reg. Guide 4.2 at 1, 5, 6, 7, 8, 10.[42]

Moreover, and most significantly, Reg. Guide 4.2 repeatedly states that issues "identified as Category 1 issues in the GEIS, are adequately addressed for all applicable nuclear plants. The NRC will not require additional analysis in plant-specific [ERs] unless new and significant information has been identified . . . The applicant may adopt the findings in the GEIS for Category 1 issues if no new and significant information is discovered." Id. at 25 (emphasis added); see also id. at 2, 7.

According "special weight" to Reg. Guide 4.2 as directed by the Commission, Indian Point, CLI-15-6, 81 NRC at 356, and recognizing that it "reflect[s] a body of experience and informed judgment" developed by the NRC Staff, Holowecki, 522 U.S. at 399, we find that it

---

41 The Supreme Court has stated that an agency's interpretative statements "reflect a body of experience and informed judgment to which courts and litigants may properly resort for guidance. As such, they are entitled to a measure of respect . . . ." Holowecki, 552 U.S. at 399 (internal citations omitted); see also Entergy Nuclear Operations, Inc. (Indian Point, Units 2 & 3), CLI-15-6, 81 NRC 340, 356 (2015) ("Guidance documents that are developed to assist in compliance with applicable regulations are . . . entitled to special weight.") (internal citation omitted).

42 Accord Standard Review Plans for Environmental Reviews for Nuclear Power Plants: Operating License Renewal, NUREG-1555, at iii (supp. 1, rev. 1, June 2013) (providing instructions for NRC Staff in "conducting an environmental review for the renewal of a nuclear power plant operating license") (emphasis added).

provides strong support for concluding that "[a]pplicants for renewal of power reactor operating licenses," including SLR applicants, may "use the guidance in [Reg. Guide 4.2] to develop the [ER] required under 10 C.F.R. 51.53(c)." Reg. Guide 4.2 at 56. Accordingly, SLR applicants need "not [conduct] additional analysis in . . . [ERs for Category 1 issues] unless new and significant information is identified." Id. at 25.[43]

A contrary conclusion—in addition to being discordant with the regulatory purpose, regulatory structure, and Reg. Guide 4.2—would result in the following untenable interplay between the NRC's environmental review procedures in 10 C.F.R. Part 51 and its adjudicatory procedures in 10 C.F.R. Part 2. First, assume that we accept petitioners' argument that section 51.53(c)(3) does not apply to SLRs and, accordingly, that we admit a contention alleging that FPL's ER is deficient because it fails to consider a Category 1 issue on a plant-specific basis. Further, assume that thereafter the NRC Staff issues a draft SEIS that, consistent with regulatory requirements, likewise does not consider that Category 1 issue on a plant-specific basis. Pursuant to the agency's contention-migration tenet,[44] the admitted contention would become a challenge to the NRC Staff's draft SEIS. Because the NRC Staff's non-consideration of the Category 1 issue on a plant-specific basis fully comports with its environmental review responsibilities under NEPA and Part 51, see Balt. Gas & Elec. Co., 462 U.S. at 101; supra note 35 and accompanying text, the contention would be subject to summary dismissal on the

---

[43] The Supreme Court has instructed that in assessing the deference to be accorded to an interpretative rule, a tribunal should "consider whether the agency has applied its position with consistency." Holowecki, 552 U.S. at 399–400. The current version of Reg. Guide 4.2 has been applied by the agency and relied upon by the nuclear industry for over five years. Plainly, FPL relied upon it when preparing this ER, see ER at 1-7, and FPL's reliance was consistent with the agency's expectation embodied in NUREG-1555. See supra note 42.

[44] "[A] contention 'migrates' when a licensing board construes a contention challenging [an ER] as a challenge to a subsequently issued Staff NEPA document without the petitioner amending the contention." Crow Butte Res., Inc. (In Situ Leach Facility, Crawford, Neb.), CLI-15-17, 82 NRC 33, 42 n.58 (2015).

alternative grounds that it was (1) outside the scope of the proceeding, see 10 C.F.R. § 2.309(f)(1)(iii); or (2) an impermissible challenge to an agency regulation. See id. § 2.335(a). We do not believe that the Commission intended to craft a regulatory scheme that would require litigants and licensing boards to engage in a senseless adjudicatory process that, in practice, would result in the wasteful expenditure of private and governmental resources in derogation of the public interest. We therefore decline to credit petitioners' interpretation of section 51.53(c)(3), which would compel this absurd result.[45]

In sum, based on a holistic review of 10 C.F.R. § 51.53(c)(3) that considers (1) regulatory language and structure; (2) regulatory purpose and history; (3) interpretative rules; and (4) efficiency, logic, and practicality, we are persuaded that the Commission did not intend to restrict section 51.53(c)(3) to initial license renewals. Accordingly, we conclude that FPL's ER need not consider generic Category 1 issues on a site-specific basis but, instead, may rely on the Category 1 findings in the GEIS and Table B-1, and we will assess petitioners' contentions in that light.[46]

---

45 Cf. Griffin v. Oceanic Contractors, Inc., 458 U.S. 564, 575 (1982) ("It is true that interpretations of a statute which would produce absurd results are to be avoided if alternative interpretations consistent with the legislative purpose are available.").

46 Given the significance of this legal issue of first impression, we will refer our ruling on this matter to the Commission pursuant to 10 C.F.R. § 2.323(f)(1). We note that this issue is pending before a licensing board in another SLR proceeding, signifying that it will likely be a recurring issue until resolved by the Commission. See Beyond Nuclear, Inc.'s Hearing Request and Petition to Intervene, Exelon Generation Co. (Peach Bottom Atomic Power Station, Units 2 & 3), Nos. 50-277/278-SLR (Nov. 19, 2018).

3. A Response to the Dissent

The dissent would lead this Licensing Board to an irrational result based on its conviction that section 51.53(c)(3), by its plain and (allegedly) unambiguous language, excludes SLRs and necessarily applies only to initial license renewals. See Dissent at 1–3, 18. With respect, the dissent is incorrect.[47]

To support its restrictive reading of section 51.53(c)(3), the dissent cites the canon of statutory interpretation expressio unius est exclusio alterius, see Dissent at 3, which means "the mention of one thing implies the exclusion of another." Shook, 132 F.3d at 782. The dissent views the Commission's use of the word "initial" as necessarily precluding SLRs. See Dissent at 4 ("Something is either 'initial,' . . . or it is not. No room exists for anything else.").

However, the expressio unius canon is not an inflexible rule of law commanding that the mere mention of one thing means the exclusion of another; rather, it is "used as a starting point in [regulatory] construction" to ascertain the intent of the drafter. Shook, 132 F.3d at 782. The force of the canon in a particular case, like "[t]he force of any negative implication, . . . depends on context." NLRB v. Sw. Gen., Inc., __ U.S. __, __, 137 S. Ct. 929, 940 (2017) (internal quotations omitted). Thus, whether the word "initial" in section 51.53(c)(3) necessarily excludes SLRs from the regulation's scope is a matter of Commission intent, to be determined by considering "whether or not the [Commission's] mention of one thing . . . does really necessarily, or at least reasonably, imply the preclusion of alternatives." Shook, 132 F.3d at 782; accord Sw. Gen., Inc., __ U.S. at __, 137 S. Ct. at 940 (applying expressio unius "only when circumstances support [] a sensible inference that the term left out must have been meant to be excluded") (internal citation omitted). Our review of the circumstances surrounding the proposal and

47 To be clear, we agree with the dissent's statement that, pursuant to its plain language, section 51.53(c)(3) applies to applicants seeking an "initial renewed license." Dissent at 2. Our interpretation of section 51.53(c)(3) gives full (but not preclusive) effect to this phrase.

issuance of the Part 51 regulatory amendments, see supra Part III.A.2, reveals that the mention of initial license renewals in section 51.53(c)(3) does not support a reasonable inference (much less a necessary one) that the Commission intended to exclude SLRs.[48]

Significantly, the dissent does not dispute that its restrictive reading of section 51.53(c)(3) places that regulation in irreconcilable tension with "sections 51.71(d), 51.95(c), and 10 C.F.R. Part 51, Subpart A, Appendix B," Dissent at 8, which all refer broadly to "license renewals" rather than restrictively to "initial" license renewals. To harmonize its interpretation with these other portions of Part 51 in light of the 1991 regulatory history, the dissent suggests (but "do[es] not advocate", id. at 9 n.38) that "the word 'initial' would need to be read into [these regulatory provisions]." Id. at 8. That the dissent's interpretation would result in the de facto revision of three regulations powerfully illustrates the infirmity of its analysis. Such a wholesale adjudicatory revision to the Part 51 regulatory structure in derogation of Commission intent is both unsupportable and impermissible.[49]

According to the dissent, the fact that Part 51 provides for periodic updates of the GEIS does not mean that an SLR applicant can rely on the GEIS to prepare its ER; rather, "it simply means that when the GEIS is used [by the NRC Staff to prepare an SEIS,] the information it contains is reasonably up-to-date." Dissent at 7 n.32. In our view, however, it is nonsensical—indeed, absurd—to conclude that Part 51 authorizes the NRC Staff to rely on the GEIS when

---

48 The dissent's analysis relies significantly on the snippet of regulatory history in the 1991 proposed rule that stated the rule would apply "to one renewal of the initial license for up to 20 years beyond [its] expiration." Dissent at 4. However, this phrase was omitted from the regulatory history in the 1996 final rule—and with good reason. It did not comport with the regulatory purpose and structure, both of which supported a conclusion that the Commission did not intend to restrict section 51.53(c)(3) to initial license renewals. See supra Part III.A.2.

49 In addition to suggesting an extensive regulatory revision in the guise of interpreting section 51.53(c)(3), the dissent proposes a "short-term [procedural] solution" for SLR applicants and the NRC Staff to follow in conducting their Part 51 environmental review. See Dissent at 16. This "short-term [procedural] solution," however, would also constitute an impermissible adjudicatory revision of Part 51 in derogation of Commission intent.

preparing an SEIS, but prohibits an SLR applicant from doing so when preparing an ER. After all, in light of the periodic update of the GEIS, now, as in 1996, "[w]hen the GEIS and SEIS are combined, they cover all issues that NEPA requires be addressed in an EIS for a nuclear power plant license renewal proceeding." Massachusetts, 522 F.3d at 120. Moreover, because (as we have shown) the Commission did not intend to exclude SLR applicants from using section 51.53(c)(3) in the preparation of ERs, it necessarily follows that the Commission did not intend to preclude SLR applicants from relying on the updated GEIS in the preparation of ERs. The updated GEIS (including its codification and regulatory history) as well as the agency's interpretative rules support this conclusion.

Notably, if there were any question in 1991 and 1996 about whether updated GEIS findings, as codified in Part 51, could validly be applied to SLRs, an affirmative answer could be gleaned from the following discussion in the regulatory history:

> (1) License renewal will involve nuclear power plants for which the environmental impacts of operation are well understood as a result of data evaluated from operating experience to date; (2) activities and requirements associated with license renewal are anticipated to be within this range of operating experience, thus environmental impacts can reasonably be predicted; and (3) changes in the environment around nuclear power plants are generally gradual and predictable with respect to characteristics important to environmental impact analyses.

1991 Proposed Rule, 56 Fed. Reg. at 47,016 (emphasis added); accord 1996 Final Rule, 61 Fed. Reg. at 28,467–68. The above principles, which explain the creation of Category 1 issues and justify their use in ERs and SEISs, apply with equal force to initial license renewals and SLRs. The dissent's contrary view is not tenable.

The dissent also expresses concern that our interpretation of section 51.53(c)(3) runs afoul of the Administrative Procedure Act (APA) by (1) effecting a de facto change to the regulation, see Dissent at 1; (2) side-stepping the rulemaking process, thereby denying the public an opportunity to comment on the rule change, see id. at 14; and (3) prejudicing petitioners who, due to their uncertainty about whether section 51.53(c)(3) applies to SLRs, fail to invoke section 2.335 to seek a waiver of a GEIS finding codified in Part 51. See id. These concerns are unfounded.

First, our interpretation does not effect a de facto regulatory change; rather, it gives effect to Commission intent that has been rooted in the Part 51 regulatory purpose and structure from the outset. See supra Part III.A.2. Nothing in the APA forbids a regulatory interpretation that is permitted by the regulatory language, consistent with the regulatory purpose, supported by the regulatory structure, reinforced by published regulatory guidance, and reasonably relied upon by the industry.[50]

Nor is there merit to the dissent's concern that our interpretation improperly side-steps the rulemaking process and denies the public the opportunity to comment on a rule change. For the reasons already discussed, our interpretation does not effect a rule change and, accordingly, the public was not improperly denied an opportunity to comment. Rather, the public had an opportunity to comment between the rule's proposal in 1991 and its issuance in 1996. We note, moreover, that immediately before the agency issued the final rule in 1996, it gave the public an additional 30-day comment period, announcing that "[t]he NRC is soliciting public comment on this rule for a period of 30 days. . . . Absent a determination by the NRC that the rule should be modified, based on comments received, the final rule shall be effective on August 5, 1996. The comment period expires on July 5, 1996." 1996 Final Rule, 61 Fed. Reg. at 28,467.

---

50 The dissent asserts that "the majority's application of the regulation creates . . . a significant uncertainty about what regulatory standards are applicable" to SLRS. Dissent at 1. However, nothing in the instant record suggests that the regulated industry has any uncertainty about the regulatory standards that apply to SLRs. When FPL prepared its ER, it did so in accordance with the prescribed process in section 51.53(c)(3) in reasonable reliance on (1) the Part 51 regulatory purpose and structure; (2) the guidance statements in Reg. Guide 4.2; and (3) the agency's expectation embodied in NUREG-1555. See supra note 43.

Nor does this record support the dissent's claim, Dissent at 1, that "the majority's application of the regulation creates . . . an obstacle to a petitioner's ability to know how to properly frame its contentions." See infra note 51 and accompanying text.

Although it is true that SACE and Joint Petitioners did not invoke section 2.335 to seek a waiver of a GEIS finding, their failure to do so was not based on any misapprehension regarding the applicability of section 51.53(c)(3) to FPL's SLR. To the contrary, these petitioners recognized that the applicability of section 51.53(c)(3) to SLRs was an open question, see, e.g., Joint Pet'rs Pet. at 16 n.71; SACE Reply at 3–9, and they made a conscious litigation choice not to take the precautionary step of invoking section 2.335. Petitioners were not unfairly prejudiced.[51]

Finally, the dissent opines that, unless its interpretation is accepted, the NRC might be encouraged to take improper "short cuts to amending its regulations in future adjudicatory proceedings." Dissent at 15. This concern lacks merit because it is grounded on the erroneous premise that section 51.53(c)(3) applies only to initial license renewal applicants. Moreover, although we decline to base our regulatory analysis on the notion that the NRC might engage in administrative misconduct in future adjudicatory proceedings, see Nat'l Small Shipment Traffics Conference, Inc. v. Interstate Commerce Comm'n, 725 F.2d 1442, 1450 (D.C. Cir. 1984), we nevertheless note that "the APA contains a variety of constraints" and remedies that serve to prevent agencies from taking improper short cuts when revising their regulations. Perez v. Mortg. Bankers Ass'n, __ U.S. __, __, 135 S. Ct. 1199, 1209 (2015).

[51] In the litigation context, it is axiomatic that when a regulation (or statute) lacks clarity, it is incumbent on a party or its representative to (1) identify the uncertainty; and (2) pursue a litigation strategy that protects the party's interests. Where, as here, a party refrains from advancing an argument, that argument is deemed to be waived. See e.g., Hormel v. Helvering, 312 U.S. 552, 556 (1941); District of Columbia v. Air Fla., Inc., 750 F.2d 1077, 1084–85 (D.C. Cir. 1984).

B. SACE ESTABLISHES STANDING, AND EACH OF ITS TWO PROFFERED CONTENTIONS IS ADMISSIBLE IN PART

1. SACE Establishes Standing

SACE satisfies the requirements for representational standing, which are discussed supra Part II.A.[52] SACE states that it is "a nonprofit, nonpartisan membership organization that promotes responsible energy choices that solve global warming problems and ensure clean, safe and healthy communities throughout the Southeast." SACE Pet. at 3. The environmental interests it seeks to protect in this proceeding are thus germane to its organizational purpose. Further, SACE provides declarations from three members who (1) live within 50 miles of the Turkey Point site and therefore have standing in their own right pursuant to the proximity presumption; and (2) authorize SACE to represent their interest in this proceeding, thus rendering it unnecessary for them to participate as individuals. See id., attach. 1, Decl. of Dan Kipnis ¶¶ 2, 4 (June 19, 2018); id., attach. 2, Decl. of Mark P. Oncavage ¶¶ 2, 4 (June 25, 2018); id., attach. 3, Decl. of Richard Reynolds ¶¶ 2, 4 (June 20, 2018).

2. Each of SACE's Two Proffered Contentions is Admissible in Part

SACE proffers two contentions alleging deficiencies in FPL's ER, and both are admissible in part. The Board admits Contention 1 to the extent it challenges the adequacy of the ER's discussion of the impacts of continued operation of the cooling canal system (CCS) on the American crocodile and its critical seagrass habitat. The Board admits Contention 2 to the extent it claims that the ER improperly fails to consider as a reasonable alternative to the proposed action a scenario under which the existing CCS is replaced with draft mechanical cooling towers. We reject as inadmissible the other portions of Contentions 1 and 2.

52 Neither FPL nor the NRC Staff challenges SACE's representational standing. See FPL Answer to SACE Pet. at 2; NRC Staff Answer to Joint Pet'rs Pet. and SACE Pet. at 10–11.

a. Contention 1 Is Admissible in Part

In Contention 1, SACE asserts that the ER contains an inadequate discussion of the environmental impacts of the CCS and, accordingly, that there is no basis for its conclusion that the environmental effects of operating the CCS through the subsequent renewal term will be small. See SACE Pet. at 6, 8. In support of this assertion, SACE identifies three putative defects in the ER (which we designate as Contentions 1A, 1B, and 1C), each of which involves an alleged inadequate discussion of the environmental impacts of the CCS. See id. at 6–7. We examine each alleged defect in turn.

i. Contention 1A: Inadequate Analysis of Environmental Impacts of CCS on Crocodile Habitat, Biscayne Aquifer, and Biscayne Bay

SACE claims that the ER underestimates or ignores “the environmental impacts to the surrounding water resources by continuing to use the [CCS] for cooling of Turkey Point Units 3 and 4.” SACE Pet. at 6. This part of the contention challenges the ER’s alleged failure “to provide an adequate analysis of the environmental impacts of the CCS on the chemistry of groundwater, surface water and its aquatic life, and the CCS’[s] own ecosystem.” Id. SACE asserts that the ER incorrectly minimizes the significance of the CCS’s environmental impacts on (1) the American crocodile habitat and, as a result, on the crocodile population, id. at 19–20; (2) the Biscayne Aquifer related to the hypersaline plume, id. at 17–18; and (3) the Biscayne Bay related to nutrient releases. Id. at 18–19.

The NRC Staff does not oppose admission of Contention 1A insofar as it challenges the adequacy of the ER’s “analysis of the impacts of continued CCS operation on the critical habitat of the American crocodile.” NRC Staff Answer to Joint Pet’rs Pet. and SACE Pet. at 59. FPL disagrees, arguing that SACE provides no factual support to show that “the decline in American crocodile nest and hatchling numbers observed in 2015 and 2016 (as reported in the ER) indicate a long-term trend that will somehow be exacerbated by continued CCS operations and extend through the SLR period.” FPL Answer to SACE Pet. at 36. Further, FPL cites a newspaper article that reported substantial increases in the number of nests and hatchlings in the CCS for 2018. Id. at 35.[53] Finally, FPL argues that this aspect of the contention fails to raise a genuine dispute because it ignores the ER's discussion of FPL's crocodile management plan. Id. at 36.

We agree with the NRC Staff that this aspect of the contention is admissible. Although the ER discusses a crocodile management plan, we conclude that SACE raises a genuine factual dispute as to whether the ER adequately assesses the impacts of continued operation of the CCS on the American crocodile and its critical seagrass habitat. As the NRC Staff pointed out, see NRC Staff Answer to Joint Pet'rs Pet. and SACE Pet. at 60, SACE does not dispute the adequacy of FPL's crocodile monitoring and protection plan, but rather challenges the ER's conclusion that "the American crocodile population continues to remain in a much stronger position than before the . . . CCS was established." SACE Pet. at 19 (citing ER at 3-195). The impacts of a license renewal on threatened species is a factual issue that is within the scope of this proceeding, and SACE has provided expert support for its claim that the CCS is degrading the seagrass habitat by exposing it to excessive levels of salt and nutrients. See SACE Pet. at 20 (citing attach. 8, Expert Report of James Fourqurean, Ph.D. at 1–3 (May 14, 2018)). Although the ER acknowledges that a decline in the crocodile population has occurred in recent years, SACE argues that it must also take a hard look at the fact that this decline signals a critical loss of seagrass bed habitat for a threatened species caused by operation of the CCS, see SACE Pet. at 19, and that it must address the "cumulative effects of the CCS on the American Crocodile." Id. at 27. We agree. We therefore admit Contention 1A as follows: The ER fails adequately to analyze the impacts (including cumulative) of continued CCS operation on the American Crocodile and its critical seagrass habitat.

---

[53] FPL cites the following newspaper article: Theresa Java, Turkey Point's Canal Berms Ideal for Crocodile Clutches, Keysnews.com (Aug. 8, 2018), https://keysnews.com/article/story/turkey-points-canal-berms-ideal-for-crocodile-clutches/.

We conclude that all other aspects of Contention 1A are not admissible. First, to the extent Contention 1A claims that the ER underestimates the impacts related to tritium releases to groundwater, it is inadmissible because (1) it lacks the requisite support, see 10 C.F.R. § 2.309(f)(1)(v); and (2) it fails to raise a genuine dispute with the ER. See id. § 2.309(f)(1)(vi). Although SACE's experts provide support regarding tritium releases to Biscayne Bay, see SACE Reply at 12–13, they fail to do so regarding tritium releases to groundwater. Moreover, although SACE's petition states that the hypersaline plume includes radioactive tritium, and that tritium, among other pollutants, affects "the underlying Biscayne Aquifer and its protected G-II groundwater," SACE Pet. at 6, SACE provides no explanation for why releases of "tritium as one of numerous contaminants . . . pose[s] an unacceptable environmental risk" to groundwater. SACE Reply at 10. The ER acknowledges that "tritium is routinely released to the cooling canals and migrates into the groundwater," but states that the releases are "in concentrations that do not present an environment or health risk either onsite or offsite." ER at 3-114. SACE does not specifically dispute this, and its experts do not provide support for the claim that the environmental impacts of tritium releases on groundwater have been understated or that measured tritium concentrations are above permissible levels. This aspect of the contention is therefore inadmissible pursuant to section 2.309(f)(1)(v) and (vi).

With regard to the other aspects of Contention 1A relating to impacts to the Biscayne Bay and Aquifer, the NRC Staff and FPL argue that they constitute impermissible challenges to the regulations. Specifically, the NRC Staff states, and FPL agrees, that the following environmental impacts challenged by SACE constitute Category 1 issues that cannot be challenged in this litigation in the absence of a waiver, which SACE has not sought:

> [T]he environmental impacts . . . [regarding] (1) altered salinity gradients in surface waters, (2) groundwater quality degradation, (3) exposure of aquatic organisms to radionuclides, (4) the effects of non-radiological contaminants on aquatic organisms, (5) cooling system impacts on terrestrial resources, and (6) radiation (tritium) exposures to the public.

NRC Staff Answer to Joint Pet'rs Pet. and SACE Pet. at 62, 63; see FPL Answer to SACE Pet. at 14–15. We agree that SACE's challenges in Contention 1A relating to the above impacts implicate Category 1 issues, and are thus outside the scope of this proceeding under 10 C.F.R. § 2.309(f)(1)(iii). Because SACE did not seek a waiver, these challenges must also be rejected pursuant to 10 C.F.R. § 2.335.[54]

ii. Contention 1B: Inadequate Analysis of Mitigation Measures to Reduce Salinity Resulting from Operation of CCS

In Contention 1B, SACE argues that the ER overstates the "effectiveness of existing and planned mitigative measures to reduce and remove the hypersaline plume," SACE Pet. at 21–22, and fails to account for the "[n]egative impacts of mitigation measures to reduce salt levels in the CCS." Id. at 23–24; see also id. at 7 (alleging that the ER fails to consider that FPL's mitigative efforts to "freshen" the CCS to reduce its salinity will negatively impact FPL's attempts to reduce the hypersaline plume).

The NRC Staff responds that SACE's argument essentially challenges the adequacy of the ER's discussions related to "altered salinity gradients in surface waters" and "groundwater quality degradation," both of which are Category 1 issues and, therefore, not subject to direct or indirect challenge absent a waiver pursuant to 10 C.F.R. § 2.335. See NRC Staff Answer to Joint Pet'rs Pet. and SACE Pet. at 62–63. FPL makes a similar argument, stating that this

---

[54] FPL further argues that SACE's claims regarding these impacts to the Biscayne Aquifer and Bay lack factual support. See FPL Answer to SACE Pet at 15. Specifically, FPL argues that the ER has "fully recognized and disclosed" the plume migration and its impacts to the Biscayne Aquifer, and that FPL is in compliance with the relevant Florida Department of Environmental Protection (FDEP) Consent Order and Miami-Dade County Department of Regulatory and Economic Resources (DERM) Consent Agreement, which were entered into specifically to address CCS-related groundwater impacts. Id. at 18–20. As to any alleged CCS impacts to the Biscayne Bay, FPL argues that "the impairment status of Biscayne Bay/Card Sound is unrelated to the operation of the CCS[, and] SACE and its experts provide no facts to support a contrary conclusion, or their claim that alleged 'nutrient seepage from the CCS' is having significant adverse impacts on Biscayne Bay water quality." Id. at 22 (quoting SACE Pet. at 19). We agree with FPL that this provides an alternative ground for inadmissibility pursuant to 10 C.F.R. § 2.309(f)(1)(v).

aspect of the contention is inadmissible pursuant to Commission precedent establishing that license renewal applicants "'need not address mitigation for issues' designated Category 1." See FPL Answer to SACE Pet. at 22–23 (quoting Entergy Nuclear Generation Co. (Pilgrim Nuclear Power Station), CLI-10-14, 71 NRC 449, 471 (2010)). FPL thus argues that "SACE's challenges to the adequacy of FPL's CCS-related mitigation measures (which involve Category 1 issues) are outside the scope of this proceeding as a matter of law." Id. at 23. We agree that Contention 1B is inadmissible for the alternative reasons that (1) it is an impermissible challenge to a Category 1 issue pursuant to section 2.335; and (2) it is outside the scope of this proceeding pursuant to section 2.309(f)(1)(iii).[55]

iii. Contention 1C: Inadequate Analysis of Cumulative Environmental Impacts

Finally, SACE argues that the ER "ignores or underestimates the cumulative impacts of past and future operations of the CCS." SACE Pet. at 7. In particular, SACE objects to the ER's failure to examine several issues within its cumulative impact analysis, including:

(1) FPL's efforts to contain pollutants from the CCS, including an examination of the "effectiveness and adverse effects of all of its mitigation measures, past, present, and proposed," id. at 25;

(2) The "combined effects of the L-31E levee and evaporation from the CCS on the degree to which the CCS and the underlying aquifer have become hypersaline and contaminated other parts of the aquifer and Biscayne Bay," id. at 26;

(3) The "cumulative impacts of the CCS, combined with other environmental factors, on hypersalinity in the CCS and the

---

55 The NRC Staff and FPL also oppose admission of the challenge to mitigation measures because it depends on the following unsupported assumptions: FDEP's and/or DERM's mitigation measures are inadequate; FPL will not comply with FDEP's Consent Order and/or DERM's Consent Agreement; and FDEP and/or DERM will not enforce their own legal requirements. See NRC Staff Answer to Joint Pet'rs Pet. and SACE Pet. at 64–65; FPL Answer to SACE Pet. at 23–26. FPL further argues that SACE's claims about mitigation measures are factually incorrect, unsupported, and require the NRC Staff to reexamine and/or overrule the judgments of state regulators. See FPL Answer to SACE Pet. at 26–29. We agree that the above arguments constitute alternative grounds for inadmissibility.

aquifer beneath," including the "interaction of environmental factors such as salinity, turbidity, and algal concentrations with the operation of the CCS," id.;

(4) The "degree to which FPL, by attempting to mitigate one environmental problem (hypersalinity in the CCS) has seriously aggravated another environmental problem: groundwater and surface water pollution," including the "net result of increasing the hydraulic head on the hypersaline plume by pumping more water into the CCS at the same time that FPL attempts to draw the plume back to the site boundary by pumping out the aquifer," id. at 27;

(5) The impacts due to "demand for water to cool or freshen the CCS . . . in relation to the demand for water to restore the Everglades, such as the water in the L-31E Canal." Id.

Additionally, SACE challenges the ER's conclusion that the cumulative impacts "will be small because FPL will comply with its permits for the CCS" because "the history of Turkey Point's operation shows that FPL is not in compliance with its permits." Id. at 24.

We conclude that Contention 1C is not admissible. First, regarding the cumulative impacts related to hypersalinity and mitigation measures, as with Contention 1B, each of the alleged omissions relates to environmental impacts that involve Category 1 issues (i.e., altered salinity gradient and groundwater degradation). This aspect of Contention 1C is inadmissible for the alternative reasons that it is (1) an impermissible challenge to a Category 1 issue pursuant to section 2.335; and (2) outside the scope of this proceeding pursuant to section 2.309(f)(1)(iii). See NRC Staff Answer to Joint Pet'rs Pet. and SACE Pet. at 62; FPL Answer to SACE Pet. at 8–12.

Second, the aspect of Contention 1C that attacks the adequacy of the ER's analysis of cumulative impacts in light of FPL's history of noncompliance with its permits relating to the CCS is inadmissible for failing to raise a genuine dispute pursuant to section 2.309(f)(1)(vi). The ER's conclusion that cumulative impacts will be small is based on the mitigation measures imposed by FDEP in a Consent Order and by DERM in a Consent Agreement. See FPL Answer to SACE Pet. at 42. Notably, SACE does not assert that FPL currently is violating any requirement imposed by these regulatory agencies. Nor does SACE make any credible showing that (1) FDEP or DERM will fail to enforce State of Florida and local environmental requirements; or (2) FPL will commit a future violation that would alter the cumulative impacts analysis in the ER. Rather, SACE essentially argues that FPL's past violations of permit requirements, standing alone, are sufficient to raise a genuine dispute with the ER's conclusion that cumulative environmental impacts of the CCS will be small because FPL will comply with its current permit. We disagree. Pursuant to binding case law, we accord "substantial weight" to the determination of FDEP and DERM that FPL will comply with its legal obligations. See Pub. Serv. Co. of N.H. (Seabrook Station, Units 1 & 2), CLI-77-8, 5 NRC 503, 527 (1977) (holding that a finding of environmental acceptability made by a competent state authority [pursuant to a thorough hearing] "is properly entitled to substantial weight in the conduct of our own NEPA analysis.") (internal quotation marks omitted); cf. Pac. Gas & Elec. Co. (Diablo Canyon Power Plant, Units 1 & 2), CLI-03-2, 57 NRC 19, 29 (2003) (absent evidence to the contrary, Commission will assume that licensee will comply with license obligations). FPL's past violations in this case, standing alone, do not constitute sufficient information to give rise to a genuine dispute with the assumption that FDEP and DERM will enforce, and FPL will comply with, the legally mandated mitigation measures in the permits. See Fla. Power & Light Co. (Turkey Point Nuclear Generating Units 3 & 4), CLI-16-18, 84 NRC 167, 174–75 n.38 (2016).[56]

Finally, we conclude that SACE's argument concerning the potential water use conflict between freshening the CCS and other programs like the Central Everglades Restoration Program (CERP) lacks factual support and does not raise a genuine dispute with FPL's license renewal application. See NRC Staff Answer to Joint Pet'rs Pet. and SACE Pet. at 61. SACE argues that because FPL has been allowed "to remove water from the L-31E Canal on an

[56] This is not to say that the NRC Staff, in compiling the draft SEIS, is absolved from conducting an independent review of the relevant permits pursuant to its assessment of cumulative impacts. See Tr. at 131–33, 215–16. SACE provides no basis for concluding that the NRC Staff would fail to conduct such a review.

emergency basis to reduce salinity levels in the CCS" there is the potential for "conflict with the use of canal water reserved for the CERP." SACE Pet. at 15. SACE therefore argues, on this basis alone, that the ER was required to analyze the cumulative impacts of the demand for water to freshen the CCS in relation to the demand for water to restore the Everglades. Id. at 27. This possible use of water on an emergency basis at some unspecified point in the future is too speculative a concern to raise a genuine dispute. Moreover, SACE does not provide the required facts or expert opinions to support admission of this aspect of Contention 1C. The only factual support it provides is that the L-31E canal was once used to supply water to the CCS, and it might be used again at some time in the future because the ER does not fully rule out the possibility of using that canal for freshening. See SACE Reply at 19. SACE cites to its expert report for the proposition that there may be conflicts over the need for water from the L-31E Canal for the CERP and the CCS's freshening program. SACE Pet. at 13–14 (citing attach. 4, Expert Report of William Nuttle at 10 [hereinafter Nuttle Report]). But that portion of the report does not discuss use of the L-31E Canal for freshening CCS water; instead, it discusses the potential for the hydraulic plume to reach and impact the quality of the L-31E Canal, which is a different issue. See Nuttle Report at 10. Therefore, Contention 1C is not admitted.[57]

b. Contention 2 Is Admissible in Part

In Contention 2, SACE argues that FPL's ER improperly "failed to consider the reasonable alternative of cooling the Turkey Point Units 3 and 4 reactors with mechanical draft cooling towers." SACE Pet. at 29. SACE asserts that FPL is required to consider reasonable mitigation alternatives pursuant to 10 C.F.R. §§ 51.45 and 51.53(c)(2), see id., and SACE provides the report of an expert who opined that mechanical cooling towers would (1) eliminate the adverse environmental impacts of the CCS; (2) allow the CCS to be restored to a thriving

[57] SACE also argues that the ER fails to discuss the "cumulative effects of the CCS on the American Crocodile." SACE Pet. at 27. This argument is included in the portion of Contention 1A that we found to be admissible. See supra Part III.B.2.a.i.

seagrass community and wildlife habitat; and (3) be a feasible and cost-effective alternative to the CCS. See id. at 30–31 (citing attach. 10, Expert Report of Bill Powers (May 14, 2018) [hereinafter Powers Report]).

The NRC Staff acknowledges that it has a regulatory obligation to consider reasonable "alternatives available for reducing or avoiding adverse environmental effects." NRC Staff Answer to Joint Pet'rs Pet. and SACE Pet. at 68–69 (quoting 10 C.F.R. § 51.71(d)). The Staff does not dispute that SACE provides an adequate factual basis for its assertion that mechanical draft towers are a reasonable alternative to the CCS, nor does the Staff dispute SACE's statement that FPL's ER "omits consideration of a cooling tower alternative." Id. at 68. The Staff therefore does not oppose admitting Contention 2 "insofar as it asserts that the Applicant's [ER] omits consideration of mechanical draft cooling towers in connection with license renewal of Turkey Point Units 3 and 4, as a reasonable alternative to [the existing CCS]." Id.

We conclude that Contention 2 is an admissible contention of omission. Contrary to FPL's assertion, see FPL Answer to SACE Pet. at 51, Contention 2 is within the scope of the proceeding, and it raises a genuine dispute on a material fact to the extent it alleges that FPL's ER improperly fails to consider mechanical draft cooling towers as a reasonable alternative for reducing or avoiding adverse impacts on the threatened American Crocodile and its critical seagrass habitat. See SACE Pet. at 30; Powers Report at 1–5; supra Part III.B.2.a.i. Although neither the NRC Staff nor FPL is required to select the most environmentally superior alternative, NRC regulations require the ER and the EIS to consider "alternatives available for reducing or avoiding adverse environmental impacts." 10 C.F.R. §§ 51.45(c) and 51.71(d); see S. Nuclear Operating Co. (Early Site Permit for Vogtle ESP Site), LBP-07-3, 65 NRC 237, 259–

261, 280 (2007) (admitting a contention regarding dry cooling as a NEPA alternative in light of the sensitive biological resources affected).[58]

We therefore admit Contention 2 as follows: In light of the adverse impact of continued CCS operations on the threatened American crocodile and its critical seagrass habitat, the ER is deficient for failing to consider mechanical draft cooling towers as a reasonable alternative to the CCS in connection with the license renewal of Turkey Point Units 3 and 4.[59]

---

[58] To be clear, Contention 2 focuses on the ER's failure to consider mechanical draft cooling towers as a reasonable and feasible alternative to the existing CCS for reducing or avoiding adverse environmental effects to sensitive biota. The NRC Staff states, and we agree, that the admissible scope of Contention 2 does not extend to requiring a discussion of the environmental impacts resulting from operation of the CCS, because Contention 2 does not point to any alleged deficiencies in the ER regarding its discussion of environmental impacts of CCS operation. See NRC Staff Answer to Joint Pet'rs Pet. and SACE Pet. at 69.

[59] Prior to oral argument, we understood the Staff to acknowledge that Contention 2 satisfied the admissibility requirements in 10 C.F.R. § 2.309(f)(1) as a contention of omission. See NRC Staff Answer to Joint Pet'rs Pet. and SACE Pet. at 68–69. At oral argument, however, the Staff seemed to take the position that, on the one hand, it did not oppose admission of Contention 2 as a contention of omission, see Tr. at 156, but that, on the other hand, neither NEPA nor NRC regulations requires FPL or the NRC Staff to consider mechanical cooling towers as a reasonable alternative to the CCS. See, e.g., id. at 156, 158, 159. In petitioners' view, the position taken by the NRC Staff at oral argument was "very different" from the position it took in its brief. See id. at 255. Petitioners therefore requested that the NRC Staff be required to provide its seemingly new views in writing so the other participants would have the opportunity to respond. See id. We granted petitioners' request, id. at 257; supra notes 19 and 20, and based on our review of the supplemental briefs, we conclude that the NRC Staff's "clarified position" has no material impact on its position (or our determination) that Contention 2 satisfies the admissibility criteria as a contention of omission.

After the supplemental briefs had been filed, petitioners moved for leave to respond to what they perceived as a newly raised argument in FPL's brief. See Petitioners' Motion for Leave to Respond to Applicant's Response to the NRC Staff's Clarification Regarding the Admissibility of Proposed Cooling Tower Contentions (Jan. 15, 2019); Petitioners' Response to Applicant's New Arguments on the Admissibility of Petitioners' Cooling Tower Contentions (Jan. 15, 2019). FPL and the NRC Staff opposed petitioners' motion. See Applicant's Answer to Petitioners' Joint Motion for Leave to Respond to Applicant's Response to the NRC Staff's Clarification (Jan. 22, 2019); NRC Staff's Answer to Petitioners' Motion for Leave to Respond to Applicant's Response to the NRC Staff's Clarification (Jan. 25, 2019). Given our ruling on the admissibility of Contention 2, we deny petitioners' motion as moot.

C. JOINT PETITIONERS ESTABLISH STANDING, AND PROFFER TWO CONTENTIONS THAT ARE ADMISSIBLE IN PART

1. Joint Petitioners Establish Standing

Joint Petitioners consist of the following three organizations: (1) Friends of the Earth, Inc. (FOE); (2) Natural Resources Defense Council, Inc. (NRDC); and (3) Miami Waterkeeper, Inc. (Waterkeeper). All three organizations have demonstrated that the interests they seek to protect in this proceeding are germane to their organizational purposes.[60] Further, all three organizations provide declarations from members who (1) live within 50 miles of the Turkey Point site and therefore have standing in their own right pursuant to the proximity presumption; and (2) authorize their respective organizations to represent their interests in this proceeding, thus rendering it unnecessary for them to participate as individuals. See, e.g., Joint. Pet., attach. B, Decl. of Anne Hemingway Feuer ¶¶ 1, 4, 14 (June 29, 2018) (member of FOE); id., attach. H, Decl. of Phillip Stoddard ¶¶ 1, 3, 13 (July 24, 2018) (member of NRDC); id., attach. J, Decl. of Daniel Parobok ¶¶ 4, 7 (July 30, 2018) (member of Waterkeeper). Joint Petitioners, therefore, satisfy the requirements for representational standing. See supra Part II.A.[61]

2. Joint Petitioners Proffer Two Contentions that are Admissible in Part

Joint Petitioners proffer five contentions (Contentions 1-E though 5-E) alleging deficiencies in FPL's ER. We conclude that Contentions 1-E and 5-E are admissible in part. Specifically, we admit Contention 1-E to the extent it claims that the ER improperly failed to

---

[60] See Joint Pet'rs Pet. at 2 (FOE's mission includes "defend[ing] the environment" and "minimiz[ing] the risks that nuclear facilities pose to its members and to the general public."); id. at 5 (NRDC's mission includes "maintain[ing] and enhanc[ing] environmental quality" by working to "minimize the risks that nuclear facilities pose to its members and to the general public."); id. at 6–7 (Waterkeeper's mission includes "defend[ing], protect[ing], and preserv[ing] the aquatic integrity of South Florida's watershed and wildlife.").

[61] Neither FPL nor the NRC Staff challenges Joint Petitioner's representational standing. See FPL Answer to Joint Pet'rs Pet. at 2; NRC Staff Answer to Joint Pet'rs Pet. and SACE Pet. at 9–10.

consider mechanical draft cooling towers as a reasonable alternative to the CCS.[62] We also admit Contention 5-E to the extent it challenges the ER's failure to recognize Turkey Point Units 3 and 4 as a source of ammonia in surrounding freshwater wetlands, as well as its failure to consider the impacts of ammonia discharges on threatened and endangered species and their critical habitat. We reject as inadmissible the other portions of Contentions 1-E and 5-E, and all of Contentions 2-E, 3-E, and 4-E.

a. Contention 1-E Is Admissible in Part

In Contention 1-E, Joint Petitioners assert that the ER "fails to consider a reasonable range of alternatives to the proposed action, as required by NEPA and NRC implementing regulations." Joint Pet'rs Pet. at 15–16. More particularly, they argue that the ER improperly omits consideration of the "reasonable and feasible" alternative of replacing the CCS with mechanical draft cooling towers to reduce the adverse environmental impacts of the CCS. Id. at 16, 19. Joint Petitioners provide factual information in support of their assertion that mechanical draft cooling towers would be a reasonable and feasible alternative, see id. at 19–22, and they claim that failing to discuss this alternative violates 10 C.F.R. § 51.45(c), which requires the ER to include a discussion of "'alternatives available for reducing or avoiding adverse environmental effects,'" including impacts on "American crocodiles, an endangered species," and the "American crocodile habitat." Id. at 18, 23, 24.

Consistent with its position concerning SACE's Contention 2, the NRC Staff does not oppose admitting this contention "insofar as it asserts that [FPL's ER] omits consideration of mechanical draft cooling towers in connection with license renewal of Turkey Point Units 3 and 4, as a reasonable alternative to use of the plants' [CCS]." NRC Staff Answer to Joint Pet'rs Pet. and SACE Pet. at 29–30. FPL, on the other hand, argues that Contention 1-E is

62 This admissible portion of Contention 1-E is identical to the portion of SACE Contention 2 that we found to be admissible. See supra Part III.B.2.b.

inadmissible in its entirety for essentially the same reasons it argued against admitting SACE Contention 2. See FPL Answer to Joint Pet'rs Pet. at 8–9.

For the reasons we admitted SACE Contention 2, and subject to the same limitations, see supra Part III.B.2.b, we admit Contention 1-E as follows: In light of the adverse impact of continued CCS operations on the threatened American crocodile and its critical seagrass habitat, the ER is deficient for failing to consider mechanical draft cooling towers as a reasonable alternative to the CCS in connection with the license renewal of Turkey Point Units 3 and 4.[63]

b. Contention 2-E Is Not Admissible

In Contention 2-E, Joint Petitioners allege that "the [ER] fails to adequately consider the cumulative impacts of continued operation of Units 3 and 4." Joint Pet'rs Pet. at 30. Specifically, they argue that section 4.12 of the ER does not adequately address the cumulative impacts on water resources from the reasonably foreseeable effects of climate change on the

63 Contention 1-E also appears to challenge the ER's (1) discussion of the environmental impacts of continued CCS operation, see Joint Pet'rs Pet. at 19, 23–24, and (2) failure to consider other unspecified "alternatives to the proposed action." Id. at 15. Those aspects of the contention are not admissible because, contrary to 10 C.F.R § 2.309(f)(1)(v) and (vi), they fail to provide support sufficient to demonstrate a genuine dispute on a material issue of law or fact, or to include references to specific portions of the ER that they dispute. See NRC Staff Answer to Joint Pet'rs Pet. and SACE Pet. at 30–31.

CCS, including sea level rise[64] and increasing air temperature.[65] Id. at 30–31. Joint Petitioners assert that the "reasonably foreseeable impacts from sea level rise will increase the risk of flooding at Turkey Point, including the potential for overtopping or breach[ing] of the canal system, leading to direct discharges of polluted canal water into surface water resources, including Biscayne Bay." Id. at 38. The "[h]igher air temperatures," they assert, "will increase the rate of evaporation in the [CCS] leading to more saline conditions. Higher salinity in the [CCS] will . . . adversely impact groundwater resources." Id.

We agree with the NRC Staff and FPL that this contention is not admissible. See NRC Staff Answer to Joint Pet'rs Pet. and SACE Pet. at 34–41; FPL Answer to Joint Pet'rs Pet. at 27–36. First, even accepting Joint Petitioners' claims regarding future increases in sea level and air temperature, they fail to link those changes to the impacts of Turkey Point's continued operation. Joint Petitioners make conclusory assertions that (1) "sea level rise will increase the risk of flooding . . . , including the potential for overtopping or breach[ing] of the [CCS], leading to direct discharges of polluted canal water into surface water resources," Joint Pet'rs Pet. at 38; and (2) hotter air temperature will "increase the rate of evaporation in the [CCS] leading to more

[64] In support of their arguments regarding sea level rise, Joint Petitioners rely on the expert opinion of Dr. Robert Kopp, who states, inter alia, that "[t]hrough 2060, . . . there is between a 68 percent chance and a 95 percent chance that average sea-level rise at Key West [which Dr. Kopp posits as a comparable location to Turkey Point] will exceed 1 foot above the National Tidal Datum Epoch." Joint Pet'rs Pet., attach. N, Decl. of Dr. Robert Kopp at 12 (July 26, 2018). Dr. Kopp provides several probability estimates of future sea level rise, using a number of alternative assumptions. He states that, assuming storm characteristics do not change, the frequency and extent of extreme flooding associated with coast storms will increase because "a tide or storm of a given magnitude will produce a more extreme total water level than it would have with lower average sea level." Id. at 13. Consequently, "[i]f the sea level rises by one foot, . . . the probability of storms increasing water levels to the height of 2.0 feet becomes 50 [percent] rather than 1 [percent]." Joint Pet'rs Pet. at 35.

[65] With respect to increasing temperature, Joint Petitioners aver that in the Southeast United States for the 2036–2065 time period, air temperature increases are projected to range from 3.4 to 4.3 degrees Fahrenheit, Joint Pet'rs Pet. at 35, and changes in temperature extremes are projected to be 5.79 degrees Fahrenheit for the warmest day of the year and 11.09 degrees Fahrenheit for the "warmest 5-day, 1-in-10-year event" compared to the 1976–2005 period. Id. at 35–36.

saline conditions." Id. But they provide no support for their claims regarding putative environmental impacts. For example, they fail to discuss such necessary information as the relationship between their projected sea levels and the relevant elevations of the Turkey Point site, its sea level barriers, or the CCS, to support their claim that the site will be flooded and the CCS will be overtopped or breached. Similarly, although an increase in air temperature can lead to increased evaporation in the CCS, Joint Petitioners provide no support to demonstrate that the higher temperatures they postulate would increase evaporation in the CCS to any particular extent, much less to an extent that would be sufficient to increase the CCS salinity such that it would, in turn, affect the environment. Their failure to provide adequate support for these assertions renders the contention inadmissible pursuant to 10 C.F.R. § 2.309(f)(1)(v).

Additionally, to the extent Contention 2-E expresses concerns about overtopping and increased salinity of the CCS, it is also inadmissible pursuant to 10 C.F.R. § 2.309(f)(1)(vi) for failing to provide sufficient information to show a genuine dispute on a material issue of fact. Specifically, Joint Petitioners do not discuss how these impacts are reasonably foreseeable in light of the 2016 consent order between FPL and the FDEP that requires FPL to (1) "prevent releases of groundwater from the CCS to surface waters connected to Biscayne Bay that result in exceedances of surface water quality standards in Biscayne Bay"; and (2) perform a "thorough inspection of the CCS periphery" and "address any material breaches or structural defects." FDEP v. FPL, OGC File No. 16-0241 (Consent Order), at 7, 10–12 (June 20, 2016) [hereinafter Consent Order]. Even if overtopping were to occur, Joint Petitioners do not explain how it would impair the environment given that the consent order requires FPL to maintain an average annual CCS salinity at or below 34 practical salinity units (PSU) and to submit a detailed report outlining the potential sources of the nutrients found in the CCS and to implement a plan to minimize these nutrient levels. See id. at 7–10. Similarly, with respect to their argument that increased air temperature will result in higher CCS salinity, Joint Petitioners fail to explain why it is reasonably foreseeable that a temperature rise will lead to increased

CCS salinity in light of the consent order's requirement that FPL achieve an average annual CCS salinity at or below 34 PSU at the completion of the fourth year of freshening activities, and maintain that salinity thereafter. See id. at 7. Joint Petitioners' failure to address the above features of FPL's consent order renders Contention 2-E's concerns about overtopping and increased salinity inadmissible pursuant to section 2.309(f)(1)(vi).[66]

Finally, to the extent that Contention 2-E asserts that the ER fails adequately to address cumulative impacts on groundwater from the continued operation of the CCS during the renewal period, see Joint Pet'rs Pet. at 31, the contention ignores that FPL's ER discusses the cumulative impacts to groundwater resulting from the operation of Turkey Point Units 3 and 4 in combination with impacts to groundwater resulting from operation of "the other Turkey Point facilities and . . . from other projects and activities in the surrounding area," by incorporating by reference the cumulative impacts discussion in the 2016 EIS that was prepared for the combined licenses for Turkey Point Units 6 and 7. See ER at 4-68.[67] The ER concludes that the cumulative impacts to groundwater will be small and are managed because "FPL continues to comply with its permits for groundwater withdrawals and injection, the FDEP [consent order]

---

[66] As discussed supra Part III.B.2.a.iii, any past incidents of FPL's failure to comply with the consent order do not, standing alone, constitute sufficient information to give rise to a genuine dispute in light of the case-law supported assumptions that FDEP will enforce, and FPL will comply with, the mandated obligations in the consent order.

[67] The 2016 EIS discusses the contribution from Turkey Point Units 3 and 4, as well as the effect of FPL's consent order with FDEP requiring freshening of the CCS, and the 2015 consent agreement with Miami-Dade County for remediating the hypersaline plume. See [EIS] for Combined Licenses (COLs) for Turkey Point Nuclear Plant Units 6 and 7, NUREG-2176, Vol. 2, at table 7-1 (Oct. 2016) [hereinafter Turkey Point Units 6 & 7 EIS].

It appears that FPL's ER does not cite to a specific page of the 2016 EIS. The Commission has admonished that it does not expect a litigant to merely reference large portions of material where doing so would force a tribunal to "sift through it in search of asserted factual support." NextEra Energy Seabrook, LLC (Seabrook Station, Unit 1), CLI-12-5, 75 NRC 301, 332 (2012). In our view, this admonition applies with equal force to an applicant's preparation of an ER. FPL's failure to provide a page-specific cite, however, does not change the Board's conclusion as to this contention's admissibility.

for freshening of the cooling canals, and the [consent agreement] with Miami-Dade County for remediation of the hypersaline plume." Id. at 4-69. Further, the ER cites NRC Reg. Guide 4.2, stating that for resource areas that are regulated through a permitting process "it may be assumed that cumulative impacts are managed as long as facility operations are in compliance with their respective permits." Id. Contention 2-E fails to provide sufficient information to raise a genuine dispute regarding these determinations in the ER, and for this reason it is not admissible pursuant to section 2.309(f)(1)(vi).

c. Contention 3-E Is Not Admissible

In Contention 3-E, Joint Petitioners claim that "[t]he [ER] (§§ 3 and 5) fails to comply with 10 C.F.R. § 51.53(c)(3)(iv) because it fails to analyze new and significant information regarding the effect of sea level rise on [the following] Category 1 and 2 issues," Joint Pet'rs Pet. at 39: (1) termination of plant operations and the decommissioning process (Category 1 issue), see id. at 45; (2) cumulative impacts on affected resources (Category 2 issue), see id. at 43–44; and (3) surface and groundwater use conflicts collectively labelled as "water resources" (Category 2 issues). See id. at 44.

The NRC Staff and FPL argue that this contention is not admissible. See NRC Staff Answer to Joint Pet'rs Pet. and SACE Pet. at 43–46; FPL Answer to Joint Pet'rs Pet. at 36–45. We agree.

First, as Joint Petitioners concede, Joint Pet'rs Pet. at 40, the aspect of Contention 3-E that implicates "[t]ermination of plant operations and decommissioning" constitutes a challenge to a Category 1 issue. See 10 C.F.R. pt. 51, subpt. A, app. B, table B-1. This aspect of Contention 3-E is not admissible because it (1) is not subject to challenge in this adjudicatory proceeding where Joint Petitioners have failed to seek a rule waiver, see id. § 2.335; Entergy

Nuclear Vt. Yankee, LLC (Vt. Yankee Nuclear Power Station), CLI-07-3, 65 NRC 13, 18 n.15 (2007); and (2) is outside the scope of this proceeding. See 10 C.F.R. § 2.309(f)(1)(iii).[68]

Second, as to the portion of Contention 3-E that asserts the ER's "cumulative effects analysis . . . fails entirely to discuss the sea level rise-related impacts upon affected resources," Joint Pet'rs Pet. at 43–44, this aspect of the contention—which is reasonably characterized as a contention of omission—is not admissible, because it ignores that the ER incorporates by reference the Turkey Point 6 and 7 EIS, which does analyze the cumulative impacts of continued operation of nuclear reactors at the site in combination with climate change and sea level rise. See ER at 4-68; Turkey Point Units 6 & 7 EIS at I-5 to I-6. This aspect of Contention 3-E fails to raise a genuine dispute as required by 10 C.F.R. § 2.309(f)(1)(vi).

Finally, the portion of Contention 3-E alleging that the ER improperly ignores water resource conflicts insofar as it fails to "account for the effect sea level rise will have on freshwater availability, ground water resources, and release of polluted cooling water into Biscayne Bay," Joint Pet'rs Pet. at 44, fails to raise a genuine dispute. Although Joint Petitioners allege "frequent interchange of water from Biscayne Bay and the [CCS]," id. at 45, they provide no explanation for why this would cause conflicts in water use for either surface or groundwater resources. Instead, Joint Petitioners simply assert that sea level rise will eliminate the "closed-loop" nature of the CCS, but they do not explain why this would create or

---

[68] FPL argues that this aspect of Contention 3-E is also inadmissible pursuant to section 2.309(f)(1)(v) because Joint Petitioners offer no support for their claim that sea level rise will affect FPL's ability to terminate plant operations and decommission the plant. See FPL Answer to Joint Pet'rs Pet. at 40. The NRC Staff argues that this aspect of Contention 3-E constitutes a challenge to an operating licensing issue that is beyond the scope of this SLR proceeding and, hence, is inadmissible pursuant to section 2.309(f)(1)(iii). NRC Staff Answer to Joint Pet'rs Pet. and SACE Pet. at 46. We agree with both arguments.

exacerbate water use conflicts for either resource, thus rendering this aspect of Contention 3-E inadmissible pursuant to section 2.309(f)(1)(vi).[69]

d. Contention 4-E Is Not Admissible

In Contention 4-E, Joint Petitioners argue that the "[ER] (§ 3) erroneously fails to describe the reasonably foreseeable affected environment during the subsequent license renewal period (2032–2053) in violation of 10 C.F.R. § 51.53(c)(2)," which "renders Applicant's analyses of environmental impacts (§ 4), mitigating actions (§ 6), and alternatives analysis (§ 8) legally insufficient." Joint Pet'rs Pet. at 47. In particular, Joint Petitioners assert that the ER "fails to discuss the changes [caused by climate change] in the surrounding environment and their effects on Turkey Point, including sea level rise, increased air temperature, increased surface water temperature, acidification, annual precipitation, drought, and increased storm intensity." Id. at 48.

The NRC Staff and FPL argue that Contention 4-E is not admissible. See NRC Staff Answer to Joint Pet'rs Pet. and SACE Pet. at 46–51; FPL Answer to Joint Pet'rs Pet. at 46–54. We agree.

Joint Petitioners are simply incorrect in asserting that the ER fails to address the effects of climate change during the license renewal period. The 2013 GEIS contains the potential effects of climate change that Joint Petitioners claim are missing from the ER, including sea level rise, increased air temperature, increased water temperature, increased water acidity,

[69] Joint Petitioners also do not explain how sea level rise will eliminate the "closed loop" nature of the CCS in light of FPL's consent order with FDEP, which requires that FPL conduct a "thorough inspection of the CCS periphery" and "address any material breaches or structural defects." Consent Order at 7, 10–12. Nor do they explain how any overtopping of the CCS would result in any significant environmental impacts in light of the consent order's requirements that FPL (1) maintain an average annual CCS salinity at or below 34 PSU; (2) submit a detailed report outlining the potential sources of nutrients in the CCS, and implement a plan to minimize these nutrient levels; and (3) prevent releases of groundwater from the CCS to surface waters connected to Biscayne Bay that result in exceeding of surface water quality standards in Biscayne Bay. See id. at 7–12; see also NRC Staff Answer to Joint Pet'rs Pet. and SACE Pet. at 45; FPL Answer to Joint Pet'rs Pet. at 44.

increased precipitation, drought, and more intense hurricanes. See 2013 GEIS at 4-237 to 4-241.[70] The ER, in turn, describes the effects of climate change when combined with the effects of the proposed action. See ER at 4-69, 4-71. Additionally, the ER cites the Staff's EIS for the Turkey Point Units 6 and 7 combined licenses, which also discusses the effects of climate change at the site. See ER at 4-68. Contention 4-E is thus based on an erroneous factual premise, which renders it inadmissible pursuant to 10 C.F.R. § 2.309(f)(1)(v) and (vi).[71]

e. Contention 5-E Is Admissible in Part

In Contention 5-E, Joint Petitioners allege the ER "fails to address the adverse effect of operating the [CCS] for an additional 20 years on surface waters, freshwater wetlands, and endangered species present in those wetlands" in violation of 10 C.F.R. § 51.53(c)(3)(ii)(E). Joint Pet'rs Pet. at 58–59. Specifically, Joint Petitioners fault the ER for giving "no consideration to how the salinization of freshwater wetlands caused by the [CCS] will impact threatened or endangered species, and otherwise harm important plant and animal habitats," id. at 59, and for failing "to consider the impacts of ammonia discharges on threatened and endangered species and important habitat." Id. at 63. Regarding the latter assertion, Joint Petitioners provide factual support for concluding that (1) violations of surface water ammonia standards have been

---

70 Section 4.12.3.2 of the 2013 license renewal GEIS describes the environmental impacts that could occur from changes in global and regional climate conditions, including generic descriptions of potential long-term impacts with examples of resource changes that could occur due to climate change. See GEIS at 4-237 to 4-241. Section 4.13 of the GEIS describes the cumulative impacts of the proposed action, focusing on resources that could be affected by the incremental impacts from continued operations associated with license renewal. See id. at 4-243 to 4-249.

71 Moreover, to the extent Joint Petitioners assert in Contention 4-E that section 51.53(c)(2) requires the ER to describe the "reasonably foreseeable affected environment during the subsequent license renewal period," Joint Pet'rs Pet. at 47, they are incorrect as a matter of law. The regulation requires that ERs "describe in detail the affected environment around the plant," not the "reasonably foreseeable" environment. 10 C.F.R. § 51.53(c)(2). This legal error also renders Contention 4-E inadmissible pursuant to section 2.309(f)(1)(iv) for failing to show that the issue raised is material to the findings the NRC must make to support the action in this proceeding.

observed in canals near Turkey Point; and (2) Turkey Point is a key source of that ammonia. See id. at 62 (citing attach. P, Letter from Wilbur Mayorga, Chief of Environmental Monitoring and Restoration Division, DERM, to Matthew J. Raffenberg, Senior Director of Environmental Licensing and Permitting, FPL (July 10, 2018)).

FPL opposes admission of Contention 5-E in its entirety as outside the scope, immaterial, unsupported, and failing to demonstrate a genuine dispute with the ER. See FPL Answer to Joint Pet'rs Pet. at 54–60.

The NRC Staff does not oppose admitting the portion of Contention 5-E that relates to "the impact of ammonia releases from Turkey Point Units 3 and 4 on endangered and threatened species." NRC Staff Answer to Joint Pet'rs Pet. and SACE Pet. at 54. The NRC Staff "recognizes that the impacts of continued operation of the CCS on threatened and endangered species and critical habitat is a Category 2 issue" that must be analyzed in the supplemental EIS on a site-specific basis, id. & n.225, and in the Staff's view, Joint Petitioners submitted sufficient supporting information to raise a genuine dispute with the ER regarding their assertions that "Turkey Point is a source of ammonia in freshwater wetlands surrounding the site, and that the potential impacts of such ammonia releases during the period of continued operation on threatened and endangered species should be analyzed." Id. at 54. The Staff opposes admitting all other portions of Contention 5-E. See id.

For the reasons stated by the NRC Staff, we conclude that Contention 5-E satisfies the admissibility requirements in 10 C.F.R. § 2.309(f)(1) to the extent it relates to the impact of ammonia releases from Turkey Point Units 3 and 4 on endangered and threatened species and their critical habitat. We therefore admit Contention 5-E as follows: The ER is deficient in its failure to recognize Turkey Point as a source of ammonia in freshwater wetlands surrounding the site, and in its failure to analyze the potential impacts of ammonia releases during the renewal period on threatened and endangered species and their critical habitat.[72]

The remaining portions of Contention 5-E are not admissible. First, to the extent that Contention 5-E asserts that the ER improperly fails to consider the impact of salinization on surface waters and freshwater wetlands caused by the CCS, see Joint Pet'rs Pet. at 59, it raises an impermissible challenge to a Category 1 issue. See 10 C.F.R. pt. 51, app. B, Table B-1 (identifying as Category 1 issues the impacts of license renewal to altered salinity gradients in surface waters, groundwater quality degradation at plants with cooling ponds in salt marshes (including Turkey Point, see 2013 GEIS at 4-50), and cooling system impacts on terrestrial resources in wetlands). This aspect of Contention 5-E is (1) not litigable in this adjudicatory proceeding where Joint Petitioners have failed to seek a waiver, see 10 C.F.R. § 2.335; and (2) outside the scope of this proceeding. See id. § 2.309(f)(1)(iii).[73]

Likewise inadmissible is the portion of Contention 5-E concerning the impacts of salinization on threatened and endangered species in the wetlands. That aspect of Contention 5-E assumes that (1) FDEP's 2016 Consent Order does not establish adequate mitigation measures to address the salinity issues caused by the CCS; (2) FPL will fail to comply with the

---

[72] Joint Petitioners also assert that the CCS causes unspecified "other pollutants" to migrate into nearby surface waters and adversely impact the habitats of threatened and endangered species. See Joint Pet'rs Pet. at 59. Their failure to identify these putative "other pollutants" or to provide specific facts or expert opinion to support their claim renders this aspect of Contention 5-E inadmissible pursuant to 10 C.F.R. § 2.309(f)(1)(v).

[73] Joint Petitioners may not circumvent the regulatory bar against challenging a Category 1 issue by alleging the existence of new and significant information. See Joint Pet'rs Pet. at 60–62 (alleging significant migration of salt intrusion). As the Commission has held, "the new and significant information requirement in 10 C.F.R. § 51.53(c)(3)(iv) [does] not override, for the purposes of litigating the issues in an adjudicatory proceeding, the exclusion of Category 1 issues in 10 C.F.R. § 51.53(c)(3)(i) from site-specific review. . . . [A] waiver [is] required to litigate any new and significant information relating to a Category 1 issue." Limerick, CLI-12-19, 76 NRC at 384.

Consent Order; and/or (3) FDEP will fail to enforce the Consent Order and its regulations.[74] As we previously explained, absent evidence to the contrary (which Joint Petitioners fail to provide), we presume that FDEP will enforce, and FPL will comply with, the legally mandated measures in the Consent Order. See supra Part III.B.2.a.iii; see also supra note 55. We thus conclude that this aspect of Contention 5-E is inadmissible pursuant to 10 C.F.R. § 2.309(f)(1)(v) and (vi) for failing to provide sufficient information to give rise to a genuine dispute.

D. MR. GOMEZ FAILS TO PROFFER AN ADMISSIBLE CONTENTION

FPL argues that Mr. Gomez's petition should be rejected as a threshold matter because (1) it is untimely; (2) it does not comply with the NRC's mandatory E-Filing requirements; and (3) it fails to demonstrate standing. See FPL Answer to Gomez Pet. at 4–13. The NRC Staff disagrees with FPL regarding Mr. Gomez's standing, stating that he "has shown that he has standing to intervene, based on the proximity presumption." NRC Staff Answer to Gomez Pet. at 9. However, the Staff agrees that Mr. Gomez's petition should be denied because it was late and improperly filed and served. See id. at 26–29.

We need not address any of these threshold issues, because we agree with the NRC Staff and FPL that none of the contentions proffered by Mr. Gomez is admissible. See NRC Staff Answer to Gomez Pet. at 26–43; FPL Answer to Gomez Pet. at 13–24.[75]

---

[74] The 2016 Consent Order requires FPL to submit and implement a plan that will "halt the westward migration of the hypersaline plume within 3 years of commencement of the remediation project and retract the hypersaline plume to the L-31E canal within 10 years." Consent Order at 9. FPL must report on the effectiveness of this plan at the conclusion of the fifth year of the plan's implementation. If the plan is ineffective, FPL must provide an alternative plan for FDEP approval, and then implement the FDEP-sanctioned plan. See id. at 10.

[75] The ten contentions proffered by Mr. Gomez are located in ten numbered paragraphs and subparagraphs in the section of his Petition entitled "Petitioner[']s Contentions." See Gomez Pet. at unnumbered pp. 1–7.

1. Contentions 1 and 2 Are Not Admissible

The first two putative contentions in Mr. Gomez's Petition constitute requests for extensions of time. First, Mr. Gomez opines that FPL's application was not available to the public for a sufficient time to allow adequate review, and he therefore requests an extension of sixty days beyond August 1, 2018, to allow "petitions for hearing, submissions of contention and limited appearance statements." Gomez Pet. at unnumbered p. 2. Second, Mr. Gomez asserts that there "are current municipal board & committee motions in process within [the] City of Miami in support of an extension to the public comment period and to enable a formal response by the City of Miami Commission." Id. Mr. Gomez therefore requests that "an [unspecified] extension [of time for] public comments be allowed in order to reasonably accommodate the City of Miami Commission with an opportunity to review the active motion[s] . . . and comment if [it] rules in favor of entering said comment." Id.

Mr. Gomez's requests for extensions of time do not constitute contentions challenging FPL's license renewal application, and they fail on their face to satisfy the contention admissibility requirements in 10 C.F.R. § 2.309(f)(1). See NRC Staff Answer to Gomez Pet. at 31–32.[76]

2. Contention 3 Is Not Before This Board

In Contention 3, Mr. Gomez requests "an [unspecified] extension [of time] in order to have sufficient opportunity to submit formal environmental scoping comments on issues arising under [NEPA]." Gomez Pet. at unnumbered p. 2. This portion of Mr. Gomez's Petition is not before us, because in its referral memorandum of Mr. Gomez's Petition to the Atomic Safety and Licensing Board Panel, the Office of the Secretary excluded this particular request and,

[76] Mr. Gomez's requests would not have fared any better if he had characterized them as extension requests. As the NRC Staff correctly states, his first request is untimely and is not supported by good cause, see NRC Staff Answer to Gomez Pet. at 31, and his second request is outside the scope of this adjudicatory proceeding. See id. at 32.

instead, referred it to the Office of the Executive Director for Operations for appropriate action. See Letter from Annette L. Vietti-Cook, Secretary, U.S. Nuclear Regulatory Commission, to E. Roy Hawkens, Chief Administrative Judge, Atomic Safety and Licensing Board Panel (Aug. 9, 2018).

3. Contention 4 Is Not Admissible

In Contention 4, Mr. Gomez contends that the "unlined cooling canals are leaking a host of caustic poisonous chemicals and highly saline waste water into our water supply." Gomez Pet. at unnumbered p. 3. He refers to a "clean up regime" that "FPL has currently entered into . . . with Miami-Dade County via the Department of Environmental Resource Management," id., and he requests that the "License Renewal Applications be withheld and withdrawn until the current clean up . . . is completed" and "until any law suits related to potential clean water act violations stated within ongoing FPL law suits . . . [are] settled." Id. at unnumbered pp. 3–4.

This environmental contention fails to provide a specific statement of law or reference a specific portion of the application that is disputed, as required by 10 C.F.R. § 2.309(f)(1)(i) and (vi). Additionally, to the extent Contention 4 asserts that FPL's renewal application is deficient pursuant to NEPA until an environmental clean-up is completed and any law suits related to potential Clean Water Act violations within ongoing FPL law suits are settled, see Gomez Pet. at unnumbered pp. 3–4, it is outside the scope of this proceeding pursuant to section 2.309(f)(1)(iii), because, as explained supra Part III.A.1, NEPA "seeks to guarantee process, not specific outcomes." Massachusetts v. NRC, 708 F.3d 63, 67 (1st Cir. 2013). Contention 4 also fails to satisfy section 2.309(f)(1)(v), because none of its assertions is supported by specific facts or expert opinions. And because Contention 4 lacks proper support, it fails to raise a genuine dispute on a material issue of law or fact, as required by section 2.309(f)(1)(vi).

4. Contention 5 Is Not Admissible

Contention 5 is a contention of omission in which Mr. Gomez asserts that FPL's ER fails to comply with 10 C.F.R. § 52.99(c) because the "Alternative Energy Sources review [does] not include solar nor wind power in [its] analysis." Gomez Pet. at unnumbered p. 4.

The legal basis for Contention 5 is flawed, because the regulatory requirement on which Mr. Gomez relies, section 52.99(c), governs combined license (COL) applications, not license renewals, thus rendering the contention inadmissible pursuant to section 2.309(f)(1)(ii) and (iii) as lacking a basis and outside the scope of this proceeding. Moreover, Contention 5 is based on an erroneous factual predicate. Contrary to Mr. Gomez's assertion, FPL's ER does include an analysis of solar and wind power alternatives. See ER at 7-4, 7-6 to 7-7, 7-9 to 7-10. Contention 5 is thus also inadmissible for failing to raise a genuine dispute with the ER as required by section 2.309(f)(1)(vi).

5. Contention 6 Is Not Admissible

Contention 6 is a contention of omission in which, again relying on section 52.99(c), Mr. Gomez asserts that the ER is incomplete because it fails to include a discussion of whether FPL intends to seek any power uprates for Units 3 and 4 during the renewal period. See Gomez Pet. at unnumbered pp. 4–5. Such a discussion is required, he claims, because if FPL were to seek a power uprate, and if one were granted, it could cause the plant's "safe maximum operating temperature" to be exceeded and entail "the risk of further expanding the poisonous and high salinity plume" in the groundwater. Id.

The legal basis for Contention 6 is flawed, because the regulatory requirement on which Mr. Gomez relies, section 52.99(c), governs COL applications, not license renewals, thus rendering the contention inadmissible pursuant to section 2.309(f)(1)(ii) and (iii) as lacking a basis and outside the scope of this proceeding. Contention 6 is also outside the scope of this proceeding because power uprates are a matter related to current plant operations and governed by 10 C.F.R. Part 50, not the license renewal requirements in Part 51 (environmental) or Part 54 (safety). Moreover, Mr. Gomez's concern that FPL might request an uprate sometime during the renewal period that might, in turn, implicate safety and environmental matters is based on unsupported conjecture and is therefore inadmissible pursuant to 2.309(f)(1)(v). Finally, Contention 6 fails to challenge a specific portion of FPL's application, much less raise a genuine dispute of material fact or law, as required by section 2.309(f)(1)(vi).

6. Contention 7 Is Not Admissible

In Contention 7, Mr. Gomez includes a block quote that appears to combine portions of "the current EIS, GEIS and SEIS and related supplements and [appendices]" to support his assertions that the ER is deficient because it is "based on the egregious misrepresentation and [sheer] lack of local governing sea level rise projections" and "how that impacts its high level waste and spent fuel onsite storage." Gomez Pet. at unnumbered p. 5.

To the extent that Contention 7 alleges that rising sea levels pose a potential risk to safe plant operations, including spent fuel storage, it raises a current licensing basis safety issue under 10 C.F.R. Part 50 that is outside the scope of this proceeding, contrary to section 2.309(f)(1)(iii). To the extent Contention 7 alleges an environmental issue concerning onsite storage of spent nuclear fuel, it raises a non-litigable and inadmissible Category 1 issue. See 10 C.F.R. pt. 51, subpt. A, app. B. Additionally, Contention 7 fails to satisfy section 2.309(f)(1)(v), because the block quote on which Mr. Gomez relies does not support his claim that there is an "egregious misrepresentation" or "lack of local governing sea level rise projections" in FPL's license renewal application.[77] Finally, Contention 7 fails to specify any

---

[77] The NRC Staff accurately states that Mr. Gomez's block quote is "unattributed, and its reliability or meaning cannot be discerned." NRC Staff Answer to Gomez Pet. at 39. The NRC Staff also observes that Mr. Gomez's Petition includes a "[s]upplemental page" that quotes an excerpt from the Commission's decision on FPL's application for COLs for Turkey Point Units 6 and 7, Fla. Power & Light Co., (Turkey Point Nuclear Generating Units 6 & 7), CLI-18-1, 87 NRC 39, 59 (2018), regarding sea level rise at the site. See NRC Staff Answer to Gomez Pet. at 39–40. We agree with the NRC Staff that Mr. Gomez's mere quotation from CLI-18-1 does nothing to advance the admissibility of Contention 7. See id.

portion of FPL's application that is inadequate, and thus fails to establish a genuine material dispute with the application, as required to section 2.309(f)(1)(vi).

7. Contention 8 Is Not Admissible

Contention 8 alleges the NRC improperly concluded in the "current EIS, GEIS and SEIS and related supplements and appendi[ces]" that the "[e]nvironmental effects are not detectable or are so minor that they will neither destabilize nor noticeably alter any important attribute of the resource." Gomez Pet. at unnumbered p. 5. Mr. Gomez asserts that this conclusion "contradict[s] . . . current environmental facts" because "a federal law suit is in play related to potential EPA violations, [and] an increasing plume migrates and expands both easterly and westerly from the current position threatening both our water supply and our federally protected bay." Id.

Although Mr. Gomez does not give a specific citation for the quote on which he bases Contention 8, the NRC Staff identified this quote as "the NRC's general definition of a 'SMALL' impact, as presented in its environmental impact statements prepared pursuant to NEPA, without reference to any particular environmental issue." NRC Answer to Gomez Pet. at 41. Contention 8 thus neither references a specific relevant portion of the license renewal application, nor demonstrates that a genuine dispute exists with the applicant, as required by section 2.309(f)(1)(vi). Moreover, Mr. Gomez fails to provide support for his position, as required by section 2.309(f)(1)(v), because he fails to identify the federal lawsuit he relies on, and he fails to explain his assertion that the law suit represents the "current environmental facts." Gomez Pet. at unnumbered p. 5.

8. Contention 9 Is Not Admissible

In Contention 9, Mr. Gomez states that FPL "is currently in negotiation[s] with Miami-Dade [County] related to [reclaimed wastewater] required to recharge the current cooling canals to a low enough temperature to maintain the cooling function." Gomez Pet. at unnumbered p. 6. Mr. Gomez describes "fears that the waste water discharge may negatively impact [FPL's ability through compliance with its consent order] to reduce [the introduction of] phosphorous and other caustic compounds into the bay and our water supply." Id. He requests that the application be "withheld and withdrawn until the water demand issue is resolved . . . for safe operation of the plant without further threatening our bay or drinking and agricultural water supply." Id.

Again, Mr. Gomez fails to provide alleged facts or expert opinions to support his assertion that the use of wastewater to recharge the cooling canals may present a threat to drinking water, groundwater, and safe operation of the plant, as required by section 2.309(f)(1)(v).[78] Nor does he refer to the specific sources and documents on which he intends to rely, as required by section 2.309(f)(1)(v). He also fails to reference a specific portion of the license renewal application that he disputes, as required by section 2.309(f)(1)(vi).

9. Contention 10 Is Not Admissible

In Contention 10, Mr. Gomez asserts that the license renewal application is deficient pursuant to 10 C.F.R. § 52.103(b) for the following reasons: (1) FPL allegedly projects a sea level rise of one foot by 2100,[79] which he asserts is inconsistent with projections of sea level rise by the United Nations, the U.S. Army Corps of Engineers, and the National Oceanic and Atmospheric Administration of, respectively, 31", 61", and 81"; and (2) FPL improperly fails to follow the POANHI – Process for Ongoing Assessment of Natural Hazard Information – SECY-15-0137 portion of the Post-Fukushima Near-Term Task Force Recommendations 2.2. See Gomez Pet. at unnumbered p. 6.

---

[78] Contention 9 does not even provide adequate support for the proposition that Turkey Point Units 3 and 4 will use reclaimed wastewater as an additional source of cooling and CCS freshening during the renewal period. See FPL Answer to Gomez Pet. at 23 ("[T]here is no firm expectation or assumption in the [license renewal application] that Turkey Point Units 3 and 4 will use reclaimed wastewater during the SLR period.").

[79] Mr. Gomez initially states that FPL's sea level rise projection is "1"" (i.e., one inch), but in a later sentence he states the projection is one foot. See Gomez Pet. at unnumbered p. 6. We agree with the NRC Staff's assumption that Mr. Gomez means one foot. See NRC Staff Answer to Gomez Pet. at 42.

The legal basis for Contention 10 is flawed, because the regulatory requirement on which Mr. Gomez relies, section 52.103(b), governs COL applications, not license renewals, thus rendering the contention inadmissible pursuant to section 2.309(f)(1)(ii) and (iii) as lacking a basis and outside the scope of this proceeding. Additionally, although Mr. Gomez asserts that the license renewal application projects a one-foot sea level rise by 2100, he fails to specify where this projection appears in the application, if at all, and he thus fails to raise a genuine dispute with the application, as required by section 2.309(f)(1)(vi). The POANHI process that Mr. Gomez asserts should be used by FPL pertains to operational safety issues under 10 C.F.R. Part 50 with respect to flooding hazards, rather than to the aging management safety issues involved in the license renewal process; accordingly, this aspect of Contention 10 is not within the scope of this proceeding, as required by section 2.309(f)(1)(iii). Finally, to the extent that Contention 10 endeavors to raise an environmental challenge, it fails to provide any support or explanation as to how sea level rise, in combination with the effects of the continued operation of Turkey Point, will impact the environment, as required by section 2.309(f)(1)(v).

E. MONROE COUNTY, FLORIDA MAY PARTICIPATE AS AN INTERESTED GOVERNMENTAL PARTICIPANT

As relevant here, a licensing board "will afford an interested . . . local governmental body (county, municipality or other subdivision) . . . that has not been admitted as a party under § 2.309, a reasonable opportunity to participate in a hearing." 10 C.F.R. § 2.315(c). Section 2.315(c) does not require a demonstration of standing from an entity that seeks to participate as an interested governmental participant. Rather, it requires the entity to (1) identify those contentions on which it intends to participate; and (2) designate a single representative for the hearing. See id. The designated representative may

> introduce evidence, interrogate witnesses where cross examination by the parties is permitted, advise the Commission without [being required] to take a position with respect to the issue, file proposed findings in those proceedings where findings are permitted, and petition for review by the Commission under section 2.341 with respect to the admitted contentions.

Id.

As indicated supra Part I, Monroe County, Florida filed a request to participate as an interested governmental participant. The request explains that Monroe County borders Miami-Dade County and comprises natural resources including the Florida Keys, three national parks, four national wildlife refuges, and three state aquatic preserves. See Monroe County Request at unnumbered p. 1. Given its proximity to the Turkey Point facility,[80] Monroe County is concerned about the adverse impact of the CCS on (1) the County's drinking water; and (2) Biscayne Bay, which will threaten the tourism and fishing industries on which the County's identity and economy are based. See id. at unnumbered p. 2. Monroe County identifies SACE's two contentions as those in which it intends to participate, see id. at unnumbered p. 3, and it designates the Monroe County Board of County Commissioners as its representative. See id. at unnumbered p. 2.

We conclude that Monroe County satisfies the regulatory criteria for participating in this proceeding as an interested governmental participant, and we grant its request to participate on SACE's two contentions, as admitted.

[80] The NRC Staff advises that the Turkey Point facility and the CCS appear to be located about eight miles and four miles, respectively, from the nearest boundary of Monroe County. See NRC Staff Response to Monroe County at 5 n.23.

IV. CONCLUSION AND ORDER

For the foregoing reasons, we (1) grant SACE's hearing request, admitting Contention 1A and Contention 2 as framed by this Board;[81] (2) grant Joint Petitioners' hearing request, admitting Contention 1-E and Contention 5-E as framed by this Board;[82] (3) deny Mr. Gomez's hearing request; and (4) grant Monroe County's request to participate as an interested governmental participant.

Pursuant to 10 C.F.R. § 2.323(f)(1), we refer to the Commission our ruling infra Part III.A that section 51.53(c)(3) applies to the preparation of ERs in SLR proceedings. See supra note 46.

We deny as moot petitioners' motion dated January 15, 2019, which requested permission to respond to an FPL filing. See supra note 59.

This proceeding shall be conducted pursuant to the Simplified Hearing Procedures for NRC Adjudications described in Subpart L of 10 C.F.R. Part 2.

---

[81] SACE Contention 1A (as admitted) states: The ER fails adequately to analyze the impacts (including cumulative) of continued CCS operation on the American Crocodile and its critical seagrass habitat. See supra p. 33.

SACE Contention 2 (as admitted) is identical to Joint Petitioners' Contention 1-E (as admitted) and states: In light of the adverse impact of continued CCS operations on the threatened American crocodile and its critical seagrass habitat, the ER is deficient for failing to consider mechanical draft cooling towers as a reasonable alternative to the CCS in connection with the license renewal of Turkey Point Units 3 and 4. See supra p. 41.

[82] Joint Petitioners' Contention 1-E (as admitted) is identical to SACE Contention 2 (as admitted) and states: In light of the adverse impact of continued CCS operations on the threatened American crocodile and its critical seagrass habitat, the ER is deficient for failing to consider mechanical draft cooling towers as a reasonable alternative to the CCS in connection with the license renewal of Turkey Point Units 3 and 4. See supra p. 44.

Joint Petitioners' Contention 5-E (as admitted) states: The ER is deficient in its failure to recognize Turkey Point as a source of ammonia in freshwater wetlands surrounding the site, and in its failure to analyze the potential impacts of ammonia releases during the renewal period on threatened and endangered species and their critical habitat. See supra pp. 52–53.

This Memorandum and Order is subject to appeal in accordance with the provisions in 10 C.F.R. § 2.311(b) and (d)(1).

It is so ORDERED.

THE ATOMIC SAFETY
AND LICENSING BOARD

/RA/

E. Roy Hawkens, Chairman
ADMINISTRATIVE JUDGE

/RA/

Dr. Michael F. Kennedy
ADMINISTRATIVE JUDGE

Rockville, Maryland
March 7, 2019

Judge Abreu, Concurring in Part, and Dissenting in Part

I. Introduction

While I agree with the majority's rulings on standing and, to a degree, contention admissibility as outlined in section III below, I must dissent from an important aspect of their contention admissibility findings because I respectfully disagree with their opinion that 10 C.F.R. § 51.53(c)(3) applies to subsequent license renewal. The plain language of the regulation states that it applies to an initial not a subsequent renewal. The APA requires a regulation adopted through notice and comment to be amended through notice and comment. Especially here, where the majority's application of the regulation creates both a significant uncertainty about what regulatory standards are applicable and an obstacle to a petitioner's ability to know how to properly frame its contentions, proper notice is essential. Although the agency's approach to subsequent license renewals may have evolved since section 51.53(c)(3) was proposed in 1991, to use that evolution as an excuse for an adjudicatory body to de facto change the regulation would subvert the intent of the APA and potentially risk the agency's credibility as to the openness, clarity, and reliability of its regulations—three of the agency's "Principles of Good Regulation."[1]

II. Analysis of Section 51.53(c)(3)

FPL and the Staff ask us to ignore the plain language of section 51.53(c)(3) because, they claim, it does not reflect the Commission's intent. They would have us ignore the word "initial" and apply the rule to subsequent license renewal applications because, as FPL and the Staff assert, reading the regulation in accordance with its plain language leads to an "absurd" result.[2] The majority likewise frames the issue before us as a "question of Commission intent"

---

1 See NRC Principles of Good Regulation (ADAMS Accession No. ML14135A076).

2 FPL Surreply at 4; NRC Staff Response to FPL Surreply at 1–2.

and concludes that the Commission intended section 51.53(c)(3) to apply to all license renewal applications.[3] But the majority delves too deeply to find its answer. The regulation is clear on its face, and reading it in accordance with its plain language presents no absurdity or conflict with the agency's regulatory structure. Therefore, neither the Board nor the Commission has the authority to effectively amend a regulation to reflect new Commission "intent" outside of the notice and comment process.[4] When presented with an unambiguous regulation, an agency may not, "under the guise of interpreting [that] regulation, . . . create de facto a new regulation."[5] Because the NRC promulgated section 51.53(c)(3) through notice-and-comment rulemaking, it must use the same procedure if it wants to amend or repeal the rule.[6]

The "interpretation of any regulation must begin with the language and structure of the provision itself."[7] Contrary to the majority's characterization,[8] section 51.53(c)(3) is not "silent" as to its scope. The regulation is quite specific, and we must give all of its words full effect.[9] It applies to applicants: (1) seeking an "initial renewed license"; and (2) holding an operating

license, construction permit, or combined license issued as of June 30, 1995.[10] These applicants must include in their environmental reports the information described in 10 C.F.R. § 51.53(c)(2), along with various "conditions and considerations" that, among other things, allow them to take advantage of the generic determinations in the GEIS for Category 1 environmental issues.[11] "[T]he admitted rules of statutory construction declare that a legislature is presumed to have used no superfluous words. Courts are to accord a meaning, if possible, to every word in a statute."[12] The oft-used principle, "expressio unius est exclusio alterius" (that is, the mention of one thing is the exclusion of the other), is instructive here.[13] Of the categories of license renewal applicants, the Commission chose "initial," thus implying that this was done to the exclusion of "subsequent."[14] Had the Commission meant "initial and subsequent," it could have said just that, or "initial" simply could have been deleted.

The majority relies on Federal Express Corp. v. Holowecki to support its approach to discerning the Commission's intent regarding the scope of section 51.53(c)(3).[15] But unlike here, Holowecki involved a statute and implementing regulations whose language left some

---

[10] 10 C.F.R. § 51.53(c)(3) (emphasis added).

[11] Id.

[12] Platt v. Union Pac. R.R. Co., 99 U.S. 48, 58 (1878).

[13] See, e.g., Christensen, 529 U.S. at 582–83.

[14] The force of the "expressio unius" principle depends on context; the analysis "will turn on whether, looking at the structure of the statute and perhaps its legislative history, one can be confident that a normal draftsman when he expressed 'the one thing' would have likely considered the alternatives that are arguably precluded." Shook v. D.C. Fin. Responsibility & Mgmt. Assistance Auth., 132 F.3d 775, 782 (D.C. Cir. 1998). As discussed below, "initial," by definition, necessarily precludes "subsequent," and the regulatory history further supports its preclusive effect. Therefore, based on context, it is fair to say that the Commission, in choosing to include the word "initial," considered but nevertheless excluded all other alternatives. See id.

[15] See Majority at 15.

room for interpretation: what constitutes a "charge" when alleging unlawful age discrimination.[16] Here, using the word "initial" by definition limits the regulation's scope. Something is either "initial," i.e., first, or it is not.[17] No room exists for anything else.

Resorting to regulatory history is unnecessary when the meaning of a regulation is clear.[18] But even so, the regulatory history here supports an interpretation of the word "initial" as a limitation on the application of section 51.53(c)(3). In the Statements of Consideration for the 1991 proposed rule, the NRC anticipated that a licensee might file multiple license renewal applications, but nevertheless limited application of the efficiencies to be gained by the Part 51 amendments. The NRC stated that the safety considerations for license renewal application reviews outlined in Part 54 "could be applied to multiple renewals of an operating license for various increments," but in the very next sentence stated that the environmental considerations in the Part 51 amendments would apply only "to one renewal of the initial license for up to 20 years beyond [its] expiration."[19] This history of the Part 51 amendments demonstrates that the word "initial" in section 51.53(c)(3) was used with forethought. In 1991, the agency intended the Part 51 amendments for license renewal reviews to apply to one renewal, not multiple renewals.

When the final rule was promulgated in 1996, the Statements of Consideration analyzed the comments received and explained major changes in response to those comments—for example, the agency's decision to prepare a supplemental environmental impact statement for

each license renewal application, rather than an environmental assessment.[20] The NRC did not repeat the "one-renewal" rationale, but to do so was not necessary; no comments about the one-renewal limitation on Part 51 were reported.[21] And the NRC reaffirmed that the changes in the final rule, while substantial, did not alter "the generic approach and scope" of the 1991 proposed rule.[22] Significantly, the final rule retained the word "initial" in section 51.53(c)(3).[23] Moreover, despite several changes to Part 51 since 1996, including changes to section 51.53(c)(3), "initial" remains in the rule to this day.[24]

Notably, in the 2009 proposed rule that accompanied the agency's proposed revisions to the GEIS, the NRC repeated the scope of section 51.53(c)(3) in the Statements of Consideration, explaining that it applies to "initial license renewal."[25] This slight phrasal change

---

[20] See Final Rule, Environmental Review for Renewal of Nuclear Power Plant Operating Licenses, 61 Fed. Reg. 28,467, 28,468 (June 5, 1996) [hereinafter 1996 Final Rule].

Reg. 66,598 (Nov. 10, 2014) (making minor revisions for clarity and to correct typographical errors) [hereinafter Final Rule, Miscellaneous Corrections]; Final Rule, Revisions to Environmental Review for Renewal of Nuclear Power Plant Operating Licenses, 78 Fed. Reg. 37,282 (June 20, 2013) (updating the number and scope of the environmental issues to be addressed in license renewal proceedings consistent with the revised GEIS); Final Rule, Licenses, Certifications, and Approvals for Nuclear Power Plants, 72 Fed Reg. 49,352, 49,432 (Aug. 28, 2007) (adding "combined licenses" to section 51.53(c)(3)) [hereinafter Final Rule, Licenses, Certifications, and Approvals]; Final Rule, Changes to Requirements for Environmental Review for Renewal of Nuclear Power Plant Operating Licenses, 64 Fed. Reg. 48,496 (Sept. 3, 1999) (expanding generic findings regarding transportation of spent fuel and waste); Final Rule, Environmental Review for Renewal of Nuclear Power Plant Operating Licenses, 61 Fed. Reg. 66,537 (Dec. 18, 1996) (making "minor clarifying and conforming changes and add[ing] language inadvertently omitted from Table B-1" of the 1996 final rule).

[25] Proposed Rule, Revisions to Environmental Review for Renewal of Nuclear Power Plant Operating Licenses, 74 Fed. Reg. 38,117, 38,128 (July 31, 2009).

from the rule's text (i.e., "initial renewed license") demonstrates the agency's awareness of the rule's scope, revealing much more than would a rote copy-and-paste, and shows that the rule means what it says: it applies to "initial license renewal," not to "any" renewal.[26]

It is quite a stretch to interpret the agency's failure to repeat the "one-renewal" rationale for Part 51 in the 1996 Statements of Consideration as signaling a complete abandonment of its original position. Nor does it make sense to further assume that retention of the word "initial" in the final rule was a mere ministerial error. Rather, it makes far more sense to assume that the agency meant what it said originally. Had the NRC abandoned its one-renewal limit on the 1991 Part 51 amendments without expressly explaining why, the agency's action would have been subject to challenge as "arbitrary and capricious."[27] And even if we assume that the word "initial" had been retained by mistake for several years, the Commission could have, and still could, fix the error with the same notice process it has used with past Part 51 changes.[28]

---

[26] Despite this, the majority maintains that there is "nothing in the regulatory history indicating that the scope of section 51.53(c)(3)—in 1996 or thereafter—was intended to be restricted to initial license renewals," Majority at 16 n.33, and avoids mentioning that nothing in the post-1996 regulatory history directly indicates that the regulation applies to subsequent license renewal. Moreover, the majority's observation is off target. Because the rule's stated application only to initial license renewals is unchanged to this day, the relevant regulatory history is the expressed intent when the rule was promulgated.

[27] See 5 U.S.C. § 706(2)(A).

[28] See, e.g., Final Rule, Miscellaneous Corrections, 79 Fed. Reg. at 66,600 (direct final rule; good cause found to waive notice and comment). If, as the majority asserts, the 1996 final rule's lack of mention of section 51.53(c)(3)'s "initial" qualifier shows intent not to limit the application of this regulation to one renewal, then why wasn't 51.53(c)(3) changed to reflect that intent in one of the several amendments that were made since 1996? See Majority at 16. Even if the lack of change was a simple oversight, the proper way to correct that oversight is through rulemaking. While the agency could try to justify a "good cause" waiver of the notice requirements in 5 U.S.C. § 553 for a quick fix to the rule, see 5 U.S.C. § 553(b)(3)(B), in my view, removing "initial" would have a substantive impact on subsequent license renewal applicants and hearing petitioners, thus requiring notice-and-comment rulemaking, but that is for the agency to decide.

FPL and the Staff can conceive of no reason why the Commission might place a limit on the use of the GEIS determinations in the environmental report beyond one renewal of a power reactor license.[29] Similarly, the majority finds that reading the rule consistent with its plain language would "undermine the regulatory purpose" of injecting efficiencies into the license renewal process.[30] But limiting the use of the rule for preparation of environmental reports to one license renewal was not an unreasonable approach for the agency to take, considering its obligations under NEPA. The Commission has recognized "the NRC's continuing duty to take a 'hard look' at new and significant information for each 'major federal action' to be taken."[31] So the agency reasonably could have determined that after a certain point—here, following the term of the initial license plus twenty years—the environmental impacts of license renewal should be considered afresh in the environmental report. The GEIS (in its original and revised form) bears this out. As Petitioners point out, references throughout the GEIS indicate that it contemplates only the forty-year term of the original license plus twenty years, for a total of sixty years—not the eighty or more years allowed for subsequent license renewal.[32] Of note, as part of the discussion of severe accidents, the revised GEIS expressly states that "the revision only

---

29 See FPL Surreply at 4, 9–10; NRC Staff Response to FPL Surreply at 11–13.

30 Majority at 18.

31 Exelon Generation Co., LLC (Limerick Generating Station, Units 1 and 2), CLI-13-7, 78 NRC 199, 216 (2013) (quoting Marsh v. Or. Nat. Res. Council, 490 U.S. 360, 374 (1989)).

32 See Pet'rs. Response to FPL Surreply at 5–8. As its discussion makes clear, see Majority at 18–19, the majority basically accepts FPL's argument that "[t]he Commission's decision to retain the 10-year GEIS review and update provision in its 2013 revisions to Part 51 would make no sense if it had intended for the GEIS and Table B-1 to apply only to initial operating license renewals." FPL Surreply at 6. But the fact that the Commission expressed an intent to update the GEIS periodically in no way means that the GEIS analyses cover the temporal scope of a subsequent license renewal. Rather it simply means that when the GEIS is used the information it contains is reasonably up-to-date. Certainly, an applicant may reference the GEIS to make preparation of its environmental report more efficient, but it may not use section 51.53(c)(3)'s protections until the regulation is updated to include subsequent license renewals.

covers one initial license renewal period for each plant (as did the 1996 GEIS)," confirming that both the revised and the original GEIS look only at the temporal period of one license renewal.[33]

FPL and the Staff nonetheless assert, and the majority agrees, that the plain language of section 51.53(c)(3), with its use of the word "initial" in the environmental report instructions, cannot be reconciled with the rules governing the preparation of an environmental impact statement in sections 51.71(d), 51.95(c), and 10 C.F.R. Part 51, Subpart A, Appendix B, which refer generally to license renewal.[34] FPL and the Staff argue that the Staff is required to incorporate information from the GEIS for Category 1 issues for all power plant license renewal applications, initial and subsequent.[35] But the more general reference to license renewal in sections 51.95 and 10 C.F.R. Part 51, Subpart A, Appendix B dates to the 1991 proposed rule when the NRC explained that the "[P]art 51 amendments apply to one renewal of the initial license for up to 20 years."[36] And the 1996 final rule included 10 C.F.R. § 51.71(d) and the general reference to the "license renewal" stage, but within the context of a rule that retained the same "generic approach and scope" of the proposed rule.[37] The use of the plural to describe the amendments to Part 51 as a whole, not just section 51.53(c)(3), is telling. Therefore, if one wanted to resort to regulatory history, as the majority does, to reconcile the language of these sections in a manner consistent with each other, the word "initial" would need to be read into sections 51.71(d), 51.95(c), and 10 C.F.R. Part 51, Subpart A, Appendix B, rather than out of

36 1991 Proposed Rule, 56 Fed. Reg. at 47,017 (emphasis added); see also id. at 47,029.

37 1996 Final Rule, 61 Fed. Reg. at 28,468.

section 51.53(c)(3), as the majority effectively suggests, even though that is not the outcome they seek.[38]

The Staff further argues that section 51.53(c)(3) must apply to subsequent license renewal applications, notwithstanding the word "initial," because "the Commission has not promulgated any other requirements that specifically apply to an environmental report submitted for [a subsequent license renewal application]."[39] But this is not really an issue.[40] Applicants seeking a subsequent license renewal still must meet the requirements in 10 C.F.R. § 51.53(c)(1) and (c)(2). Section 51.53(c)(2) requires a license renewal applicant to include in the environmental report a description of the proposed action, a detailed description of the "affected environment around the plant," "the modifications directly affecting the environment or any plant effluents, and any planned refurbishment activities," as well as "the environmental impacts of alternatives and any other matters described in [10 C.F.R.] § 51.45."[41] Section 51.45, in turn, provides general requirements for environmental reports, with the exception, cross-referenced as section 51.53(c) and reflected in section 51.53(c)(2), that license renewal

---

38 See 1991 Proposed Rule, 56 Fed. Reg. at 47,017. Further, section 51.53(c)(3)'s greater specificity, that it applies only to initial renewal, rather than any renewal, is an indicator that "initial" should not be ignored. "Ordinarily, where a specific provision conflicts with a general one, the specific governs." Edmond v. United States, 520 U.S. 651, 657 (1997) (citing Busic v. United States, 446 U.S. 398, 406 (1980)); see also Union of Concerned Scientists v. NRC, 711 F.2d 370, 381 (D.C. Cir. 1983) (determining that between the general provisions in the APA and the more specific requirements in the Atomic Energy Act, the Atomic Energy Act controls). To be clear, I do not advocate that "initial" should now be read into other sections of Part 51. I am simply saying that the 1991 proposed regulations had inconsistencies. Given that, we must look at the plain language, which is supported by the Statements of Consideration, for the foundation of the interpretation of section 51.53(c)(3), regardless of the inconsistencies. These inconsistencies must be addressed through rulemaking.

39 NRC Staff Response to FPL Surreply at 10 (emphasis omitted).

40 And if it were an issue, the agency would need to promulgate regulations through the rulemaking process.

41 10 C.F.R. § 51.53(c)(2).

environmental reports "need not discuss the economic or technical benefits and costs of either the proposed action or alternatives except if these benefits and costs are either essential for a determination regarding the inclusion of an alternative in the range of alternatives considered or relevant to mitigation."[42] Sections 51.53(c)(1) and (c)(2), together with the cross-reference to the general requirements in section 51.45, thus would seem to ensure that sufficient information is available to aid the Staff in the development of an environmental impact statement, which as the majority notes, is the intended purpose of an environmental report.[43]

Even if applying the plain language of section 51.53(c)(3) may be inefficient in some instances, applying the regulation as written is not what produces a "discordant," "untenable," or even an "absurd" result, as the majority asserts.[44] Instead, what has created this inefficiency is the agency's change of policy without a parallel change to the implementing regulation. As discussed above, the agency made the conscious policy decision to limit the use of the Part 51 amendments to one renewal per reactor unit when the rule was proposed in 1991, which was not changed in the 1996 final rule. But if the agency now finds this policy objectionable or inefficient, we are not the ones to provide a remedy in this adjudication. When faced with a similar choice in Griffin v. Oceanic Contractors, the Court declined to ignore the plain language of a statute, observing that it has "refus[ed] to nullify statutes, however hard or unexpected the particular effect."[45] The Court further reasoned that "'[l]aws enacted with good intention, when put to the test, frequently, and to the surprise of the law maker himself, turn out to be

[44] Id. at 24–25.

[45] 458 U.S. 564, 575 (1982) (holding under terms of statute, district court was required to impose $300,000 penalty on ship owner for failing, without good cause, to promptly pay a seaman $412.50 in earned wages).

mischievous, absurd or otherwise objectionable. But in such case, the remedy lies with the law making authority, and not with the courts.'"[46]

Just as the "remedy for . . . dissatisfaction with the results [of applying the plain language of a statute] lies with Congress, and not with th[e] Court," the remedy for dissatisfaction with the results of applying section 51.53(c)(3) according to its plain text lies with the NRC in its rulemaking authority, not the Board.[47] If the Commission wishes to abandon its "initial renewal" provision, it has a clear path to do so: the NRC must amend the regulation the same way in which the regulation was adopted—through the rulemaking process.[48]

FPL and the Staff also claim, and the majority agrees, that the Staff Requirements Memorandum for SECY-14-0016 compels an interpretation of the regulations that would require use of the GEIS determinations when preparing the environmental report in subsequent license renewal proceedings.[49] This argument fails for two reasons. First, the documents associated with the Commission's action on SECY-14-0016 do not support such an interpretation. Although the Staff, in its paper, discussed its activities relative to the environmental impacts of license renewal, the Staff dismissed the need to amend Part 51 in a single sentence, stating that it "does not recommend updating the environmental regulatory framework under 10 [C.F.R.] Part 51 . . . because environmental issues can be adequately addressed by the existing GEIS and through future GEIS revisions."[50] At the same time, the options laid out for Commission

48 See Mortg. Bankers, 575 U.S. at __, 135 S. Ct. at 1206.

49 See Majority at 20; FPL Surreply at 12–14; NRC Staff Response to FPL Surreply at 10–11, 13.

50 "Ongoing Staff Activities to Assess Regulatory Considerations for Power Reactor Subsequent License Renewal," Commission Paper SECY-14-0016 (Jan. 31, 2014) at 5, encl. 1 (ADAMS Accession No. ML14050A306) [hereinafter SECY-14-0016]. A common-sense view of how we got to this point is that the word "initial" in 51.53(c)(3) has simply been overlooked when

action in the Staff's paper, as well as the Staff's recommended option, all pertained to safety concerns.[51] And the voting record for SECY-14-0016 reflects that the Commission was responding to the safety aspects of subsequent license renewal and whether changes should be made to 10 C.F.R. Part 54, rather than any potential changes to the environmental regulations in Part 51.[52]

Second, even were we to assume that the Staff Requirements Memorandum for SECY-14-0016 implies a Commission determination that no change to Part 51 was necessary because the rules and the GEIS already applied to subsequent license renewal, neither the Commission's nor the Staff's interpretation is sufficient to amend section 51.53(c)(3).[53] FPL and

---

Part 51 has been reviewed the past several years while the requirements for subsequent license renewal were being considered. If not this, then how else could the Staff tell the Commissioners in this SECY paper that updating Part 51 is not recommended? But just because "initial' has been overlooked, this does not give the Board authority to change its meaning to what the Staff wants today.

[51] SECY-14-0016, at 1–2, 5–9.

[52] See Commission Voting Record, "SECY-14-0016—Ongoing Staff Activities to Assess Regulatory Considerations for Power Reactor Subsequent License Renewal" (Aug. 29, 2014) (ADAMS Accession No. ML14245A118). Rather than approving anything, the Commission disapproved the Staff's recommendation to initiate a rulemaking pertaining to Part 54. Staff Requirements—SECY-14-0016—Ongoing Staff Activities to Assess Regulatory Considerations for Power Reactor Subsequent License Renewal (Aug. 29, 2014) (Adams Accession No. ML14241A578) [hereinafter SRM-SECY-14-0016].

Also, it seems strange that these distinctly amorphous circumstances are the best evidence of Commission intent FPL and the Staff (and the majority) can point to in the context of what is apparently the last instance in which the Commission dealt with the rule provisions in question. Given its obvious significance, if the Commission had been fully aware of this section 51.53(c)(3) issue, surely some definitive indication of the Commission's "intent" would have been expressed. Perhaps the first opportunity the Commission may actually have to directly express its "intent" on this subject may be in response to this Board's referred ruling on this issue. See 10 C.F.R. § 2.323(f)(1).

[53] See, e.g., Christensen, 529 U.S. at 588 (declining to defer to an agency interpretation that conflicted with an unambiguous regulation because to do so "would be to permit the agency, under the guise of interpreting a regulation, to create de facto a new regulation"). The same rationale applies to FPL's reference to the July 2018 status report the agency sent to the U.S. Senate Committee on Environment and Public Works, which FPL claims demonstrates "that the Commission views the current Part 51 regulatory framework," including the GEIS, "as

the Staff argue that we should accept their interpretation of section 51.53(c)(3) because to do otherwise would lead to an "absurd result." But it is far more absurd to read out of the regulation a word that has been retained over the course of several years and that was the product of a rulemaking involving broad public participation, including public meetings and workshops, at the time it was adopted.[54] Nor do we have the authority to do so.

Although the Commission has not issued a formal statement directly addressing the issue before us, such an interpretive rule would also put the agency at risk. As the Court has cautioned, "when an agency's decision to issue an interpretive rule, rather than a legislative rule, is driven primarily by a desire to skirt notice-and-comment provisions," the agency may be challenged under the "arbitrary and capricious standard."[55] Under the APA, an agency must "provide more substantial justification when 'its new policy rests upon factual findings that contradict those which underlay its prior policy; or when its prior policy has engendered serious reliance interests [in the written regulation] that must be taken into account. It would be arbitrary and capricious to ignore such matters.'"[56]

---

applicable to [subsequent license renewal applications]." FPL Surreply at 14–15. Even assuming the status report is an expression of that intent, the report to Congress would not be enough to overcome the plain language of section 51.53(c)(3). See Christensen, 529 U.S. at 588.

54 See 1996 Final Rule, 61 Fed. Reg. at 28,469 (describing several public meetings and workshops over a rulemaking history spanning almost ten years). The majority describes a hypothetical that "would result in the wasteful expenditure of private and governmental resources." Majority at 25. This brings to mind TVA v. Hill, in which use of a federally funded multi-million-dollar dam project was halted to protect a small fish. Although not operating the dam similarly could have been described as a "wasteful expenditure," the Court declined to use such an excuse to go beyond the plain meaning of the Endangered Species Act. 437 U.S. 153, 187 (1978). Congress thereafter passed legislation to exempt the dam from the Endangered Species Act so that the dam could operate. See Pub. L. No. 96-69, 93 Stat. 437, 449–50 (1979). The legislature fixed the problem it created, rather than the Court.

55 Mortg. Bankers, 575 U.S. at __, 135 S. Ct. at 1209.

56 Id. (quoting Fox Television, 556 U.S. at 515).

Sidestepping the rulemaking process denies the public an opportunity to comment on a not-insignificant change to the NRC's regulations. And, in this case, that change would add another hurdle for petitioners. In past license renewal adjudicatory proceedings, a petitioner raising a challenge to a Category 1 issue had to meet the requirements for a waiver petition in 10 C.F.R. § 2.335, in addition to the contention admissibility requirements in 10 C.F.R. § 2.309, because such a contention would have been a challenge to the rule.[57] In those proceedings, however, applicants were seeking the initial renewal of their licenses, and therefore section 51.53(c)(3) plainly applied. To expect this case's petitioners to have sought a waiver of a regulation that does not clearly apply to this subsequent license renewal proceeding would be unfair.[58]

While I agree that the agency's current intent is to streamline the subsequent license renewal process, the agency has not amended 51.53(c)(3) to keep up with the evolved policy. The agency's expressed intent at the time the regulation was proposed was clearly that it applies only to initial license renewal. Looking to current intent while trying to explain away the expressed original intent of the regulation is a bridge too far. The agency's intent today may not be the same as the agency's intent when the regulation was created, but that original intent is what ultimately matters for regulatory interpretation. As the Appeal Board explained in the Shoreham proceeding, "[a]lthough administrative history and other available guidance may be consulted for background information and the resolution of ambiguities in a regulation's language, its interpretation may not conflict with the plain meaning of the wording used in that

[57] See Exelon Generation Co., LLC (Limerick Generating Station, Units 1 and 2), CLI-12-19, 76 NRC 377, 384, 386 (2012); Entergy Nuclear Vermont Yankee, LLC (Vermont Yankee Nuclear Power Station), CLI-07-3, 65 NRC 13, 16 (2007); Florida Power & Light Co. (Turkey Point Nuclear Generating Plant, Units 3 and 4), CLI-01-17, 54 NRC 3, 22–23 (2001).

[58] Cf. Limerick, CLI-13-7, 78 NRC at 203 (offering a belated opportunity to submit a waiver petition after resolving "an apparent ambiguity in [the] license renewal regulations").

regulation."[59] The majority's tortuous approach to determining the regulation's applicability wipes away the plain meaning and the original regulatory intent, and instead skips to the Staff's more recent guidance documents and to the inconsistency the agency created when it did not update section 51.53(c)(3) to match that new intent.

The agency's new position clearly conflicts with the plain language of the rule, and we may not fix the problem in this adjudication.[60] To do so would run afoul of the APA and set a troubling precedent that might encourage the agency to take short cuts to amending its regulations in future adjudicatory proceedings. The majority points out the inefficiency of admitted contentions then becoming inadmissible if the regulations are applied as written,[61] but this inefficiency was created by the agency that is responsible for ensuring that the regulations are up-to-date. An agency may not create a situation that is inconsistent with an existing regulation and then use that disparity as an excuse to make a de facto amendment without notice and comment. For example, if the agency can change the meaning of "initial," what is to

59 Shoreham, ALAB-900, 28 NRC at 288.

60 See "Standard Review Plan for Review of Subsequent License Renewal Applications for Nuclear Power Plants," NUREG-2192 at 1.1-2 (July 2017) (ADAMS Accession No. ML17188A158) (providing that the Staff reviewer will check that the applicant has prepared its environmental report "in accordance with the guidelines in NUREG–1555, 'Standard Review Plans for Environmental Reviews for Nuclear Power Plants, Supplement 1: Operating License Renewal,'" which refers generally to license renewal applicants); accord "Preparation of Environmental Reports for Nuclear Power Plant License Renewal Applications," Reg. Guide 4.2 (supp. 1, rev. 1) (June 2013) (ADAMS Accession No. ML13067A354) (referring generally to "license renewal applications") [hereinafter Reg. Guide 4.2]. But see Reg. Guide 4.2 at 33 (guiding the applicant to show the relationships between plant operation and resource attributes, and "[i]f any adverse impacts are identified," guiding the applicant to describe "the mitigation measures that have been used to reduce the adverse impacts during the initial license period or that are expected to be used during the license renewal period and their expected effects") (emphasis added)).

61 Majority at 24–25.

stop it from changing the June 30, 1995, limitation in section 51.53(c)(3) without notice and comment?[62]

If the NRC truly wants section 51.53(c)(3) to apply to subsequent license renewals, it must amend its regulations via the rulemaking process. Until that is completed, a short-term solution might be for the NRC to allow FPL and similarly situated subsequent license renewal applicants the option to reference the information in the GEIS for Category 1 issues in their environmental reports (rather than generating that information anew), thus gaining the procedural efficiencies that the Staff and the Commission may desire for subsequent license renewal.[63] But until section 51.53(c)(3) is revised to include subsequent license renewal

---

62 The NRC might again be presented with a need to amend section 51.53(c)(3) when the time comes for a combined license holder to seek a renewed license. Although the agency amended the regulation in 2007 to include "combined licenses," section 51.53(c)(3) is limited to license holders as of "June 30, 1995," at which time no combined license had been issued, thereby precluding its use for those licensees. See Final Rule, Licenses, Certifications, and Approvals, 72 Fed. Reg. at 49,432, 49,513; Southern Nuclear Operating Co. (Vogtle Electric Generating Plant, Units 3 and 4), CLI-12-2, 75 NRC 63, 122 (2012) (authorizing issuance of the first combined licenses). The "June 30, 1995," restriction also appears in Part 51, Subpart A, Appendix B, but this appendix does not include combined licenses among the types of licenses that may be renewed using the GEIS-associated efficiencies in the rule.

63 Applicants for subsequent license renewal still retain the efficiencies accorded under Part 54, as contemplated in the original rulemaking and reaffirmed by the Commission in SECY-14-0016. See, e.g., 1991 Proposed Rule at 47,017 ("The [P]art 54 rule could be applied to multiple renewals of an operating license for various increments."); SRM-SECY-14-0016 (disapproving the Staff's recommendation to initiate a rulemaking to amend Part 54 for power reactor subsequent license renewal). I recognize that in the long run, the outcome is not in question: section 51.53(c)(3) will end up applying to any renewal, either because the Commission upholds the majority's decision or because the agency changes the regulation via the notice-and-comment process. The real issue is what road the Commission takes to get there. And given the short-term solution proposed above, no immediacy exists here that might counsel in favor of taking action outside the rulemaking process and risking an APA violation. In the interim, the Staff has the option of incorporating information from the GEIS in the supplemental environmental impact statement. But given that there is some question as to whether the GEIS contemplates the temporal scope of subsequent license renewal, see supra Dissent notes 32–33 and accompanying text, the Staff should ensure that its environmental review of subsequent license renewal applications is sufficiently forward-looking. Cf. New York v. NRC, 681 F.3d 471, 478–79, 483 (D.C. Cir. 2012) ("[A] generic analysis must be forward looking and have enough breadth to support the Commission's conclusions."), and petition for review denied, 824 F.3d 1012 (D.C. Cir. 2016).

applicants, petitioners must be allowed to challenge the substantive viability of any GEIS analyses incorporated by reference, without having to request a section 2.335 waiver, provided that they meet the standards for intervention in section 2.309. Requiring petitioners to meet only the contention admissibility standards would not shift the burden, as FPL would have it,[64] but instead maintains the status quo, given that contentions challenging environmental report Category 1 issues in subsequent license renewal proceedings do not challenge the regulations as currently written.[65]

III. Standing and Contention Admissibility

I concur with the majority's rulings on standing for SACE and the Joint Petitioners and on the admission of limited portions of contentions related to the discussion of the cooling tower alternative, the effects on the American crocodile, the source of surface water ammonia, and the impacts of ammonia discharges.[66] I concur with the majority not to admit all other contentions, or portions of contentions, whose inadmissibility was based on reasons that did not include the need for a section 2.335 waiver.

I also concur with allowing Monroe County to join as an interested government participant regarding SACE's two admitted contentions. And finally, I concur in the majority's determination to refer its ruling on the section 51.53(c)(3) matter to the Commission pursuant to 10 C.F.R. § 2.323(f)(1).

---

64 See Tr. at 65–66.

65 By the same token, if any admitted contentions challenging Category 1 issues were outstanding if and when a rulemaking change to section 51.53(c)(3) becomes effective (thus precluding Category 1 items from being subject to adjudicatory consideration in a subsequent license renewal proceeding), the sponsors of those contentions should be afforded a reasonable opportunity, in accordance with section 2.335(b), to submit a rule waiver petition regarding the subject matter of those contentions.

66 Regarding the admission of ammonia-related issues, although section 51.53(c)(3)(ii)(E) is referenced, the Joint Petitioners also noted that if section 51.53(c)(3) does not apply to subsequent license renewal applications, section 51.53(c)(1) and (c)(2) (along with section 51.45) apply in the alternative. Joint Pet'rs Pet. at 16 n.71.

Relative to the contentions the majority has judged inadmissible due to, at least in part, the need for a section 2.335 waiver to challenge a Category 1 issue, I abstain from endorsing that result due to my conviction that section 51.53(c)(3), as written, cannot apply to subsequent license renewal applications.

SUPPLEMENTARY INFORMATION:

I. Obtaining Information and Submitting Comments

A. Obtaining Information

Please refer to Docket ID NRC–2017–0060 when contacting the NRC about the availability of information for this action. You may obtain publicly-available information related to this action by any of the following methods:

• *Federal Rulemaking website:* Go to *http://www.regulations.gov* and search for Docket ID NRC–2017–0060. A copy of the collection of information and related instructions may be obtained without charge by accessing Docket ID NRC–2017–0060 on this website.

• *NRC's Agencywide Documents Access and Management System (ADAMS):* You may obtain publicly-available documents online in the ADAMS Public Documents collection at *http://www.nrc.gov/reading-rm/adams.html.* To begin the search, select ''*ADAMS Public Documents*'' and then select ''*Begin Web-based ADAMS Search.*'' For problems with ADAMS, please contact the NRC's Public Document Room (PDR) reference staff at 1–800–397–4209, 301–415–4737, or by email to *pdr.resource@nrc.gov.* A copy of the collection of information and related instructions may be obtained without charge by accessing ADAMS Accession Nos: ML19057A161, ML19057A167, and ML19057A169. The supporting statement is available in ADAMS under Accession No. ML19057A101.

• *NRC's PDR:* You may examine and purchase copies of public documents at the NRC's PDR, Room O1–F21, One White Flint North, 11555 Rockville Pike, Rockville, Maryland 20852.

• *NRC's Clearance Officer:* A copy of the collection of information and related instructions may be obtained without charge by contacting the NRC's Clearance Officer, David Cullison, Office of the Chief Information Officer, U.S. Nuclear Regulatory Commission, Washington, DC 20555–0001; telephone: 301–415–2084; email: *Infocollects.Resource@nrc.gov.*

B. Submitting Comments

The NRC cautions you not to include identifying or contact information in comment submissions that you do not want to be publicly disclosed in your comment submission. All comment submissions are posted at *http://www.regulations.gov* and entered into ADAMS. Comment submissions are not routinely edited to remove identifying or contact information.

If you are requesting or aggregating comments from other persons for submission to the OMB, then you should inform those persons not to include identifying or contact information that they do not want to be publicly disclosed in their comment submission. Your request should state that comment submissions are not routinely edited to remove such information before making the comment submissions available to the public or entering the comment into ADAMS.

II. Background

Under the provisions of the Paperwork Reduction Act of 1995 (44 U.S.C. Chapter 35), the NRC recently submitted a proposed collection of information to OMB for review entitled, ''NRC Form 361, Reactor Plant Event Notification Worksheet; NRC Form 361A, Fuel Cycle and Materials Event Notification Worksheet; NRC Form 361N, Non-Power Reactor Event Notification Worksheet.'' The NRC hereby informs potential respondents that an agency may not conduct or sponsor, and that a person is not required to respond to, a collection of information unless it displays a currently valid OMB control number.

The NRC published a **Federal Register** notice with a 60-day comment period on this information collection on September 25, 2018 (83 FR 48472).

1. *The title of the information collection:* NRC Form 361, Reactor Plant Event Notification Worksheet, NRC Form 361A, Fuel Cycle and Materials Event Notification Worksheet; NRC Form 361N, Non-Power Reactor Event Notification Worksheet.''

2. *OMB approval number:* 3150–XXXX.

3. *Type of submission:* New.

4. *The form number if applicable:* NRC Form 361, NRC Form 361A, NRC Form 361N.

5. *How often the collection is required or requested:* On occasion, as defined, NRC licensee events are reportable when they occur.

6. *Who will be required or asked to respond:* Holders of NRC licenses for commercial nuclear power plants, fuel cycle facilities, NRC material licensees, and non-power reactors.

7. *The estimated number of annual responses:* 537.

8. *The estimated number of annual respondents:* 537.

9. *An estimate of the total number of hours needed annually to comply with the information collection requirement or request:* 268.5 hours.

10. *Abstract:* The NRC requires its licensees to report by telephone certain reactor events and emergencies that have potential impact to public health and safety. In order to efficiently process the information received through such reports for reactors, the NRC created Forms 361 to provide a templated worksheet for recording the information. NRC licensees are not required to fill out or submit the worksheet, but the form provides the usual order of questions and discussion to enable a licensee to prepare answers for a more clear and complete telephonic notification. Without the templated format of the NRC Forms 361, the information exchange between licensees and NRC Headquarters Operations Officers via telephone could result in delays as well as unnecessary transposition errors.

Dated at Rockville, Maryland, this 1st day of April 2019.

For the Nuclear Regulatory Commission.

David C. Cullison,

NRC Clearance Officer, Office of the Chief Information Officer.

[FR Doc. 2019–06550 Filed 4–3–19; 8:45 am]

BILLING CODE 7590–01–P

NUCLEAR REGULATORY COMMISSION

[Docket Nos. 50–250, 50–251; NRC–2018–0101]

Florida Power & Light Company; Turkey Point Nuclear Generating Unit Nos. 3 and 4

AGENCY: Nuclear Regulatory Commission.

ACTION: Draft supplemental environmental impact statement; request for comment.

SUMMARY: The U.S. Nuclear Regulatory Commission (NRC) is issuing for public comment draft plant-specific Supplement 5, Second Renewal, to the Generic Environmental Impact Statement (GEIS) for License Renewal of Nuclear Plants, NUREG–1437, regarding the subsequent renewal of Facility Operating License Nos. DPR–31 and DPR–41 for an additional 20 years of operation for Turkey Point Nuclear Generating Unit Nos. 3 and 4 (Turkey Point). The Turkey Point facility is

located in Miami-Dade County, Florida. Possible alternatives to the proposed action (subsequent license renewal) include no action and reasonable replacement power and cooling water system alternatives.

DATES: Submit comments by May 20, 2019. Comments received after this date will be considered, if it is practical to do so, but the NRC is able to ensure consideration only for comments received on or before this date.

ADDRESSES: You may submit comments by any of the following methods:

- *Federal Rulemaking Website:* Go to *http://www.regulations.gov* and search for Docket ID NRC–2018–0101. Address questions about NRC dockets to Jennifer Borges; telephone: 301 287–9127; email: *Jennifer.Borges@nrc.gov.* For technical questions, contact the individual listed in the **FOR FURTHER INFORMATION CONTACT** section of this document.
- *Mail comments to:* Office of Administration, Mail Stop: TWFN–7–A60M, ATTN: Program Management, Announcements and Editing Staff, U.S. Nuclear Regulatory Commission, Washington, DC 20555–0001.
- *Email comments to: TurkeyPoint34SLREIS.Resource@nrc.gov*

For additional direction on obtaining information and submitting comments, see ''Obtaining Information and Submitting Comments'' in the **SUPPLEMENTARY INFORMATION** section of this document.

FOR FURTHER INFORMATION CONTACT: David Drucker, Office of Nuclear Reactor Regulation, U.S. Nuclear Regulatory Commission, Washington, DC 20555–0001; telephone: 301–415–6223; email: *David.Drucker@nrc.gov.*

Please refer to Docket ID NRC–2018–0101 when contacting the NRC about the availability of information regarding this document. You may obtain publicly-available information related to this document by any of the following methods:

- *Federal Rulemaking Website:* Go to *http://www.regulations.gov* and search for Docket ID NRC–2018–0101.
- *NRC's Agencywide Documents Access and Management System (ADAMS):* You may access publicly-available documents online in the ADAMS Public Documents collection at *http://www.nrc.gov/reading-rm/adams.html.* To begin the search, select ''*Begin Web-based ADAMS Search.*'' For problems with ADAMS, please contact the NRC's Public Document Room (PDR) reference staff at 1–800–397–4209, 301–415–4737, or by email to *pdr.resource@nrc.gov.* The ADAMS accession number for each document referenced in this document (if that document is available in ADAMS) is provided the first time that the document is referenced here. Draft plant-specific Supplement 5, Second Renewal, to the GEIS for License Renewal of Nuclear Plants, NUREG–1437, is available in ADAMS under Accession No. ML19078A330.
- *NRC's PDR:* You may examine and purchase copies of public documents at the NRC's PDR, Room O1–F21, One White Flint North, 11555 Rockville Pike, Rockville, Maryland 20852.
- *Library:* A copy of draft plant-specific Supplement 5, Second Renewal, to the GEIS for License Renewal of Nuclear Plants, NUREG–1437, is available at the following locations: Homestead Branch Library, 700 N. Homestead Blvd., Homestead, FL 33033; Naranja Branch Library, 14850 SW 280th St., Homestead, FL 33032; South Dade Regional Library, 10750 SW 211th St., Miami, FL 33189; and Downtown Miami Branch, 101 West Flagler St., Miami, FL 30130.

B. Submitting Comments

Please include Docket ID NRC–2018–0101 in the subject line of your comment submission, in order to ensure that the NRC is able to make your comment submission available to the public in this docket.

The NRC cautions you not to include identifying or contact information in comment submissions that you do not want to be publicly disclosed. The NRC will post all comment submissions at *http://www.regulations.gov* as well as enter the comment submissions into ADAMS. The NRC does not routinely edit comment submissions to remove identifying or contact information.

If you are requesting or aggregating comments from other persons for submission to the NRC, you should inform those persons not to include identifying or contact information that they do not want to be publicly disclosed in their comment submission. Your request should state that the NRC does not routinely edit comment submissions to remove such information before making the comment submissions available to the public or entering the comment into ADAMS.

II. Discussion

The NRC is issuing for public comment draft plant-specific Supplement 5, Second Renewal, to the GEIS for License Renewal of Nuclear Plants, NUREG–1437, regarding the subsequent renewal of Facility Operating License Nos. DPR–31 and DPR–41 for an additional 20 years of operation for Turkey Point Unit Nos. 3 and 4. Draft plant-specific Supplement 5, Second Renewal, to the GEIS includes the preliminary analysis that evaluates the environmental impacts of the proposed action and alternatives to the proposed action. The NRC's preliminary recommendation is that the adverse environmental impacts of subsequent license renewal for Turkey Point are not so great that preserving the option of subsequent license renewal for energy-planning decisionmakers would be unreasonable.

III. Public Meetings

The NRC staff will hold two public meetings prior to the close of the public comment period to present an overview of the draft plant-specific supplement to the GEIS and to accept public comment on the document. The meetings will be held on May 1, 2019, from 1:00 p.m. to 3:00 p.m. and from 6:00 p.m. to 8:00 p.m. at the City of Homestead City Hall, 100 Civic Court, Homestead, FL 33030. There will be an open house one hour before each meeting for members of the public to meet with NRC staff members and sign in to speak. The meetings will be transcribed and will include: (1) A presentation of the contents of the draft plant-specific supplement to the GEIS and (2) the opportunity for interested government agencies, organizations, and individuals to provide comments on the draft plant-specific supplement to the GEIS. To be considered in the final supplement to the GEIS, comments must be provided either at the transcribed public meetings or submitted in writing by the comment deadline identified above. Persons may pre-register to attend or present oral comments at the meetings by contacting Mr. William Burton, the NRC Project Manager, at 301–415–6332, or by email at *William.Burton@nrc.gov* no later than Tuesday, April 23, 2019. Members of the public may also register to provide oral comments within 15 minutes before the start of the meetings. Individual oral comments may be limited by the time available, depending on the number of persons who register. If special equipment or accommodations are needed to attend or present information at the public meeting, the need should be brought to Mr. Burton's attention no later than Tuesday, April 23, 2019, to provide the NRC staff adequate notice to determine whether the request can be accommodated.

NATURAL RESOURCES DEFENSE COUNCIL'S, FRIENDS OF THE EARTH'S, AND MIAMI WATERKEEPER'S MOTION TO MIGRATE CONTENTIONS & ADMIT NEW CONTENTIONS IN RESPONSE TO NRC STAFF'S SUPPLEMENTAL DRAFT ENVIRONMENTAL IMPACT STATEMENT

I. INTRODUCTION

Pursuant to 10 C.F.R. § 2.309(c) and the Atomic Safety and Licensing Board's ("Board") Revised Scheduling Order,[1] Natural Resources Defense Council, Friends of the Earth, and Miami Waterkeeper (together "Intervenors") hereby move for the migration and admission of amended and new contentions regarding the Draft Supplemental Environmental Impact Statement[2] ("DSEIS") for Florida Power and Light Company's ("Applicant") proposed subsequent license renewal issued by the Nuclear Regulatory Commission ("NRC" or "Commission") Staff in March 2019.

Intervenors respectfully submit the migration or amendment of previously admitted

[1] Order (Granting in Part Intervenor's Joint Motion for Partial Reconsideration of Initial Scheduling Order) (Apr. 2, 2019) (ML19092A386) (providing that the deadline for answer opposing a dispositive motion is 30 days after May 10, 2019) (hereinafter "Scheduling Order").

[2] NUREG-1437, Supp. 5, Second Renewal, "Generic Environmental Impact Statement for License Renewal of Nuclear Plants, Supplement 5, Second Renewal, Regarding Subsequent License Renewal for Turkey Point Nuclear Generating Unit Nos. 3 and 4, Draft Report for Comment" (Mar. 2019) (ML19078A330) (hereinafter "DSEIS").

contentions (Contentions 1-E and 5-E) and respectfully request admission of four new contentions (Contentions 6-E, 7-E, 8-E, and 9-E). The migrated or amended contentions simply assert that the DSEIS fails either to address or to address adequately previously-identified omissions contained in the Applicant's Environmental Report.

The new contentions concern the NRC Staff's analysis of "new and significant" information for one existing Category 1 issue[3] – groundwater quality degradation (plants with cooling ponds in salt marshes), and one "new issue" – water quality impacts on adjacent water bodies (plants with cooling ponds in salt marshes).[4] Intervenors also move to admit new contentions based on information that was previously unavailable and which remain unaddressed in the DSEIS.[5] This new information demonstrates that several conclusions about environmental impacts in the DSEIS are unsupported by the evidence; particularly those conclusions that rely on Applicant's compliance with the 2015 Consent Agreement between Applicant and Miami-Dade County[6] and the 2016 Consent Order between Applicant and the Florida Department of Environmental Protection ("FDEP")[7] that govern "freshening" in the cooling canal system and

---

[3] Generally, Category 1 issues are "beyond the scope of a license renewal hearing," unless a waiver is granted. *Florida Power & Light Co.* (Turkey Point Nuclear Generating Plant, Units 3 and 4), CLI-01-17, 54 NRC 3, 15 (July 19, 2001); 10 C.F.R. § 2.335(b). Intervenors do not believe a waiver is necessary here, but submit a waiver for the new contentions out of an abundance of caution. NRDC's, FOE's, and Miami Waterkeeper's Petition for Waiver of 10 C.F.R. §§ 51.53(C)(3) and 51.71(D) and 10 C.F.R. Part 51, Subpart A, Appendix B.

[4] DSEIS at 4-2.

remediation of Applicant's hypersaline plume.[8]

II. BACKGROUND

A. Procedural Background

On August 1, 2018 and pursuant to 10 C.F.R. § 2.309 and the NRC's Federal Register notice published at 83 Fed. Reg. 19,304 (May 2, 2018), Intervenors submitted a Request for Hearing and Petition to Intervene[9] in the above-captioned matter. To safeguard our and our members' environmental, aesthetic, health-based and economic interests, Intervenors articulated five contentions in the Petition. These contentions addressed various deficiencies in Applicant's Environmental Report,[10] submitted as part of the subsequent renewal license application for Turkey Point Nuclear Generating Station, Units 3 and 4, in Miami-Dade County, Florida.

Following full briefing and a hearing on the admissibility of each contention, the Board on March 7, 2019 issued Memorandum and Order LBP-19-3 granting Intervenors' hearing request.[11] In that Order, the Board also found that Intervenors had established standing and admitted in part two of the five contentions. On March 19, 2019, Intervenors, Applicant, and the

---

[8] *See, e.g.*, DSEIS at 4-23 ("[U]pon consideration of the FDEP's and DERM's existing requirements and their continuing oversight of FPL's site remediation efforts, the NRC staff concludes that the impacts on adjacent surface water bodies via the groundwater pathway from the [cooling canal system] during the subsequent license renewal term would be SMALL and, therefore, the new information that has been identified is not significant."); DSEIS at 4-27 ("[T]he NRC staff concludes that as a result of FPL's operation of its recovery well system and continued regulatory oversight and enforcement of the terms of the consent order and consent agreement by the FDEP and DERM, the impacts on groundwater quality from operations during the subsequent license renewal term would be SMALL."). DSEIS at 4-117 ("The NRC Staff expects that continued operation of the freshening system, combined with proper operation and maintenance of the [cooling canal system], will result in no substantial contribution to cumulative impacts on groundwater quality or associated impacts on surface water quality in Biscayne Bay during the subsequent license renewal period.").

[9] Request for Hearing and Petition to Intervene Submitted by Friends of the Earth, Natural Resources Defense Council, and Miami Waterkeeper (Aug. 1, 2018) (ML18212A418) ("Petition").

[10] Turkey Point Nuclear Plant, Units 3 and 4, Appendix E, Applicant's Environmental Report Subsequent Operating License Renewal Stage (Jan. 2018) (ML1813A145) (hereinafter "Environmental Report").

[11] *Fla. Power & Light Co.* (Turkey Point Nuclear Generating Station Units 3 & 4), LBP-19-3, 89 N.R.C. __ (slip op.) (Mar. 7, 2019) ("Order").

NRC Staff filed a joint motion regarding the hearing schedule, mandatory disclosures, and hearing file obligations in this proceeding.[12] The Board issued an Initial Scheduling Order that provided Intervenors the opportunity to review initial disclosures provided by the parties and then rely on them to file new and amended contentions.[13] Thereafter, at Intervenors' request the Board made modest changes to the Initial Scheduling Order that continued to allow Intervenors to rely on initial disclosures in the new and amended contentions, but also allowed Intervenors to rely on the same in opposing any dispositive motions.[14]

On April 1, 2019, Applicant filed an appeal of the Order,[15] and on April 26, 2019, Intervenors opposed the appeal.[16] The NRC Staff agreed with Intervenors that the Board had correctly admitted the contentions.[17] This appeal is pending before the Commission. In March 2019, NRC Staff issued the DSEIS. Based on the DSEIS, on May 20, 2019, Applicant filed two motions to dismiss Intervenors' contentions as moot.[18] On June 10, 2019, Intervenors opposed these motions,[19] and the NRC Staff supported them.[20] These motions are currently pending

before the Board.[21]

Intervenors timely filed comments on the DSEIS on May 20, 2019[22] and today timely file amended and new contentions based on the DSEIS.

B. <u>Legal Standards</u>

A license renewal application review typically implicates issues that fall into one of two broad areas: safety/aging management issues, and public health/environmental impacts. Petitioner's contentions are focused on environmental and public health impacts. The scope of the environmental review is defined by 10 C.F.R. Part 51, the NRC's "Generic Environmental Impact Statement for License Renewal of Nuclear Plants," NUREG- 1437 (May 1996) (the "GEIS"), and the initial hearing notice and order.[23] Some environmental issues that might otherwise be germane in a license renewal proceeding have been resolved generically for all plants and are normally, therefore, "beyond the scope of a license renewal hearing."[24] These "Category 1" issues are classified in 10 C.F.R. Part 51, Subpart A, Appendix B. Category 1 issues may be raised when a petitioner (1) demonstrates that there is new and significant information subsequent to the preparation of the GEIS regarding the environmental impacts of license renewal; (2) files a petition for a rulemaking with the NRC; or (3) seeks a waiver pursuant to 10 C.F.R. § 2.335.[25]

---

[21] If the Board finds that a contention is not moot, that contention should migrate. On the other hand, if the Board finds a contention is moot, then the contention should be amended.

[25] *Turkey Point*, 54 NRC at 10-12; *see also* 10 C.F.R. § 51.53(c)(3)(iv) (new and significant information).

NRC regulations dictate that contentions arising pursuant to NEPA must initially be "based on the applicant's environmental report."[26] Once the NRC Staff has published its DSEIS, the Commission has explained that contentions originally challenging an environmental report automatically migrate to challenge the NRC Staff's DSEIS.[27] This so-called "migration tenet obviates the requirement to file the same contention (and litigate its admissibility) three times—once against the [Environmental Report], once against the DEIS, and once against the final environmental impact statement."[28] However, a contention may only migrate if the information in the subsequent DSEIS is "sufficiently similar to the information in the [Environmental Report]."[29]

If the information in the DSEIS is not sufficiently similar to what the contention challenged in the Environmental Report, an intervenor must file a motion to amend the admitted contention and/or to admit a new contention.[30] For example, a contention challenging an omission in the environmental report may not migrate to challenge the adequacy of new information or analysis provided in the DSEIS; the contention would need to be amended.[31] New and amended contentions are admissible as long as the intervenor demonstrates good cause by showing that the contention is supported by new information that (1) was not previously available; (2) is materially different from information that was previously available, and (3) is

timely filed.[32] In addition, an amended or new contention must also satisfy the general contention admissibility requirements of 10 C.F.R. § 2.309(f)(1), including providing: (i) "a specific statement of the issue of law or fact to be raised or controverted," (ii) "a brief explanation of the basis for the contention," (iii) a demonstration "that the issue raised in the contention is within the scope of the proceeding," (iv) a demonstration "that the issue raised in the contention is material to the findings the NRC must make,"[33] (v) "a concise statement of the alleged facts or expert opinions which support the [intervenor's] position on the issue," and (vi) "sufficient information to show that a genuine dispute exists with the applicant/licensee on a material issue of law or fact."

III. AMENDED OR MIGRATED CONTENTIONS

In its April 2, 2019 Scheduling Order, the Board ruled that new or amended contentions based on the DSEIS will be considered timely if filed on or before June 24, 2019.[34] Here, we timely update our two existing, admitted contentions to apply to the NRC Staff's DSEIS. While recognizing NRC regulations do not explicitly require Intervenors to migrate our already-admitted contentions by motion, we nevertheless refile these contentions now out of an abundance of caution, in order to preclude any subsequent assertion by the NRC Staff, the Applicant, or a reviewing tribunal that Intervenors have not pursued their rights as secured by the U.S. Constitution, the National Environmental Policy Act ("NEPA"), 42 U.S.C. § 4323 *et seq*., or regulations promulgated by the Council on Environmental Quality or the NRC. Thus, we

[33] A "material" issue is one that would make a difference in the outcome of the proceeding. Rules for Practice for Domestic Licensing Proceedings—Procedural Changes in the Hearing Process, 54 Fed. Reg. 33,168, 33,172 (Aug. 11, 1989). *Entergy Nuclear Vermont Yankee, LLC & Entergy Nuclear Operations, Inc.* (Vermont Yankee Nuclear Power Station), LBP-4-28, 60 NRC 548, 557 (Nov. 22, 2004).

[34] Scheduling Order at 3 (the revised scheduling order set the deadline for new or amended contentions based on the DSEIS at 45 days after initial disclosures due on May 10, 2019).

submit that all our objections that applied to the Applicant's Environmental Report now apply to the DSEIS. Further, boards have previously explained that "if there is any question about whether an admitted contention merits a new/amended contention motion relative to the Staff's environmental document, the best approach seemingly would be to make a filing that treats the contention as if it were new/amended or, perhaps most prudently, argues in the alternative."[35] Below, we therefore argue in the alternative to either migrate Contentions 1-E and 5-E or amend the contentions.

A. <u>Contention 1-E</u>

In its March 7, 2019 Order, the Board admitted Intervenors' Contention 1-E as a contention of omission as follows:

> In light of the adverse impact of continued cooling canal system operations on the threatened American crocodile and its critical seagrass habitat, the [Environmental Report] is deficient for failing to consider mechanical draft cooling towers as a reasonable alternative to the [cooling canal system] in connection with the license renewal of Turkey Point Units 3 and 4.[36]

Intervenors move to amend this Contention based on new and materially different information in the DSEIS. However, if the Board finds that the Contention is not admissible as amended, Intervenors alternatively move to migrate Contention 1-E as originally admitted.

***<u>AMENDMENDED CONTENTION 1-Eb</u>*: The DSEIS fails to analyze adequately mechanical draft cooling towers as a reasonable alternative that could mitigate adverse impacts of the cooling canal system in connection with the license renewal of Turkey Point Units 3 and 4.**

The Board should amend and admit Contention 1-E as Contention 1-Eb because good cause exists to amend the contention and Contention 1-Eb meets the admissibility requirements

---

[35] *Strata Energy, Inc.* (Ross In Situ Recovery Uranium Project), LBP-13-10, 78 NRC 117 (July 26, 2013).

[36] Order at 44.

in 10 C.F.R. § 2.309(f).

First, good cause—defined as timely and based on previously unavailable and materially different information[37]—exists to amend Contention 1-E as Contention 1-Eb. Per the Board's Scheduling Order, this motion to amend is timely.[38] The DSEIS also includes new information that was previously unavailable in the Environmental Report; whereas the Environmental Report omitted cooling towers as an alternative to the cooling canal system, the DSEIS now includes a shallow, inadequate evaluation of cooling towers as a cooling water system alternative.[39] It is this inadequate evaluation that the amended Contention 1-Eb now challenges. Because the basic form of a contention cannot change through migration—i.e. "challeng[ing] the soundness of the information provided [rather than] claim[ing] that necessary information has been omitted"—Intervenors respectfully move to amend Contention 1-E from claiming an omission in the Environmental Report to challenging the adequacy of analysis newly included in the DSEIS.[40] Thus, there is good cause to amend Contention 1-E.

And, second, as we explain below, Contention 1-Eb meets the requirements in 10 C.F.R. § 2.309(f)(1) regarding contention admissibility. The Board should therefore admit Contention 1-Eb as amended.

1. Statement of the issue of law or fact to be raised or controverted (10 C.F.R. § 2.309(f)(1)(i))

The DSEIS fails to comply with 10 C.F.R. § 51.71(d) because it fails to include an adequate analysis of "alternatives available for reducing or avoiding adverse environmental

---

[37] 10 C.F.R. § 2.309(f)(2) and 2.309(c)(1).

[38] Scheduling Order at 3.

[39] *See e.g.,* DSEIS at 2-12 – 2-13.

[40] *Private Fuel Storage, LLC*, LBP-01-23, 54 NRC at 172 n.3.

effects."[41] While the DSEIS considers a cooling water system alternative to the cooling canal system,[42] the DSEIS at best only analyzes the adverse impacts of constructing and operating the alternative;[43] the DSEIS unlawfully fails, however, to provide any analysis of the benefits to endangered species and the environment (described below) that would follow from replacing the cooling canal system with the cooling water system alternative. Intervenors have already shown in the Petition that cooling towers are a reasonable and feasible alternative to the cooling canal system,[44] and the NRC Staff seem to agree as they included cooling towers as the cooling water system alternative in the DSEIS.[45] However, the NRC Staff failed to complete an *adequate* alternatives analysis by failing to discuss how replacing the existing cooling canal system with cooling towers would reduce adverse impacts to Category 2 issues, as required by NRC regulations.

2. Brief explanation of basis for the contention (10 C.F.R. § 2.309(f)(1)(ii)); concise statement of the alleged facts or expert opinions supporting the contention (10 C.F.R. § 2.309(f)(1)(v)); and statement that a genuine dispute exists with the licensee on a material issue of law or fact (10 C.F.R. § 2.309(f)(1)(vi))

NEPA and NRC regulations require that a DSEIS "[r]igorously explore and objectively evaluate all reasonable alternatives."[46] An agency's consideration of reasonable alternatives is "the heart" of NEPA.[47] Specifically, NRC regulations require that a DSEIS include a mitigation

---

[41] 10 C.F.R. § 51.71(d).

[42] DSEIS at 2-12 – 2-13.

[43] *See e.g.,* DSEIS at 4-11, 4-18 – 4-19, 4-41 – 4-42, 4-48, 4-59 – 4-60, and 4-70.

[44] Petition at 19-22.

[45] DSEIS at 2-12 – 2-13.

[46] 40 C.F.R. § 1502.14. The Council on Environmental Quality's regulations implementing NEPA apply to all federal agencies, including the NRC. *Union Neighbors United, Inc. v. Jewell*, 831 F.3d 564, 569 n.1 (D.C. Cir. 2016) (citing 40 C.F.R. § 1500.3).

[47] *Union Neighbors United,* 831 F.3d at 575 (citing 40 C.F.R. § 1502.14).

discussion analyzing "alternatives available for reducing or avoiding adverse environmental effects" of the proposed project.[48] This mitigation discussion must include an analysis of "*benefits* and costs of the proposed action *and alternatives*."[49] It is a vital part of the "action forcing" function of NEPA because "[w]ithout such a discussion, neither the agency nor other interested groups and individuals can properly evaluate the severity of the adverse effects."[50]

The DSEIS fails to satisfy the NEPA and NRC requirements to rigorously explore benefits and costs of a reasonable alternative available for reducing or avoiding adverse environmental effects of the relicensing. The DSEIS purports to satisfy NEPA's obligation to consider alternatives available for reducing adverse impacts of the cooling canal system by including the cooling water system alternative. Unlike for all the other alternatives examined, however, the DSEIS fails to analyze how the cooling water system alternative compares to the proposed action.[51] The DSEIS plays lip service to this requirement by claiming that it "evaluates an alternative cooling water system technology for Turkey Point Units 3 and 4 that might be used to mitigate the potential impacts associated with continued use of the existing cooling canal system."[52] But the DSEIS at best analyzes the *adverse* impacts of cooling towers; it is devoid of any substance on the environmental benefits of the alternative, for example the adverse impacts of the proposed action *that the alternative could reduce or avoid*, as required by 10 C.F.R. §

[48] 10 C.F.R. § 51.71(d).

[49] *Id.* (emphasis added).

[50] *Robertson v. Methow Valley Citizens Council*, 490 U.S. 332, 352 (1989). *See also Hydro Res., Inc.* (P.O. Box 777, Crownpoint, New Mexico 87313), LBP-06-19, 64 NRC 53, 93 (Aug. 21, 2006) ("Mitigation must be discussed in sufficient detail to ensure that environmental consequences have been fairly evaluated").

[51] DESIS at 2-20 – 2-21 (In section 2.4 Comparison of Alternatives, the DESIS explains why the proposed action is preferable to the four other alternatives—no action, new nuclear, natural gas combined-cycle, and natural gas combined-cycle and solar photovoltaic combination—but makes no mention of the cooling water system alternative).

[52] DSEIS at 2-12.

51.71(d). Specifically, the DSEIS fails to consider how the cooling water system alternative could reduce acknowledged adverse impacts to (1) threatened, endangered, and protected species and essential fish habitat and (2) groundwater use conflicts.

a. Replacing the existing cooling canal system with cooling towers would reduce adverse impacts related to threatened, endangered, and protected species and essential fish habitat.

The DSEIS concludes that operating the cooling canal system another 20 years is "likely to adversely affect the American crocodile and eastern indigo snake," two special status species, and may affect other species.[53] Further, the DSEIS states that there would be SMALL to MODERATE impingement and entrainment impacts and thermal impacts on aquatic organisms.[54] The DSEIS acknowledges that the cooling canal system contributes to these adverse impacts.[55] Thus replacing the cooling canal system with cooling towers could reduce the adverse impacts to species and their habitat.

Both temperature and salinity in the cooling canals have increased. This has resulted in decreased nesting and fewer American crocodiles observed in the cooling canals.[56] In 2017, the FWS explained that:

> [T]here has been a reduction in the number of crocodile nests produced within the [cooling canal system]. A total of 9 nests were observed in 2015 and 8 in 2016. The decrease in nesting in the [cooling canal system] has occurred with a concomitant decrease in the number of crocodiles observed within the [cooling canal system]…. In addition, the body condition of many of the crocodiles

[53] DSEIS at xviii.

[54] *Id.*

[55] *See e.g.* DSEIS at 4-50, 4-54 ("The NRC staff acknowledges EAI's conclusion regarding seagrass and recognizes that thermal discharges associated with Turkey Point have contributed not only to the disappearance of seagrass within the [cooling canal system], but also to the decline of fish and other aquatic biota and the observed shift towards more heat-tolerant species in recent years."), 4-56; *see also* Biological Assessment for the Turkey Point Nuclear Generating Unit Nos. 3 and 4 Proposed Subsequent License Renewal, at 33 (Dec. 2018) (hereinafter "Biological Assessment") ("the NRC staff concludes that the current conditions within the [cooling canal system] are having an adverse impact on American crocodile nesting and hatchling success.").

[56] *See* Biological Assessment at 32.

> observed within the [cooling canal system] has decreased (i.e., animals appear emaciated and much thinner than healthy animals of the same total length). Moreover, anecdotal evidence suggests that a majority of the fish and invertebrate species that used to provide prey for the crocodile in the waters of the [cooling canal system] no longer occur or are greatly diminished in numbers… [These issues] are thought to be the result of the recent increase in water temperature and salinity, and decrease in water quality within the waters of [cooling canal system] observed during the past few years, beginning in 2013… [The cause for the decrease in water quality conditions] include [Applicant's] recent increase in power production from nuclear Units 3 and 4, [and] the discharge of vegetative cutting within the [cooling canal system].[57]

Increased temperature and salinity have also caused seagrass, that "once covered 50 percent of the system," to die off.[58] This has significantly changed the aquatic resources in the cooling canal system, such that "species diversity within the system has declined over time."[59] Furthermore, the cooling canal system has driven the westward migration of a hypersaline plume,[60] resulting in salination of freshwater wetlands that are habitat for a range threatened and endangered species, including the Florida panther, American crocodile, indigo snake, snail kite, red knot and wood stork.[61] Thus, ceasing operation of the cooling canal system as a heat sink and replacing them with cooling towers, while keeping the canals in place, could protect existing species habitat. With an adequate effort to freshen the canals, and without the dangerously high temperatures of the recent past, the canals would continue to provide valuable critical habitat into the future.[62]

The DSEIS fails, however, to adequately consider these benefits of the cooling tower

[62] *See* Section IV.B.

alternative. In analyzing the alternative's impacts on aquatic resources, the DSEIS focuses on the adverse impacts of the alternative, for example stating that "[c]onstruction of cooling towers on the Turkey Point site would result in the permanent loss or impairment of sensitive aquatic habitats and could affect ecosystem function and connectivity."[63] The DSEIS analysis of the alternative in regards to species is even less adequate as it fails to even conduct the analysis. The DSEIS makes the excuse that "the magnitude and significance of adverse impacts on special status species and habitats would depend on the location and layout of the cooling towers, the design of the cooling towers, operational parameters, and the special status species and habitats present in the area when the alternative is implemented."[64] But these location and design parameters would not change the fact that Turkey Point Units 3 and 4 stopped utilizing the cooling canal system as a heat sink.

An analysis on the change to the cooling canal system should cooling towers be built should have been conducted to rigorously and objectively evaluate the alternative. But the DSEIS fails to complete this analysis and therefore fails to adequately analyze an alternative that could reduce or avoid adverse impacts of the project.

b. Replacing the existing cooling canal system with cooling towers would reduce adverse impacts related to groundwater use conflicts.

Turkey Point Units 3 and 4 currently rely on the cooling canal system as their cooling water system—the Units discharge heated water into the cooling canal system and, as the water travels through the cooling canal system, it loses heat through evaporation.[65] But, as the evaporation removes heat, it of course also removes water. Over the years, this water has been

---

[63] DSEIS at 4-60.

[64] DSEIS at 4-70.

[65] DSEIS at 3-11.

replenished by (1) freshwater from precipitation, (2) saline water from the Biscayne aquifer, and occasionally (3) brackish water from the Florida aquifer.[66] However, as discharge from Units 3 and 4 has become hotter (increasing evaporation) and droughts have become more common (decreasing the freshwater precipitation replenishment), the salinity of the cooling canal system has increased. Units 3 and 4 are therefore a main contributing factor to the increased salinity of the cooling canal system.[67] And replacing the Unit's reliance on the cooling canal system with the alternative of cooling towers for their cooling water system would help reduce the salinity of the cooling canal system and the adverse impacts originating from that salinity.

The DSEIS acknowledges that the cooling canal system's increased salinity creates adverse impacts, including: die-off of sea grass, increased algae blooms, and the hypersaline plume.[68] But to redress the salinity levels in the cooling canal system—and reduce these adverse impacts—the DSEIS only analyzes adding more brackish water to the cooling canal system from the Florida aquifer and attempting to withdraw the hypersaline plume through wells.[69] Rather than reduce adverse impacts, these actions in fact only create new ones; evidence suggests the plan to withdraw the hypersaline plume will not be successful[70] and the DSEIS acknowledges that these actions will exacerbate groundwater use conflict by substantially increasing groundwater use and leading to drawdown of offsite production wells.[71]

Rather than focus on these subpar mitigation plans, the DSEIS should have completed the

[71] *Id.* at 4-28–4-33, 4-115.

analysis it claims it would, by "evaluat[ing] an alternative cooling water system technology for Turkey Point Units 3 and 4 that might be used to mitigate the potential impacts associated with continued use of the existing cooling canal system."[72] By replacing the heat sink function of the cooling canals with cooling towers, an original substantial factor in the hypersalinity that created a host of adverse impacts could be addressed. The DSEIS should have completed this analysis so that "interested groups and individuals can properly evaluate the severity of the adverse effects."[73] But while the DSEIS analyzes groundwater demand for freshening the cooling canal system,[74] it does not analyze how ending the heat contribution of Turkey Point Units 3 and 4 to the cooling canals could freshen the water and reduce the groundwater impacts faster. The DSEIS only states that "the NRC staff expects that groundwater demands for [cooling canal system] freshening would decrease over time commensurate with the reduction in thermal discharge to the [cooling canal system] from Turkey Point Units 3 and 4, some use of groundwater (or other water sources) would likely continue into the future,"[75] but does not compare how significant this change would be. Thus, an analysis on the change to the cooling canal system and groundwater use conflict should cooling towers be built should have been conducted. But the DSEIS fails to complete this analysis and therefore fails to adequately analyze an alternative that could reduce or avoid adverse impacts of the project.

3. The issue raised in the contention is within the scope of the proceeding (10 C.F.R. § 203.9(f)(1)(iii))

NRC regulations broadly divide the scope of a license renewal proceeding into (1) safety/aging management issues, and (2) environmental impacts. This contention concerns environmental impacts. The scope of the required environmental review is established by 10 C.F.R. Part 51 and the GEIS for license renewals.[76] This contention is within the scope of the proceeding because it challenges the sufficiency of the environmental analysis in the DSEIS.

4. The issue raised in the contention is material to the findings the NRC must make to support the action involved in the proceeding (10 C.F.R. § 2.309(f)(1)(iv))

An issue is "material" if "the resolution of the dispute would make a difference in the outcome of the licensing proceeding."[77] "This means that there must be some link between the claimed error or omission regarding the proposed licensing action and the NRC's role in protecting public health and safety or the environment."[78] The issue raised in this contention—the DSEIS's failure to comply with NRC's regulations requiring rigorous consideration of alternatives—relates directly to the NRC's role in protecting public health and safety and the environment. NEPA imposes requirements on the NRC to ensure environmental protection. The failure to comply with these requirements is material to the findings NRC must make to support relicensing.

***MIGRATED CONTENTION 1-E*: In light of the adverse impact of continued cooling canal system operations on the threatened American crocodile and its critical seagrass habitat, the DSEIS is deficient for failing to consider mechanical draft cooling towers as a reasonable alternative to the cooling canal system in connection with the license renewal of Turkey Point Units 3 and 4.**

[78] *Id.*

In the alternative, if the Board finds that Contention 1-Eb is not admissible, Intervenors request that Contention 1-E migrate as presently admitted, with the term "Environmental Report" in the contention updated to the "DSEIS." Contention 1-E can migrate as admitted because the omission of information in the Environmental Report that the Contention challenges is sufficiently similar to the omission of information in the DSEIS. Thus, Contention 1-E now challenges that the NRC Staff's DSEIS fails to consider mechanical draft cooling towers as a reasonable alternative to the cooling canal system in light of the adverse impacts of continued operation of the cooling canal system on the threatened American crocodile and its critical seagrass.[79]

A contention migrates if the information it challenges in the Environmental Report is sufficiently similar to information included in the DSEIS. We must therefore first understand what information the contention aimed to challenge in the Environmental Report. As admitted, Contention 1-E on its face is specifically a claim that the Environmental Report omits analysis of cooling towers as an alternative *that could mitigate adverse impacts* of the cooling canal system specifically on the American crocodile and its critical seagrass habitat. In admitting the Contention, the Board's Order found that Contention 1-E "raises a genuine dispute on a material fact to the extent it alleges that [Applicant's Environmental Report] improperly fails to consider mechanical draft cooling towers as a reasonable alternative *for reducing or avoiding adverse impacts on the threatened American Crocodile and its critical seagrass habitat*."[80] By including the qualifying phrase regarding impacts to the American crocodile in the admitted Contention

[79] This issue has already been briefed by parties in their Motions to Dismiss as Moot. If the Board finds that the DSEIS does not moot Contention 1-E, the Contention should be allowed to migrate.

[80] *Turkey Point*, LBP-19-3, 89 NRC __ (slip op. at 40) (emphasis added). This statement appears in the Board's analysis of another Intervenor Southern Alliance for Clean Energy's ("SACE") Contention 2, but the Board admitted Joint Petitioners' Contention 1-E "subject to the same limitations" as its admission of SACE's Contention 2. *See* LBP-19-3, 89 NRC __ (slip op. at 44).

language, the Board focused the scope of the Contention on the omission of how the cooling towers could reduce adverse impacts of the cooling canal system specifically on this species and its habitat.

Like the Environmental Report, the DSEIS also fails to include a discussion of the reduction of adverse impacts to the American crocodile and its habitat that would be achieved by installing cooling towers. In the DSEIS "the NRC staff concludes that the proposed Turkey Point subsequent license renewal is likely to adversely affect the American crocodile … and may result in adverse modification to designated critical habitat for the American crocodile."[81] However, while the DSEIS claims it "evaluates an alternative cooling water system to mitigate the potential impacts associated with the continued use of the existing cooling canal system,"[82] the DSEIS actually only analyzes certain potential adverse impacts of the cooling towers. It omits any specific analysis of benefits of utilizing cooling towers as an alternative to the cooling canal system to mitigate the acknowledged adverse impact of the canal system on the American crocodile and its habitat.[83] Thus, the DSEIS is sufficiently similar to the Environmental Report in its failure to analyze the mechanical draft cooling towers as a reasonable alternative to the cooling canal system in light of the adverse impact of continued operation of the cooling canal system on the threatened American crocodile and its critical seagrass habitat; Contention 1-E should be allowed to migrate.

B. Contention 5-E

The Board admitted Contention 5-E as follows:

---

[81] DSEIS at 4-23.

[82] DSEIS at iii.

[83] *See e.g.,* 2017 Biological Opinion at 68 (discussing select adverse impacts of cooling canal system on American crocodiles without discussing cooling towers as an alternative).

> The Environmental Report is deficient in its failure to recognize Turkey Point as a source of ammonia in freshwater wetlands surrounding the site, and in its failure to analyze the potential impacts of ammonia releases during the renewal period on threatened and endangered species and their critical habitat.[84]

Because the DSEIS is sufficiently similar to the Environmental Report in that both omitted any analysis of the potential impacts of ammonia on the threatened and endangered species identified by the Contention or on their critical habitat, Contention 5-E must be migrated with respect to the NRC Staff's DSEIS. In the alternative, if the Board finds that the DSEIS is not sufficiently similar to the Environmental Report on this issue, Intervenors move to amend Contention 5-E.

MIGRATED CONTENTION 5-E: **The DSEIS is deficient in its failure to analyze the potential impacts of ammonia releases during the renewal period on threatened and endangered species and their critical habitat.**

A contention migrates if the information it challenges in the Environmental Report is sufficiently similar to information included in the DSEIS. We must therefore first understand what information the contention aimed to challenge in the Environmental Report. To determine a contention's scope, the Board first analyzes the language of the contention, and, if the scope is not clear on the contention's face, the Board considers the statement of basis accompanying the contention.[85] The scope of Contention 5-E, as admitted and clarified in the basis statement, encompasses the impact of ammonia from continued operation of Turkey Point Units 3 and 4 on the following six threatened or endangered species and their habitat: the "Florida panther, American crocodile, indigo snake, snail kite, red knot and wood stork."[86]

The Environmental Report failed to consider the impact of ammonia discharges on these threatened and endangered species and important habitat. Similarly, the DSEIS also fails to

[84] Order at 52-53 (emphasis added).

[85] *Private Fuel Storage,* LBP-01-23, 54 NRC at 171.

[86] Petition at 60. *See also* Joint Petitioners' Answer Opposing FPL's Motion to Dismiss Joint Petitioners' Contention 5-E as Moot (June 10, 2019).

include this specific analysis. As the NRC's Biological Assessment for the subsequent relicensing of Turkey Point Units 3 & 4 notes, a specific evaluation of ammonia's impacts must consider "[s]everal water quality parameters, including pH, temperature, and salinity; the rate and duration of exposure; *and a species' specific physiobiology*. . . ."[87] While the DSEIS at least contemplates the impact of ammonia on one endangered species—the West Indian manatee—it fails to analyze this issue for the six species identified in Intervenors' contention.[88] Thus, the DSEIS is sufficiently similar to the Environmental Report in its failure to analyze the impact of ammonia discharges from Turkey Point Units 3 and 4 on the six named threatened or endangered species and their habitat. Contention 5-E should be allowed to migrate.[89]

***AMENDMENDED CONTENTION 5-Eb*: The DSEIS is deficient in its analysis of the potential impacts of ammonia releases during the renewal period on threatened and endangered species and their critical habitat.**

In the alternative, the Board should amend and admit Contention 5-E as Contention 5-Eb because good cause exists to amend the contention and Contention 5-Eb meets the admissibility requirements in 10 C.F.R. § 2.309(f).

First, good cause—defined as timely and based on new and materially different information[90]—exists to amend Contention 5-E as Contention 5-Eb. Per the Board's Scheduling Order, this motion to amend is timely.[91] The DSEIS also includes new information that was previously unavailable in the Environmental Report; whereas the Environmental Report did not

[87] Biological Assessment at 60.

[88] *See id* at 30-47, 51-55, 57-62.

[89] This issue has already been briefed by parties in their Motions to Dismiss as Moot. If the Board finds that the DSEIS does not moot Contention 5-E, the Contention should be allowed to migrate.

[90] 10 C.F.R. § 2.309(f)(2) and 2.309(c)(1).

[91] Scheduling Order at 3.

acknowledge that Turkey Point is a source of ammonia,[92] the DSEIS now admits to this fact but includes only a spotty, inadequate evaluation of how Turkey Point's continued operation as a source of ammonia will impact threatened and endangered species.[93] It is this inadequate evaluation that Contention 5-Eb now challenges. Because the basic form of a contention cannot change through migration—i.e. "challeng[ing] the soundness of the information provided [rather than] claim[ing] that necessary information has been omitted"—Intervenors respectfully move to amend Contention 5-E from claiming an omission in the Environmental Report to challenging the adequacy of analysis in the DSEIS.[94] Thus, there is good cause to amend Contention 5-E.

And, second, as we explain below, Contention 5-Eb meets the requirements in 10 C.F.R. § 2.309(f)(1) regarding contention admissibility. The Board should therefore admit Contention 5-Eb as amended.

1. Statement of the issue of law or fact to be raised or controverted (10 C.F.R. § 2.309(f)(1)(i))

NRC regulations require the DSEIS to consider the effects of Turkey Point's continued operation on endangered species.[95] The DSEIS acknowledges that Turkey Point is a source of ammonia,[96] but it gives inadequate consideration to how the ammonia released will impact threatened or endangered species, or otherwise harm important plant and animal habitats, over the next 20 years. This failure violates NEPA.

2. Brief explanation of basis for the contention (10 C.F.R. § 2.309(f)(1)(ii)); concise statement of the alleged facts or expert opinions supporting the contention (10

---

[92] ER at 9-13, 3-93 – 3-94.

[93] DSEIS at 3-52, 2-12 – 2-13.

[95] 10 C.F.R. § 51.71 (requiring a DSEIS analyze Category 2 issues); s*ee also,* 10 C.F.R. Part 51, Subpart A, Appendix B (listing "threatened, endangered, and protected species and essential fish habitat" as a Category 2 issue).

[96] DSEIS at 3-52.

C.F.R. § 2.309(f)(1)(v)); and statement that a genuine dispute exists with the licensee on a material issue of law or fact (10 C.F.R. § 2.309(f)(1)(vi))

Turkey Point discharges ammonia from the cooling canal system to nearby surface waters via the Biscayne Aquifer. Specifically, violations of surface water ammonia standards have been observed in canals near Turkey Point.[97] The DSEIS acknowledges that Miami-Dade County has offered evidence that Turkey Point is a key source of the ammonia and is responsible for the violations of water quality standards.[98]

Ammonia can have direct and highly toxic effects on the aquatic environment.[99] While the DSEIS speaks generally to the effects of elevated ammonia on water quality[100] and "aquatic organisms," it does not mention any threatened or endangered species in this discussion.[101] Individualized analysis by species is vital because, as the NRC's Biological Assessment for the subsequent relicensing of Turkey Point Units 3 & 4 notes, a specific evaluation of ammonia's impacts must consider "[s]everal water quality parameters, including pH, temperature, and salinity; the rate and duration of exposure; and a *species' specific physiobiology*. . . ."[102]

Yet the DSEIS fails to consider the impacts of ammonia discharges on all but one threatened and endangered species and important habitat.[103] For example, in the Biological Assessment's Section 5.1.2 on "Impacts to the American Crocodile and Designated Critical

---

[97] Letter from Wilbur Mayorga (Miami-Dade County, Division of Environmental Resources Management) to Matthew J. Raffenberg (Applicant) at 1-2 (July 10, 2018) ("Mayorga – Raffenberg Letter").

[98] DSEIS at 3-52 (citing Mayorga – Raffenberg Letter).

[99] DSEIS at 4-65; Final Aquatic Life Ambient Water Quality Criteria for Ammonia – Freshwater 2013, 78 Fed. Reg. 52,192 (Aug. 22, 2013).

[100] DSEIS at 3-42 – 3-44.

[101] DSEIS at 4-65.

[102] Biological Assessment at 60 (Dec. 2018) (emphasis added).

[103] *See* Biological Assessment.

Habitat," the word ammonia does not even appear.[104] One need only compare the NRC's analysis of ammonia impacts on another species—the West Indian manatee—to grasp the inadequacy of the remainder of DSEIS's analysis.[105] There, the NRC attempted to connect the dots by specifically addressing the impacts of ammonia—not "nutrients" generally—on the manatee.[106] Further, the DSEIS provides no explanation why this level of analysis was included for the manatee and not any other species. Thus, the DSEIS's analysis of how ammonia may impact threatened and endangered species is inadequate.

3. The issue raised in the contention is within the scope of the proceeding (10 C.F.R. § 203.9(f)(1)(iii))

NRC regulations plainly require the DSEIS to address the effects of Turkey Point's continued operations on endangered species.[107] The effects on these resources in Turkey Point's cooling canal system are therefore within the scope of this proceeding.

4. The issue raised in the contention is material to the findings the NRC must make to support the action involved in the proceeding (10 C.F.R. § 2.309(f)(1)(iv))

A contention is "material" to the NRC's duty to make environmental findings if the issue of law or fact it raises "is of possible significance to the result of the proceeding. This means that there should be some significant link between the claimed deficiency and either the health and safety of the public or the environment."[108] There is a significant link between the issue raised in

this contention—Applicant's failure to assess the impacts of Turkey Point's operations on threatened and endangered species—and "the health and safety of the public or the environment."[109] NRC regulations require the DSEIS to include such an analysis. Each aspect of the contention relates directly to an impact on the environment and, thus, is material to the findings the NRC must make to support relicensing.

IV. NEW CONTENTIONS

A. Overview

Intervenors offer the following new contentions. Each new contention is based on information that did not appear in the Environmental Report, was unavailable at the time Intervenors filed their initial petition to intervene, is raised in timely fashion pursuant to the Board's Scheduling Order, is materially different, and establishes a genuine dispute on a material issue of law or fact that is within the scope of this proceeding.[110]

These contentions address what is generally categorized as a Category 1 issue (groundwater quality degradation (plants with cooling ponds in salt marshes)) as well as an issue that is neither Category 1 or Category 2 (water quality impacts on adjacent water bodies (plants with cooling ponds in salt marshes)). While Intervenors believe a waiver under 10 C.F.R. § 2.335(b) is not necessary in order for Intervenors to assert contentions addressing these issues, we also submit a waiver out of an abundance of caution.[111]

B. New Information

[109] *Id.*

[110] 10 C.F.R. §§ 2.309(f)(1), 2.309(c)(1).

[111] NRDC's, FOE's, and Miami Waterkeeper's Petition for Waiver of 10 C.F.R. §§ 51.53(C)(3) and 51.71(D) and 10 C.F.R. Part 51, Subpart A, Appendix B (June 24, 2019).

Intervenors rely on the following new information in support of their new contentions.

1. Miami-Dade County Petition for Administrative Hearing ("MDC Petition").[112] On September 17, 2018, Miami-Dade County filed a petition challenging Everglades Mitigation Bank Phase II Permit Modification No. 0193232-182 (the "Permit Modification"). The Permit Modification requires Applicant to: (i) change the "elevation of water control structures to a lower, fixed elevation, which will drain more water from the L-31E canal" and (ii) allow the transfer of *more* than 7,000 acre-feet of water per year through the L-31E levee to Applicant's mitigation lands south of the plant.[113]

As the following excerpts from the MDC Petition demonstrate, and as confirmed by the Dr. William Nuttle, Applicant's compliance with the Permit Modification substantially changes the region's hydrological profile.

- The 2015 Consent Agreement between Applicant and Miami-Dade requires Applicant to "rais[e] the control elevations of the FPL Everglades Mitigation Bank culvert weirs to no lower than 0.2 feet below the 2.4 foot trigger of the S-20 structure and maintain[] this elevation."[114]
- These "culvert weirs" are water control structures that determine how much freshwater is diverted from the L-31E canal to Applicant's southern mitigation bank lands.[115]
- "One goal of the weir elevation requirements in the County's Consent Agreement was to maintain more water on the surface landscape in the wetland areas to the west of the Cooling Canal System; that additional water creates a hydrologic 'head' that acts as a counterbalance to prevent additional saltwater intrusion in the groundwater area. These areas to the west of the Cooling Canal System are the same areas where FPL's hypersaline

[113] MDC Petition at 1.

[114] MDC Petition ¶ 13.

[115] MDC Petition ¶ 14.

groundwater plume has been detected."[116]

The MDC Petition further indicates that Applicant's compliance with the new control elevation requirements will lead to materially significant environmental impacts:

- The Permit Modification's new "control elevation requirement may exacerbate the existing water quality violations that FPL is otherwise working to abate and remediate, thus hindering the progress of those efforts and harming wetlands in the Model Lands area."[117]
- "[S]etting the control elevation of the L-31E water control structures [at the new, lower level] is not sustainable from a broader water management perspective."[118]

2. New Reports – Newly available data indicates that the 2015 Consent Agreement between Applicant and Miami-Dade County ("MDC Consent Agreement")[119] and the 2016 Consent Order between Applicant and FDEP[120] are not achieving the anticipated results regarding mitigation of the hypersaline plume and salinity management in the cooling canal system.[121] This data includes information found in the following:

- Turkey Point Cooling Canal System Baseline CSEM Report (Oct. 2018).
- FPL, 2018 Annual Turkey Point Power Plant Remediation/Restoration Report (Dec. 2018).
- FPL Recovery Well System Startup Report (Oct. 5, 2018).

[118] MDC Petition ¶ 24.

[119] Miami-Dade County, "Consent Agreement Concerning Water Quality Impacts Associated with the Cooling Canal System at Turkey Point Power Plant" (Oct. 6, 2015) (ML16335A219) (referenced in DSEIS as MDC 2015a).

[120] FDEP, "Consent Order, OGC File 13 Number 16-0241, between the State of Florida Department of Environmental Protection and 14 Florida Power & Light Company regarding settlement of Matters at Issue [Westward Migration of 15 Hypersaline Water from the Turkey Point Facility and Potential Releases to Deep Channels on 16 the Eastern and Southern Side of the Facility]" (June 20, 2016) (ML16216A12) (referenced in DSEIS as FDEP 2016e).

[121] *See* DSEIS at 3-49 (suggesting that "more favorable climatic conditions . . . should help to reduce [cooling canal system] water salinities to 34 PSU").

3. Expert Report and Opinions of Dr. William Nuttle, Ph.D, which state:

- New information provided by Miami-Dade County points to material and significant changes to the hydrology of the Turkey Point region as the result of water management decisions since Florida Power & Light (FPL) submitted its Environmental Report.[122]

- Applicant's compliance with this modified permit exacerbates impacts from operating the cooling canal system on groundwater, surface water, and ecological resources in the Model Lands Basin.[123]

- New information on mechanisms of drought in south Florida provides evidence that "more favorable climatic conditions" that are being relied on to meet salinity targets in the CCS are unlikely to occur.[124]

- The ongoing dispute between the County and FDEP over setting the elevation of the weirs along the L-31E canal is evidence that achieving compliance with requirements for remediation established by DERM and FDEP does not reliably predict future compliance with state and local water quality requirements.[125]

4. Expert Report and Opinions of E.J. Wexler, P.Eng, which states:

- Tetra Tech modeling from 2016 has serious flaws that are especially critical in light of new water quality information showing that Applicant was unable to achieve freshening of the cooling canal system with the addition of 10 to 15 MGD of brackish water from the Floridan aquifer.[126]

- Mr. Wexler's modeling demonstrates that retraction of the hypersaline plume is not likely to occur without the addition of more wells and increased pumped volumes.[127]

- Modeling indicates that freshening of the cooling canal system is the key driver to retraction of the hypersaline plume; not pumping.[128]

- Applicant's models (Tetra Tech 2016a, 2016b, and 2017) indicate that

[128] *Id*. at 4.

meeting the 2016 order with FDEP is not achievable with the number of wells and pumping volumes proposed.[129]

- More analysis would be required to determine whether additional withdrawals would have harmful environmental effects.[130]

5. Expert opinion of Dr. James Fourqurean, Ph.D., which states:

- The seagrass beds of Biscayne Bay and the rest of south Florida require very low nutrient loading to survive. In essence, seagrasses are killed and replaced by fast-growing, noxious seaweed or planktonic algae if nutrient delivery is increased. Nutrient delivery can be increased either by increasing the concentration of nutrients in discharges, OR by increasing the volume of water containing nutrients, even at very low nutrient concentrations that would pass drinking water quality standards.[131]

- The seagrasses along the coastline of the Cooling Canal System (CCS) existed for thousands of years in a nutrient-limited state, which means any addition of new nutrients changes the balance of these ecosystems. Increased nutrients harm the ecosystem by increasing the rates of primary production by marine plants. Increase in growth rates means that faster-growing, noxious marine plants, like macroalgae (seaweeds) and microscopic algae and photosynthetic bacteria, overgrow and outcompete seagrasses and corals for light, leading to the losses of corals and seagrasses.[132]

- Around the world, there are many nutrients that can limit noxious plant growth, but most often, the nutrients that limit this growth are either nitrogen or phosphorus. In south Biscayne Bay, phosphorus is limiting to phytoplankton and macroalgae. This means that addition of phosphorus will upset the ecological balance of seagrass beds as has been exhibited in Northern Biscayne By and Florida Bay. Upsetting the balance of populations of aquatic flora and fauna by nutrient addition is a violation of Florida surface water quality standards.[133]

- Current seagrass species composition and abundance data collected by ongoing seagrass monitoring programs show that there are places where Turtle Grass biomass offshore from the CCS is unusually dense compared to other areas in southern Biscayne Bay, likely as a consequence of increased P

[129] *Id*. at 5.

[130] *Id*.

[131] Fourqurean Decl. at 2.

[132] *Id*. at 4.

[133] *Id*.

availability in the region and concentrated by the operations of the adjacent CCS. The P sources are likely to be the result of Turkey Point operations that includes chemical components added for cleaning, biomass death that occurred within the CCS in 2014, and any nutrient pulled into the system from the surrounding environment that has been concentrated overtime as the freshwater evaporates away over the life of the plant.[134]

- The nearshore seagrass beds are incredibly efficient at removing P from the water column and storing P at vanishingly small concentrations. In fact, even 30 feet from large point-sources of P in Florida Bay, it is not possible to measure increases in P concentrations in the water column because it has all been captured by the algal and seagrass communities. This P capture causes increased plant growth and ecosystem imbalances. This imbalance first leads to an actual increase in the abundance of seagrass, but rapidly it causes a change in species composition, first to faster-growing seagrasses, then to seaweeds, then to microscopic algae.[135]

- Groundwater discharges along the coast of southern Biscayne Bay contain elevated concentrations of phosphorus and tritium, so that any process that causes groundwater discharge to the local seagrasses will supply the limiting nutrient (P) that upsets the balance of the ecosystem. Groundwater under the seagrass meadows of this part of Biscayne Bay contain tritium at concentrations that can only be explained by this water coming from the CCS.[136]

- The geology underlying the CCS and the adjacent seagrass meadows is based on limestone, which is made of calcium carbonate minerals. Calcium carbonate minerals strongly absorb orthophosphate onto their surfaces. But, respiration by plants, animals and bacteria dissolve calcium carbonate minerals, releasing the orthophosphate absorbed to the surfaces. During normal conditions, south Florida ecosystems are incredibly efficient at holding on to captured phosphorus– so much so that the impacts caused by adding P to seagrass beds in south Florida for even short periods can still be measured 30 years after the P additions. On the other hand, bacteria cause added N captured by south Florida ecosystems to be rapidly removed from those ecosystems. These facts result in P additions causing permanent and cumulative imbalances in nearshore marine waters of the Keys while N additions cause imbalances that can be corrected by the cessation of N addition.[137]

---

[134] *Id*. at 5.

[135] *Id*. at 6.

[136] *Id*.

[137] *Id*. at 7.

- An imbalance of the seagrasses that form the near-shore habitat near the CCS in Biscayne Bay and provide the food at the base of the food chain harms the fish and wildlife that use these habitats and therefore effects fishing, recreational activities such as bird watching and other activities based on that habitat change and eventual loss.[138]

C. The Information Intervenors' Rely On Satisfy the "Good Cause" Standard in 10 C.F.R. § 2.309(c)(1).

New contentions are properly admissible upon a showing of good cause that (1) "[t]he information upon which the filing is based was not previously available," (2) "[t]he information upon which the filing is based is materially different from information previously available," and (3) "[t]he filing has been submitted in a timely fashion based on the availability of the subsequent information."[139] Each of the new sources of information Intervenor relies on for its new contentions meets these requirements. Good cause therefore exists for admitting each new contention.

1. The MDC Petition.

a. Not Previously Available. 10 C.F.R. § 2.309(c)(1)(i).

Intervenors base their new contentions in part on the Miami-Dade Petition, which is dated September 17, 2018. Intervenors filed their Petition to Intervene on August 1, 2018[140] and their Reply Brief on September 10, 2018.[141] Thus, the MDC Petition was not available at the time of Intervenors' Petition or Reply Brief.

---

[138] *Id.* at 8.

[139] 10 C.F.R. § 2.309(c)(1). New and amended contentions must also meet the 6-part test governing admissibility in 10 C.F.R. § 2.309(f)(1).

[140] Petition at 1.

[141] Reply in Support of Request for Hearing and Petition to Intervene Submitted by Friends of the Earth, Natural Resources Defense Council, and Miami Waterkeeper (Sept. 10, 2018) (ML18253A280).

b. Materially different information from what was previously available. 10 C.F.R. § 2.309(c)(1)(ii).

Information is "materially different" "[u]nless it looks genuinely plausible that inclusion of an additional factor or use of other assumptions and models may change the cost-benefit conclusions."[142] Materiality in this context "relates to the magnitude of the difference between the previously available information and currently available information."[143]

The MDC Petition satisfies the "materially different" requirement because it provides information showing that it "looks genuinely plausible" that Applicant will not be able to comply with the MDC Consent Agreement. The DSEIS relies heavily on Applicant's ability to comply with this Agreement in its analysis of environmental impacts from the continued operation of Turkey Point Units 3 and 4.[144] This includes the DSEIS conclusion with respect to impacts on adjacent surface water bodies via the groundwater pathway.[145]

In the MDC Petition, Miami-Dade challenges a new requirement imposed on Applicant by the FDEP through a modified permit. The modified permit requires Applicant to take steps that that would materially change the region's hydrology, exacerbate Applicant's water quality

---

[142] *See DTE Electric Co.* (Fermi Nuclear Power Plant, Unit 2), LBP-17-1, 85 NRC at 4 (Jan. 10, 2017).

[143] *S. Nuclear Operating Co.* (Vogtle Elec. Generating Plant, Units 3 & 4), LBP-10-01, 71 N.R.C. 165, 183 n.9 (2010).

[144] *See, e.g.*, DSEIS at 4-23 ("[U]pon consideration of the FDEP's and DERM's existing requirements and their continuing oversight of FPL's site remediation efforts, the NRC staff concludes that the impacts on adjacent surface water bodies via the groundwater pathway from the [cooling canal system] during the subsequent license renewal term would be SMALL and, therefore, the new information that has been identified is not significant.");

DSEIS at 4-27 ("[T]he NRC staff concludes that as a result of FPL's operation of its recovery well system and continued regulatory oversight and enforcement of the terms of the consent order and consent agreement by the FDEP and DERM, the impacts on groundwater quality from operations during the subsequent license renewal term would be SMALL.");

DSEIS at 4-117 ("The NRC Staff expects that continued operation of the freshening system, combined with proper operation and maintenance of the [cooling canal system], will result in no substantial contribution to cumulative impacts on groundwater quality or associated impacts on surface water quality in Biscayne Bay during the subsequent license renewal period.").

[145] DSEIS at 4-23.

violations, and interfere with Applicant's remedial efforts under the MDC Consent Agreement. As noted in the MDC Petition, FDEP modified Applicant's Mitigation Bank Phase II permit by lowering control elevations of the L-31E water control structure to an unchanging level of 1.8 feet NGVD.[146] The MDC Petition asserts that this new "control elevation requirement may adversely impact water resources upstream of the area, is not sustainable over the long term, and interferes with protecting water quality in the L-31E canal from chloride contamination and addressing the existing inland migration of the salt intrusion front in this area."[147] It "may exacerbate the existing water quality violations that [Applicant] is otherwise working to abate and remediate, thus hindering the progress of those efforts and harming wetlands in the Model Lands area."[148] Further, "setting the control elevation of the L-31E water control structures at an unchanging level of 1.8 feet NGVD is not sustainable from a broader water management perspective."[149]

The MDC Petition establishes facts that are materially different than the information previously available in several ways. First, the MDC Petition is relevant to issues and related conclusions that appear for the first time in the DSEIS.[150] These conclusions rely heavily on oversight and compliance with requirements predicated on a different hydrologic regime. Miami-Dade is now on record stating those predicate conditions have materially changed.

[146] MDC Petition ¶ 23.

[147] MDC Petition ¶ 23.

[148] MDC Petition ¶ 23.

[149] MDC Petition ¶ 24.

[150] *See., e.g.*, DSEIS at 4-2 ("The NRC staff . . . identified one new issue (i.e., water quality impacts on adjacent water bodies (plants with cooling ponds in salt marshes))"); DSEIS at 4-21 ("Specifically, the GEIS (NUREG-1437) did not consider how a nuclear power plant with a cooling pond in a salt marsh may indirectly impact the water quality of adjacent surface water bodies via a groundwater pathway. This constitutes a new, site-specific issue with respect to Turkey Point . . . .").

Second, the MDC Petition is "materially different" than previous information because it demonstrates FDEP's and Miami-Dade's "existing requirements" are incompatible.[151] Miami-Dade states that FDEP's permit modification "may exacerbate the existing water quality violations that [Applicant] is otherwise working to abate and remediate, thus hindering the progress of those efforts and harming wetlands . . . ."[152] Finally, the very fact that two agencies with oversight over water resources disagree is material to this proceeding. Logically, the NRC cannot conclude that compliance with and oversight by FDEP *and* Miami-Dade's requirements will result in SMALL environmental impacts when Miami-Dade is on record stating FDEP's requirements are incompatible with its own. Nor can the NRC rely on the mere existence of a permit requirement as a substitute for NEPA review.[153]

Intervenors also offer the expert opinions of Dr. William Nuttle to further explain why the concerns listed in the MDC Petition are justified and material to this proceeding. Dr. Nuttle explains that lowering weirs in the L-31E canal will drain freshwater from the Model Lands Basin, which sits west of the L-31E canal. This has the effect of lowering the water table throughout the Model Lands Basin, which reduces the natural hydraulic barrier against the encroachment of saltwater into the Biscayne aquifer, and it increases the vulnerability of water supply wells adjacent to the Model Lands Basin to degradation by saltwater intrusion, including the risk of degradation by the hypersaline plume emanating from the cooling canal system.

[151] *See, e.g.*, DSEIS at 4-23 (relying on "FDEP's and DERM's existing requirements and their continuing oversight of FPL's site remediation efforts" to conclude impacts via the groundwater pathway would be SMALL); DSEIS at 4117 ("The NRC staff finds that it is reasonable to expect that FPL's freshening well system would continue to be operated during the subsequent license renewal term, and for as long as necessary to maintain compliance with the terms of the 2015 consent agreement with Miami-Dade Count DERM [] and the 2016 FDEP consent order [].").

[152] MDC Petition ¶ 23.

[153] *Sierra Club v. Fed. Energy Regulatory Comm'n*, 867 F.3d 1357, 1375 (D.C. Cir. 2017) (citing *Calvert Cliffs' Coordinating Comm. V. Atomic Energy Comm'n*, 449 F.2d 1109, 1122–23 (D.C. Cir. 1971).

Lowering the water table in the Model Lands Basin also increases the flow of saline water into the L-31E canal and movement throughout the basin, which further degrades the freshwater wetlands.

These hydrological conditions are materially different than those presented in the Environmental Report according both to Dr. Nuttle and Miami-Dade. The record in this proceeding is devoid of any evidence that addresses environmental impacts complained of by Miami-Dade.

c. Timely. 10 C.F.R. § 2.309(c)(iii).

Section 2.309(c)(iii) does not define the term "timely." Thus, the Board has "a degree of latitude" in determining compliance with this standard.[154] The Board may, as it has done here, "define timeliness by specifying a deadline for timely filing a new or amended contention following a 'triggering event' that makes the previously unavailable/materially different information available so as to be the basis for the new or amended contention."[155] Further, the Board has previously ruled that while "intervenors must respond to new information when it first becomes available, they need not do so until the information is actually used by the NRC Staff to form its conclusions on impacts in the DSEIS."[156]

The Board's Scheduling Order established a June 24, 2019 deadline for filing of new and amended contentions. Intervenors' new contentions are filed in accordance with that deadline and are therefore timely. Additionally, to Intervenors' knowledge, there was no record of the MDC Petition in this proceeding until after the Board's April 2, 2019 Scheduling Order. On

---

[154] *Crow Butte Res., Inc.* (Marsland Expansion Order) LBP-18-3 at 8 (July 20, 2018).

[155] *Id.*

[156] *Powertech USA, Inc*. (Dewey-Burdock In Situ Uranium Recovery Facility), LBP-13-09, 78 NRC 37, 93 (2013).

April 3, 2019, Applicant submitted "more recent additional information to support the Staff's review of [Applicant's Subsequent License Renewal Application] for Turkey Point Units 3 and 4."[157] The 2018 Annual Report appears to be the first time the MDC Petition is mentioned by Applicant in connection or referenced in any of the NRC Staff's NEPA-related documents in this proceeding.[158] In turn, the NRC Staff listed the 2018 Annual Report in its initial disclosures dated May 10, 2019.[159] Thus, any contention based on the MDC Petition is timely.

2. New Reports.

a. Not previously available. 10 C.F.R. § 2.309(c)(1)(i).

The new reports referenced in paragraph 2, Section IV(B), above, were not available when Intervenors filed their petition on August 1, 2018. Applicant released the "Turkey Point Cooling Canal System Baseline CSEM Report" and "Recovery Well System Startup Report in October 2018; and the "2018 Annual Turkey Point Power Plant Remediation/Restoration Report" in December 2018. Thus, this information was not previously available.

b. Materially different information from what was previously available. 10 C.F.R. § 2.309(c)(1)(ii).

These reports are materially different than information previously available in the Environmental Report. The Environmental Report did not state that Applicant's efforts to reach 34 PSU in the cooling canals system were ineffective. In contrast, the DSEIS explains that Applicant's modelers predicted freshening efforts "would require less than a year to reduce

[157] *See* Letter from William Maher, Senior Licensing Direct, Florida Power & Light Co., to NRC, Enclosure 3 (ML19095B380).

[158] *See* 2018 Annual Report at 18 (referencing MDC DERM's challenge to the FDEP Permit modification) (ML191095B494).

[159] NRC Staff Initial Disclosures, Hearing File Index at 19, Doc. ID# NRC-0280 (May 10, 2019) (ML19130A049). While the NRC Staff index dates this record December 31, 2018, Applicant submitted it to the NRC on April 3, 2019 to provide "more recent additional information for the SLRA Environmental Report."

salinities in the [cooling canal system] to 35 PSU."[160] Yet average salinity concentrations in the cooling canal system only reached 64.9 PSU.[161] The DSEIS also explained for the first time that these "modelers anticipate that under more favorable climatic conditions (e.g., less severe dry seasons), the addition of Upper Floridan aquifer water should help to reduce [cooling canal system]."[162] The previous statement indicates that the modeling efforts were not sufficient and that further inquiry is necessary to determine what climatic conditions are needed to meet the salinity target and whether those conditions are likely to occur. These inquiries are absent in the DSEIS. Without any evidence that Applicant will be able to meet its salinity targets, the only thing left supporting the DSEIS conclusions is the mere existence of a requirements and agencies to oversee them. This is not enough to satisfy NEPA, particularly when, as noted above in Section IV.C.1., those agencies are at loggerheads.[163]

c. Timely Submitted. 10 C.F.R. § 2.309(c)(iii).

Intervenors today submit new contentions based on the new reports pursuant to the April 2, 2019 Scheduling Order. It is timely for this reason alone. However, additionally, Applicant did not submit the "2018 Annual Turkey Point Power Plant Remediation/Restoration Report" or the "Recovery Well System Startup Report" to the NRC Staff until April 3, 2019 as part of a package of "more recent additional information to support the Staff's review of [Applicant's Subsequent License Renewal Application]."[164] This is after the Board issued the April 2, 2019 Scheduling Order and also after the NRC Staff released the DSEIS for public comment in March

---

[160] DSEIS at 3-49.

[161] *Id.*

[162] DSEIS at 3-49.

[163] *Sierra Club v. Fed. Energy Regulatory Comm'n*, 867 F.3d 1357, 1375 (D.C. Cir. 2017) (citing *Calvert Cliffs' Coordinating Comm. V. Atomic Energy Comm'n*, 449 F.2d 1109, 1122–23 (D.C. Cir. 1971).

[164] ML19095B380.

2019.

Lastly, contentions based on the new reports are timely because the DSEIS is the first environmental document in this proceeding that relies on an unsubstantiated statement by Applicant's modelers that more favorable climatic conditions will achieve salinity targets in the cooling canal system. Before that, Intervenors could not have addressed the basis for the Staff's conclusion because the Staff had not made it.[165]

3. New Expert Opinions.

a. Not previously available. 10 C.F.R. § 2.309(c)(1)(i).

The new expert opinions that Intervenors supply herein were not previously available. They rely in part on the new information described in paragraphs 1 and 2 in Section IV.B., above. To the extent that an expert opinion addresses information that predates Intervenors' August 1, 2018 Petition, that information was no previously "available" because Applicant failed to reference the information to support its conclusions.[166] In addition, the DSEIS references Applicant's 2017 Annual Monitoring Report to explain that Applicant's efforts to reduce salinities in the cooling canal system were substantially worse than Applicant predicted while the Environmental Report did not.[167]

b. Materially different information from what was previously available. 10 C.F.R. § 2.309(c)(1)(ii).

The expert opinions are materially different than what was previously available because they rely on new information and provide evidence that creates a genuine dispute of fact and law

[165] *See Powertech USA, Inc.* (Dewey-Burdock In Situ Uranium Recovery Facility), LBP-13-09, 78 NRC 37, 93 (2013) (while "intervenors must respond to new information when it first becomes available, they need not do so until the information is actually used by the NRC Staff to form its conclusions on impacts in the DSEIS.").

[166] These include FPL 2017b and Tetra Tech 2016.

[167] DSEIS at 3-49.

regarding several conclusions in the DSEIS. At the most basic level, unlike conclusions in the Environmental Report and DSEIS, the expert opinions of Dr. Nuttle and Mr. Wexler provide evidence that ongoing efforts to remediate the hypersaline plume and reduce salinity levels in the cooling canals are not working, will not work, and therefore cannot be relied on to conclude that environmental impacts associated with the cooling canal system will be SMALL or insignificant during the subsequent license renewal period.

Dr. Fourqurean's report, which updates an earlier submission in this proceeding, describes ongoing impacts to seagrass communities adjacent to the cooling canal system. Since his previous submission, he has analyzed seagrass samples for indications of excess phosphorous loadings in surface waters adjacent to the cooling canal system. He only recently presented these results of his seagrass in April 2019. The results show measurable impacts on seagrass that are likely caused by operation of the cooling canal system. The data indicate signs of abnormally high phosphorus levels in areas that hydrological models indicate are impacted by discharges from the cooling canal system via the groundwater pathway. The continued loading of phosphorus leads to an imbalance of nutrients and the eventual death of seagrass, which is a foundation species in essential fish habitat for Biscayne Bay. These new findings contradict conclusions in the DSEIS that impacts on adjacent water bodies have been slight.[168]

Thus, these opinions, jointly or severally, are materially different than information that was previously available. Each opinion presents information that was not previously available and addresses information in the DSEIS that is materially different from what Applicant presented in the Environmental Report.

---

[168] DSEIS at 4-23.

c. Timely Submitted. 10 C.F.R. § 2.309(c)(iii).

Intervenors are submitting this new information pursuant to the April 2, 2019 Scheduling Order. It is therefore timely for this reason alone. The expert opinions are also timely because they rely on the new data described above, which for reasons explained there, are being brought forward in a timely manner.

D. <u>NEW CONTENTION 6-E</u>: The DSEIS Fails to Take the Requisite "Hard Look" at the Impacts on Surface Waters via the Groundwater Pathway.

1. Statement of the issue of law or fact to be raised or controverted (10 C.F.R. § 2.309(f)(1)(i).

The DSEIS violates NEPA's requirement to take a "hard look" at the environmental impacts of the proposed action because its evaluation of impacts on nearby surface waters via the groundwater pathway is inadequate. The DSEIS's conclusion that these impacts will be SMALL is unsupported by and contrary to the evidence and unlawfully substitutes the existence of permit requirements and oversite for a proper NEPA analysis.

2. Brief explanation of the basis for the contention. 10 C.F.R. § 2.309(f)(ii).

When conducting a NEPA analysis of a model's outputs, an agency must take into consideration the environmental implications and impacts of inaccurate results. If an agency bases its decision on an unreliable model that has shown to provide insufficient or incorrect information, then they have failed to employ the required "hard look" imposed by NEPA.[169]

The DSEIS fails to comply with NEPA's "hard look" requirement for precisely this reason. In section 4.5.1.1 of the DSEIS, the NRC Staff conclude that impacts on adjacent surface water bodies via the groundwater pathway from the cooling canal system during the subsequent license renewal term would be SMALL, and therefore new information identified by

---

[169] *Lands Council v. Powell*, 395 F.3d 1019, 1035 (9th Cir. 2005).

the NRC staff is not significant.[170] In reaching this conclusion, however, the NRC staff relied on "the FDEP's and DERM's existing requirements and their continuing oversight of FPL's site remediation efforts,"[171] and this reliance is misplaced.

The DSEIS recognizes that Applicant's efforts to reduce salinity in the cooling canal system through the addition of water pumped from the Upper Floridan aquifer have been unsuccessful.[172] This effort to "freshen" the cooling canal system did not achieve the 34 PSU annual average as predicted by Applicant's modelers. Those modelers, according to the DSEIS, suggested that more favorable climatic conditions should help to achieve the desired salinity.[173] But this statement is not supported by any effort to determine what climatic conditions would be necessary to achieve the salinity target, or whether these necessary climatic conditions will or are likely to exist during the subsequent license renewal period. Without this necessary information, the DSEIS is simply assuming that continued oversight by state and county regulators will produce a solution to address environmental impacts from the cooling canal system. But the mere "existence of permit requirements overseen by another . . . state permitting authority cannot substitute for a proper NEPA analysis."[174]

The new reports and expert opinions provided by Intervenors in support of Contention 6-E, on the other hand, further demonstrate that Applicant's remedial and freshening efforts are not sufficient to address environmental impacts from the cooling canal system now or in the

---

[170] DSEIS at 4-23.

[171] *Id.*

[172] *Id.* at 3-49.

[173] *Id.*

[174] *Sierra Club v. Fed. Energy Regulatory Comm'n*, 867 F.3d 1357, 1375 (D.C. Cir. 2017) (citing *Calvert Cliffs' Coordinating Comm. V. Atomic Energy Comm'n*, 449 F.2d 1109, 1122–23 (D.C. Cir. 1971).

future.[175] Further, recent data demonstrates that the cooling canal system has degraded nearby surface waters and placed vital seagrass communities in jeopardy from phosphorus loadings attributable to the cooling canal system.[176] This is in contrast to information presented in the DSEIS indicating otherwise.[177]

3. The issue raised in the contention is within the scope of the proceeding. 10 C.F.R. § 2.309(f)(iii).

NRC regulations broadly divide the scope of a license renewal proceeding into (1) safety/aging management issues, and (2) environmental impacts. The scope of the required environmental review is specifically established by 10 C.F.R. Part 51 and the GEIS for license renewals.[178] The GSEIS generically resolves certain "Category 1" issues, such that they are "beyond the scope of a license renewal hearing."[179]

Contention 6-E is within the scope of the proceeding. It challenges conclusions about environmental impacts that are not supported by the evidence in the DSEIS. Further, it addresses a "new site-specific issue that has been identified [by the NRC Staff] for Turkey Point,"[180] and therefore the Category 1 prohibition does not apply.

4. The issue raised in the contention is material to the findings the NRC must make to support the action involved in the proceeding. 10 C.F.R. § 2.309(f)(1)(iv).

A contention is "material" to the NRC's duty to make environmental findings if the issue of law or fact it raises "is of possible significance to the result of the proceeding. This means that

[180] DSEIS at 4-23 (describing this as a "new site-specific issue that has been identified for Turkey Point").

there should be some significant link between the claimed deficiency and either the health and safety of the public or the environment."[181] The issue raised in this contention relates directly to the NRC's role in protecting public health and safety and the environment. NEPA imposes requirements on the NRC to ensure environmental protection. The failure to comply with these requirements is material to the findings NRC must make to support relicensing.

5. **Provide a concise statement of the alleged facts or expert opinions which support the petitioner's position on the issue and on which the petitioner intends to rely at the hearing, together with references to the specific sources and documents on which the petitioner intends to rely to support its position on the issue. 10 C.F.R. § 2.309(f)(1)(v).**

See section IV.B, above.

6. **Provide sufficient information to show that a genuine dispute exists on a material issue of law or fact. This information must include references to specific portions of the application that the petitioner disputes and the supporting reasons for each dispute, or, if the petitioner believes that the application fails to contain information on a relevant matter as required by law, the identification of each failure and the supporting reasons for the petitioner's belief. 10 C.F.R. § 2.309(f)(1)(vi).**

Intervenors dispute the NRC Staff's conclusion in section 4.5.1.1 of the DSEIS that impacts on adjacent surface water bodies via the groundwater pathway from the cooling canal system during the subsequent license renewal term would be SMALL.[182]

The NRC Staff's conclusion presumes that compliance with the FDEP Consent Order and the Miami-Dade Consent Agreement will effectively manage salinity conditions in the cooling canal system and therefore prevent adverse impacts on adjacent surface water bodies. The Staff's conclusion, however, is based on numerical modeling that has proven unreliable and

---

[181] *In re Entergy Nuclear Vt. Yankee L.L.C. & Entergy Nuclear Operations*, 60 N.R.C. 548, 556, 2004 NRC LEXIS 247, *16-17 (N.R.C. November 22, 2004).

[182] DSEIS at 4-23.

unsupported assertions by Applicant's modelers that more favorable climatic conditions will resolve the problem.[183] Intervenors offer evidence and expert opinions that Applicant's ongoing efforts to manage salinity issues are not, and will not, reach required target salinity levels or effectively remediate the hypersaline plume.[184]

The DSEIS also describes the existing impacts on adjacent waterbodies via the groundwater pathway as minimal or undetected.[185] Intervenors offer Dr. Fourqurean's report, which demonstrates impacts on water quality in Biscayne Bay via the groundwater pathway are impacting seagrass communities and that continued operation of the cooling canal system is likely to violate narrative water quality standards.[186]

Intervenors have, therefore, provided sufficient information to establish a genuine dispute exists on a material issue of fact or law. The environmental impacts from continued operation of Units 3 and 4 during the subsequent licensing period will not result in SMALL impacts.

E. New Contention 7-E: The DSEIS Fails to Take the Requisite "Hard Look" at Impacts to Groundwater Quality.

1. Statement of the issue of law or fact to be raised or controverted (10 C.F.R. § 2.309(f)(1)(i).

The DSEIS violates NEPA's requirement to take a "hard look" at the environmental impacts of the proposed action because its evaluation of groundwater quality degradation is inadequate. Contention 7-E is limited to those conclusions regarding the "new information" that the NRC Staff identified and evaluated in the DSEIS.[187] The Staff concluded that "site-specific

---

[183] DSEIS at 3-49.

[184] *See* Section IV.B, above.

[185] DSEIS at 4-23.

[186] *See* Section IV.B.5, above.

[187] DSEIS at 4-2.

impacts for this issue at the Turkey point site are MODERATE for current operations, but will be SMALL during the subsequent license renewal term."[188] These conclusions doo not satisfy the "hard look" requirement because they are unsupported by the evidence, contrary to the evidence including evidence provided by Intervenors, and unlawfully substitute the existence of state and county requirements and oversite for a proper NEPA analysis.

2. Brief explanation of the basis for the contention. 10 C.F.R. § 2.309(f)(ii).

NEPA and NRC regulations require a "hard look" at the environmental consequences of the proposed action.[189] Under the NRC's NEPA regulations, this analysis may rely on "conclusions as amplified by the information in the GEIS for issues designated as Category 1.[190] There is no NRC regulation, however, that prohibits Intervenors from challenging new information identified and evaluated by the NRC Staff in a DSEIS with respect to a Category 1 issue.

Here, the DSEIS provides in section 4.5.1.2 that "the NRC staff has concluded that the site-specific impacts for [groundwater quality impacts] at the Turkey point site are MODERATE for current operations, but will be SMALL during the subsequent license renewal term as a result of ongoing remediation measures and State and county oversight, now in place at Turkey point."[191] The NRC Staff's conclusion that impacts to groundwater will be SMALL during the subsequent license renewal term is not supported by the facts and is flawed for the reasons described in Section IV.D.2, above. Because the remediation/freshening efforts are not working, and are not expected to work in the future, the impacts to groundwater will be either

[190] 10 C.F.R. § 51.71(d).

[191] DSEIS at 4-27.

MODERATE or LARGE.

3. The issue raised in the contention is within the scope of the proceeding. 10 C.F.R. § 2.309(f)(iii).

NRC regulations broadly divide the scope of a license renewal proceeding into (1) safety/aging management issues, and (2) environmental impacts. The scope of the required environmental review is specifically established by 10 C.F.R. Part 51 and the GEIS for license renewals.[192] The GSEIS generically resolves certain "Category 1" issues, such that they are "beyond the scope of a license renewal hearing."[193]

Contention 7E is within the scope of the proceeding. It challenges conclusions about environmental impacts that are not supported by the evidence in the DSEIS. Further, it addresses site-specific "new and significant" information that NRC Staff identified and analyzed on its own accord.

4. The issue raised in the contention is material to the findings the NRC must make to support the action involved in the proceeding. 10 C.F.R. § 2.309(f)(1)(iv).

The issue raised in this contention is within the scope of the proceeding for the same reasons as expressed in IV.D.4, above.

5. Provide a concise statement of the alleged facts or expert opinions which support the petitioner's position on the issue and on which the petitioner intends to rely at the hearing, together with references to the specific sources and documents on which the petitioner intends to rely to support its position on the issue. 10 C.F.R. § 2.309(f)(1)(v).

See section IV(B), above.

6. Provide sufficient information to show that a genuine dispute exists on a material issue of law or fact. This information must include references to specific portions of the application that the petitioner disputes and the supporting reasons for each dispute, or, if the petitioner believes that the

[192] *Entergy Nuclear Vermont Yankee, LLC* (Vermont Yankee), LBP-06-20, 64 NRC 131, 148-49 (2006).

[193] *Florida Power & Light Co.* (Turkey Point Nuclear Generating Plant, Units 3 and 4), CLI-01-17, 54 NRC 3, 15 (July 19, 2001); *see* 10 C.F.R. § 51.53(c)(3)(i).

application fails to contain information on a relevant matter as required by law, the identification of each failure and the supporting reasons for the petitioner's belief. 10 C.F.R. § 2.309(f)(1)(vi).

Intervenors contest the NRC Staff's conclusion in section 4.5.1.2 of the DSEIS that new and significant information it identified for groundwater quality impacts from the cooling canal system during the subsequent license renewal term would be SMALL.[194] The NRC Staff concludes that current impacts are MODERATE, the Staff concluded that impacts "will be SMALL during the subsequent license renewal term as result of ongoing remediation measures and State and county oversight, now in place at Turkey Point."[195] For the reasons stated in Section IV.D.6 above, including referenced expert opinions, the Staff's conclusion that impacts will be SMALL during the subsequent license renewal period is unsupported by the evidence, is contrary to the evidence including evidence provided by Intervenors, and unlawfully substitutes the existence of state and county requirements and oversite for a proper NEPA analysis.

Intervenors have, therefore, provided sufficient information to establish a genuine dispute exists on a material issue of fact or law. The environmental impacts from continued operation of Units 3 and 4 during the subsequent licensing period will not result in SMALL impacts on groundwater quality.

F. <u>NEW CONTENTION 8-E</u>: The DSEIS Fails to Take the Requisite "Hard Look" at Cumulative Impacts on Water Resources.

1. Statement of the issue of law or fact to be raised or controverted (10 C.F.R. § 2.309(f)(1)(i).

The DSEIS violates NEPA's requirement to take a "hard look" at the cumulative environmental impacts of the proposed subsequent license renewal for water resources. This

[194] DSEIS at 4-27.

[195] *Id.*

conclusion is unsupported by the evidence, is contrary to the evidence including evidence provided by Intervenors, and unlawfully substitutes the existence of state and county requirements and oversite for a proper NEPA analysis.

2. Brief explanation of the basis for the contention. 10 C.F.R. § 2.309(f)(ii).

The DSEIS violates NEPA's requirement to take a "hard look" at the cumulative environmental impacts with respect to water resources. The evaluation of cumulative impacts is a Category 2 issue that is subject to site-specific analysis. In section 4.16.2.1 of the DSEIS, the NRC Staff concludes that Applicant's recovery well system will be "successful" in retracting the hypersaline plume before the end of the current license period and "result in beneficial impacts on groundwater quality within the Biscayne aquifer. . . ."[196] In addition, the NRC Staff:

> expects the continued operation of the freshening system, combined with proper operation and maintenance of the [cooling canal system], will result in no substantial contribution to cumulative impacts on groundwater quality or associated impacts on surface water quality in Biscayne Bay during the subsequent license renewal period.[197]

The basis for this Contention mirror those in Sections IV.D.2 and IV.E.2, above, which are incorporated here by reference.

3. The issue raised in the contention is within the scope of the proceeding. 10 C.F.R. § 2.309(f)(iii).

NRC regulations broadly divide the scope of a license renewal proceeding into (1) safety/aging management issues, and (2) environmental impacts. The scope of the required environmental review is specifically established by 10 C.F.R. Part 51 and the GEIS for license renewals.[198] Contention 8-E is within the scope of the proceeding. It challenges conclusions

---

[196] DSEIS at 4-116 – 117.

[197] DSEIS at 4-117.

[198] *Entergy Nuclear Vermont Yankee, LLC* (Vermont Yankee), LBP-06-20, 64 NRC 131, 148-49 (2006).

about environmental impacts that are not supported by the evidence in the DSEIS. Further, it addresses a Category 2 issue—cumulative impacts.

4. **The issue raised in the contention is material to the findings the NRC must make to support the action involved in the proceeding. 10 C.F.R. § 2.309(f)(1)(iv).**

The issue raised in this contention is within the scope of the proceeding for the same reasons as expressed in IV.D.4, above.

5. **Provide a concise statement of the alleged facts or expert opinions which support the petitioner's position on the issue and on which the petitioner intends to rely at the hearing, together with references to the specific sources and documents on which the petitioner intends to rely to support its position on the issue. 10 C.F.R. § 2.309(f)(1)(v).**

See section IV.B, above.

6. **Provide sufficient information to show that a genuine dispute exists on a material issue of law or fact. This information must include references to specific portions of the application that the petitioner disputes and the supporting reasons for each dispute, or, if the petitioner believes that the application fails to contain information on a relevant matter as required by law, the identification of each failure and the supporting reasons for the petitioner's belief. 10 C.F.R. § 2.309(f)(1)(vi).**

Intervenors contest the NRC Staff's conclusions in section 4.16.2.1 of the DSEIS regarding cumulative impacts to water resources as referenced in Section IV.F.1, above. These conclusions rely on the success of Applicant's remediation and freshening efforts. As discussed above in Section IV.D.6 and IV.E.6, Intervenors have provided evidence and expert opinions contesting the NRC Staff's reliance on Applicant's remediation and freshening efforts. This evidence, which Intervenors incorporate here by reference, demonstrate a genuine dispute on a material issue of law or fact regarding the cumulative impacts analysis for water resources. The Staff's analysis is unsupported by the evidence, contrary to the evidence including evidence provided by Intervenors, and unlawfully substitutes the existence of state and county requirements and oversite for a proper NEPA analysis.

G. <u>New Contention 9-E:</u> The DSEIS Fails to Take the Requisite "Hard Look" at Impacts to Groundwater Use Conflicts.

1. Statement of the issue of law or fact to be raised or controverted (10 C.F.R. § 2.309(f)(1)(i).

The DSEIS violates NEPA's requirement to take a "hard look" at the environmental impacts of the proposed action because its evaluation of impacts of groundwater use conflicts is inadequate. This conclusion is unsupported by the evidence, is contrary to the evidence including evidence provided by Intervenors, and unlawfully substitutes the existence of state and county requirements and oversite for a proper NEPA analysis.

2. Brief explanation of the basis for the contention. 10 C.F.R. § 2.309(f)(ii).

The DSEIS violates NEPA's requirement to take a "hard look" at groundwater use conflicts from the proposed subsequent relicensing application.

The DSEIS concludes that these impacts will be SMALL for the Biscayne aquifer and MODERATE for the Upper Floridan aquifer during the subsequent license renewal term.[199] This conclusion does not satisfy the "hard look" requirement because it is unsupported by the evidence, is contrary to the evidence, including evidence provided by Intervenors, and unlawfully substitutes the existence of state and county requirements and oversite for a proper NEPA analysis.

3. The issue raised in the contention is within the scope of the proceeding. 10 C.F.R. § 2.309(f)(iii).

NRC regulations broadly divide the scope of a license renewal proceeding into (1) safety/aging management issues, and (2) environmental impacts. The scope of the required environmental review is specifically established by 10 C.F.R. Part 51 and the GEIS for license

[199] DSEIS at 4-33.

renewals.[200] Contention 8E is within the scope of the proceeding. It challenges conclusions about environmental impacts that are not supported by the evidence in the DSEIS. Further, it addresses a Category 2 issue—groundwater use conflicts.

4. **The issue raised in the contention is material to the findings the NRC must make to support the action involved in the proceeding. 10 C.F.R. § 2.309(f)(1)(iv).**

The issue raised in this contention is within the scope of the proceeding for the same reasons as expressed in IV.D.4, above.

5. **Provide a concise statement of the alleged facts or expert opinions which support the petitioner's position on the issue and on which the petitioner intends to rely at the hearing, together with references to the specific sources and documents on which the petitioner intends to rely to support its position on the issue. 10 C.F.R. § 2.309(f)(1)(v).**

See section IV.B, above.

6. **Provide sufficient information to show that a genuine dispute exists on a material issue of law or fact. This information must include references to specific portions of the application that the petitioner disputes and the supporting reasons for each dispute, or, if the petitioner believes that the application fails to contain information on a relevant matter as required by law, the identification of each failure and the supporting reasons for the petitioner's belief. 10 C.F.R. § 2.309(f)(1)(vi).**

Intervenors contest the NRC Staff's conclusion in section 4.5.1.2 of the DSEIS that impacts from the proposed subsequent license renewal on groundwater use conflicts will be SMALL with respect to the Biscayne aquifer and MODERATE with respect to the Upper Floridan aquifer.[201] These conclusions are based on analyses performed by Applicant suggesting that "current and projected groundwater withdrawals associated with [Applicant's] operation of its Biscayne aquifer marine well and recovery well systems would be unlikely to have any

[200] *Entergy Nuclear Vermont Yankee, LLC* (Vermont Yankee), LBP-06-20, 64 NRC 131, 148-49 (2006).

[201] DSEIS at 4-33.

noticeable, adverse impact on any supply wells beyond the confines of the Turkey Point site."[202] The Staff's conclusion is based on modeled projections on drawdown impacts and salinity reductions through operation of the recovery well system.[203] These, in turn, rely on the presumption that Applicant's current groundwater withdrawal rates will remain the same (or lower) and that the ongoing effort to mitigate the hypersaline plume will achieve its objectives. The DSEIS also relies on an unsubstantiated statement that Applicant "does not anticipate the need to withdraw groundwater at a rate exceeding its current permits and/or authorizations during the subsequent license renewal period."[204]

Intervenors contest this conclusion with evidence demonstrating that current effort to mitigate the hypersaline plume and reduce salinity in the cooling canal system to 34 PSU are not working and are unlikely to work in the future.[205] Retraction of the hypersaline plume is not likely to occur without the addition of more wells and increased pumped volumes.[206] Existing analyses referenced in the DSEIS are therefore inadequate to support the Staff's conclusions on groundwater use conflicts because the rate of groundwater withdrawal necessary to hit salinity targets and retract the hypersaline plume is substantially higher than evaluated in the DSEIS.[207] Thus, Intervenors have provided sufficient information in support of this contention to establish a genuine dispute exists on a material issue of fact or law.

NATURAL RESOURCES DEFENSE COUNCIL'S, FRIENDS OF THE EARTH'S, AND MIAMI WATERKEEPER'S PETITION FOR WAIVER OF 10 C.F.R. §§ 51.53(C)(3) AND 51.71(D) AND 10 C.F.R. PART 51, SUBPART A, APPENDIX B

Pursuant to 10 C.F.R. § 2.335(b), Natural Resources Defense Council, Friends of the Earth, and Miami Waterkeeper (together "Intervenors") hereby petition for a limited waiver of 10 C.F.R. §§ 51.53(c)(3) and 51.71(d) and 10 C.F.R. Part 51, Subpart A, Appendix B to the extent the Atomic Safety and Licensing Board ("Board") interprets those regulations to preclude Intervenors from submitting new contentions 6E and 7E challenging the NRC Staff's analysis in the Draft Supplemental Environmental Impact Statement for subsequent license renewal regarding Turkey Point, Units 3 and 4 ("DSEIS")[1] regarding two issues: (1) groundwater quality degradation (plants with cooling ponds in salt marshes) and (2) water quality impacts on adjacent water bodies (plants with cooling ponds in salt marshes).[2] This waiver request is supported by

[1] NUREG-1437, Supp. 5, Second Renewal, "Generic Environmental Impact Statement for License Renewal of Nuclear Plants, Supplement 5, Second Renewal, Regarding Subsequent License Renewal for Turkey Point Nuclear Generating Unit Nos. 3 and 4, Draft Report for Comment" (Mar. 2019) (ML19078A330) ("DSEIS").

[2] By this Petition, Intervenors seek a waiver of any other rules or regulations in addition to 10 C.F.R. § 51.53(c)(3) and 10 C.F.R. Part 51, Subpart A, Appendix B to the extent the Board interprets those regulations to preclude Intervenors from submitting new contentions challenging the analysis in the DSEIS regarding the issues described above.

the attached Declaration of Friends of the Earth's counsel, Kenneth Rumelt ("Rumelt Decl.").

I. INTRODUCTION AND BACKGROUND

On August 1, 2018 and pursuant to 10 C.F.R. § 2.309 and the NRC's Federal Register notice published at 83 Fed. Reg. 19,304 (May 2, 2018), Intervenors submitted a Request for Hearing and Petition to Intervene[3] in the above-captioned matter. To safeguard our and our members' environmental, aesthetic, health-based and economic interests, Intervenors articulated five contentions in the Petition. These contentions addressed various deficiencies in Florida Power & Light Co.'s ("Applicant") Environmental Report, submitted as part of the subsequent renewal license application for Turkey Point Nuclear Generating Station, Units 3 and 4, in Miami-Dade County, Florida.

Following full briefing and a hearing on the admissibility of each contention, the Board on March 7, 2019 issued Memorandum and Order LBP-19-3 granting Intervenors' hearing request ("Order").[4] In that Order, the Board also found that Intervenors had established standing and admitted in part two of the five contentions. The Board then issued, and subsequently amended, a scheduling order that provided Intervenors the opportunity to review initial disclosures provided by the parties and then rely on them to file new and amended contentions.[5]

On April 1, 2019, Applicant filed an appeal of the Order,[6] and on April 26, 2019,

---

[3] Request for Hearing and Petition to Intervene Submitted by Friends of the Earth, Natural Resources Defense Council, and Miami Waterkeeper (Aug. 1, 2018) (ML18212A418) ("Petition to Intervene").

[4] *Fla. Power & Light Co.* (Turkey Point Nuclear Generating Station Units 3 & 4), LBP-19-3, 89 N.R.C. __ (slip op.) (Mar. 7, 2019) ("Order").

[5] Initial Scheduling Order at 3 (establishing the deadline to file new and amended contentions as 45 days following the later of the issuance of the DSEIS or the Initial Disclosures) (Mar. 21, 2019); Order (Granting in Part Intervenors' Joint Motion for Partial Reconsideration of Initial Scheduling Order) (Apr. 2, 2019).

[6] Florida Power & Light Company's Appeal of LBP-19-3 (Apr. 1, 2019) (ML19091A302) ("Appeal"). FPL did not challenge Intervenors' standing before the Commission.

Intervenors opposed the appeal.[7] The NRC Staff agreed with Intervenors that the Board had correctly admitted the contentions.[8] This appeal is pending before the Commission.

In March 2019, NRC Staff issued the DSEIS. Based on the DSEIS, on May 20, 2019, Applicant filed two motions to dismiss Intervenors' contentions as moot.[9] On June 10, 2019, Intervenors opposed these motions,[10] and the NRC Staff supported them.[11] These motions are currently pending before the Board. Intervenors timely filed comments on the DSEIS on May 20, 2019.[12]

Today, Intervenors timely filed amended and new contentions based on the DSEIS. Among other issues, the new contentions concern the NRC Staff's analysis of "new and significant" information for one existing Category 1 issue (groundwater quality degradation (plants with cooling ponds in salt marshes)) and one "new issue" that is neither Category 1 nor 2 (water quality impacts on adjacent water bodies (plants with cooling ponds in salt marshes)).[13]

This Petition for Waiver requests a waiver of 10 C.F.R. §§ 51.53(c)(3) and 51.71(d) and 10 C.F.R. Part 51, Subpart A, Appendix B ("Appendix B") to the extent those the Board interprets those regulations to preclude Intervenors from submitting Contentions 6E and 7E

challenging the analysis in the DSEIS regarding (1) groundwater quality degradation (plants with cooling ponds in salt marshes) and (2) water quality impacts on adjacent water bodies (plants with cooling ponds in salt marshes).

II. STATUTORY AND REGULATORY FRAMEWORK

a. The Scope of a License Renewal Proceeding

A license renewal application review typically implicates issues that fall into one of two broad areas: safety/aging management issues, and public health/environmental impacts. Intervenors' new contentions focus on environmental and public health impacts. The scope of the environmental review is defined by 10 C.F.R. Part 51, the NRC's "Generic Environmental Impact Statement for License Renewal of Nuclear Plants," NUREG- 1437 (May 1996) (the "GEIS"), and the initial hearing notice and order.[14]

Some environmental issues that might otherwise be germane in an initial license renewal proceeding have been resolved generically for all plants and are normally, therefore, "beyond the scope of a license renewal hearing."[15] These "Category 1" issues are classified in 10 C.F.R. Part 51, Subpart A, Appendix B.

b. Standards for Waiver of Application of NRC Rule or Regulation

Under 10 C.F.R. § 2.335(b), any "participant to an adjudicatory proceeding . . . may petition that the application of a specified Commission rule or regulation or any provision thereof . . . be waived or an exception be made for the particular proceeding." Section 2.335(b) further provides that "[t]he sole ground for petition of waiver or exception is that special circumstances

[14] *See, e.g., Vermont Yankee*, 64 N.R.C. at 148–49.

[15] *Florida Power & Light Co.* (Turkey Point Nuclear Generating Plant, Units 3 and 4), CLI-01-17, 54 NRC 3, 15 (July 19, 2001); *see* 10 C.F.R. § 51.53(c)(3)(i). Intervenors explicitly reassert and do not waive their argument that 10 C.F.R. § 51.53(c)(3)'s provision exempting a license renewal applicant's environmental report from addressing Category 1 issues applies only to an initial license renewal, as made clear by the provision's plain terms, and does not apply to a subsequent license renewal proceeding.

with respect to the subject matter of the particular proceeding are such that the application of the rule or regulation (or a provision of it) would not serve the purposes for which the rule or regulation was adopted."[16]

In interpreting § 2.335(b), the Commission has articulated a four-factor test, sometimes referred to as the *Millstone* factors, which a waiver petitioner must satisfy.[17] To set aside a Commission rule or regulation in an adjudicatory proceeding, a petitioner must demonstrate that:

> (i) the rule's strict application would not serve the purposes for which it was adopted;
>
> (ii) special circumstances exist that were not considered, either explicitly or by necessary implication, in the rulemaking proceeding leading to the rule sought to be waived;
>
> (iii) those circumstances are unique to the facility rather than common to a large class of facilities; and
>
> (iv) waiver of the regulation is necessary to reach a significant safety [or environmental][18] problem.[19]

All four *Millstone* factors must be met to justify a rule waiver.[20]

III. ARGUMENT

a. NRC Regulations Do Not Require a Waiver in Order to Challenge the DSEIS's Analysis in This Instance

For the reasons below, the requested waiver is not necessary in order for Intervenors to assert new contentions regarding groundwater quality degradation (plants with cooling ponds in

---

[16] 10 C.F.R. § 2.335(b).

salt marshes) or water quality impacts on adjacent water bodies (plants with cooling ponds in salt marshes).

Groundwater quality degradation (plants with cooling ponds in salt marshes).[21] No NRC regulation prohibits Intervenors from challenging new information identified and evaluated by the NRC Staff in a DSEIS with respect to a Category 1 issue. A waiver, therefore, is not necessary to submit a contention challenging the adequacy of the DSEIS's analysis regarding this issue.[22]

Water quality impacts on adjacent water bodies (plants with cooling ponds in salt marshes).[23] As the NRC Staff recognized in the DSEIS, this issue is neither Category 1 nor Category 2.[24] No NRC regulation prohibits Intervenors from challenging new information identified and evaluated by the NRC Staff in a DSEIS with respect to an issue that is neither Category 1 nor Category 2. A waiver, therefore, is not necessary to submit a contention challenging the adequacy of the DSEIS's analysis regarding this issue.

In an abundance of caution, however, Intervenors submit this Petition requesting the Board to waive application of Sections 51.53(c)(3) and 51.71(d) and Appendix B and any other rules or regulations that the Board interprets to prohibit Intervenors from challenging the adequacy of the DSEIS's analysis (including analysis of new information) regarding these issues.

b. Intervenors Satisfy the Criteria for a Waiver

---

[21] *See* DSEIS at 4-24 to 4-28.

[22] *See* Order at 27 (A DSEIS must "address any new and significant information of which it becomes aware, which might affect the applicability of the Commission's generic Category 1 determinations in the proceeding."); *id.* at n.102 (citing cases); *Deukmejian v. NRC*, 751 F.2d 1287, 1298 (D.C. Cir. 1984) (explaining that "The [NRC's] obligations under NEPA [include] a continuing duty to supplement EISs which have already become final whenever the discovery of significant new information renders the original EIS inadequate").

[23] *See* DSEIS at 4-21 to 4-23.

[24] DSEIS at 4-21 to 4-22.

Petitioners have satisfied the requirements of 10 C.F.R. § 2.335(b) and *Millstone*. Each of the four *Millstone* factors weighs in favor of issuing the requested waiver.

i. Strict Application of the Regulations Would Not Serve the Purposes for Which They Were Adopted (*Millstone* Factor 1)

Application of Sections 51.53(c)(3) and 51.71(d) and Appendix B in this case to preclude Intervenors from asserting Contentions 6E and 7E would unjustifiably prevent Intervenors from challenging the sufficiency of the DSEIS's analysis of new information. The DSEIS's analysis of the two issues referenced above is the first analysis to address this new information in the subsequent license renewal proceeding. Intervenors (and more broadly, the public) have not yet had an opportunity to review or challenge the sufficiency of this information. Interpreting Sections 51.53(c)(3) and 51.71(d) and Appendix B to prevent challenges to analysis of new information would be contrary to NEPA's requirement that agencies "broad[ly] disseminat[e]" information to "permit[] the public and other government agencies to react to the effects of a proposed action at a meaningful time."[25]

Interpreting sections 51.53(c)(3) and 51.71(d) and Appendix B to prevent challenges to analysis of new information would not serve the purposes of the NRC's regulatory scheme providing for generic resolution of certain issues (Category 1) and site-specific resolution of others (Category 2). The requirement to prepare a supplement to a GEIS is intended to ensure that "[w]hen the GEIS and SEIS are combined, they cover all issues that NEPA requires be addressed in an EIS for a nuclear power plant license renewal proceeding."[26] Allowing a petitioner to challenge the adequacy of analysis pertaining to new information regarding a Category 2 issue while preventing such a challenge with respect to new information regarding a

[26] *Massachusetts v. United States*, 522 F.3d 115, 120 (1st Cir. 2008).

Category 1 issue (or, in the case of water quality impacts to adjacent water bodies, an entirely new issue that is neither Category 1 nor 2) would not serve the purposes for which sections 51.53(c)(3) and 51.71(d) and Appendix B were adopted.

ii. Special Circumstances Exist That are Unique to Turkey Point and That Were Not Considered in the Rulemaking Proceeding Limiting the Scope of SEISs Regarding Subsequent License Renewal (*Millstone* Factors 3 and 4)

Turkey Point Units 3 and 4 have a long and well-documented history of impacts to groundwater and surface water caused by the Units' cooling canal system and the hypersaline plume that has resulted from operation of the system.[27] These impacts have resulted in numerous enforcement actions by state and county regulators and the requirement that the Applicant engage in extraordinary measures to mitigate those harms. Turkey Point is the only nuclear generating unit that uses a cooling canal system. No other nuclear generating unit's cooling system has resulted in a hypersaline plume that has migrated through groundwater, threatening local drinking supplies. These impacts are undoubtedly "special circumstances" meriting the requested waiver.

It is beyond dispute that, in either the rulemaking proceeding concerning the scope of environmental review required for a subsequent license renewal or the GEIS prepared for subsequent license renewal proceedings, the NRC did not consider issues of salinity in cooling canals or the possibility that operation of a cooling canal system might result in a hypersaline plume migrating through surrounding groundwater. The DSEIS itself recognized that the GEIS "did not consider how a nuclear power plant with a cooling pond in a salt marsh may indirectly impact the water quality of adjacent surface water bodies via a groundwater pathway" and that

[27] *See* DSEIS at 3-46 to 3-49, 3-56 to 3-73.

the issue "constitutes a new, site-specific issue with respect to Turkey Point."[28] Special circumstances exist that are unique to Turkey Point and that were not considered in either the rulemaking proceeding limiting the scope of an environmental review for subsequent license renewal proceedings or the GEIS issued for subsequent license renewal proceedings.

iii. Waiver is Necessary to Reach a Significant Environmental Issue (*Millstone* Factor 4)

Waiver is necessary to permit Intervenors to raise new information regarding the environmental impacts of the hypersaline plume on groundwater and adjacent surface water—undoubtedly a significant environmental issue.[29] The hypersaline plume poses a significant threat to surrounding natural resources. The DSEIS recognizes that the saltwater interface has advanced inland west and north from Turkey Point at an average rate of 460 feet per year, threatening the drinking water source for a large portion of South Florida.[30] To mitigate these impacts, Applicant has been forced to take extensive (but largely unsuccessful) measures to halt the advance of the hypersaline plume. Waiver of these regulations is necessary to reach this significant environmental issue because Intervenors have no other avenue by which it can assert that the DSEIS's analysis of new information is insufficient.

IV. CONCLUSION

For these reasons, Intervenors respectfully request a waiver of 10 C.F.R. §§ 51.53(c)(3) and 51.71(d) and 10 C.F.R. Part 51, Subpart A, Appendix B to the extent the Board interprets those regulations to preclude Intervenors from submitting new contentions challenging the analysis in the DSEIS regarding two issue: (1) groundwater quality degradation (plants with

---

[28] DSEIS at 4-21.

[29] As stated *supra* at Section III.a, Intervenors contend that a waiver is not necessary to raise these issues.

DECLARATION OF E.J. WEXLER IN SUPPORT OF
THE FRIENDS OF THE EARTH, NATURAL RESOURCES DEFENSE COUNCIL &
MIAMI WATERKEEPER

I, E.J. Wexler, P.Eng. (Ontario), being competent to provide this Declaration, declare as follows:

1. I am a hydrogeologist with over expertise in groundwater modeling. I hold a Masters' Degree in Civil Engineering, a M.S. in Earth Sciences, and a B.E. in Civil Engineering. Since 2002, I have been Director of Modeling Services for Earthfx, Inc., where I lead a team of surface water and groundwater modelers. A copy of my curriculum vitae is attached as Attachment A.
2. I have been retained to offer expert opinions on behalf of Intervenors in this proceeding. I am offering an updated version of my June 24, 2019 report in this matter to remove information that may be subject to copyright.
3. The facts in my Expert Report are true and correct to the best of my knowledge, and the opinions expressed in my Expert Report are based on my best professional judgment.

I declare under penalty of perjury under the laws of the United States that the foregoing is true to the best of my knowledge.

Eliezer J. Wexler

Executive Summary

Evaporation from the Florida Power and Light (FPL) Cooling Canal System (CCS) has increased the salinity of the CCS water to values as high as 90 practical salinity units (PSU) or almost three times that of seawater. This hypersaline water has seeped out through the unlined canals, entered the underlying Biscayne Aquifer, and due to its higher density, the hypersaline water has moved to depth in the aquifer and formed a large body of hypersaline groundwater. Field studies have confirmed that high salinity groundwater has migrated westward of the CCS. Results of recent groundwater modeling analyses by Tetra Tech (2018) have also confirmed that migration of saline water from the CCS over a 45 year period was the prime contributor to the presence of a large body of hypersaline groundwater and observed changes in the location of the freshwater/saltwater (FW/SW) interface.

Under a 2016 consent order between FPL and the Florida Department of Environmental Protection (FDEP), FPL is required to maintain the average annual salinity of the CCS at or below 34 PSU, halt the westward migration of hypersaline water from the CCS, and reduce the westward extent of the hypersaline plume to the L-31E Canal within 10 years. A recovery well system consisting of 10 deep groundwater extraction wells has been installed along the western edge of the CCS with the intent of retracting the hypersaline water. The draft supplemental environmental impact statement (SEIS) has accepted analyses by Tetra Tech (2016a) that the recovery system will achieve this objective.

It was noted that the Tetra Tech analyses assumed that the CCS would be maintained at 34 PSU for the duration of the recovery period. New water quality information shows that FPL was unable to achieve freshening (i.e., reducing average salinity) within the CCS despite the addition of an average of 12.8 million gallons per day (MGD) of brackish water from the Upper Floridan Aquifer to the CCS from November 2016 to May 2017, salinities in the CCS did not go down to 35 PSU (FPL 2017a); rather, average salinity concentrations in the CCS were 64.9 PSU in May 2017 (FPL 2017b). My analysis using the Tetra Tech model shows that without freshening the CCS, the recovery system will not be able to meet the target of retracting the hypersaline water. My analysis also points out other limitations in the Tetra Tech analyses and the reliability of the model predictions. We also present results from a new, independently developed model that examines processes within the CCS and indicates that freshening of the CCS will be difficult to achieve with the volumes of water currently being used and the locations selected for adding the water.

My opinions are based on data regarding the hydrogeology, hydrology, and water quality of both surface water and groundwater in the South Dade area available to me as of May 2019, and on my prior numerical modeling studies conducted by myself in the vicinity of the CCS and on reviews of modeling work prepared by Tetra Tech on behalf of FPL.

Background:

Cooling Canal System and Hypersaline Plume

The Florida Power and Light (FPL) Cooling Canal System (CCS) is a “closed loop” system that originally contained seawater from Biscayne Bay. The canals are not lined and the system interacts with the underlying groundwater. Inputs into the canals include treated process water, rainfall, stormwater runoff, and groundwater infiltration. Losses include evaporation and seepage from the canals. Over time, evaporation has increased the salinity of the CCS water to values as high as 90 practical salinity units (PSU) or almost three times that of seawater. During the same period, this water entered the underlying Biscayne Aquifer. Due to its higher density, the hypersaline water has moved to depth in the aquifer and formed a body of water with elevated concentrations that has migrated westward of the CCS. The extent of the hypersaline water in the Biscayne Aquifer has been confirmed by water quality samples from monitoring wells and electromagnetic mapping (EM) surveys (e.g., FPL, 2018, Appendix G).

A consent order (Florida Department of Environmental Protection, 2016) between FPL and the FDEP requires FPL to add water from alternative sources to maintain the average annual salinity of the CCS at or below 34 PSU, halt the westward migration of hypersaline water from the CCS, and reduce the westward extent of the hypersaline plume to the L-31E Canal within 10 years. FPL constructed five wells to extract up to 15 MGD of brackish water (2.5 PSU) from the Floridan Aquifer with the bulk of the water used to freshen the CCS (i.e. reduce average CCS salinity). A groundwater recovery well system consisting of 10 deep extraction wells, located along the western edge of the CCS, was constructed and went into operation in May 2018. The wells extract water near the base of the Biscayne Aquifer at a permitted rate of 14 MGD. The water is disposed of through a deep injection well.

Modeling the Extent of the Hypersaline Plume

A key aspect of the draft supplemental environmental impact statement (SEIS), from a groundwater perspective, is the discussion of the results of groundwater modeling studies conducted related to (1) assessing the historic impacts of the CCS on the water quality in the Biscayne Aquifer and (2) the likely effectiveness of proposed recovery wells in retracting the zone of hypersaline water back to the CCS and retracting the freshwater/saltwater (FW/SW) interface back from its current position.

With respect to historic impacts, the draft SEIS cites Hughes et al. (2010), who evaluated the combined effects of salinity and temperature and other variables associated with operation of the CCS and demonstrated that hypersaline water would move downward beneath the CCS to the bottom of the of the Biscayne Aquifer in a period ranging from days to several years. The modeling also indicated that the inland migration of the FW/SW interface, to the west of the CCS, was closely related to high total dissolved solids (TDS) levels. The Hughes et al. (2010) model was mainly intended to demonstrate the likely fate of hypersaline discharge from the CCS and did not attempt to relate the movement to any other factors affecting the FW/SW interface in the area. Tetra-Tech adopted the Hughes et al. (2010) model and used it in early analyses (prior to 2016) of hypersaline water from the CCS.

I independently developed and calibrated a three-dimensional density-dependent groundwater flow/solute transport model for the area surrounding a rock quarry close to the FPL site. A significant effort was directed to recreating the hydrologic history of the South Dade area starting in 1945 to the present and on representing the migration of the FW/SW interface over time. There was also an effort made to incorporate measured values of aquifer properties based on U.S. Geological Survey (USGS) studies (e.g. Fish and Stewart, 1991 and Merritt, 1997). While the primary focus of the modeling effort was to examine the impact of the quarry development on the position of the FW/SW interface, simulations showed that since its inception, the CCS was the key influence on the migration of the freshwater/saltwater in the Model Lands area. As salinities in the CCS have increased over time, there was a corresponding westward migration of the FW/SW toward the quarry. This more detailed work confirmed the results of the Hughes et al. (2010) simulations and was later shown to be in good agreement with field data from wells and EM surveys.

The Tetra Tech (2016a) model closely followed the implementation of my earlier work but differed in critical areas that limit its effectiveness as a predictive tool especially in the western part of their model. I conducted a critical review of the Tetra Tech (2016a) model. In particular, it was noted that the Tetra Tech (2016a) model did not honor observed regional values but applied local values from on-site testing uniformly across the South Dade area. Changes were made to improve the model calibration as documented in subsequent reports (Tetra Tech, 2016b, 2017c) but these are not cited in the draft SEIS and still did not did not honor observed regional values. Updates to the recovery well analysis made using the revised models were not conducted or have not been presented. We have focussed our analysis on the adequacy of the model and the reliability of the model in light of new information on water quality in the study area.

Finally, Tetra-Tech updated the model for a 2018 "attribution analysis". Additional changes were made with significant modifications to the hydraulic conductivity values used in the model. Model results demonstrated that the CCS was the prime contributor to changes in the location of the FW/SW interface, confirming my earlier results. Updated analyses of the effectiveness of the recovery wells based on the Tetra Tech (2018) model were not conducted or have not been presented.

Analysis of Recovery Wells in Light of New Evidence.

A common point in the modeling analyses discussed above, especially the new 2018 attribution analysis, is that the extent of the hypersaline plume is the result of about 45 years of seepage from a very large contributing body (the CCS). For remediation efforts to be successful, they should be based on a similar spatial scale and time frame. Retracting the hypersaline plume in a highly permeable aquifer with a limited number of wells in a 10 year period will be a considerable challenge. The draft SEIS, however, simply accepts the FPL statement that "that operation of its recovery well system will achieve retraction of the plume back to the FPL site (i.e., Turkey Point site) boundary within 10 years, as required by the 2016 consent order with FDEP". This conclusion was based on the Tetra Tech (2016a) modeling of a recovery system with 10 deep wells spaced about 4000 ft apart along L-31 west of the site. The modeling results for the recovery well system predicted retraction of the westward plume to the edge of the CCS by about 5 years and complete retraction within 10 years, with minor aquifer drawdown impacts.

The Tetra Tech (2016a) modeling has some serious flaws that are especially critical in light of new water quality information showing that FPL was unable to achieve freshening of the CCS even with the addition 10 to 15 MGD of brackish water from the Floridan aquifer. [Specifically, new water quality information shows that FPL was unable to achieve freshening of the CCS even with the addition of an average of 12.8 MGD of Upper Floridan aquifer brackish water to the CCS from November 2016 to May 2017, salinities in the CCS did not go down to 35 PSU (FPL 2017a), at the end of May 2017, average salinity concentrations in the 25 CCS were 64.9 PSU (FPL 2017b)]. Most significantly, the Tetra Tech (2016a) simulations of the recovery wells included the assumption that TDS in the CCS would be brought down to 35 PSU at the outset of recovery well operations.

To test the effect of not being able to achieve the 35 PSU target, I first conducted separate simulations with and without the remedial pumping using the Tetra Tech (2017) model (the most recent model files for Alternative 3D provided by FPL for review). The results indicated that much of the change in the area west of the CCS was due to freshening of the CCS rather than the pumping.

Additional simulations with the FPL model and no freshening of the CCS (i.e. the CCS remains at 60 PSU) resulted in hypersaline water continuing to move west of the CCS. Results showing the simulated relative chloride levels in Layer 8 (the "Lower High Flow zone" in the Tetra Tech (2016a) model) for the baseline conditions (pumping and freshening) are shown in Figure 1. The 1.0 relative salinity contour represents seawater salinity and is mostly near the CCS boundary. Results without freshening are shown in Figure 2 and show the 1.0 contour as much as 12,000 ft west of the CCS. These results indicate that, without being able to achieve freshening at the current time or in the future, the retraction of the hypersaline water is not likely to occur without the addition of more wells and increased pumped volumes. More analysis would be required to determine whether the additional withdrawals would have harmful effects and the additional water may, therefore, be unavailable. Thus despite the considerable lead time cited in the draft SEIS, groundwater remediation and improvement may not be possible prior to the subsequent period of extended operations without significant changes to the CCS operations and recovery well system.

It should be also be noted that the FPL models (Tetra Tech, 2016a, 2016b, and 2017) showed that pumping would not pull the hypersaline plume back in the deeper layers (e.g., model Layer 10 near the aquifer base) within the 10 year period despite that pump screens being located in the deep layers. Figure 3 shows the simulated concentrations in the Layer 10 after 10 years of pumping and freshening. The concentrations within and west of the CCS remain above sea water concentrations. These results indicate again that meeting the 2016 consent order with FDEP is not achievable with the number of wells and pumping volumes proposed.

As was noted above, the Tetra Tech (2017) model was changed significantly for the 2018 attribution assessment but the recovery wells analysis was not updated or reported. If this model represents an improved understanding of the area, there is a need to verify that the proposed recovery system can meet its design objectives.

In particular, the horizontal hydraulic conductivity values have been changed from the previous (2017 update) model, with the newer values being generally higher. The spatial distribution of the high and low hydraulic conductivity values within Layer 8 (the most permeable layer) has been altered significantly. The zone of high hydraulic conductivity in the southwest part of the CCS (centered between TPGW-2 and TPGW-17) (shown in Figure 4) has been removed and relatively low values are assigned below the CCS and to the west in the 2018 model (Figure 5). This results in reduced westward migration of hypersaline water in the 2018 analyses. Layer 8 contributes the most to the transmissivity of the Fort Thompson Formation (the high permeability unit forming the principal part of the Biscayne Aquifer) and significant changes in transmissivity of this unit can be seen. Figure 6 shows the transmissivity of the Fort Thompson Formation (model Layers 3 to 11) in the Tetra Tech (2017) model (Figure 7), in thousands of ft^2/d with a zone of high transmissivity within the southwestern part of the CCS. Figure 8 shows the transmissivity of the Fort Thompson Formation with the high transmissivity zone absent. Transmissivities west of Card Sound Road are generally higher in the 2018 model but still well below the observed values (e.g., Fish and Stewart, 1991 or Hughes and White, 2014).

The spatial distributions of hydraulic conductivity in the 2017 and 2018 Tetra Tech models are based on the use of the pilot point technique for automated parameter estimation, a technically advanced and accepted method. It should be recognized that the method can easily accommodate known values in the interpolation of hydraulic conductivities, such as data from Fish and Stewart and other sources, but this was not done by Tetra Tech. As well, the number of pilot points used (16) is extremely small for a study area of this size and with the known high degree of spatial heterogeneity. This partly explains the large shifts in property values between model versions. These deficiencies need to be examined further as they can compromise the effectiveness of the model to be used in the analysis of recovery wells.

The earlier model (Tetra Tech, 2016a) did not simulate ET processes directly. Instead, a net recharge was calculated as the recharge rate minus ET. However, recharge rates were set to zero when ET exceeded recharge (Tetra Tech, 2016a). This negated the effect of groundwater ET processes that, at times, reversed the natural eastward flow in the Model Lands area and facilitated the westward movement of hypersaline water from the CCS. The 2018 model now simulates groundwater ET when ET exceeds recharge. The analysis of recovery well performance should be updated to see if the retraction of the plume can still be achieved in light of the increased ET rates.

Recharge and evaporation rates were set to zero over the CCS in the Tetra Tech (2016a) model and these processes are not simulated. Instead, the water levels and concentrations in the CCS were specified as boundary conditions based on external water budget model calculations, a process that can lead to inconsistencies. As well, because of the large size of the CCS, the linear geometry of the berms and canals, and the placement of flow restriction measures, mixing of water in the CCS may not be uniform, as is assumed in the Tetra Tech model.

As part of this review, I developed a more refined model of the study area that attempted to better represent flow in the CCS and the effect of evaporation and adding water to the CCS. Key features of the model are described in a draft report (Earthfx, 2019). Simulations of future conditions were conducted with flow in the CCS, evaporation, and the introduction of 10 MGD of Floridan water and 14 MGD from the recovery wells. The recirculation of water option was used in SEAWAT to estimate the concentrations of the recovery well water and to represent the recirculation of water through the plant. Concentrations vary over time from the starting conditions (about 1.71 relative salinity (60 PSU)) and reach a relative equilibrium by 2028. Simulated concentrations are shown in Figure 8 and indicate that placement of the Floridan and recovery water along the west side of the CCS has helped in preventing movement of the hypersaline water over most of the western boundary of the CCS but the bulk of the CCS is still hypersaline and a breakout zone occurs in the northeast corner due to the higher water levels in that area.

While the Earthfx (2019) model differs from the Tetra Tech (2016a) model, the results indicate that more analysis is required to understand the dynamics of CCS and the effects of where freshening water is applied. The current spreadsheet water balance model used is in the FPL environmental report is not adequate for this analysis.

Figures

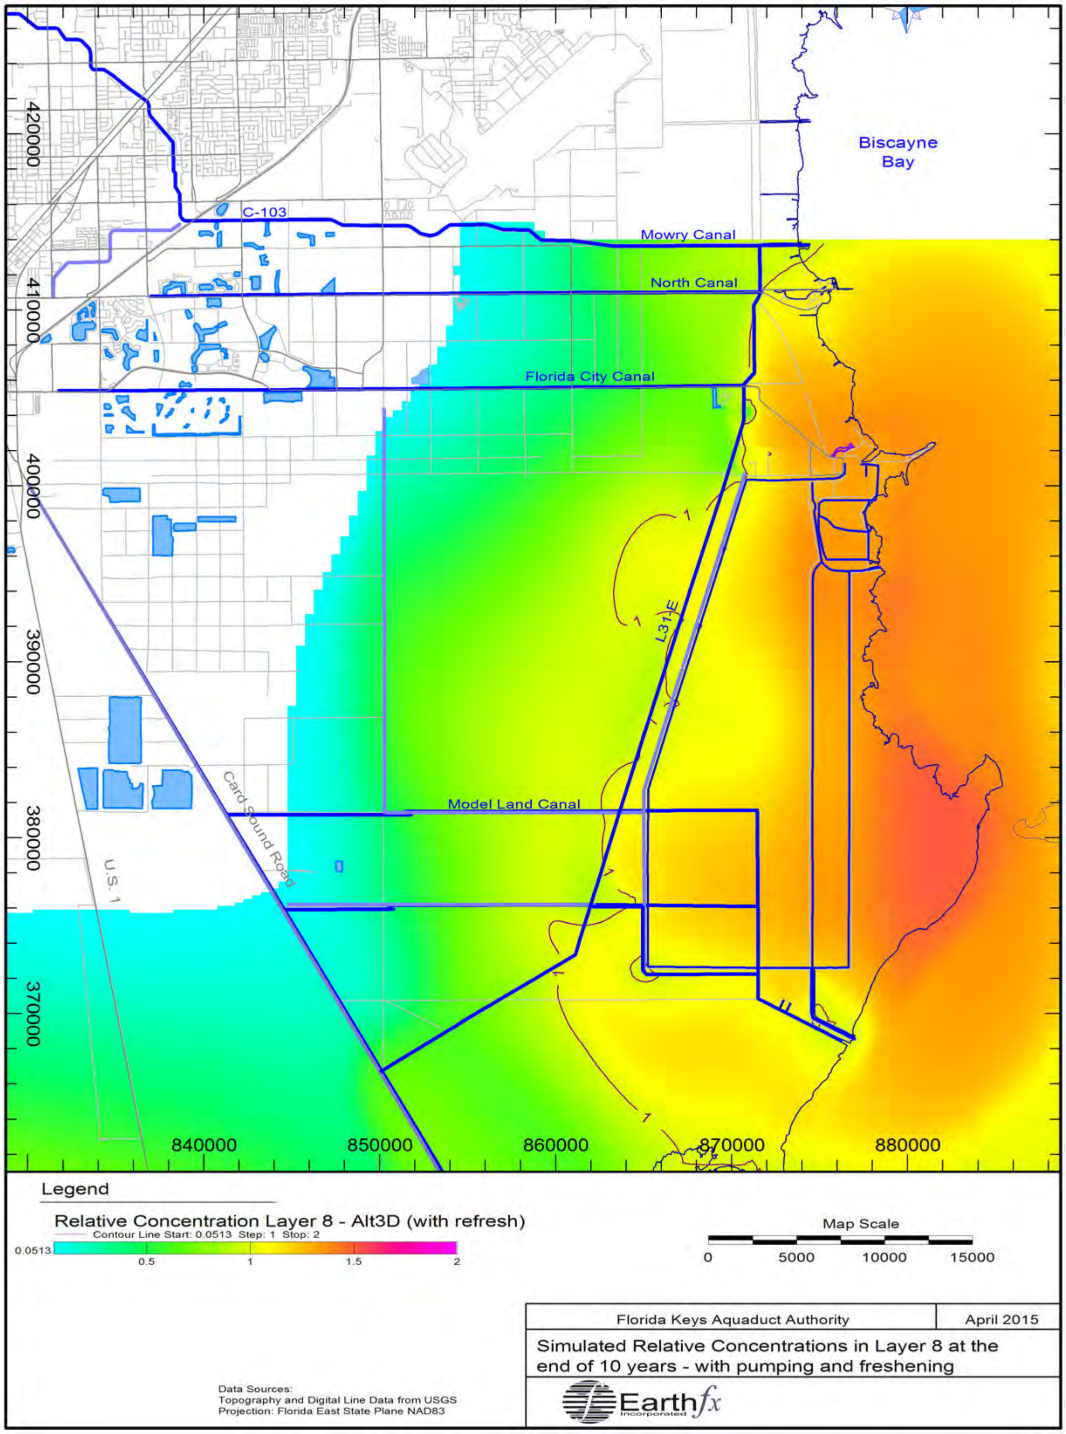

Figure 1: Simulated relative salinity values (with 1.0 equivalent to seawater) in Tetra Tech (2017) model Layer 8 (the "Lower High Flow zone") after 10 years of pumping the recovery wells and with freshening of the CCS to 35 PSU (relative salinity of 1). Note that the 1.0 contour has generally drawn close to the CCS boundary, that the relative salinity beneath the CCS is still above 1.0, and that there is a zone of higher salinity outside the northwest corner of the CCS.

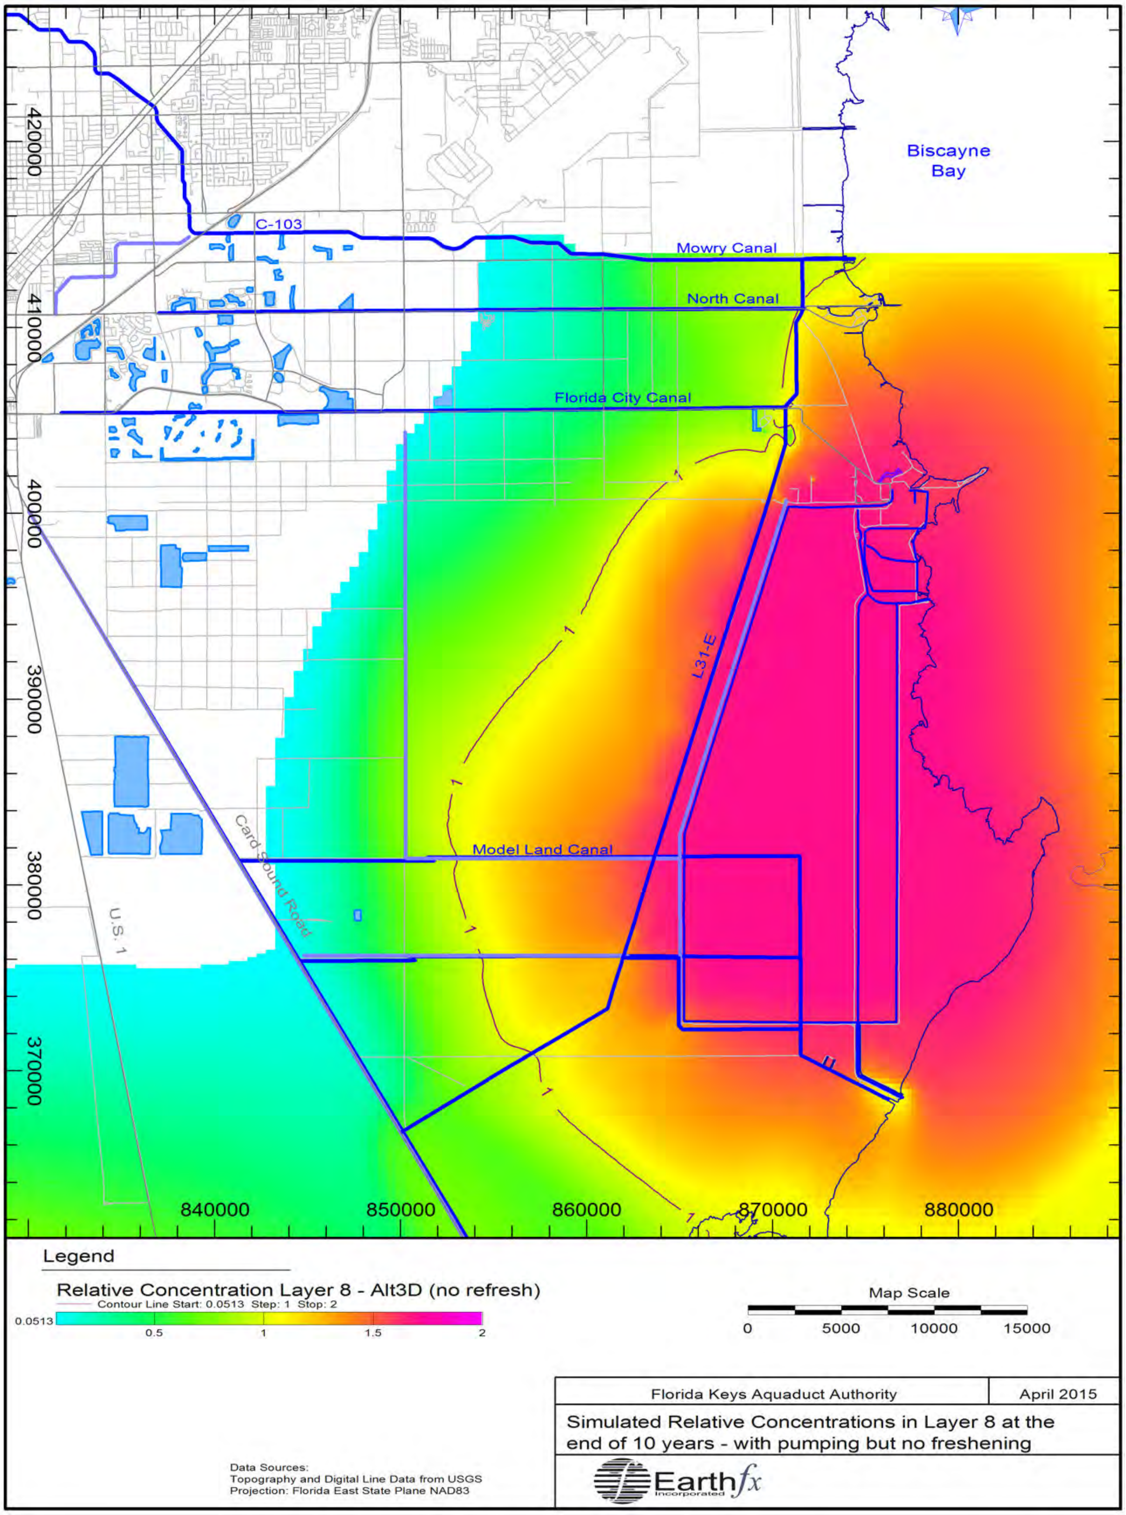

Figure 2: Simulated relative salinity values (with 1.0 equivalent to seawater) in Tetra Tech (2017) model Layer 8 (the "Lower High Flow zone") after 10 years of pumping the recovery wells and with the CCS at 60 PSU (relative salinity of 1.71). Note that the 1.0 contour is up to 12,000 ft west of the CCS boundary.

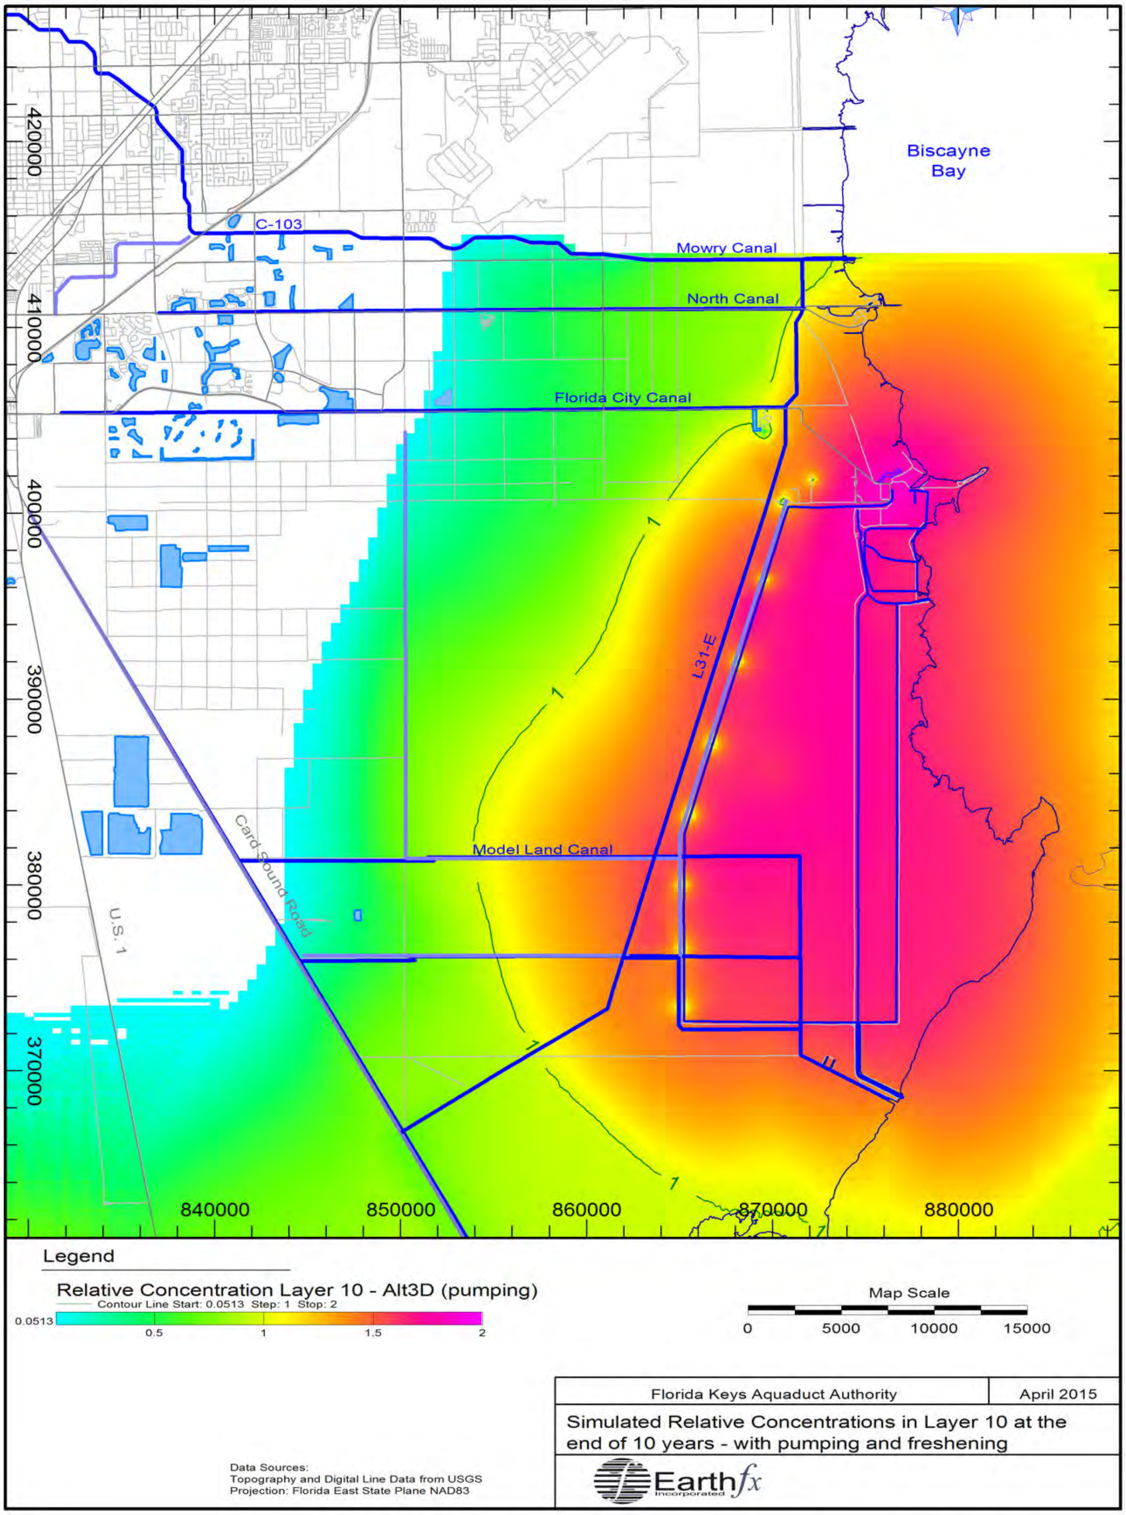

Figure 3: Simulated relative salinity values (with 1.0 equivalent to seawater) in Tetra Tech (2017) model Layer 10 (near the base of the Biscayne Aquifer) after 10 years of pumping the recovery wells and with the CCS at 35 PSU (relative salinity of 1.0). Note that the 1.0 contour is located over 10,500 ft west of the CCS boundary and that the relative salinity beneath the CCS is still above 60 PSU (relative salinity of 1.7).

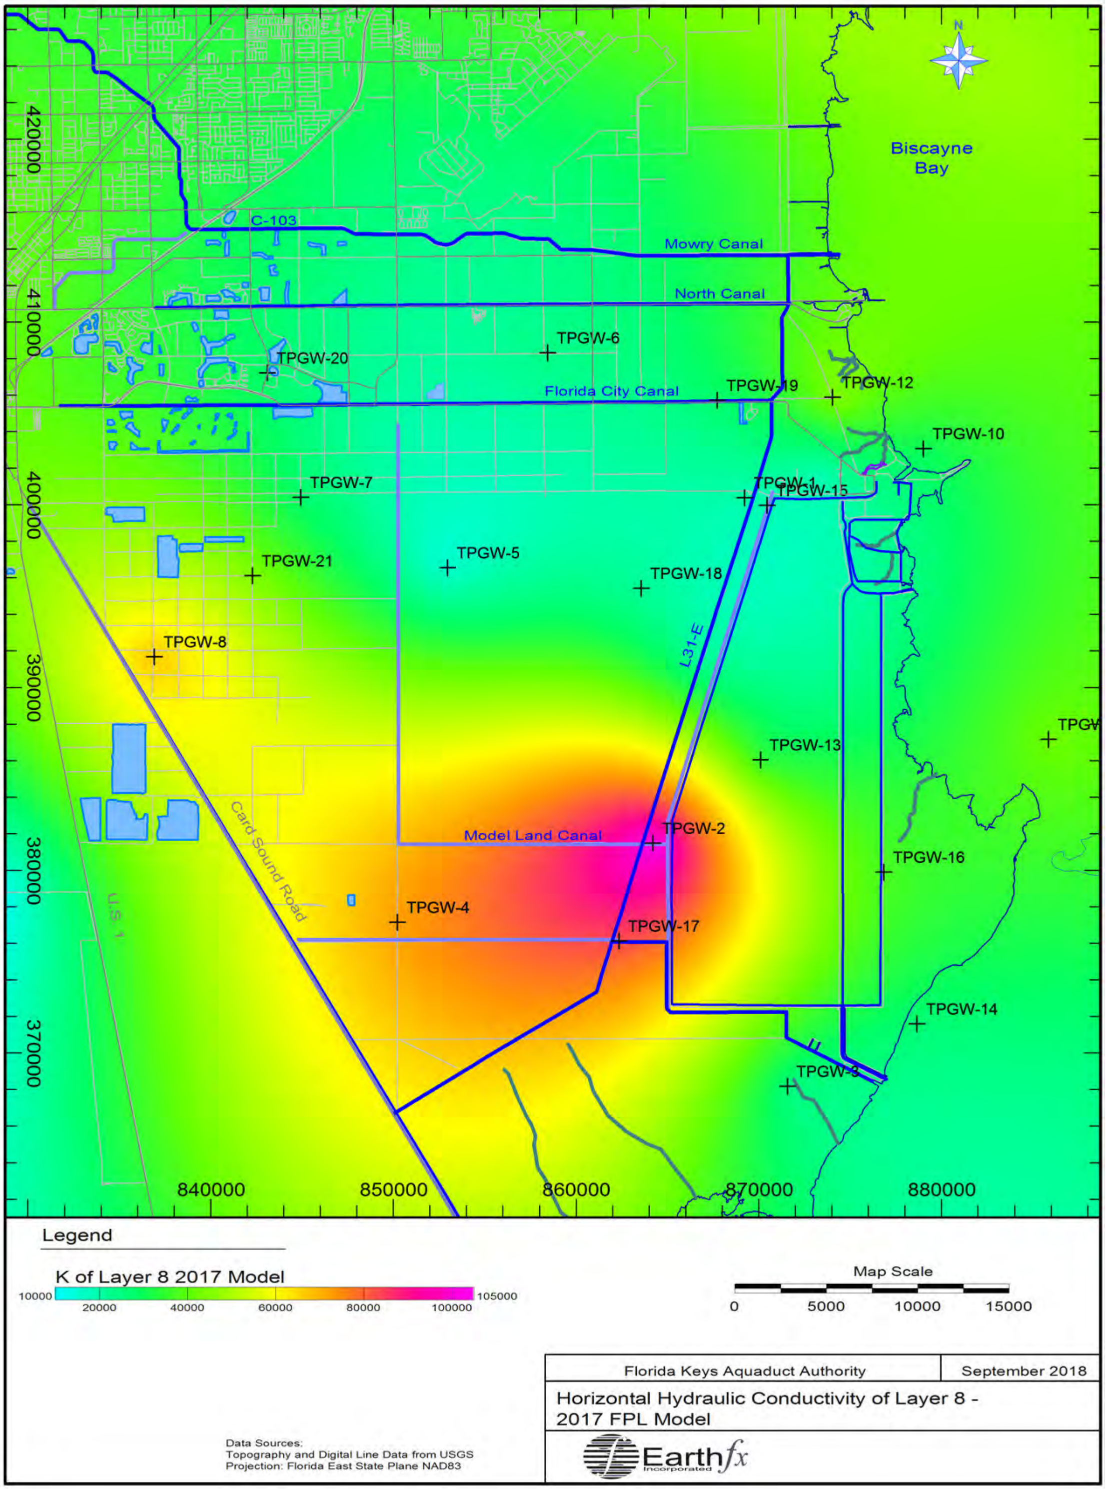

Figure 4: Hydraulic conductivity values assumed for Layer 8 (Lower High Flow Zone) in the Tetra Tech (2017) model.

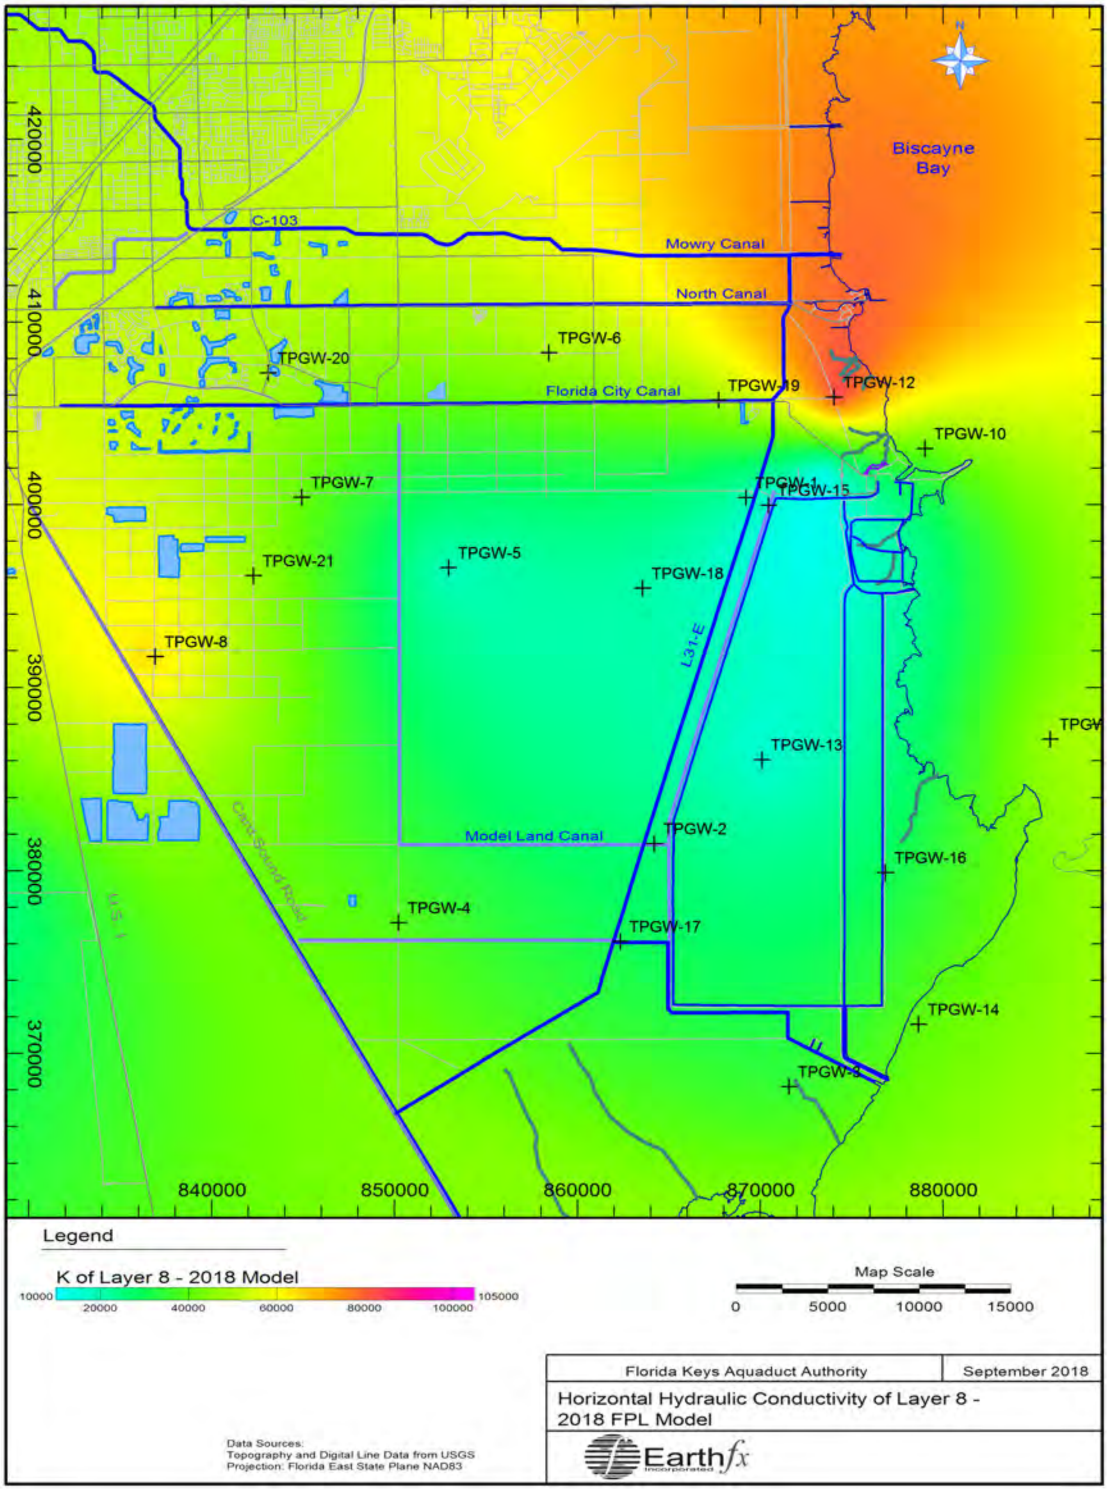

Figure 5: Hydraulic conductivity values assumed for Layer 8 (Lower High Flow Zone) in the Tetra Tech (2018) model.

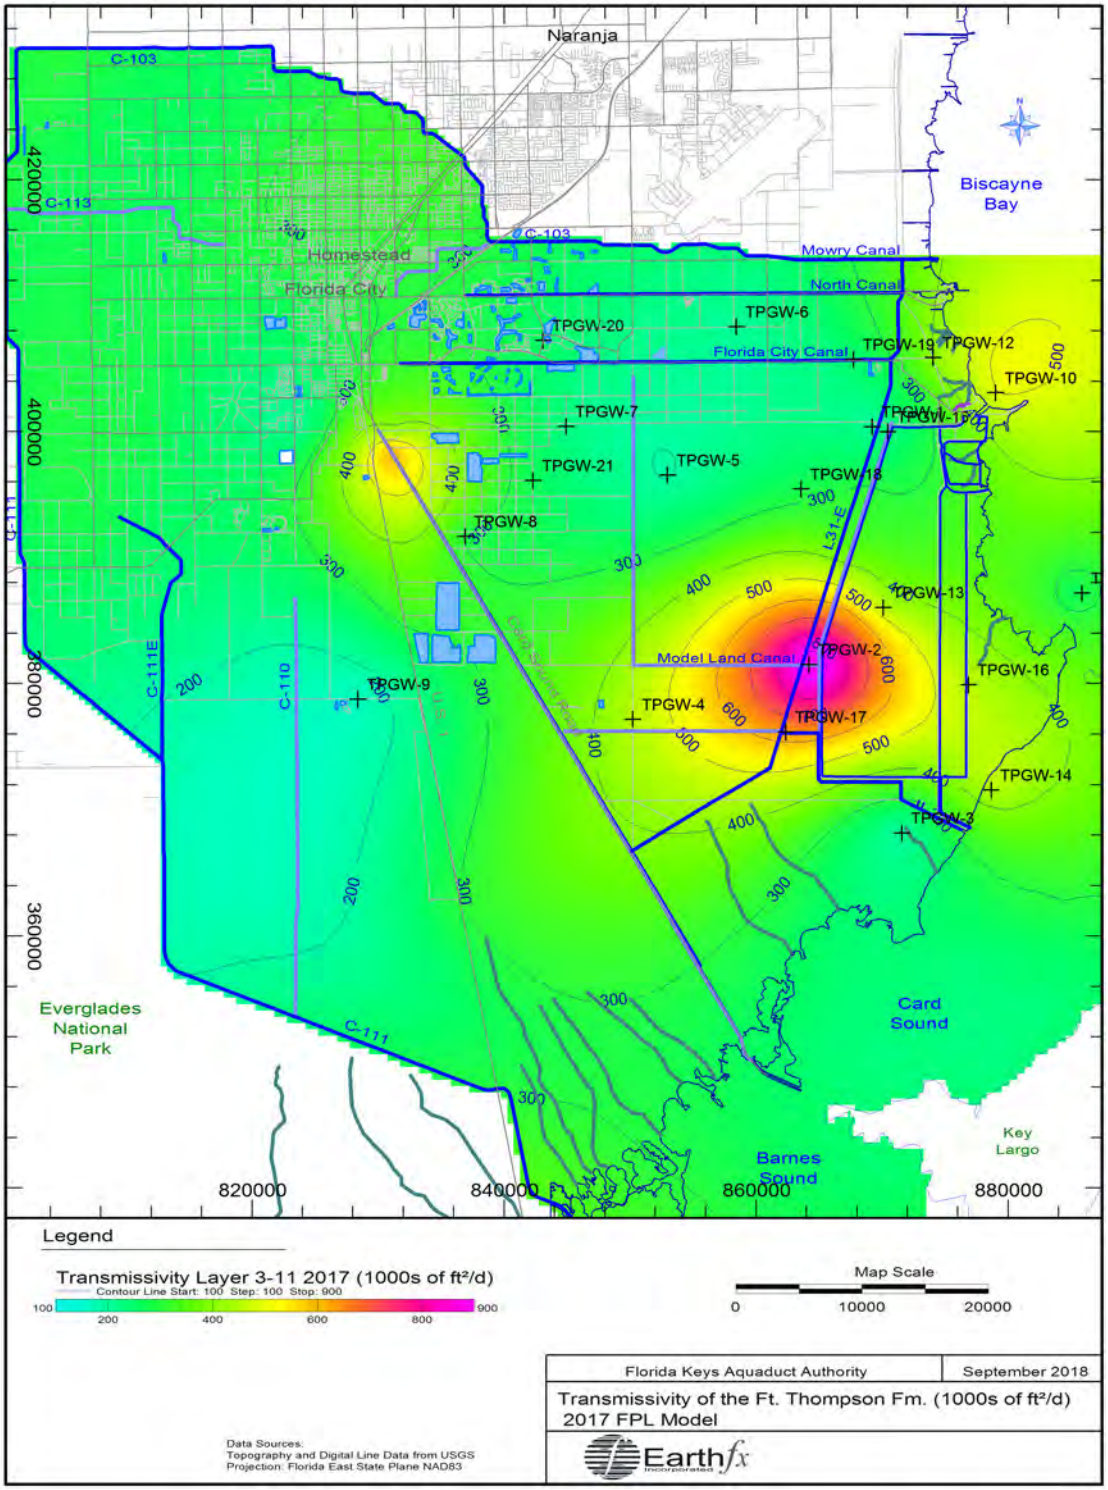

Figure 6: Calculated transmissivities for the Ft. Thompson Formation using the hydraulic conductivity values assumed for Layers 3 to 11 in the Tetra Tech (2017) model.

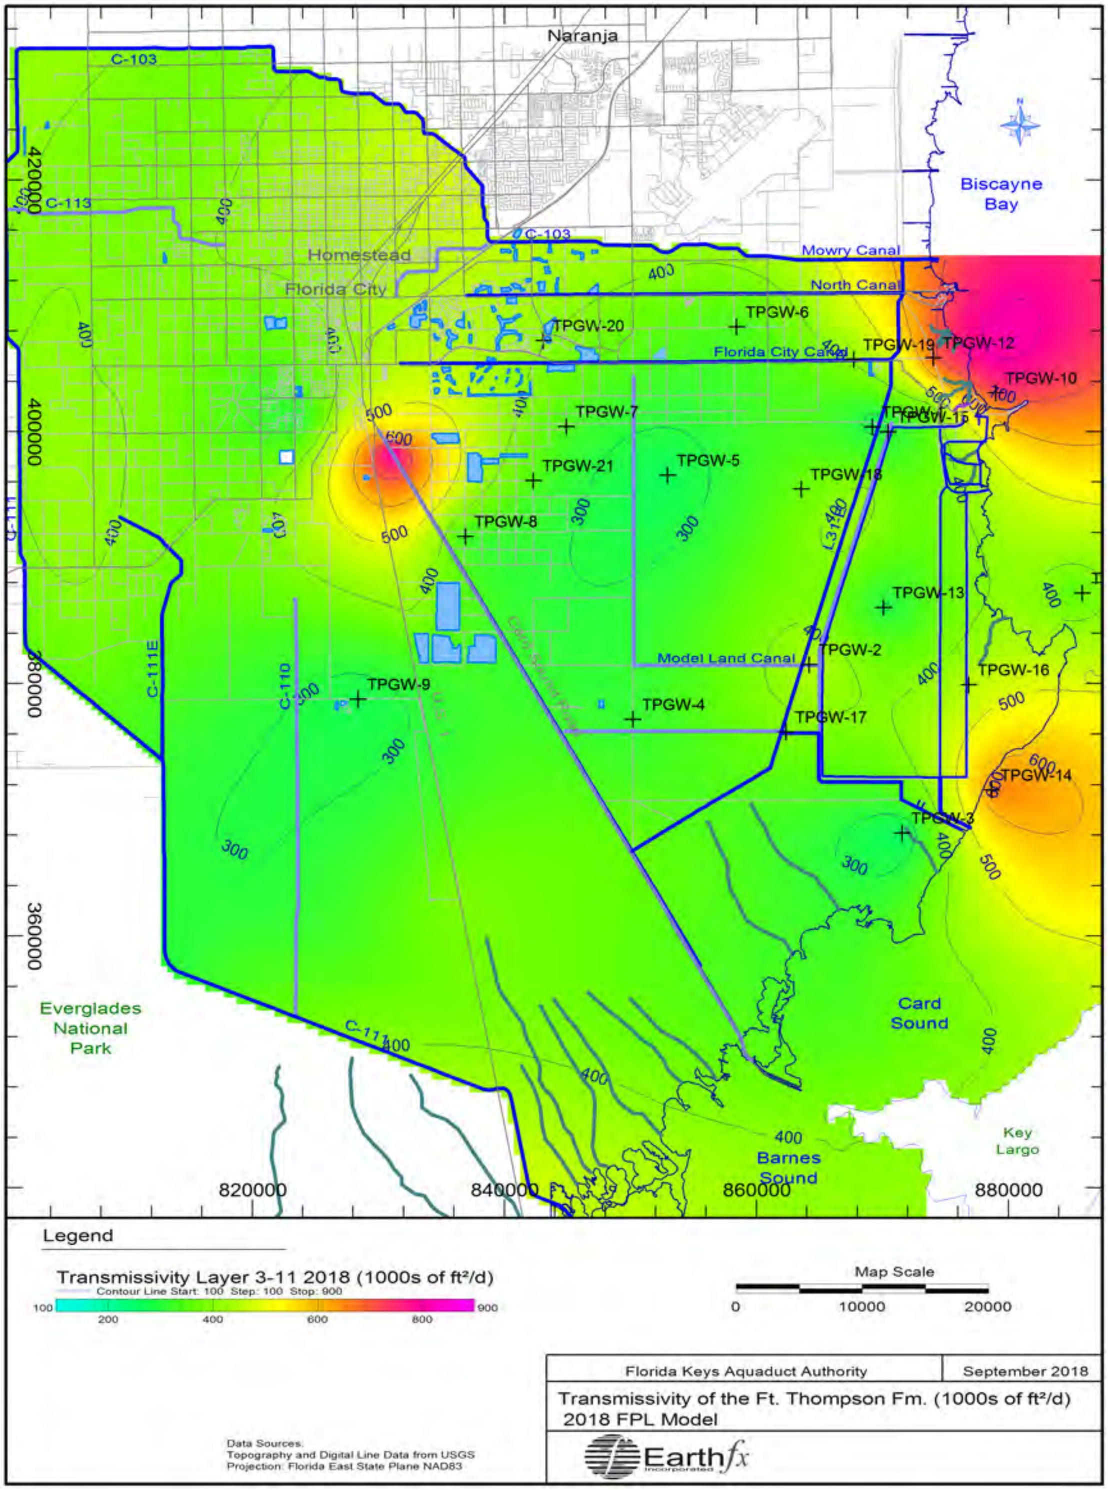

Figure 7: Calculated transmissivities for the Ft. Thompson Formation using the hydraulic conductivity values assumed for Layers 3 to 11 in the Tetra Tech (2018) model.

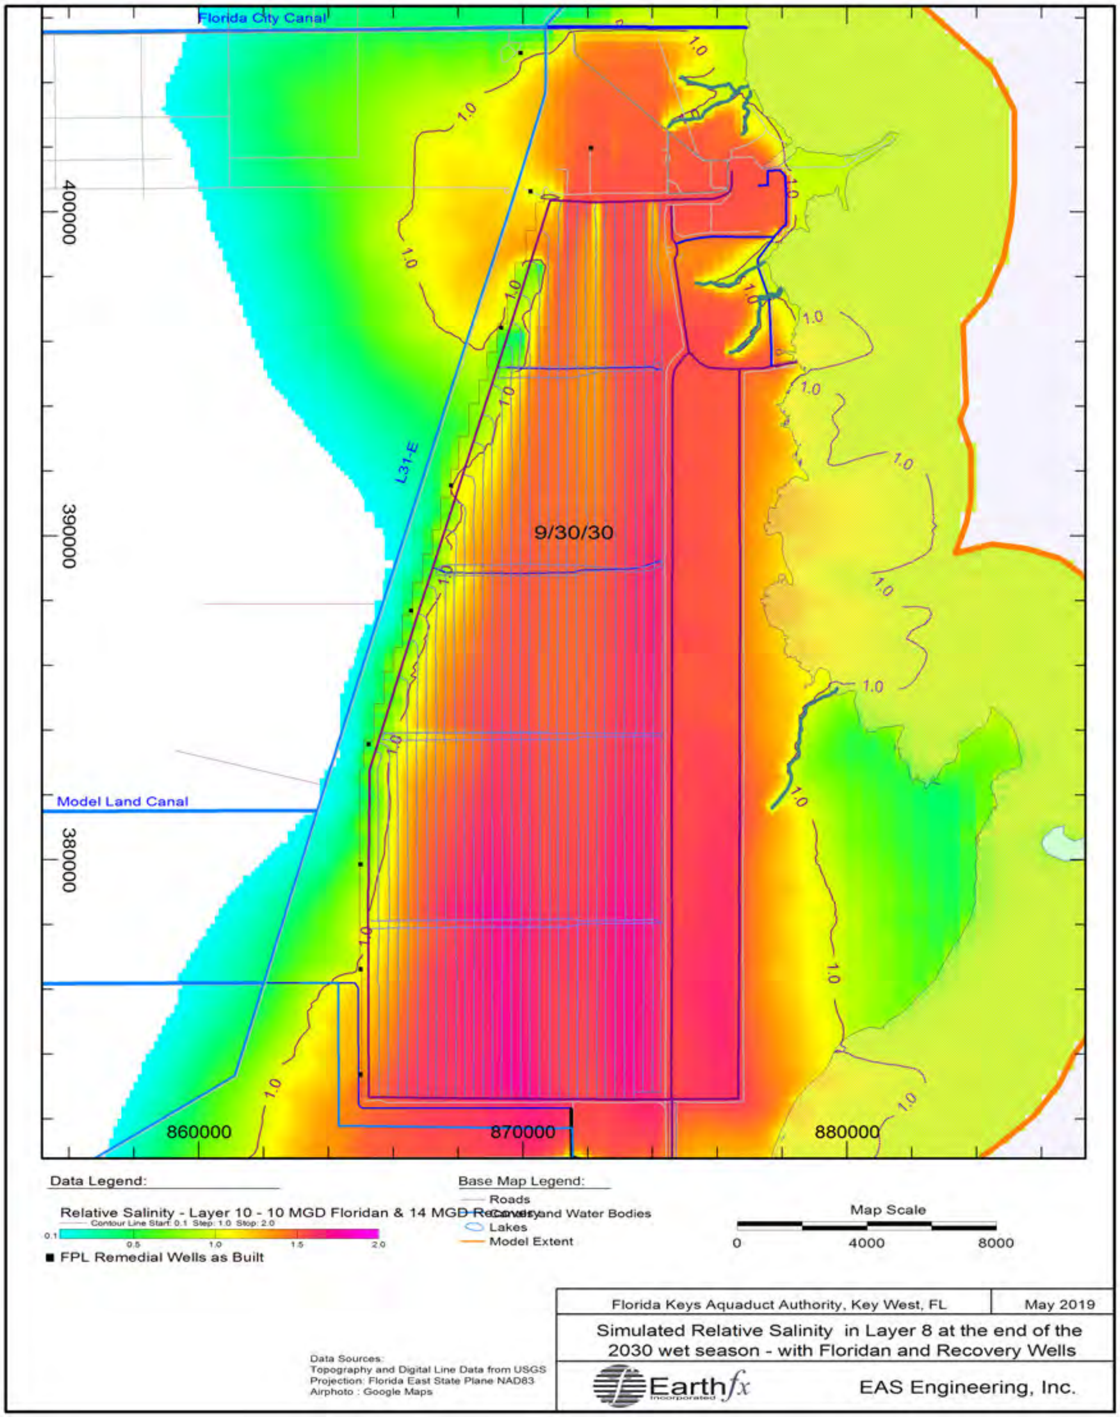

Figure 8: Simulated relative salinity values in the new Earthfx model in Layer 8 (between -30 to -35 NGVD, roughly equivalent to Layers 5/6 in the Tetra Tech models) at the end of the 2030 wet season. Note that relative salinity is greater than 1.0 (> 35 PSU) over most of the CCS. Areas of low salinity occur along the west boundary due to the effects of adding Floridan Aquifer water and due to pumping of the recovery wells. Small plumes of lower salinity occur in the northern part of the CCS due to the addition of Floridan water at these locations.

E. J. Wexler, M.Sc., M.S.E., P.Eng.

Vice-President and Director of Modeling Services

BIOGRAPHY

E.J. Wexler is Vice-President and Director of Modeling Services at Earth*fx* and has over 35 years of experience in groundwater modeling, contaminant hydrogeology, geostatistical analysis, and model code development. He has taught graduate courses in groundwater at universities in Canada, FL, and NY. He worked as a research hydrologist and groundwater modeling specialist for the USGS in Reston, VA, Long Island, NY, and Miami, FL. Mr. Wexler is a licensed engineer in the Province of Ontario, Canada.

EDUCATION

- B.E. Civil Engineering, City University of New York (1977)
- M.S.E. Civil Engineering, Princeton University (1978)
- M.Sc. Earth Science, University of Waterloo (1988)

PROFESSIONAL EXPERIENCE

Director of Modeling Services, Earthfx Inc. ***2002 - Present***

Mr. Wexler is the Director of Modeling Services at Earth*fx* where he leads a team of surface and groundwater modelers. Mr. Wexler's experience at Earth*fx* includes:

- Directing groundwater flow and contaminant transport studies, with an emphasis on integrated groundwater/surface water modeling using GSFLOW.
- Technical Manager for Source Water Protection studies in southern Ontario. This included regional groundwater flow modeling studies for aquifer and wellhead vulnerability assessment and hydrologic modeling for water quality and water quantity risk assessment.
- Technical Manager for Lake Simcoe Protection Plan studies in southern Ontario. These subwatershed studies assessed regional groundwater flow, delineated ecologically significant groundwater recharge areas, and quantified the impact of land development, drought, and climate change on watershed function.
- Project Manager for an Integrated Catchment Management Plan for in Northern Oman.
- Member of Scientific Peer Review team for evaluating the Tampa Bay Water/SWFWMD North Tampa Bay integrated model.
- Conducted integrated GW/SW modeling study for a large-land development in Ft. Meyers, FL and a study of FW/SW interface movement in the Homestead, FL area.
- Project Manager for hydrogeologic data analyses in South Florida related to the Comprehensive Everglades Restoration Program (CERP)
- Developed geostatistical analysis codes (3-D kriging and variogram analysis) for VIEWLOG and advanced water quality analysis modules for SiteFX.

Hydrogeologist/Hydrologist, Gartner Lee Limited ***1990 - 2002***

As a senior hydrogeologist at Gartner Lee, Mr. Wexler directed groundwater modeling, groundwater resources management and contaminant hydrogeology studies in Canada, Florida and the Middle East. Selected projects where he was principal investigator include:

- Development of a groundwater flow and contaminant transport model for a low-level radioactive waste disposal site and evaluation of remedial measures.
- Development of a groundwater flow model for St. Thomas, U.S. Virgin Islands used to investigate the source of volatile organic compounds affecting water supply wells.
- Development of surface water and groundwater models to assess the impact of artificial recharge on the water balance, groundwater flow patterns and salt water intrusion in the arid coastal regions of Northern Oman.
- Co-development of MODNET, a surface water and groundwater model based on the USGS MODFLOW model and the USACE UNET surface water model for SFWMD.

Research Hydrologist, U.S. Geological Survey, Miami, Florida 1986 - 1990

Mr. Wexler researched and developed models for simulating groundwater/surface water interaction. He also investigated the effects of density-dependent groundwater flow and solute transport on the feasibility of freshwater storage and recovery in saline aquifers (ASR) at Cape Coral, FL. He developed a coupled, regional-scale/fine-scale flow and transport model for simulating leachate migration at landfills in West Palm Beach, FL. He served as the Groundwater Discipline Specialist and Digital Modeling Specialist and was responsible for technical review and quality control for other surface water and groundwater modeling investigations.

Hydrologist, U.S. Geological Survey, Long Island, New York 1981 - 1985

Mr. Wexler was the Project Chief of a groundwater contaminant transport study at a sanitary landfill site. He investigated the local hydrogeology and studied the physical and geochemical controls on the transport of groundwater solutes. He developed flow and transport models for the study area and simulated long-term contaminant migration.

Research Hydrologist, U.S. Geological Survey, Reston Virgina 1979 - 1981

Mr. Wexler was responsible for developing and testing finite-element models for simulating groundwater flow, solute transport and parameter estimation. E.J. consulted on field application of these models to sites in Maine, Kansas, and California.

LBP-19-06

UNITED STATES OF AMERICA
NUCLEAR REGULATORY COMMISSION

ATOMIC SAFETY AND LICENSING BOARD

Before Administrative Judges:

E. Roy Hawkens, Chairman
Dr. Michael F. Kennedy
Dr. Sue H. Abreu

In the Matter of	Docket Nos. 50-250-SLR & 50-251-SLR
FLORIDA POWER & LIGHT COMPANY	ASLBP No. 18-957-01-SLR-BD01
(Turkey Point Nuclear Generating Units 3 and 4)	July 8, 2019

MEMORANDUM AND ORDER
(Granting FPL's Motions to Dismiss Joint Intervenors'
Contentions 1-E and 5-E as Moot)

In LBP-19-03, this Licensing Board granted a hearing request from Friends of the Earth, Inc., Natural Resources Defense Council, Inc., and Miami Waterkeeper, Inc. (collectively, Joint Intervenors) and admitted two environmental contentions of omission they proffered challenging Florida Power & Light Company's (FPL's) subsequent license renewal application for Turkey Point Nuclear Generating Units 3 and 4. Thereafter, following the NRC Staff's issuance of the Draft Supplemental Environmental Impact Statement (DSEIS), FPL moved to dismiss the two contentions as moot based on new information in the DSEIS. For the reasons discussed below, we conclude that the new information in the DSEIS has cured the omissions identified in the two contentions, and we grant FPL's motions to dismiss.

I. BACKGROUND

This proceeding concerns the subsequent license renewal application submitted by FPL for two nuclear power reactors, Turkey Point Units 3 and 4, near Homestead, Florida.[1] As relevant here, on March 7, 2019, this Licensing Board granted hearing requests from Joint Intervenors and Southern Alliance for Clean Energy (SACE). See LBP-19-3, 89 NRC __, __ (slip op. at 63) (2019). We admitted two contentions of omission proffered by Joint Intervenors — Contentions 1-E and 5-E — alleging that FPL improperly failed to include required information in its Environmental Report (ER). See id. at __ n.82 (slip op. at 63 n.82).[2] We also admitted two environmental contentions proffered by SACE. See id. at __ n.81 (slip op. at 63 n.81).

On April 9, 2019, SACE withdrew from this proceeding as part of a global settlement with FPL. See [SACE's] Notice of Withdrawal (Apr. 9, 2019). In light of SACE's withdrawal, the only remaining contentions in this proceeding are Joint Intervenors' Contentions 1-E and 5-E. Contention 1-E claims that "[i]n light of the adverse impact of continued [cooling canal system (CCS)] operations on the threatened American crocodile and its critical seagrass habitat, the ER is deficient for failing to consider mechanical draft cooling towers as a reasonable alternative to the CCS in connection with the license renewal of Turkey Point Units 3 and 4." LBP-19-3, 89 NRC at __ n.82 (slip op. at 63 n.82). Contention 5-E asserts that "[t]he ER is deficient in its

---

[1] See [FPL], Turkey Point Nuclear Plant Units 3 & 4 Subsequent License Renewal Application (rev. 1 Apr. 2018) (ADAMS Accession No. ML18113A146).

[2] "A contention of omission is one that alleges an application suffers from an improper omission, whereas a contention of adequacy raises a specific substantive challenge to how particular information or issues have been discussed in the application." Fla. Power & Light Co. (Turkey Point Nuclear Generating Plant, Units 6 & 7), LBP-11-6, 73 NRC 149, 200 n.53 (2011); accord Pac. Gas & Elec. Co. (Diablo Canyon Nuclear Power Plant, Units 1 & 2), CLI-16-11, 83 NRC 524, 534 (2016) ("Contentions that claim a failure to include an entire subject matter or study might be considered contentions of omission. Contentions that argue for alternative analyses or refinements to [an] analysis might be characterized as contentions of 'adequacy.'") (internal footnote omitted) (citing, e.g., Duke Energy Corp. (McGuire Nuclear Station, Units 1 & 2; Catawba Nuclear Station, Units 1 & 2), CLI-02-28, 56 NRC 373, 382–83 (2002)).

failure to recognize Turkey Point as a source of ammonia in freshwater wetlands surrounding the site, and in its failure to analyze the potential impacts of ammonia releases during the renewal period on threatened and endangered species and their critical habitat." Id.

In March 2019, the NRC Staff issued a DSEIS for Turkey Point Units 3 and 4.[3] Pursuant to the migration tenet,[4] Contentions 1-E and 5-E, which originally challenged FPL's ER, became challenges to the NRC Staff's DSEIS.

On May 20, 2019, FPL moved this Board to dismiss Contentions 1-E and 5-E as moot, arguing that information in the NRC Staff's DSEIS cured the omissions identified in those contentions.[5]

On June 10, 2019, the NRC Staff filed an answer supporting FPL's motions to dismiss both contentions as moot.[6] Joint Intervenors filed answers opposing FPL's motions.[7]

For the reasons discussed below, we grant FPL's motions to dismiss Contentions 1-E and 5-E as moot.

[7] See Joint Petitioners' Answer Opposing FPL's Motion to Dismiss Joint Petitioners' Contention 1-E as Moot (June 10, 2019) [hereinafter Answer Opposing Motion to Dismiss Contention 1-E]; Joint Petitioners' Answer Opposing FPL's Motion to Dismiss Joint Petitioners' Contention 5-E as Moot (June 10, 2019) [hereinafter Answer Opposing Motion to Dismiss Contention 5-E].

II. LEGAL STANDARD

It is undisputed that Contentions 1-E and 5-E are contentions of omission. A contention of omission claiming that an ER fails to include required information can be cured by the applicant supplying the missing information in a revised ER or by the NRC Staff supplying the missing information in an environmental impact statement (EIS). See McGuire/Catawba, CLI-02-28, 56 NRC at 384. When the missing information "is later supplied by the applicant or considered by the Staff in a draft EIS, the contention is moot" and should be dismissed. Id. at 383; accord USEC, Inc. (American Centrifuge Plant), CLI-06-9, 63 NRC 433, 444 (2006).

III. ANALYSIS

A. CONTENTION 1-E HAS BEEN RENDERED MOOT BY THE NRC STAFF'S DSEIS

Pursuant to the migration tenet, see supra note 4, Contention 1-E alleges that the NRC Staff's DSEIS improperly "fail[s] to consider mechanical draft cooling towers as a reasonable alternative to the CCS" in light of "the adverse impact of continued CCS operations on the threatened American crocodile and its critical seagrass habitat." LBP-19-3, 89 NRC at __ n.82 (slip op. at 63 n.82). FPL and the NRC Staff argue that the DSEIS's extensive discussion of mechanical draft cooling towers as an alternative to the CCS renders Contention 1-E moot. See Motion to Dismiss Contention 1-E at 4; NRC Staff Answer at 5–7. We agree.

Section 2.2.3 of the DSEIS considers the use of mechanical draft cooling towers "that might be used to mitigate the potential impacts associated with continued use of the existing [CCS]." DSEIS at 2-12. Under the cooling towers alternative evaluated by the NRC Staff, Turkey Point Units 3 and 4 would each use three closed-cycle, wet-cooling towers to dissipate heat from the reactor cooling water systems. See id. at 2-13. These mechanical draft cooling towers would be octagonal in shape and extend about 70 feet in height and 250 feet in diameter. See id. The primary source of cooling water is assumed to be reclaimed wastewater.

See id. Cooling water makeup would be about 38 million gallons per day, and consumptive water use would be about 29 million gallons per day. See id.

Under the mechanical draft cooling towers alternative, Turkey Point Units 3 and 4 would no longer use the CCS, which, the NRC Staff reasons, would result in (1) less heat being discharged to the CCS, which could cause the water in the CCS to become less saline and, thus, more hospitable for threatened species; and (2) less flow within the CCS, which could cause the water in the CCS to become stagnant and less hospitable for threatened species. See DSEIS at 4-68.[8] FPL would still be required to take the CCS restorative actions mandated by a 2016 Consent Order with the State of Florida[9] and a 2015 Consent Agreement with Miami-Dade County,[10] see id., which compel FPL to, inter alia, decrease the salinity in the CCS, develop a nutrient management plan for the CCS, and restore seagrass within portions of the CCS.[11] The NRC Staff concludes that, under these circumstances, "the CCS would likely continue to provide habitat for [Endangered Species Act]-listed species." Id.

The DSEIS evaluated the environmental consequences of the mechanical draft cooling towers alternative with respect to each resource area that would be affected. See DSEIS

---

[8] As the DSEIS explains, even if Units 3 and 4 no longer use the CCS, all liquid discharges from the Turkey Point facility, including storm water, would continue to flow into the CCS. See DSEIS at 4-35. Additionally, Unit 5 — an operating fossil-fueled unit that uses cooling towers, see id. at 3-8 — would continue to discharge cooling tower blowdowns to the CCS. See id. at 4-35. CCS water would continue to be circulated through retired fossil-fueled Units 1 and 2; however, this circulation would not add heat to the CCS. See id. at 3-8, 4-35.

[9] See Fla. Dep't of Envtl. Prot. v. FPL, OGC File No. 16-02441, Consent Order (June 20, 2016) (ADAMS Accession No. ML16216A216) [hereinafter Florida Consent Order].

[10] See Miami-Dade County, Dep't of Regulatory and Econ. Res., Division of Envtl. Res. Mgmt. v. FPL, Consent Agreement (Oct. 7, 2015) (ADAMS Accession No. ML15286A366) [hereinafter Miami-Dade Consent Agreement].

[11] See NRR, Biological Assessment for the Turkey Point Nuclear Generating Unit Nos. 3 and 4 Proposed Subsequent License Renewal at 36 (Dec. 2018) (ADAMS Accession No. ML18353A835) [hereinafter Biological Assessment] (incorporated by reference in the DSEIS at 4-60). The Biological Assessment explains how temperature, salinity, and water quality in the CCS affect American crocodile health, prey species, and habitat. See id. at 32–44.

§ 4.2.7 (impacts on land use and visual resources); id. § 4.3.7 (air quality and noise impacts); id. § 4.4.7 (geologic impact); id. § 4.5.7 (impact on surface water and groundwater resources); id. § 4.6.7 (impact on terrestrial resources); id. § 4.7.7 (impact on aquatic resources); id. § 4.8.3.4 (impact on special status species and habitats); id. § 4.9.4 (historic and cultural resources impacts); id. § 4.10.7 (socioeconomics and transportation impacts); id. § 4.11.7 (human health impact); id. § 4.12.4 (environmental justice impact); id. § 4.13.7 (waste management impact).

Table 2-2 of the DSEIS, in turn, summarizes the impact of the mechanical draft cooling towers alternative on different areas including terrestrial resources, aquatic resources, and special status species and habitats. See DSEIS at 2-22 to 2-23.

Notwithstanding the NRC Staff's encompassing consideration of mechanical draft cooling towers as an alternative to the CCS, the Staff ultimately determined that it "cannot forecast a particular level of impact" by the towers on the American crocodile and its habitat, DSEIS at 2-23, because, according to the NRC Staff, "the magnitude and significance of adverse impacts . . . would depend on the location and layout of the cooling towers, the design of the cooling towers, operational parameters, and the [crocodiles and habitat] present in the area when the alternative is implemented." Id. at 4-70.

Joint Intervenors assert that the above determination in the DSEIS "is not an analysis. It is a failure to analyze. It is an omission. Thus Contention 1-E is not moot and should not be dismissed." Answer Opposing Motion to Dismiss Contention 1-E at 6. We disagree.

We conclude that Contention 1-E's omission is cured because the DSEIS expressly considers mechanical draft cooling towers as an alternative to the CCS, as well as the capacity of cooling towers to reduce adverse impacts on the American crocodile and its habitat. Contrary to Joint Intervenors' assertion, the NRC Staff's professed inability to forecast a particular level of impact on the American crocodile and its habitat cannot fairly be characterized as a wrongful omission given the Staff's explanation that a more precise forecast is not possible because it would depend on factual information that is not currently available. See DSEIS at 4-70.[12] Rather, in our judgment, the alleged deficiency now advanced by Joint Intervenors is in the nature of a claim of adequacy that must be advanced, if at all, as a new contention. See supra note 2; infra note 18 and accompanying text.

Because the DSEIS now considers mechanical draft cooling towers as a reasonable alternative to the CCS in light of the CCS's adverse impact on the American crocodile and its habitat, Contention 1-E is moot.

B. CONTENTION 5-E HAS BEEN RENDERED MOOT BY THE NRC STAFF'S DSEIS

Pursuant to the migration tenet, see supra note 4, Contention 5-E alleges that the NRC Staff's DSEIS improperly fails to (1) "recognize Turkey Point as a source of ammonia in freshwater wetlands surrounding the site"; and (2) "analyze the potential impacts of ammonia releases during the renewal period on threatened and endangered species and their critical habitat." LBP-19-3, 89 NRC at __ n.82 (slip op. at 63 n.82). FPL and the NRC Staff argue that the DSEIS cures both omissions, thereby rendering Contention 5-E moot. See Motion to Dismiss Contention 5-E at 3–6; NRC Staff Answer at 8–12. We agree.

Regarding the first omission, Joint Intervenors do not dispute that it has been cured. The DSEIS explicitly recognizes the existence of ammonia in the CCS caused by the decay of organic material, see DEIS at 3-42,[13] and it acknowledges that ammonia is transported from the CCS by the outflow of water into groundwater that then travels to adjacent surface water bodies. See id. at 3-41, 3-44. This discussion renders the first omission moot.

---

[12] The NRC Staff was similarly unable to make a forecast in this resource area for the no-action alternative and the replacement power alternatives. See DSEIS at 2-22, 2-23.

[13] According to the DSEIS, between June 2010 and May 2016, ammonia concentrations in the CCS ranged from below detectable levels to 0.3 milligrams per liter (mg/L), with an average concentration of 0.04 mg/L, which is more than an order of magnitude below the Miami-Dade County water quality standard for ammonia of 0.5 mg/L. See DSEIS at 3-42, 4-22; Biological Assessment at 15.

Joint Intervenors argue, however, that the second omission in Contention 5-E is not moot because the DSEIS allegedly fails to address the potential impacts of ammonia releases on the following threatened and endangered species and their habitat: the Florida panther, American crocodile, indigo snake, snail kite, red knot, and wood stork. See Answer Opposing Motion to Dismiss Contention 5-E at 3. We disagree.

The DSEIS states that, although ammonia concentrations in the CCS are below the Miami-Dade County ammonia water quality standard, see supra note 13, sampling data in 2015 and 2016 revealed concentrations of ammonia exceeding that standard in stagnant water at the bottom of two deep excavations outside of and adjacent to the CCS. See DSEIS at 4-22; see also Biological Assessment at 61 (stating that several other sampling locations in remnant, stagnant canals revealed ammonia concentrations in 2018 above the Miami-Dade County water quality standard).[14] Under the regulatory direction of the State of Florida and Miami-Dade County, FPL is taking steps to eliminate the excess ammonia problem in these stagnant, excavated areas. See DSEIS at 4-23; see also id. at 3-50 to 3-52; Biological Assessment at 60. In light of FPL's restorative actions, the NRC Staff states that "elevated ammonia levels are not expected to be a long-term issue." Biological Assessment at 61.

Moreover, pursuant to the Florida Consent Order and Miami-Dade Consent Agreement, "FPL maintains an extensive water quality monitoring program [in which it] monitors the CCS, Biscayne Bay, Card Sound, and other nearby water bodies for ammonia . . . among other

---

[14] The DSEIS states that ammonia concentrations "at the bottom of these excavations may be influenced by groundwater that has been in contact with CCS waters." DSEIS at 3-50. However, according to the DSEIS, the fact that ammonia concentrations in the bottom samples were consistently higher than ammonia levels in the CCS implies that "some of the ammonia in the [excavations] was coming from other sources," including runoff from "agriculture, urban, and wetland land use." Id.; see also FPL, Site Assessment Report, Ammonia in Surface Waters, Turkey Point Facility at 21 (Mar. 17, 2017) ("[T]he observed presence of ammonia [at the bottom of excavations] is consistent with nitrogen cycling of organic matter under [] anoxic [i.e., low oxygen] conditions such as are present at the bottom of a dead-end canal.") (referred to in DSEIS as FPL 2017c and cited, e.g., at 3-51).

nutrients and parameters." Biological Assessment at 60. The NRC Staff states that, "[t]o date, FPL has identified no evidence of an ecological impact on the areas surrounding the CCS and no discernible influence from the CCS on Biscayne Bay." Id. Given the totality of these circumstances, the DSEIS concludes that "the impacts [of ammonia] on adjacent surface water bodies via the groundwater pathway from the CCS during the subsequent license renewal period would be SMALL." DSEIS at 4-23.[15]

Finally, the DSEIS "analyzes the potential impacts of the proposed Turkey Point subsequent license renewal [on the six threatened and endangered species specified by Joint Intervenors]," DSEIS at 4-60, and it summarizes the impacts in Table 4-4. See id. at 4-60 to 4-61. We conclude that NRC Staff analyzed ammonia releases within and around the Turkey Point site and considered the impacts on the listed species and their habitats such that the second omission in Contention 5-E is cured, thereby rendering the contention moot.

---

15 Aside from the samples collected from the bottom of the excavated areas and remnant canals showing elevated ammonia levels that FPL is remediating, the NRC Staff found that no other ammonia sample concentration from the CCS or within Biscayne Bay near the CCS exceeded the Miami-Dade surface water standard for ammonia. See DSEIS at 3-51; accord Biological Assessment at 62.

Joint Intervenors nevertheless argue that the NRC Staff's analysis remains deficient because it fails to analyze ammonia impacts on the six listed species or their habitats as specifically as it analyzed ammonia impacts on the West Indian manatee. See Answer Opposing Motion to Dismiss Contention 5-E at 7.[16] Contrary to Joint Intervenors' understanding, this type of argument does not preserve Contention 5-E as a contention of omission; rather, it constitutes a challenge to the adequacy of the Staff's analysis and must be advanced, if at all, as a new contention. See supra note 2; infra note 18 and accompanying text.

IV. CONCLUSION

For the foregoing reasons, we grant FPL's motions and dismiss as moot Contentions 1-E and 5-E.[17]

---

[16] While assessing the environmental impacts of ammonia on the West Indian manatee (also a threatened species), the NRC Staff stated that it "assumes that the relevant State water quality criteria are reasonably protective of manatees because under Section 303(c) of the Clean Water Act, the Environmental Protection Agency or the State is required to adopt water quality standards to restore and maintain the chemical, physical, and biological integrity of the Nation's waters." Biological Assessment at 60–61. "Therefore, if waters inhabited by manatees meet water quality criteria for ammonia, the NRC staff assumes that there would be no lethal effects or impairment to growth, survival or reproduction to manatee individuals." Id. at 61.

[17] Any mandatory disclosure obligations associated with those contentions are terminated. See 10 C.F.R. § 2.336(d); see also Licensing Board Order (Granting in Part Intervenors' Joint Motion for Partial Reconsideration of Initial Scheduling Order) (Apr. 2, 2019) at 3 n.3 (unpublished) [hereinafter Revised Scheduling Order].

Although our dismissal of Joint Intervenors' contentions disposes of all the admitted contentions in this case, we do not terminate this proceeding at the Licensing Board level for the following reason: in compliance with the governing Scheduling Order, see Revised Scheduling Order at 3, Joint Intervenors have timely proffered new contentions based on the DSEIS, including new contentions alleging that the curative information in the DSEIS has given rise to contentions of adequacy.[18] See [Joint Intervenors'] Motion to Migrate Contentions & Admit New Contentions in Response to NRC Staff's [DSEIS] at 8–17, 21–25 (June 24, 2019). We thus retain jurisdiction of this case, and we shall address Joint Intervenors' motion in a subsequent memorandum and order.

It is so ORDERED.

[18] That a contention of omission has been cured and dismissed as moot does not perforce insulate the new curative information from challenge. However, to challenge the adequacy of the new information, an intervenor must timely file a new contention that addresses the factors in 10 C.F.R. § 2.309(f)(1). ARGUMENT

Pursuant to 10 C.F.R. § 2.341, Friends of the Earth, Natural Resources Defense Council, and Miami Waterkeeper (together "Intervenors") seek review of the Atomic Safety and Licensing Board's ("Board") decisions in LBP-19-3[1] and LPB-19-06.[2] Respectfully, the Nuclear Regulatory Commission ("Commission") should reverse these decisions and allow Intervenors to amend their contentions to address deficiencies still remaining in the Draft Supplemental Environmental Impact Statement for the SLRA ("DSEIS").

I. SUMMARY OF DECISION FOR WHICH REVIEW IS SOUGHT

On August 1, 2018, Intervenors submitted a Request for Hearing and Petition to Intervene, which articulated five contentions.[3] These contentions addressed deficiencies in Florida Power & Light Co.'s ("Applicant's") Environmental Report ("ER"),[4] submitted as part of its subsequent license renewal application ("SLRA") for Turkey Point Nuclear Generating Station, Units 3 and 4, in Miami-Dade County, Florida.

On March 7, 2019, the Board issued Opinion LBP-19-3, admitting two of the five contentions in part[5] and determining as a matter of law that 10 C.F.R. § 51.53(c)(3) applies to

[5] Intervenors did not immediately appeal the denial of their remaining contentions from this Order as, under NRC regulations and precedent, it would be a disfavored interlocutory appeal. *See* 10 C.F.R. § 2.311; *Private Fuel Storage L.L.C.,* (Independent Spent Fuel Storage Installation) CLI-01-1, 53 NRC 1, 5 (Jan. 10, 2001) ("We have

subsequent license renewal proceedings to extend an initial license renewal. While the Board referred its ruling on §51.53(c)(3) to the Commission,[6] 120 days have since passed so the Board's ruling is final.[7]

In March 2019, the NRC Staff published the DSEIS for the SLRA.[8] Pursuant to the migration tenet,[9] Intervenors' admitted contentions challenging the ER became challenges to the DSEIS. On May 20, 2019, Applicant filed two motions to dismiss Intervenors' contentions as moot.[10] On June 10, 2019, Intervenors opposed these motions[11] while the NRC Staff supported them.[12] On July 8, 2019, the Board issued Order LBP-19-06 "disposing of all admitted contentions in the case."[13]

While the Board decided not to "terminate this proceeding at the Licensing Board level" because "Joint Intervenors have timely proffered new contentions based on the DSEIS,"[14] the

---

repeatedly held that refusal to admit a contention, where the intervenor's other contentions remain in litigation, does not constitute a pervasive effect on the litigation calling for interlocutory review.").

[13] Dismissal at 11.

[14] *Id.*

Board's latest decision "disposes of at least a major segment of the case."[15] This decision therefore could be interpreted to be a final agency action. Thus, Intervenors petition for review now in order to preserve all their claims.

II. STANDARD OF REVIEW

"The Commission defers to a Board's rulings on standing and contention admissibility in the absence of clear error or abuse of discretion."[16] While the Commission's review of factual findings is deferential, it will correct findings when there is "strong reason to believe that a board has overlooked or misunderstood important evidence."[17] The Commission reviews legal questions "de novo."[18]

III. DECISIONS AT ISSUE

Intervenors petition the Commission to review the Board's Order LBP-19-3 ruling on a legal question and on a finding that three of Intervenors' filed contentions were inadmissible in their entirety and that two of the contentions were inadmissible in part.

A. The Board Erred by Determining 10 C.F.R. § 51.53(c)(3) Applies to the Preparation of an ER in SLR Proceedings.

The NRC codified its NEPA obligations in 10 C.F.R. Part 51. For "initial" license renewal applications, these regulations divide environmental issues into generic (Category 1) and

site-specific (Category 2) issues.[19] Section 51.53(c)(3) provides that applicants for "initial" license renewals need not include any site-specific review of Category 1 issues in their ER. Applicant interpreted §51.53(c)(3) to apply to subsequent license renewal proceedings and therefore avoided site-specific review of Category 1 issues throughout its ER. Intervenors argued §51.53(c)(3) does not apply to "subsequent" license renewal proceedings in their Petition to Intervene and subsequent briefings before the Board.[20]

A majority of the Board concluded that §51.53(c)(3) applies to all license renewal proceedings.[21] The Board's decision is erroneous. On its face, §51.53(c)(3) applies only to *initial* license renewals,[22] and therefore, limitations in §51.53(c)(3)(i) on challenging Category 1 issues do not apply to *subsequent* license renewal applications.[23] While the Board's majority disagreed with Intervenors and held that §51.53(c)(3) also applies to *subsequent* license renewals,[24] Judge Abreu concluded in dissent that "the majority's tortuous approach to determining the regulation's applicability wipes away the plain meaning and the original regulatory intent."[25]

In its holding, the majority dismissed "the plain regulatory language" of 51.53(c)(3) as "*not* answer[ing] the question presented, because it neither directs the Commission to apply

section 51.53(c)(3) to [subsequent license renewal] applicants, nor does it forbid the Commission from doing so."[26] The Board then spent 20 "tortuous" pages explaining why the Commission's intent in drafting §51.53(c)(3) does not mean what it says.

The plain language of §51.53(c) clearly states that subsections (c)(1) and (c)(2) apply generally to "renewal of a license" while subsection (c)(3) applies to applications for "an *initial* renewed license."[27] Both the courts and the NRC apply the principle of statutory construction, "equally applicable to regulatory construction, [] that a text should be construed so that effect is given to all of its provisions, so no part will be inoperative or superfluous, void or insignificant."[28] Subsection (c)(3) is the only paragraph in §51.53 that employs the limiting term "initial" to modify the types of license renewal to which the subsection applies. The Board read that important distinction entirely out of the regulation, drastically altering its scope. The Board also overlooked the fact that §51.53(c)(3) excludes another class of applicants—those that did not "hold[] an operating license . . . as of June 30, 1995." The Board's holding that §51.53(c)(3) applies to *all* subsequent license renewal renders this text superfluous too and effectively amends §51.53(c)(3) as follows:

> For those applicants seeking a~~**n initial**~~ renewed license~~ **and holding an operating license, construction permit, or combined license as of June 30, 1995**~~, the environmental report shall include the information required in paragraph (c)(2) of this section . . .

---

[26] LBP-19-3, 89 NRC __,__ (slip op. at 15) (emphasis in original).
[27] 10 C.F.R. § 51.53.
[28] *U.S. Dep't of Energy* (High-Level Waste Repository), LBP-10-22, 72 NRC 661, 671 n.25 (2010) (citing *Silverman v. Eastrich Multiple Investor Fund, LP.,* 51 F.3d 28, 31 (3d Cir. 1995) (original alterations omitted)).

The majority never addressed this textual point.[29] "Of the categories of license renewal applicants, the Commission chose 'initial,' thus implying that this was done to the exclusion of 'subsequent.' Had the Commission meant 'initial and subsequent,' it could have said just that, or 'initial' simply could have been deleted."[30]

In striking "initial" from the regulation, the Board "delve[d] too deeply to find its answer"[31] because, as Judge Abreu said, "looking to current intent while trying to explain away the expressed original intent of the regulations is a bridge too far."[32] The Board's reference to various guidance documents and administrative history is unavailing. While these "may be consulted for background information and the resolution of ambiguities in a regulation's language, its interpretation may not conflict with the plain meaning of the wording used in that regulation."[33]

And even so, a broader review of the regulatory history reveals that the Commission intended to apply §51.53 to initial license renewals only.[34] As Judge Abreu noted, when the Commission proposed this rule, it "anticipated that a licensee might file multiple license renewal

[29] *See also* Dissent at 15–16 ("[I]f the agency can change the meaning of 'initial,' what is to stop it from changing the June 30, 1995, limitation . . . without notice and comment?").
[30] Dissent at 3.
[31] *Id*. at 2.
[32] *Id*. at 14.
[33] *Calvert Cliffs 3 Nuclear Project, LLC, & Unistar Nuclear Operating Servs., LLC* (Calvert Cliffs Nuclear Power Plant, Unit 3), 70 NRC 198, 214 (2009) (citing *Abourezk v. Reagan*, 785 F.2d 1043, 1053 (D.C. Cir. 1986), aff'd, 484 U.S. 1 (1987)); *GUARD v. NRC*, 753 F.2d 1144, 1146 (D.C. Cir. 1985).
[34] Dissent at 4–8.

applications, but nevertheless limited application of the efficiencies to be gained by the Part 51 amendments [to "initial" license renewal applications]."[35] As Judge Abreu further noted:

> The NRC stated that the safety considerations for license renewal application reviews . . . "could be applied to multiple renewals of an operating license for various increments," but in the very next sentence stated that the environmental considerations in the [] amendments would apply on 'to one renewal of the initial license for up to 20 years beyond its expiration.[36]

Thus, "the agency intended the [] amendments for license renewal reviews to apply to one renewal, not multiple renewals."[37]

The Board, moreover, lacks authority to strike any language because it "runs afoul of the APA and set[s] a troubling precedent."[38] An agency cannot *de facto* amend a regulation promulgated through notice and comment rulemaking without again going through notice and comment.[39] Doing so "denies the public an opportunity to comment on a not-insignificant change to the NRC's regulations."[40] No reasonable interpretation of § 51.53(c)(3) can expand the scope of that application to subsequent license renewal applications.

The NRC Staff recently demonstrated site-specific analysis of Category 1 issues is not a wasted effort. In its Draft Supplemental Environmental Impact Statement, the NRC Staff reviewed site-specific impacts from Applicant's cooling canal system ("CCS") and came to

[35] Dissent at 4.
[36] Dissent at 4 (emphasis in original, original modifications omitted).
[37] Dissent at 4.
[38] Dissent at 15.
[39] *See, e.g., Perez v. Mortg. Bankers Ass'n,* 135 S. Ct. 1199, 1206 (2015) (It is black letter law that the Administrative Procedure Act requires an agency to "use the same procedures when they amend or repeal a rule as they used to issue the rule in the first instance."); *see also* Dissent at 2 (citing same).
[40] Dissent at 14.

conclusions distinct from those in the NRC's Generic EIS. The Staff found that *site-specific* impacts from the hypersaline plume on groundwater resources "at the Turkey Point site are MODERATE for current operations"[41] while the NRC's GEIS found that impacts on "Groundwater quality degradation (plants with cooling ponds in salt marshes) are SMALL."[42]

B. The Board Erred by Denying Contention 1-E with respect to Several Category 2 Issues.

Contention 1-E challenged the ER's failure to consider mechanical draft cooling towers as a reasonable alternative to reduce adverse impacts from the CCS on several Category 2 issues.[43] The Board partially admitted Contention 1-E, but only as a reasonable alternative with respect to impacts on a threatened species and their critical habitat.[44] Thus, an evaluation of a cooling tower alternative would not address impacts from the CCS on two Category 2 issues, groundwater use conflicts and radionuclides released to groundwater.[45] Intervenors raised this issue before the Board.[46]

The Board erred in denying Contention 1-E with respect to CCS impacts on the issues noted above. The Board limited Contention 1-E to impacts on the American Crocodiles and its habitat for the same reasons two reasons it limited Petitioner SACE's Contention 2.[47] First, the Board held that SACE Contention 2 "focuses" on cooling towers as an alternative for "reducing

[47] LBP-19-3, 89 NRC __,__ (slip op. at 44). The Southern Alliance for Clean Energy ("SACE") submitted separate contentions in this proceeding.

or avoiding adverse environmental effects to *sensitive biota*."[48] Second, the Board held the SACE contention "does not point to any alleged deficiencies in the ER regarding its discussion of environmental impacts of CCS operation" and directs the reader to "see" the Staff's Answer for further information.[49] Neither of these reasons justify limiting the scope Contention 1-E.

On the first point, the Board overlooked the fact that, unlike the SACE contention, Contention 1-E does not "focus" on impacts to "sensitive biota." For example, Contention 1-E states the ER failed to consider cooling towers as an alternative to reduce adverse impacts on groundwater use conflicts.[50] On the second point, the Board erred because the adequacy of the ER's discussion of impacts from the CCS is beyond the scope of Contention 1-E, which if granted only requires a *comparison* of CCS impacts with those of the cooling tower alternative. Applicant can still make this comparison even if Intervenors failed to establish a genuine dispute over the ER's analysis of CCS impacts. Therefore, the Board's decision not to admit these portions of Contention 1-E was in error.

C. The Board Erred in Denying Contention 2-E Regarding the ER's Flawed Analysis of Cumulative Impacts.

Contention 2-E challenged the ER's failure to take a hard look at the cumulative impacts of the continued operation of Units 3 and 4 on surface water and groundwater.[51] Intervenors argued the ER (1) failed to consider the cumulative impacts of sea level rise (increased flooding

---

[51] Petition at 30–39.

and storm surge overtopping the cooling canal system and releasing pollutants to surface waters) and increased temperatures (increased salinity in cooling canal system that worsens impacts on water resources); [52] and (2) erroneously assumed cumulative impacts associated with the hypersaline plume emanating from Applicant's CCS will be "small" because of state and county oversight.[53] The Board found that Contention 2-E was inadmissible, concluding that Intervenors had failed to provide adequate support for their assertions and failed to provide sufficient information to raise a genuine dispute of material fact.[54] The Board erred on both accounts.

1. **The Board erred by overlooking evidence presented by Intervenors demonstrating an increased risk that flooding will overtop the CCS during the SLR period and release pollutants to nearby surface waters.**

The Board held that Intervenors only made "conclusory assertions."[55] On overtopping the CSS—which the ER did not address—the Board faulted Intervenors for not discussing "such necessary information as the relationship between their projected sea levels and the relevant elevations of the Turkey Point site, its sea level barriers, or the CCS, to support their claim that the site will be flooded and the CCS will be overtopped . . . ."[56] The Board erred, however, because it "overlooked or misunderstood important evidence."[57] Intervenors provided an expert declaration as evidence of rising seas and increased risk of flooding during the SLR period.[58]

[55] LBP-19-3, 89 NRC __, __ (slip op. at 45).
[56] LBP-19-3, 89 NRC __,__ (slip op. at 46). Notably, Applicant did not include this "necessary" information in the ER.
[57] *Powertech (USA), Inc.*, CLI-16-20, (slip op. at 10–11) (2016).
[58] Petition at 33–36.

Intervenors further explained that Applicant's own flood risk study found certain of the plant's flood barriers were not high enough to protect safety-related systems with an anticipated 0.39-foot sea level rise *before* its current license expires[59] and that these systems *could not be reached* without floodwaters first overtopping the cooling canal system.[60] The Board never explained why this information is insufficient to demonstrate an increased risk of overtopping during the SLR period when the ER fails to discuss this issue at all.

2. The Board concluded erroneously that state oversight will prevent overtopping and release of water from the CCS to nearby surface waters.

The Board ruled that Contention 2-E failed to demonstrate a genuine dispute of material fact or law because, in its view, state and county regulatory oversight would prevent releases of *groundwater* from the CCS to *surface waters* connected to Biscayne Bay and address material breaches or structural defects in the CCS.[61] Intervenors explained that flooding is not a groundwater-to-surface water issue and that even the most structurally sound flood wall can be overtopped.[62]

The Board further held that even if overtopping were to occur, Intervenors failed explain how it would "impair the environment" given requirements in a consent order for Applicant to maintain low annual average salinity levels and monitor and minimize nutrient levels.[63]

[59] Petition at 37.
[60] Reply at 24 (citing FP&L, Letter, "NEI-12-06, Revision 2, Appendix G, G.4.2, Mitigating Strategies Assessment (MSA) for FLEX Strategies report for the New Flood Hazard Information," ADAMS Accession No. ML17012A065 (Dec. 20, 2016).
[61] LBP-19-3, 89 NRC __,__ (slip op. at 46) (emphasis added).
[62] Reply at 25–26.
[63] LBP-19-3, 89 NRC __,__ (slip op. at 46).

Assuming *arguendo* the consent order effectively addresses salinity and nutrients, Intervenors explained that the consent order does not address other pollutants in the cooling canal system, which is an "industrial wastewater system for operations at Turkey Point" and contains "tritium, ammonia, and sediment."[64] The discharge of any pollutant from Turkey Point into Biscayne Bay without a Clean Water Act permit is unlawful.[65] The Board overlooked or misunderstood all of these facts.

3. The Board committed legal error by assuming Applicant's compliance with a state consent order would yield "small" cumulative environmental impacts.

The Board committed legal error by relying on Applicant's compliance with a state consent order to find cumulative impacts to water resources from Applicant's CCS would be "small."[66] Intervenors raised this issue below.[67] While NRC Reg. Guide 4.2 provides applicants may assume cumulative impacts are managed "as long as facility operators are in compliance with their respective *permits*,"[68] the Board failed to explain how this guidance applies to *consent orders*, which are put in place precisely because the company violated its permits. Also, the Board overlooked or misunderstood the fact that the consent order *does not presume* Applicant will be able to remediate its environmental impacts; rather, it allows Applicant to develop a

[68] Preparation of Environmental Reports for Nuclear Power Plant License Renewal Applications, Regulatory Guide 4.2, at 49 (supp. 1, rev. 1 June 2013) (ML13067A354) (emphasis added) (hereinafter "Reg. Guide 4.2").

"Plan B" if "Plan A" fails.[69] As such, the Board presumes more than the consent order upon which it is relying. Under the Board's holding, an applicant may conclude cumulative impacts are "small" even though its compliance is actually causing "moderate" impacts or worse.[70] Neither Reg. 4.2 nor the cases cited in LBP-19-3 address this point.[71] The Board's decision is in error, without governing precedent, and implicates a substantial and important question of law or policy.[72]

4. The Board erred by relying on the cumulative impacts analysis in the 2016 EIS for Units 6 and 7, which does not analyze cumulative impacts on groundwater from operating Units 3 and 4 during the SLR period.

The Board rejected Contention 4-E regarding the ER's failure to address adequately cumulative impacts on groundwater from the CCS.[73] The Board held Intervenors "ignore[d]" the ER's discussion of these impacts,[74] finding that the ER incorporated by reference (without any page citations) the cumulative impacts discussion from the 2016 EIS for Turkey Point Units 6 and 7.[75] But the board overlooked or misunderstood a critical fact that Intervenors addressed in

[74] *Id.* (slip op. at 47).
[75] *Id.* (slip op. at 47). The Board indirectly admonished Applicant for not including a page citation to the 2016 EIS, but (for unknown reasons) that did not change the Board's conclusion on admissibility. (slip op. at 47 n.67). The

the proceedings below—the 2016 EIS does not discuss cumulative impacts from operating *Units 3 and 4 during the SLR period*.[76] The differences between these units are significant; namely, Units 6 and 7 do not rely on the CCS for an ultimate heat sink. The 2016 EIS, moreover, does not even contemplate the continued operation of Units 3 and 4 beyond the current license, nor could it; the 2016 EIS predates Applicant's SLRA for Units 3 and 4 by more than a year.

The Board's error becomes obvious upon review of the 2016 EIS, which predicts increased temperatures will lead to more evapotranspiration, reducing overall recharge to Biscayne aquifer (a primary drinking water source in South Florida) and sea level rise will push the freshwater-seawater interface in the aquifer further inland; both of which further stress inland freshwater demand.[77] The 2016 EIS concludes that *Units 6 and 7* would have little impact in this new environment because—unlike Units 3 and 4—they use reclaimed water for most of their needs.[78]

5. The Board erred by requiring Intervenors to prove higher temperatures during the SLR period would increase evaporation by a "particular extent."

Contention 2-E challenged the ER for failing to adequately address cumulative impacts of operating Units 3 and 4 during the SLR period when temperatures will be higher.[79] The Board dismissed this portion of Contention 2-E, holding that Intervenors did not demonstrate higher

---

Board cites to Table 7-1 in Vol. 2 of the 2016 EIS in support of its holding, which merely indicates that Applicant was "developing a plan" for remediating the hypersaline plume. That same table does not reference or contemplate continued operation of Units 3 and 4 beyond the current license.

[76] Reply at 36.

[79] Petition at 30–31.

temperatures "would increase evaporation in the CCS to any particular extent, much less to an extent that would be sufficient to increase the CCS salinity such that it would . . . affect the environment."[80] But the Board applied the wrong standard for contention admissibility by requiring Intervenors prove the merits of their contentions. Intervenors provided sufficient support for this contention in the form of an expert declaration and Applicant's own experiences dealing with higher air temperatures.[81] The ER, in contrast, did not analyze the effect of rising temperatures at all. All that is required at the preliminary stage of contention admissibility is for petitioners to support their contention with ample evidence that the ER lacked sufficient information and analysis indicating "that further inquiry is appropriate."[82] Here, the Board abused its discretion by requiring Intervenors to prove more than is necessary for purposes of contention admissibility. The information provided demonstrates, rather than speculates, that temperatures will be higher and that high temperatures have caused adverse environmental impacts at Turkey Point. Since the ER fails to address these issues at all, further inquiry is appropriate.

D. The Board Erred in Denying Contention 3-E

Contention 3-E challenged that the ER contained no analysis of new and significant information regarding sea level rise.[83] Intervenors' arguments in this contention were simple: (1)

---

[80] LBP-19-3, 89 NRC __,__ (slip op. at 46).
[81] Petition at 35–38 (citing declaration of Dr. Kopp and Applicant's "Request for Enforcement Discretion Regarding Technical Specification 3/4.7.4, Ultimate Heat Sink," (ML14204A083) (July 21, 2014), encl. at 3).
[82] *Mgmt. Co., LLC* (Palisades Nuclear Plant), ASLBP 05-842-03-LR, 63 NRC 314, 342 (2006).
[83] Petition at 39–47.

NEPA and NRC regulations require Applicant to analyze new and significant information that "would provide a seriously different picture of the environmental consequences of the proposed action than previously considered in the GEIS;"[84] (2) there is a meaningful probability of sea level rise of at least two feet, and by more than three feet if emission trends continue on their current path, during the license renewal term;[85] (3) storm surges may add one foot to "well above the highest observed historically" to the trend of sea level rise at any given time;[86] and (4) neither the GEIS nor the ER addresses how sea level rise will affect the following Category 1 or 2 issues: surface water use conflicts (Category 2) and groundwater use conflicts (plants that withdraw more than 100 gallons per minute) (Category 2) (collectively "water resources conflicts"), cumulative impacts (Category 2), and termination of plant operations and decommissioning (Category 1).[87]

The Board found Contention 3-E inadmissible.[88] The Board's decision is an abuse of discretion founded on clear errors. First, the Board erroneously concluded that Intervenors failed to raise a genuine dispute as to the new and significant information on water resources conflicts.[89] The Board held that Intervenors "provide[d] no explanation for why [frequent interchange of water from Biscayne bay and the cooling canal system] would cause conflicts in

---

[89] *Id.* (slip op. at 49).

water use for either surface or groundwater resources."[90] But Intervenors explained that the elimination of the "closed-loop" nature of the cooling canal system due to sea level rise will release radionuclides and other pollution in the environment, effecting freshwater availability like groundwater resources.[91] Intervenors therefore established that the ER omitted sea level rise effects on water resources and provided support for that belief.

Second, the Board concluded that, as a contention of omission, the allegation of a failure to address new and significant information regarding cumulative impacts was inadmissible because the ER in fact included the analysis by incorporating the Environmental Impact Statement for Turkey Point Units 6 and 7 ("2016 EIS").[92] But a review of the portions of the ER cited to by the Board that purportedly "incorporate by reference" the 2016 EIS reveals that the ER did no such thing.[93] The Board implied that the ER incorporated the 2016 EIS's discussion of climate-change cumulative impacts, but nowhere on the page of the ER cited by the Board does the discussion reference climate change or sea level rise.[94] Further, the ER's brief mention of the

---

[90] *Id*.
[91] Petition at 44.
[92] LBP-19-3, 89 NRC __, __ (slip op. at 49).
[93] *Id*. (citing ER at 4-68).
[94] ER at 4-68 ("The EIS considered the contributing projects to be those of Turkey Point existing and proposed units, and historical point and non-point-source discharges have affected the water quality of streams and rivers near Turkey Point. The EIS considered that some water bodies near Turkey Point are listed as impaired (CWA 303[d]) and designation of the waters of Biscayne National Park as an Outstanding Florida Water.") ("The EIS analysis determined that cumulative impacts would be MODERATE, with the proposed Units 6 and 7 contribution being of small significance.") ("The EIS prepared by NRC for Turkey Point Units 6 and 7 analyzed cumulative impacts to groundwater considering the groundwater withdrawals and injections of [Turkey Point Units 3 and 4] and the other Turkey Point facilities and those from other projects and activities in the surrounding area . . . [In the EIS, the] NRC determined the cumulative impacts to be SMALL given the hydrologic characteristics of the affected aquifers, fate and transport processes, and the monitoring and management programs required by the State.").

2016 EIS is not sufficient to incorporate by reference even the limited section regarding water resources; it is certainly not sufficient to incorporate an entirely different section of the document (its discussion of climate change- or sea level rise-related impacts), let alone to incorporate the entire document.[95] Even if it could, the 2016 EIS does not analyze the cumulative impacts of climate change and sea level rise. While the 2016 EIS discusses cumulative impacts to water resources in Chapter 7, it does not discuss climate change or sea level rise as a contributing factor in the analysis.[96] Where the 2016 EIS does discuss the effect of climate change on the evaluation of environmental impacts in Appendix I, it only determines that "climate change may substantially alter the affected environment described in Chapter 2" of the 2016 EIS and that there will be "no shift in the Chapter 5-assigned impacts on water use and water quality caused by the operation of the proposed plant due to a reasonably foreseeable alteration in the environmental baseline associated with climate change."[97] Nowhere does the 2016 EIS consider the cumulative impacts of sea level rise plus the additional projects identified.

Third, the Board determined that, regardless of new and significant information, termination and decommissioning is a Category 1 issue and is therefore outside the scope of the proceeding.[98] This reasoning is in clear error and an abuse of discretion. NRC regulations require

---

[95] Additionally, the ER cites to its internal citation "NRC. 2016a," which is a citation to Volume 1 of the EIS, not the entire EIS. ER at 4-68 & 10-17. Volume 1 only contains chapters 1-6, not Chapter 7 on cumulative impacts nor the Appendix I pages that the Board cited. *See* NRC, Environmental Impact Statement for Combined Licenses (COLs) for Turkey Point Nuclear Plant Units 6 and 7 (NUREG-2176) (2016) available at https://www.nrc.gov/reading-rm/doc-collections/nuregs/staff/sr2176/ (hereinafter "2016 EIS").

an ER to consider any new and significant information—for both Category 2 *and Category 1* issues.[99] "[E]ven where the GEIS has found that a particular impact applies generically (Category 1), the applicant must still provide additional analysis in its [ER] if new and significant information may bear on the applicability of the Category 1 finding at its particular plant."[100] Therefore, the fact that termination and decommissioning are a Category 1 issue should not have impacted the contention's admissibility. As there is new and significant information regarding termination and decommissioning, Applicant (and NRC Staff) had a duty under NRC regulations to consider that information.

E. The Board Erred in Denying Contention 4-E by Overlooking the 2016 EIS Finding that "Climate Change Will Provide a New Environment that the Operations of [Units 3 and 4] Will Affect."

Intervenors challenged §3 of the ER for failing to describe the affected environment during the SLR period (2032–2053), which Intervenors termed the "reasonably foreseeable affected environment." This failure rendered the analyses of environmental impacts (§4), mitigating actions (§6), and alternatives analysis (§8) legally insufficient for using the an incorrect baseline.[101] The Board found Contention 4-E inadmissible, concluding that Intervenors were "simply incorrect that the ER fails to address the effects of climate change during the license renewal period."[102] It explained that the 2013 GEIS, ER (at 4-69, 4-71) and the 2016 EIS

---

[99] 10 C.F.R. § 51.53(c)(3)(iv); *Mass. v. U.S.*, 522 F.3d 115, 120 (1st Cir. 2008).

[102] LBP-19-3, 89 NRC __,__ (slip op. at 50).

for Units 6 and 7 all "contain," "describe," or "discuss" "the effects of climate change."[103] But this overlooks the critical question raised in Contention 4-E—whether the ER evaluated environmental impacts using the correct baseline.

The 2016 EIS found that "climate change will provide a *new environment* that the operations of [Units 3 and 4] will affect."[104] Yet the ER evaluated impacts of SLR on the "old" environment. For example, the 2016 EIS recognizes that sea level rise will stress freshwater demand inland of Turkey Point plant.[105] It further recognizes an increase in temperature will reduce overall recharge to a critical south Florida drinking water resource.[106] Yet the ER never considers the impact of operating Units 3 and 4 under these stressed conditions. Critically, the ER never considers whether Applicant's groundwater usage for Units 3 and 4 will have worse impacts on groundwater use conflicts (a Category 2 issue) when that resource is stressed in SLR period's "new environment." In contrast, the 2016 EIS addressed the issue, concluding that Units 6 and 7 would have little impact in this new environment because they use reclaimed water for most of their needs.[107] This analysis is lacking in the ER because measures the impacts of Units 3 and 4 against the wrong baseline conditions.

The ER's "descri[ption of] the effects of climate change when combined with the effects of the proposed action" at 4-69 and 4-71 (cumulative impacts analysis) does not cure the defect

---

either. Intervenors explained[108] that these pages focus on the plant's *contribution to* climate change indicators,[109] warming trends,[110] and climate change effects;[111] whereas Contention 4-E addresses impacts of continued operation on the "new environment" that Units 3 and 4 "will affect." Similarly, the ER's vague reference to the 2016 EIS for Units 6 and 7 does not cure the defect. The Board overlooked the fact that the 2016 EIS does not address cumulative impacts of operating Units 3 and 4; only Units 6 and 7.[112]

As Intervenors stated in the proceedings below, the ER's failure to set an appropriate baseline against which to measure the project's impacts violates NEPA.[113] This is made clear in *AquAlliance v. U.S. Bureau of Reclamation*. There, an agency violated NEPA by relying on modeled historical data that was "no longer a reasonable guide to the future for water management" instead of a climate model that predicted a significant decline in water availability.[114] The same error exists here—the 2016 EIS predicts a significant decline in water availability during the SLR period, yet the ER measures Units 3 and 4's impacts on water use conflicts against today's conditions.

F. The Board Erred in Denying Contention 5-E with Respect to Impacts of CCS Operations on Surface Waters and Freshwater Wetlands.

Contention 5-E challenged the ER's failure to consider the effects of continued operation of the CCS on the environment; specifically, how "the salinization of freshwater wetlands caused by the cooling canal system will impact threatened or endangered species, and otherwise harm important plant and animal habitats."[115] The Board admitted a portion of Contention 5-E relating to ammonia, but rejected the remaining portions.[116] It held the remaining portions either raised an impermissible challenge to a Category 1 issue or failed to address the consent order between Applicant and the state.[117] The Board erred on both counts.

The Board erred as a matter of law because the limitation on challenging Category 1 issues does not apply to subsequent license renewal applications.[118] The Board also erred as a matter of law by relying on the consent order between Applicant and the state for the reasons stated in Section III.C.3, above.

Assuming *arguendo* the §51.53(c)(3) limitation did apply, the NRC Staff's Draft Supplemental Environmental Impact Statement ("DSEIS") for the SLRA explains why the Board still erred. It states "the GEIS (NUREG-1437) did not consider how a nuclear power plant with a cooling pond in a salt marsh may indirectly impact the water quality of adjacent surface water bodies via a groundwater pathway. This constitutes a new, site-specific issue with respect to

Turkey Point . . . ."[119] The Staff explained in briefing that "a waiver is not required to litigate the issue of water quality impacts on adjacent water bodies (plants with cooling ponds in salt marshes)."[120] The Staff explained that it "analyzed this *site-specific issue* for the first time in the DSEIS. *The issue was not analyzed in the GEIS*. Thus, no Commission regulation codifies the NRC Staff's environmental determinations with respect to this issue, and no waiver of any Commission rule is required to litigate it."[121]

IV. THE COMMISSION SHOULD GRANT INTERVENORS' PETITION FOR REVIEW

The Commission considers several factors in determining whether to grant a petition for review.[122] The Petition raises substantial and important questions of law and policy. The Petition seeks review of the Board's majority holding that 10 C.F.R. § 51.53(c)(3) applies to all subsequent license renewal proceedings.[123] It was not a unanimous decision, however. Judge Abreu authored a lengthy dissent, cited frequently in this decision, that warrants the Commission's attention. The resolution of this issue is important and relevant for all future SLR applications, which for reasons stated above, Intervenors assert require SLR applicants to consider site-specific impacts for all issues in their ERs, not just Category 2 issues.

---

119 DSEIS at 4-21.
120 NRC Staff's Answer to Joint Intervenors' (1) Amended Motion to Migrate or Amend Contentions 1-E and 5-E and to Admit Four New Contentions, and (2) Petition for Waiver at 55 (Sep. 22, 2019) (ML19200A300).
121 *Id*. (emphasis added).
122 10 C.F.R. § 2.341(b)(4).
123 *See* section III.A, above.

The Petition two more substantial and important questions of law or policy. First, whether an applicant (and the NRC) can rely on compliance with state and county oversight in the evaluation of cumulative impacts. As Applicant observed elsewhere, this legal issue has broad significance in NRC proceedings.[124] Second, several contentions raise substantial and important questions regarding climate change and how applicants and the Commission will comply with NEPA in light of the "new environment" that this and other plants will affect.

Last, granting this Petition is in the public interest. The Turkey Point plant is located adjacent to Biscayne Bay in Southeast Florida. It is also the only nuclear power plant that uses a 5,900-acre CCS as the ultimate heat sink for its operations. This is also the source of a hypersaline plume that is harming groundwater and surface water resources in a region where water resources are already stressed. It is in the public's interest to ensure the NRC makes an informed decision about extending Applicant's license until 2053 when, as the NRC has already found, there will be a "new environment" that the plant will affect. With respect, that analysis is lacking and there appears to be no interest in taking a hard look at the reasonably foreseeable impacts of operating Units 3 and 4 when the affected environment will be more stressed due to increased temperatures and higher sea levels. Granting this Petition and giving Intervenors an opportunity to present their case at a hearing would only further the public's interest, particularly when the SLR would not take effect for another 13 years.

[124] Florida Power & Light Company's Answer to Intervenors' Petition for Waiver of Certain 10 C.F.R. Part 51 Regulations (July 19, 2019) at 16 (ML19200A298).

V. CONCLUSION

The Commission should remedy these clear errors in material facts and departures from governing precedents and established law, which raise substantial and important questions of law and policy warranting review.[125]

Respectfully submitted,

able to reinvigorate thinly-supported original arguments later in a proceeding.

JUDGE HAWKENS: Thank you.

Do counsel at this point want to take a 10-minute break or do you want to push through for the next contention?

I'll start with Joint Intervenors.

MR. RUMELT: Your Honor, I think Joint Intervenors will need to switch our counsel table. So, it may make sense to take a short break.

JUDGE HAWKENS: All right. Let's take a 10-minute break. Let's reconvene at 11:30.

(Whereupon, the above-entitled matter went off the record at 11:18 a.m. and resumed at 11:30 a.m.)

JUDGE HAWKENS: We're going to start now with now with Contention 5-E(b). It's conceivable -- excuse me, with Contention 6-E, and it's conceivable we could do both 6-E and 7-E before the lunch break. But we'll finish 6-E and see how Counsel feel at that point. 6-E, I believe, Mr. Rumelt?

MR. RUMELT: Rumelt, yes.

JUDGE HAWKENS: Is going to be -- how much time would you like for rebuttal, sir?

MR. RUMELT: I would like three minutes

for rebuttal, please.

JUDGE HAWKENS: All right.

MR. RUMELT: Your Honors, Contention 6-E relates to the surface water impacts by the groundwater pathway from the cooling canal system. And Your Honors' first question asked how is this discussion in the DSEIS different from the environmental report. And I think the simple answer, there was no discussion of this issue in the Environmental Report. And so everything is new.

Moving on to the second bullet point, the Board asked can previously available information be used to challenge a new discussion in the DSEIS. Well, first, I think we do have here a new discussion in the DSEIS. And I'll point the Board to the preamble from the Board's promulgation of the rules that are governing this proceeding. And this is at 77 Federal Register, and the specific page cite is 46566.

In there, the Commission said, and I quote, An NRC document with a new conclusion based on previously available information not contained in the Applicant's environmental report, such as information from a previously available but unreferenced study, might be a proper subject for a contention.

So what's clear from the preamble is that an Intervenor can raise new contentions based on previously available information. So it doesn't foreclose that possibility.

Now, we recognize that there's not any case law directly on point here with the specific facts here. But there is case law that recognizes this principle that staff's discussion in analysis is different. It needs to be treated separately as far as information goes from information that may have existed in the past. And I'd point Your Honors to Powertech case for that proposition.

Specifically, the Board held there that the Intervenors need not respond to new information when the information's actually -- until, sorry, the information is actually used by the NRC staff to form its conclusions on impacts in the DSEIS, okay.

In addition, the Board wrote that there's no way for Intervenors to know what use, if any, NRC staff may make of a response to a request for additional information or a study in the DSEIS.

And an Intervenor is entitled to see the DSEIS and then file any new or amended contentions, based on what appears in the DSEIS. To do otherwise would place an impossible burden on the Intervenor and an unreasonable requirement that the Intervenor divine what use, if any, the NRC staff will make of that information in the DSEIS.

And that's really the position that Intervenors were placed in here. If we look to the environmental report -- well, going back a little bit. We heard argument this morning about modeling studies that were performed in order to determine how much water to add to the cooling canal system to deal with the salinity issue. This is the freshening effort.

And the model that was referenced was work done by Tetra Tech. And if you look through the reference list, in the environmental report, this is not a single reference to any Tetra Tech study, let alone the 2014 study that the staff pointed to in the DSEIS.

In addition, we also heard argument kind of one side pointing to the other, the other pointing back about whether this information is available and how Intervenors would obtain it. We heard the NRC staff say well, you have to go to FPL. FPL said, well, you really have to go to the regulators.

And at the end of the day there was, you know, a statement from Counsel for FPL that our experts who were retained for this matter were able to get a copy or obtain access to the report through litigation, which at least my client certainly wasn't involved in.

And if the standard is you have to go through litigation in a separate proceeding in order to obtain that information, that cannot be considered available to anybody in the public. That's a significant effort, obviously, and one that no Intervenor should be required to go through.

With respect to, you know, the modeling effort that's been done and the conclusions that are in the DSEIS, we're really faced with a significant problem that I think the Board has recognized. There are several of the questions that it's presented. We have a situation where the NRC staff in the DSEIS has recognized actual data which was not included in the environmental report.

And the actual data is showing that salinity levels have not gone down as predicted in the very modeling that the NRC staff is relying on in the DSEIS. And there's a statement recognized by the staff again in the DSEIS that the modelers anticipate that more favorable climatic conditions, i.e., less severe dry seasons, with that change, the addition of upper Florida and aquifer water, should help to reduce CCS water salinities to 34 PSU, practical salinity units.

And that's the target, that's the goal that FPL has to meet. And there's no evidence on the record, and you know, in the ER and specifically here in the DSEIS that that salinity level will ever be reached. There's no evidence that anybody considered what favorable, more favorable climatic conditions would be required in order to meet the 34 PSU standard.

And then second, there's no effort to look at whether any of those conditions would exist in the reasonable, in the future, including the subsequent license renewal period.

And so the conclusion that's been made by the staff in the DSEIS with respect to a number of different environmental impacts is fundamentally flawed. And ultimately, if you take, if you look at the modeling and you understand that it's flawed, it's not working. They haven't met their targets, and there's no effort to determine whether or not they will be able to meet it, understanding data as it exists today.

All that the staff is left with is an assumption that continued oversight is going to rectify the situation somehow. And as we pointed out in our briefing, there's a DC Circuit case that's binding on the NRC, a NEPA case that says agencies cannot rely on the mere existence of permits and oversight to avoid the responsibility of conducting a proper NEPA analysis. And that's what we have here.

So if we look to the rest of the Board's questions, does, you know, does the staff rely solely on the existence of this oversight, the answer is yes.

JUDGE HAWKENS: That's your view.

MR. RUMELT: That's our view.

JUDGE HAWKENS: All right, thank you.

MR. RUMELT: And it's the logical conclusion from what's been said in the DSEIS.

All right, and then Your Honors asks how does the staff reconcile this difference between what's been actually modeled and the outcome that has been measured in the DSEIS. And we're not aware of anywhere in the DSEIS that there is any reconciliation of those two competing facts.

Your Honors ask about climatic assumptions that were used in this 2014 Tetra Tech analysis that, again, was not included or referenced in the environmental report. And to the best of our knowledge, the climatic assumptions appear at page two to three in that Tetra Tech report. And it appears to be based off 22 months of hydrological and salinity data from September 2010 to May 2012.

And, again, we go back to the understanding that the modeling has not been predicted, and it will take more favorable climatic conditions in order for that modeling to, I'm sorry, in order for the efforts to reach the 34 PSU to be fruitful.

And last, the Board asks whether the DSEIS mentions, or I'm sorry, whether the assumptions in the modeling reflect the 30.5 degree increase in temperature that is recognized elsewhere in the DSEIS, whether that's built into any of the modeling or has been considered. And Your Honors, we're not aware of any place where that has been addressed.

I have no further.

JUDGE KENNEDY: Excuse me, do you have any support for the other side of the equation is that -- do you have any support for the statement that would say this target cannot be met in the ensuing 12 years or 13? I can't do the math, but we have at least more than a decade going forward. Is there anything in your pleadings that would lead us to draw the conclusion that it could not be met?

MR. RUMELT: Your Honor, we submitted with our motion for new and amended contentions three expert reports. I believe two of those expert reports address the issue that you're raising directly. One of those reports is by Dr. William Nuttle, a hydrologist. And Dr. Nuttle addresses the issue of the more favorable climatic conditions specifically and references new studies on the future, what we can anticipate the future will be in terms of climate.

In addition, the Intervenors submitted the modeling report of Mr. E.J. Wexler. And Mr. Wexler's report demonstrates that under the current plan to freshen the canal system, it cannot work. And I would refer to Mr. Wexler's report for all of the information in support of that opinion.

JUDGE KENNEDY: Thank you.

MR. RUMELT: You're welcome.

JUDGE HAWKENS: Mr. Turk, you may proceed.

MR. TURK: Thank you, Your Honor. I think we're going to continue to split time 50-50 with the Applicants.

JUDGE HAWKENS: Very well.

MR. TURK: The difficulty with all of the four new contentions, 6-E, 7-E, 8-E, and 9-E, is that the Intervenors did not cite specific information or data in support of any of the four contentions. They had one section in their pleading section, IV(b), which contained new information. That new information was very extensive.

It included some things that were not submitted in support of the contentions, such as the Miami-Dade County petition, some other proceedings going on outside of the NRC's purview. They cited three reports that apparently had been submitted, or earlier versions had been submitted by another Intervenor in this proceeding. Those are the reports by Fourqurean, Wexler, and Nuttle, whose reports had been relied upon by SACE, S-A-C-E in support of their contentions.

So it's very difficult to say where in the new information submitted by the Intervenors is the specific support upon which they're relying in support of any one of these contentions. So that's, that'll be true for 6-E, as well as all the others. So that's the first problem.

The case law at the Commission is clear that the Board and other parties are not required to expend their resources and time trying to figure out where in the mass of information submitted by Intervenor are the specific support for a contention. That is something that the Intervenors had the burden of demonstrating and pleading, which they have not done.

The Intervenors claim that the staff relied solely upon governmental efforts by the state of Florida and Miami-Dade County to achieve the results of retraction of the plume and freshening of the CCS. That's not true, that's one of the factors that the staff considered.

As I mentioned previously, the staff also considered the groundwater modeling that's been done, as well as the results of the freshening efforts that have taken place to date. So to say that we only are relying on the state and county is wrong.

But there is another point to be made, and that is that Commission case law establishes that it is appropriate for the Board and the parties to assume that state regulators will take, will do what is necessary for them to do to achieve their desired results. And so reliance on the state and county to take regulatory actions if necessary is not improper.

JUDGE KENNEDY: Mr. Turk? Could you help us understand a little better why the, let's take the modeling for example, provides the staff with confidence that these target objectives will be met?

MR. TURK: Yes, Your Honor. So the

cognizant regulatory authorities for the Clean Water Act are either EPA, or in this instance, the state of Florida. We rely upon those agencies to establish appropriate goals and to assure themselves that the technical analyses that are provided by a company, here Florida Power and Light, are adequate.

We do not question whether the state was correct or not in accepting results or in getting whatever modifications to the studies that they may have determined to be appropriate. We do review those studies. We look to see if they're reasonable, we look to see if they support a certain conclusion. But we don't go behind the scenes and say, well, why did you model it this way rather than another way, because that's the state's authority.

JUDGE KENNEDY: Do you, does the staff consider any uncertainties in those models, and do they -- I'll let you.

MR. TURK: Yes.

JUDGE KENNEDY: But I guess what I'm curious about is, you know, what possibly is at work here is there's different climatic conditions, there may be suggestions that there need to be different refreshening rates and freshening rates.

Does the staff get involved in reviewing the models, in looking at was there any uncertainty studies done. Is there, are these bounding analysis, are they, do they cover the range of climatic conditions, on and on and on? I mean it's not clear to me from the DSEIS that this was done.

MR. TURK: We do look at the uncertainties, Your Honor, and the uncertainties are reflected in the draft SEIS. But we don't do a detailed probe of their analysis as if it had been submitted to the NRC for evaluation and acceptance. That's up to the state.

JUDGE KENNEDY: My only recollection of what's recognized in terms of uncertainties is a recognition that there's uncertainties in the models. Is there any more characterization than that in a DSEIS?

MR. TURK: I believe the DSEIS recognizes not just uncertainties in the model, but also uncertainties in the conditions, the assumptions that go into the model, as well as uncertainties in the product of the model.

JUDGE KENNEDY: But there was no attempt to quantify the impact of those uncertainties on model results.

MR. TURK: Not in a quantitative sense,

Your Honor. But that does affect the qualitative assessment of the projected results.

JUDGE KENNEDY: Yeah, I guess I'm just trying to get at the staff's confidence in, again, meeting the objective. And one of the points you, one of the aspects you point to is the modeling, you know, what played a factor in the staff's acceptance of meeting the objective.

And yet there still seems to be uncertainties that weren't evaluated or quantified, and I guess I was really trying to, maybe I missed it somewhere.

MR. TURK: No, you're correct, Your Honor. But we do consider the uncertainties, as I mentioned, and we don't come up with a flat answer. We recognize that there might be some variation in the results due to uncertainties. And that's reflected in our overall finding.

JUDGE ABREU: And where did --

MR. TURK: And in our discussion.

JUDGE ABREU: Where in the EIS is there a discussion of that uncertainty analysis? So if I wanted to understand the modeling, the range of the modeling thinking, where in the EIS could I see that?

MR. TURK: Your Honor, for that I'd have

to look over the lunch break and get back to you.

JUDGE ABREU: Okay, that'll be fine.

JUDGE KENNEDY: Maybe this will be a lunch break question too, but you also referred to data. You said modeling and data. When you say data, what are you referring to? Is this plant data that's been taken, or maybe I misheard you, sir. I heard that the staff relied on modeling and data.

MR. TURK: So to the extent that I was referring to data, those would be the results of groundwater monitoring that had been conducted.

JUDGE KENNEDY: So groundwater monitoring data.

MR. TURK: Yes.

JUDGE KENNEDY: Okay, thank you.

JUDGE ABREU: And so just specifically for Contention 6, does the modeling describe, there's a lot of the modeling description on 3-49 in the DSEIS. Does that modeling assume that the groundwater withdrawal rates during the SLR term will be no more than are currently allowed under the local regulators?

MR. TURK: Currently allowed, yes. The Intervenors are mistaken. They say that we assume that withdrawal will not be any greater than is currently being conducted. In fact the, what we used was the actual affirmative maximum, which is greater than the withdrawals that are being made now, both by Florida Power and Light as well as other users.

JUDGE ABREU: So it was modeled at that, using that assumption.

MR. TURK: Yes.

JUDGE ABREU: And can I tell that from what is in the EIS?

MR. TURK: Yes.

JUDGE ABREU: And where is that?

MR. TURK: I have to get you page references, but there are several places where we talk about use of the maximum permitted level provides a conservative bounding number.

JUDGE ABREU: Okay, so it was limit, so it was -- so the next question was then were there model, was there any modeling of any groundwater withdrawal rates greater than currently permitted?

MR. TURK: Not that I'm aware of, and there's a good reason for that. At least from the staff's perspective, we don't know if the state or other regulators might in the future authorize greater withdrawals than they do now. Where would we stop? Is it a two percent increase, a 10 percent, 100 percent? We have no way to say what might happen in the future.

JUDGE ABREU: Isn't that essentially what a NEPA analysis does --

MR. TURK: No.

JUDGE ABREU: Is look into the future?

MR. TURK: It does not look at speculative conditions. We can only assess what we know to be true. We know that FPL is allowed to take out a maximum, as stated in their permit. Let me give you an example.

Florida Power and Light is authorized to take out approximately 28 million gallons per day from the Biscayne Aquifer for both freshening efforts and other uses. They're currently taking out, I believe 19 million gallons per day, which is far less than they're authorized.

With respect to freshening efforts, they're authorized -- within that number they're authorized to take out 14 million gallons per day. They're taking out 13.

So their current withdrawals, and in fact those withdrawals may have decreased, I don't know, but in the SEIS we mentioned that they're currently taking 13, which is less than the maximum permitted level of 14 million gallons per day. So that's the maximum of what we know to be a fact that we can reliably discuss in the EIS.

JUDGE ABREU: So when we talk about then the climate conditions, in the EIS there is mention about the potential for the average temperature to increase by about three and a half degrees Fahrenheit between now and 2050. That was in the EIS. But in the discussion of the modeling, it talked about an assumption of more favorable climate conditions.

So how -- put that together with, you're talking about, because you're saying something about we really can't assume what might happen in the future, yet we have information that says these things are expected to happen. So where, how does that all fit together?

MR. TURK: The statement, the second statement you refer to, which talks about more favorable climatic conditions, would have a different, or might have an ameliorative effect. That's simply a qualitative statement that does not affect our finding.

It's simply a recognition that recently, there had been drought conditions and there had recently been significant hurricanes, both of which affected the evaporation rate and the salinity levels in the CCS. So the statement you referred to is simply a recognition that as conditions change, there's a different outcome. It did not affect our assessment of the impact of the CCS.

JUDGE ABREU: So that assumption was not used in the modeling?

MR. TURK: It's not something that was -- that came from the modeling. I believe that was just a staff qualitative statement saying weather conditions can affect the outcomes.

JUDGE ABREU: So were climate conditions considered as part of the modeling?

MR. TURK: My --

JUDGE ABREU: Since that affects salinity, it sounds like something that has an impact on the output of that model or the --

MR. TURK: One moment here.

JUDGE ABREU: Yeah.

MR. TURK: So I'm very lucky to have Mr. Folk with me at the table, I thank him for his help on this. The consent order and consent agreement, which were issued by the state and the county regulators, require FPL to achieve certain results within ten years. Conditions in the year 2050 don't affect that. The current requirements are that by 20, I guess it would be 2027-ish, maybe 2028, that the conditions must meet the state and county's goals. So the weather in 2050 wouldn't matter to affect that.

But he also, Mr. Folk also informs me that the statement in the EIS that discussed potential future weather conditions might have an ameliorative effect -- I shouldn't say that word, I stumble over it every time I use it. That was simply to indicate that a return to more normal, historically normal weather conditions, would result in more favorable conditions in the CCS.

But it's not meant to say that our analysis depends upon that happening.

JUDGE ABREU: All right, where in the EIS can someone tell what assumptions were made for the modeling? That -- you -- let me make sure I clarify. Earlier you said that the modeling was a factor, the results of the modeling were a factor in the staff's decision.

So let me back up a second. Earlier you said that based on the groundwater modeling, that that was a factor in making your determination that the impact would be small. Is that a correct?

MR. TURK: Yes.

JUDGE ABREU: Okay, so if the modeling was used, where can I find in the EIS the assumptions used for the modeling?

MR. TURK: The EIS itself does not discuss all the details of the modeling. But it does give a reference to where the reader can go to find more information on that point.

JUDGE ABREU: And that is?

MR. TURK: So for instance, we have three references to the Tetra Tech models. The reference is Tetra Tech 2014, 2014-A, and I believe 2017.

JUDGE ABREU: And what is --

MR. TURK: Oh, 2016, I'm sorry, 2016.

JUDGE ABREU: And how does an outsider get those, those models? Get those references?

MR. TURK: If I'm not mistaken, I'd look at the EIS to be sure, but I believe they're in ADAMS, in the NRC's documents access.

JUDGE ABREU: So that even though there was no ML number, there is an ML number. So you were mentioning earlier about making sure to reference things clearly. But -- so if you could get us those ML numbers, that could be helpful.

MR. TURK: Your Honor, I'm looking in the draft SEIS.

JUDGE ABREU: Yeah.

MR. TURK: At page 6-31.

JUDGE ABREU: Okay.

MR. TURK: And there are --

JUDGE ABREU: 6-31, okay, that's reference section.

MR. TURK: Five different Tetra Tech reports.

JUDGE ABREU: Yup.

MR. TURK: Each of which either has an ADAMS accession number.

JUDGE ABREU: Okay, great.

MR. TURK: Or a website where the document can be seen.

JUDGE ABREU: Okay, great, excellent. All right, so in the, so I were to pull up those references, I would get, within them I would be able to find a list of the assumptions made that were used in the modeling.

MR. TURK: You should find a description or narrative at least of the assumptions.

JUDGE ABREU: Okay.

JUDGE HAWKENS: You had said, Mr. Turk, that the staff takes a look at the models. It sounds like a high altitude assessment for reasonableness, is that correct?

MR. TURK: The staff employs hydrogeologists and groundwater specialists, who I'm sure take a great interest in these kinds of reports. So they read them and they look not just to see what's the bottom line, but they look at how the modeling was conducted. I'm sure they look at the assumptions that went into it. And they reach their own level of comfort with those reports --

JUDGE HAWKENS: There's really an independent assessment, then, by the NRC staff of the report and the reasonableness of the model?

MR. TURK: Yes. Although no special finding is made on that, because we do rely upon the state to whom those reports were submitted in the first instance. But in order to inform our decision on what are impacts, our people would look at those reports, at those reports and at the modeling, to be sure they're satisfied that they can rely upon them.

JUDGE HAWKENS: So am I correct in saying you, the staff, reviews it so it will have a level of confidence that the models are reasonable?

MR. TURK: Yes, Your Honor.

JUDGE HAWKENS: But that conclusion is not reflected in the DSEIS, is that correct?

MR. TURK: It's implicit. The fact that

we cite it and rely upon it indicates that we're satisfied with it. If we were not, we would have gone back to FPL and said we looked at this report, it's bogus, you need to do more. But I'm not aware of any time that that's happened in this application in respect to Tetra Tech's work.

JUDGE HAWKENS: Thank you.

JUDGE ABREU: Returning to an earlier topic we had, which is what defines a hard look. So when we're discussing, say, this contention, what, how would you define what would indicate a hard look had been taken?

MR. TURK: So I would supplement what Mr. Wachutka mentioned to you. To me, a hard look means that we look at all relevant information and analyses that could help us in our evaluation of an impact. So we go out, we ask an applicant, a request for additional information. If we find that the environmental report is lacking information or is not satisfactory to us, we may use our own knowledge of reference texts.

We may compare, for instance, a groundwater modeling report to established textbooks in the field to determine is this an acceptable and previously accepted approach to do modeling. I'm not saying that was done here, but that's the kind of question we might ask when we see a report.

And we'd look for other information that becomes available to us, not from the applicant but from other sources or that are publically available to anyone, so.

JUDGE ABREU: So what I'm hearing you say is that we're going to consider all the factors that matter.

MR. TURK: Yes.

JUDGE ABREU: Is kind of the important part.

MR. TURK: All the factors and all the information that's available.

JUDGE ABREU: For that specific topic.

MR. TURK: Yes.

JUDGE ABREU: And so in the EIS, to document that that hard look occurred, would it be correct to say that we would expect to find here are the factors we considered before making our determine -- we, I'm speaking in your terms, not us. Here's the, the staff would say here's what we looked at, and here's the assumptions we made, if we had to make any assumptions. But here's the data and here's our reasoning.

MR. TURK: Yes, that's pretty --

JUDGE ABREU: Is that what you would say is a hard look?

MR. TURK: Yes.

JUDGE ABREU: Okay.

MR. TURK: Now, I can't say that every bit of data would be explicitly discussed in the EIS. That'd be far too much to put into a single document. But we provide the reference list, and that reference list comprises the information that we look at.

JUDGE ABREU: So in the, in Contention 6, the way it's phrased is that, I believe in the, at the end of the discussion of the contention, or not the contention, of the impacts on surface water via groundwater, it basically said that upon consideration of the existing requirements in the county and state oversight, we find small.

But before that was a big discussion of the modeling. Even though the concluding sentence based on what the regulators are doing, we think it's small, would it be correct to say that what they really meant to say was based on our look at all the modeling and all the factors considered, as well as the fact that the state and county are regulating this, we think the impact is small?

MR. TURK: That's correct.

JUDGE ABREU: So the way it's phrased didn't really communicate the full decisionmaking of the staff, in a sense.

MR. TURK: Well, that's only one of the statements that appears in the EIS.

JUDGE ABREU: True, but right at that kind of critical point.

MR. TURK: Right at that point, yes.

JUDGE ABREU: It made it sound a bit like, well, they've got it regulated, so our impact is small. Even though there was all this other discussion before it, it wasn't clear how the two were integrated, based on the phrasing in the EIS.

MR. TURK: In that particular location, correct. But as we mentioned in our response to the contentions, the staff also had a lengthy discussion in chapter 3 of the EIS, which talks about the existing --

JUDGE ABREU: The 3-49 page.

MR. TURK: Yes.

JUDGE ABREU: I'll believe you're referring to.

MR. TURK: I'll accept that, Your Honor, I don't have it right in front of me.

JUDGE ABREU: But that's a page where there was much discussion about the details of modeling.

MR. TURK: That's right. And also even in Chapter 4, there's more discussion of modeling.

JUDGE ABREU: Mm hm.

MR. TURK: So the one particular segment by itself is out of context. It's not the complete basis for the staff's finding.

JUDGE ABREU: Okay, thank you.

MR. TURK: Your Honor, I don't really have much more. I think I've gone far enough. If you have any specific questions you'd like me to answer, I can.

JUDGE KENNEDY: Yeah, I guess I, somewhere between 6, 7, 8, and 9, I really want to keep, bring back up the topic of the staff's conclusions. I think we've been talking about the modeling. You referred to modeling and data, and then there's the modeling the data and reliance on state and local government oversight and enforcement.

I think I'm still struggle with trying to get a sense of if we take the modeling, how does the staff communicate to the public that what they see in the modeling provides them confidence that the targets are going to be met in the context of the data that was available or has purported to be available that says they may not be met?

Then there's data that you reference, which I think I need to understand exactly which data you're referring to. And then the overall reliance on state and local oversight intervention. Are those three equal poles that the table sits on, or are they, is the, is one much greater than the other? How should we view that?

MR. TURK: So in our normal review, both safety and environmental, an applicant will submit reports to us from modeling results to us. And we will then evaluate it as a matter of first impression. You may, Your Honor, you may be familiar with that practice where, no matter what the technical issue, we look at a report and we reach a judgement on it and we discuss the adequacy of the report.

We'll send out requests for additional information about that report specifically. These reports are not submitted to the NRC for our evaluation and acceptance, they were submitted to the state of Florida. The Clean Water Act, in fact, prohibits the NRC from making technical judgements about the adequacy of things like that.

There's established case law, I believe

there's the Limerick decision, where the Commission in fact cited discussion, I believe it was Senator Muskie, who clearly stated, I can get the citation if you give me a moment, but clearly stated that federal agencies are prohibited from second-guessing or from challenging the EPA determinations or state determinations on matters of groundwater quality, matters that are covered by the Clean Water Act.

So it's not our place to challenge the report and assess specifics regarding its adequacy. But we are entitled to look at the report, determine if we're comfortable relying on it, and to describe the environmental impacts that result from reliance on that report.

JUDGE KENNEDY: So if you were to pick one of those points, if I was to ask you what gave you the confidence in 2028 that the objectives in the CCS salinity would be met, what do you point to?

MR. TURK: I would point primarily to three things. One is that the results of the freshening conducted up to the point of the DSEIS publication. And later we'll talk about up to the date of FSEIS. But the freshening results had been successful. The governmental agencies at the state and county levels are performing their role.

They're involved in regulatory oversight, and they have the authority to do what's necessary to reach those goals. And we've seen the modeling reports, which give us confidence in their prediction. And that's what those reports do, they predict that following a certain remedial course of action will achieve the results desired by the state and county.

JUDGE KENNEDY: So all three.

MR. TURK: Those three.

JUDGE KENNEDY: Thank you.

JUDGE HAWKENS: Anything else, Mr. Turk?

MR. TURK: No, Your Honors, thank you.

JUDGE HAWKENS: I think your seven and a half minutes has expired.

MR. TURK: I'm sure they have.

JUDGE HAWKENS: Mr. O'Neill, you may proceed.

MR. O'NEILL: Okay, thank you, Your Honor. I want to begin just by emphasizing some key legal points at the outset here, and respond to the notion that FPL is not meeting the objectives. It is in full compliance with both the consent order and the consent agreement. That encompasses the CCS freshening activities, the hypersaline plume extraction activities, and other things required by the consent order and consent agreement.

And it has not missed any interim salinity target. In fact, FPL is only about just past midway through the four-year initial period prescribed by the consent order for the salinity reduction, you know, meeting the target of 34 PSU. So that initial target I think is May 2021. And again, you know, they have seen substantial reductions of salinities down to the order of 50, 51 PSU.

And I think it's important to note when we talk about the issue of public confidence. That confidence, you know, from our perspective, comes very much from the legal framework that is in place here. And that being the consent order above else.

And because if further actions prove necessary down the road, say they, FPL does need to, you know, introduce additional water, whether it's through more wells or increased pumping rates, they still would be in compliance with the consent order. I mean, the consent order specifically recognizes the possibility that the target may not be achieved. And we can't, you know, say it won't or it will at this juncture, but it recognizes that possibility.

I think it's paragraph 20A, and it's quoted on page 3-49 of the DSEIS, that if FPL fails to reach an average annual salinity of at or below 34 PSU by the required time periods, then the consent order requires them to submit a plan within 60 days of that failure to the FDEP detailing additional measures and a revised timeframe for achieving the 34 PSU target. So that is specifically built into the consent order.

And the other thing I might add is that the results of the freshening activities are reported to the state annually, and daily water quality and salinity data is actually available, you know, to the state agencies. And at this point, they haven't expressed any concerns relative to FPL's progress in meeting the objectives or, you know, recommended any course corrections.

So again, from our perspective, that's a significant source of confidence.

JUDGE HAWKENS: Mr. O'Neill, does the state have the ultimate authority to direct you, direct FPL to shut down if during the subsequent license renewal period it becomes clear you're not able to achieve the environmental goals?

MR. O'NEILL: That I do not know, Your Honor. I don't know if that would factor into the Public Service Commission process or not, I don't, yeah. I've been informed that it would likely involve, you know, some regulatory compliance, excuse me, fines and alternative mitigation strategies would have to be developed, so yeah.

JUDGE HAWKENS: All right.

JUDGE ABREU: But if you did not have a permit from them could you operate?

MR. O'NEILL: No, the permit is definitely required, yes.

JUDGE ABREU: So theoretically, if they withdrew the permit, you'd shut down.

MR. BESSETTE: One moment, Your Honor.

MR. O'NEILL: Yeah, Your Honor, I just want to emphasize again that, you know, the consent order does contemplate this possibility, and the prescribed action is to develop an alternative strategy, you know, for achieving the 34 PSU in a revised timeline. So it doesn't contemplate shutdown.

JUDGE ABREU: But --

MR. O'NEILL: But to answer your question, certainly, you know, the company does have to have, you know, a valid NPDES permit or a permit that governs cooling water discharges to the canals, yes.

JUDGE ABREU: Right, so in theory, if for some reason things just went horrible, the state could just, could take away the permit or, you know, say you're not fulfilling the consent order and do whatever they do.

MR. O'NEILL: But again, we have no reason, we believe that is unlikely hypothetical, and it's all, yeah.

JUDGE ABREU: But in the sense of possibilities, it is on the list. Unlikely, but.

MR. O'NEILL: The state can ultimately, yeah.

JUDGE ABREU: They do have that control over you, is what I'm --

MR. O'NEILL: Control to issue the permit, yes.

JUDGE ABREU: Yes.

MR. O'NEILL: And to modify the permit if necessary, yeah.

You know, another point I wanted to address is as relates to, you know, future climactic conditions. And you know, there's this discussion of well, how do we know what the conditions will be like. And I think this board, in Footnote 71 of LBP-19-03, said that NRC regulations require that environmental reports, and by extension the staff's draft SEIS, you know, must describe in detail the affected environment around the plant, not the reasonably foreseeable affected environment during the SLR period.

So I think that's just consistent with the broader NEPA principle that, you know, we can't engage in crystal ball inquiries about whether conditions will be wetter or drier, you know, 30 years from now. We just simply can't know that with any certainty, you know, and that really goes beyond NEPA's rule of reason.

JUDGE ABREU: And those, the Tetra Tech models that are referenced in the EIS, if one were to look in those references, what type of information would one find, such as the assumptions that were input for the model, that type of thing? Are those all available in detail in there?

MR. O'NEILL: Yes, I think you'd find fairly detailed descriptions of the models. You know, for example, the water and salt balance model, that was developed in the 2012 timeframe, in connection with extended power uprate proceeding.

And there was a report issued that's publically available through the state's websites, that 2012 pre-uprate comprehensive report, that provides quite a bit of detail on the water and salt balance model.

And I know FPL also describes the model in its annual remediation and our restoration status reports. And it's certainly not going to include, you know, the spreadsheet itself, but it is going to describe the basic assumptions.

JUDGE ABREU: But it would give someone who wanted to say, gee, does this make sense --

MR. O'NEILL: Exactly.

JUDGE ABREU: Be able to go in and say, okay, I can see what their thinking process was.

MR. O'NEILL: Yes, yes, Your Honor. And on that point I did want to emphasize as well that the model that's related to, you know, the salinity of the CCS system is a stochastic model. So it basically is based on past weather sequences.

So it basically kind of assume that the past weather will predict the future. So it encompasses things like, you know, precipitation amounts, temperature gradients, you know, seepage in and out of the canal system, that type of thing.

And there definitely has been some confusion about the discussion I think on page 3-49 of the DSEIS, because that talks about the model I think in the 2014 timeframe. And that was the initial model developed in 2012, which is based on two years of data, weather data. And one of the years was wetter than normal, and so it was a bit skewed in that sense.

And FPL has since incorporated I think seven or eight years of weather data, and they recalibrate the model annually. And they actually do calibrate the models, kind of predictions or simulations against actual data, you know, water level data, salinity data from the canal system and the match is very good. It's been described to me as a very tight model. So we disagree vigorously with the notion that the model is defective or deficient, so.

I had a number of issues I would have liked to have gotten into, if it's --

JUDGE HAWKENS: I'll tell you, why don't you take four more minutes.

MR. O'NEILL: Okay, Your Honor. Yeah, Your Honor, one issue I really did want to touch on is the, and again, it relates to the staff, and it's ultimately their responsibility, but the nature of their review or obligations under NEPA, I think there's some very instructive NRC case law on this point.

Basically holds that the NRC has to exercise its independent judgement in identifying and assessing the reasonably foreseeable impacts of a proposed licensing action. So in doing so, it's relates to groundwater and that our discussion earlier really focused on the issues here.

I'm not disputing that our discussion earlier has significance, serious significance on Contention 7-E. But we can't get away from the fact that Contention 6-E also addresses the staff's ultimate conclusion that's based on oversight in freshening and remediation of the cooling canal system impacts.

It's the same core set of facts and issues. And it just depends on which issue you're looking at from there. You make one turn it goes to surface water. The other way it's groundwater.

There was a statement that things are progressing as planned. I see my time is up.

JUDGE HAWKENS: Please complete your thought.

MR. RUMELT: We've heard several times that salinity management is progressing as planned. Well, that's very much contrary to what's in the DSEIS. The DSEIS says that the model is predicted that salinity would reach 34 PSU within a year of beginning those efforts. So, you know, I'm not sure what other plan there is, but the plan that's stated in the DSEIS is less than a year we'll get there. So in terms of progressing as planned, it seems that the answer is, no, they're not progressing as planned.

JUDGE HAWKENS: I don't think that's exactly accurate. Again, Mr. O'Neill said it's not until May 2021 for that 34 PSU to be achieved.

MR. RUMELT: That, Your Honor --

JUDGE HAWKENS: That's the modeling aspect of it, as opposed to they were saying, well, perhaps in a year.

MR. RUMELT: There's certainly a deadline for achieving the goal, and that's not what I'm referring to. I'm referring to the understanding that when they did the modeling and made the decisions to engage in this salinity management effort, the model said less than a year. And that's the progress that everybody expected initially and that hasn't come to fruition. I fully, you know, I agree that they have additional time. I'm not disputing that. But as planned and as forecast by the models, and these were the decision documents that everyone relied on to determine what to do, the forecast was less than a year.

MR. O'NEILL: Can I respond, Your Honor?

JUDGE HAWKENS: I'd like to hear your response, yes. I was about to ask Mr. Turk to respond, but, since you volunteered, I will allow you and then allow to Mr. Turk to supplement, if he wishes.

MR. O'NEILL: I appreciate that, but I think the big problem here stems from the fact that Mr. Rumelt is focused on a model that has essentially been outdated or superseded. I mean, it's the same underlying water and salt balance model. But as I tried to explain before, the discussion of DSEIS on page 349 refers that the Tetra Tech 2014 A memo, and, again, that's when the model was in its kind of embryonic stages, if you will, and it was based on about two years, actually about 22 months of data, and one of those years was particularly wet and that kind of skewed the initial simulations.

Since that time, FPL or Tetra Tech have updated the model to incorporate a lot more weather data. And, again, I mentioned a stochastic model. And so it provides a much, encompasses a much broader range of hydrologic conditions, including drier conditions. And based on that refined model, FPL determined that a longer period of time, the four-year period that's reflected in the consent order, would be needed to reduce the average annual salinity to 34 PSU. And FPL actually explained this in a comment on the draft SEIS. The accession number for FPL's comments are ML 19141A047. That's a matter of public record.

But, again, I had to kind of dispel any notion that that specific model, the 2014 one, really is still even relevant. Again, the model has been subsequently updated and recalibrated. And, again, based on that, that's where the four-year period came from and that's reflected in the consent order.

JUDGE HAWKENS: We'll give you the final word, Mr. Rumelt, in just a second. I want to give Mr. Turk the opportunity to weigh in.

MR. TURK: Your Honor, I would only note that the prediction for the DSEIS is not what are the current conditions and is the model showing that things will be fine in one year or two years or four years. We're looking at the subsequent license renewal period 13 years from now, and our conclusion, based on all of the evidence and the predictive modeling that's occurred, as well as the continued state and county oversight, is that, by the time we get to SLR, the impacts will be as described in the DSEIS. Small.

JUDGE KENNEDY: Again, when you talk about that modeling, is that different than the 26 -- again, I get 2014 and 20 -- what you've described on 349 in the DSEIS, is there a different model that you're referring to now than that model? Because we're back to why you have such confidence that these targets are going to be met.

MR. TURK: Just one moment, Your Honor.

JUDGE KENNEDY: Sure.

MR. TURK: Your Honor, I think the confusion is that there are two different models that we're talking about. At page 3-49, there's the description of the 2014 Tetra Tech model that was used to estimate the freshening that would be required. In Section 4.5.1.2, there's a different model that's discussed, and that's the predictive modeling about the, the predictive modeling done by Tetra Tech regarding the pulling back of the hypersaline plume. That's a 2016 model, so that's different from the model that's being discussed on page 3-49.

JUDGE KENNEDY: There is a connection between the salinity and the CCS and the remediation of the plume. Does the 2016 model include updated information on the salinity level in the CCS when you did a predictive estimate of the remediation of the plume? I can understand why I'm confused.

MR. TURK: Just one moment, Your Honor.

I don't know the answer as we sit here today, Your Honor. Perhaps FPL knows the answer.

MR. O'NEILL: Yes, Your Honor, I guess I tried to explain it before, but I understand that the salinity level of the CCS is accounted for in the, you know, the plume retraction model. We'll call it that. It's --

JUDGE KENNEDY: The 2016 model?

MR. O'NEILL: That is maybe -- I know 2016, I know they also did some sensitivity studies in the 2018 time frame, too, but 2016, yes. And from talking to our technical folks, my understanding is that, you know, the model does assume 34 PSU. Now, getting into new and amended information, and counsel may object, but my understanding is, since we've seen the system has been operating since, I guess it was May of 2018, and FPL just prepared its first annual monitoring report that actually addresses the progress that's seen and it is indicating a very significant hydraulic barrier being created by the ten-well recovery system. In other words, whether it's 34 or 51, you know, the kind of the salinity of the system now, it doesn't matter because the wells are being that effective in preventing the plume from moving further, further west.

JUDGE HAWKENS: Is this hydraulic barrier, is that discussed in the DSEIS?

MR. O'NEILL: Well, certainly, the recovery well system is discussed at length. I mean, I'm kind of using the term hydraulic barrier. It's essentially you're creating a --

JUDGE HAWKENS: Right. That makes sense to me. I just don't recall seeing that term in the DSEIS.

MR. O'NEILL: No, no, no, I think it is -- but the wells are, I think, Figure 3-14 of the DSEIS, actually. So is the location of the ten recovery wells, yes, and discusses the amount of water that they're actually withdrawing from the ground and where it's coming from and, you know, the reviews that the various agencies did.

JUDGE HAWKENS: So your position, Mr. O'Neill, would be that the fact that the model regarding the retraction of the plume has an input of 34 PSU, which is inaccurate and has no material impact on the reasonableness of the models and the accuracy of the models?

MR. O'NEILL: Yes, although I wouldn't necessary consider it to be inaccurate. I mean, again, you know, the ultimate goal is within several years to have, you know, the PSU approaching 34 PSU. And then, of course, the groundwater extraction system, that time line is ten years in terms of the plume retraction. And, again, I think, ultimately, from our perspective, we have to kind of look at reality, what is the system itself doing. Again, the model is a useful tool. I mean, it can kind of help FPL and the regulators understand, you know, what factors are most heavily influencing the movement of the plume, you know, but --

JUDGE HAWKENS: Which we knew is the salinity of the --

MR. O'NEILL: Well, actually, that is one clarification I do want to make. I know --

JUDGE HAWKENS: Well, that's what the DSEIS says.

MR. O'NEILL: Yes, although it refers to the movement, it's the largest contributing factor of the movement of the saltwater interface and there is a distinction between that and the hypersaline plume. The saltwater interface is basically where the water has a salinity of 34 PSU, you know, like ocean water, and that is affected by other factors. Certainly, the plume itself, you know, affects the saltwater interface movement and, of course, if you're retracting that, it's going to affect the movement of the saltwater interface. But there's other kind of regional processes that affect that, as well. I just wanted to make that clarification.

JUDGE HAWKENS: Thank you for your patience, Mr. Rumelt. You have the podium again.

MR. RUMELT: I object.

(Laughter.)

MR. RUMELT: I think it's fairly obvious that we would strenuously object to the introduction of new information.

JUDGE HAWKENS: I've heard that objection earlier, so I understand what you're saying.

MR. RUMELT: Maybe we can make a deal. But, I mean, I think we fleshed out, to an extent, a lot of the facts here. The modeling of the hypersaline plume was based on 34 PSU in the cooling canal, which is not accurate. You know, the only predictive modeling for the salinity in the cooling canal system is the 2014 Tetra Tech analysis. There may have been other, you know, they may have looked at the model to see whether or not it's accurate and, you know, looked at how it's performing. But as far as I know and based on our review of the DSEIS, there's no other prediction of when the cooling canal system salinities will reach 34 PSU. The only one I'm aware of and our modeling expert was aware of was in 2014. And I have nothing further.

JUDGE HAWKENS: Thank you.

JUDGE KENNEDY: Mr. Turk, this morning you pointed us to five Tetra Tech reports that's referenced in the SEIS, draft SEIS. I guess what we're understanding now is these models have different applications, so, for example, the 2014 may be applicable to the salinity content of the CCS and the 2016 model may be relevant to the remediation of the plume. Is there any place where all of this modeling is drawn together in the SEIS to support both conclusions, or are we stuck with -- and what do I do with the other three Tetra Tech reports? What do I --

MR. TURK: Well, Your Honor, they're all referenced in the body of the draft SEIS.

JUDGE KENNEDY: At various places.

MR. TURK: Yes. So each of these references is designated with a unique number. For instance, the 2014 report, there are two reports. One is designated 2014 A, which is a technical memorandum dated May 9, 2014 regarding evaluation of required Floridan water for salinity reduction in the CCS. 2014 B is evaluation of the draw down in the upper

Floridan Aquifer due to proposed salinity reduction-based withdrawals. I think it's probably the 2014 B report that is discussed in the DSEIS, but I'd have to look there to verify. Mr. Folk is nodding his agreement.

So in the DSEIS, when you see a Tetra Tech report referenced, they'll give you that unique designation. You can go to page 6-31 and see which of those reports it is, and then you can go to the ML number that's listed for that report and find the details.

JUDGE KENNEDY: So by tracing the references, I can understand the context in which each of the reports are used?

MR. TURK: Yes.

JUDGE KENNEDY: Okay. That's really what I would, that's a better way to say it.

MR. TURK: Thank you.

MR. O'NEILL: Your Honor, I would confirm that I actually did go to some of those references and was able to pull reports through the state's website. The ones that didn't have accession numbers, they were accessible through a portal. I can't recall right now if it was South Florida Water Management District or the FDEP, but I was able to pull the reports.

TABLE OF CONTENTS

EXECUTIVE SUMMARY

Background

By letter dated January 30, 2018, Florida Power & Light Company (FPL) submitted to the U.S. Nuclear Regulatory Commission (NRC) an application requesting subsequent license renewal for the Turkey Point Nuclear Generating Unit Nos. 3 and 4 renewed facility operating licenses (Agencywide Documents Access and Management System (ADAMS) Package Accession No. ML18037A812). FPL subsequently supplemented its application by letters dated February 9, 2018 (ADAMS Accession No. ML18044A653), February 16, 2018 (ADAMS Package Accession No. ML18053A123), March 1, 2018 (ADAMS Package Accession No. ML18072A224), and April 10, 2018 (ADAMS Package Accession No. ML18113A132). The Turkey Point Unit No. 3 current renewed facility operating license (DPR-31) expires at midnight on July 19, 2032; the Turkey Point Unit No. 4 current renewed facility operating license (DPR-41) expires at midnight on April 10, 2033. In its application, FPL requested license renewal for a period of 20 years beyond the dates when the current renewed facility operating licenses expire, to July 19, 2052 for Turkey Point Unit No. 3 and April 10, 2053 for Turkey Point Unit No. 4.

Pursuant to Title 10 of the *Code of Federal Regulations* (10 CFR) 51.20(b)(2), the renewal of a power reactor operating license requires preparation of an environmental impact statement (EIS) or a supplement to an existing EIS. In addition, 10 CFR 51.95(c), "Operating License Renewal Stage," states that, in connection with the renewal of an operating license, the NRC shall prepare an EIS, which is a supplement to the Commission's NUREG–1437, "Generic Environmental Impact Statement for License Renewal of Nuclear Plants."

Once the NRC officially accepted FPL's application, the NRC staff began the environmental review process as described in 10 CFR Part 51, "Environmental Protection Regulations for Domestic Licensing and Related Regulatory Functions." The environmental review begins by the NRC publishing a notice of intent in the *Federal Register* to prepare a supplemental environmental impact statement (SEIS) and to conduct environmental scoping. To prepare the Turkey Point SEIS, the NRC staff performed the following:

- conducted two public scoping meetings on May 31, 2018, near the Turkey Point site in Homestead, FL
- conducted a severe accident mitigation alternatives in-office audit in Rockville, MD, from July 5 to July 13, 2018, and an onsite environmental audit at Turkey Point from June 19 to July 22, 2018
- reviewed FPL's environmental report (ER) and compared it to NUREG–1437, "Generic Environmental Impact Statement for License Renewal of Nuclear Plants" (the GEIS)
- consulted with Federal, State, Tribal, and local government agencies

- conducted a review of the issues following the guidance set forth in NUREG–1555, Supplement 1, Revision 1, "Standard Review Plans for Environmental Reviews for Nuclear Power Plants, Supplement 1: Operating License Renewal," Final Report
- published a draft SEIS for public comment on April 4, 2019, as noticed in the *Federal Register* (84 FR 13322). The draft SEIS was available for public comment through May 20, 2019
- considered public comments received during the scoping process
- considered public comments received on the draft SEIS

Proposed Action

FPL initiated the proposed Federal action (i.e., issuance of renewed facility operating licenses) by submitting an application for subsequent license renewal of Turkey Point. The existing Turkey Point renewed facility operating licenses expire at midnight on July 19, 2032, for Unit No. 3 (DPR-31) and April 10, 2033, for Unit No. 4 (DPR-41). The NRC's Federal action is to decide whether to issue renewed licenses authorizing an additional 20 years of operation. If the NRC issues the renewed licenses, Turkey Point Unit Nos. 3 and 4 would be authorized to operate until July 19, 2052 and April 10, 2053, respectively. The regulation at 10 CFR 2.109, "Effect of Timely Renewal Application," states that if a licensee of a nuclear power plant files an application for renewal of an operating license at least 5 years before the expiration of the existing license, the existing license will not be deemed to have expired until the NRC staff completes its safety and environmental reviews of the application, and the NRC makes a final decision on whether to issue a renewed license for the additional 20 years.

Purpose and Need for Proposed Action

The purpose and need for the proposed action (i.e., issuance of renewed licenses) is to provide an option that allows for power generation capability beyond the term of the current nuclear power plant operating licenses to meet future system generating needs. Energy-planning decisionmakers such as States, utility operators, and, where authorized, Federal agencies (other than the NRC) may determine these future system generating needs. The Atomic Energy Act of 1954, as amended, and the National Environmental Policy Act of 1969, as amended, require the NRC to perform a safety review and an environmental review of the proposed action. The above definition of purpose and need reflects the NRC's recognition that, unless there are findings in the safety review or in the environmental review that would lead the NRC to reject a license renewal application, the NRC does not have a role in the energy-planning decisions as to whether a particular nuclear power plant should continue to operate.

Environmental Impacts of License Renewal

This SEIS evaluates the potential environmental impacts of the proposed action. The NRC designates the environmental impacts from the proposed action as SMALL, MODERATE, or LARGE. NUREG–1437, "Generic Environmental Impact Statement for License Renewal of Nuclear Plants" (the GEIS), evaluates 78 environmental issues related to plant operation and classifies each issue as either a Category 1 issue (generic to all or a distinct subset of nuclear power plants) or a Category 2 issue (specific to individual power plants). Category 1 issues are those that meet all the following criteria:

- The environmental impacts associated with the issue apply either to all plants or, for some issues, to plants having a specific type of cooling system or other specified plant or site characteristics.
- A single significance level (i.e., SMALL, MODERATE, or LARGE) has been assigned to the impacts except for collective offsite radiological impacts from the fuel cycle and from high-level waste and spent fuel disposal.
- Mitigation of adverse impacts associated with the issue is considered in the analysis, and it has been determined that additional plant-specific mitigation measures are likely not to be sufficiently beneficial to warrant implementation.

SMALL: Environmental effects are not detectable or are so minor that they will neither destabilize nor noticeably alter any important attribute of the resource.
MODERATE: Environmental effects are sufficient to alter noticeably, but not to destabilize, important attributes of the resource.
LARGE: Environmental effects are clearly noticeable and are sufficient to destabilize important attributes of the resource.

For Category 1 issues, no additional site-specific analysis is required in this SEIS unless new and significant information is identified. As discussed below, the NRC staff did not identify any information that is both new and significant during its review of Florida Power & Light Company's (FPL's) environmental report, the site audits, the scoping period, or its review of public comments on the draft SEIS, that would change the conclusions in the GEIS. Therefore, there are no impacts related to these Category 1 issues beyond those already discussed in the GEIS.

Category 2 issues are site-specific issues that do not meet one or more of the criteria for Category 1 issues; therefore, a SEIS must include additional site-specific review for these non-generic issues. In this SEIS, the NRC staff evaluated Category 2 issues applicable to Turkey Point, as well as cumulative impacts and considered new information regarding severe accident mitigation alternatives (SAMAs).

The NRC staff identified and evaluated new and potentially significant information for two existing Category 1 issues (i.e., groundwater quality degradation (plants with cooling ponds in salt marshes) and cooling system impacts on terrestrial resources (plants with once-through cooling systems or cooling ponds)). In addition, the NRC staff identified and evaluated one new issue not categorized as Category 1 or 2 (i.e., water quality impacts on adjacent water bodies (plants with cooling ponds in salt marshes)). As described in Chapter 4 of this SEIS, the impacts of each of these issues is SMALL. Chapter 4 also presents the process for identifying new and significant information.

Table ES-1 summarizes the Category 2 issues relevant to Turkey Point and the NRC staff's findings related to those issues. If the NRC staff determined that there were no Category 2 issues applicable for a particular resource area, the findings of the GEIS, as documented in Appendix B to Subpart A, "Environmental Effect of Renewing the Operating License of a Nuclear Power Plant," of 10 CFR Part 51, are incorporated for that resource area.

Table ES-1 Summary of NRC Conclusions Relating to Site-Specific Impacts of Subsequent License Renewal at Turkey Point

Resource Area	Relevant Category 2 Issues	Impacts
Groundwater Resources	- Groundwater use conflicts (plants that withdraw more than 100 gallons per minute) - Radionuclides released to groundwater	SMALL to MODERATE SMALL
Terrestrial Resources	- Effects on terrestrial resources (non-cooling system impacts)	SMALL
Aquatic Resources	- Impingement and entrainment of aquatic organisms (plants with once-through cooling systems or cooling ponds) - Thermal impacts on aquatic organisms (plants with once-through cooling systems or cooling ponds)	SMALL to MODERATE SMALL to MODERATE
Special Status Species and Habitats	- Threatened, endangered, and protected species and essential fish habitat	Likely to adversely affect the American crocodile and eastern indigo snake[(a)] May affect, but is not likely to adversely affect or no effect to all other species May result in adverse modification to American crocodile critical habitat[(a)] No adverse modification to West Indian manatee critical habitat No adverse effects on Essential Fish Habitat No effects to sanctuary resources of the Florida Keys National Marine Sanctuary
Historic and Cultural Resources	- Historic and cultural resources	Would not adversely affect known historic properties or historic and cultural resources
Human Health	- Electric shock hazards	SMALL
Environmental Justice	- Minority and low-income populations	No disproportionately high and adverse human health and environmental effects
Cumulative Impacts	- Cumulative Impacts	See SEIS Section 4.16

[(a)] This table summarizes the NRC staff's conclusions regarding special status species and habitats. Separately, in a July 25, 2019, biological opinion, the FWS concluded that the continued operation of Turkey Point through the duration of the proposed subsequent license renewal period is not likely to jeopardize the continued existence of the American crocodile or eastern indigo snake and will not adversely modify the critical habitat of the American crocodile.

Alternatives

As part of its environmental review, the NRC is required to consider alternatives to license renewal and to evaluate the environmental impacts associated with each alternative. These alternatives can include other methods of power generation (replacement power alternatives), as well as not renewing the Turkey Point operating licenses (the no-action alternative).

In total, the NRC staff initially considered 16 replacement power alternatives; the NRC staff later dismissed 13 of these because of technical, resource availability, or commercial limitations that currently exist and that the NRC staff believes are likely to still exist when the current Turkey Point licenses expire.

This left three feasible and commercially viable replacement power alternatives which, in addition to the no-action alternative, the staff evaluates in depth in this report:

- new nuclear power
- natural gas combined-cycle
- combination alternative: natural gas combined-cycle and solar photovoltaic (PV)

These are the 13 additional alternatives that the NRC staff considered but ultimately dismissed:

- solar power
- wind power
- biomass power
- demand-side management
- hydroelectric power
- geothermal power
- wave and ocean energy
- municipal solid waste
- petroleum-fired power
- coal (integrated gasification combined-cycle)
- fuel cells
- purchased power
- delayed retirement of nearby generating facilities

The NRC staff evaluated the environmental impacts of each replacement power alternative, using the same resource areas that it used in evaluating the impacts from subsequent license renewal. In addition, this SEIS evaluates the environmental impacts of an alternative cooling water system, which might be used to mitigate potential impacts associated with the continued use of the existing cooling canal system. Finally, this SEIS evaluates any new and significant information that could alter the conclusions of the SAMA analysis that was performed previously, in connection with the initial license renewal of Turkey Point Unit Nos. 3 and 4.

Recommendation

The NRC staff's recommendation is that the adverse environmental impacts of subsequent license renewal for Turkey Point are not so great that preserving the option of license renewal for energy-planning decisionmakers would be unreasonable. The NRC staff based its recommendation on the following:

- the analysis and findings in NUREG–1437, “Generic Environmental Impact Statement for License Renewal of Nuclear Plants”
- the environmental report submitted by FPL
- the NRC staff’s consultation with Federal, State, Tribal, and local government agencies
- the NRC staff’s independent environmental review
- the NRC staff’s consideration of public comments received during the scoping process
- the NRC staff’s consideration of public comments received on the draft SEIS

1 INTRODUCTION

The U.S. Nuclear Regulatory Commission's (NRC's) environmental protection regulations in Title 10 of the *Code of Federal Regulations* (10 CFR) Part 51, "Environmental Protection Regulations for Domestic Licensing and Related Regulatory Functions," implement the National Environmental Policy Act of 1969, as amended (42 U.S.C. 4321 et seq.). This Act is commonly referred to as NEPA. The regulations at 10 CFR Part 51 require the NRC to prepare an environmental impact statement (EIS) before making a decision on whether to issue an operating license or a renewed operating license for a nuclear power plant.

The Atomic Energy Act of 1954, as amended (42 U.S.C. 2011 et seq.) (AEA), specifies that licenses for commercial power reactors can be granted for up to 40 years. The initial 40-year licensing period was based on economic and antitrust considerations rather than on technical limitations of the nuclear facility. NRC regulations permit these licenses to be renewed beyond the initial 40-year term for an additional period of time, limited to 20-year increments per renewal, based on the results of an assessment to determine whether the nuclear facility can continue to operate safely during the proposed period of extended operation. There are no limitations in the AEA or NRC regulations restricting the number of times a license may be renewed.

The decision to seek a renewed license rests entirely with nuclear power facility owners and typically is based on the facility's economic viability and the investment necessary to continue to meet NRC safety and environmental requirements. The NRC makes the decision to grant or deny a renewed license based on whether the applicant has demonstrated reasonable assurance that it can meet the environmental and safety requirements in the agency's regulations during the period of extended operation.

1.1 Proposed Federal Action

Florida Power & Light Company (FPL) initiated the proposed Federal action by submitting an application for subsequent license renewal for Turkey Point Nuclear Generating Unit Nos. 3 and 4 (Turkey Point or Turkey Point Units 3 and 4). The current renewed licenses expire at midnight on July 19, 2032, for Unit No. 3 (DPR-31) and at midnight on April 10, 2033, for Unit No. 4 (DPR-41). The NRC's Federal action is to decide whether to issue renewed licenses for an additional 20 years.

1.2 Purpose and Need for the Proposed Federal Action

The purpose and need for the proposed Federal action (issuance of subsequent renewed licenses for Turkey Point Unit Nos. 3 and 4) is to provide an option that allows for power generation capability beyond the term of the current renewed nuclear power plant operating licenses to meet future system generating needs. Such needs may be determined by energy-planning decisionmakers such as State regulators, utility owners, and Federal agencies other than the NRC. This definition of purpose and need reflects the NRC's recognition that, unless there are findings in the NRC's safety review (required by the Atomic Energy Act) or findings in the NRC's environmental analysis (required by NEPA) that would lead the NRC to reject a subsequent license renewal application, the NRC does not have a role in energy-planning decisions as to whether a particular nuclear power plant should continue to operate.

1.3 Major Environmental Review Milestones

FPL submitted an environmental report (ER) (FPL 2018f) as an appendix to its subsequent license renewal application (SLRA) on January 30, 2018 (FPL 2018a). After reviewing the SLRA and environmental report, as supplemented on February 9 (FPL 2018b), February 16 (FPL 2018c), March 1 (FPL 2018d), and April 10, 2018 (FPL 2018e), the NRC staff accepted the application for a detailed technical review on April 26, 2018 (NRC 2018a). On May 2, 2018, the NRC staff published a *Federal Register* notice of acceptability and opportunity for hearing (Volume 83 of the *Federal Register* (FR), page 19304 (83 FR 19304)). On May 22, 2018, the NRC published another notice in the *Federal Register* (83 FR 23726) informing members of the public of the staff's intent to conduct an environmental scoping process, thereby beginning a 30-day scoping comment period.

The NRC staff held two public scoping meetings on May 31, 2018, near the Turkey Point site in Homestead, FL. In January 2019, the NRC issued its "Supplemental Environmental Impact Statement Scoping Process Summary Report, Turkey Point Nuclear Generating Unit Nos. 3 and 4, Miami-Dade County, Florida," which includes the comments received during the scoping process and the NRC staff's responses to those comments (NRC 2019a).

To independently verify information that FPL provided in its environmental report, the NRC staff conducted an onsite audit at Turkey Point in June 2018, and an in-office severe accident mitigation alternatives audit at NRC headquarters in July 2018. In a letter dated July 20, 2018, the staff summarized the onsite audit and listed the attendees (NRC 2018c). In a letter dated August 31, 2018, the staff summarized the in-office severe accident mitigation alternatives audit and listed the attendees (NRC 2018d). During these audits, the NRC staff held meetings with plant personnel, reviewed site-specific documentation, toured the facility, and held a government-to-government meeting hosted by the U.S. National Park Service.

Upon completion of the scoping period and audits, and completion of its review of FPL's environmental report and related documents, the NRC staff compiled its findings in a draft supplemental environmental impact statement (SEIS) issued on March 31, 2019 (Agencywide Documents Access and Management System (ADAMS) Accession No. ML19078A330) (NRC 2019m), as noticed in the *Federal Register* (84 FR 13322) on April 4, 2019. The NRC staff made the draft SEIS available for public comment through May 20, 2019. Based on the information gathered during the public comment period and any new information received, the NRC staff amended the draft SEIS, as necessary, and published this final SEIS. Changes made to the draft SEIS in response to comments, as well as changes made to include updated information and minor corrective and editorial revisions, are marked with a change bar (vertical line) on the side margin of the page where the changes were made. Figure 1-1 shows the major milestones of the environmental review portion of the NRC's subsequent license renewal application review process.

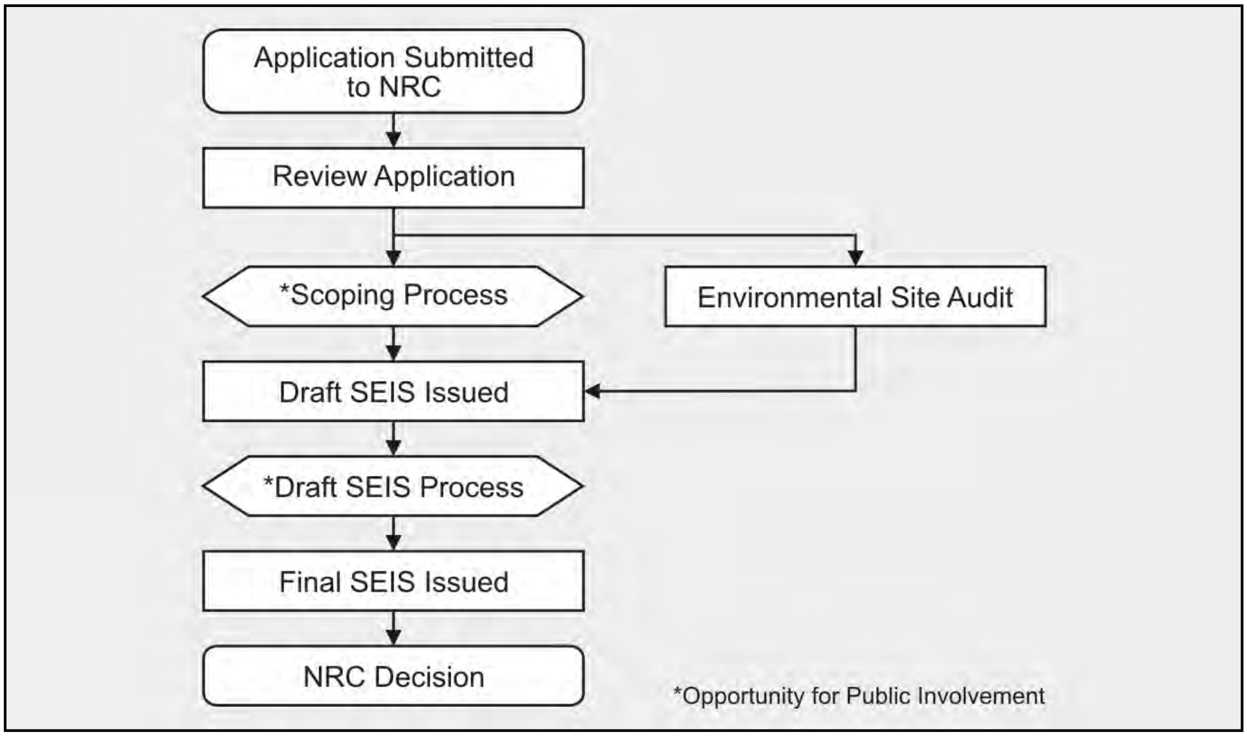

Figure 1-1 Environmental Review Process

The NRC has established a license renewal process that can be completed in a reasonable period of time and that includes clear requirements to assure safe plant operation for up to an additional 20 years of plant life. This process consists of separate environmental and safety reviews, which the NRC staff conducts simultaneously and documents in two reports: (1) the SEIS documents the environmental review and (2) the safety evaluation report (SER) documents the safety review. The staff's findings in the SEIS and the SER are both factors in the NRC's decision to grant or deny the issuance of a renewed license. This process is used for both initial and subsequent license renewal.

1.4 Generic Environmental Impact Statement

To improve the efficiency of its license renewal review process, the NRC staff performed a generic assessment of the environmental impacts associated with license renewal. NUREG–1437, "Generic Environmental Impact Statement for License Renewal of Nuclear Power Plants" (known as the GEIS) (NRC 1996, NRC 1999, NRC 2013a), documents the results of the NRC's systematic approach to evaluating the environmental consequences of renewing the licenses of individual nuclear power plants and operating them for an additional 20 years. In the GEIS, the staff analyzed in detail and resolved those environmental issues that could be resolved generically. The NRC issued the GEIS in 1996 (NRC 1996), Addendum 1 to the GEIS in 1999 (NRC 1999), and Revision 1 to the GEIS in 2013 (NRC 2013a). Unless otherwise noted, all references to the GEIS include the original 1996 GEIS, Addendum 1, and the 2013 revision. The conclusions in the GEIS apply to both initial and subsequent license renewal.

The GEIS establishes separate environmental impact issues for the NRC staff to independently evaluate. Appendix B to Subpart A of 10 CFR Part 51, "Environmental Effect of Renewing the

Operating License of a Nuclear Power Plant," provides a summary of the staff's findings in the GEIS. For each environmental issue addressed in the GEIS, the NRC staff:

- describes the activity that affects the environment
- identifies the population or resource that is affected
- assesses the nature and magnitude of the impact on the affected population or resource
- characterizes the significance of the effect for both beneficial and adverse effects
- determines whether the results of the analysis apply to all plants
- considers whether additional mitigation measures would be warranted for impacts that would have the same significance level for all plants

The NRC established its standard of significance for impacts using the Council on Environmental Quality terminology for "significant." The NRC established three levels of significance for potential impacts—SMALL, MODERATE, and LARGE—as defined below.

SMALL: Environmental effects are not detectable or are so minor that they will neither destabilize nor noticeably alter any important attribute of the resource.

MODERATE: Environmental effects are sufficient to alter noticeably, but not to destabilize, important attributes of the resource.

LARGE: Environmental effects are clearly noticeable and are sufficient to destabilize important attributes of the resource.

Significance indicates the importance of likely environmental impacts and is determined by considering two variables: **context** and **intensity**.

Context is the geographic, biophysical, and social context in which the effects will occur.

Intensity refers to the severity of the impact in whatever context it occurs.

The GEIS includes a determination of whether the analysis of the environmental issue could be applied to all plants (or a distinct subset of plants, as defined in the GEIS) and whether additional mitigation measures would be warranted. Issues are assigned a Category 1 (generic to all or a subset of plants) or Category 2 (site-specific) designation. As established in the GEIS, Category 1 issues are those that meet the following three criteria:

- The environmental impacts associated with the issue have been determined to apply either to all plants or, for some issues, to plants that have a specific type of cooling system or other specified plant or site characteristics.
- A single significance level (i.e., SMALL, MODERATE, or LARGE) has been assigned to the impacts (except for collective offsite radiological impacts from the fuel cycle and from high-level waste and spent fuel disposal).
- Mitigation of adverse impacts associated with the issue has been considered in the analysis, and it has been determined that additional plant-specific mitigation measures are likely not to be sufficiently beneficial to warrant implementation.

For generic issues (Category 1), the SEIS requires no additional site-specific evaluation unless new and significant information has been identified. Chapter 4 of this report describes the process for identifying new and significant information for site-specific analysis. Site-specific issues (Category 2) are those that do not meet the three criteria of Category 1 issues; therefore, the GEIS requires additional site-specific review for these issues.

The 2013 GEIS evaluates 78 environmental issues, provides generically applicable findings for numerous issues (subject to the consideration of any new and significant information on a site-specific basis), and concludes that a site-specific analysis is required for 17 of the 78 issues. Figure 1-2 illustrates the license renewal environmental review process. The results of that site-specific review are documented in the SEIS.

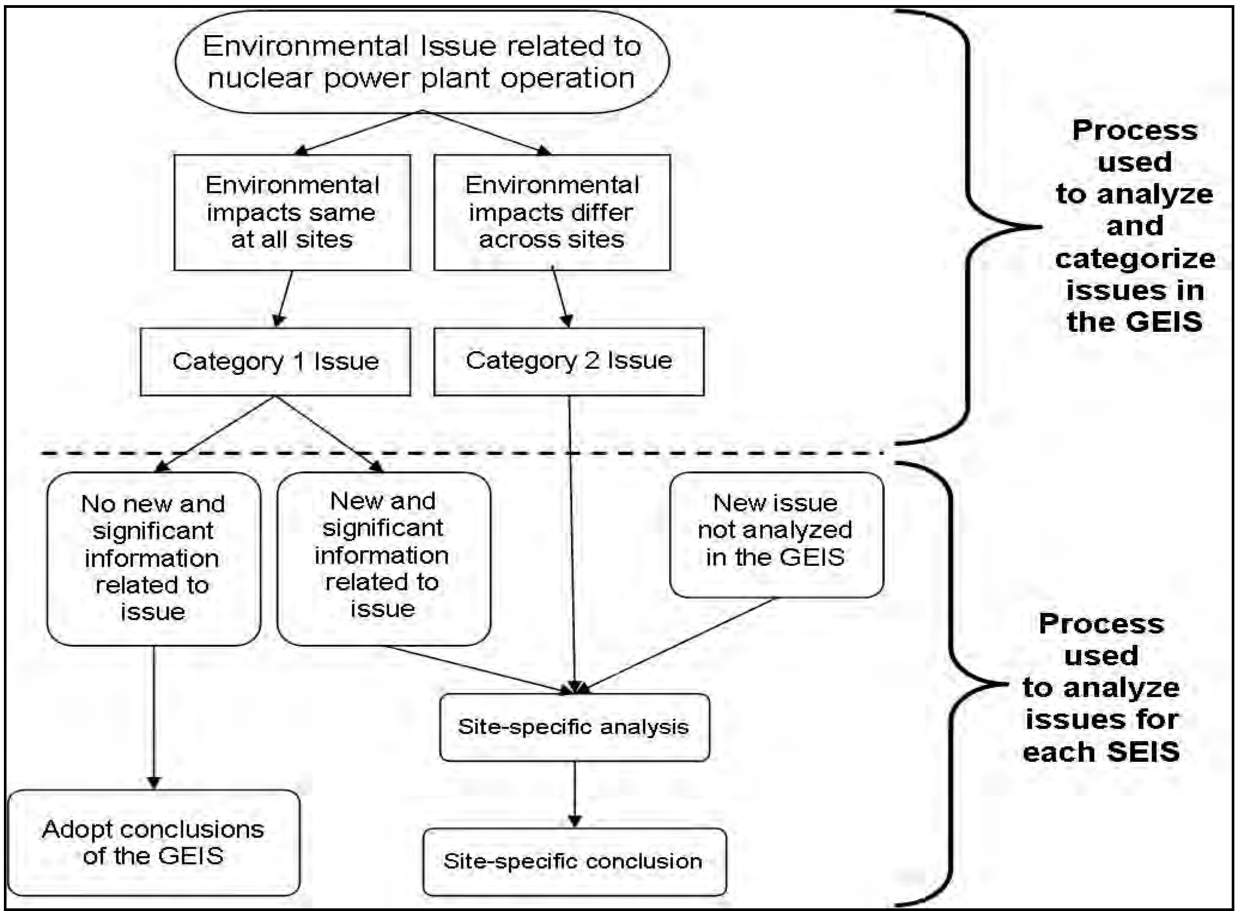

Figure 1-2 Environmental Issues Evaluated for License Renewal

1.5 Supplemental Environmental Impact Statement

This SEIS presents the NRC staff's final analysis of the environmental effects of the continued operation of Turkey Point through the subsequent license renewal period, alternatives to subsequent license renewal, and mitigation measures for minimizing adverse environmental impacts. Chapter 4, "Environmental Consequences and Mitigating Actions," contains an analysis and comparison of the potential environmental impacts from subsequent license renewal and alternatives to subsequent license renewal. Chapter 5, "Conclusion," presents the NRC's recommendation on whether the environmental impacts of subsequent license renewal are so great that preserving the option of subsequent license renewal would be unreasonable. In issuing the final SEIS, the NRC staff considered the comments it had received on the previously published draft SEIS. The NRC staff will make its final recommendation to the Commission on Turkey Point Units 3 and 4 subsequent license renewal in the record of decision to be issued following issuance of this final SEIS.

In the preparation of the Turkey Point SEIS, the NRC staff carried out the following activities:

- reviewed the information provided in FPL's environmental report
- consulted with Federal, State, Tribal, and local government agencies
- conducted an independent environmental review, including the environmental and severe accident mitigation analysis site audits
- considered public comments received during the scoping process
- considered public comments received on the draft SEIS

New and significant information. To merit additional review, information must be both new and significant and it must bear on the proposed action or its impacts.

New information can come from many sources, including the applicant, the NRC, other agencies, or public comments. If the information reveals a new issue, the staff will first analyze the issue to determine whether it is within the scope of the license renewal environmental evaluation. If the staff determines that the new issue bears on the proposed action, the staff will then determine the significance of the issue for the plant and analyze the issue in the SEIS, as appropriate.

1.6 Decisions To Be Supported by the SEIS

This SEIS supports the NRC's decision on whether to issue renewed operating licenses for Turkey Point for an additional 20 years. The regulation at 10 CFR 51.103(a)(5) specifies the NRC's decision standard as follows:

> In making a final decision on a license renewal action pursuant to Part 54 of this chapter [10 CFR], the Commission shall determine whether or not the adverse environmental impacts of license renewal are so great that preserving the option of license renewal for energy planning decisionmakers would be unreasonable.

There are many factors that the NRC takes into consideration when deciding whether to renew the operating license of a nuclear power plant. The analyses of environmental impacts in this SEIS will provide the NRC's decisionmaker (in this case, the Commission) with important environmental information for use in the overall decisionmaking process. Other decisions are made outside the regulatory scope of license renewal, by the NRC or other decisionmakers. These include decisions related to: (1) changes to plant cooling systems, (2) disposition of spent nuclear fuel, (3) emergency preparedness, (4) safeguards and security, (5) need for power, and (6) seismicity and flooding (NRC 2013a).

1.7 Cooperating Agencies

The U.S. National Park Service, Southeast Region (NPS), is participating in the environmental review of subsequent license renewal for Turkey Point as a cooperating agency. The NPS does not have any specific regulatory actions related to the proposed subsequent license renewal;
