ORAL ARGUMENT NOT YET SCHEDULED

No. 20-1026

IN THE UNITED STATES COURT OF APPEALS
FOR THE DISTRICT OF COLUMBIA CIRCUIT

FRIENDS OF THE EARTH, NATURAL RESOURCES DEFENSE COUNCIL, INC., AND MIAMI WATERKEEPER,
Petitioners,

v.

UNITED STATES NUCLEAR REGULATORY COMMISSION AND UNITED STATES OF AMERICA,
Respondents.

Petition for Review of a Final Order of the
United States Nuclear Regulatory Commission

DEFERRED JOINT APPENDIX
VOLUME 1 of 4

JA00001 TO JA00346

RECORD OF DECISION

U.S. NUCLEAR REGULATORY COMMISSION

DOCKET NOS. 50-250 AND 50-251

SUBSEQUENT LICENSE RENEWAL APPLICATION FOR

TURKEY POINT NUCLEAR GENERATING UNIT NOS. 3 AND 4

BACKGROUND

The U.S. Nuclear Regulatory Commission (NRC) received an application dated January 30, 2018 (Agencywide Documents Access and Management System (ADAMS) Package Accession No. ML18037A812), from Florida Power & Light Company (FPL), filed pursuant to Section 103 of the Atomic Energy Act of 1954, as amended, Title 10 of the *Code of Federal Regulations* (10 CFR) Part 51, “Environmental Protection Regulations For Domestic Licensing And Related Regulatory Functions,” and 10 CFR Part 54, “Requirements for Renewal of Operating Licenses for Nuclear Power Plants,” for subsequent license renewal of the renewed operating licenses for Turkey Point Nuclear Generating Unit Nos. 3 and 4 (Turkey Point or Turkey Point Units 3 and 4). FPL subsequently supplemented its application by letters dated February 9, 2018 (ADAMS Accession No. ML18044A653), February 16, 2018 (ADAMS Package Accession No. ML18053A123), March 1, 2018 (ADAMS Package Accession No. ML18072A224), and April 10, 2018 (ADAMS Package Accession Nos. ML18102A521 and ML18113A132).

The Atomic Energy Act of 1954, as amended (42 U.S.C. 2011 et seq.) (AEA), specifies that licenses for commercial power reactors can be granted for an initial period of up to 40 years. NRC regulations permit these licenses to be renewed beyond the initial 40-year term for an additional period of time, limited to 20-year increments per renewal, based on the results of an assessment to determine whether the nuclear facility can continue to operate safely during the proposed period of extended operation. There are no limitations in the AEA or NRC regulations restricting the number of times a license may be renewed.

The NRC granted initial renewed licenses to FPL for Turkey Point Units 3 and 4 on June 6, 2002. The Turkey Point Unit 3 current renewed facility operating license (DPR-31) and the Turkey Point Unit 4 current renewed facility operating license (DPR-41) expire on July 19, 2032, and April 10, 2033, respectively. The subsequent renewed operating licenses would authorize FPL to operate Turkey Point Units 3 and 4 until July 19, 2052, and April 10, 2053, respectively.

Turkey Point Units 3 and 4 are Westinghouse pressurized-water nuclear reactors located on approximately 9,460 acres (ac) (38.3 square kilometers (km^2)) of FPL-owned land. Each reactor is designed to produce a core thermal power output of 2,644 megawatts-thermal (MWt) with a corresponding gross electrical output of approximately 811 megawatts-electric (MWe) for Unit 3 and 821 MWe for Unit 4. The Turkey Point site is located on the southeastern coast of Florida in unincorporated southeastern Miami-Dade County. The site borders Biscayne Bay and Card Sound to the east, and is adjacent to Biscayne National Park.

In addition to nuclear generating Units 3 and 4, the Turkey Point site also hosts three fossil fuel power plants: Units 1 and 2 are retired natural-gas/oil steam-generating units, and Unit 5 is an operating natural-gas combined-cycle steam generating unit. In addition to these five currently operating and retired units, the NRC has previously issued combined licenses (COLs) to FPL, authorizing the construction and operation of two new nuclear plants (Turkey Point Units 6 and 7); those plants have not yet been constructed. The Turkey Point site also features a 5,900-ac (24 km^2) artificial body of water called the cooling canal system (CCS) that is used by Units 3 and 4 for reactor heat rejection, as well as by Units 1 and 2 for operation in synchronous condenser mode and by Unit 5 for the discharge of blowdown. The yet to be constructed nuclear reactors (Units 6 and 7) will not use the CCS.

On April 18, 2018, the NRC staff published a notice of receipt of the subsequent license renewal application in the *Federal Register* (FR) (83 FR 17196). On May 2, 2018, the NRC staff published a notice that it had accepted the application for review and provided notice of an opportunity to request a hearing or petition to intervene (83 FR 19304). As discussed below, an adjudicatory proceeding concerning the application was then conducted.

Section 102 of the National Environmental Policy Act of 1969, as amended (NEPA), directs Federal agencies to prepare a detailed statement in advance of making a decision on major Federal actions that may significantly affect the quality of the human environment. In accordance with the Commission's regulations in 10 CFR Part 51, the NRC prepares an environmental impact statement (EIS) or a site-specific supplement to an EIS (SEIS) for all applications to renew reactor operating licenses pursuant to 10 CFR 51.20(b)(2), regardless of the action's environmental impact significance. In this instance, the NRC's major Federal action is to decide whether to issue subsequent renewed operating licenses for Turkey Point Units 3 and 4, authorizing operation for an additional 20 years through July 19, 2052, and April 10, 2053, respectively.

On May 22, 2018, the NRC staff published a notice of intent to prepare a supplemental environmental impact statement and conduct an environmental scoping process in the Federal Register (83 FR 23726). In addition, Federal, State, and local agencies, as well as Tribal governments, were notified and asked to provide comments on and to participate in the environmental scoping process and review. On May 31, 2018, the NRC staff held public scoping meetings near the Turkey Point site in Homestead, FL, to obtain public input on the proper scope of the NRC's environmental review of the Turkey Point Units 3 and 4 subsequent license renewal application. The NRC issued a scoping summary report on January 31, 2019 (ADAMS Accession No. ML18342A014).

The National Park Service, Southeast Region (NPS) participated in the environmental review as a cooperating agency under a Memorandum of Understanding with the NRC (ADAMS Accession No. ML18355A847). The NPS provided special expertise for the areas in and around the adjacent Biscayne National Park; however, impact determinations made in the EIS should not be attributed to NPS, but only to the NRC. The NPS's participation in connection with the EIS does not imply NPS concurrence with the NRC staff's impact determinations.

ENVIRONMENTAL IMPACT STATEMENT

In accordance with 10 CFR 51.95(c), "Operating License Renewal Stage," the NRC staff documents its environmental review of a license renewal application and publishes it as a site-specific supplemental environmental impact statement (called a SEIS), as a supplement to NUREG-1437, "Generic Environmental Impact Statement for License Renewal of Nuclear Plants" (called the GEIS) (ADAMS Accession Nos. ML13106A241, ML13106A242, and ML13106A244). The GEIS documents the results of the NRC's systematic approach to evaluating the environmental consequences of issuing renewed operating licenses for nuclear power plants authorizing an additional 20 years of operation beyond the end of the current license term. The GEIS serves to facilitate the NRC's environmental review process for license renewal by identifying and evaluating environmental impacts that are considered generic and common to all (or a distinct class of) nuclear power plants (Category 1 issues). For Category 1 issues, no additional site-specific analysis is required in the site-specific SEIS unless new and significant information is identified that would change the conclusions in the GEIS. The GEIS also identifies site-specific issues (Category 2 issues). For Category 2 issues, an additional site-specific review is required, and the NRC staff documents the results of that review in the SEIS.

The NRC established a standard of significance for each NEPA issue evaluated in the GEIS based on the Council on Environmental Quality's (CEQ) regulations on how to evaluate significance (see Title 40, "Protection of Environment," of the *Code of Federal Regulations* (40 CFR) 1508.27, "Significantly"). The term "significantly," as explained by the CEQ, requires consideration of both of the following:

1) Context—as in the geographic, biophysical, and social context in which the effects will occur.

2) Intensity—which refers to the severity of the impact in whatever context it occurs.

Since the significance and severity of an impact can vary with the setting of the proposed action, the NRC considered both "context" and "intensity" as defined in Council on Environmental Quality regulations at 40 CFR 1508.27. Context is the geographic, biophysical, and social context in which the effects will occur. In the case of license renewal, the context is the environment surrounding the nuclear power plant. As stated above, intensity refers to the severity of the impact in whatever context it occurs. Based on this, the NRC established a three-level standard of significance for potential impacts, SMALL, MODERATE, and LARGE, as defined below.

SMALL: Environmental effects are not detectable or are so minor that they will neither destabilize nor noticeably alter any important attribute of the resource.

MODERATE: Environmental effects are sufficient to alter noticeably, but not to destabilize, important attributes of the resource.

LARGE: Environmental effects are clearly noticeable and are sufficient to destabilize important attributes of the resource.

FPL submitted its license renewal application and environmental report under the NRC's 2013 revised rule governing license renewal environmental reviews, as codified in 10 CFR Part 51.[1] The 2013 GEIS[2] provided the technical bases for the list of NEPA issues and associated environmental impact findings for license renewal that are contained in Table B–1, "Summary of Findings on NEPA Issues for License Renewal of Nuclear Power Plants," in Appendix B to subpart A of 10 CFR Part 51.

The NRC's environmental review included an environmental scoping process. The scoping process included two public meetings held in Homestead, FL, on May 31, 2018. On March 31, 2019, the NRC staff issued a draft SEIS as "Generic Environmental Impact Statement for License Renewal of Nuclear Plants, Supplement 5, Second Renewal, Regarding Subsequent License Renewal for Turkey Point Nuclear Generating Unit Nos. 3 and 4, Draft Report for Comment," NUREG-1437, Supplement 5, Second Renewal (ADAMS Accession No. ML19078A330).

A 45-day comment period began on April 5, 2019, when the U.S. Environmental Protection Agency (EPA) published a Notice of Availability in the *Federal Register* (84 FR 13662) of the draft SEIS to allow members of the public, interested organizations and stakeholders, and governmental agencies to comment on the results of the staff's environmental review. The comment period ended on May 20, 2019. Additionally, the NRC held two public meetings on May 1, 2019, to discuss the preliminary findings in the draft SEIS.

Among other concerns, the continued operation of the cooling canal system and its potential impact on certain environmental resources was the focus of considerable concern expressed by members of the public and government agencies. The draft SEIS characterized the complex interaction of the cooling canal system with the environment and described potential impacts of continued cooling canal operation on surface water, groundwater, and biologic resources. These concerns were addressed by the NRC staff in the final SEIS.

The NRC staff made the final SEIS (FSEIS) for the Turkey Point Units 3 and 4 subsequent license renewal application publicly available on October 25, 2019 (ADAMS Package Accession No. ML19295F526). All substantive comments received during the draft SEIS comment period are included in Appendix A of the FSEIS. Neither FPL nor the NRC staff identified any new and significant information related to Category 1 issues that would call into question the conclusions in the GEIS, with respect to the subsequent license renewal period of extended operation for Turkey Point Units 3 and 4. In the FSEIS, the NRC staff recommended that the Commission determine that the adverse environmental impacts of subsequent license renewal for Turkey Point are not so great that preserving the option of subsequent license renewal for energy-planning decisionmakers would be unreasonable. This recommendation is based on: (1) the analysis and findings in the GEIS; (2) the NRC staff's review of information provided in the environmental report and other documents submitted by FPL; (3) the NRC staff's consultation with Federal, State, local, and Tribal agencies; (4) the NRC staff's independent environmental

[2] U.S. Nuclear Regulatory Commission. 2013. NUREG-1437, "Generic Environmental Impact Statement for License Renewal of Nuclear Plants," Rev. 1, Vols. 1–3 (ADAMS Accession Nos. ML13106A241, ML13106A242, and ML13106A244). June 2013.

review; and (5) the NRC staff's consideration of public comments received during the scoping process and on the Draft Supplemental Environmental Impact Statement. Pursuant to 10 CFR 51.102(b) and 10 CFR 51.103(a)(1)-(5), the NRC staff has prepared this concise public record of decision (ROD) to document its action on the Turkey Point Units 3 and 4 subsequent license renewal application. In accordance with 10 CFR 51.103(c), this ROD incorporates by reference the material contained in the FSEIS.

DECISION

Pursuant to 10 CFR 54.29, "Standards for issuance of a renewed license," a renewed license may be issued by the Commission if the Commission finds, in part, that the license renewal application satisfies the requirements of 10 CFR Part 54, and any applicable requirements of Subpart A of 10 CFR Part 51 have been satisfied; pursuant to 10 CFR 51.102, this includes the completion of a Record of Decision.

This Record of Decision and the FSEIS, which is incorporated by reference herein, document the NRC's final decision regarding the environmental review of the Turkey Point Units 3 and 4 subsequent license renewal application, in accordance with 10 CFR 51.103(a)(5), that the adverse environmental impacts of subsequent license renewal for Turkey Point Units 3 and 4 are not so great that preserving the option of license renewal for energy-planning decisionmakers would be unreasonable.

In making its final decision on the proposed Federal action to authorize the continued operation of Turkey Point Units 3 and 4 through July 19, 2052, and April 10, 2053, respectively, the NRC must make a favorable safety finding. The purpose of the NRC's safety review of a license renewal application is to determine if the applicant has adequately demonstrated that the effects of aging will not adversely affect the intended functions of any safety-related structures or components as specified in 10 CFR 54.4 and 10 CFR 54.21. The applicant must demonstrate that the effects of aging will be adequately managed so that the intended functions will be maintained in accordance with the plants' current licensing basis throughout the license renewal period. The NRC staff documented the results of its safety review in its "Safety Evaluation Report Related to the Subsequent License Renewal of Turkey Point Nuclear Generating Units 3 and 4," issued July 22, 2019 (ADAMS Accession No. ML19191A057).

Further, the Advisory Committee on Reactor Safeguards (ACRS) completed its review and report in accordance with 10 CFR 54.25, "Report of the Advisory Committee on Reactor Safeguards," with respect to the application for subsequent renewal of the Turkey Point Units 3 and 4 renewed operating licenses. The ACRS completed its review during its 666th meeting, held on September 4–6, 2019, and documented its findings recommending subsequent renewal of the Turkey Point Unit 3 and 4 licenses in a letter to the Commission dated October 7, 2019 (ADAMS Accession No ML19283A168).

Several requests for hearing and petitions to intervene were filed in response to the notice of opportunity for hearing that was published on May 2, 2018 (83 FR 19304). An NRC Atomic Safety and Licensing Board (Board) was appointed and an adjudicatory proceeding was commenced. The Board granted two petitions to intervene and admitted several contentions on March 7, 2019 (LBP-19-3) (ADAMS Accession No. ML19067A003). The Board later dismissed the remaining contentions in a decision issued on July 8, 2019 (LBP-19-6) (ADAMS Accession

No. ML19189A252), and denied all outstanding contentions and terminated the proceeding before the Board in its Memorandum and Order of October 24, 2019 (LBP-19-8) (ADAMS Accession No. ML19297F366). Appeals from the Board's decisions in LBP-19-3, LBP-19-6 and LBP-19-8, and the Board's referred ruling in LBP-19-3, are pending before the Commission at this time.

PURPOSE AND NEED

The purpose and need for the proposed Federal action (issuance of subsequent renewed licenses for Turkey Point Units 3 and 4) is to provide an option that allows for power generation capability beyond the term of the current renewed nuclear power plant operating licenses to meet future system generating needs. Such needs may be determined by energy-planning decisionmakers such as State regulators, utility owners, and Federal agencies other than the NRC. This definition of purpose and need reflects the NRC's recognition that, unless there are findings in the NRC's safety review (required by the Atomic Energy Act) or findings in the NRC's environmental analysis (required by NEPA) that would lead the NRC to reject a license renewal application, the NRC does not have a role in energy-planning decisions as to whether a particular nuclear power plant should continue to operate.

The issuance of a renewed license is just one of a number of conditions that a licensee must meet to be able to operate its nuclear power plant during the license renewal term. Ultimately, the appropriate energy-planning decisionmakers and Florida Power & Light will decide whether the plants will continue to operate based on the need for power or other factors within the State and County's jurisdiction or the purview of the owners.

NRC EVALUATION OF THE PROPOSED ACTION AND ALTERNATIVES

In license renewal environmental reviews, the NRC considers the environmental consequences of the proposed action (i.e., renewing the operating license), the environmental consequences of the no-action alternative (i.e., not renewing the operating license), and the environmental consequences of various alternatives for replacing the nuclear power plant's generating capacity. Section 102(2)(C)(iii) of NEPA and the NRC's regulations require the consideration of alternatives to the proposed action in the EIS. In this case, the proposed action is issuance of renewed operating licenses for Turkey Point Units 3 and 4, which will authorize the applicant to operate the plant for an additional period beyond the expiration date of the current licenses. Chapter 2 of the SEIS, "Alternatives Including the Proposed Action," and Chapter 4, "Environmental Consequences and Mitigating Actions," present the NRC staff's evaluation and analysis of the environmental impacts of the proposed action and alternatives to license renewal that were considered in detail, as well as those alternatives that were eliminated from detailed study. The evaluation considered environmental impacts of each alternative across the following impact areas: land use and visual resources, air quality and noise, geologic environment, water resources, terrestrial resources, aquatic resources, special status species, historic and cultural resources, socioeconomics, human health, environmental justice, and waste management. In addition to replacement power alternatives, the SEIS evaluates an alternative cooling water system to mitigate potential impacts associated with the continued use of the existing cooling canal system.

As explained in the purpose and need for the proposed Federal action, outside of the safety and environmental reviews, the NRC does not have a role in the energy planning decisions as to whether a particular nuclear power plant should continue to operate. Should the operating license not be renewed and the nuclear plant shuts down at the end of its current license, the appropriate energy planning decisionmakers will decide how best to replace the nuclear power plant's generating capacity. In evaluating alternatives to license renewal, the NRC considered energy technologies or options currently in commercial operation, as well as technologies not currently in commercial operation but likely to be commercially available by the time the current Turkey Point Units 3 and 4 operating licenses expire.

For a replacement power alternative to be considered reasonable, it must be both (1) commercially viable on a utility scale and (2) operational before the reactor's operating license expires or (3) expected to become commercially viable on a utility scale and operational before the expiration of the reactor's operating license. The current renewed operating licenses for Turkey Point Units 3 and 4 expire on July 19, 2032, and April 10, 2033, respectively. Therefore, to be considered in this evaluation, reasonable alternatives had to be available (i.e., constructed, permitted, and connected to the grid) by those dates. To determine whether alternatives were reasonable, or likely to be commercially suitable to replace Turkey Point, the NRC staff reviewed energy-relevant statutes, regulations, and policies; the state of technologies; and information on energy outlook from sources such as the Energy Information Administration, other organizations within the U.S. Department of Energy, industry sources and publications, and information submitted by FPL in its environmental report.

<u>Evaluation of Alternatives</u>

i. No-Action Alternative

At some point, all operating nuclear power plants will permanently cease operations and undergo decommissioning. The no-action alternative represents a decision by the NRC to not issue renewed operating licenses to a nuclear power plant beyond the current operating license term. Under the no-action alternative, the NRC does not issue the subsequent renewed operating licenses for Turkey Point, such that the units would shut down at or before the expiration of the current licenses in July 2032 (Unit 3) and April 2033 (Unit 4). The GEIS describes the environmental impacts that arise directly from permanent plant shutdown. The NRC expects shutdown impacts to be relatively similar whether they occur at the end of the current license term (i.e., after 60 years of operation) or at the end of a subsequent renewed license term (i.e., after 80 years of operation).

After permanent shutdown, plant operators will initiate decommissioning in accordance with 10 CFR 50.82, "Termination of license." The decommissioning GEIS (ADAMS Accession Nos. ML023470327, ML023500228, and ML023500295) describes the environmental impacts from decommissioning a nuclear power plant and related activities. The analysis in the decommissioning GEIS bounds the environmental impacts of decommissioning at such time as FPL terminates reactor operations at Turkey Point. Chapter 4 of the license renewal GEIS and Section 4.15.2 of the Turkey Point SEIS describe the incremental environmental impacts of subsequent license renewal on decommissioning activities.

Termination of operations at Turkey Point would result in the total cessation of electrical power production by Turkey Point Units 3 and 4. The no-action alternative does not expressly meet the purpose and need of the proposed action because the no-action alternative does not provide a means of delivering baseload power to meet future electric system needs. Assuming that a need exists for the power generated by Turkey Point Units 3 and 4 at the time of their shutdown, the no-action alternative would likely create a need for a replacement power alternative. The NRC staff's environmental review includes a comparison of the environmental impacts of subsequent license renewal with the impacts of a range of energy sources that might be chosen in the event that the current renewed Turkey Point licenses are not subsequently renewed.

ii. Alternative Energy Sources

In evaluating alternatives to subsequent license renewal, the NRC considered energy technologies or options currently in commercial operation, as well as technologies not currently in commercial operation, but likely to be commercially available by the time the current Turkey Point renewed operating licenses expire.

The GEIS presents an overview of some alternative energy technologies but does not conclude which alternatives are most appropriate. Because alternative energy technologies are continually evolving in capability and cost, and because regulatory structures have changed to either promote or impede the development of particular technologies, the analyses in the FSEIS rely on a variety of sources of information to determine which alternatives would be available and commercially viable when the current licenses expire. FPL's environmental report provides a discussion of replacement power alternatives. In addition to the information FPL provided in its environmental report, the NRC staff's analyses relied on appropriate Federal, State, and industry information sources.

In total, the NRC staff considered 16 replacement power alternatives to the proposed action and eliminated 13 of these from detailed study because of existing technical, resource availability, or commercial limitations. These limitations are likely to continue when the current Turkey Point renewed licenses expire, rendering these alternatives not feasible or commercially viable. The no-action alternative (i.e., not issuing subsequent renewed licenses) was also considered. Alternatives considered, but eliminated from detailed study were as follows:

solar power
wind power
biomass power
demand-side management
hydroelectric power
geothermal power
wave and ocean energy
municipal solid waste
petroleum-fired power
coal-fired power
fuel cells
purchased power
delayed retirement of other generating facilities.

The basis for the elimination of each of these alternatives is explained in Section 2.3 of the final SEIS.

This left three reasonable replacement power alternatives for in-depth evaluation:

- new nuclear generation
- natural gas combined cycle (NGCC)
- combination alternative (NGCC and solar power)

These three alternatives are described in Sections 2.2.2.1 through 2.2.2.3 of the FSEIS, and NRC staff's in-depth evaluation of these alternatives is presented in Chapter 4 of the FSEIS. The alternatives selected for detailed evaluation in the FSEIS are briefly described below.

New Nuclear Alternative

The NRC staff considers the construction of a new nuclear plant to be a reasonable alternative to Turkey Point subsequent license renewal. The NRC staff determined that there may be sufficient time for FPL to prepare and submit an application, build, and operate two new nuclear units using a certified design before the Turkey Point Units 3 and 4 licenses expire in 2032 and 2033.

In 2018, as part of a separate licensing action, the NRC issued combined licenses (COLs) to FPL for the construction and operation of two new Westinghouse AP1000 reactor units at the Turkey Point site. For the purpose of this subsequent license renewal analysis, the NRC staff assumed two separate Westinghouse AP1000 reactors would replace Turkey Point Units 3 and 4. For the new nuclear alternative, the replacement power facility would be located within the Turkey Point property, but outside the current footprints of Turkey Point Units 3 and 4. Accordingly, the heat rejection demands of these new nuclear reactors would also be similar to those of Turkey Point Units 3 and 4. As stated in FPL's environmental report, the new nuclear alternative would use a mechanical draft cooling tower system. This closed-cycle cooling system would primarily use reclaimed wastewater from the Miami-Dade Water and Sewer Department, with saltwater produced from radial collection wells under Biscayne Bay used as a temporary backup source.

The NRC staff also considered the installation of multiple small modular reactors as a new nuclear alternative to renewing the Turkey Point Unit 3 and 4 licenses. Small modular reactors generate approximately 300 MW or less, so they have lower initial capacity than that of traditional large-scale units. However, they have greater siting flexibility because they can fit in locations not large enough to accommodate traditional nuclear reactors. The NRC staff assumes that the resource requirements and key characteristics associated with constructing and operating small modular reactors would be bounded by the larger nuclear units evaluated in the SEIS.

Natural Gas Combined-Cycle Alternative

The NRC staff considers the construction of a natural gas combined-cycle power plant to be a reasonable alternative to Turkey Point subsequent license renewal because natural gas is a feasible, commercially available option for providing baseload electrical generating capacity beyond the expiration of Turkey Point's current licenses.

Baseload natural gas combined-cycle power plants have proven their reliability and can have capacity factors as high as 87 percent. For this alternative, the NRC staff assumes that three natural gas units would be constructed and operated to replace Turkey Point's generating capacity. Together, the three units would collectively replace Turkey Point's approximate net generating capacity of 1500 MWe.

The NRC staff assumes that the natural gas combined-cycle plant would use a closed-cycle cooling system with mechanical draft cooling towers. Because of the high overall thermal efficiency of this type of plant, the natural gas combined-cycle alternative would require less cooling water than Turkey Point subsequent license renewal. Onsite visible structures could include the cooling towers, exhaust stacks, intake and discharge structures, transmission lines, natural gas pipelines, and an electrical switchyard.

Combination Alternative

The NRC staff considers construction of an alternative that combines construction of new natural gas combined-cycle and new solar power generating facilities to be a reasonable alternative to Turkey Point subsequent license renewal because these sources, when combined, provide a feasible, commercially available option for providing baseload electrical generating capacity beyond the expiration of Turkey Point's current licenses. The staff assumes that the natural gas combined-cycle facility and one of the four solar plants would be located within the Turkey Point property and would use existing available site infrastructure to the extent practicable. The other three solar facilities would be located at offsite locations within the region of influence, specifically within Miami-Dade and Broward counties.

The natural gas portion of the combination alternative would be generated using a natural gas combined-cycle plant. Although similar in function and appearance to the natural gas plant described above, the natural gas plant considered under the combination alternative would have slightly less generating capacity. Specifically, this slightly smaller plant would collectively replace 1,420 MWe of Turkey Point's approximate net generating capacity.

The NRC staff assumes that the natural gas plant would similarly use a closed-cycle cooling system with mechanical draft cooling towers.

The NRC staff considers the construction of solar photovoltaic facilities to be a reasonable alternative to subsequent license renewal when combined with natural gas combined-cycle facilities.

The solar portion of the combination alternative would be generated using a utility-scale solar photovoltaic facility comprised of four units. Operating at a 26 percent capacity factor, the solar units collectively would have an approximate net generating capacity of 80 MWe. When combined with the natural gas portion of this alternative, the total power produced would be sufficient to replace Turkey Point's approximate net generating capacity of 1500 MWe.

iii. Alternative Cooling Water Source

The NRC staff also evaluated in the FSEIS an alternative cooling water system technology for Turkey Point Units 3 and 4 that might be used to mitigate the potential impacts associated with continued use of the existing cooling canal system. The purpose of this analysis is for the NRC staff to compare an alternative closed-cycle cooling system approach with the proposed action to inform the NRC's licensing decision, decisions by other decisionmakers, and the public, as applicable, under NEPA. However, the NRC has neither the statutory nor the regulatory authority to determine which cooling water system or technology should be used, or to decide other permitting issues, for which the State of Florida has been delegated regulatory authority under the Clean Water Act.

The NRC staff's analysis of the alternative cooling water system draws upon an application, which FPL submitted to the NRC in 2009 for COLs to build and operate two new nuclear reactors (Turkey Point Units 6 and 7) on the Turkey Point site. The NRC staff conducted an environmental review of that COL application and published it as NUREG–2176, "Environmental Impact Statement for Combined Licenses (COLs) for Turkey Point Nuclear Plant Units 6 and 7" (ADAMS Package Accession No. ML16335A219). Section 3.2.2.2 of the COL EIS describes a cooling water system alternative to Turkey Point's existing cooling canal system that consists of onsite mechanical draft cooling towers. Under the cooling water system alternative that is evaluated by the NRC staff in the subsequent license renewal FSEIS, Turkey Point Units 3 and 4 would each use three similar closed-cycle wet-cooling towers (six cooling towers in total) to dissipate heat from the reactor cooling water systems.

As in the new nuclear alternative, the primary source of cooling water is assumed to be reclaimed wastewater.

The CCS would continue to operate regardless of the proposed Turkey Point license renewal because it supports retired fossil fuel Units 1 and 2. FPL plans to continue to use water from the CCS to support these units' operation in synchronous condenser mode over the course of the proposed subsequent license renewal period. Additionally, fossil fuel Unit 5 would remain in operation and would continue to discharge blowdown to the CCS. Furthermore, requirements of the October 7, 2015, Consent Agreement between FPL and Miami-Dade County and the June 20, 2016, Consent Order between FPL and the Florida Department of Environmental Protection would continue to apply.

iv. Summary

In the FSEIS for the Turkey Point subsequent license renewal, the NRC staff considered the environmental impacts associated with subsequent license renewal and with alternatives to subsequent license renewal, including alternative power generation technologies; the impacts of not renewing the Turkey Point Unit 3 and 4 operating licenses (the no-action alternative); and the impacts of an alternative to operation of the cooling canal system. The FSEIS concludes that environmental impacts of the proposed action (subsequent renewal of the Turkey Point operating licenses) would be SMALL for all impact categories except for groundwater resources and aquatic resources. The impacts to groundwater resources range from SMALL to MODERATE because of groundwater use conflicts during subsequent license renewal. Due to impingement, entrainment, and thermal impacts on the aquatic organisms in the cooling canal system, the impact of the Turkey Point subsequent license renewal to aquatic resources would be SMALL to MODERATE.

As summarized in Table 2-2 of the FSEIS ("Summary of Environmental Impacts of the Proposed Action and Alternatives," reproduced below in Table 1), each of the three reasonable replacement power alternatives have environmental impacts in at least two resource areas that are greater than the environmental impacts of the proposed action of subsequent license renewal. In addition, the replacement power alternatives also involve the environmental impacts inherent to new construction projects. If the NRC adopts the no-action alternative and does not issue subsequent renewed licenses for Turkey Point, energy-planning decisionmakers would likely implement one of the three replacement power alternatives discussed in-depth in Chapter 4 of the FSEIS. Based on the NRC staff's review of these three replacement power alternatives, the no-action alternative, and the proposed action, the staff concludes that the environmentally preferred alternative is the proposed action of subsequent license renewal. Therefore, the NRC staff proposes to recommend that the NRC issue subsequent renewed operating licenses for Turkey Point Units 3 and 4.

Table 1 Summary of Environmental Impacts of the Proposed Action and Alternatives

Impact Area (Resource)	Turkey Point Subsequent License Renewal (Proposed Action)	No-Action Alternative	New Nuclear Alternative	Natural Gas Combined-Cycle Alternative	Combination Alternative (Natural Gas Combined-Cycle and Solar Photovoltaic)	Cooling Water System Alternative
Land Use	SMALL	SMALL	SMALL to MODERATE	SMALL to MODERATE	SMALL to LARGE	SMALL
Visual Resources	SMALL	SMALL	SMALL to MODERATE	SMALL to MODERATE	SMALL to LARGE	SMALL to MODERATE
Air Quality	SMALL	SMALL	SMALL	SMALL to MODERATE	SMALL to MODERATE	SMALL
Noise	SMALL	SMALL	SMALL to MODERATE	SMALL to MODERATE	SMALL to MODERATE	SMALL to MODERATE

(a) The NRC staff concludes that Turkey Point subsequent license renewal is likely to adversely affect the American crocodile and the eastern indigo snake, and may result in adverse modification to designated critical habitat of the American crocodile. The NRC staff concludes that proposed action may affect, but is not likely to adversely affect, the Florida panther, West Indian manatee, red knot, wood stork, loggerhead sea turtle, green sea turtle, leatherback sea turtle, hawksbill sea turtle, Kemp's ridley sea turtle, and smalltooth sawfish. The NRC staff concludes that the proposed action would result in no adverse modification to designated critical habitat of the West Indian manatee. The NRC staff's evaluation of impacts to federally listed species and critical habitats under the U.S. Fish and Wildlife Service's jurisdiction appears in the NRC's Biological Assessment (ADAMS Accession No. ML18353A835). The FWS's separate evaluation and conclusions appear in a July 25, 2019, biological opinion (ADAMS Accession No. ML19221B583), which is described in Section 4.8.1.1 of this SEIS. The NRC staff's evaluation of impacts to federally listed species and critical habitats under the National Marine Fisheries Service's jurisdiction appears in Section 4.8.1.1 of this SEIS. The NRC staff concludes that the proposed action would have no adverse effects on Essential Fish Habitat. The NRC staff's evaluation of impacts to Essential Fish Habitat appears in Section 4.8.1.2 of this SEIS. The NRC staff concludes that the proposed action would not affect the sanctuary resources of the Florida Keys National Marine Sanctuary. The NRC staff's evaluation of sanctuary resources appears in Section 4.8.1.3 of this SEIS.

(b) The types and magnitudes of adverse impacts to species listed pursuant to the Endangered Species Act of 1973, as amended (16 U.S.C. 1531 et seq.), designated critical habitat, and Essential Fish Habitat would depend on Turkey Point shutdown activities, the proposed alternative site, plant design, and operation, as applicable, and on the listed species and designated critical habitats present when the alternative is implemented. Therefore, the NRC staff cannot forecast a particular level of impact for this alternative.

(c) Based on (1) the location of National Register of Historic Places-eligible historic properties within the area of potential effect, (2) tribal input, (3) FPL's cultural resource protection plans, (4) the fact that no license renewal-related physical changes or ground-disturbing activities would occur, (5) Florida State Historic Preservation Office input, and (6) cultural resource assessment, license renewal would not adversely affect any known historic properties (Title 36 of the *Code of Federal Regulations* 800.4(d)(1), "No Historic Properties Affected").

(d) As a result of facility shutdown, land-disturbing activities or dismantlement are not anticipated as these would be conducted during decommissioning. Therefore, facility shutdown would have no immediate effect on historic properties or historic and cultural resources.

(e) Since the alternative would be located at the Turkey Point site, which has a low archeological potential, and avoidance of significant resources would be possible, this alternative would not adversely affect known historic properties.

(f) The impacts from the construction and operation of the solar component would depend on where solar facilities are constructed. The historic and cultural resource impact could range from no adverse effect to adverse effect.

(g) The chronic effects of electromagnetic fields on human health associated with operating nuclear power and other electricity generating plants are uncertain.

(h) There would be no disproportionately high and adverse impacts to minority and low-income populations.

(i) A reduction in tax revenue resulting from the shutdown of Turkey Point could decrease the availability of public services in the Turkey Point area. However, the effects to minority and low-income populations would not be disproportionately high and adverse.

(j) Based on the analysis of human health and environmental impacts presented in this SEIS, the location of the alternative, and the assumed alternative design and characteristics, this alternative would not likely have disproportionately high and adverse human health and environmental effects on minority and low-income populations.

(k) This alternative would not likely have disproportionately high and adverse human health and environmental effects on minority and low-income populations. However, this determination would depend on the location of the solar facilities. Therefore, the NRC staff cannot determine whether the solar portion of the combination alternative would result in disproportionately high and adverse human health and environmental effects on minority and low-income populations.

(l) NUREG–2157, "Generic Environmental Impact Statement for Continued Storage of Spent Nuclear Fuel," (ADAMS Accession No. ML14198A440) discusses the environmental impact of spent fuel storage for the timeframe beyond the licensed life for reactor operations.

UPDATED STATUS OF ENDANGERED SPECIES ACT SECTION 7 CONSULTATION

In conjunction with its review of the license renewal application, the NRC staff conducted consultation under Section 7 of the Endangered Species Act (ESA) of 1973, as amended, with the National Marine Fisheries Service (NMFS). Appendix C.1 of the FSEIS describes the status of the staff's consultation with the NMFS, which was not yet concluded when the staff completed the FSEIS. On April 1, 2019, the NRC staff requested the NMFS's concurrence with the staff's determinations that the proposed action may affect, but is not likely to adversely affect, the loggerhead sea turtle (*Caretta caretta*), green sea turtle (*Chelonia mydas*), leatherback sea turtle (*Dermochelys coriacea*), hawksbill sea turtle (*Eretmochelys imbricata*), and smalltooth sawfish (*Pristis pectinata*) (ADAMS Accession No. ML19091A128). On June 7, 2019, the NRC staff transmitted its determinations for two additional species, Kemp's ridley sea turtle (*Lepidochelys kempii*) and Nassau grouper (*Epinephelus striatus*) to the NMFS (ADAMS Accession No. ML19158A503). The staff determined that the proposed action may affect, but is not likely to adversely affect, the Kemp's ridley sea turtle. The staff also determined that the proposed action would have no effect on the Nassau grouper, because NMFS had previously determined in a 2017 consultation with the NRC that the Nassau grouper would not occur in the action area, and the staff had identified no new information during its review for subsequent license renewal indicating that this species would occur in the action area.

On October 22, 2019, the NMFS concurred with the NRC staff's determinations that the proposed action may affect, but is not likely to adversely affect, the loggerhead sea turtle (*Caretta caretta*), green sea turtle (*Chelonia mydas*), leatherback sea turtle (*Dermochelys coriacea*), hawksbill sea turtle (*Eretmochelys imbricata*), Kemp's ridley sea turtle (*Lepidochelys kempii*), and smalltooth sawfish (*Pristis pectinata*). The NMFS also concluded that the proposed action may affect, but is not likely to adversely affect, the Nassau grouper (*Epinephelus striatus*). The NMFS's concurrence concluded consultation for the proposed Turkey Point license renewal. Accordingly, the NRC has fulfilled its obligations under ESA Section 7(a)(2) with respect to the proposed action for federally listed species and critical habitats under the jurisdiction of the NMFS.

With respect to federally listed species and critical habitats under the jurisdiction of the U.S. Fish and Wildlife Service (FWS), the NRC staff consulted with the FWS on the proposed action in 2018 and 2019. On July 25, 2019, the FWS issued a biological opinion for Turkey Point. In its opinion, the FWS concluded that the continued operation of Turkey Point through the duration of the proposed subsequent license renewal period is not likely to jeopardize the continued existence of the American crocodile (*Crocodylus acutus*) or eastern indigo snake (*Drymarchon corais couperi*) and will not adversely modify the critical habitat of the American crocodile. The biological opinion includes an incidental take statement (ITS) applicable to the American crocodile and eastern indigo snake. The ITS's terms and conditions are nondiscretionary and must be undertaken by the NRC so that they become binding conditions of the renewed licenses, if granted, for the exemption in ESA Section 7(o)(2) to apply. Accordingly, the NRC will include conditions in the Turkey Point subsequent renewed facility operating licenses requiring FPL to adhere to the specific requirements within the ITS. Appendix A.1 of the FSEIS describes the staff's consultation with the FWS in more detail.

MITIGATION MEASURES

The NRC has taken all practicable measures within its jurisdiction to avoid or minimize environmental harm from the proposed action (subsequent license renewal). The NRC has determined that no additional mitigation measures are warranted and therefore is not imposing any license conditions in connection with mitigation measures for the continued operation of Units 3 and 4, apart from insertion of a condition regarding the ITS in Appendix B (Environmental Protection Plan) of the current licenses, which will continue in effect during the subsequent license renewal term. The NRC notes that Turkey Point is also subject to requirements including permits, authorizations, and regulatory orders imposed by other Federal, State, and local agencies governing facility operation, including the cooling canal system. For example, the National Pollutant Discharge Elimination System (NPDES) permit issued to FPL imposes effluent limitations and monitoring requirements as well as best management practices to ensure that impacts to water quality and aquatic life are minimized. The NRC is not requiring any new environmental monitoring programs beyond what is required for the NPDES permits or otherwise required under the NRC's regulations, as described in the FSEIS.

CONSIDERATION OF EMERGING INFORMATION AND COMMENTS ON THE FSEIS

Issuance of 2019 Annual Monitoring Report

The NRC staff's FSEIS includes consideration of FPL's annual monitoring reports through the period ending May 31, 2018. In August 2019, FPL issued the Turkey Point Plant Annual Monitoring Report for 2019. This report covers the period June 1, 2018, through May 31, 2019. The report summarizes the latest analytical results from FPL's meteorological, hydrologic, water quality, and ecological community monitoring that covers the Turkey Point CCS, Biscayne Bay, Card Sound, marshlands, mangrove areas, and canals adjacent to the CCS. FPL conducts this monitoring to assess the horizontal and vertical effects and extent of CCS water on existing and projected surface water, groundwater and ecological conditions surrounding Turkey Point. FPL conducts this monitoring under the auspices of the State of Florida's Department of Environmental Protection (FDEP), SFWMD, and the Miami-Dade County Department of Environmental Resources Management (DERM).

The NRC staff was unable to incorporate the information from the 2019 monitoring report in the Turkey Point FSEIS because FPL had not published the 2019 report by the time the NRC staff's environmental review concluded and the Turkey Point FSEIS was being prepared for publication. In the Turkey Point FSEIS, the NRC staff considered and carefully evaluated analytical results and conclusions contained in FPL's 2018 Turkey Point Plant Annual Monitoring Report, as summarized throughout the FSEIS including, but not limited to, sections 3.5.1.4, 3.5.2.2, 3.6.2, and 3.7.4.

Following FPL's issuance of the 2019 monitoring report, the NRC staff examined the report to determine whether the latest published data present new and significant information such that a supplement to the Turkey Point FSEIS would be required, in accordance with 10 CFR 51.92(a). The staff's review identified no substantial changes in monitoring results or trends for hydrologic parameters, surface water quality, groundwater quality, or ecological communities that would change any conclusions presented in the FSEIS. Therefore, the NRC staff determined that no supplement to the Turkey Point FSEIS was required.

Comments on the FSEIS

On November 1, 2019, the EPA issued the Notice of Availability for the FSEIS regarding the Turkey Point Units 3 and 4 subsequent license renewal application (84 FR 58713). On December 2, 2019, NRC staff received a letter from EPA Region 4 providing comments on the FSEIS. The NRC staff has carefully reviewed the letter and the comments attached thereto. After thorough review and consideration, the staff has determined that the issues discussed in the EPA's comments were previously considered and addressed in the FSEIS and Appendix A thereto, as further amplified below in response to EPA's comments. Therefore, the staff has concluded that no further evaluation of these comments is required, and no change to the staff's conclusions is warranted.

First, in its comments on the FSEIS, the EPA reaffirmed its request that the NRC add language to the renewed operating licenses for Turkey Point Units 3 and 4, or to the ROD, requiring FPL to implement alternative water quality mitigation measures should FPL be unable to achieve mandated groundwater remediation objectives prescribed by the Florida Department of Environmental Protection and Miami-Dade County associated with the cooling canal system operations. As previously described in the NRC staff's October 25, 2019, letter to EPA (ADAMS Accession No. ML19295F527) and in the NRC staff's responses to EPA and other stakeholder comments contained in Appendix A, Section A.2.11, of the FSEIS, the NRC does not have regulatory authority to require FPL to comply with the Clean Water Act; such regulatory authority resides with the EPA and its delegee, the State of Florida. Likewise, the NRC does not have regulatory authority to require FPL to comply with consent agreements or consent orders issued by the FDEP or the DERM and, therefore, cannot make compliance with orders issued by other agencies a condition of the NRC license. Neither does the NRC have the regulatory authority to require that FPL implement an alternative closed-loop cooling water system or other measures as a license condition if requirements imposed by the FDEP or DERM are unsuccessful in achieving their objectives. Similarly, the NRC's regulatory authority does not enable it to incorporate such language into this ROD.

Second, the NRC staff acknowledges the EPA's observation that a discussion in Section 3.5.1.1 ("Potential for Flooding at the Turkey Point Site") of the FSEIS does not describe the detailed model that was used by FPL to conduct flooding and storm surge analyses for the Turkey Point site, and EPA's recommendation that the NRC provide a description of the modeling and associated rationale supporting storm surge and flooding analyses in future assessments. In this regard, as noted in the FSEIS, the flood hazard analysis for Turkey Point Units 3 and 4 was performed by FPL in connection with the NRC's oversight of the current operating licenses at Turkey Point Units 3 and 4, and not in connection with the subsequent license renewal. More specifically, in 2012, the Commission ordered all nuclear power plant licensees to conduct appropriate flood hazard revaluations based on recommendations from the NRC's Japan Near-Term Task Force that was commissioned after the March 11, 2011, Great Tohoku Earthquake and subsequent tsunami, impacting the Fukushima Dai-ichi nuclear power plants. As discussed in the FSEIS at page 3-42, FPL submitted its updated flooding analysis on June 29, 2017, as required; a detailed description of that analysis ("Turkey Point Nuclear Generating Station Flooding Focused Evaluation Summary") is contained in the document cited in the FSEIS at page 3-42 as NRC 2017b (ADAMS Accession No. ML17212B180). Following its review of FPL's analysis, the NRC staff determined that FPL conducted the flood hazard reevaluation for

Turkey Point Units 3 and 4 using NRC-approved modeling approaches and applicable guidance, including Nuclear Energy Institute (NEI) 16-05, Revision 1, "External Flooding Assessment Guidelines" (ADAMS Accession No. ML16165A178). The NRC staff's letter approving FPL's analysis, dated July 3, 2018, is available at ADAMS Accession No. ML18158A548; this document was inadvertently not cited on page 3-42 of the FSEIS, and should have been identified and listed in Chapter 6. More generally, historic and current information relating to the scope, process, relevant guidance, and status of the facility-specific flood hazard reevaluation activities can be found on the NRC's public web site at https://www.nrc.gov/reactors/operating/ops-experience/japan-dashboard/flooding.html.

DETERMINATION

Based on the NRC staff's (a) independent review, analysis, and evaluation contained in the subsequent license renewal FSEIS; (b) careful consideration of all of the identified social, economic, and environmental factors; (c) input received from other agencies, organizations, and the public; and (d) consideration of mitigation measures, the NRC has determined that the standards for the issuance of a subsequently renewed operating license, with respect to the environmental matters as described in 10 CFR 54.29(b), have been met and that the requirements of Section 102 of NEPA have been satisfied. The NRC has determined that the adverse environmental impacts or issuing subsequent renewed operating licenses for Turkey Point Units 3 and 4 are not so great that preserving the option of license renewal for energy-planning decisionmakers would be unreasonable.

Dated at Rockville, MD, this 4th day of December, 2019,

APPROVED BY:

/RA/

Anna H. Bradford, Director
Division of New and Renewed Licenses
Office of Nuclear Reactor Regulation

UNITED STATES
NUCLEAR REGULATORY COMMISSION
WASHINGTON, D.C. 20555-0001

FLORIDA POWER & LIGHT COMPANY

DOCKET NO. 50-250

TURKEY POINT NUCLEAR GENERATING UNIT NO. 3

SUBSEQUENT RENEWED FACILITY OPERATING LICENSE NO. DPR-31

The U.S. Nuclear Regulatory Commission (the Commission) having previously made the findings set forth in Renewed License No. DPR-31 issued on June 6, 2002, has now found that:

a. The application for Subsequent Renewed Facility Operating License No. DPR-31 filed by Florida Power and Light Company, complies with the standards and requirements of the Atomic Energy Act of 1954, as amended (the Act), and the Commission's rules and regulations set forth in 10 CFR Chapter I and all required notifications to other agencies or bodies have been duly made;

b. Actions have been identified and have been or will be taken with respect to (1) managing the effects of aging during the subsequent period of extended operation on the functionality of structures and components that have been identified to require review under 10 CFR 54.21(a)(1), and (2) time-limited aging analyses that have been identified to require review under 10 CFR 54.21(c), such that there is reasonable assurance that the activities authorized by this subsequent renewed operating license will continue to be conducted in accordance with the current licensing basis, as defined in 10 CFR 54.3, for the Turkey Point Unit 3 plant, and that any changes made to the plant's current licensing basis in order to comply with 10 CFR 54.29(a) are in accord with the Act and the Commission's regulations;

c. The facility will operate in conformity with the application, as amended, the provisions of the Act, and the rules and regulations of the Commission;

d. There is reasonable assurance (i) that the facility can be operated at steady state power levels up to 2644 megawatts thermal in accordance with this subsequent renewed operating license without endangering the health and safety of the public, and (ii) that such activities will be conducted in compliance with the rules and regulations of the Commission;

e. Florida Power and Light Company is technically and financially qualified to engage in the activities authorized by this subsequent renewed operating license in accordance with the rules and regulations of the Commission;

f. The applicable provisions of 10 CFR Part 140 have been satisfied;

g. The subsequent renewal of this renewed operating license will not be inimical to the common defense and security or to the health and safety of the public; and

h. After weighing the environmental, economic, technical and other benefits of the facility against environmental costs and considering available alternatives, the issuance of Subsequent Renewed Facility Operating License No. DPR-31 is in accordance with

10 CFR Part 51 of the Commission's regulations and all applicable requirements have been satisfied.

On the basis of the foregoing findings regarding this facility, Renewed Facility Operating License No. DPR-31, issued on June 6, 2002, is superseded by Subsequent Renewed Facility Operating License No. DPR-31, which is hereby issued to Florida Power and Light Company (FPL), to read as follows:

1. This subsequent renewed operating license applies to the Turkey Point Nuclear Generating Unit No. 3 nuclear power reactor, a pressurized, light water moderated and cooled reactor, and associated steam generators and electrical generating equipment (the facility). The facility is located on the applicant's Turkey Point site in Miami-Dade County, about 25 miles south of Miami, Florida, and is described in the Final Safety Analysis Report as supplemented and amended, and the Environmental Report as supplemented and amended.

2. Subject to the conditions and requirements incorporated herein, the Commission hereby licenses FPL:

   A. Pursuant to Section 104b of the Atomic Energy Act of 1954, as amended (the Act), and 10 CFR Part 50, "Licensing of Production and Utilization Facilities," to possess, use, and operate the facility as a utilization facility at the designated location on the Turkey Point site, in accordance with the procedures and limitations set forth in this subsequent renewed operating license;

   B. Pursuant to the Act and 10 CFR Part 70, to receive, possess, and use at any time special nuclear material as reactor fuel, in accordance with the limitations for storage and amounts required for reactor operation, as described in the Final Safety Analysis Report, as supplemented and amended;

   C. Pursuant to the Act and 10 CFR Parts 30, 40, and 70 to receive, possess, and use at any time any byproduct, source and special nuclear material as sealed neutron sources for reactor startup, sealed sources for reactor instrumentation and radiation monitoring equipment calibration, and as fission detectors in amounts as required;

   D. Pursuant to the Act and 10 CFR Part 30 to receive, possess, and use at any time 100 millicuries each of any byproduct material without restriction to chemical or physical form, for sample analysis or instrument calibration or associated with radioactively contaminated apparatus;

   E. Pursuant to the Act and 10 CFR Parts 40 and 70 to receive, possess, and use at any time 100 milligrams each of any source or special nuclear material without restriction to chemical or physical form, for sample analysis or instrument calibration or associated with radioactively contaminated apparatus;

   F. Pursuant to the Act and 10 CFR Parts 30 and 70, to possess, but not separate, such byproduct and special nuclear materials as may be produced by the operation of Turkey Point Units Nos. 3 and 4.

3. This subsequent renewed operating license shall be deemed to contain and is subject to the conditions specified in the following Commission regulations: 10 CFR Part 20, Section 30.34 of 10 CFR Part 30, Section 40.41 of 10 CFR Part 40, Sections 50.54 and 50.59 of 10 CFR Part 50, and Section 70.32 of 10 CFR Part 70; and is subject to all

applicable provisions of the Act and to the rules, regulations, and orders of the Commission now or hereafter in effect, and is subject to the additional conditions specified below:

A. Maximum Power Level

The applicant is authorized to operate the facility at reactor core power levels not in excess of 2644 megawatts (thermal).

B. Technical Specifications

The Technical Specifications contained in Appendix A, as revised through Amendment No. 292, are hereby incorporated into this subsequent renewed license. The Environmental Protection Plan contained in Appendix B is hereby incorporated into this subsequent renewed operating license. The licensee shall operate the facility in accordance with the Technical Specifications and the Environmental Protection Plan.

C. Final Safety Analysis Report

The licensee's Final Safety Analysis Report supplement submitted pursuant to 10 CFR 54.21(d), as revised on November 1, 2001, describes certain future inspection activities to be completed before the period of extended operation. The licensee shall complete these activities no later than July 19, 2012.

The Final Safety Analysis Report supplement as revised on November 1, 2001, described above, shall be included in the next scheduled update to the Final Safety Analysis Report required by 10 CFR 50.71(e)(4), following the issuance of this renewed license. Until that update is complete, the licensee may make changes to the programs described in such supplement without prior Commission approval, provided that the licensee evaluates each such change pursuant to the criteria set forth in 10 CFR 50.59 and otherwise complies with the requirements in that section.

D. Fire Protection

FPL shall implement and maintain in effect all provisions of the approved fire protection program that comply with 10 CFR 50.48(a) and 10 CFR 50.48(c), as specified in the licensee amendment requests dated June 28, 2012 and October 17, 2018 (and supplements dated September 19, 2012; March 18, April 16, and May 15, 2013; January 7, April 4, June 6, July 18, September 12, November 5, and December 2, 2014; and February 18, 2015; October 24, and December 3, 2018; and January 31, 2019), and as approved in the safety evaluations dated May 28, 2015 and March 27, 2019. Except where NRC approval for changes or deviations is required by 10 CFR 50.48(c), and provided no other regulation, technical specification, license condition or requirement would require prior NRC approval, the licensee may make changes to the fire protection program without prior approval of the Commission if those changes satisfy the provisions set forth in 10 CFR 50.48(a) and 10 CFR 50.48(c), the change does not require a change to a technical specification or a license condition, and the criteria listed below are satisfied.

Risk-Informed Changes that May Be Made Without Prior NRC Approval

A risk assessment of the change must demonstrate that the acceptance criteria below are met. The risk assessment approach, methods, and data shall be acceptable to the NRC and shall be appropriate for the nature and scope of the change being evaluated; be based on the as-built, as-operated, and maintained plant; and reflect the operating experience at the plant. Acceptable methods to assess the risk of the change may include methods that have been used in the peer-reviewed fire PRA model, methods that have been approved by NRC through a plant-specific license amendment or NRC approval of generic methods specifically for use in NFPA 805 risk assessments, or methods that have been demonstrated to bound the risk impact.

(a) Prior NRC review and approval is not required for changes that clearly result in a decrease in risk. The proposed change must also be consistent with the defense-in-depth philosophy and must maintain sufficient safety margins. The change may be implemented following completion of the plant change evaluation.

(b) Prior NRC review and approval is not required for individual changes that result in a risk increase less than $1x10^{-7}$/year (yr) for CDF and less than 1×10^{-8}/yr for LERF. The proposed change must also be consistent with the defense-in-depth philosophy and must maintain sufficient safety margins. The change may be implemented following completion of the plant change evaluation.

Other Changes that May Be Made Without Prior NRC Approval

1. Changes to NFPA 805, Chapter 3, Fundamental Fire Protection Program

Prior NRC review and approval are not required for changes to the NFPA 805, Chapter 3, fundamental fire protection program elements and design requirements for which an engineering evaluation demonstrates that the alternative to the Chapter 3 element is functionally equivalent or adequate for the hazard. The licensee may use an engineering evaluation to demonstrate that a change to an NFPA 805, Chapter 3, element is functionally equivalent to the corresponding technical requirement. A qualified fire protection engineer shall perform the engineering evaluation and conclude that the change has not affected the functionality of the component, system, procedure, or physical arrangement, using a relevant technical requirement or standard.

The licensee may use an engineering evaluation to demonstrate that changes to certain NFPA 805, Chapter 3, elements are acceptable because the alternative is "adequate for the hazard." Prior NRC review and approval would not be required for alternatives to four specific sections of NFPA 805, Chapter 3, for which an engineering evaluation demonstrates that the alternative to the Chapter 3 element is adequate for the hazard. A qualified fire protection engineer shall perform the engineering evaluation and conclude that the change has not affected the functionality of the component, system, procedure, or physical arrangement, using a relevant technical requirement or standard. The four specific sections of NFPA 805, Chapter 3, are as follows:

- "Fire Alarm and Detection Systems" (Section 3.8);
- "Automatic and Manual Water-Based Fire Suppression Systems" (Section 3.9);
- "Gaseous Fire Suppression Systems" (Section 3.10); and
- "Passive Fire Protection Features" (Section 3.11).

This License Condition does not apply to any demonstration of equivalency under Section 1.7 of NFPA 805.

2. Fire Protection Program Changes that Have No More than Minimal Risk Impact

Prior NRC review and approval are not required for changes to the licensee's fire protection program that have been demonstrated to have no more than a minimal risk impact. The licensee may use its screening process as approved in the NRC safety evaluation dated May 28, 2015, to determine that certain fire protection program changes meet the minimal criterion. The licensee shall ensure that fire protection defense-in-depth and safety margins are maintained when changes are made to the fire protection program.

<u>Transition License Conditions</u>

1. Before achieving full compliance with 10 CFR 50.48(c), as specified by 2. and 3. below, risk-informed changes to the licensee's fire protection program may not be made without prior NRC review and approval unless the change has been demonstrated to have no more than a minimal risk impact, as described in 2. above.

2. The licensee shall implement the modifications to its facility, as described in Enclosure 1, Attachment S, Table S-2, "Plant Modifications Committed," of FPL letter L-2014-303, dated 11/05/2014, to complete the transition to full compliance with 10 CFR 50.48(c) by the end of the second refueling outage (for each unit) following issuance of the license amendment. The licensee shall maintain appropriate compensatory measures in place until completion of these modifications.

3. The licensee shall implement the items listed in Enclosure 5, Attachment S, Table S-3, "Implementation Items," of FPL letter L-2018-219, dated 12/3/2018, with the exception of items 12, 18 and 19, no later than 12 months after issuance of the license amendment dated 5/28/2015. Items 12, 18 and 19 are associated with modifications in Table S-2 and will be completed in accordance with Transition License Condition 2 above.

E. The licensee shall fully implement and maintain in effect all provisions of the Commission-approved physical security, training and qualification, and safeguards contingency plans including amendments made pursuant to provision of the Miscellaneous Amendments and Search Requirements revisions to 10 CFR 73.55 (51 FR 27817 and 27822) and to the authority of 10 CFR 50.90 and 10 CFR 50.54(p). The combined set of plans, which contains Safeguards Information protected under 10 CFR 73.21, is entitled: "Florida Power and Light Turkey Point Nuclear Plant Physical Security Plan, Training and Qualification Plan, Safeguards Contingency Plan, and Independent Spent Fuel Storage Installation Security Program - Revision 15" submitted by letter dated August 3, 2012.

The licensee shall fully implement and maintain in effect all provisions of the Commission-approved cyber security plan (CSP), including changes made pursuant to the authority of 10 CFR 50.90 and 10 CFR 50.54(p). The Turkey Point Nuclear Generating Station CSP was approved by License Amendment No. 245 as supplemented by a change approved by Amendment Nos. 256 and 266.

F. 1. The licensee shall restrict the combined number of fuel assemblies loaded in the existing spent fuel pool storage racks and cask pit rack to no more than the capacity of the spent fuel pool storage racks. This condition applies at all times, except during activities associated with a reactor core offload/reload refueling condition. This restriction will ensure the capability to unload and remove the cask pit rack when cask loading operations are necessary.

2. The licensee shall establish two hold points within the rack installation procedure to ensure proper orientation of the cask rack in each unit's spent fuel pool. Verification of proper cask pit rack orientation will be implemented by an authorized Quality Control inspector during installation of the racks to ensure consistency with associated spent fuel pool criticality analysis assumptions.

G. Mitigation Strategy License Condition

Develop and maintain strategies for addressing large fires and explosions and that include the following key areas:

(a) Fire fighting response strategy with the following elements:

1. Pre-defined coordinated fire response strategy and guidance
2. Assessment of mutual aid fire fighting assets
3. Designated staging areas for equipment and materials
4. Command and control
5. Training of response personnel

(b) Operations to mitigate fuel damage considering the following

1. Protection and use of personnel assets
2. Communications
3. Minimizing fire spread
4. Procedures for implementing integrated fire response strategy
5. Identification of readily-available pre-staged equipment
6. Training on integrated fire response strategy
7. Spent fuel pool mitigation measures

(c) Actions to minimize release to include consideration of:

1. Water spray scrubbing
2. Dose to onsite responders

H. PAD TCD Safety Analyses

1. PAD 4.0 TCD has been specifically approved for use for the Turkey Point licensing basis analyses. Upon NRC's approval of a revised generic version of PAD that accounts for Thermal Conductivity Degradation (TCD), FPL will within six months:

   a. Demonstrate that PAD 4.0 TCD remains conservatively bounding in licensing basis analyses when compared to the new generically approved version of PAD w/TCD, or
   b. Provide a schedule for the re-analysis using the new generically approved version of PAD w/TCD for any of the affected licensing basis analyses

I. FPL is authorized to implement the Risk Informed Completion Time Program as approved in License Amendment No. 284 subject to the following conditions:

1. FPL will complete the items listed in the table of implementation items in the enclosure to FPL letter L-2018-118 dated June 12, 2018 prior to implementation of the Risk Informed Completion Time Program.

2. The risk assessment approach and methods, shall be acceptable to the NRC, be based on the as-built, as-operated, and maintained plant, and reflect the operating experience of the plant as specified in RG 1.200. Methods to assess the risk from extending the completion times must be PRA methods accepted as part of this license amendment, or other methods approved by the NRC for generic use. If the licensee wishes to change its methods, and the change is outside the bounds of this license condition, the licensee will seek prior NRC approval via a license amendment.

J. Subsequent License Renewal License Conditions

1. The information in the Final Safety Analysis Report (FSAR) supplement submitted pursuant to 10 CFR 54.21(d), as revised during the subsequent license renewal application review process, and FPL commitments as listed in Appendix A of the "Safety Evaluation Report Related to the Subsequent License Renewal of Turkey Point Generating Units 3 and 4," dated July 22, 2019, are collectively the "Subsequent License Renewal FSAR Supplement." This Supplement is henceforth part of the FSAR, which will be updated in accordance with 10 CFR 50.71(e). As such, FPL may make changes to the programs, activities, and commitments described in the Subsequent License Renewal FSAR Supplement, provided FPL evaluates such changes pursuant to the criteria set forth in 10 CFR 50.59, "Changes, Tests, and Experiments," and otherwise complies with the requirements in that section.

2. The Subsequent License Renewal FSAR Supplement, as defined in renewed license condition (J)(1) above, describes programs to be implemented and activities to be completed prior to the subsequent period of extended operation, which is the period following the July 19, 2032, expiration of the initial renewed license.

   a. FPL shall implement those new programs and enhancements to existing programs no later than 6 months before the subsequent period of extended operation.

   b. FPL shall complete those activities by the 6-month date prior to the subsequent period of extended operation or by the end of the last refueling outage before the subsequent period of extended operation, whichever occurs later.

   c. FPL shall notify the NRC in writing within 30 days after having accomplished item (2)(a) above and include the status of those activities that have been or remain to be completed in item (2)(b) above.

3. FPL shall complete the replacement of a portion of the existing containment spray system carbon steel piping with stainless steel piping by December 1, 2024, so that any remaining carbon steel piping will not normally be internally exposed to borated water during the subsequent period of extended operation. The scope of replacement is the carbon steel piping from the stainless steel to the carbon steel dissimilar metal weld for the two containment

spray piping headers (3A and 3B) at penetrations P-19A and P-19B to a minimum plant elevation of 65 feet inside containment. FPL shall notify the NRC in writing within 60 days following completion of the refueling outage during which the piping replacement is completed. The notification will confirm the elevation of the air-to-borated-water interface inside the piping and confirm that the installation of the stainless steel piping exceeds this elevation.

4. This subsequent renewed license is effective as of the date of issuance, and shall expire at midnight July 19, 2052.

FOR THE NUCLEAR REGULATORY COMMISSION

/RA/

Ho K. Nieh, Director
Office of Nuclear Reactor Regulation

Appendix A - Technical Specifications for Unit 3
Appendix B - Environmental Protection Plan

Date of Issuance: December 4, 2019

UNITED STATES
NUCLEAR REGULATORY COMMISSION
WASHINGTON, D.C. 20555-0001

FLORIDA POWER & LIGHT COMPANY

DOCKET NO. 50-251

TURKEY POINT NUCLEAR GENERATING UNIT NO. 4

SUBSEQUENT RENEWED FACILITY OPERATING LICENSE NO. DPR-41

The U.S. Nuclear Regulatory Commission (the Commission) having previously made the findings set forth in Renewed License No. DPR-41 issued on June 6, 2002, has now found that:

a. The application for Subsequent Renewed Facility Operating License No. DPR-41 filed by Florida Power and Light Company, complies with the standards and requirements of the Atomic Energy Act of 1954, as amended (the Act), and the Commission's rules and regulations set forth in 10 CFR Chapter I and all required notifications to other agencies or bodies have been duly made;

b. Actions have been identified and have been or will be taken with respect to (1) managing the effects of aging during the subsequent period of extended operation on the functionality of structures and components that have been identified to require review under 10 CFR 54.21(a)(1), and (2) time-limited aging analyses that have been identified to require review under 10 CFR 54.21(c), such that there is reasonable assurance that the activities authorized by this subsequent renewed operating license will continue to be conducted in accordance with the current licensing basis, as defined in 10 CFR 54.3, for the Turkey Point Unit 4 plant, and that any changes made to the plant's current licensing basis in order to comply with 10 CFR 54.29(a) are in accord with the Act and the Commission's regulations;

c. The facility will operate in conformity with the application, as amended, the provisions of the Act, and the rules and regulations of the Commission;

d. There is reasonable assurance (i) that the facility can be operated at steady state power levels up to 2644 megawatts thermal in accordance with this subsequent renewed operating license without endangering the health and safety of the public, and (ii) that such activities will be conducted in compliance with the rules and regulations of the Commission;

e. Florida Power and Light Company is technically and financially qualified to engage in the activities authorized by this subsequent renewed operating license in accordance with the rules and regulations of the Commission;

f. The applicable provisions of 10 CFR Part 140 have been satisfied;

g. The subsequent renewal of this renewed operating license will not be inimical to the common defense and security or to the health and safety of the public; and

h. After weighing the environmental, economic, technical and other benefits of the facility against environmental costs and considering available alternatives, the issuance of Subsequent Renewed Facility Operating License No. DPR-41 is in accordance with 10 CFR Part 51 of the Commission's regulations and all applicable requirements have been satisfied.

On the basis of the foregoing findings regarding this facility, Renewed Facility Operating License No. DPR-41, issued on June 6, 2002, is superseded by Subsequent Renewed Facility Operating License No. DPR-41, which is hereby issued to Florida Power and Light Company (FPL), to read as follows:

1. This subsequent renewed operating license applies to the Turkey Point Nuclear Generating Unit No. 4 nuclear power reactor, a pressurized, light water moderated and cooled reactor, and associated steam generators and electrical generating equipment (the facility). The facility is located on the applicant's Turkey Point site in Miami-Dade County, about 25 miles south of Miami, Florida, and is described in the Final Safety Analysis Report as supplemented and amended, and the Environmental Report as supplemented and amended.

2. Subject to the conditions and requirements incorporated herein, the Commission hereby licenses FPL:

   A. Pursuant to Section 104b of the Atomic Energy Act of 1954, as amended (the Act), and 10 CFR Part 50, "Licensing of Production and Utilization Facilities," to possess, use, and operate the facility as a utilization facility at the designated location on the Turkey Point site, in accordance with the procedures and limitations set forth in this subsequent renewed operating license;

   B. Pursuant to the Act and 10 CFR Part 70, to receive, possess, and use at any time special nuclear material as reactor fuel, in accordance with the limitations for storage and amounts required for reactor operation, as described in the Final Safety Analysis Report, as supplemented and amended;

   C. Pursuant to the Act and 10 CFR Parts 30, 40, and 70 to receive, possess, and use at any time any byproduct, source and special nuclear material as sealed neutron sources for reactor startup, sealed sources for reactor instrumentation and radiation monitoring equipment calibration, and as fission detectors in amounts as required;

   D. Pursuant to the Act and 10 CFR Part 30 to receive, possess, and use at any time 100 millicuries each of any byproduct material without restriction to chemical or physical form, for sample analysis or instrument calibration or associated with radioactively contaminated apparatus;

   E. Pursuant to the Act and 10 CFR Parts 40 and 70 to receive, possess, and use at any time 100 milligrams each of any source or special nuclear material without restriction to chemical or physical form, for sample analysis or instrument calibration or associated with radioactively contaminated apparatus;

   F. Pursuant to the Act and 10 CFR Parts 30 and 70, to possess, but not separate, such byproduct and special nuclear materials as may be produced by the operation of Turkey Point Units Nos. 3 and 4.

3. This subsequent renewed operating license shall be deemed to contain and is subject to the conditions specified in the following Commission regulations: 10 CFR Part 20, Section 30.34 of 10 CFR Part 30, Section 40.41 of 10 CFR Part 40, Sections 50.54 and 50.59 of 10 CFR Part 50, and Section 70.32 of 10 CFR Part 70; and is subject to all applicable provisions of the Act and to the rules, regulations, and orders of the Commission now or hereafter in effect, and is subject to the additional conditions specified below:

A. Maximum Power Level

The applicant is authorized to operate the facility at reactor core power levels not in excess of 2644 megawatts (thermal).

B. Technical Specifications

The Technical Specifications contained in Appendix A, as revised through Amendment No. 282, are hereby incorporated into this subsequent renewed operating license. The Environmental Protection Plan contained in Appendix B is hereby incorporated into this subsequent renewed license. The licensee shall operate the facility in accordance with the Technical Specifications and the Environmental Protection Plan.

C. Final Safety Analysis Report

The licensee's Final Safety Analysis Report supplement submitted pursuant to 10 CFR 54.21(d), as revised on November 1, 2001, describes certain future inspection activities to be completed before the period of extended operation. The licensee shall complete these activities no later than April 10, 2013.

The Final Safety Analysis Report supplement as revised on November 1, 2001, described above, shall be included in the next scheduled update to the Final Safety Analysis Report required by 10 CFR 50.71(e)(4), following the issuance of this renewed license. Until that update is complete, the licensee may make changes to the programs described in such supplement without prior Commission approval, provided that the licensee evaluates each such change pursuant to the criteria set forth in 10 CFR 50.59 and otherwise complies with the requirements in that section.

D. Fire Protection

FPL shall implement and maintain in effect all provisions of the approved fire protection program that comply with 10 CFR 50.48(a) and 10 CFR 50.48(c), as specified in the licensee amendment requests dated June 28, 2012 and October 17, 2018 (and supplements dated September 19, 2012; March 18, April 16, and May 15, 2013; January 7, April 4, June 6, July 18, September 12, November 5, and December 2, 2014; and February 18, 2015; October 24, and December 3, 2018; and January 31, 2019), and as approved in the safety evaluations dated May 28, 2015 and March 27, 2019. Except where NRC approval for changes or deviations is required by 10 CFR 50.48(c), and provided no other regulation, technical specification, license condition or requirement would require prior NRC approval, the licensee may make changes to the fire protection program without prior approval of the Commission if those changes satisfy the provisions set forth in 10 CFR 50.48(a) and 10 CFR 50.48(c), the change does not require a change to a technical specification or a license condition, and the criteria listed below are satisfied.

Risk-Informed Changes that May Be Made Without Prior NRC Approval

A risk assessment of the change must demonstrate that the acceptance criteria below are met. The risk assessment approach, methods, and data shall be acceptable to the NRC and shall be appropriate for the nature and scope of the change being evaluated; be based on the as-built, as-operated, and maintained plant; and reflect the operating experience at the plant. Acceptable methods to assess the risk of the change may include methods that have been used in the peer-reviewed fire PRA model, methods that have been approved by NRC through a plant-specific license amendment or NRC approval of generic methods specifically for use in NFPA 805 risk assessments, or methods that have been demonstrated to bound the risk impact.

(a) Prior NRC review and approval is not required for changes that clearly result in a decrease in risk. The proposed change must also be consistent with the defense-in-depth philosophy and must maintain sufficient safety margins. The change may be implemented following completion of the plant change evaluation.

(b) Prior NRC review and approval is not required for individual changes that result in a risk increase less than $1x10^{-7}$/year (yr) for CDF and less than 1×10^{-8}/yr for LERF. The proposed change must also be consistent with the defense-in-depth philosophy and must maintain sufficient safety margins. The change may be implemented following completion of the plant change evaluation.

<u>Other Changes that May Be Made Without Prior NRC Approval</u>

1. Changes to NFPA 805, Chapter 3, Fundamental Fire Protection Program

Prior NRC review and approval are not required for changes to the NFPA 805, Chapter 3, fundamental fire protection program elements and design requirements for which an engineering evaluation demonstrates that the alternative to the Chapter 3 element is functionally equivalent or adequate for the hazard. The licensee may use an engineering evaluation to demonstrate that a change to an NFPA 805, Chapter 3, element is functionally equivalent to the corresponding technical requirement. A qualified fire protection engineer shall perform the engineering evaluation and conclude that the change has not affected the functionality of the component, system, procedure, or physical arrangement, using a relevant technical requirement or standard.

The licensee may use an engineering evaluation to demonstrate that changes to certain NFPA 805, Chapter 3, elements are acceptable because the alternative is "adequate for the hazard." Prior NRC review and approval would not be required for alternatives to four specific sections of NFPA 805, Chapter 3, for which an engineering evaluation demonstrates that the alternative to the Chapter 3 element is adequate for the hazard. A qualified fire protection engineer shall perform the engineering evaluation and conclude that the change has not affected the functionality of the component, system, procedure, or physical arrangement, using a relevant technical requirement or standard. The four specific sections of NFPA 805, Chapter 3, are as follows:

- "Fire Alarm and Detection Systems" (Section 3.8);
- "Automatic and Manual Water-Based Fire Suppression Systems" (Section 3.9);
- "Gaseous Fire Suppression Systems" (Section 3.10); and
- "Passive Fire Protection Features" (Section 3.11).

This License Condition does not apply to any demonstration of equivalency under Section 1. 7 of NFPA 805.

2. Fire Protection Program Changes that Have No More than Minimal Risk Impact

Prior NRC review and approval are not required for changes to the licensee's fire protection program that have been demonstrated to have no more than a minimal risk impact. The licensee may use its screening process as approved in the NRC safety evaluation dated May 28, 2015, to determine that certain fire protection program changes meet the minimal criterion. The licensee shall ensure that fire protection defense-in-depth and safety margins are maintained when changes are made to the fire protection program.

Transition License Conditions

1. Before achieving full compliance with 10 CFR 50.48(c), as specified by 2. and 3. below, risk-informed changes to the licensee's fire protection program may not be made without prior NRC review and approval unless the change has been demonstrated to have no more than a minimal risk impact, as described in 2. above.

2. The licensee shall implement the modifications to its facility, as described in Enclosure 1, Attachment S, Table S-2, "Plant Modifications Committed," of FPL letter L-2014-303, dated 11/05/2014, to complete the transition to full compliance with 10 CFR 50.48(c) by the end of the second refueling outage (for each unit) following issuance of the license amendment. The licensee shall maintain appropriate compensatory measures in place until completion of these modifications.

3. The licensee shall implement the items listed in Enclosure 5, Attachment S, Table S-3, "Implementation Items," of FPL letter L-2018-219, dated 12/3/2018, with the exception of items 12, 18 and 19, no later than 12 months after issuance of the license amendment dated 5/28/2015. Items 12, 18 and 19 are associated with modifications in Table S-2 and will be completed in accordance with Transition License Condition 2 above.

E. The licensee shall fully implement and maintain in effect all provisions of the Commission-approved physical security, training and qualification, and safeguards contingency plans including amendments made pursuant to provision of the Miscellaneous Amendments and Search Requirements revisions to 10 CFR 73.55 (51 FR 27817 and 27822) and to the authority of 10 CFR 50.90 and 10 CFR 50.54(p). The combined set of plans, which contains Safeguards Information protected under 10 CFR 73.21, is entitled: "Florida Power and Light Turkey Point Nuclear Plant Physical Security Plan, Training and Qualification Plan, Safeguards Contingency Plan, and Independent Spent Fuel Storage Installation Security Program - Revision 15" submitted by letter dated August 3, 2012.

The licensee shall fully implement and maintain in effect all provisions of the Commission-approved cyber security plan (CSP), including changes made pursuant to the authority of 10 CFR 50.90 and 10 CFR 50.54(p). The Turkey Point Nuclear Generating Station CSP was approved by License Amendment No. 241 as supplemented by a change approved by Amendment Nos. 252 and 261.

F. 1. The licensee shall restrict the combined number of fuel assemblies loaded in the existing spent fuel pool storage racks and cask pit rack to no more than the capacity of the spent fuel pool storage racks. This condition applies at all times, except during activities associated with a reactor core offload/reload refueling condition. This restriction will ensure the capability to unload and remove the cask pit rack when cask loading operations are necessary.

2. The licensee shall establish two hold points within the rack installation procedure to ensure proper orientation of the cask rack in each unit's spent fuel pool. Verification of proper cask pit rack orientation will be implemented by an authorized Quality Control inspector during installation of the racks to ensure consistency with associated spent fuel pool criticality analysis assumptions.

G. Mitigation Strategy License Condition

Develop and maintain strategies for addressing large fires and explosions and that include the following key areas:

(a) Fire fighting response strategy with the following elements:

1. Pre-defined coordinated fire response strategy and guidance
2. Assessment of mutual aid fire fighting assets
3. Designated staging areas for equipment and materials
4. Command and control
5. Training of response personnel

(b) Operations to mitigate fuel damage considering the following

1. Protection and use of personnel assets
2. Communications
3. Minimizing fire spread
4. Procedures for implementing integrated fire response strategy
5. Identification of readily-available pre-staged equipment
6. Training on integrated fire response strategy
7. Spent fuel pool mitigation measures

(c) Actions to minimize release to include consideration of:

1. Water spray scrubbing
2. Dose to onsite responders

H. PAD TCD Safety Analyses

1. PAD 4.0 TCD has been specifically approved for use for the Turkey Point licensing basis analyses. Upon NRC's approval of a revised generic version of PAD that accounts for Thermal Conductivity Degradation (TCD), FPL will within six months:

   a. Demonstrate that PAD 4.0 TCD remains conservatively bounding in licensing basis analyses when compared to the new generically approved version of PAD w/TCD, or
   b. Provide a schedule for the re-analysis using the new generically approved version of PAD w/TCD for any of the affected licensing basis analyses

I. FPL is authorized to implement the Risk Informed Completion Time Program as approved in License Amendment No. 278 subject to the following conditions:

1. FPL will complete the items listed in the table of implementation items in the enclosure to FPL letter L-2018-118 dated June 12, 2018 prior to implementation of the Risk Informed Completion Time Program.

2. The risk assessment approach and methods, shall be acceptable to the NRC, be based on the as-built, as-operated, and maintained plant, and reflect the operating experience of the plant as specified in RG 1.200. Methods to assess the risk from extending the completion times must be PRA methods accepted as part of this license amendment, or other methods approved by the NRC for generic use. If the licensee wishes to change its methods, and the change is outside the bounds of this license condition, the licensee will seek prior NRC approval via a license amendment.

J. Subsequent License Renewal License Conditions

1. The information in the Final Safety Analysis Report (FSAR) supplement submitted pursuant to 10 CFR 54.21(d), as revised during the subsequent license renewal application review process, and FPL commitments as listed in Appendix A of the "Safety Evaluation Report Related to the Subsequent License Renewal of Turkey Point Generating Units 3 and 4," dated July 22, 2019, are collectively the "Subsequent License Renewal FSAR Supplement." This Supplement is henceforth part of the FSAR, which will be updated in accordance with 10 CFR 50.71(e). As such, FPL may make changes to the programs, activities, and commitments described in the Subsequent License Renewal FSAR Supplement, provided FPL evaluates such changes pursuant to the criteria set forth in 10 CFR 50.59, "Changes, Tests, and Experiments," and otherwise complies with the requirements in that section.

2. The Subsequent License Renewal FSAR Supplement, as defined in renewed license condition (J)(1) above, describes programs to be implemented and activities to be completed prior to the subsequent period of extended operation, which is the period following the April 10, 2033, expiration of the initial renewed license.

    a. FPL shall implement those new programs and enhancements to existing programs no later than 6 months before the subsequent period of extended operation.

    b. FPL shall complete those activities by the 6-month date prior to the subsequent period of extended operation or by the end of the last refueling outage before the subsequent period of extended operation, whichever occurs later.

    c. FPL shall notify the NRC in writing within 30 days after having accomplished item (2)(a) above and include the status of those activities that have been or remain to be completed in item (2)(b) above.

3. FPL shall complete the replacement of a portion of the existing containment spray system carbon steel piping with stainless steel piping by December 1, 2024, so that any remaining carbon steel piping will not normally be internally exposed to borated water during the subsequent period of extended operation. The scope of replacement is the carbon steel piping from the stainless steel to the carbon steel dissimilar metal weld for the two containment spray piping headers (4A and 4B) at penetrations P-19A and P-19B to a minimum plant elevation of 65 feet inside containment. FPL shall notify the NRC in writing within 60 days following completion of the refueling outage during which the piping replacement is completed. The notification will confirm the elevation of

the air-to-borated water interface inside the piping, and confirm that the installation of the stainless steel piping exceeds this elevation.

4. This subsequent renewed license is effective as of the date of issuance, and shall expire at midnight April 10, 2053.

NUCLEAR REGULATORY COMMISSION

10 CFR Part 51

RIN 3150-AD 94

Environmental Review for Renewal of Operating Licenses

AGENCY: Nuclear Regulatory Commission.

ACTION: Proposed rule.

SUMMARY: The Nuclear Regulatory Commission (NRC) is proposing to amend its regulations to establish new requirements for environmental review of applications to renew operating licenses for nuclear power plants. The proposed amendments would define the number and scope of environmental impacts that would need to be addressed as part of a license renewal application. Concurrent with the proposed amendments, the NRC is publishing for comment (1) a draft generic environmental impact statement, (2) a draft regulatory guide, (3) a draft environmental standard review plan, and (4) a draft regulatory analysis, which supplement the proposed amendments. A workshop on the proposed amendments and the draft generic environmental impact statement will be held during the comment period.

DATES: Comment period expires December 16, 1991. Comments received after this date will be considered if it is practical to do so, but the Commission is able to assure consideration only of comments received on or before this date. Notification of intent to attend the workshop, concurrent session preferences, and desire to participate as a panelist during a specific session should be received by the staff no later than October 4, 1991. Comments on the proposed agenda received by the staff by October 4, 1991, will be considered in developing the final workshop agenda. A final agenda and detailed information on each session will be available after October 18, 1991. This information will be mailed to all individuals and organizations who notify the NRC of their intent to attend and to others who request it. The workshop will be held on November 4 and 5, 1991.

ADDRESSES: Send comments to: The Secretary of the Commission, U.S. Nuclear Regulatory Commission, Washington, DC 20555, Attention: Docketing and Services Branch, or hand deliver comments to the Office of the Secretary, One White Flint North, 11555 Rockville Pike, Rockville, Maryland between 7:30 a.m. and 4:15 p.m. on Federal workdays. Copies of comments received may be examined at the NRC Public Document Room, 2120 L Street NW., (Lower Level), Washington, DC between the hours of 7:45 a.m. and 4:15 p.m. on Federal workdays. The workshop will be held at the Rosslyn Westpark Hotel, 1900 North Fort Myer Drive, Arlington, Virginia 22209. Send notification of intent to attend and desire to participate as a panelist during a specific session to Donald Cleary, Office of Nuclear Regulatory Research, U.S. Nuclear Regulatory Commission, Washington, DC 20555.

FOR FURTHER INFORMATION CONTACT: Donald Cleary, Division of Safety Issues Resolution, Office of Nuclear Regulatory Research, U.S. Nuclear Regulatory Commission, Washington, DC 20555, telephone (301) 492-3936.

SUPPLEMENTARY INFORMATION:

I. Introduction

The Commission is proposing to amend 10 CFR part 51 to improve the efficiency of the process of environmental review when an applicant seeks to renew an operating license for up to an additional 20 years. To prepare for possible license renewal applications, the Commission considered the merits of relying on the existing framework for environmental review in part 51 rather than revising part 51. In reaching its decision to revise part 51, the Commission considered the following factors: (1) License renewal will involve nuclear power plants for which the environmental impacts of operation are well understood as a result of data evaluated from operating experience to date; (2) activities and requirements associated with license renewal are anticipated to be within this range of operating experience, thus environmental impacts can reasonably be predicted; and (3) changes in the environment around nuclear power plants are generally gradual and predictable with respect to characteristics important to environmental impact analyses.

The Commission has conducted a study of the potential environmental impacts of license renewal. The objective of the study was to (1) identify all the potential impacts to the environmental and other National Environmental Policy Act (NEPA) issues associated with plant license renewal, (2) determine which of these environmental impacts and other NEPA issues could be evaluated generically for all plants, and (3) determine the significance of these issues that could be generically evaluated. The analyses and results of this study are presented in the draft Generic Environmental Impact Statement (GEIS) (NUREG-1437), which is being published for comment concurrently with this proposed rule. The staff concludes in the GEIS that only a limited number of the total potential impacts cannot be evaluated generically. Those impacts that cannot be evaluated generically will have to be evaluated for each plant before its license is renewed. However, the environmental impacts that can be generically evaluated will not have to be evaluated for each plant.

The GEIS provides the basis for this rulemaking. To develop the GEIS, the NRC staff followed the recommended procedures of the Council on Environmental Quality (CEQ), including scoping activities such as consulting the CEQ and other Federal agencies, a public workshop held on November 12–14, 1989 (54 FR 41980; October 13, 1989), and publication of a Notice of Intent to prepare the GEIS (55 FR 29967; July 23, 1990).

The proposed rule addresses the potential environmental impacts that are generically evaluated for all plants in the GEIS and codifies the findings in the GEIS. In addition, those potential impacts that are not generically evaluated in the GEIS are identified in the proposed rule to be evaluated on a plant-specific basis. By assessing and codifying certain potential environmental impacts on a generic basis, no need exists to address these impacts for each future license renewal. The proposed amendments should result in considerable savings to the NRC, the nuclear utility industry, and the nuclear utility ratepayers, while ensuring that the environmental impacts of license renewal are evaluated, as required by the NEPA.

The basic information and the supporting analysis of environmental impacts that serve as the basis of this proposed rulemaking are presented in the draft GEIS, NUREG–1437. The draft GEIS and these proposed amendments to 10 CFR part 51 also provide the basis for developing a license renewal draft supplement to Regulatory Guide 4.2, "Preparation of Environmental Reports for Nuclear Power Stations," which provides guidance on the format and content of the environmental report to be submitted as part of the license renewal application. Additionally, the staff also prepared a draft Environmental Standard Review Plan (NUREG–1429) to provide guidance to the staff on the scope of the review necessary to implement the proposed amendments to part 51.

II. Background

A. License Renewal—10 CFR Part 54

A significant number of the operating licenses for the existing nuclear power plants are due to expire in the early part of the 21st century. The NRC anticipates that a number of licensees will submit applications to renew an operating license 10 to 20 years before the license expires. The first of these applications is expected in the near future. The NRC has issued a proposed rule, 10 CFR Part 54, "Requirements for Renewal of Operating Licenses for Nuclear Power Plants" (55 FR 29043; July 17, 1990), that would establish the requirements that an applicant must meet, the information that must be submitted to the NRC for review so that the agency can determine whether these requirements have in fact been met, and the application procedures. The proposed part 54 permits the renewal of an operating license for up to an additional 20-year increment beyond the expiration of its current license (initial licensee authorize 40 years of operation). The part 54 rule could be applied to multiple renewals of an operating license for various increments. However, the part 51 amendments apply to one renewal of the initial license for up to 20 years beyond the expiration of the initial license.

License renewal for each plant will be based on the current licensing basis (i.e., the original licensing basis for the plant as amended during the initial license term) and changes, as necessary, to address the effects of age-related degradation on systems, structures, and components important to license renewal. To comply with 10 CFR part 54, the licensee shall assess and determine those activities and modifications that are necessary, at the time of license renewal and throughout the renewal term, to ensure continued safe operation of the plant. Each licensee shall identify and incorporate those activities necessary for managing aging into its licensing basis, thereby ensuring that acceptable margins of safety are preserved throughout the license renewal term. In addition, each applicant for a license renewal shall submit an environmenal report that complies with the requirements of 10 CFR part 51, the NRC regulations governing environmental protection for domestic licensing.

B. Environmental Review

The scope of the NRC's National Environmental Policy Act (NEPA) review is found in 10 CFR part 51. To meet the provisions of 10 CFR 51.45, the applicant shall submit an environmental report (ER) that discusses (1) the impact of the proposed action on the environment, (2) any adverse environmental impacts that cannot be avoided, (3) alternatives to the proposed action, (4) the relationship between local short-term uses of the environment and maintenance and enhancement of long-term productivity, and (5) any irreversible or irretrievable commitments of resources. In addition, the licensee shall submit an analysis that considers and balances the environmental effects of the proposed action and the alternatives available for reducing or avoiding adverse environmental effects, as well as the benefits of the action. The NRC will independently review this material and publish the results.

Before issuing a construction permit (CP) or an operating license (OL) for a nuclear power plant, the NRC is required to assess the potential environmental impacts of the plant to ensure that the issuance of a permit or license is consistent with the NEPA and the NRC implementing regulations of the NEPA in 10 CFR part 51. For those plants licensed subsequent to the enactment of the NEPA, baseline quantitative studies and monitoring programs were often developed for comparison with data gathered from later programs if adverse effects of construction or operation were reasonably inferred from information obtained during the gathering of preconstruction or operational baseline phases. These studies were part of the applicant's environmental report and were reviewed in the staff's final environmental statement (FES) for the specific plant. These studies and programs were restricted to the impact assessment of important resources and important species described in the staff's guidance documents such as Regulatory Guide 4.2, and Environmental Standard Review Plans (NUREG–0555). The staff's final assessments of these programs were normally summarized in each plant-specific FES. On the basis of these reviews, appropriate environmental parameters would have been proposed for monitoring or for special studies.

Although two operating nuclear power plants were licensed before the NEPA was enacted and do not have FESs, the GEIS did consider and envelop these plants. Accordingly, the Commission believes that no reason exists to treat these two plants differently in the environmental review for each plant's license renewal.

Additionally, nonradiological discharges of pollutants to receiving waters from operating nuclear power plants that are licensed by the NRC are subject to limitations or monitoring under the Federal Water Pollution Control Act (FWPCA), administered by the U.S. Environmental Protection Agency (EPA) or designated State agencies. The resultant reporting requirements of a National Pollutant Discharge Elimination System (NPDES) permit are relied upon by the EPA and designated State agencies to provide data on potential problems. Permits are subject to review and approval every 5 years and may be modified by the permitting authority on the basis of an analysis of data generated from plant-specific NPDES monitoring programs.

The Commission considers that one of its responsibilities under the NEPA is to be cognizant of significant environmental impacts during the term of a plant's operations. For impacts involving degradation of the aquatic environment, the reporting requirements of an NPDES permit authorized by the FWPCA are generally relied upon to alert the NRC to potential problems. In addition, the Commission includes conditions in its licenses to protect the environment in accordance with 10 CFR 50.36(b). These conditions identify appropriate requirements for reporting and recording environmental data and for monitoring requirements to protect the nonaquatic environment under 10 CFR part 50, a license may also reference environmental protection plans, environmental technical specifications, and radiological technical specifications. Therefore, the environmental effect of current operating reactors is well known and the probable future effect if licenses are renewed can be predicted with some confidence. This practice is consistent with regulations promulgated by the CEQ that direct agencies to adopt monitoring and enforcement programs, where appropriate. As a result of the staff's environmental reviews, certain environmental conditions, including monitoring requirements, may be included in NRC licenses. Licensees submit the information from monitoring of these conditions to the NRC on a routine basis, and the Commission responds as appropriate.

C. Use of Generic Rulemaking

The Commission has previously endorsed the generic rulemaking process and recognized the advantages of generic rulemaking. In an interim policy statement on generic rulemaking to improve nuclear power plant licensing, these advantages were identified:

(a) enhance stability and predictability of the licensing process by providing regulatory criteria and requirements in discrete generic areas on matters which are significant in the review and approval of license applications; (b) enhance public understanding and confidence in the integrity of the licensing process by bringing out for public participation important generic issues which are of concern to the agency and the public; (c) enhance administrative efficiency in licensing by removing, in whole or in part, generic issues from staff review and adjudicatory resolution in individual licensing proceedings and/or by establishing the importance (or lack of importance) of various safety and environmental issues to the decision process; (d) assist the Commission in resolving complex methodology and policy issues involved in recurring issues in the review and approval of individual licensing applications; and (e) yield an overall savings in the utilization of resources in the licensing process by the utility industry, those of the public whose interest may be affected by the rulemaking, the NRC and other Federal, State, and local governments with an expected improvement in the quality of the decision process.[1]

The NRC has used this generic approach in several part 51 rulemakings. Table S–4 of § 51.52 that gives the environmental impacts of the transportation of radioactive waste and nuclear fuel is an example. Applicants meeting certain criteria can use the information in Table S–4 as the basis for their evaluation of the environmental impacts of the transportation of radioactive waste and spent fuel. They are not required to conduct their own analysis of these impacts. Other examples of past generic part 51 rulemakings are Table S–3 of § 51.51 that gives the environmental impacts of the nuclear fuel cycle and § 51.53 and § 51.95, that eliminate the requirement to consider need for power and alternative energy sources for nuclear reactors at the operating license stage (47 FR 12940, March 26, 1982). Therefore, this rule is consistent with the NRC policy.

III. Proposed Action

A. Proposed Amendments

The proposed amendments to 10 CFR part 51 would establish new requirements for environmental review of an application to renew a license for a single plant. These amendments would require the applicant to address only those environmental issues that require a plant-specific assessment as part of an application for each plant. Applicants for all plants will have to assess environmental impacts on threatened and endangered species and impacts on local transportation during periods of refurbishment activities related to license renewal. These refurbishment activities are those activities that are planned for and performed on a nuclear power plant to prepare the plant for operation during the period the license is being renewed. These activities include equipment replacements, overhauls, maintenance, inspection, and testing. For other issues, all applicants either will have to demonstrate that their plants fall within defined bounds of plants for which a generic conclusion about an issue can be reached, or, if an issue does not fall within these bounds, assess that issue. Also, as part of its ER, an applicant will have to include an analysis of whether or not the findings of the assessment of each issue overturns the favorable cost-benefit balance for license renewal found in proposed appendix B to 10 CFR part 51.

The proposed amendments codify the conclusions of the GEIS for those issues for which a generic conclusion can be reached. The proposed appendix B, which summarizes the Commission's findings on the scope and magnitude of environmental and other effects of renewing the operating license of each nuclear power plant, is added to 10 CFR part 51. In the proposed appendix, the Commission also states its finding that the "renewal of any operating license for up to 20 years will have accrued benefits that outweigh the economic, environmental, and social costs of license renewal * * *."

In addition, the proposed amendments eliminate the requirement that the NRC staff must prepare a supplemental environmental impact statement (EIS) for every license renewal application; instead, the amendments permit the staff to prepare an environmental assessment (EA) if certain conditions are met. The basis for this proposed change is the GEIS finding that only a limited number of potential impacts need to be addressed to renew a license for each plant.

The Commission believes that, in many instances, this limited set of potential environmental issues will be found to have impacts that are nonexistent or small and, therefore, could be analyzed in an EA that results in a finding of no significant impact (FONSI). If no significant impacts are found in the EA, the NRC will issue a FONSI. If a FONSI cannot be made, the environmental review process would require developing a draft EIS for public comment and a final supplemental EIS. The supplemental EIS would evaluate the environmental impacts identified in the EA and their effect on the overall cost-benefit balance. The NRC will issue a supplemental EIS if any of the issues addressed are determined to have impacts that are negative and either moderate or large, as the terms are defined in proposed Appendix B of Subpart A of Part 51. Impacts that otherwise might be considered moderate could be mitigated to small by commitments made in a license renewal application.

The proposed amendments would define those environmental issues that need to be addressed in an application to renew a license for a single plant. The Commission wishes to emphasize the importance of the public commenting at this time on environmental reviews in the GEIS and the findings in the proposed rule. After the final rule is published, comment on environmental impacts of a licensing renewal action for a plant will be limited to those impacts

[1] Generic Rulemaking To Improve Nuclear Power Plant Licensing, Interim Policy Statement, 43 FR 58377; December 14, 1978.

that the rule requires to have a plant-specific evaluation.

However, the adoption of the proposed amendments would not preclude reopening environmental issues if significant new information becomes available. A petition to amend 10 CFR part 51 will be acted upon if new information warrants a reopening of issues. The Commission plans to periodically review the GEIS findings contained in appendix B to part 51 and its supporting documentation.

Environmental Impacts To Be Reviewed To Renew a License for Each Plant

The Commission concludes that the adverse environmental impacts of license renewal are minor compared to the benefits to be gained from continued operation for up to an additional 20 years beyond the initial license period. However, the proposed amendments require that each applicant address in its ER those environmental issues for which no generic conclusion can be reached.

The NRC staff, in its GEIS, divided its conclusions about environmental impacts into three categories and further drew a conclusion about the significance of each impact.

The NRC drew one of the following three conclusions about each impact:

Category 1. The NRC reached a conclusion about this impact that applies to all affected plants.

Category 2. The NRC reached a conclusion about this impact that applies to all affected plants that are within certain bounds.

Category 3. The NRC reached a conclusion about this impact that the licensee shall evaluate this impact for each plant for which it applies to renew a license.

The NRC then determined whether the significance of an impact about which it had drawn one of these three conclusions is "small," "moderate,"or "large."

• A small impact is so minor that it warrants neither detailed investigation nor consideration of mitigative actions when the impact is negative.

• A moderate impact is usually evident and usually warrants consideration of mitigation alternatives when the impact is negative.

• A large impact involves either a severe penalty or a major benefit and mitigation alternatives are always considered when an impact is negative.

The following includes 2 Category 3 issues and combines 22 Category 2 issues into 10 issues. The issues which must be addressed are as follows:

(1) The applicant must submit an assessment of potential impacts on threatened or endangered species.

(2) Aquatic impacts of entrainment, impingement, and heat shock are potential problems at plants with once-through or cooling-pond heat dissipation systems. However, plant operations and effluents that have the potential to cause these impacts are under the regulatory authority of EPA of State authorities. The permit process authorized by the FWPCA is an adequate mechanism for control and mitigation of these potential aquatic impacts. If an applicant to renew a license has appropriate EPA or State permits, further NRC review of these potential impacts is not warranted. Therefore, the proposed rule requires an applicant to provide the NRC with certification that it holds FWPCA permits, or if State regulation applies, current State permits. If the applicant does not so certify, it must assess these aquatic impacts.

(3) Potential aquatic impacts from any refurbishment activities would be minor or insignificant if best management practices are used to control soil erosion or spills. The proposed rule requires applicants to submit evidence of a construction impact control program.

(4) For plants located at inland sites and using cooling ponds, the applicant must assess groundwater quality impacts.

(5) For plants using Ranney wells or pumping 100 or more gallons per minute and having wells in the cone of depression, the applicant must assess groundwater-use conflicts.

(6) For potential terrestrial impacts, the NRC staff, in the GEIS, concluded that the only potential impact that need be evaluated to renew a license for each plant was any potential impact on important plant and animal habitats. These could include wetlands, wildlife concentration areas, and certain plant life environments. The proposed rule requires applicants to assess any potential impacts on such plant and animal habitats if construction activities generated by refurbishment or extended operation could affect these resources.

(7) The proposed amendments required any license renewal applicant, whose site does not have access to a low-level radioactive waste disposal facility, to assess environmental impacts of low-level waste management.

(8) Each applicant must verify that adequate provisions have been taken to ensure that transmission line electric shock effects are not a health hazard. The applicant may rely on National Electric Safety Codes for this assessment.

(9) An applicant with a plant at a site in a low-population area, as defined by numerical criteria on population and distance from sizable cities or in areas where growth control measures are in effect, must access housing impacts.

(10) For socioeconomic impacts, all applicants must assess potential transportation impacts during refurbishment.

(11) Applicants with plants using cooling ponds, lakes, or canals, or discharging cooling water to small rivers must address effects of microbiological organisms on human health.

(12) Applicants who exceed threshold criteria for cost of refurbishment, operating and maintenance, and fuel costs must submit a cost analysis to demonstrate the cost advantages of license renewal over the most reasonable replacement alternative. Applicants must also assess for certain plants the geothermal alternative.

B. Generic Environmental Impact Statement

The GEIS establishes the bounds and significance of potential environmental impacts at all 118 light-water nuclear power reactors currently licensed to operate or expected to be licensed to operate in the United States (113 nuclear power plants were licensed to operate as of June 30, 1992, plus Bellefonte Units 1 and 2, Comanche Peak Unit 2, and Watts Bar Units 1 and 2). For the GEIS, the NRC staff assessed all environmental issues that may be of concern to the NRC in its reviews of applications to renew operating licenses at these 118 nuclear power plants. The scope of these issues reflects the potential effects of plant refurbishment activities associated with license renewal, an additional 20 years of plant operation, and possible change in the plant environmental setting. For this analysis, all of the environmental issues identified were combined into 104 issues. For each type of environmental impact, the staff attempts to establish generic findings encompassing as many nuclear power plants as possible. Plant- and site-specific information is used in developing these generic findings. In conjunction with the proposed rule change, this GEIS also provides an applicant seeking to renew an operating license information and analyses that it may reference in the application. Further guidance on the format, content, and analysis standards for environmental documentation in their application is provided in draft Regulatory Guide 4.2, Supplement 1.

The analytical approach to assessing environmental impacts in this GEIS involves four stages:

(1) Characterize each issue on the basis of information from past plant construction and current operating experience to establish a baseline.

(2) Assess the extent to which activities and requirements associated with license renewal may differ from the baseline.

(3) Assess potential relevant changes in the environment and estimate trends for the technology and economics of alternative energy sources.

(4) Combine these separate analyses to fully characterize the nature and magnitude of impacts and other issues that will result from the refurbishments necessary for license renewal and the potential environmental impacts of operating plants for 20 years beyond their current 40-year licensing limit.

The upper bound scenario of refurbishment activities and plant operation that may be brought about by license renewal is described in detail in appendix B to the GEIS. All plants are considered enveloped by appendix B to the GEIS. The range of environmental issues considered in the GEIS was identified from past studies of nuclear power plant construction and operation (principally EISs), consultations with Federal and State regulatory agencies, and input from the nuclear utility industry and the general public.

The analyses in the GEIS drew on an extensive body of published materials from government, industry, academia, and other sources about operation and maintenance of nuclear power plants and their effects on the environment. Additional plant-specific information not otherwise available was collected by the Nuclear Utilities Management and Resources Council (NUMARC) and made available to Oak Ridge National Laboratory (ORNL) for use in the report. This information is available in the NRC Public Document Room. A team of environmental specialists from ORNL interviewed Federal, State, and local regulatory officials, as well as persons from business and other private organizations in the vicinity of nuclear power plants, as part of the effort to establish the scope for the GEIS.

The objectives of the GEIS are to (1) provide an understanding of the types and severity of environmental impacts that may occur as a result of renewing operating licenses for nuclear power plants, (2) identify and assess those impacts expected to be generic to license renewal, and (3) define the issues that need to be addressed by the NRC and the applicants in plant-specific license renewal proceedings.

The broad topical areas covered are surface-water quality, aquatic ecology, groundwater, terrestrial ecology, human health, socioeconomics, postulated accidents, waste management, decommissioning, need for generating capacity, and alternatives to license renewal.

In the GEIS, the NRC staff identified and evaluated the significance of the environmental impact of each of 104 environmental issues associated with the renewal of individual plant licenses. For 80 issues, the staff reached a generic conclusion that the potential environmental impacts are acceptable. For 22 issues, this conclusion could be reached for some subset of all nuclear power plants that were within bounds defined in the GEIS. For 2 issues, the staff concluded that no generic conclusion on impacts could be reached.

The Commission is proposing to limit the scope of environmental review for each plant license renewal to only those impacts for which no generic conclusion could be reached (i.e., Categories 2 and 3). All applicants will be required to provide appropriate information and analyses in their license renewal applications for all Category 2 and 3 impacts identified in the GEIS.

An evaluation of the impacts that have been assessed on a generic basis is summarized in a proposed new appendix B to part 51.

The NRC's NEPA review procedures in part 51 require "a preliminary analysis which considers and balances the environmental and other effects of the proposed action and the alternatives available for reducing or avoiding adverse environmental and other effects, as well as the environmental, economic, technical, and other benefits of the proposed action" (§ 51.71(d)). This analysis is found in chapter 10 of the GEIS. Table 10.1, "Summary of Conclusions on NEPA Issues" in the GEIS is included in these proposed amendments as proposed Table B.1 of appendix B of subpart A of part 51. The table lists each environmental issue addressed in the GEIS, states the conclusions, and includes an assessment of the benefit or cost involved. The major benefit is the electric energy that would be produced by a plant whose license is renewed. The major economic costs are those for refurbishing and for operating and maintaining a plant during the renewal term of up to 20 years. For those adverse environmental impacts that can be assessed generically (Category 1 and, for a subset of plants, Category 2), the adverse impact is identified as small. For environmental impacts for which generic conclusions can be reached, Table B–1 shows that no adverse environmental impacts exist that would offset the benefits of license renewal.

The other NEPA review requirements in 10 CFR part 51 that have been codified in Table B–1 are a review of short- and long-term benefits and productivity and irreversible commitments of resources. The principal short-term benefit from continued operation of nuclear plants is the production of electrical energy from an existing capital asset.

The Commission finds that the resource commitments involved in license renewal do not differ from resource commitments required during the initial operating license term. However, additional nuclear fuel will be used, and small amounts of materials will be used for plant refurbishment. A minor amount of additional land would be used.

Summary of Issues Analyzed in the GEIS

The following describes those environmental issues that were examined for the GEIS, and summarizes the conclusions by major topical area.

1. Surface Water Quality

For the GEIS, the NRC staff examined water quality, water-use conflicts, altered salinity gradients, altered current patterns, temperature effects on sediment transport, altered thermal stratification, scouring caused by discharged cooling water, eutrophication, discharge of chlorine or other biocides or chemical contaminants, and discharge of sanitary wastes.

Aquatic impacts from plant refurbishment activities to support license renewal could occur at any type of plant if erosion or spills occur. In the GEIS, the staff concluded that "best management practices" need to be used during refurbishment to prevent adverse impacts. Site-specific mitigation measures can be implemented during refurbishment to prevent or minimize construction-related aquatic impacts from erosion or spills. These impacts are normally of limited duration and affect only a portion of the aquatic environment. Potential impacts on threatened or endangered species cannot be assessed generically and will require plant-specific analysis.

2. Aquatic Ecology

For the GEIS, the staff examined impingement and entrainment, heat shock, cold shock, thermal plume barriers to migration, premature emergence of aquatic insects, stimulation of nuisance organisms, gas supersaturation, low dissolved oxygen in the discharge, accumulation of contaminants in sediment or biota, and losses from predators, parasites, and disease.

For nuclear power plants using once-through cooling systems, the operational experience of existing plants indicates that many early concerns about aquatic resources have not materialized. Neither the published literature nor the responses of regulatory and resource agencies have revealed potential concerns about such early issues as phytoplankton and zooplankton entrainment and premature emergence of aquatic insects in thermal discharges. Although significant localized effects of these stresses have occasionally been demonstrated, the populations' rapid regeneration and biological compensatory mechanisms are sufficient to preclude long-term or far-field impacts.

However, some issues involving aquatic resources warranted further monitoring, and in some cases, mitigative measures to define and correct adverse impacts. The entrainment and impingement of fish and the discharge of large volumes of heated effluents into small or warm ambient waters were a source of concern at some nuclear power plants. These issues were examined and resolved through the mechanisms of NPDES permits and associated FWPCA 316(a) and (b) determinations and were either found to be acceptable or actions were implemented to mitigate the problems. For a few plants, the NPDES process has not been completed and the issues relating impingement, entrainment, and thermal discharges have not all been resolved. For these plants, issues relating to intake and discharge effects on fish and shellfish may be unresolved.

Resource agencies are expending major efforts to restore anadromous fish runs, particularly salmon and American shad, through water quality improvements, stocking, and removal of migration barriers. As a result, a number of the agencies have expressed concerns about future impingement and entrainment impacts at plants that operate on certain rivers. These concerns are routinely addressed during the NPDES permit renewal process. Nuclear power plants with once-through cooling systems that currently discharge cooling water near the upper temperature limits of their NPDES permits may find complying with those requirements increasingly difficult if climates change and ambient water temperatures warm in the coming decades. Under these conditions, such plants may need to modify their operations during the warmest months or rely more on helper cooling towers to prevent adverse thermal impacts. Continuing to consult resource agencies and permitting agencies and to promptly resolve NPDES permit issues are expected to ensure that future changes in the environment do not lead to unacceptable impacts on aquatic ecology.

3. Groundwater Use and Quality

For the GEIS, the NRC staff examined groundwater use and quality; groundwater-use conflicts, including use of Ranney wells; and groundwater quality degradation and concluded that ground-water use conflicts and quality degradation may be a problem at certain plants. Groundwater quality at some river sites may be degraded by induced infiltration of poor-quality river water into an aquifer that supplies large quantities of plant cooling water.

Sites with closed-cycle cooling ponds may degrade groundwater quality. For those plants located inland, the quality of groundwater in the vicinity of ponds must be shown to remain within the State regulatory agency's defined-use category.

4. Terrestrial Ecology

For the GEIS, the NRC staff examined refurbishment impacts, cooling tower impacts on crops and native plants, bird collisions with cooling towers and transmission lines, cooling-pond impacts, power line right-of-way management, electromagnetic field effects, and effects on floodplains and wetlands, threatened or endangered species, air quality, and land use.

Refurbishment activities would disturb only small areas of land and should result in no significant loss of terrestrial habitats. Air quality impacts from refurbishment are not expected to lead to significant environmental impact. Salt draft from cooling towers at nuclear plants has not been shown to threaten agricultural crops, orchards, or other cultivated vegetation. Cooling tower operation has not been reported to reduce crops yields except in situations where crops were experimentally placed next to cooling towers. No significant adverse impacts of transmission lines and their maintenance was identified. Potential refurbishment impacts that will require an analysis for each plant would be those that may occur if one or more important terrestrial resources (wetlands, endangered species) would be affected.

5. Public Health

For the GEIS, the NRC staff examined radiation exposures to the public, occupational radiation exposures from refurbishment and extended operation, acute and chronic health effects of the electromagnetic fields of transmission lines, microbiological organisms associated with the cooling system known as the ultimate heat sink and noise.

For the GEIS, the staff assessed public health impacts from refurbishment activities and extended operation. Occupational exposure and doses to the public are expected to remain well within regulatory limits. The 9 plants using cooling ponds, lakes, or canals and the 14 plants discharging to small rivers have the potential to influence thermophilic organisms. Health questions related to public use of affected waters need to be addressed by utilities for each plant license renewal. The potential for electrical shock-induced currents from transmission lines should be reviewed with respect to the National Electric Safety Code (NESC) recommendations. Biological and physical studies of 60-Hz electromagnetic fields have not demonstrated consistent evidence linking harmful effects with field exposures.

6. Socioeconomics

For the GEIS, the staff assessed impacts in the following socioeconomic areas: housing, taxes, public services (excluding transportation), transportation, offsite land use, economic structure, and historic and aesthetic resources. They examined impacts from refurbishment activities as well as extended operation of nuclear power plants and reached generic conclusions for taxes, public services, excluding transportation, offsite land use, transportation impacts during continued operation, economic structure, and historic and aesthetic resources. These impacts may be either positive (taxes, employment, income) or negative, but small, and thus need not be addressed for each plant.

Housing impacts during refurbishment could be negative and potentially significant (moderate or large impact) for plants located in areas categorized as "low" population or as those that have growth control measures to limit housing development. In particular circumstances, transportation impacts during refurbishment could also be negative and significant. As a result, only housing and transportation issues need to be evaluated for each plant.

7. Uranium Fuel Cycle

For the GEIS, the NRC staff assessed the impacts of the uranium fuel cycle, which is based on the values given in 10 CFR 51.51 Table S–3, and analyzed the radiological impact from radon-222 and technetium-99. Categories of natural resource use that were analyzed include land use, water consumption and thermal effluents, radioactive releases, burial of transuranic and high- and low-level wastes, and radiation doses from transportation and occupational exposures. Radiological and nonradiological impacts were found to be small.

8. Waste Management

For the GEIS, the NRC staff examined the potential environmental impacts from the generation of various types of wastes during refurbishment and extended operation for an additional 20 years. More specifically, the staff examined nonradiological waste, mixed waste, low-level radiological waste storage and disposal, spent fuel storage and disposal, and transportation.

In the GEIS, the staff concluded that license renewal would have only minor impacts on mixed waste and nonradiological waste management activities. For low-level radioactive waste, onsite storage was judged to be adequate as suitable land is available at all plants for interim storage of additional waste from refurbishment and extended plant operation if disposal sites continue to accept waste in normal increments. The conclusions regarding low-level radioactive waste disposal hinge on the timely implementation of present plans for siting regional compact and individual State disposal sites. If circumstances change and the GEIS assumptions are no longer valid, these impacts would need to be addressed for each plant.

The greater volume of spent fuel resulting from up to 20 years of operation beyond the 40-year license can be safely accommodated onsite through dry or pool storage at all plants. The staff concluded that radioactive waste transportation impacts were small and bounded by the values in 10 CFR 51.52, Table S–4.

9. Postulated Accidents

For Chapter 5 of the GEIS, the NRC staff evaluated the environmental impacts of postulated accidents for the license renewal period. This evaluation included severe accidents as well as design-basis accidents. For design-basis accidents, all plants have had a previous evaluation of their environmental impacts. In addition, the licensees will be required to maintain acceptable design and performance criteria throughout the plant license renewal period. The calculated releases from design-basis accidents would not be expected to change. Therefore, the NRC staff concluded that the design of the plants associated with impacts from design-basis accidents remains acceptable. Severe accident environmental impacts were not evaluated in the past for all plants. However, since 1981, all plant FESs have included an analysis of severe accidents. In addition, in the past 10 years, extensive work has taken place on severe accident analysis and safety issue resolution. Therefore, the severe accident analyses done previously in support of FESs (a total of 27 FESs contain analyses of severe accidents) plus the results of other severe accident analyses done in the past were utilized and extrapolated to predict the severe accident environmental impacts for all plants at the midpoint of their license renewal period. For this assessment, the staff evaluted the environmental impacts of releases of radioactive materials to the atmosphere and groundwater as well as fallout over land and water. In addition, they evaluated the economic consequences of such accidents and the need to evaluate severe accident mitigation design alternatives (SAMDAs).

In the GEIS, the staff concluded that the environmental impacts of severe accidents during the license renewal period represent a low risk to the population and environment. Although the offsite consequences are potentially large, they are of low likelihood. Because of the low likelihood, the staff concluded that these impacts need not be considered further for each plant license renewal application. In addition to the low risk, Commission policy is to consider SAMDAs only at the initial construction stage (during which plant design features may be more easily incorporated). Accordingly, SAMDA evaluations at the license renewal stage are not necessary.

10. Decommissioning

For the GEIS, the staff examined radiation doses, waste management, air quality, water quality, ecological resources, economic impacts, and socioeconomic impacts.

The physical requirements and attendant effects of decommissioning nuclear power plants after a 20-year license renewal period are not expected to be different from those of decommissioning at the end of the current 40-year license period. Decommissioning after a 20-year license renewal period would increase the occupational dose by about 0.5 person-rem and the public dose by a negligible amount. License renewal would not increase the quantity or classification of low-level radioactive waste generated by decommissioning to any appreciable extent. Air and water quality and ecological impacts of decommissioning would not change as a result of license renewal.

Considerable uncertainty exists about the cost of decommissioning. While license renewal would not be expected to change the ultimate cost of decommissioning, it would reduce the present value of the cost. The socioeconomic effects of decommissioning will depend on the magnitude of the decommissioning effort, the size of the community, and other economic activities at the time. However, the NRC does not expect that the impacts would be increased by decommissioning at the end of a 20-year license renewal period rather than at the end of the current license term. Because the NRC can reach a generic conclusion on the acceptability of the incremental impacts of decommissioning for all plants, impacts on decommissioning need not be evaluated for each plant license renewal application.

11. Need for Generating Capacity

Projections of the demand for electric power from 1991 to 2030 in each of the 11 Department of Energy regions indicate that a need will exist for the generating capacity represented by license renewal of plants in all 11 regions. The projection included demands for both individual and utility service areas, which showed that the generating capacity of each nuclear power plant would be needed to meet the nation's electric power demand.

12. Alternatives to License Renewal

In chapter 8 of the GEIS, the staff established the need for the electric-generating capacity represented by the renewal of operating licenses. Chapter 9 of the GEIS addresses how the demand for this generating capacity could be filled by alternatives to license renewal and weighed the alternatives against that of license renewal.

In the GEIS, the staff concluded that new fossil-fuel and nuclear power plants are reasonable alternatives for replacing of retired nuclear capacity because they are proven commercial power-generating technologies, they can provide the baseload capacity currently generated by large nuclear units, and they are available nationwide. However, on balance, none of these alternatives offer significant environmental advantages over license renewal. In fact, license renewal of existing nuclear generating capacity would delay or eliminate the environmental impacts associated with constructing replacement power plants. The principal issues associated with operation of new fossil plants are emissions of pollutants. This includes SO_x, NO_x, and CO_x which contribute to the degradation of air quality, including acid rain and decreased visibility, and increase the potential for global warming and climate change. Although license renewal is expected to be more advantageous than new fossil or new nuclear plants from a cost perspective in most situations, a decision to seek license renewal is a prerogative of individual utilities. For the GEIS, the staff evaluated several studies and developed an independent estimate. Each study focused on comparing the costs of license renewal and new coal-generated capacity. From this comparison, the staff concluded that license renewal offers significant savings under a diverse set of conditions over new coal-generated capacity. However, differences in operating parameters and performance of nuclear plants would affect the actual cost savings for each plant.

With respect to renewable energy sources, the staff finds that wind, sun, water, and biomass are not preferred near-term alternatives to license renewal because of technological limitations (nonbaseload power sources), availability, and economics. The potential exists for small-scale regional application of geothermal energy to replace a small fraction of current nuclear baseload capacity.

Therefore, in the GEIS, the staff concludes, for the nation as a whole, license renewal is preferable to replacing the generating capacity with a new facility. Because some uncertainty is associated with the economic costs of license renewal caused by the plant-specific nature of the refurbishment required, a limited data submittal including analysis of cost of refurbishment, should accompany each license renewal application. If these data meet the threshold criterion, no analysis of alternatives need accompanying the license application. If the submittal shows that license renewal cannot meet the threshold criterion, the applicant should submit an analysis of the most reasonable alternative. In addition, licensees for plants in California, Oregon, Washington, or Arizona should submit a cost comparison of license renewal to geothermal energy.

C. Regulatory Guidance To Support the 10 CFR Part 51 Revisions

To ensure proper implementation of the revised sections of 10 CFR part 51, the NRC is issuing a draft regulatory guide and a draft environmental standard review plan for license renewal. Both documents are being published concurrently with these proposed amendments. The draft guide, identified as Draft Supplement 1 to Regulatory Guide 4.2, establishes a uniform format and content acceptable to the staff for structuring and presenting the environmental information to be compiled and submitted by an applicant to renew an operating license. More specifically, this draft regulatory guide describes the content of environmental information to be included in a license renewal application, including the criteria to address appropriate Category 2 issues as specified in the proposed amendments to 10 CFR part 51.

Draft "Environmental Standard Review Plan for License Renewal" (ESRP–LR) NUREG–1429 provides guidance for the NRC staff when performing a 10 CFR part 51 environmental review of an application to renew an operating license. The plan parallels Regulatory Guide 4.2, Supplement 1. The primary purpose of the ESRP–LR is to ensure that these reviews are focused on those environmental concerns associated with license renewal as described in 10 CFR part 51. Specifically, it provides guidance to the NRC staff about environmental issues that should be reviewed and provides acceptance criteria to help the reviewer evaluate the information submitted as part of the license renewal appliation. It is also the intent of this plan to make information about the regulatory process available and to improve communication between the NRC, interested members of the public, and the nuclear power industry, thereby increasing understanding of the review process.

D. Public Comments on Advance Notice of Proposed Rulemaking

On July 23, 1990, the NRC published in the **Federal Register** an advance notice of proposed rulemaking (ANPR) (55 FR 29964) and a companion notice of intent to prepare a generic environmental impact statement (55 FR 29967). Advice and recommendations on the proposed rulemaking were invited from all interested persons. Comments were requested on nine specific questions. Comment were received from 29 groups and individuals. Two private individuals were opposed to the rulemaking. Of five citizens groups; one supported, three supported with qualifications, and one opposed the rulemaking. Of the two State agencies responding, one supported the rulemaking and one supported it with qualifications. Three Federal agencies supported the rulemaking with qualifications. All 16 NRC nuclear power plant licensees commenting on the ANPR supported the rulemaking. The one industry group that submitted comments supported the rulemaking. A summary of comments on each question and the staff response are as follows:

Question No. 1. Is a generic environmental impact statement or an environmental assessment required by the NEPA to support this propoed rulemaking or can the rulemaking be supported by a technical study?

Comments: Strong support for a generic environmental survey (GES) rather than a full GEIS to provide the technical basis for the rulemaking was expressed by the NUMARC, nuclear utilities, the U.S. Department of Energy, and Americans for Nuclear Energy, Inc. The EPA and the State of Wisconsin Public Service Commission (WPSC) support development of a comprehensive GEIS. Other comments offered no specific opinion on a GEIS versus a generic environmental survey. Supporters of the generic environmental survey approach stated that it is legally acceptable and would be less costly and less subject to delays. Supporters of a comprehensive GEIS believed that it is a feasible approach and a prudent one.

NRC Response: The NRC believes that while the GES provides an alternative approach to rulemaking, the GEIS approach is preferable and has been used to develop the proposed rule. The purpose of this rulemaking is to resolve as many National Environmental Policy Act (NEPA) issues as possible before beginning plant-by-plant license renewal reviews. Although the NRC recognized the possibility that not all NEPA issues would be fully resolvable in the GEIS, the NRC did not wish to make *a priori* judgments about which issues could be resolved generically and which could not. Also, even though some issues may not be fully resolved generically, the analyses performed for the GEIS have helped sharpen and focus the issues that must be addressed in specific license renewal reviews. To these ends the NEPA procedures specified in 10 CFR part 51 and followed in developing the GEIS do have the advantage of resulting in a comprehensive GEIS and rule that have been extensively reviewed by multiple outside, interested parties and therefore, will be stronger in focusing and limiting environmental discussion during license renewal.

In addition, a GES need not follow NEPA-mandated public comment requirements. It is envisioned as a scientific document, whose contents are similar in some ways to a GEIS, but it is published in final form without public comment. However, a GES need discuss neither alternatives to license renewal nor the cost-benefit balance of the major federal action (license renewal) under discussion. Therefore, use of a GES as support for limiting environmental discussion a license renewal hearings would weaken this rulemaking endeavor because of the lack of public participation in commenting on this cornerstone document and lack of compliance with the full-disclosure provision of NEPA.

Question No. 2. What alternative forms of codifying the findings of the generic environmental impact statement should be considered?

Comments: This question was not specifically addressed by most commenters. The NUMARC recommended that the findings of the GEIS be codified by classifying potential environmental impacts of license renewal into four categories that it described.

NRC Response: The NRC believes that the categories used in the GEIS and the results of the evaluation in chapter 10 of the GEIS permit codification of findings that is at least as adequate as would result from the NUMARC recommendation. The approach taken in the proposed rulemaking to codify the results of the GEIS is a mix of the four approaches identified in the ANPR.

Question No. 3. What activities associated with license renewal will lead to environmental impacts?

Comments: Several respondents addressed this question in general terms. NUMARC stated: "In general, most of the activities associated with license renewal that may have environmental impacts are the same activities considered in environmental evaluations for the initial licenses." Activities associated with license renewal are more fully discussed in a document that NUMARC submitted with its comments. The document is "Study of Generic Environmental Issues Related to License Renewal," dated May 9, 1989. A State agency identified a number of replacement activities that would result in generating low-level radioactive waste and radiation doses to workers engaged in these activities.

NRC Response: In May 1989, NUMARC submitted a study to the NRC in the context of the rulemaking on 10 CFR Part 54, "Requirements for Renewal of Operating Licenses for Nuclear Power Plants." Information on plant modification and operation activities associated with license renewal in this document was reviewed and considered in preparing the GEIS. Activities associated with license renewal that were identified by the State agency are addressed in the GEIS in chapter 2 and appendix B.

Question No. 4. What topical areas should be covered in the generic environmental impact statements? Should the proposed outline be supplemented or restructured?

Comments: Respondents to this question identified priority topics that should be covered in the GEIS and commented on the completeness of the scope of these topics. Those addressing the scope of such topics generally were satisfied with the list in the ANPR. Most concerns were with the balance of the treatment of topics within the outline. NUMARC, supported by member utilities, believed that some topics such as plant modifications associated with license renewal and decommissioning are unduly emphasized by being given major section status. A number of respondents discussed topical areas already identified in the ANPR about which they were particularly concerned. Several topics not identified in the ANPR were identified as concerns by one or more respondents. Concern was expressed that the pool of trained nuclear engineers is diminishing. Thus, operators may be less well qualified in the future. A respondent stated that each type of reactor should be treated separately. A Federal agency stated that the GEIS could assess the utilities' efforts to comply with the Public Utilities Regulatory Policy Act (PURPA) for financial assistance to private cogeneration facilities and that it could also assess the utilities' efforts to comply with State and local conservation efforts.

The WPSC raised the following four points not explicitly covered in the ANPR:

(1) Regarding the need for generating capacity, whether the NRC should defer to the relevant State agency's determination of need for generating capacity;

(2) Whether an accident that has the potential for leading to a demand by the public that all reactors be shut down could jeopardize the supply of electricity;

(3) Whether plant management history will be considered in a license renewal decision; and

(4) Whether embrittlement of the reactor pressure vessel may result in shutting plants down for susceptibility to pressurized thermal shock soon after extending the license.

NRC Response: The NRC believes that the scope of the GEIS accommodates most of the issues of concern raised in the comments. However some issues raised are beyond the scope of the GEIS. The NRC will ensure the qualification of operators in the future through NRC regulations, especially 10 CFR Part 55, "Operator's Licenses". The NRC has not explicitly assessed compliance with PURPA and State and local conservation efforts on a utility-by-utility basis and it does not believe it is necessary to do so. Conservation and cogeneration projections are already incorporated in forecasts of need for generating capacity.

Regarding WPSC's comment that the NRC should defer to the determination of need that relevant State agencies made, the NRC encourages State agencies to review analyses in the GEIS for consistency with their own analyses and to comment on any significant disagreements between them. Regarding the concern about a possible public demand to shut down all reactors after a severe accident at one, the NRC assumes in the GEIS that the programs described in Chapter 5 of the GEIS will maintain a low probability of a severe accident and that a shutdown of all reactors is speculative. Management history is not an issue that is addressed in the GEIS or the proposed rule. Although management action will be continually monitored through the operating life of any plant, it will not be a major topic evaluated to renew a license. The NRC will consider the embrittlement status of the reactor pressure vessel for a license renewal, and its status may indeed limit the term or bar the issuance of a renewed license.

Question No. 5. For each topical area, what are the specific environmental issues that should be addressed?

Comments: NUMARC was the only respondent who specifically addressed this question. Several other respondents did identify specific topics and environmental issues that concerned them. These other responses are addressed under Question No. 4. NUMARC referred the NRC to the detailed areas treated in the NUMARC report titled "Study of Generic Environmental Issues Related to License Renewal," dated May 9, 1989, and submitted to the NRC in May 1989.

NRC Response: The NUMARC report has been reviewed and was considered in developing the scope and analyses of the GEIS.

Question No. 6. For each topical area and each specific issue, what information and data are required to perform generic analyses? Where do the information and data exist?

Comments: NUMARC referred to its study submitted to the NRC titled, "Study of Generic Environmental Issues Related to License Renewal," and point out that the study contains relevant information and an extensive list of data sources. The EPA offered to provide information about the effect of electromagnetic frequency radiation and global climate change. The WPSC stated that information about the need for power, the amount of conservation that is technically and economically possible, and load management exists at each utility and at the corresponding State utility commission.

NRC Response: All information in the NUMARC study was reviewed and was used as appropriate in developing the GEIS. The NRC considered the EPA's information and guidance on effects of electromagnetic frequency radiation and global climate change. In the GEIS, the NRC took a regional generic approach about the need for power, conservation, and load management. The NRC believes this is an adequate analysis to establish the need for generating capacity for each plant but is requesting comment on its analysis.

Question No. 7. For each topical area and each specific issue, what criteria should be used to judge the significance of the environmental impact?

Comments: This question was specifically addressed by NUMARC and Yankee Atomic Electric Company. NUMARC provided the more detailed response, and it was consistent with the Yankee Atomic response. NUMARC made a number of general observations about the significance criteria embodied in the NRC practice in the environmental and associated safety areas and in the CEQ guidelines. They provided examples of significant criteria for endangered species, impacts to aquatic biota, and radiological impacts.

NRC Response: These comments generally support the approach to determine the significance of environmental issues employed in the GEIS.

Question No. 8. For each topical area and each specific issue, what is the potential for successful analysis?

Comments: NUMARC addressed this question in detail. Commenting utilities supported the NUMARC response. Other responses ranged from a general statement that generic treatment is not feasible to a general statement that generic treatment is feasible. Several commenters each mentioned doubts about the possibility of generic treatment of at least some of the following: need for generating capacity, alternatives, climate change, impacts from refurbishment and continued operation, and severe accidents. NUMARC stated that "nearly all, if not all, of the impacts associated with license renewal have been found amenable to generic analysis." Using the four categories of generic conclusions (see Question No. 2), NUMARC presented conclusions on the categorization of various impacts from plant operation, plant modification, accidents, decommissioning, need for generating capacity, and alternative generating capacity.

NRC Response: The NRC considered the positions offered in comments on the potential of generic analysis for each topical area and each specific issue. The NRC findings are summarized in chapter 10 of the GEIS. The NRC believes that the approach taken in the GEIS resulted in generic conclusions that both encompass site- and region-specific considerations and consider forecasting uncertainties.

Question No. 9. What length of extended operating time can reasonably be addressed in the proposed rulemaking? To what extent is it possible to reach generic conclusions about the environmental impacts that would be applicable to plants having renewed operating licenses expiring in the year 2030, 2040, or 2050?

Comments: Several commenters had doubts about the accuracy of long-term forecasts of need for generating capacity, alternative energy sources, climate change, and severe accidents. NUMARC specifically addressed this question and pointed out that environmental impact evaluations are performed for new plants for 40 to 50 years into the future, but that unlike new plants, applicants who will apply for plant license renewal have an operating history with accumulated monitoring data. NUMARC also stated that the NRC has the option of revising the GEIS at any future time if experience shows an impact that deviates significantly from its predicted value.

NRC Response: The NRC agrees with NUMARC's observations and believes the conclusions reached in the GEIS issue reflect careful consideration of future uncertainties.

IV. Questions

Public comment on conclusions about potential environmental impacts is being solicited as part of this rulemaking. The Commission will evaluate comments on this notice and the draft GEIS before publishing a final rule.

In addition to general comments on the proposed rulemaking, the Commission is especially interested in public responses to the following questions:

(1) Should the NRC staff have the flexibility, as provided in the proposed rule, to choose to prepare an environmental assessment instead of a supplemental environmental impact statement for each plant license to be renewed? In answering this question, please consider whether it makes a difference if this proposed rulemaking is supported by a generic environmental survey rather than a full GEIS?

(2) For presenting a full discussion of environmental impacts from postulated accidents as required by the NEPA:

(a) Is the exposure index (EI) method, as used in chapter 5 of the GEIS to predict potential environmental impacts of atmospheric releases of radioactive material from a severe accident, sufficient to present for consideration the potential impacts from severe accident of atmospheric releases for all plants for the license renewal period? If not, what alternative analyses would be acceptable?

(b) Is the method of analysis of radionuclide deposition from fallout over open bodies of water from severe accidents of atmospheric releases, as used in chapter 5 of the GEIS, sufficient to present for consideration the potential impacts of atmospheric fallout for all plants? If not, what alternative analyses would be acceptable?

(c) Is the method of analysis of releases to groundwater from severe accidents, as used in chapter 5 of the GEIS, sufficient to present for consideration the potential impacts of releases to groundwater for all plants? If not, what alternative analyses would be acceptable?

(3) It is reasonable to conclude that, based upon the calculated low risk to the environment from severe accidents and the June 13, 1980, Commission Policy Statement on accident considerations under the NEPA (45 FR 40101), SAMDAs need not be considered in individual license renewal applications? If not, what alternative would be acceptable?

(4) What significant environmental issues, if any, have not been evaluated in the GEIS?

(5) Which evaluations presented, if any, are not sufficient for drawing generic conclusions?

(6) What additional analyses can be done to further address the Category 2 and 3 items? For example, what screening criteria could be applied to local transportation during

refurbishment and to threatened and endangered species to change these issues from Category 3 to Category 2? Are the criteria for meeting the defined bounding conditions for each of the Category 2 items sufficiently clear?

(7) The GEIS and this proposed action apply to all plants currently holding an OL or CP, except for Washington Nuclear Plant 1 and 3, Grand Gulf 2, and Perry 2. Should these plants be included in the scope of this action?

V. Availability of Documents

The principal supporting documents of this supplementary information are as follows:

(1) Draft Generic Environmental Impact Statement, NUREG–1437

(2) Draft Regulatory Analysis: Proposed Part 51 Amendments, NUREG–1440

(3) Draft Supplement to Regulatory Guide 4.2 (DG–4002)

(4) Draft Environmental Standard Review Plan—License Renewal, NUREG–1429

A free single copy of each of these documents, to the extent of supply, may be requested by those who are considering commenting by writing to the U.S. Nuclear Regulatory Commission, Washington, DC 20555 (ATTN: Distribution and Mail Services Section). Copies of all documents cited in the supplementary information are available for inspection and/or for copying for a fee, in the NRC Public Document Room, 2120 L St. NW. (Lower Level), Washington, DC.

In addition, copies of NRC documents cited here may be purchased from the Superintendent of Documents, U.S. Government Printing Office, PO Box 37082, Washington, DC 20013–7082. Copies are also available for purchase from the National Technical Information Service, 5285 Port Royal Road, Springfield, VA 22161.

VI. Workshop

A workshop is being scheduled during which experts with a diversity of perspectives can review the technical basis of the proposed amendments. Such interaction is expected to contribute information for the NRC to consider that may not otherwise have surfaced through written comments on the proposed amendments. In addition, the workshop may provide additional information that will assist those who comment in developing written comments.

The workshop is being designed to focus on the substantive technical findings of the GEIS codified in the proposed amendment. Workshop sessions will correspond to the major topical areas found in the GEIS and appendix B of subpart A of 10 CFR part 51. Workshop participants will be experts selected from industry, Federal and State agencies, and environmental organizations. Each workshop concurrent session will be limited to 15 participants and will be conducted in a panel format. Questions and statements from the audience will be taken if time permits.

Comments are invited on the following tentative agenda.

Day 1

7:45–8:30 Registration
8:30–8:45 Welcome
8:45–9:00 Workshop objectives, structure, ground rules
9:00–10:15 General Session—GEIS and proposed 10 CFR part 51 rulemaking overview
10:15–10:30 Break
10:30–11:45 General Session (cont.)
11:45–1:00 Lunch
1:00–3:00 *Concurrent Sessions*
A. Surface Water, Aquatic Ecology, Groundwater
B. Terrestrial Ecology, Land Use
C. Socioeconomics
3:00–3:15 Break
3:15–5:15 *Concurrent Sessions*
D. Decommissioning
E. Human Health
F. Need for Generating Capacity and Direct Economic Costs and Benefits

Day 2

8:30–10:15 *Concurrent Sessions*
G. Postulated Accidents
H. Solid Waste Management
I. Alternatives
10:15–10:30 Break
10:30–11:45 Concurrent Sessions G, H and I (cont.)
11:45–1:00 Lunch
1:00–2:00 General Session—NEPA Process
2:00–3:00 Summary and Conclusion of Sessions

VII. Submittal of Comments in an Electronic Format

Commenters are encouraged to submit, in addition to the original paper copy, a copy of their letter in an electronic format on IBM PC DOS-compatible 3.5- or 5.25-inch, double-sided, double-density (DS/DD) diskettes. Data files should be provided in Wordperfect 5.1. ASCII code is also acceptable or, if formatted text is required, data files should be provided in IBM Revisable-Form Text Document Content Architecture (RFT/DCA) format.

VIII. Environmental Impact: Categorical Exclusion

The NRC has determined that this proposed regulation is the type of action described in categorical exclusion 10 CFR 51.22(c)(3). Therefore neither an environmental impact statement nor an environmental assessment has been prepared for this proposed regulation. This action is procedural in nature in that it pertains to the type of environmental information to be reviewed.

IX. Paperwork Reduction Act Statement

This proposed rule amends information collection requirements that are subject to the Paperwork Reduction Act of 1980 (44 U.S.C. 3501 *et seq.*). This rule has been submitted to the Office of Management and Budget for review and approval of the paperwork requirements. Public reporting burden for this collection of information is estimated to average about 3000 hours per response, including the time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing the collection of information. Send comments regarding this burden estimate or any other aspect of this collection of information, including suggestions for reducing this burden, to the Information and Records Management Branch (MNBB–7714), U.S. Nuclear Regulatory Commission, Washington, DC 20555 and to the Desk Officer Office of Information and Regulatory Affairs, NEOB–3019 (3150–0021), Office of Management and Budget, Washington, DC 20503.

X. Regulatory Analysis

The Commission has prepared a draft regulatory analysis on this proposed regulation. The analysis examines the costs and benefits of the alternatives considered by the Commission. The two alternatives considered were (a) retaining the existing part 51 review process for license renewal, which requires that all review be done on a plant-specific basis, and (b) amending part 51 to allow a portion of the environmental review to be conducted on a generic basis. The conclusions of the draft regulatory analysis show substantial cost savings of alternative (b) over alternative (a).

The draft analysis is available for inspection in the NRC Public Document Room, 2120 L Street, NW. (Lower Level), Washington, DC. Copies of the analysis are available as described in Section V of this proposed rule. The Commission requests public comment on the draft regulatory analysis. Comments on the draft analysis may be submitted to the NRC as indicated under the addresses' heading.

XI. Regulatory Flexibility Act Certification

As required by the Regulatory Flexibility Act of 1980, 5 U.S.C. 605(b), the Commission certifies that this proposed rule will not have a significant impact on a substantial number of small entities. The proposed rule states application procedures and environmental information to be submitted by nuclear power plant licensees to facilitate the NRC's obligations under the NEPA. Nuclear power plant licensees do not fall within the definition of small businesses as defined in section 3 of the Small Business Act, 15 U.S.C. 632, the Small Business Size Standards of the Small Business Administrator (13 CFR part 121), or the Commission's Size Standards (50 FR 50241; December 9, 1985).

XII. Backfit Analysis

The rulemaking does not constitute a "backfit" as defined in 10 CFR 50.109(a)(1) and a backfit analysis need not be prepared. This rule addresses procedural requirements for considering the environmental effects of issuing a renewed operating license for a nuclear power plant. The Commission has not previously addressed these requirements either in rulemaking or in guidance documents. Moreover, policy considerations weigh against considering part 51 and its amendments as a "backfit." The primary impetus for the Backfit Rule was "regulatory stability," namely, that once the Commission decides to issue a license, the terms and conditions for operating under that license would not be arbitrarily changed *post hoc*. Regulatory stability is not a relevant issue with respect to license renewal. This rule has only a prospective effect upon nuclear power plant licensees. No licensee currently holds a renewed nuclear power plant operating license and therefore, no valid expectations could be changed regarding the terms and conditions for holding a renewed operating license.

List of Subjects in 10 CFR Part 51

Administrative practice and procedure, Environmental impact statement, Nuclear materials, Nuclear power plants and reactors, Reporting and recordkeeping requirements.

For the reasons set out in the preamble and under the authority of the Atomic Energy Act of 1954, as amended; the Energy Reorganization Act of 1974, as amended; the National Environmental Policy Act of 1969, as amended; and 5 U.S.C. 553; the NRC is proposing to adopt the following amendments to 10 CFR part 51.

PART 51—ENVIRONMENTAL PROTECTION REGULATIONS FOR DOMESTIC LICENSING AND RELATED REGULATORY FUNCTIONS

1. The authority citation for part 51 continues to read as follows:

Authority: Sec. 161, 68 Stat. 948, as amended (42 U.S.C. 2201); secs. 201, as amended, 202, 88 Stat. 1242, as amended, 1244 (42 U.S.C. 5841, 5842). Subpart A also issued under National Environmental Policy Act of 1969, secs. 102, 104, 105, 83 Stat. 853–854, as amended (42 U.S.C. 4332, 4334, 4335); and Pub. L. 95–604, Title II, 92 Stat. 3033–3041. Sections 51.20, 51.30, 51.60, 51.61, 51.80, and 51.97 also issued under secs. 135, 141, Pub. L. 97–425, 96 Stat. 2232, 2241, and sec. 148, Pub. L. 100–203, 101 Stat. 1330–223 (42 U.S.C. 10155, 10161, 10168). Section 51.22 also issued under sec. 274, 73 Stat. 688, as amended by 92 Stat. 3036–3038 (42 U.S.C. 2021) and under Nuclear Waste Policy Act of 1982, sec. 121, 96 Stat. 2228 (42 U.S.C. 10141). Sections 51.43, 51.67, and 51.109 also under Nuclear Waste Policy Act of 1982, sec. 114(f), 96 Stat. 2216, as amended (42 U.S.C. 10134(f)).

2. Section 51.20 is amended by revising paragraph (b)(2) to read as follows:

§ 51.20 Criteria for and identification of licensing and regulatory actions requiring environmental impact statements.

* * * * *

(b) * * *

(2) Issuance of a full-power or design-capacity license to operate a nuclear power reactor pursuant to part 50 of this chapter, or issuance or renewal of a full-power or design-capacity license to operate a testing facility or a fuel reprocessing plant pursuant to part 50 of this chapter.

* * * * *

2A. Footnotes 3 through 8 in part 51 are redesignated as footnotes 5 through 10.

3. Section 51.53 is revised to read as follows:

§ 51.53 Supplement to environmental report.

(a) *General.* Any supplement to an environmental report prepared under the provisions of this section may incorporate by reference any information contained in a prior environmental report or supplement thereto that relates to the same production or utilization facility or any information contained in a final environmental document previously prepared by the NRC staff that relates to the same production or utilization facility. Documents that may be referenced include, but are not limited to, the final environmental impact statement; supplements to the final environmental impact statement, including supplements prepared at the license renewal stage; environmental assessments and records of decisions prepared in connection with the construction permit, the operating license, and any license amendment for that facility.

(b) *Operating license stage.* Each applicant for a license to operate a production or utilization facility covered by § 51.20 shall submit with its application the number of copies, as specified in § 51.55, of a separate document, entitled "Supplement to Applicant's Environmental Report—Operating License Stage," which will update "Applicant's Environmental Report—Construction Permit Stage." Unless otherwise required by the Commission, the applicant for an operating license for a nuclear power plant shall submit this report only in connection with the first licensing action authorizing full-power operation. In this report, the applicant shall discuss the same matters described in §§ 51.45, 51.51, and 51.52, but only to the extent that they differ from those discussed or reflect new information in addition to that discussed in the final environmental impact statement prepared by the Commission in connection with the construction permit. Unless otherwise required by the Commission, no discussion of need for power or alternative energy sources or alternative sites for the facility or of any aspect of the storage of spent fuel for the facility within the scope of the generic determination in § 51.23(a) and in accordance with § 51.23(b) is required in this report.

(c) *Operating license renewal stage.* (1) Each applicant for renewal of a license to operate a nuclear power plant under part 54 of this chapter shall submit with its application the number of copies, as specified in § 51.55, of a separate document, entitled "Supplement to Applicant's Environmental Report—Operating License Renewal Stage."

(2) The supplemental report must contain a description of the proposed action, including the applicant's plans to modify the facility or its administrative control procedures as described in accordance with § 54.21(e) of this chapter. The report must describe in detail the modifications directly affecting the environment or affecting plant effluents that affect the environment.

(3) For those applicants seeking an initial renewal license and holding an operating license as of June 30, 1992, or

who hold an operating license for Bellefonte Unit 1 or 2, Comanche Peak Unit 2, or Watts Bar Unit 1 or 2, the scope of issues to be addressed in the supplemental report will be limited to the following:

(i) Unless otherwise required by the Commission, no discussion of license renewal issues identified as Category 1 issues in appendix B of subpart A of this part is required in the supplemental report.

(ii) For those issues identified as Category 2 in appendix B of subpart A of this part, the supplemental report must contain a demonstration that:

(A) The nuclear power plant uses only cooling towers for primary condenser cooling or that the license renewal applicant holds current Clean Water Act 316(b) determinations and if necessary a 316(a) variance in accordance with 40 CFR part 125, or equivalent State permits. If no such demonstration can be made, an assessment of the impact of the individual nuclear power plant license renewal on fish and shellfish resources resulting from heat shock and impingement and entrainment must be provided.

(B) The nuclear power plant is not located at an inland site or does not have cooling ponds. If no such demonstration can be made, an assessment of the impact of the individual nuclear power plant license renewal on groundwater quality must be provided.

(C) The nuclear power plant does not use Ranney wells and either does not pump 100 or more gallons per minute of groundwater or does not have private wells located within the cones of depression of the nuclear power plant wells. If no such demonstration can be made, an assessment of the impact of the individual nuclear power plant license renewal on groundwater-use conflicts must be provided.

(D) Construction activities that are related to license renewal that involve additional onsite land use will not affect important plant and animal habitats. If no such demonstration can be made, an assessment of the impact of the individual plant license renewal on important plant and animal habitats must be provided.

(E) No major construction activities associated with the nuclear power plant license renewal will take place at the site. If no such demonstration can be made, a construction impact control program that will mitigate potential impacts on the aquatic environment from soil erosion or spills must be implemented and a description of this program must be provided.

(F) The nuclear power plant is in a medium or high population area[3] and not in an area where growth-control measures that limit housing development are in effect. If no such demonstration can be made, an assessment of the impact of the individual nuclear power plant license renewal on housing availability must be provided.

(G) The design of the transmission lines of the nuclear power plant meets the recommendations of the National Electric Safety Code for preventing electric shock from induced currents. If no such demonstration can be made, an assessment of the impact of the individual nuclear power plant license renewal on the potential electric shock hazard from the transmission lines of the plant must be provided.

(H) The nuclear power plant does not use a cooling pond, lake, or canal and does not discharge water to a small river. If no such demonstration can be made, an assessment of the impact of thermophilic organisms in the affected water on the health of recreational users must be provided.

(I) The nuclear power plant will have access to a low-level radioactive waste disposal facility through a low-level waste compact or an unaffiliated State. If no such demonstration can be made, a presentation of capability and plans for interim waste storage must be provided with an assessment of potential ecological habitat destruction caused by construction activities.

(J) The replacement of equivalent generating capacity by a coal-fired plant has no demonstrated cost advantage[4] over the individual nuclear power plant license renewal. If no such demonstration can be made, a justification for choosing the license renewal alternative must be provided. For nuclear power plants located in California, Oregon, Washington, or Arizona, applicants to renew a license must also provide an assessment of geothermal generating capacity as an alternative to license renewal in addition to the cost demonstration results.

(iii) For those issues identified in Category 3 in appendix B of subpart A of this part, the supplemental report must contain an assessment about the following:

(A) The impact of renewing the license for the nuclear power plant on threatened or endangered species.

(B) The impact of renewing the license for the nuclear power plant on local transportation during periods of license-renewal-related refurbishment activities.

(4) The supplemental report must contain an analysis of whether the assessment required by paragraphs (c)(3)(ii)–(iii) of this section changes the findings documented in Table B–1 of appendix B of subpart A of this part that the renewal of any operating license for up to 20 years will have accrued benefits that outweigh the economic, environmental, and social costs of license renewal.

(d) *Postoperating license stage.* Each applicant for a license amendment authorizing the decommissioning of a production or utilization facility covered by § 51.20 and each applicant for a license or license amendment to store spent fuel at a nuclear power plant after expiration of the operating license for the nuclear power plant shall submit with its application the number of copies, as specified in § 51.55, of a separate document, entitled "Supplement to Applicant's Environmental Report—Post Operating License Stage," which will update "Supplement to Applicant's Environmental Report—Operating License Stage," and "Supplement to Applicant's Environmental Report—Operating License Renewal Stage," as appropriate, to reflect any new information or significant environmental change associated with the applicant's proposed decommissioning activities or with the applicant's proposed activities with respect to the planned storage of spent fuel. Unless otherwise required by the Commission, in accordance with the generic determination in § 51.23(a) and the provisions in § 51.23(b), the applicant shall only address the environmental impact of spent fuel storage for the term of the license applied for.

4. In § 51.55, paragraph (a) is revised to read as follows:

§ 51.55 Environmental report—number of copies; distribution.

(a) Each applicant for a license to construct and operate a production or utilization facility covered by paragraph (b)(1), (b)(2), (b)(3) or (b)(4) of § 51.20,

[3] An area is considered to have a medium or high population if any of the following conditions is satisfied:

(a) The plant is within 20 miles of a city of 25,000;

(b) The plant is within 50 miles of a city of 100,000;

(c) The population of the area within 20 miles of the plant is 75,000 or more;

(d) The population of the area within 50 miles of the plant is 1,500,000 or more; or

(e) The population of the area within 20 miles of the plant is 50,000 or more and, within 50 miles of the plant, the population is 400,000 or more.

[4] In performing the cost demonstration, costs of refurbishment, construction, fuel, operation, and maintenance must be considered.

each applicant for renewal of an operating license for a nuclear power plant, each applicant for a license amendment authorizing the decommissioning of a production or utilization facility covered by § 51.20, and each applicant for a license or license amendment to store spent fuel at a nuclear power plant after expiration of the operating license for the nuclear power plant shall submit to the Director of the Office of Nuclear Reactor Regulation or the Director of the Office of Nuclear Material Safety and Safeguards, as appropriate, 41 copies of an environmental report or any supplement to an environmental report. The applicant shall retain an additional 109 copies of the environmental report or any supplement to the environmental report for distribution to parties and Boards in the NRC proceedings; Federal, State, and local officials; and any affected Indian tribes; in accordance with written instructions issued by the Director of the Office of Nuclear Reactor Regulation or the Director of the Office Nuclear Material Safety and Safeguards, as appropriate.

* * * * *

5. Section 51.95 is revised to read as follows:

§ 51.95 Supplement to final environmental impact statement; environmental assessment.

(a) *General.* Any supplement to a final environmental impact statement or any environmental assessment prepared under the provisions of this section may incorporate by reference any information contained in a final environmental document previously prepared by the NRC staff that relates to the same production or utilization facility. Documents that may be referenced include, but are not limited to, the final environmental impact statement; supplements to the final environmental impact statement, including supplements prepared at the operating license stage; environmental assessments and records of decisions prepared in connection with the construction permit, the operating license, and any license amendment for that facility. A supplement to a final environmental impact statement will include a request for comments as provided in § 51.73.

(b) *Operating license stage.* In connection with the issuance of an operating license for a production or utilization facility, the NRC staff will prepare a supplement to the final environmental impact statement on the construction permit for that facility, which will update the prior environmental review. The supplement will only cover matters that differ from or that reflect significant new information concerning matters discussed in the final environmental impact statement. Unless otherwise determined by the Commission, a supplement on the operation of a nuclear power plant will not include a discussion of need for power or alternative energy sources or alternative sites or of any aspect of the storage of spent fuel for the nuclear power plant within the scope of the generic determination in § 51.23(a) and in accordance with § 51.23(b), and will only be prepared in connection with the first licensing action authorizing full-power operation.

(c) *Operating license renewal stage.* In connection with the renewal of an operating license for a nuclear power plant under part 54 of this chapter, the NRC staff will prepare an environmental assessment or, if warranted, a supplemental environmental impact statement. Unless otherwise determined by the Commission, the environmental assessment or the supplemental environmental impact statement will address only the matters in § 51.53(c) of this part. A supplemental environmental impact statement is required if significant impacts are found in the environmental assessment.

(d) *Postoperating license stage.* In connection with the amendment of an operating license to authorize the decommissioning of a production or utilization facility covered by § 51.20 or with the issuance, amendment, or renewal of a license to store spent fuel at a nuclear power plant after expiration of the operating license for the nuclear power plant, the NRC staff will prepare a supplemental environmental impact statement for the postoperating license stage or an environmental assessment, as appropriate, which will update the prior environmental review. Unless otherwise required by the Commission, in accordance with the generic determination in § 51.23(a) and the provisions of § 51.23(b), a supplemental environmental impact statement for the postoperating license stage or an environmental assessment, as appropriate, will address the environmental impacts of spent fuel storage only for the term of the license, license amendment, or license renewal applied for.

6. A new appendix B is added to subpart A, 10 CFR part 51 to read as follows:

Appendix B to Subpart A—Environmental Effect of Renewing the Operating License of a Nuclear Power Plant

The Commission has considered the environmental and other costs and benefits of alternatives to granting a renewed operating license for a nuclear power plant to a licensee who holds an operating license as of June 30, 1992, or who holds an operating license for Bellefonte Unit 1 or 2, Comanche Peak Unit 2, or Watts Bar Unit 1 or 2. The Commission has found that the renewal of any operating license for up to 20 years will have accrued benefits that outweigh the economic, environmental, and social costs of license renewal, subject to an evaluation of those issues identified as Category 2 (only for those nuclear power plants that are outside the envelope defined in each issue) and Category 3 in Table B-1. Table B-1 summarizes the Commission findings on the scope and magnitude of environmental and other effects of renewing the operating license for a nuclear power plant as required by section 102(2) of the National Environmental Policy Act of 1969, as amended. The Commission will periodically review the material in this appendix and update it if necessary.

TABLE B-1. SUMMARY OF FINDINGS ON NEPA ISSUES FOR LICENSE RENEWAL OF NUCLEAR POWER PLANTS

Issue	Category[1]	Findings[2]
PART I. NEED FOR GENERATING CAPACITY		
Need for generating capacity via license renewal	1	LARGE BENEFIT. License renewal of an individual nuclear power plant will be needed to meet generating capacity requirements in the service area and to avoid constructing and operating new generating facilities which would otherwise be necessary to replace the retired nuclear plant.

TABLE B-1. SUMMARY OF FINDINGS ON NEPA ISSUES FOR LICENSE RENEWAL OF NUCLEAR POWER PLANTS—Continued

Issue	Category[1]	Findings[2]
PART II. IMPACTS OF ALTERNATIVES		
Advances of alternatives to license renewal	1	NO ADVANTAGE. License renewal of an individual nuclear power plant is found to be preferable to replacement of the generating capacity with a new facility to the year 2020. License renewal is found to be preferable, both environmentally and economically[3] to either new fossil-fuel or new nuclear capacity. Wind, solar photovoltaic cells, solar thermal power, hydropower, and biomass are found to be not preferable to license renewal because of technological limitations, availability, and economics. Geothermal power could be competitive in areas where geothermal resources are readily available. These areas are in the states of California, Oregon, Washington, and Arizona.
PART III. BENEFITS/COST ASSESSMENT BENEFITS		
Direct Economic		
Generating capacity	1	LARGE BENEFIT. Will provide from 72 $\times$ 10³ to 1270 $\times$ 10³ net kW(e) reflecting the smallest to the largest plant.
Electric energy	1	LARGE BENEFIT. Will provide from 391 $\times$ 10⁶ to 6898 $\times$ 10⁶ kWh/yr reflecting the smallest to the largest plant.
Avoided costs	2[3]	SMALL TO LARGE BENEFIT. Compared to replacement of electric generating capacity with a new coal-fired plant, license renewal offers savings under a diverse set of conditions.
Indirect		
Local taxes Refurbishment	1	SMALL BENEFIT. Tax revenues will increase due to capital improvements.
Local taxes Renewal term	1	SMALL BENEFIT. The impact of tax revenues may vary from small to large depending on the total tax base of the taxing jurisdictions.
Employment Refurbishment	1	SMALL BENEFIT. Impacts on regional employment will be small to moderate depending on the total employment base of the region, and will be short-lived.
Employment Renewal term	1	SMALL BENEFIT. Impacts on regional employment will be small to large depending on the total employment base of the region.
COSTS Direct Economic[3]		
Refurbishment	2	MODERATE COST. Refurbishment costs will vary widely depending on specific plant requirements. In general, costs will be significantly lower relative to the capital cost of new coal-fired plants.
Fuel	2	SMALL COST. Fuel costs will be much lower than for a new coal-fired plant.
Operation and maintenance	2	LARGE COST. O&M costs will vary widely depending on specific plant performance but on the average they will be significantly more that for a new coal-fired plant.
Environmental and Socioeconomic Surface Water Quality, Hydrology, and Use (for all plants)		
Effects of refurbishment on surface-water quality	2	SMALL COST. Impacts are expected to be minor and insignificant during refurbishment if there are no major construction activities associated with the individual plant license renewal or if best management practices (BMPs) are employed to control soil erosion and spills; applicant must provide evidence of approved BMPs in license renewal application.
Effects of refurbishment on surface-water use	1	SMALL COST. Water use during refurbishment will not change or will be reduced during reactor outage.
Altered current patterns at intake and discharge structures	1	SMALL COST. Has not been found to be a problem at operating nuclear power plants and is not expected to be a problem during the license renewal term.
Altered salinity gradients	1	SMALL COST. Has not been found to be a problem at operating nuclear power plants and is not expected to be a problem during the license renewal term.
Altered thermal stratification of lakes	1	SMALL COST. Has not been found to be a problem at operating nuclear power plants and is not expected to be a problem during the license renewal term.
Temperature effects on sediment transport capacity	1	SMALL COST. Has not been found to be a problem at operating nuclear power plants and is not expected to be a problem during the license renewal term.
Scouring caused by discharged cooling water	1	SMALL COST. Has not been found to be a problem at operating nuclear power plants and is not expected to be a problem during the license renewal term.
Eutrophication	1	SMALL COST. Has not been found to be a problem at operating nuclear power plants and is not expected to be a problem during the license renewal term.
Discharge of chlorine or other biocides	1	SMALL COST. Effects are readily controlled through National Pollutant Discharge Elimination System (NPDES) permit and periodic modifications, if needed, and is not expected to be a problem during the license renewal term.
Discharge of sanitary wastes	1	SMALL COST. Effects are readily controlled through NPDES permit and periodic modifications, if needed, and is not expected to be a problem during the license renewal term.
Discharge of other chemical contaminants (e.g., metals)	1	SMALL COST. Has not been found to be a problem at operating nuclear power plants with cooling-tower-based heat dissipation systems. Has been satisfactorily mitigated at other plants. It is not expected to be a problem during the license renewal term.

TABLE B-1. SUMMARY OF FINDINGS ON NEPA ISSUES FOR LICENSE RENEWAL OF NUCLEAR POWER PLANTS—Continued

Issue	Category[1]	Findings[2]
Water-use conflicts	1	SMALL COST. Has not been found to be a problem at operating nuclear power plants with once-through heat dissipation systems. The issue has been a concern at two nuclear power plants with cooling ponds and at two plants with cooling towers, but it will be resolved with appropriate state or regional regulatory agencies outside of NRC license renewal actions. It is not expected to be a problem during the license renewal term.
Aquatic Ecology (for all plants)		
Refurbishment	1	SMALL COST. During plant shutdown and refurbishment there will be negligible effects on aquatic biota due to a reduction of entrainment and impingement of organisms or reduced release of chemicals.
Accumulation of contaminants in sediments or biota	1	SMALL COST. Has been a concern at a single nuclear power plant with a cooling pond, but has been satisfactorily mitigated. Has not been found to be a problem at operating nuclear power plants with cooling towers or once-through cooling systems, or a cooling pond, except for one plant. It was successfully mitigated at that plant. It is not expected to be a problem during the license renewal term.
Entrainment of phytoplankton and zooplankton	1	SMALL COST. Has not been found to be a problem at operating nuclear power plants and is not expected to be a problem during the license renewal term.
Cold shock	1	SMALL COST. Has been satisfactorily mitigated at operating nuclear plants with once-through cooling systems and has not endangered fish populations. Has not been found to be a problem at operating nuclear power plants with cooling towers or cooling ponds. It is not expected to be a problem during the license renewal term.
Thermal plume barrier to migrating fish	1	SMALL COST. Has not been found to be a problem at operating nuclear power plants and is not expected to be a problem during the license renewal term.
Premature emergence of aquatic insects	1	SMALL COST. Has not been found to be a problem at operating nuclear power plants and is not expected to be a problem during the license renewal term.
Gas supersaturation (gas bubble disease)	1	SMALL COST. Previously a concern at a small number of operating nuclear power plants with once-through cooling systems, but has been satisfactorily migated. Has not been found to be a problem at operating nuclear power plants with cooling towers or cooling ponds. It is not expected to be a problem during the license renewal term.
Low dissolved oxygen in the discharge	1	SMALL COST. Has been a concern at one nuclear power plant with a once-through cooling system, but issue will be monitored in the NPDES permit renewal process. Has not been found to be a problem at operating nuclear power plants with cooling towers or cooling ponds. It is not expected to be a problem during the license renewal term.
Losses from predation, parasitism, and disease among organisms exposed to sublethal stresses.	1	SMALL COST. Has not been found to be a problem at operating nuclear power plants and is not expected to be a problem during the license renewal term.
Stimulation of nuisance organisms (e.g., shipworms)	1	SMALL COST. Has been satisfactorily mitigated at the single nuclear power plant with a once-through cooling system where it was a problem. Has not been found to be a problem at operating nuclear power plants with cooling towers or cooling ponds. It is not expected to be a problem during the license renewal term.
Aquatic Ecology (for plant with once-through heat dissipation systems)		
Entrainment of fish and shellfish in early life stages	2	SMALL COST. Has not been found to be a problem at most operating plants and is not expected to be a problem during the license renewal term. Licensees of plants that do not have an approved Clean Water Act 316(b) determination or equivalent State permit at the time of license renewal application must evaluate the entrainment issue in the license renewal application.
Impingement of fish and shellfish	2	SMALL COST. Has not been found to be a problem at most operating plants and is not expected to be a problem during the license renewal term. Licensees, of plants that do not have an approved Clean Water Act 316(b) determination or equivalent State permit if required at the time of license renewal application must evaluate the impingement issue in the license renewal application.
Heat shock	2	SMALL COST. Has not been found to be a problem at most operating plants and is not expected to be a problem during the license renewal term. Licensees, of plants that do not have an approved Clean Water Act 316(b) determination or equivalent State permit, if required, at the time of license renewal application must evaluate the heat shock issue in the license renewal application.
Aquatic Ecology (for plants with cooling-tower-based heat dissipation systems)		
Entrainment of fish and shellfish in early life stages	1	SMALL COST. Has not been found to be a problem at operating nuclear power plants with this type of cooling system and is not expected to be a problem during the license renewal term.
Impingement of fish and shellfish	1	SMALL COST. Has not been found to be a problem at operating nuclear power plants with this type of cooling system and is not expected to be a problem during the license renewal term.
Heat shock	1	SMALL COST. Has not been found to be a problem at operating nuclear power plants with this type of cooling system and is not expected to be a problem during the license renewal term.

TABLE B-1. SUMMARY OF FINDINGS ON NEPA ISSUES FOR LICENSE RENEWAL OF NUCLEAR POWER PLANTS—Continued

Issue	Category[1]	Findings[2]
Aquatic Ecology (for plants with cooling pond heat dissipation systems)		
Impingement of fish	2	SMALL COST. Has not been found to be a problem at most operating plants and is not expected to be a problem during the license renewal term. Licensees of plants that do not have an approved Clean Water Act 316(b) determination or equivalent State permit at the time of license renewal application must evaluate the impingement issue in the license renewal application.
Entrainment of fish in early life stages	2	SMALL COST. Has not been found to be a problem at most operating plants and is not expected to be a problem during the license renewal term. Licensees of plants that do not have an approved Clean Water Act 316(b) determination or equivalent State permit at the time of license renewal application must evaluate the entrainment issue in the license renewal application.
Heat shock	2	SMALL COST. Has not been found to be a problem at most operating plants and is not expected to be a problem during the license renewal term. Licensees of plants that do not have an approved Clean Water act 316(a) determination or equivalent State permit, if required at the time of license renewal application must evaluate the heat shock issue in the license renewal application.
Groundwater Use and Quality, Impacts of Refurbishment		
Groundwater-use and quality	1	SMALL COST. Extensive dewatering during the original construction on some sites will not be repeated during refurbishment on any sites. Any plants wastes produced during refurbishment will be handled in the same manner as in current operating practices and is not expected to be a problem during the license renewal term.
Groundwater Use and Quality, Impacts of Operation		
Groundwater-use conflicts (potable and service water)	2	SMALL COST. Has not been found to be a problem at most operating plants and is not expected to be a problem during the license renewal term. Plants pumping 100 or more gpm *and* having private wells located within cones of depression of reactor wells are required to assess for use conflict during the license renewal term.
Groundwater-use conflicts (water pumped for dewatering)	2	SMALL COST. Has not been found to be a problem at most operating plants and is not expected to be a problem during the license renewal term. Plants pumping 100 or more gpm *and* having private wells located within cones of depression of plant wells are required to assess for use conflict during the license renewal term.
Groundwater-use conflicts (surface water used as makeup water—potentially affecting aquifer recharge).	1	SMALL COST. Water use conflicts are small and will be resolved as necessary through surface water regulatory mechanism outside of NRC license renewal process and is not expected to be a problem for any plant during the license renewal term.
Groundwater-use conflicts (Ranney wells)	2	SMALL COST. Ranney wells can result in potential groundwater depression beyond site boundary. Impacts of large groundwater withdrawal for cooling tower makeup at nuclear power plants using Ranney wells must be evaluated at the time of application for license renewal.
Groundwater-quality degradation (Ranney wells)	1	SMALL COST. Groundwater quality at river sites may be degraded by induced infiltration of poor-quality river water into an aquifer that supplies large quantities of reactor cooling water. However, the lower quality infiltrating water would not preclude the current uses of groundwater and is not expected to be a problem during the license renewal term.
Groundwater-quality degradation (saltwater intrusion)	1	SMALL COST. Nuclear power plants do not contribute significantly to saltwater intrusion.
Groundwater-quality degradation (cooling ponds)	2	SMALL COST. Sites with closed-cycle cooling ponds may degrade groundwater quality. This is not an issue for those plants located in salt marshes. However, for those plants located inland, the quality of the groundwater in the vicinity of the ponds must be shown to be adequate to allow continuation of current uses.
Terrestrial Resources		
Refurbishment impacts	2	SMALL COST. Insignificant impact if no loss of important plant and animal habitat occurs. If important plant and animal habitats are affected the potential impact will be assessed at the time of license renewal.
Cooling tower impacts on crops	1	SMALL COST. Salt drift, icing, fogging, or increased humidity associated with cooling tower operation have not been found to be a problem at operating nuclear power plants and is not expected to be a problem during the license renewal term.
Cooling tower impacts on native plants	1	SMALL COST. Salt drift, icing, fogging, or increased humidity associated with cooling tower operation have not been found to be a problem at operating nuclear power plants and is not expected to be a problem during the license renewal term.
Birds colliding with cooling towers	1	SMALL COST. Has not been found to be a problem at operating nuclear power plants and is not expected to be a problem during the license renewal term.
Cooling pond impacts on terrestrial resources	1	SMALL COST. No significant damage to vegetation has been observed as a result of fogging, icing, or increased relative humidity at nuclear reactor cooling ponds. The low levels of water contaminants in cooling ponds are not a threat to wildlife using the ponds. No significant impact is expected at any nuclear power plant during the license renewal term.
Power line right of way management (cutting and herbicide application).	1	SMALL COST. Periodic vegetation control causes cyclic changes in the density of wildlife populations dependent on the right-of-way, but long-term densities appear relatively stable. Numerous studies show neither significant positive nor negative effects of power line right-of-way on wildlife. No significant impact is expected at any nuclear power plant during the license renewal term.
Birds colliding with power lines	1	SMALL COST. Has not been found to be a problem at operating nuclear power plant and is not expected to be a problem during the license renewal term.

TABLE B-1. SUMMARY OF FINDINGS ON NEPA ISSUES FOR LICENSE RENEWAL OF NUCLEAR POWER PLANTS—Continued

Issue	Category[1]	Findings[2]
Impacts of electromagnetic fields (EMFs) on flora and fauna (plants, agricultural crops, honeybees, wildlife, livestock).	1	SMALL COST. No significant impacts of electromagnetic fields on terrestrial flora and fauna have been identified as is not expected to be a problem during the license renewal term.
Floodplains and wetland on power line right of way	1	SMALL COST. Periodic vegetation control is necessary in forested wetlands underneath power lines and can be achieved with minimal damage to the wetland. On rare occasions when heavy equipment may need to enter a wetland to repair a power line, impacts can be minimized through the use of standard practices. No significant impact is expected at any nuclear power plant during the license renewal term.
	Threatened or Endangered Species (for all plants)	
Threatened or endangered species	3	Generally, reactor refurbishment and continued operation is not expected to adversely affected threatened or endangered species. However, consultation with appropriate agencies must occur to determine if, in fact, threatened or endangered species are present and if they will be adversely affected.
	Air Quality	
Air quality	1	SMALL COST. Air quality impacts from reactor refurbishment associated with license renewal are expected to be small.
	Land Use	
Cnsite land use	1	SMALL COST. Projected on-site land use changes required during refurbishment and the renewal period would be a small fraction of any nuclear power plant site.
	Human Health, Impacts of Refurbishment	
Radiation exposures to the public	1	SMALL COST. During refurbishment, the gaseous effluents would result in doses well below the natural background dose. Applicable regulatory dose limits to the public are not expected to be exceeded.
Occupational radiation exposures	1	SMALL COST. Average occupational doses from refurbishment are expected to be within the range of annual average doses experienced for pressurized-water reactors and boiling-water reactors. Upper-limit cancer and genetic risks from radiation exposure from the incremental doses from refurbishment are expected to be less than 1% of the natural cancer and genetic risks.
	Human Health, Impacts of Operation During License Renewal	
Microbiological organisms (occupational health)	1	SMALL COST. Occupational health questions are expected to be resolved using industrial hygiene principles to minimize worker exposures.
Microbiological organisms (public health)	2	SMALL COST. Has not been found to be a problem at most operating plants and is not expected to be a problem during the license renewal term. At the time of license renewal of plants using cooling ponds, lakes, or canals and plants discharging to small rivers applicants will assess the impact of thermophilic organisms on the health of recreational users of affected water.
Noise	1	SMALL COST. Has not been found to be a problem at operating plants and is not expected to be a problem at any reactor during the license renewal term.
Electromagnetic fields, acute effects (electric shock)	2	SMALL COST. Has not been found to be problem at most operating plants and is not expected to be a problem during the license renewal term. If it cannot be found at the time of license renewal that the transmission lines of the plant meets the National Electric Safety Code recommendations regarding the prevention of shock from induced currents then an assessment of the potential electric shock hazard from the transmission lines of the plant must be provided.
Electromagnetic fields, chronic effects	1	SMALL COST. Biological and physical studies of 60-Hz electromagnetic fields have not found consistent evidence linking harmful effects with field exposures.
Radiation exposures to public	1	SMALL COST. Present radiation doses to the public are very small with respect to natural background radiation; and doses from refurbishment are expected to be similar in magnitudes.
Occupational radiation exposures	1	SMALL COST. Projected maximum occupational doses during the license renewal term are within the range of doses experienced and are considerably below the 5 rem exposure limit.
	Socioeconomics	
Housing impacts of refurbishment	2	SMALL COST. Not expected to be a problem at any plant located in a medium or high population area and not in an area where growth control measures that limit housing development are in effect. Housing impacts of the workforce associated with refurbishment will be assessed at the time of license renewal for plants located in sparsely populated areas or in areas with growth control measures that limit housing development.
Housing impacts of license renewal term	2	SMALL COST. Not expected to be a problem at any plant located in a medium or high population area and not in an area where growth control measures that limit housing development are in effect. Housing impacts of the workforce associated with refueling/maintenance outages will be assessed at the time of license renewal for plants located in sparsely populated areas or in areas with growth control measures that limit housing development.
Public service impacts of refurbishment	1	SMALL COST. Refurbishment induced population growth will be small and will not strain local infrastructure at any plant.

TABLE B-1. SUMMARY OF FINDINGS ON NEPA ISSUES FOR LICENSE RENEWAL OF NUCLEAR POWER PLANTS—Continued

Issue	Category[1]	Findings[2]
Transportation impacts of refurbishment	3	Impacts are generally expected to be small, however, they must be assessed for each plant to consider the increase in traffic associated with the additional workers and the local road and traffic control conditions.
Public service (including transportation) impacts during license renewal term.	1	SMALL COST. No significant impacts are expected during the license renewal term.
Offsite land-use impacts of refurbishment	1	SMALL COST. Impacts will not be significant at any plant because plant-induced population growth will have little effect on land use patterns.
Offsite land-use impacts of license renewal term	1	SMALL COST. Changes in land use would be associated with population and tax revenue changes resulting from license renewal of a plant. These changes are expected to be small for all plants.
Historic resources impacts of refurbishment	1	SMALL COST. No significant impacts are expected during refurbishment.
Historic resources impacts of license renewal term (transmission lines).	1	SMALL COST. No significant impacts are expected during the license renewal term.
Historic resources impacts of license renewal term (normal operations).	1	SMALL COST. No significant impacts are expected during the license renewal term.
Aesthetic impacts of refurbishment	1	SMALL COST. No significant impacts are expected during refurbishment.
Aesthetic impacts of license renewal term	1	SMALL COST. Impacts will be small to moderate depending on the visual intrusiveness of the plant on historic and aesthetic resources in the area.
Aesthetic impacts of license renewal term (transmission lines).	1	SMALL COST. No significant impacts are expected during the license renewal term.
Uranium Fuel Cycle		
Radiological and nonradiological impacts	1	SMALL COST. Impacts on the U.S. population from radioactive gaseous and liquid releases including radon-222 and technetium-99 is small compared with the impacts of natural background radiation. Nonradiological impacts on the environment are small.
Environmental Impacts of Postulated Accidents		
Design-basis accidents	1	SMALL COST. Regulations require that consequences from design basis events remain acceptable for every plant.
Severe accidents (atmospheric releases)	1	SMALL COST. Risks from atmospheric releases is small.
Severe accidents (fallout onto open bodies of water)	1	SMALL COST. Risk from both the drinking water pathway and the aquatic food pathway are small and interdiction can further reduce both sufficiently for all plants.
Severe accidents (releases from groundwater)	1	SMALL COST. Interdiction and the low probability of base mat penetration yield a low risk to the public for all plants.
Severe accidents (economic consequences)	1	SMALL COST. Predicted costs due to postulated accidents range from $2,000/reactor-year to $374,000/reactor-year.
Severe accident mitigation design alternatives	1	SMALL COST. Low risk to the environment from severe accidents.
Solid Waste Management		
Nonradiological waste	1	SMALL COST. No changes to generating systems are anticipated for license renewal. Existing regulations will ensure proper handling and disposal at all plants.
Low-level radioactive waste storage	2	SMALL COST. Impacts will be small for plants having access to offsite disposal space. For those plants denied the use of off-site disposal space due to delayed compact plans, the potential for ecological habitat disturbance due to construction of on-site storage facilities must be evaluated.
Low-level radioactive waste disposal	2	SMALL COST. Off-site disposal facilities are planning to handle refurbishment and normal operations waste streams for an additional 20 years. If implementation of plans is delayed, plants in affected compact regions or unaffiliated states must plan for extended interim storage for an indefinite period of time and evaluate the impacts of such storage.
Mixed waste	1	SMALL COST. License renewal will not increase the small, continuing risk to human health and the environment posed by mixed waste at all plants.
Spent fuel	1	SMALL COST. A 50% greater volume of spent fuel from an additional 20 years of operation can be safely accommodated on-site with small environmental effects through dry or pool storage at all plants if a permanent repository or monitored retrievable storage facility is not available.
Transportation	1	SMALL COST. Rail and truck transport corridors can safely accommodate increased shipments of radioactive wastes associated with license renewal. Shipments would result in impacts within the scope of the Table S.4 rule and therefore would result in acceptable impact
Decommissioning		
Radiation doses	1	SMALL COST. Doses to the public are small regardless of which decommissioning method is used. Occupational doses would increase no more than 1 man-rem due to buildup of long-lived radionuclides during the license renewal term.
Waste management	1	SMALL COST. Decommissioning at the end of a 20-year license renewal period would generate no more solid wastes than at the end of the current license term. No increase in the quantities of Class C or greater than Class C wastes would be expected.
Air quality	1	SMALL COST. Air quality impacts of decommissioning are expected to be negligible whether at the end of the current operating term or at the end of the license renewal term.
Water quality	1	SMALL COST. The potential for significant water quality impacts from erosion or spills is no greater if decommissioning occurs after a 20-year license renewal period or after the original 40-year operation period, and measures are readily available to avoid such impacts.

TABLE B–1. SUMMARY OF FINDINGS ON NEPA ISSUES FOR LICENSE RENEWAL OF NUCLEAR POWER PLANTS—Continued

Issue	Category[1]	Findings[2]
Ecological resources	1	SMALL COST. Decommissioning after either the initial operating period or after a 20 year license renewal period is not expected to have any direct ecological impacts.
Socioeconomic impacts	1	SMALL COST. Decommissioning would have some short-term socioeconomic impacts. The impacts would not be increased by delaying decommissioning until the end of a 20-year relicense period, but they might be decreased by population and economic growth.

[1] The numerical entries in this column are based on the following category definitions: Category 1: A generic conclusion on the impact has been reached for all affected nuclear power plants. Category 2: A generic conclusion on the impact has been reached for affected nuclear power plants that fall within defined bounds. Category 3: A generic conclusions on the impact was not reached for any affected nuclear power plants.

[2] The findings in this column apply to Category 1 issues and Category 2 issues if a plant falls within the bounds of the generic analysis. For Part I of this table, the entry in this column indicates the level of need. For Part II of this table, the entry in this column indicates the relative advantages of alternatives to license renewal. For Part III of this table, the entries in this column are benefits or costs, as indicated by the following headings: *Small* impacts are so minor that they warrant neither detailed investigation or consideration of mitigative actions when such impacts are negative. *Moderate* impacts are likely to be clearly evident and usually warrant consideration of mitigation alternatives when such impacts are negative. *Large* impacts involve either a severe penalty or a major benefit and mitigation alternatives are always considered when such impacts are negative.

[3] The uncertainty associated with the economic cost of license renewal leads to the requirement that an applicant demonstrate for license renewal that no cost advantage exists for replacing the plant's equivalent generating capacity by a new coal-fired power plant. If no such demonstration can be made, and applicant shall justify choosing the license renewal alternative. The justification will include an assessment comparing the cost of license renewal to the cost of reasonable alternative replacement generating capacity. Costs considered must include refurbishment and construction, fuel, and operation, and maintenance.

Dated at Rockville, Maryland, this 10th day of September, 1991.

For the Nuclear Regulatory Commission.

Samuel J. Chilk,

Secretary of the Commission.

BILLING CODE 7590–01–M

FEDERAL DEPOSIT INSURANCE CORPORATION

12 CFR Part 323

RIN 3064–AB05

Appraisals

AGENCY: Federal Deposit Insurance Corporation (FDIC).

ACTION: Notice of proposed rulemaking.

SUMMARY: The FDIC is proposing to amend part 323 to exempt additional transactions from the requirements of the final appraisal rule published on August 20, 1990 (55 FR 33879). If adopted, the proposed amendment would: (1) Eliminate the requirement for regulated institutions to obtain appraisals by certified or licensed appraisers for real estate-related financial transactions having a value, as defined in the rule, of $100,000 or less; (2) permit regulated institutions to use appraisals prepared for loans insured or guaranteed by an agency of the federal government if the appraisal conforms to the requirements of the federal insurer or guarantor; and (3) add a definition of "real estate" and "real property" to clarify that the appraisal regulation does not apply to mineral rights, timber rights, or growing crops.

The FDIC is proposing these amendments to address concerns raised by state nonmember insured banks concerning the cost of complying with the appraisal requirement for certain loans which have not resulted in substantial losses to such banks. If adopted, this proposal would decrease the number of real estate-related financial transactions requiring an appraisal prepared by a certified or licensed appraiser in accordance with the FDIC's final appraisal rule, thereby reducing costs associated with those transactions.

FDIC is soliciting comments regarding all aspects of the proposed rule and is requesting that comments include specific information regarding real estate related loans held by banks where the transaction value is: $50,000 or below; $50,001 to $100,000; and above $100,000. All comments received by the FDIC will be reviewed and given appropriate consideration.

DATES: Comments must be received by November 18, 1991.

ADDRESSES: Comments should be directed to: Hoyle L. Robinson, Executive Secretary, FDIC, 550 17th Street, NW., Washington, DC 20429. Comments may be hand delivered to room F–400 on business days between 8:30 a.m. and 5 p.m. Comments may also be inspected at the same location and times. (FAX number: (202) 898–3838.)

FOR FURTHER INFORMATION CONTACT: (For information on supervisory issues) James D. Leitner, Examination Specialist, Division of Supervision, (202) 898–6790, or Robert F. Miailovich, Assistant Director, DOS, (202) 898–6918; (for information on legal issues) Walter P. Doyle, Counsel, Legal Division, (202) 898–3682; (for information on liquidation issues) N. Jack Taylor, Senior Liquidation Specialist, Division of Liquidation, (202) 898–7326; FDIC, 550 17th Street, NW., Washington, DC 20429.

SUPPLEMENTARY INFORMATION:

Discussion

Background

Title XI of the Financial Institutions Reform, Recovery, and Enforcement Act of 1989 ("FIRREA") directed the FDIC, and the other financial institutions regulatory agencies,[1] to publish appraisal rules for federally related transactions within the jurisdiction of each agency. In accordance with statutory requirements, FDIC's final rule sets minimum standards for appraisals used in connection with federally related transactions and identified those federally related transactions that require a state certified appraiser and those that require either a state certified or licensed appraiser. The final rule was published August 20, 1990 (55 FR 33879).

When Services of Appraiser Required

Section 1121 of FIRREA, 12 U.S.C. 3350, defines a "federally related transaction" as a real estate-related financial transaction which, *inter alia*, requires the service of an appraiser. In the notice of proposed rulemaking published February 22, 1990 (55 FR 6266), the FDIC stated its intention not to require the services of a certified or licensed appraiser for transactions below a $15,000 threshold and asked for specific comment on "the amount and appropriateness of the *de minimis* "level" below which the services of an appraiser would not be required.

The FDIC received over 200 comments on the threshold provision, the overwhelming majority of which suggested raising the threshold. Suggested values ranged from $20,000 to $250,000, with the greatest number of commenters recommending that the threshold be raised to $100,000. However, because title XI of FIRREA expressed a preference for uniform

2. DESCRIPTION OF NUCLEAR POWER PLANTS AND SITES, PLANT INTERACTION WITH THE ENVIRONMENT, AND ENVIRONMENTAL IMPACT INITIATORS ASSOCIATED WITH LICENSE RENEWAL

2.1 INTRODUCTION

Currently, 118[1] commercial nuclear power plants are located at 74 sites in 33 of the contiguous United States. Of these, 57 sites are located east of the Mississippi River, with most of this nuclear capacity located in the Northeast (New England states, New York, and Pennsylvania); the Midwest (Illinois, Michigan, and Wisconsin); and the Southeast (the Carolinas, Georgia, Florida, and Alabama). No commercial nuclear power plants are located in Alaska or Hawaii. Approximately half of these 74 sites contain two or three nuclear units per site. Three of the 118 plants have been shut down and will be decommissioned. The plant characteristics and environmental settings for these nuclear power plant sites are provided in Appendix A. Table 2.1 provides a summary overview of the plants considered in preparing this Generic Environmental Impact Statement (GEIS).

The total capacity of generating U.S. commercial nuclear power plants is approximately 99 GW(e), with plant generating capacities ranging from 67 MW(e) to 1270 MW(e). In 1992, the U.S. electric utility industry generated about 2.8×10^{12} kWh, 21.6 percent of which was supplied by nuclear power. The range of annual electricity production for these plants is approximately 390×10^6 kWh/year to 6900×10^6 kWh/year using an assumed annual capacity factor of 62 percent. It is anticipated that the electric utility industry will seek to operate many of these nuclear power plants beyond the current operating license term of 40 years. This GEIS examines how these plants and their interactions with the environment would change if such plants were allowed to operate (under the proposed license renewal regulation 10 CFR Part 54) for a maximum of 20 years past the term of the original plant license of 40 years.

The purpose of this section is to provide an orientation from the perspective of environmental considerations and assessments. Section 2.2 describes commercial nuclear power plants and their major features and plant systems. Section 2.3 describes the ways nuclear power plants interact with and affect the environment. The license renewal rule, particularly its requirements that may result in changes to nuclear plant environmental impacts, is discussed in Section 2.4. Section 2.5 reviews the generation of particular environment impacts, or precursors to such impacts, that are typical of current nuclear plant operation. It discusses the "baseline" values to be used in comparing incremental effects resulting from license renewal. Section 2.6 describes major refurbishment activities and changes that could occur at nuclear power plants during license renewal refurbishment and the extended years of operation. This section provides the background for more thorough evaluations and environmental impact assessments discussed in Sections 3 through 10.

2.2 PLANT AND SITE DESCRIPTION AND PLANT OPERATION

2.2.1 External Appearance and Setting

Nuclear power plants generally contain four main buildings or structures:

- Containment or reactor building. A massive containment structure that houses the reactor vessel, the suppression pool [boiling-water reactors (BWRs) only], steam generators, pressurizer [pressurized-water reactors (PWRs) only], pumps, and associated piping. The building is generally designed to withstand such disasters as hurricanes, earthquakes, and aircraft collisions. The containment's ability to withstand such disasters, as well as the effects of accidents initiated by system failures, is the principal deterrent to release of radioactive materials to the environment.
- Turbine building. Plant structures that house the steam turbine and generator, condenser, waste heat rejection system, pumps, and equipment that supports those systems.
- Auxiliary buildings. Buildings that house such support systems as the ventilation system, the emergency core cooling system, the water treatment system, and the waste treatment system, along with fuel storage facilities and the plant control room.
- Cooling towers. Structures designed to remove excess heat from the condenser without dumping such heat directly into water bodies.

A plant site also contains a large switchyard, where the electric voltage is stepped up and fed into the regional power distribution system, and may also include various administrative and security buildings. During the operating life of a plant, its basic appearance remains unchanged.

Typically, nuclear power plant sites and the surrounding area are flat-to-rolling countryside in wooded or agricultural areas. More than 50 percent of the sites have 80-km (50-mile) population densities of less than 200 persons per square mile, and over 80 percent have 80-km (50-mile) densities of less than 500 persons per square mile. The most notable exception is the Indian Point Station, located within 80 km (50 miles) of New York City, which has a projected 1990 population density within 80 km (50 miles) of almost 2000 persons per square mile.

Site areas range from 34 ha (84 acres) for the San Onofre Nuclear Generating Station in California to 12,000 ha (30,000 acres) for the McGuire Nuclear Station in North Carolina. As shown in Table 2.1, 28 site areas range from 200 to 400 ha (500 to 1000 acres), and an additional 12 sites are in the 400- to 800-ha (1000- to 2000-acre) range. Thus, almost 60 percent of the plant sites encompass 200 to 800 ha (500 to 2000 acres). Larger land-use areas are associated with plant cooling systems that include reservoirs, artificial lakes, and buffer areas.

2.2.2 Reactor Systems

U.S. reactors employed for domestic electric power generation are conventional (thermal) light-water reactors (LWRs), using water as moderator and coolant. The two types of LWRs are PWRs (Figure 2.1) and BWRs (Figure 2.2). Of the 118 power reactors in the United States, 80 are PWRs and 38 are BWRs.

[c]OT = once through; NDCT = natural draft cooling tower; MDCT = mechanical draft cooling tower; CCCP = closed cycle cooling pond, lake, or reservoir.

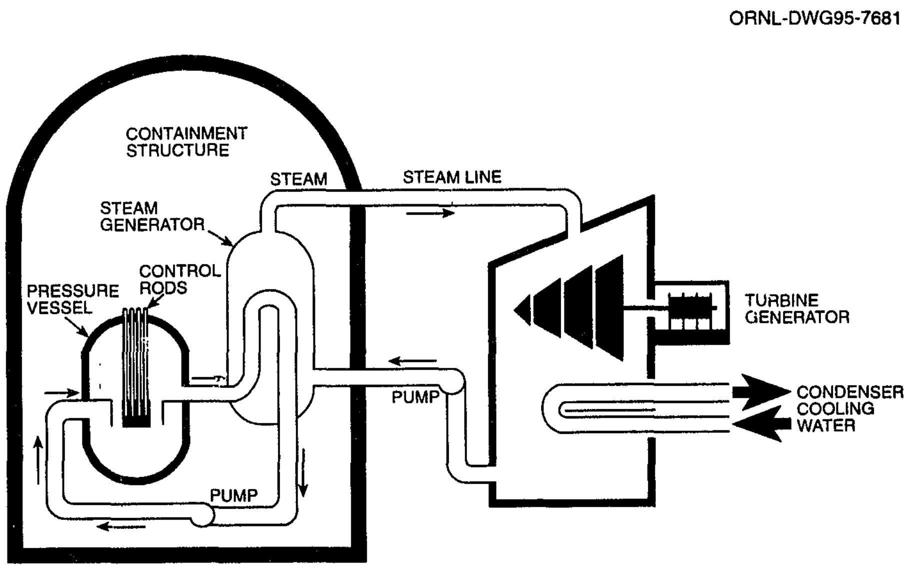

Figure 2.1 Pressurized-water-reactor power generation system.

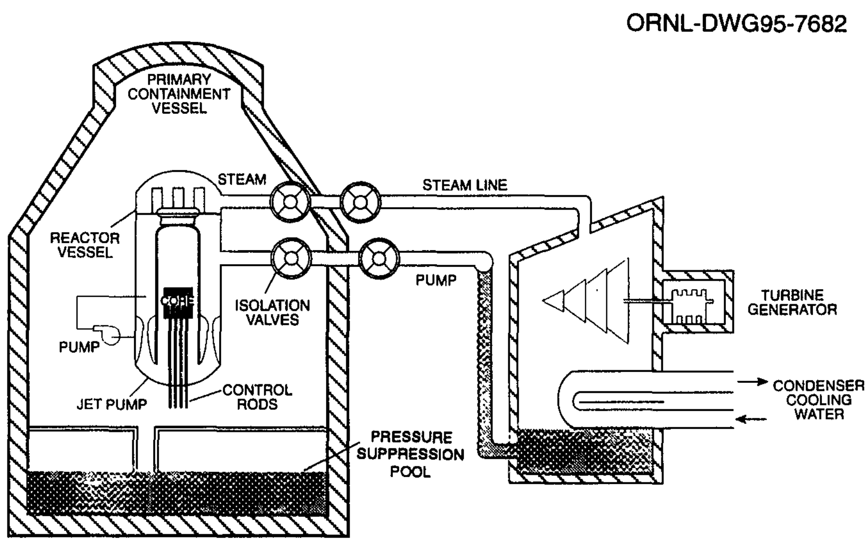

Figure 2.2 Boiling-water-reactor generating system.

In the PWR, reactor heat is transferred from the primary coolant to a secondary coolant loop that is at a lower pressure, allowing steam to be generated in the steam generator. The steam then flows to a turbine for power production. In contrast, the BWR generates steam directly within the reactor core, which passes through moisture separators and steam dryers and then flows to the turbine.

All domestic power reactors employ a containment structure as a major safety feature to prevent the release of radionuclides in the event of an accident. PWRs employ three types of containments: (1) large, dry containments; (2) subatmospheric containments; and (3) ice condenser containments. Of the 80 U.S. PWRs, 65 have large, dry containments; 7 have subatmospheric containments; and 8 have ice condenser containments. BWR containments typically are composed of a suppression pool and dry well. Three types of BWR containments (Mark I, Mark II, and Mark III) have evolved. There are 24 Mark I, 10 Mark II, and 4 Mark III containment designs in the United States.

NUREG/CR-5640 provides a comprehensive overview and description of U.S. commercial nuclear power plant systems.

2.2.3 Cooling and Auxiliary Water Systems

The predominant water use at a nuclear power plant is for removing excess heat generated in the reactor by condenser cooling. The quantity of water used for condenser cooling is a function of several factors, including the capacity rating of the plant and the increase in cooling water temperature from the intake to the discharge. The larger the plant, the greater the quantity of waste heat to be dissipated, and the greater the quantity of cooling water required.

In addition to removing heat from the reactor, cooling water is also provided to the service water system and to the auxiliary cooling water system. The volume of water required for these systems for once-through cooling is usually less than 15 percent of the volume required for condenser cooling. In closed-cycle cooling, the additional water needed is usually less than 5 percent of that needed for condenser cooling.

Of the 118 nuclear reactors, 48 use closed-cycle cooling systems (see Table 2.2, which groups the 74 plant sites into three broad categories according to environment). Most closed-cycle systems use cooling towers. Some closed-cycle system units use a cooling lake or canals for transferring heat to the atmosphere. Once-through cooling systems are used at 70 units. A few of these systems are augmented with helper cooling towers to reduce the temperature of the effluent released to the adjacent body of water.

In closed-cycle systems, the cooling water is recirculated through the condenser after the waste heat is removed by dissipation to the atmosphere, usually by circulating the water through large cooling towers constructed for that purpose. Several types of closed-cycle cooling systems are currently used by the nuclear power industry. Recirculating cooling systems consist of either natural draft or mechanical draft cooling towers, cooling ponds, cooling lakes, or cooling canals. Because the predominant cooling mechanism associated with closed-cycle systems is evaporation, most of the water

[a]Of the 48 plants with closed-cycle cooling systems, 15 use mechanical draft cooling towers, 25 use natural draft cooling towers, 4 use a canal system, and 4 use a cooling lake. Of the 70 plants with once-through cooling systems, 24 discharge to a river, 11 discharge to the Great Lakes, 19 discharge to the ocean or an estuary, and 16 discharge to a reservoir or lake. Five of the once-through plants can also switch to cooling towers.

used for cooling is consumed and is not returned to a water source.

In a once-through cooling system, circulating water for condenser cooling is drawn from an adjacent body of water, such as a lake or river, passed through the condenser tubes, and returned at a higher temperature to the adjacent body of water. The waste heat is dissipated to the atmosphere mainly by evaporation from the water body and, to a much smaller extent, by conduction, convection, and thermal radiation loss.

All sites with two or three reactors use the same cooling system for all reactors, except for two sites: Arkansas Nuclear One in Arkansas and Nine Mile Point in New York. These two sites use once-through cooling for one unit and closed-cycle for the other.

For both once-through and closed-cycle cooling systems, the water intake and discharge structures are of various configurations to accommodate the source water body and to minimize impact to the aquatic ecosystem. The intake structures are generally located along the shoreline of the body of water and are equipped with fish protection devices (ORNL/TM-6472). The discharge structures are generally of the jet or diffuser outfall type and are designed to promote rapid mixing of the effluent stream with the receiving body of water. Biocides and other chemicals used for corrosion control and for other water treatment purposes are mixed with the condenser cooling water and discharged from the system.

In addition to surface water sources, some nuclear power plants use groundwater as a source for service water, makeup water, or potable water. Other plants operate dewatering systems to intentionally lower the groundwater table, either by pumping or by using a system of drains, in the vicinity of building foundations.

2.2.4 Radioactive Waste Treatment Systems

During the fission process, a large inventory of radioactive fission products builds up within the fuel. Virtually all of the fission products are contained within the fuel pellets. The fuel pellets are enclosed in hollow metal rods (cladding), which are hermetically sealed to further prevent the release of fission products. However, a small fraction of the fission products escapes the fuel rods and contaminates the reactor coolant. The primary system coolant also has radioactive contaminants as a result of neutron activation. The radioactivity in the reactor coolant is the source of gaseous, liquid, and solid radioactive wastes at LWRs.

The following sections describe the basic design and operation of PWR and BWR radioactive-waste-treatment systems.

2.2.4.1 Gaseous Radioactive Waste

For BWRs, the sources of routine radioactive gaseous emissions to the atmosphere are the air ejector, which removes noncondensable gases from the coolant to improve power conversion efficiency, and gaseous and vapor leakages, which, after monitoring and filtering, are discharged to the atmosphere via the building ventilation systems.

The off-gas treatment system collects noncondensable gases and vapors that are exhausted at the condenser via the air ejectors. These off-gases are processed through a series of delay systems and filters to remove airborne radioactive particulates and halogens, thereby minimizing the quantities of the radionuclides that might be released. Building ventilation system exhausts are another source of gaseous radioactive wastes for BWRs.

PWRs have three primary sources of gaseous radioactive emissions:

- discharges from the gaseous waste management system;
- discharges associated with the exhaust of noncondensable gases at the main

condenser if a primary-to-secondary system leak exists; and

- radioactive gaseous discharges from the building ventilation exhaust, including the reactor building, reactor auxiliary building, and fuel-handling building.

The gaseous waste management system collects fission products, mainly noble gases, that accumulate in the primary coolant. A small portion of the primary coolant flow is continually diverted to the primary coolant purification, volume, and chemical control system to remove contaminants and adjust the coolant chemistry and volume. During this process, noncondensable gases are stripped and routed to the gaseous waste management system, which consists of a series of gas storage tanks. The storage tanks allow the short-half-life radioactive gases to decay, leaving only relatively small quantities of long-half-life radionuclides to be released to the atmosphere. Some PWRs are using charcoal delay systems rather than gas storage tanks (e.g., Seabrook).

2.2.4.2 Liquid Radioactive Waste

Radionuclide contaminants in the primary coolant are the source of liquid radioactive waste in LWRs. The specific sources of these wastes, the modes of collection and treatment, and the types and quantities of liquid radioactive wastes released to the environment are in many respects similar in BWRs and PWRs. Accordingly, the following discussion applies to both BWRs and PWRs, with distinctions made only where important differences exist.

Liquid wastes resulting from LWR operation may be placed into the following categories: clean wastes, dirty wastes, detergent wastes, turbine building floor-drain water,[1] and steam generator blowdown (PWRs only). *Clean wastes* include all liquid wastes with a normally low conductivity and variable radioactivity content. They consist of reactor grade water, which is amenable to processing for reuse as reactor coolant makeup water. Clean wastes are collected from equipment leaks and drains, certain valve and pump seal leaks not collected in the reactor coolant drain tank, and other aerated leakage sources. These wastes also include primary coolant. *Dirty wastes* include all liquid wastes with a moderate conductivity and variable radioactivity content that, after processing, may be used as reactor coolant makeup water. Dirty wastes consist of liquid wastes collected in the containment building sump, auxiliary building sumps and drains, laboratory drains, sample station drains, and other miscellaneous floor drains. *Detergent wastes* consist principally of laundry wastes and personnel and equipment decontamination wastes and normally have a low radioactivity content. *Turbine building floor-drain wastes* usually have high conductivity and low radionuclide content. In PWRs, *steam generator blowdown* can have relatively high concentrations of radionuclides depending on the amount of primary-to-secondary leakage. Following processing, the water may be reused or discharged.

Each of these sources of liquid wastes receives varying degrees and types of treatment before storage for reuse or discharge to the environment under the site National Pollutant Discharge Elimination System (NPDES) permit. The extent and types of treatment depend on the chemical and radionuclide content of the waste; to increase the efficiency of waste processing, wastes of similar characteristics are batched before treatment.

The degree of processing, storing, and recycling of liquid radioactive waste has steadily increased among operating plants. For example, extensive recycling of steam generator blowdown in PWRs is now the typical mode of operation, and secondary side wastewater is routinely treated. In addition, the plant systems used to process wastes are often augmented with the use of commercial mobile processing systems. As a result, radionuclide releases in liquid effluent from LWRs have generally declined or remained the same.

2.2.4.3 Solid Radioactive Waste

Solid low-level radioactive waste (LLW) from nuclear power plants is generated by removal of radionuclides from liquid waste streams, filtration of airborne gaseous emissions, and removal of contaminated material from various reactor areas. Liquid contaminated with radionuclides comes from primary and secondary coolant systems, spent-fuel pools, decontaminated wastewater, and laboratory operations. Concentrated liquids, filter sludges, waste oils, and other liquid sources are segregated by type, flushed to storage tanks, stabilized for packaging in a solid form by dewatering, slurried into 55-gal steel drums, and stored on-site in shielded Butler-style buildings or other facilities until suitable for off-site disposal (NUREG/CR-2907). These buildings usually contain volume reduction facilities to reduce the volume of LLW requiring off-site disposal (EPRI NP-5526-V1).

High-efficiency particulate filters are used to remove radioactive material from gaseous plant effluents. These filters are compacted in volume reduction facilities that have volume reduction equipment and are disposed of as solid wastes.

Solid LLW consists of contaminated protective clothing, paper, rags, glassware, compactible and noncompactible trash, and non-fuel-irradiated reactor components and equipment. Most of this waste comes from plant modifications and routine maintenance activities. Additional sources include tools and other material exposed to the reactor environment (EPRI-NP-5526-V1; EPRI NP-5526-V2). Before disposal, compactible trash is usually taken to on- or off-site VR facilities. Compacted dry active waste is the largest single form of LLW disposed from nuclear plants, comprising one-half and one-third of total average annual volumes from PWRs and BWRs, respectively (EPRI NP-5526V1).

Volume reduction efforts have been undertaken in response to increased disposal costs and the passage of the 1980 Low Level Radioactive Waste Policy Act and the 1985 Low Level Radioactive Waste Policy Amendments Act (LLRWPAA) (Pub. L. 96-573; Pub. L. 99-240), which require LLW disposal allocation systems for nuclear plants (see Section 6.3). Volume reduction is performed both on- and off-site. The most common on-site volume reduction techniques are high-pressure compacting of waste drums, dewatering and evaporating wet wastes, monitoring waste streams to segregate wastes, minimizing the exposure of routine equipment to contamination, and decontaminating and sorting radioactive or nonradioactive batches before off-site shipment. Off-site waste management vendors compact compactible wastes at ultra-high pressure (supercompaction); incinerate dry active waste; separate and incinerate oily, organic wastes; solidify the ash; and occasionally undertake waste crystallization and asphalt solidification of resins and sludges

(EPRI NP-6163; EPRI NP-5526-V1; EPRI NP-5526-V2; DOE/RW-0220).

Spent fuel contains fission products and actinides produced when nuclear fuel is irradiated in reactors, as well as any unburned, unfissioned nuclear fuel remaining after the fuel rods have been removed from the reactor core. After spent fuel is removed from reactors, it is stored in racks placed in storage pools to isolate it from the environment. Delays in siting an interim monitored retrievable storage (MRS) facility or permanent repository, coupled with rapidly filling spent-fuel pools, have led utilities to seek other storage solutions, including expansion of existing pools, aboveground dry storage, longer fuel burnup, and shipment of spent fuel to other plants (Gerstberger 1987; DOE RW-0220).

Pool storage has been increased through (1) enlarging the capacity of spent-fuel racks, (2) adding racks to existing pool arrays ("dense-racking"), (3) reconfiguring spent fuel with neutron-absorbing racks, and (4) employing double-tiered storage (installing a second tier of racks above those on the pool floor).

Efforts are under way to develop dry storage technologies; these include casks, silos, dry wells, and vaults (DOE December 1989). Dry storage facilities are simpler and more readily maintained than fuel pools. They are growing in favor because they offer a more stable means of storage and require relatively little land area (less than 0.2 ha—half an acre in most cases) (Johnson 1989). Dry storage is currently in use at about 5 percent of the sites.

2.2.4.4 Transportation of Radioactive Materials

There are four types of radioactive material shipments to and from nuclear plants: (1) routine and refurbishment-generated LLW transported from plants to disposal facilities, (2) routine LLW shipped to off-site facilities for volume reduction, (3) nuclear fuel shipments from fuel fabrication facilities to plants for loading into reactors (generally occurring on a 12- to 18-month cycle), and (4) spent-fuel shipments to other nuclear power plants with available storage space (an infrequent occurrence usually limited to plants owned by the same utility).

Workers and others are protected from exposure during radioactive material transport by the waste packaging. Operational restrictions on transport vehicles, ambient radiation monitoring, imposition of licensing standards (which ensure proper waste certification by testing and analysis of packages), waste solidification, and training of emergency personnel to respond to mishaps are also used (NUREG-0170; O'Sullivan 1988). Additional regulations may be imposed by states and communities along transportation corridors (Pub. L. 93-633; OTA-SET-304).

A typical PWR makes approximately 44 shipments of LLW per year; an average BWR makes 104 shipments per year (EPRI NP-5983). Most of this LLW is Class A waste packaged in 55-gal drums or other "Type A" containers and shipped to disposal facilities on flatbed trucks (DOE August 1989). (A "Type A" container permits no release of radioactive material under normal transportation conditions and must maintain sufficient shielding to limit radiation exposure to handling personnel).

LLW shipments require manifests that describe the contents of the packages to permit inspection by state, local, and facility personnel and to ensure that the waste is suitable for a particular disposal facility (NUREG-0945).

Currently, the only spent-fuel shipments from nuclear plants are to other plants. A few spent-fuel shipments have, in the past, been made to fuel reprocessing plants. These shipments are packaged in "Type B" casks designed to retain the highly radioactive contents under normal and accident conditions. These containers range in size from 23–36 metric tons (25–40 tons) for truck shipment (each cask is capable of holding seven fuel assemblies) to 109 metric tons (120 tons) for rail transport (with a capacity for 36 assemblies) (DOE/RW-0065). The casks are resistant to both small-arms fire and high-explosive detonation (NUREG-0170).

2.2.5 Nonradioactive Waste Systems

Nonradioactive wastes from nuclear power plants include boiler blowdown (continual or periodic purging of impurities from plant boilers), water treatment wastes (sludges and high saline streams whose residues are disposed of as solid waste and biocides), boiler metal cleaning wastes, floor and yard drains, and stormwater runoff. Principal chemical and biocide waste sources include the following:

- Boric acid used to control reactor power and lithium hydroxide used to control pH in the coolant. (These chemicals could be inadvertently released because of pipe or steam generator leakage.)
- Sulfuric acid, which is added to the circulating water system to control scale.
- Hydrazine, which is used for corrosion control. (It is released in steam generator blowdown.)
- Sodium hydroxide and sulfuric acid, which are used to regenerate resins. (These are discharged after neutralization.)
- Phosphate in cleaning solutions.
- Biocides used for condenser defouling.

Other small volumes of wastewater are released from other plant systems depending on the design of each plant. These are discharged from such sources as the service water and auxiliary cooling systems, water treatment plant, laboratory and sampling wastes, boiler blowdown, floor drains, stormwater runoff, and metal treatment wastes. These waste streams are discharged as separate point sources or are combined with the cooling water discharges.

2.2.6 Nuclear Power Plant Operation and Maintenance

Nuclear power reactors are capable of generating electricity continuously for long periods of time. However, they operate neither at maximum capacity nor continuously for the entire term of their license. Plants can typically operate continuously for periods of time ranging from 1 year to 18 months on a single fuel load. Scheduled and unscheduled maintenance outages and less than peak power generation resulting from diminished consumer demand, or operational decisions, have reduced the power output for the U.S. nuclear power industry as a whole to an average annual capacity of between 58 and 73 percent of the maximum capability for the years 1975 through 1993, inclusive (NUREG-1350, vol. 6).

Maintenance activities are routinely performed on systems and components to help ensure the safe and reliable operation of the plant. In addition, inspection, testing, and surveillance activities are conducted throughout the operational life of a nuclear power plant to maintain the current licensing basis of the plant and ensure compliance with federal, state, and local requirements regarding the environment and public safety.

Nuclear power plants must periodically discontinue the production of electricity for refueling, periodic in-service inspection (ISI), and scheduled maintenance. Refueling cycles occur approximately every 12 to 18 months. The duration of a refueling outage is typically on the order of 2 months. Enhanced or expanded inspection and surveillance activities are typically performed at 5- and 10-year intervals. These enhanced inspections are performed to comply with Nuclear Regulatory Commission (NRC) and/or industry standards or requirements such as the American Society of Mechanical Engineers Boiler and Pressure Vessel Code. Five-year ISIs are scheduled for the 5th, 15th, 25th, and 35th years of operation, and 10-year ISIs are performed in the 10th, 20th, and 30th years. Each of these outages typically requires 2 to 4 months of down time for the plant. For economic reasons, many of these activities are conducted simultaneously (e.g., refueling activities typically coincide with the ISI and maintenance activities).

Many plants also undertake various major refurbishment activities during their operational lives. These activities are performed to ensure both that the plant can be operated safely and that the capacity and reliability of the plant remain at acceptable levels. Typical major refurbishments that have occurred in the past include replacing PWR steam generators, replacing BWR recirculation piping, and rebuilding main steam turbine stages. The need to perform major refurbishments is highly plant-specific and depends on factors such as design features, operational history, and construction and fabrication details. The plants may remain out of service for extended periods of time, ranging from a few months to more than a year, while these major refurbishments are accomplished. Outage durations vary considerably, depending on factors such as the scope of the repairs or modifications undertaken, the effectiveness of the outage planning, and the availability of replacement parts and components.

Each nuclear power plant is part of a utility system that may own several nuclear power plants, fossil-fired plants, or other means of generating electricity. An on-site staff is responsible for the actual operation of each plant, and an off-site staff may be headquartered at the plant site or some other location. Typically, from 800 to 2300 people are employed at nuclear power plant sites during periods of normal operation, depending on the number of operating reactors located at a particular site. The permanent on-site work force is usually in the range of 600 to 800 people per reactor unit. However, during outage periods, the on-site work force typically increases by 200 to 900 additional workers. The additional workers include engineering support staff, technicians, specialty craftspersons, and laborers called in both to perform specialized repairs, maintenance, tests, and inspections and to assist the permanent staff with the more routine activities carried out during plant outages.

2.2.7 Power-Transmission Systems

Power-transmission systems associated with nuclear power plants consist of switching stations (or substations) located on the plant site and transmission lines located primarily off-site. These systems are required to transfer power from the generating station to the utility's network of power lines in its service area.

Switching stations transfer power from generating sources to power lines and regulate the operation of the power system. Transformers in switching stations convert the generated voltage to voltage levels appropriate for the power lines. Equipment for regulating system operation includes switches, power circuit breakers, meters, relays, microwave communication equipment, capacitors, and a variety of other electrical equipment. This equipment meters and controls power flow; improves performance characteristics of the generated power; and protects generating equipment from short circuits, lightning strikes, and switching surges that may occur along the power lines. Switching stations occupy on-site areas generally two to four times as large as areas occupied by reactor and generator buildings, but are not as visible as the plant buildings.

The length of power transmission lines constructed for nuclear plants varies from a few miles for some plants to hundreds of miles for others. Power line systems include towers (structures), insulator strings, conductors, and ground wires strung between towers. Power lines associated with nuclear plants usually have voltages of 230 kV, 345 kV, 500 kV, or 765 kV (see Section 4.5.1). They operate at a low frequency of 60 Hz (60 cycles per second) compared with frequencies of 55–890 MHz for television transmitters and 1000 MHz and greater for microwaves.

Most power line towers are double wooden poles ("H-frame" structure) or metal lattice structures that support one or two sets of conductors (three conductors per set; see Section 4.5.1). Tower height, usually between 21 and 51 m (70 and 170 ft), increases with line voltage. Strings of insulators connect the conductors to the towers. The tops of the towers support two ground wires that transmit the energy of lightning strikes to the ground. Thus, the ground wires prevent lightning strikes to the conductors, minimize the occurrence of power system outages, and protect vital power system components that could be damaged by lightning-caused power surges on the conductors.

2.3 PLANT INTERACTION WITH THE ENVIRONMENT

This section describes how nuclear plants interact with the environment. Nuclear power plants are sited, designed, and operated to minimize impacts to the environment, including plant workers. Land that could be used for other purposes is dedicated to electric power production for the life of the plant. The aesthetics of the landscape are altered because of the new plant structures; the surface and groundwater hydrology and terrestrial and aquatic ecology may be affected; the air quality may be affected; and, finally, the community infrastructure and services are altered to accommodate the influx of workers into the area. The environmental impact from plant operation is determined largely by waste effluent streams (gaseous, liquid, and solid); the plant cooling systems; the exposure of plant workers to radiation; and plant expenditures, taxes, and jobs.

Operational activities associated with nuclear power plants, including maintenance actions, often produce liquid discharges that are released to the surrounding environment. The major liquid effluent occurs in once-through cooling systems which discharge heat and chemicals into a receiving body of water, but all nuclear power plants have liquid effluents to some extent. To operate, power plants must obtain an NPDES permit that specifies discharge standards and monitoring requirements, and they are required to be strictly in compliance with the limits set by the permit. NPDES permits are issued by the Environmental Protection Agency (EPA) or a designated state water quality agency. They must be renewed every 5 years.

Any gaseous effluents generated are similarly controlled by the EPA and state permitting agencies, which require compliance with the Clean Air Act and any amendments added by the states. On-site incineration of waste products is controlled in this manner.

2.3.1 Land Use

Nuclear power plants are large physical entities. Land requirements generally amount to several hundred hectares for the plant site, of which 20 to 40 ha (50 to 100 acres) may actually be disturbed during plant construction. Other land commitments can amount to many thousands of hectares for transmission line rights-of-way (ROWs) and cooling lakes, when such a cooling option is used.

Nuclear power plants that began initial operation after the promulgation of the National Environmental Policy Act of 1969 (Pub. L. 91-190) or the Endangered Species Act of 1973 (Pub. L. 93-205) are sited and operate in compliance with these laws. Any modifications to the plants after the effective dates of these acts must be in compliance with the requirements of these laws. The Endangered Species Act applies to both terrestrial and aquatic biota. The individual states may also have requirements regarding threatened and endangered species; the state-listed species may vary from those on the federal lists.

2.3.2 Water Use

Nuclear power plants withdraw large amounts of mainly surface water to meet a variety of plant needs (Section 2.2.3). Water withdrawal rates are large from adjacent bodies of water for plants with once-through cooling systems. Flow through the condenser for a 1,000-MW(e) plant may be 45 to 65 m^3/s (700,000 to 1,000,000 gal/min). Water lost by evaporation from the heated discharge is about 60 percent of that which is lost through cooling towers. Additional water needs for service water, auxiliary systems, and radioactive waste systems account for 1 to 15 percent of that needed for condenser cooling.

Water withdrawal from adjacent bodies of water for plants with closed-cycle cooling systems is 5 to 10 percent of that for plants with once-through cooling systems, with much of this water being used for makeup of water by evaporation. With once-through cooling systems, evaporative losses are about 40 percent less but occur externally in the adjacent body of water instead of in the closed-cycle system. The average makeup water withdrawals for several recently constructed plants having closed-cycle cooling, normalized to 1,000 MW(e), are about 0.9 to 1.1 m^3/s (14,000 to 18,000 gal/min). Variation results from cooling tower design, concentration factor of recirculated water, climate at the site, plant operating conditions, and other plant-specific factors.

Consumptive loss normalized to 1,000 MW(e) is about 0.7 m^3/s (11,200 gal/min), which is about 80 percent of the water volume taken in. Consumptive water losses remove surface water from other uses downstream. In those areas experiencing water availability problems, nuclear power plant consumption may conflict with other existing or potential closed-cycle uses (e.g., municipal and agricultural water withdrawals) and in-stream uses (e.g., adequate in-stream flows to protect aquatic biota, recreation, and riparian communities). The environmental impacts of consumptive water use are considered in Sections 4.2.1 and 4.2.2.

As discussed in Section 2.2.3, some nuclear power plants use groundwater as an additional source of water. The rate of usage varies greatly among users. Many plants use groundwater only for the potable water system and require less than 0.006 m^3/s (100 gal/min); however, withdrawals at other sites can range from 0.02 to 0.2 m^3/s (400 to 3000 gal/min). Impacts associated with groundwater use are discussed in Sections 4.2.2, 4.3.2, and 4.4.3.

Nuclear plant water usage must comply with state and local regulations. Most states require permits for surface water usage. Groundwater usage regulations vary considerably from state to state, and permits are typically required.

2.3.3 Water Quality

Water quality is impacted by the numerous nonradioactive liquid effluents discharged from nuclear power plants (Section 2.1.6). Discharges from the heat dissipation system account for the largest volumes of water and usually the greatest potential impacts to water quality and aquatic systems, although other systems may contribute heat and toxic chemical contaminants to the effluent. The relatively small volumes of water required for the service water and auxiliary cooling water systems do not generally raise concerns about thermal or chemical impacts to the receiving body of water. However, because effluents from these systems contain contaminants that could be toxic to aquatic biota, their concentrations are regulated under the power plant's NPDES discharge permit. The quality of groundwater may also be diminished by water from cooling ponds seeping into the underlying groundwater table.

Sewage wastes and cleaning solvents, including phosphate cleaning solutions, are treated as sanitary wastes. They are treated before release to the environment so that, after release, their environmental impacts are minimized. In cases where nonradioactive sanitary or other wastes cannot be processed by on-site water treatment systems, the wastes are collected by independent contractors and trucked to off-site treatment facilities. Water quality issues relate to the following: NPDES permit system for regulating low-volume wastewater, adequate wastewater treatment capacity to handle increased flow and loading associated with operational changes to the plant and discharges of wastes through emission of phosphates from utility laundries, suspended solids and coliforms from sewage treatment discharges, and other effluents that cause excessive biological oxygen demand.

Many power plants are periodically treated with biocidal chemicals (most commonly some form of chlorine) to control fouling and bacterial slimes. Discharge of these chemicals to the receiving body of water can have toxic effects on aquatic organisms. The biological and water quality impacts of discharges from the discharge systems are considered in Sections 4.2, 4.3, and 4.4.

Chlorine is used widely as a biocide at nuclear power plants and represents the largest potential source of chemically toxic release to the aquatic environment. Chlorine application as a cooling system biocide is typically by injection in one of several different forms, including chlorine gas or sodium hypochlorite. It may be injected at the intake or targeted at various points (such as the condensers) on an intermittent or continuous basis. Such treatments control certain pest organisms such as the Asiatic clam or the growth of bacterial or fungal slime (TVA 1978). The control of biological pests or growths is critical to maintaining optimum system performance and minimizing operating costs (EPRI CS-3748).

Because of the evolution of the guidelines pertaining to chlorine and changes in biocide technologies over the past 15 years, the potential for any adverse impacts of chlorine has been decreasing. Improvements in dechlorination technologies are likely to significantly reduce the level of chlorine in the aquatic environment. Given the critical need for controlling biofouling in the cooling system, both alternative and chlorine treatment technologies are expected to keep pace with regulatory requirements.

All effluent discharges are regulated under the provisions of the Clean Water Act and the implementing effluent guidelines, limitations, and standards established by EPA and the states. Conditions of discharge for each plant are specified in its NPDES permit issued by the state or EPA.

2.3.4 Air Quality

Transmission lines have been associated with the production of minute amounts of ozone and oxides of nitrogen. These issues are associated with corona, the breakdown of air very near the high-voltage conductors. Corona is most noticeable for the higher-voltage lines and during foul weather. Through the years, line designs have been developed that greatly reduce corona effects.

The effluents created and released from the incineration of any waste products must comply with EPA and state requirements regarding air quality. Permits for release of controlled amounts of these effluents to the atmosphere are controlled by state permitting agencies. Because nuclear power plants generally do not produce gaseous effluents, the impact on air quality is minimal.

2.3.5 Aquatic Resources

Operation of the once-through (condenser cooling) system requires large amounts of water that are withdrawn directly from surface waters. These surface waters contain aquatic organisms that may be injured or killed through their interactions with the power plant. Aquatic organisms that are too large to pass through the intake debris screens, which commonly have a 1-cm (0.4-in.) mesh, and that cannot move away from the intake, may be impinged against the screens. If the organisms are held against the screen for long periods, they will suffocate; if they receive severe abrasions, they may die. Impingement can harm large numbers of fish and large invertebrates (e.g., crabs, shrimp, and jellyfish).

Aquatic organisms that are small enough to pass through the debris screens will travel through the entire condenser cooling system and be exposed to heat, mechanical, and pressure stresses, and possibly biocidal chemicals, before being discharged back to the body of water. This process, called entrainment, may affect a wide variety of small plants (phytoplankton), invertebrates (zooplankton), fish eggs, and larvae (ichthyoplankton). Entrainment mortality is variable. Conditions at some plants with once-through cooling may result in relatively low levels of mortality, although at such plants the volumes of water (and numbers of entrained organisms) are often high. On the other hand, generally no aquatic organisms survive at plants with closed-cycle cooling that recirculate water through cooling towers, although the volumes of water withdrawn are relatively low. Biological effects of entrainment and impingement are considered in Section 4.2.3.

Discharges from the plant heat rejection system may affect the receiving body of water through heat loading and chemical contaminants, most notably chlorine or other biocides. Heated effluents can kill aquatic organisms directly by either heat shock or cold shock. In addition, a number of indirect or sublethal stresses are associated with thermal discharges that have the potential to alter aquatic communities (e.g., increased incidence of disease, predation, or parasitism, as well as changes in dissolved gas concentrations).

As stated in Section 2.3.3, all effluent discharges are regulated by the Clean Water Act and standards established by the EPA and the individual states. Conditions of discharge for each plant are specified in the NPDES permit issued for that plant.

2.3.6 Terrestrial Resources

A number of ongoing issues associated with terrestrial resources can arise in the immediate area around the plant or its power transmission lines. Most power lines are located on easements (or ROWs) that the utility purchased from the landowner. Land uses on the easements are limited to activities compatible with power-line operation. In areas with rapidly growing vegetation, utilities must periodically cut or spray the vegetation to prevent it from growing so close to the conductors that it causes short circuits and endangers power line operation. Other terrestrial resource issues can result from changes in local hydrology. Such changes can occur from altered contouring of the land, reduced tree cover, and increased paving. These changes can reduce the value of land and contribute to local erosion and flooding. Additional impacts can include the effects of cooling tower effluent drift, reduced habitat for plants and animals, disruption of animal transit routes, and bird collisions with cooling towers and transmission lines.

Each plant planning to apply for license renewal will need to consult with the appropriate agency administering the Endangered Species Act of 1973 about the presence of threatened or endangered species. Compliance with the Endangered Species Act will be a necessary part of each plant's environmental documentation at the time of license renewal.

2.3.7 Radiological Impacts

2.3.7.1 Occupational Exposures

Plant workers conducting activities involving radioactively contaminated systems or working in radiation areas can be exposed to radiation. Most of the occupational radiation dose to nuclear plant workers results from external radiation exposure rather than from internal exposure from inhaled or ingested radioactive materials. Experience has shown that the dose to nuclear plant workers varies from reactor to reactor and from year to year. Since the early 1980s, when NRC regulatory requirements and guidance placed increased emphasis on maintaining nuclear power plant occupational radiation exposures as low as reasonably achievable, there has been a decreasing trend in the average annual dose per nuclear plant worker.

The effect of plant refurbishment on occupational doses is evaluated in Sections 3.8.2 and in Appendix B. Similarly, the effect of continued operation associated with license renewal on occupational doses is evaluated in Section 4.6.3.

2.3.7.2 Public Radiation Exposures

Commercial nuclear power reactors, under controlled conditions, release small amounts of radioactive materials to the environment during normal operation. These releases result in radiation doses to humans that are small relative to doses from natural radioactivity. Nuclear power plant licensees must comply with NRC regulations (e.g., 10 CFR Part 20, Appendix I to 10 CFR Part 50, 10 CFR Part 50.36a, and 40 CFR Part 190) and conditions specified in the operating license.

Potential environmental pathways through which persons may be exposed to radiation originating in a nuclear power reactor include atmospheric and aquatic pathways. Radioactive materials released under controlled conditions include fission products and activation products. Fission product releases consist primarily of the noble gases and some of the more volatile materials like tritium, isotopes of iodine, and cesium. These materials are monitored carefully before release to determine whether the limits on releases can be met. Releases to the aquatic pathways are similarly monitored. Radioactive materials in the liquid effluents are processed in radioactive waste treatment systems (Section 2.2.4). The major radionuclides released to the aquatic systems are tritium, isotopes of cobalt, and cesium.

When an individual is exposed through one of these pathways, the dose is determined in part by the exposure time, and in part by the amount of time that the radioactivity inhaled or ingested is retained in the individual's body. The major exposure pathways include the following:

- inhalation of contaminated air,
- drinking milk or eating meat from animals that graze on open pasture on which radioactive contamination may be deposited,
- eating vegetables grown near the site, and
- drinking (untreated) water or eating fish caught near the point of discharge of liquid effluents.

Other less important exposure pathways include external irradiation from surface deposition; consumption of animals that drink irrigation water that may contain liquid effluents; consumption of crops grown near the site using irrigation water that may contain liquid effluents; shoreline, boating, and swimming activities; and direct off-site irradiation from radiation coming from the plant.

Radiation doses to the public are calculated in two ways. The first is for the maximally exposed person (that is, the real or hypothetical individual potentially subject to maximum exposure). The second is for average individual and population doses. Doses are calculated using site-specific data where available. For those cases in which site-specific data are not readily available, conservative (overestimating) assumptions are used to estimate doses to the public.

2.3.7.3 Solid Waste

Both nonradioactive and radioactive wastes are generated at nuclear power plants. The nonradioactive waste is generally not of concern unless it is classified as Resource Conservation and Recovery Act (RCRA) waste. All waste that is hazardous, that is, classified as RCRA waste, is packaged and disposed of in a licensed landfill consistent with the provisions of RCRA.

Hazardous chemicals, properly handled and controlled, do not present a major health risk to personnel at nuclear power plants, but they must be understood and treated carefully. Hazardous chemicals may be encountered in the work environment during adjustments to the chemistry of the primary and secondary coolant systems, during biocide application for fouling of heat removal equipment, during repair and replacement of equipment containing hazardous oils or other chemicals, in solvent cleaning, and in the repair of equipment. Exposures to hazardous chemicals are minimized by observing good industrial hygiene practices. Disposal of essentially all of the hazardous chemicals used at nuclear power plants is regulated by RCRA or NPDES permits.

Solid radioactive waste consists of LLW, mixed waste, and spent fuel. LLW is generated by removal of radionuclides from liquid waste streams, filtration of airborne gaseous emissions, and removal of contaminated material from the reactor environment.

Mixed waste is LLW that contains chemically hazardous components as defined under RCRA. Mixed waste consists primarily of decontamination wastes and ion exchange resins. The volume of mixed wastes produced at nuclear power plants is typically a small fraction of their overall waste stream, accounting for less than 3 percent by volume of the annual LLW discharged.

Spent fuel is produced during reactor operations. The buildup of fission products and actinides during normal operation prevents the continued use of the fuel assembly. Spent fuel is stored at the reactor site. Uncertainty exists as to when an MRS or permanent spent-fuel repository may become available. However, NRC has examined this issue and determined that licensees may, without significant impact on the environment, store spent fuel on-site for 80 years after ceasing reactor operation (55 FR 38474).

Four major considerations must be addressed when managing solid radioactive waste: (1) the adequacy of interim storage on-site in lieu of permanent off-site disposal, (2) transport of the radiological wastes to disposal sites over the nation's highways and railways, (3) worker and public radiation exposure resulting from handling and processing operations and transportation, and (4) final disposal.

LLW is normally temporarily stored on-site before being shipped to licensed LLW disposal facilities. Previously these facilities were at Barnwell, South Carolina; Beatty, Nevada; and Hanford, Washington. Under the Low Level Radioactive Waste Policy Act of 1980 and the LLRWPAA of 1985, states must secure their own disposal capacity for LLW generated within their boundaries after 1992 by forming waste compacts that are responsible for siting regional disposal facilities, or by siting their own disposal facilities.

For disposal purposes, mixed waste is principally regulated by NRC (10 CFR Part 61). Although the LLRWPAA of 1985 required states to certify they are capable of providing storage and disposal of mixed wastes in an NRC/EPA-licensed facility by 1992, there are currently no licensed disposal facilities accepting commercially generated mixed waste. Because these facilities are not yet available, mixed waste is currently stored on-site.

Originally, disposal of spent fuel in a deep-geological repository was contemplated. However, because of delays in siting a permanent repository on the part of the Department of Energy and delays in developing an interim MRS facility, as required by the Nuclear Waste Policy Act of 1982, nuclear power plants are storing their spent fuel on-site.

LLW is compacted and packaged, typically in 55-gal drums, then transported via truck or railcar. The packaging and transportation of both LLW and mixed waste must comply with EPA requirements. NRC specifications for reviewing the environmental effects of the transport of spent fuel are contained in the Table S-4 Rule (54 FR 187; 10 CFR Part 51.52). States and communities along transportation corridors may impose additional restrictions on the transport of nuclear waste.

Workers receive radiation exposure during the storage and handling of radioactive waste and during the inspection of stored radioactive waste. However, this source of exposure is small compared with other sources of exposure at operating nuclear plants. Members of the general public are also exposed when the LLW is shipped to a disposal site. No other type of radioactive waste is currently being transported from the reactor sites. The public radiation exposures from radioactive material transportation have been addressed generically in Table S-4 of 10 CFR Part 51. Table S-4 indicates that the cumulative dose to the exposed public from the transport of both LLW and spent fuel is estimated to be about 0.03 person-sievert (3 person-rem) per reactor year.

2.3.8 Socioeconomic Factors

2.3.8.1 Work Force

Although the size of the work force varies considerably among U.S. nuclear power plants, the on-site staff responsible for operational activities generally consists of 600 to 800 personnel per reactor unit. The average permanent staff size at a nuclear power plant site ranges from 800 to 2400 people, depending on the number of operating reactors at the site. In rural or low population communities, this number of permanent jobs can provide employment for a substantial portion of the local work force. Table 2.3 depicts mean employment during normal operations in the 1975–1990 period, grouped by the number of reactors.

In addition to the work force needed for normal operations, many nonpermanent personnel are required for various tasks that occur during outages, for example, refueling outages, ISIs, or major refurbishments. Between 200 and 900 additional workers may be employed during these outages to perform the normal outage maintenance work. These are work force personnel who will be in the local community only a short time, but during these periods of extensive maintenance activities, the additional personnel will have a substantial effect on the locality. Table 2.4 indicates the levels of additional personnel typically required for different types of outages.

A substantial portion of the regular plant work force is normally involved in many of the efforts listed in Table 2.4, supplemented as needed by contractor personnel for support during specialized projects. Peak crew sizes are greatly affected by the specific requirements at each plant, utility decisions to make major repairs to systems and components to improve or sustain plant performance, and the relative phasing (schedule overlap) of these activities. Exact crew sizes can, therefore, vary widely from plant to plant.

2.3.8.2 Community

Typically, the immediate environment in which a nuclear power plant is located is rural, but the population density of the larger area surrounding the plant and the distance from a medium- or large-sized metropolitan center varies substantially across sites. Most sites, however, are not extremely remote [i.e., not more than about 30 km (20 miles) from a community of 25,000 or 80 km (50 miles) from a community of 100,000]. The significance of any given nuclear power plant to its host area will depend to a large degree on its location, with the effects generally being most concentrated in those communities

Table 2.3 Changes in mean operations-period employment at nuclear power plants over time

Operations period	One-unit plants[a]	Two-unit plants[a]	Three-unit plants[a]
Current[b]	832 (34)	1247 (28)	2404 (4)
1985-1989	841 (30)	1094 (26)	2095 (4)
1980-1984	447 (19)	946 (21)	1078 (3)
1975-1979	233 (17)	515 (16)	699 (3)

[a]Number in parentheses indicates number of plants providing data.
[b]Approximately half the respondents reported data for 1989 and half for 1990.

Table 2.4 Mean additional employment per reactor unit associated with three outage types at nuclear power plants

Outage type[a]	Number of workers
Typical planned (58)	783
In-service inspection (23)	734
Largest single (45)	1148

[a]Number in parentheses indicates number of plants providing data for the survey (NUMARC).

closest to the plant. Major influences on the local communities include the plant's effects on employment, taxes, housing, off-site land use, economic structure, and public services.

As noted in Section 2.3.8.1, the average nuclear power plant directly employs 800 to 2400 people. Many hundreds of additional jobs are provided through plant subcontractors and service industries in the area. In rural communities, industries that provide this number of jobs at relatively high wages are major contributors to the local economy. In addition to the beneficial effect of the jobs that are created, local plant purchasing and worker spending can generate considerable income for local businesses.

Nuclear power plants represent an investment of several billion dollars. Such an asset on the tax rolls is extraordinary for rural communities and can constitute the major source of local revenues for small or remote taxing jurisdictions. Often, this revenue can allow local communities to provide higher quality and more extensive public services with lower tax rates. In general, capital expenditures and large changes in public services are seldom necessitated by the presence of the plant and its operating workers, particularly after local communities have adapted to greater and more dynamic changes experienced during plant construction.

As this discussion indicates, nuclear power plants can have a significant positive effect on their community environment. These effects are stable and long term. Because these socioeconomic effects generally enhance the economic structure of the local community, nuclear power plants are accepted by the community, and indeed, become a major positive contributor to the local environs.

2.4 LICENSE RENEWAL—THE PROPOSED FEDERAL ACTION

This section provides a brief overview of the most significant requirements of the proposed revision to 10 CFR Part 54, "Nuclear Power Plant License Renewal" (FR 59, no. 174, p. 46574).

Under the license renewal rule (10 CFR Part 54), nuclear power plant licensees would be allowed to operate their plants for a maximum of 20 years past the terms of their original 40-year operating licenses provided that certain requirements are met (Section 1.1). The rule requires licensees submitting license renewal applications to perform specified types of evaluations and assessments of their facilities, and to provide sufficient information for the NRC to determine whether continued operation of the facility during the renewal term would endanger public safety or the environment.

License renewal will be based on ensuring plant compliance with its current licensing basis (i.e., the original plant licensing basis as amended during the initial license term). In addition, licensees will be required to demonstrate for certain important systems, structures, and components (SSCs) that the effects of aging will be managed in the renewal period in a manner so that the important functions of these SSCs will be maintained. The SSCs of concern in the renewal period are those which traditionally do not have readily monitorable performance or condition characteristics and include most passive, long-lived plant SSCs. Therefore, the NRC's license renewal rule requires a systematic review of, at least, passive, long-lived SSCs that support safety or other critical functions of a nuclear power plant (as delineated in the rule). To make these determinations regarding these SSCs, it is expected that licensees will implement aging management activities for SSCs for which current programs may not be adequate to ensure continued functionality in the renewal term. These aging management activities are expected to include surveillance, on-line monitoring, inspections, testing, trending, repair, refurbishment, replacement, and recordkeeping, as appropriate.

The license renewal rule seeks to ensure that the effects of aging in the period of extended operation are adequately managed. The rule allows credit for existing programs and regulatory requirements that continue to be applicable in the period of extended operation and that provide adequate management of the effects of aging for SSCs. This provision includes credit for rules or requirements, such as those incorporated in the maintenance rule, which could impact license renewal activities performed to detect and mitigate age-related functionality degradation.

The rule requires an integrated plant assessment (IPA). License renewal applicants must perform an IPA to determine which SSCs will be subject to additional review. The IPA would then determine whether additional programs, over and above the current operational and maintenance programs, are required to manage the effects of aging so that equipment function is maintained.

In addition, the license renewal rule requires licensees submitting an application for license renewal to provide the following:

- information noting any changes in the current licensing basis that occur during NRC's review of the submittal; and
- an evaluation of time-limited aging analyses (i.e., issues such as fatigue, equipment qualification, and reactor-vessel neutron embrittlement which have inherent time limits associated with them).

Key aspects of 10 CFR Part 54 could result in environmental impacts because of the requirements imposed. These key aspects are (1) the enhanced surveillance, on-line monitoring, inspections, testing, trending, and recordkeeping (SMITTR) on SSCs identified in the IPA and (2) the resulting actions taken to ensure that aging would be effectively managed and that the functionality of these SSCs would be maintained throughout the term that the new license would be in effect.

Note that the license renewal rule does not require any specific repairs, refurbishments, or modifications to nuclear facilities, but only that appropriate actions be taken to ensure the continued functionality of SSCs in the scope of the rule.

2.5 BASELINE ENVIRONMENTAL IMPACT INITIATORS ASSOCIATED WITH CONTINUED OPERATION OF NUCLEAR POWER PLANTS

The previous sections identified the various types of environmental impacts associated with current nuclear power plant operation. Before discussing incremental impacts associated with license renewal, it is useful to first establish a baseline from which to evaluate incremental effects. This baseline is provided by current experience with nuclear power plant operation and the related interactions with the environment. This section presents quantitative information on selected environmental "impact initiators." The term "impact initiators" is defined, followed by estimates of the quantities of each initiator currently generated by typical nuclear power plant operation.

2.5.1 Definition of Environmental Impact Initiators

The terms "environmental impact initiators" and "impact initiators" as used here refer to the precursors to possible environmental impacts. For example, the incremental work force needed to accomplish license renewal activities is not an environmental impact, but the associated effects on housing, transportation, schools, etc., are environmental or socioeconomic impacts. The environmental impact initiators that need to be quantified to estimate overall environmental effects resulting from license renewal are as follows:

- Labor hours and work force size associated with on-site craft workers, engineering and administrative personnel, and health physics personnel are needed to estimate socioeconomic impacts to communities affected by personnel employed temporarily at nuclear plants.
- Labor costs are used to estimate both economic impacts to affected communities and economic viability of extended plant operation through license renewal.
- Occupational radiation exposure is used to estimate radiation-related impacts to workers.
- Capital costs of hardware, materials, and equipment are used both to estimate tax-base-related impacts to affected communities and to provide information related to the overall economics of license renewal.
- Radioactive waste types, volumes, and disposal costs are used to estimate environmental impacts related to the disposal of such wastes.

These impact initiators are the key elements expected to change, relative to current nuclear plant operation, as a result of actions taken to support license renewal. Other environmental considerations, including water usage, land usage, chemical usage/discharges, and air quality, are not anticipated to change significantly as a result of license renewal activities.

The impact initiators assessed—labor force, labor costs, capital costs, occupational radiation exposure, and radioactive waste volumes—help determine most of the potential changes in environmental impacts resulting from license renewal. For example, estimates of refurbishment labor and capital cost, together with a description of the types of refurbishment activities that might be undertaken, help define potential environmental impacts related to refurbishment period land use, water use, air quality, socioeconomics, nonradiological solid wastes, etc. The impact initiators assessed form a sufficient set from which to assess most license renewal-related environmental impacts. Also, the focus is on changes in impact initiators originating from plant activities, as opposed to changes in the plant environs or receptors (e.g., changes in the population affected by the plant).

2.5.2 Baseline Environmental Impact Initiator Estimates

The following discussions provide estimates of the baseline quantities for each of the foregoing impact initiators. These baseline quantities are typical of current nuclear plant operation.

2.5.2.1 Baseline Work Force Size and Expenditures for Labor

Table 2.3 indicates that the current work force at nuclear plant sites is typically in the range of 830 to 2400 permanent staff, depending on the number of operating reactors at a site. On-site personnel responsible for operational activities generally number between 600 and 800 per reactor unit. The average number of permanent staff per reactor unit is estimated to be about 700 people, and this number is approximately the same for both BWRs and PWRs. Assuming a normal 40-hour work week for most on-site staff, this staffing translates into an annual labor effort of about 1.5 million labor hours per unit. The permanent staff is augmented by temporary workers called in to assist with outage activities and special projects. The associated expenditures for labor, including an allowance of roughly 20 percent for temporary staff to support outages and special projects, is estimated to be about $77,000,000 annually per unit.

2.5.2.2 Baseline Capital Expenditures

Nuclear power plants incur expenditures for three major types of capital additions. There are (1) major plant retrofits needed to satisfy NRC requirements to ensure safe plant operation (e.g., changes required as a result of resolution of a generic safety issue), (2) major repairs needed to keep the plant operational (such as main turbine-generator repairs), and (3) discretionary activities undertaken to improve plant performance and labor productivity (DOE/EIA-0547). Expenditures for capital additions have varied widely from plant to plant and from one year to another. In 1989, the average expenditure for capital additions was about $24 per kilowatt, or roughly $24 million for a 1000-MW(e) plant (1989 dollars). These expenditures equate to about $28 million per year per 1000-MW(e) plant in 1994 dollars.

2.5.2.3 Baseline Occupational Radiation Exposure

Occupational radiation exposures vary considerably from plant to plant and from year to year at a given plant. The long-term trends indicate that overall worker exposure has been decreasing on a per-plant basis. The average occupational exposure for the year 1989 was roughly 4.4 person-sievert (440 person-rem) per plant at BWRs and about 3 person-sievert (300 person-rem) per plant at PWRs. For the years 1991 to 1993, the average exposure for all U.S. nuclear plants was about 2.5 person-sievert (250 person-rem) per plant (NUREG-1350, v.6). Significant deviations from these averages are routinely experienced, depending largely on whether a given plant had an outage during a given year and the nature and extent of refurbishment or repair activities undertaken during outages.

2.5.2.4 Baseline Radioactive Waste Generation

Section 2.2.4.3 discussed the different types of radioactive wastes typically generated at nuclear power plants. The type of waste generated in the greatest volumes is LLW. The volume of LLW disposed of annually has shown a decreasing trend over the past several years. Most recently, the amount of LLW disposed of at PWRs has been about 250 m^3/year (8800 ft^3/year); in contrast, the amount disposed of at BWRs has been about 560 m^3/year (19,700 ft^3/year).

Small volumes of mixed wastes are also generated by nuclear plant operation. However, any such waste that cannot be treated to eliminate the chemical hazards is currently stored on-site at the nuclear plants and not shipped for disposal.

U.S. reactors generate high-level wastes, primarily in the form of spent fuel. The quantities of spent fuel generated on a per-reactor-year basis is not expected to change with license renewal.

2.6 ENVIRONMENTAL IMPACT INITIATORS ASSOCIATED WITH LICENSE RENEWAL AND CONTINUED OPERATION

2.6.1 Scope and Objectives of Section 2.6

A major objective of the GEIS is to support the proposed changes to 10 CFR Part 51 by defining the issues that need to be addressed by the NRC and the applicants in plant-specific license renewal proceedings. First, the environmental issues are defined by characterizing and evaluating the actions and activities that may be undertaken by licensees in pursuit of license renewal and extended plant life. These actions and activities are then used to characterize their associated potential environmental impacts.

This section discusses potential actions nuclear power plant licensees may undertake to achieve license renewal and an extended plant life. This section also estimates the extent of the environmental initiators associated with these actions during license renewal and the extended term of operation.

The preceding section noted that the license renewal rule requires that the functionality of important SSCs be maintained throughout the period of the renewed license. To provide this assurance, licensees will likely undertake enhanced SMITTR activities on SSCs identified in the IPA and, based on the findings of these efforts, take appropriate action to ensure that aging is effectively managed and that the functionality of these SSCs is maintained. Incremental repair, refurbishment, and/or replacement of SSCs, as well as related changes to plant operations and maintenance, may be performed to ensure that this objective is achieved. These actions, either directly or indirectly, will produce incremental impacts to the local environment. These incremental effects are over and above those expected if plants were simply to continue to operate as at present.

Licensees may also choose to undertake various refurbishment and upgrade activities at their nuclear facilities to better maintain or improve reliability, performance, and economics of power plant operation during the extended period of operation. These are activities which would be performed at the option of the licensee and which are in addition to those performed to satisfy the license renewal rule requirements.

The set of activities undertaken is expected to vary widely from plant to plant. Some plants may require little refurbishment and upgrading. Other plants may require considerable refurbishment and upgrading. For purposes of the GEIS, two types of license renewal programs were considered for which the environmental impact initiators were developed:

- a "typical" or "mid-stream" license renewal program, intended to be representative of the type of program that many plants seeking license renewal might implement, and
- a "conservative" or "bounding" program encompassing considerably more activities by licensees, intended to characterize an upper bound, or near upper bound, of the impacts that could be generated at a nuclear power plant.

Each program applies to both BWRs and PWRs. Thus, there are four separate cases or scenarios considered: a typical BWR, an upper bound or conservative BWR, a typical PWR, and a conservative PWR.

The typical scenarios can be used to estimate environmental impacts from an "average" license renewal program and to estimate the nationwide impacts of the total nuclear power plant population. The bounding license renewal scenarios, being much more conservative, are intended to address what might occur for those plants whose impacts will be considerably greater than is typical of the nuclear power reactor population as a whole.

Section 2.6.2 presents the bases and assumptions used in developing the different license renewal scenarios. Section 2.6.3 describes and characterizes the typical license renewal scenarios and the resulting environmental impact initiators. The conservative scenario program is described in Section 2.6.4.

2.6.2 Bases, Assumptions, and Approach

2.6.2.1 Structures, Systems, and Components of Interest

The SSCs of interest for assessing license renewal-related environmental impacts are those that are critical to the safe operation of the plant and that traditionally do not have readily monitorable performance characteristics, which means that the effects of aging may go undetected and lead to the loss of SSC functionality. Many structures and components in currently-licensed LWRs are subject to programs such as the maintenance rule, periodic surveillances, and periodic replacement and refurbishment and have readily monitorable performance or condition characteristics so that these programs can reveal the effects of aging in sufficient time to prevent loss of SSC functionality. However, many other nuclear plant components, such as passive, long-lived structures and components, may not be subject to programs which reveal the effects of aging in sufficient time to ensure their functionality. Therefore, these passive, long-lived structures and components are the items that may need new or incremental aging management activities. The SSCs used in the current evaluation are discussed in Sections 2.6.3.1 and 2.6.4.1 for the typical and conservative programs, respectively.

2.6.2.2 Definition of Candidate Aging Management Activities

A comprehensive list of possible license renewal-related activities with potential environmental impacts was developed. Emphasis was placed on defining those activities clearly associated with license renewal, that is, those activities which would not be included in a continuation or extrapolation of the activities that occurred during the original licensing term. The types of activities considered ranged from enhanced inspection programs to component replacement. In turn, the potential environmental impacts of each identified activity were examined and analyzed.

Following the identification of candidate SSCs and the related aging management activities for each of the different license renewal programs, quantitative estimates of potential environmental impact initiators were developed. The estimates apply to a particular approach to aging management.

The data needed to characterize aging management activities were developed in the context of the four major license renewal programs previously identified: a typical BWR, a conservative BWR, a typical PWR, and a conservative PWR. Each program consisted of the following:

- lists of SSCs for which incremental activities would be performed to ensure that safe and economical operation could be achieved throughout the extended life of the plant;
- lists of the activities performed on each SSC to manage aging;
- the number of times each activity would be performed, accounting for repetitive actions on individual SSCs and the number of similar items in the plant subject to these activities; and
- the specific times during which each activity is performed.

The generic license renewal programs utilized in this evaluation were based on similar schedules for carrying out the selected aging management activities. Any major refurbishment work called for by the programs was assumed to start shortly after a renewed license had been granted. In these example programs, this would occur in roughly year 30 of the original 40-year license term. This work was assumed to be completed over several successive outages, including one at the end of the 40th year of plant operation. Incremental SMITTR actions, and the installation of enhanced or additional surveillance and monitoring equipment and systems, were also assumed to be initiated at this time. The SMITTR actions continue throughout the remaining life of the plants. This is true for both the typical and conservative case scenarios.

2.6.2.3 Incremental Effects Only

All aging management programs of interest to the current effort deliberately omit, to the extent possible, current practice as it has evolved and is expected to evolve in the license renewal period. The programs also exclude any changes in the basic design or technology of the plant. Rather, they include only those activities that would constitute a discrete change in the plant's operation and maintenance program and would be implemented only after issuance of the renewal license. In particular, all normal repair activities, as well as any activities undertaken to satisfy recently enacted requirements such as the Maintenance Rule, are considered to fall within the scope of current practice and were excluded from consideration. Therefore, the impact initiators considered here are incremental to those resulting from the extension of current practice.

2.6.2.4 Reference Plant Size and Characteristics

All assessments presented here reflect design features and quantities consistent with 1000-MW(e) plant designs. For the PWRs, the features and sizing chosen were consistent with those for a four-loop Westinghouse plant design with a large dry containment. The BWR features used were representative of designs utilizing internal jet pumps and two recirculation loops. Mark III containment features were used.

2.6.2.5 Reference SMITTR Program

The generic BWR and PWR aging management programs used in the present evaluations for both the typical and conservative scenarios were based on the safety-centered SMITTR programs that were used in the regulatory analysis for 10 CFR Part 54 (NUREG-1362). These basic SMITTR programs were supplemented by activities planned for the Lead Plant programs (Sciacca 1/3/93 and Sciacca 1/13/93). In addition, the aging management programs used as the basis for the current impact initiator estimates included actions anticipated for non–safety-related systems and equipment, but which licensees may undertake to maintain or enhance plant availability and performance. The conservative case scenarios, in particular, assumed considerable expansion of the basic Part 54 programs to include actions on many balance-of-plant SSCs. The inclusion of activities directed toward non–safety-related SSCs considerably expanded the number of times given activities would be performed and significantly increased the variety of activities performed, compared with those considered for the 10 CFR Part 54 Regulatory Analysis. The inclusion of aging management activities beyond those characterized for safety-centered SMITTR programs enhances the comprehensiveness and conservatism of the estimates used in the preparation of the GEIS conservative cases. The typical license renewal program scenarios also include more SMITTR actions than those used for the 10 CFR Part 54 assessments, but to a lesser degree than the conservative case scenarios. The typical program SMITTR activities incremental to those anticipated under Part 54 were included to allow for voluntary actions on the part of licensees to better manage aging of balance-of-plant SSCs. All typical program activities were reviewed for possible overlap with the Maintenance Rule activities; any activities perceived to fall within the scope of the Maintenance Rule or other rules were eliminated from the programs.

2.6.2.6 Major Refurbishments and Replacements

The major refurbishment/replacement class of activities included in the license renewal programs characterized here is intended to encompass actions which typically take place only once in the life of a nuclear plant, if at all. Replacement of BWR recirculation piping and PWR steam generators falls into this category of activities. Many such activities were included in the conservative case license renewal scenarios. The items making up this category include both activities which have already been performed at some operating LWRs and activities which have not yet been performed, at least not to the extent assumed for the purpose of defining potential environmental impacts. The inclusion of activities which have already been performed on some existing nuclear plants is based on the premise that there are certain plants in the reactor population that will not have to perform these activities during the current license term, but that would elect to perform these major activities to enable safe and economic operation for the incremental term allowed with license renewal. In addition, major refurbishment activities included in these example license renewal programs encompass all areas of a nuclear power plant (e.g., structures, mechanical and electrical systems, fluid systems). This approach further ensures that the impacts characterized for the conservative case scenarios have a high probability of bounding the impacts likely to accrue to any individual plant seeking license renewal and extended plant operation.

The typical scenarios, in contrast, included fewer major refurbishment activities of this type. For these scenarios the assumption was made that most plants will have ongoing effective maintenance and refurbishment programs that preclude the need for refurbishment/replacement of all but a few components and structures.

2.6.2.7 Prototypic License Renewal Schedule

Figure 2.3 shows representative timelines for the license renewal process of a nuclear plant. The timelines shown were judged to be reasonable by the NRC staff. The schedule is applicable to both the typical and conservative license renewal scenarios. The upper timeline shows the relationship of the new license period to the initial license period. The lower line indicates the various outage types and their assumed timing over the period covered by a renewed license. The key underlying assumption for the timelines is that the licensee should be assured by the NRC 10 years before the expiration of its current operating license that the plant in question is suitable for license renewal. These 10 years are required for the licensee to arrange for alternative sources of power should a renewed license not be granted. The license renewal process is presumed to start with the licensee initiating a number of studies and analyses to support the license renewal application 3 years before submitting the application to the NRC. The NRC would then perform a detailed review of the application and, in the successful cases, issue a new license (with conditions) within 2 years after the application is received. The new license would go into effect at that point, covering the balance of the original 40-year term, as well as the additional 20-year term.

It was assumed that licensees would initiate incremental aging detection and management activities as soon as the new license was granted, as called for by 10 CFR Part 54. Discretionary major refurbishment activities might also be undertaken early into the license renewal term.

2.6.2.8 Schedule for Performing Major Refurbishment Activities

The reference schedule assumes that major refurbishment activities associated with

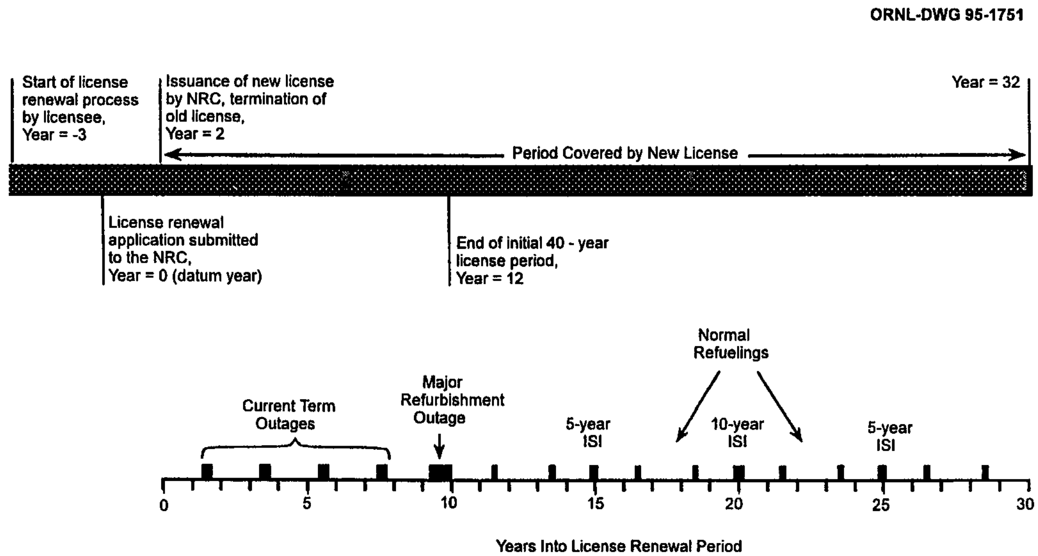

Figure 2.3 License renewal schedule and outage periods considered for environmental impact initiator definition.

license renewal are started shortly after the new license is granted, and that these are accomplished over several successive outages. They are completed by the time the plant completes its 40th year of operation, which is about 10 years into the new license term. The schedule for performing any major refurbishment activities will undoubtedly be highly plant specific, and such activities could well be spread throughout the term of the renewed license. Earlier timing of these activities provides the utilities with more time to recover the cost of the investment through the sale of energy produced. Thus, the schedules utilized for the present evaluations are reasonable, but alternative schedules are also possible.

The schedules utilized were similar for both the BWR and PWR programs. However, the typical programs have little need for an extended outage because the extent of major refurbishment activities is relatively modest. The "major refurbishment outage" duration for the typical programs was reduced compared with that deemed necessary for the conservative case scenarios.

2.6.2.9 Outage Types and Durations

Activities carried out in support of license renewal and extended plant life were assumed to be performed primarily during selected outages. Five types of outages were used: normal refuelings, 5-year ISI outages, 10-year ISI outages, current term refurbishment outages, and major refurbishment outages. Figure 2.3 illustrates when these outages are assumed to occur. The current term outages fall within the 40-year period initially covered by the plant's current license, but with license renewal they occur during the period covered by the new license.

Outage types and durations were established to allow estimation of the rates at which environmental impacts might be generated as a result of license renewal activities. For example, the number of workers required at a site for a given outage is dependent on the amount of work to be performed (labor hours), the time available to accomplish the work, and the number of labor hours expended per person-week or person-day. The number of workers so identified, in turn, allows estimation of potential socioeconomic and other impacts to affected communities.

Table 2.5 summarizes the different outage types and durations for both reactor types and for both the typical and conservative license renewal scenarios. Additional discussion of the basis used in selecting outage durations is provided in Appendix B.

2.6.3 Typical License Renewal Scenario

The characteristics of the typical license renewal program are discussed briefly in Section 2.6.3.1. Listings of the SSCs likely to be subject to incremental aging management activities are provided. Listings of the types of SMITTR actions and major refurbishment activities that may be performed as part of a typical license renewal program are reviewed and discussed in Appendix B. Section 2.6.3.2 summarizes the impact initiator quantities expected to be generated by such a program. Section 2.6.3.2 compares the impact initiator quantities for the typical program scenarios with the impactor initiator quantities currently produced from routine reactor operation.

2.6.3.1 Characterization of Typical License Renewal Programs

The characterization of license renewal programs required that three key types of information be developed: (1) identification of the SSCs likely to be subject to incremental aging management activities, (2) candidate lists of the activities to be performed on these systems and components to suitably manage aging effects that could have potential environmental consequences, and (3) identification of environmental attributes (impact initiators) associated with those activities. The typical programs are intended to be representative of the typical or "average" plant's activities in support of license renewal. However, the typical programs are still somewhat conservative; that is, some plants will not require all of the actions identified in the typical programs. The typical license renewal scenarios were based on the following.

- The Monticello and Yankee Rowe lead plant life extension (PLEX) programs were carefully reviewed. Activities included in either program were, with some exceptions, incorporated into the typical license renewal scenarios. The information obtained from the lead plants was also used to establish both the numbers of SSCs subject to a given activity and the schedule for performing such activities.
- All activities included in the Part 54 Regulatory Analysis which were pertinent to passive, long-lived SSCs and which were not likely to be implemented because of other rules or regulations were retained as incremental actions. The Part 54 activities were retained both to maintain consistency with the updated Part 54

Regulatory Analysis and to allow for a modest amount of conservatism in the typical scenarios.

- As noted previously, recently enacted rules and regulations, in particular the Maintenance Rule, were taken into account in developing typical license renewal or PLEX-related activities.
- Surveys were made to help establish the likelihood that certain major activities would be performed by typical licensees seeking license renewal. In particular, assessments were made relative to steam generator replacement and reactor vessel annealing for PWRs, and for recirculation piping replacement for BWRs. These assessments reviewed the fraction of the affected reactor population that has already performed these refurbishment/replacement activities and ascertained whether such activities might need to be repeated for extended plant life. Based on the results of these reviews, it was assumed that typical license renewal programs will not need to include many such major activities.

Table 2.5 Outage duration summary

	Outage duration (months)	
Outage type	Conservative	Typical
Refueling	2	2
5-Year in-service inspection	3	3
10-Year in-service inspection	4	3
Current-term outage (refurbishment)	4	3
Major refurbishment outage	9	4

Typical program structures, systems, and components subject to incremental activities

Tables 2.6 and 2.7 list the SSCs used in the typical program evaluations for which incremental activities are assumed to be conducted during license renewal and extended life. Table 2.6 lists the items subject to incremental SMITTR actions; Table 2.7 lists items subject to major refurbishment/replacement activities. Table 2.6 includes SSCs subject to the addition of new or improved condition monitoring systems, as well as those subject to incremental SMITTR activities. Most of the items in these tables are common to both BWRs and PWRs.

Although the specific numbers of components and design features may be different for these two reactor types, they are similar enough that the environmental impacts resulting from aging management

Table 2.6 Typical program structures and components subject to incremental SMITTR[a] activities in support of license renewal

Item	BWR/PWR[b]
AC or DC busses	Both
Actuation and instrumentation channels	Both
Bellows	BWR
Building cranes and hoists	Both
BWR control rod drive mechanisms	BWR
BWR recirculation pumps and motors	BWR
Check valves	Both
Compressed air system	Both
Containment	Both
Emergency diesel generators	Both
Fan coolers	Both
Fuel pool	Both
Heat exchangers	Both
Heating, ventilation, and air conditioning	Both
Hydraulic or air operated valves	Both
Main condensor	Both
Main generator	Both
Main turbine	Both
Metal containment, including suppression chamber	BWR
Motor-operated valves	Both
Motor-driven pumps and motors	Both
Nuclear steam supply system supports	Both
PWR critical concrete structure—containment	PWR
PWR reactor coolant pump	PWR
Reactor pressure vessel	Both
Reactor pressure vessel internals	Both
Turbine-driven pumps and turbines	Both

[a]SMITTR = surveillance, on-line monitoring, inspections, testing, trending, and recordkeeping.
[b]BWR = boiling-watert reactor; PWR = pressurized-water reactor.

Table 2.7 Typical program systems, structures, and components subject to major refurbishment or replacement activities

Item	BWR/PWR[a]
BWR safe ends and recirculation and feedwater piping inside containment	BWR
Compressed air system	Both
Containment	Both
Emergency diesel generators	Both
Main generator	Both
Major structures, including buildings and pipe enclosures	Both
Motor-operated valves	Both
Piping sections	Both
Reactor containment building	Both
Reactor pressure vessel	Both
Reactor pressure vessel internals	Both
Steam generators	PWR
Storage tanks	Both

[a]BWR = boiling-water reactor; PWR = pressurized-water reactor

activities on these items will be reasonably similar for both reactor types. Differences in the numbers of like items employed in each plant design were taken into account in assessing impacts.

Certain SSCs such as the reactor recirculation piping for BWRs and steam generators for PWRs are unique to the plant design type. Potential impacts from aging management activities on such items were treated separately for the two major plant categories.

Definition of aging management activities

The incremental aging management activities carried out to allow operation of a nuclear power plant beyond the original 40-year license term will be from one of two broad categories: (1) SMITTR actions, most of which are repeated at regular intervals, and (2) major refurbishment or replacement actions, which usually occur fairly infrequently and possibly only once in the life of the plant for any given item.

Most of the SMITTR activities included in the present assessment were taken from the Safety-Centered Aging Management program defined previously and utilized for the 10 CFR Part 54 License Renewal Regulatory Analysis (NUREG-1362). However, the current effort includes additional items and activities, because the previous analysis focused only on SSCs important to safety, whereas for the current efforts it has been assumed that licensees will also perform actions aimed at ensuring reliable and efficient electrical power production. Thus, many balance-of-plant SSCs are included here which were not included in the 10 CFR Part 54 evaluations.

In certain cases a SMITTR activity could involve replacement or refurbishment of the SSC being addressed. Any such SMITTR replacement/refurbishment activities for a particular item typically occur more than once in the extended life of the plant.

Table B.1 of Appendix B lists the incremental SMITTR actions used as the basis for estimating license renewal environmental impacts. It indicates the specific aging detection and mitigation actions performed on each SSC of concern. These activities include some which are undertaken only to improve reliability or economic performance; thus, Table B.1 includes several active components in addition to the passive, long-lived SSCs that are the focus of 10 CFR Part 54.

Table B.2 of Appendix B lists the major refurbishment or replacement activities used to estimate environmental impacts. The table indicates the fractions or portions of the SSCs involved which are subject to the stated actions. Unless otherwise noted, 100 percent of an SSC was assumed to be replaced or refurbished. As with the list of actions cited in Table B.1, the quantities assumed were based in part on the information provided in the industry pilot and lead plant studies and from reported existing industry experience on major refurbishments (Sciacca 1/3/93 and 1/13/93). In other cases engineering judgment provided the basis for the portions of the systems or structures being replaced or refurbished. The extent of major refurbishments envisioned for typical license renewal programs is fairly modest.

2.6.3.2 Typical Program Incremental Initiator Quantities

Table 2.8 summarizes the typical program impact initiator quantities resulting from the incremental SMITTR and major refurbishment/replacement activities assumed to be carried out in support of license renewal and extended plant life. Estimates of the amounts generated are shown for each of the outage types previously discussed, during which these impact initiators are expected to be generated from license renewal activities. Separate estimates are provided for BWRs and PWRs. All figures are shown on a per-plant basis (i.e., for a single nuclear plant).

A comparison of the figures shown in Table 2.8 with current reactor experience as discussed in Section 2.5.2 indicates that, for the typical license renewal scenario, incremental license renewal effects are expected to be relatively modest. For example, with current nuclear plant operation, roughly 1.5 million person-hours are expended each year for on-site operations and maintenance activities. The incremental efforts associated with license renewal-related activities are estimated to add between 500,000 and 700,000 person-hours for all such activities over the remaining

life of a typical plant. Thus, the license renewal activities would add roughly 20,000 person-hours per year, which is a small increment compared to the 1.5 million person-hours per year typical of current reactor operation.

Table 2.8 indicates that the number of additional on-site personnel needed to accomplish license renewal-related activities is quite modest for most periods when such activities will be performed. The exception is the major refurbishment outage, when an average of between 200 and 400 additional personnel may be needed. Note that these personnel are in addition to the 700- to 800-person temporary work force typically called in to assist with current outages at nuclear power plants (see Table 2.4). The estimates of additional personnel presented in Table 2.8 are based on the assumption that the incremental work efforts are spread uniformly over the entire duration of the associated outages. In reality, some peaking of staffing requirements will occur during each outage. Additional analyses were performed to evaluate the extent of such peaking, and these analyses are discussed in Appendix B. For the typical BWR license renewal scenario, these analyses indicated that the on-site temporary work force would peak at about 1000 personnel. This peak occurs during the major refurbishment outage, and it includes the temporary work force needed to accomplish refueling and routine outage activities (e.g. routine maintenance and ISI activities) as well as license renewal-related activities. For the PWR, the corresponding temporary worker requirements reach a peak at about 900 additional staff. This peak requirement occurs during the current term outages.

The incremental occupational radiation exposure estimated to accrue because of license renewal activities is between 2.5 and 5 person-sievert (250 and 500 person-rem). On an annualized basis, this represents an increase in annual exposures of about 3 to 4 percent relative to current reactor operation experience.

LLW generation resulting from license renewal activities is projected to be between 185 and 220 m^3 (6,000 and 8,000 ft^3) of as-shipped LLW over the remaining life of the plants. Currently, PWRs typically generate about 250 m^3/year (8800 ft^3/year); the amount disposed of at BWRs has been about 560 m^3/year (19,700 ft^3/year). Thus, the amount of LLW expected to be added because of license renewal activities is roughly the equivalent of one-half to one year's production of waste under current operating conditions. This represents an increment over the remaining life of the plants of about 1 to 3 percent relative to what would be produced with continued present-basis plant operation.

Table 2.8 presents several types of costs associated with license renewal and extended plant life. These include incremental costs associated with additional labor, waste disposal, capital costs, and off-site costs (off-site engineering and administrative support). For the typical BWR license renewal program, the total incremental costs are estimated to be almost \$110 million; those for the typical PWR program are estimated to be about \$90 million. Although these costs will be incurred over the remaining life of a plant, more than half of these costs might well be incurred in the first few years after a renewed license is granted. For comparison purposes, recent non-fuel operations and maintenance (O&M) costs at U.S. nuclear plants have averaged about \$75 million per year for a 1000-MW(e) plant, and capital additions have averaged about \$28 million per year (1994 dollars). Thus, the estimated labor and capital expenditures associated with incremental license renewal activities over the remaining life of a plant with a renewed license are the equivalent of roughly a year's expenditures for O&M and capital additions currently experienced by LWRs, or less than a 5 percent increase for such expenditures on an annualized basis.

2.6.4 Conservative License Renewal Scenario

The characteristics of the conservative case license renewal programs are discussed briefly in Section 2.6.4.1. As was done in Section 2.6.3.1 for the typical programs, listings are provided of the SSCs likely to be subject to incremental aging management activities. Listings of the types of SMITTR actions and major refurbishment activities that may be performed as part of a conservative license renewal program are reviewed and discussed in Appendix B. Section 2.6.4.2 summarizes the impact initiator quantities expected to be generated by such programs and compares the impact initiator quantities for the conservative program scenarios with the impactor initiator quantities currently produced in routine reactor operation.

2.6.4.1 Characterization of the Conservative Program

The conservative license renewal scenarios are intended to capture what might occur for those outlier plants whose impacts will be considerably greater than what is typical of the reactor population as a whole. Because these conservative, or bounding, programs are quite comprehensive, they subsume impacts from more atypical plants.

The conservative case license renewal scenario uses a conservative basis for projecting activities and impacts. The primary bases and assumptions are as follows.

- In contrast with the typical programs, the recently enacted rules and regulations, in particular the Maintenance Rule, were not taken into account in revising license renewal or PLEX-related activities. This simplified approach was taken because accounting for such effects would have a negligible impact on the estimates of environmental impact initiator quantities.
- All activities included in the Part 54 Regulatory Analysis were retained as incremental actions. In many instances, the number of SSCs subjected to particular SMITTR activities was increased to reflect optional actions on the part of licensees to better ensure reliable and economical service for balance-of-plant systems and components.
- The major refurbishment and replacement activities included in the programs are quite expansive and encompass all aspects of the plant designs (e.g., structural, mechanical, and electrical). Similarly, the extent of such activities for particular SSCs is considerable in most cases and is more extensive than that anticipated for the average plant seeking license renewal.
- As was previously noted, several of the major refurbishment activities included in the present estimates have already occurred at many nuclear plants. These are activities such as steam generator replacement in PWRs and recirculation piping replacement in BWRs. These activities are included in the conservative case scenarios to encompass those plants that must perform such activities to achieve the desired extended plant life and efficiency, but that have not already done so or that might have to repeat such actions.

License renewal program definition

Conservative program SSCs subject to incremental activities. The conservative program SSCs assumed to be subject to incremental SMITTR activities included all of the SSCs identified in Table 2.6 for the typical program. In addition, the conservative program included the items listed in Table 2.9. The conservative program, in most instances, also included a greater number of a given type of SSC subject to SMITTR actions than did the typical programs. For example, the conservative programs included roughly twice the number of motor-operated valves subject to incremental aging detection and mitigation actions as did the typical programs. This approach was taken with the conservative programs to encompass what might occur at outlier plants.

Both the SSCs subject to incremental SMITTR activities and those subject to major refurbishment activities for the conservative program are more inclusive than those included in the typical program scenarios. A comparison of Tables 2.6 and 2.7 with Tables 2.9 and 2.10 readily demonstrates the more comprehensive nature of the conservative program compared with the typical program scenarios.

Table 2.9 Conservative program additional structures and components subject to incremental SMITTR[a] activities in support of license renewal

Item	BWR/PWR[b]

Table 2.10 lists items subject to major refurbishment/replacement activities. Most of the items in these tables are common to both BWRs and PWRs.

Definition of conservative program aging management activities. As for the typical programs, the incremental aging management activities carried out for the conservative license renewal scenarios to allow operation beyond the original 40-year license term will include both SMITTR activities and major refurbishment activities.

The SMITTR activities associated with the conservative programs are quite similar to those developed for the typical programs, except that they cover additional types and numbers of SSCs. The scenarios developed

Table 2.10 Conservative program systems, structures, and components subject to major refurbishment or replacement activities

Item	BWR/PWR[a]
Building crane	Both

for the conservative programs assumed that many balance-of-plant SSCs would be subject to license renewal-related activities to better ensure reliable and economical operation for the extended life of the plant.

Table B.1 of Appendix B lists the incremental SMITTR actions used as the basis for estimating license renewal environmental impacts. It indicates the specific aging detection and mitigation actions performed on each SSC of concern.

Table B.1 indicates the specific SMITTR activities included in each type of program, but it does not indicate the number of SSCs subject to a particular activity. The programs defined for the conservative case scenarios in all instances match or exceed the number of SSCs included in the corresponding typical license renewal programs.

The list of major replacement and refurbishment activities included here was derived largely from areas of concern identified in the industry pilot and lead NP-5181M, EPRI NP-5289P, EPRI NP-5002). This is true for both the conservative and typical scenarios. Those studies did not necessarily indicate that all of the items addressed should be replaced or undergo major overhauls. However, for all items addressed, there was sufficient concern over their long-term integrity that investigators thought, as a minimum, that additional analysis was warranted.

Although replacement may not have been indicated for the pilot and lead plants, at least a few plants may well face extensive actions of this type to ensure safe and economical operation throughout the renewal term. Therefore, regardless of the specific determinations for the pilot and lead plants, the SSCs of concern identified in those studies form a representative list of candidate items for inclusion in major replacement and refurbishment actions for outlier plants, and thus for the conservative scenarios. Other items included in this list were drawn from actions that have already occurred at one or several operating power plants. BWR recirculation piping replacement and PWR steam generator replacement fall into this category. Although many plants will undertake the replacement of such items during the current license term, there may be other plants which would undertake such tasks only to allow for extended plant operation. Inclusion of these activities in the conservative scenario evaluations provides for an upper bound estimate of what at least a few plants may undertake for license renewal.

Table B.2 of Appendix B lists the major refurbishment or replacement activities used to estimate environmental impacts for the conservative case scenarios. Unless otherwise noted, 100 percent of an SSC was assumed to be replaced or refurbished.

2.6.4.2 Conservative Program Incremental Initiator Quantities

Table 2.11 summarizes the conservative program impact initiator quantities resulting from the incremental SMITTR and major refurbishment/replacement activities assumed to be carried out in support of license renewal and extended plant life. A comparison with the estimates provided for the typical programs (Table 2.8) indicates that the conservative program scenario estimates of impact initiator quantities are factors of four to six greater than those for the typical programs. The type of information provided in Table 2.11 is identical to that provided in Table 2.8. Separate estimates are provided for BWRs and PWRs, and all figures are shown on a per-plant basis.

Source: Science and Engineering Associates, Inc., January 1995.

A comparison of the figures shown in Table 2.11 with current reactor experience as discussed in Section 2.5.2 indicates that, for the conservative license renewal scenario, incremental license renewal effects are expected to be fairly significant. The incremental efforts associated with license renewal-related activities are estimated to add between 5 million and 7 million person-hours for all such activities over the remaining life of a conservative plant. These increments for license renewal can be compared with the roughly 1.5 million person-hours expended annually with current reactor operation.

If the license renewal efforts were uniformly spread over the 30-year period that a renewed license would be in effect, they would increase annual labor requirements by 10 to 15 percent. The effect of the incremental license renewal labor will be even more significant for certain periods. For example, the number of additional workers needed to accomplish the major refurbishment activities during the major refurbishment outage could potentially double or triple the number needed during a normally scheduled outage. The projected number of additional workers needed for the BWR major refurbishment outage is almost 900, averaged over the entire outage. For certain periods during this outage, the number of additional workers is estimated to be about 1200. For the PWR, the outage average increment in additional personnel needed for the major refurbishment outage is about 1700, and the number is expected to peak at about 2300 for certain periods during this outage. Note that these estimates of peak incremental personnel include the 700- to 800-person temporary work force typically called in to assist with current outages at nuclear power plants (see Table 2.4).

Appendix B provides additional discussion of license renewal-related incremental staffing requirements.

The overall occupational radiation exposure estimated to accrue because of conservative program license renewal activities is between 23 and 24 person-sievert (2300 and 2400 person-rem). The large increase compared with the exposures anticipated for the typical programs is largely a result of the extensive major refurbishment activities expected to be undertaken with the conservative program scenarios. On an annualized basis, this is equivalent to an increase in annual exposures of about 20 to 30 percent relative to current reactor operation experience.

LLW generation from license renewal activities is projected to be between 1,900 and 2,500 m^3 (65,000 and 90,000 ft^3) of as-shipped LLW over the remaining life of the plants. Currently, PWRs typically generate about 250 m^3/year (8800 ft^3/year); the amount disposed of at BWRs has been about 560 m^3/year (19,700 ft^3/year). Thus, the amount of LLW expected to be added because of conservative program license renewal activities represents several years worth of production of waste under current operating conditions. This represents an increment over the remaining life of the plants of about 11 percent annually for the BWRs and about 30 percent annually for the PWRs relative to what would be produced with present-basis, continued plant operation. The larger percentage of PWR LLW results primarily from the large volume of the steam generators, which it is assumed will be replaced for the conservative program.

Table 2.11 indicates that the overall incremental costs associated with conservative program license renewal activities are projected to be in the range of $450 million to $500 million per plant (1994 dollars). With current nuclear plant operation, annual expenditures for fuel, O&M, and capital costs are in the range of $150 million to $250 million, depending on individual plant conditions. Thus, the license renewal expenditures represent 2 to 4 years of current overall operating costs.

2.6.5 Impact Initiator Estimate Uncertainties

The NRC staff believes that the license renewal scenarios presented in Section 2.6.4 reasonably characterize both the nature and magnitude of licensee activities that may be undertaken in support of license renewal and extended plant life. Both the typical and conservative programs include some discretionary activities that are assumed to be undertaken by licensees to better ensure economical and reliable plant operation, and that are in addition to those activities performed to meet the requirements of 10 CFR Part 54. The licensee actions in response to the 10 CFR Part 54 requirements, believed to be fairly modest, consist of a considerably smaller set of activities than those characterized for the typical license renewal scenarios. Appendix B presents estimates of impact initiator quantities strictly related to meeting the requirements of the license renewal rule. Thus, a broad spectrum of license renewal programs are possible, and the license renewal-related environmental impacts can vary widely from one plant to another, depending on specific plant conditions and on discretionary activities undertaken by each licensee/applicant. This variability in program characteristics, coupled with uncertainties in parameter values used to estimate specific initiator quantities, results in a considerable degree of uncertainty in the estimates presented in Tables 2.8 and 2.11. Although a rigorous uncertainty analysis has not been performed, the estimates of individual impact initiators provided in Table 2.8 for the typical programs are judged to have uncertainties in the range of ±30 percent. The more bounding assumptions employed for the conservative scenarios reduce the likelihood that the actual impact initiators experienced could be much higher than those presented in Table 2.11. The uncertainty range for the Table 2.11 estimates, therefore, is judged to be on the order of +10 percent to −30 percent.

2.7 SUMMARY

This chapter described operating U.S. nuclear power plants and described the nature of their interactions with the environment. The basic requirements of the license renewal rule, 10 CFR Part 54, were reviewed with the focus on aspects which may result in incremental environmental impacts. Chapter 2 also described both typical and conservative license renewal programs characterized for the purpose of estimating license renewal-related environmental impacts. Estimates were provided of environmental impact initiators associated with these programs. These impact initiators are used in the balance of this document to identify and quantify anticipated environmental impacts associated with nuclear power plant license renewal.

2.8 ENDNOTES

1. Construction of nuclear units Grand Gulf Unit 2, Perry Unit 2, and Washington Nuclear Project Units 1, 3, 4, and 5 has been suspended; therefore,

these units are not considered in this GEIS.

2. This category is generally discussed as a separate source of liquid waste primarily for PWRs in which the water has a different radionuclide content and chemistry from primary coolant.

4. ENVIRONMENTAL IMPACTS OF OPERATION

4.1 INTRODUCTION

Nuclear power plant operations during the license renewal term will result in a continuation of most of the impacts that were occurring prior to license renewal. Some operational procedures will change, however, in response to efficiency, reliability, and safety goals. These new procedures may result in a new baseline of plant-induced impacts that will continue throughout the license renewal term. In addition, the environmental receptors such as air, water, population, and biotic communities may be changing. These receptor changes in turn will influence the significance of any plant-induced impacts. Therefore, this chapter defines the prelicense-renewal baseline for plant-induced impacts and additional impacts due to a changing environment, refurbishment, and changes in plant operation.

It is the intent of this chapter to discuss all substantive issues of concern that were identified in the scoping process (Section 1.3). This chapter is organized according to the major modes by which nuclear power plants affect the environment. Because the cooling system is a major mode of interaction with the environment and because the three types of cooling systems have substantially different effects, the first three sections address the impacts of operation for each of the three cooling system types. Transmission lines have distinctly different effects from cooling systems, so they are discussed separately in Section 4.5. Operation of nuclear power plants also has potential human health, socioeconomic, and groundwater effects that are not closely related to either the cooling system or the transmission lines. These effects are discussed in Sections 4.6, 4.7, and 4.8.

The issue of impacts to threatened or endangered species is potentially relevant to all cooling system types and to transmission lines. Review of power plant operations has shown that neither current cooling system operations nor electric power transmission lines associated with nuclear power plants are having significant adverse impacts on any threatened or endangered species. However, widespread conversion of natural habitats and other human activities continues to cause the decline of native plants and animals. As biologists review the status of species, additional species threatened with extinction are being identified; consequently, it is not possible to ensure that future power plant operations will not be found to adversely affect some currently unrecognized threatened or endangered species. In addition, future endangered species recovery efforts may require modifications of power plant operations. Similarly, operations-related land-disturbing activities (e.g., spent fuel and low-level waste storage facilities) could affect endangered species. As noted in Section 3.2, without site-specific and project-specific information, the magnitude or significance of impacts on threatened and endangered species cannot be assessed. For these reasons, the nature and significance of nuclear power plant operations on as yet unrecognized endangered species cannot be predicted; and no generic conclusion on the significance of potential impacts on endangered species can be reached. The impact on threatened and endangered species, therefore, is a Category 2 issue and will not be discussed further in this chapter.

4.2 ONCE-THROUGH COOLING SYSTEMS

A once-through cooling system can affect the environment by withdrawing a large amount of water, heating it, adding biocides, and discharging it back to the receiving body. The main issues associated with plants using such a system are (1) effects on aquatic organisms due to changes in water quality, entrainment, and impingement; (2) water-use conflicts; and (3) effects on groundwater quality, hydrology, and use. These issues as they relate to license renewal are addressed in this section.

The following sections discuss the potential effects of operation of once-through condenser cooling systems on surface water quality, hydrology, and use (Section 4.2.1) and aquatic ecology (Section 4.2.2). Section 4.2.2.2 summarizes the conclusions for each of these issues.

4.2.1 Surface Water Quality, Hydrology, and Use

This section considers how once-through cooling systems may alter surface water quality, hydrology, and quantity; the consequent biological effects of such changes and the methodology used to arrive at conclusions are described in Section 4.2.2. Each issue is described and, as appropriate, illustrated with examples from operating nuclear power plants. Any ongoing effects will probably continue into the license renewal term, assuming that the cooling system design and operation will not change for any plant under the requirements for license renewal. Judgments about the significance of these issues during the license renewal term are based on published information, agency consultation, and information provided by the utilities (Appendix F) on every nuclear power plant in the United States. The conclusions reached in Section 4.2.1 apply to all nuclear power plants with once-through cooling systems.

Seventy nuclear power plants have a once-through cooling system (see Table 2.2). The operation of once-through cooling systems alters water quality primarily through the discharge of heat and chemicals to a receiving body of water. The largest volumes of discharge are associated with the main condenser cooling system, but there are other sources of liquid effluents (e.g., the service water system and sanitary wastes). Because the volumes of water discharged from other systems are relatively small compared with those of the once-through condenser cooling system (typically around 10 percent), concern about water quality impacts of discharges has generally focused on the condenser cooling system. The amounts of heated effluent from such a system can be large; a nuclear power plant with once-through cooling discharges water at about 46 m^3/s (736,000 gal/min) per 1000 MW(e) with a temperature increase of 10°C (18°F).

4.2.1.1 Regulation of Condenser Cooling System Effluents

The U.S. Nuclear Regulatory Commission (NRC) considered the costs and benefits of alternative condenser cooling systems (including potential impacts on water quality and aquatic ecology) in the environmental statements associated with issuance of construction permits and operating licenses. Once a plant is operating, however, the continuing regulation of nonradiological impacts on water quality and aquatic ecology is primarily the responsibility of the U.S. Environmental Protection Agency (EPA) or the applicable state permitting agency. This section describes the environmental statutes that underlie the regulation of impacts on aquatic resources from operating nuclear power plants. An understanding of the requirements of these statutes and the procedures under which aquatic resources effects are controlled by the permitting agencies is important to the interpretation of the issue categories.

As with other industries, discharges from steam-electric power plants are regulated under the Clean Water Act (CWA). Because power plants discharge wastewater into surface bodies of water, they must obtain a National Pollutant Discharge Elimination System (NPDES) permit under Section 402 of the CWA (33 USC 1342). The NPDES permit specifies the discharge standards and monitoring requirements that the facility must achieve for each point of discharge or outfall. NPDES permits must be renewed every 5 years, and during the renewal process, the plant must certify that no changes have been made to the facility that would alter aquatic impacts and no significant adverse impacts on aquatic resources have been observed. An NPDES permit is issued by EPA or, more commonly, a designated state water quality agency.

Under Section 316(a) of the CWA [33 U.S.C. 1326(a)], state-established thermal effluent limitations in the NPDES permit may be modified to a less stringent level if it can be shown that the less stringent level (i.e., higher temperatures) is sufficient to "ensure the protection and propagation of a balanced, indigenous population of shellfish, fish, and wildlife" (Bugbee 1978). The regulatory agency's decision to allow alternative thermal discharge limitations is based on the utility's 316(a) demonstration, which may present considerable information about the actual or projected thermal impacts of the power plant discharge. Like the NPDES permit, the 316(a) "variance" must be renewed every 5 years, and the applicant must provide evidence to the permitting agency as to why the variance is still appropriate. A 316(a) determination is not necessary for those power plants that are able to meet state water temperature standards; this is the case for many nuclear power plants that use closed-cycle cooling systems (Appendix F). However, a biological assessment/study, similar to that which would be required by 316(a), may be required to ensure that the mixing zone meets water quality standards [Charles H. Kaplan, letter to G. F. Cada, Oak Ridge National Laboratory (ORNL), Oak Ridge, Tennessee November 19, 1990].

Section 316(b) of the CWA [33 USC 1326(b)] requires that "the location, design, construction, and capacity of cooling water intake structures reflect the best technology available for minimizing adverse environmental impact." Like NPDES permits and 316(a) determinations, 316(b) determinations are made by EPA or a state permitting agency based on data supplied in the applicant's 316(b) demonstration. The 316(b) determination need not be separated from the NPDES process. Although 316(b) determinations are usually one-time judgments that are not periodically reconsidered, a determination under CWA Section 316(b) is not permanently binding. Where circumstances have changed (e.g., fish population has changed, the initial determination was deemed inappropriate, or some adjustment in the operation of the intake structure is warranted), a full 316(b) demonstration could again be required by EPA during the license period.

The 316(a) and (b) demonstrations provide EPA (or a designated state permitting agency) a means for considering condenser cooling system effects on aquatic biota, not just on water quality per se. Other federal and state agencies with responsibilities for aquatic resources [e.g., the U.S. Fish and Wildlife Service (FWS), the National Marine Fisheries Service (NMFS), state fish and wildlife agencies] do not issue permits but are consulted in the development of NPDES permits and Section 316 determinations.

Under Section 401 of the CWA (33 USC 1341), an applicant for a federal license or permit (the utility in this case) must obtain a state water quality certification (i.e., the state must certify that the applicant's discharges will comply with state water quality standards). This requirement would apply, for example, to U.S. Army Corps of Engineers Section 404 permits for the disposal of dredged and fill material and to EPA-issued NPDES permits. Of course, issuance of an NPDES permit by a state water quality agency implies certification under Section 401.

Any pesticide must be registered under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) (7 USC 136 et seq.); this includes the various chlorine compounds, bromine compounds, and molluscicides used to control biofouling in power plants. Registration requires development of toxicity data. Under FIFRA, no one can use a biocide except in accordance with labeled instructions. Information about toxicity developed by the biocide manufacturer as a FIFRA requirement may be used to determine permissible power plant discharge concentrations for the NPDES permit.

Other potential aquatic resource issues are the subjects of particular legislation or executive orders (EOs) with specific requirements that cannot be limited or eliminated. For example, potential effects of plant modifications on floodplains and wetlands must be considered under EOs 11988 and 11990, respectively. Modifications that entail disposal of dredged material may require a permit from the U.S. Army Corps of Engineers under Section 404 of CWA (Pub. L. 92-500). Because the impacts could range from small to large depending on the details of the site and the proposed construction, the potential effect on floodplains or wetlands is a Category 2 issue.

4.2.1.2 Water Quality/Hydrology

The continued operation of once-through condenser cooling systems will allow continuation of associated hydrologic changes, including altered current patterns at intake and discharge structures, altered salinity gradients, and altered thermal stratification of lakes. Water quality effects considered in this section include temperature effects on sediment transport capacity, scouring, eutrophication, and the discharge of biocides, sanitary wastes, and heavy metals.

4.2.1.2.1 Current Patterns

Operation of the cooling system usually causes changes in water currents in the immediate vicinity of both the intake and the outfall. The extent of the changes depends on the design and siting of the intake and discharge and the nature of the body of water (Langford 1983). Because many nuclear plants are located on large rivers, lakes, reservoirs or on the seacoast, such localized altered current patterns are minor. However, plants sited near small bodies of water may have marked effects on current patterns. Operation of the cooling water system of Oyster Creek Nuclear Generating Station (NGS) changed the flows of the lower portions of Oyster Creek and South Branch Forked River from alternating flows typical of estuarine streams to unidirectional flows with constant salinity. The South Branch Forked River became an intake canal, with salt water continuously moving upstream toward the power plant. Oyster Creek, on the other hand, became a discharge canal, with heated salt water moving continuously away from the plant. Although substantial changes to the hydrology and water quality of these small streams have been documented, there have been only minor effects on nearby Barnegat Bay (Kennish et al. 1984). Changes to current patterns are of small significance if they are localized near the intake and discharge of the power plant and do not alter water use or hydrology in the wider area. Because once-through power plants are located near substantial bodies of water that are not subject to extreme changes in volume or flow rate, cooling water withdrawals and discharges do not have major effects on the hydrology of these large bodies of water. Impacts during the license renewal period are expected to be of small significance for all plants. Localized effects on current patterns would have been manifested during the initial stages of plant operation and would have been mitigated if necessary at that time. Based on a review of the published literature and operational monitoring reports, operation of the cooling system is expected to cause only small, localized changes to current patterns near the power plant and would not contribute to the cumulative impacts. Further, consultation with the utilities and regulatory agencies during preparation of the draft GEIS, as well as their comments on the draft GEIS, revealed no concerns about the individual or cumulative impacts of cooling system operations on current patterns. The impacts of altered current patterns will continue to be localized and of small significance. No change in operation of the cooling system is expected during the license renewal term, so no change in effects on current patterns is anticipated. The effects on current patterns could be reduced by changing to a closed-cycle cooling system or by reducing the plants' generation rate. However, these measures would be costly and are not reasonable in light of the small benefits that might be gained from their implementation. Hence, no additional mitigation measures to reduce the impact of cooling system operations on current patterns are necessary in the renewal period. For these reasons, the effect of once-through cooling system operation on current patterns is a Category 1 issue.

4.2.1.2.2 Salinity Gradients

Power plants operating near estuaries can also alter salinity gradients. As noted, the Oyster Creek NGS cooling system converted two brackish creeks to canals with unidirectional flows and increased salinity to an average of 17 parts per thousand, similar to Barnegat Bay (Tatham et al. 1978). The two creeks have become hydrologic extensions of the bay because of operation of the power plant, causing significant changes in the original water quality and aquatic communities in the creeks because water quality is now essentially the same as that of the bay

(Chizmadia et al. 1984). Effects do not appear to extend beyond these creeks, which are also affected by dredging and thermal and chemical discharges.

Chesapeake Bay has a large number of power plants (mostly fossil-fueled) within the mesohaline (estuarine) zone. The fact that power plant discharges can alter salinity regimes, which in turn can change the type and abundance of aquatic organisms at the discharge site, is considered in the development of NPDES permits for Maryland power plants (MDNR 1988). Although natural salinity patterns have been altered by the discharge of Chalk Point (a large fossil-fueled power plant) into a shallow mesohaline area of Chesapeake Bay, other plants in the area, including the Calvert Cliffs Nuclear Power Plant, have not had consistent discharge effects on salinity (MDNR 1988). Any localized effects on biota near these Maryland power plants are attributed to thermal and habitat changes, rather than to salinity. Changes to salinity gradients are of small significance if they are localized near the intake and discharge of the power plant and are within the normal tidal or seasonal movements of salinity gradients that characterize estuaries. Based on a review of the published literature and operational monitoring reports, operation of the cooling system is expected to cause only small, localized changes to salinity gradients near the power plant. Further, consultation with the utilities and regulatory agencies during preparation of the draft GEIS, as well as their comments on the draft GEIS, revealed no concerns about the individual or cumulative impacts of cooling system operations on salinity gradients. These organizations did not identify a need for additional mitigation of impacts associated with this issue. For example, operation of numerous once-through power plants in the Chesapeake Bay estuary has not caused significant changes in salinity gradients. The effects on salinity gradients could be reduced by changing to a closed-cycle cooling system or by reducing the plants' generation rate. However, these measures would be costly and are not reasonable in light of the small benefits that might be gained from their implementation. Hence, no additional mitigation measures to reduce the impact of cooling system operations on salinity gradients are necessary in the renewal period. For these reasons, the effects of once-through cooling system operation on salinity gradients are a Category 1 issue.

4.2.1.2.3 Thermal Effects

Discharges of heated effluents have the potential to affect water quality in five ways: (1) water temperature increases, including altered thermal stratification of lakes, (2) temperature effects on sediment transport capacity, (3) scouring, (4) lowered dissolved oxygen concentrations, and (5) eutrophication. Heated water discharges tend to remain at (or move toward) the surface of lakes and rivers. These discharges form a plume of warm water that dissipates with distance from the source by rejecting heat to the atmosphere or mixing with cooler ambient waters. Mixing tends to occur more rapidly in rivers than in lakes because of increased turbulence. Also because of turbulence, rivers do not naturally thermally stratify; as a result, alteration of temperature stratification in rivers by nuclear power plants is not an issue. Impacts of thermal discharges to water quality are of small significance if discharges are within thermal effluent limitations designed to ensure protection of water quality and if ongoing discharges have not resulted in adverse effects on the five attributes of water quality identified above.

Temperature-induced density stratification of lakes and reservoirs is a principal regulator of water quality and organism distribution in deep waters. Thermal stratification can be changed in two general ways by once-through cooling of power plants: by the discharge of heated water and by the altered circulation patterns generated by pumping cooling water into and out of the power station (Coutant 1981). Temperature elevation can intensify stratification (through surface discharge of heated water), whereas enhanced circulation may break down stratification. The relative importance of these two counteracting processes depends on the characteristics of the site and cooling system.

Destratification can increase dissolved oxygen concentrations in deeper waters and decrease the solubility of phosphorus (which contributes to eutrophication), and may be a net benefit to warm-water fisheries by expanding available habitat. For example, Larimore and McNurney compared two nearby lakes in Illinois—Lake Shelbyville, an unheated flood control reservoir, and Lake Sangchris, a cooling lake for a coal-fired power plant. In contrast with the unheated lake, Lake Sangchris did not stratify in the summer. Furthermore, largemouth bass had a longer growing season and greater annual growth in the cooling lake.

On the other hand, Coutant (1981) noted that the common practice of using cool hypolimnetic water from deep intakes for power station cooling, with surface discharge, may increase the size of the warm epilimnion and decrease the amount of habitat available to cool-water fish. For example, thermal discharges from the Oconee Nuclear Station have increased the annual heat load of Keowee Reservoir by one-third and lowered the thermocline (boundary between warm surface waters and cool bottom waters) from between 5 and 15 m to as low as 27 m (Oliver and Hudson 1987), although neither specified thermal limits nor lethal temperatures were exceeded [Oliver and Hudson 1987; Duke Power Company response to NUMARC survey (NUMARC 1990)].

The McGuire Nuclear Station withdraws cool hypolimnetic water from Lake Norman and discharges the heated water at the surface. As with Oconee, this has the effect of increasing the size of the upper layer of warm water and decreasing the habitat available for cool-water fishes (e.g., striped bass) in the hypolimnion of Lake Norman. Temperature modeling indicated that increasing the maximum upper discharge temperature from 95 to 99°F during July, August, and September would conserve cool-water fish habitat in the lake by allowing smaller withdrawal rates of hypolimnetic waters and would lower the average heat content of the lake by allowing more heat to be dissipated to the atmosphere from the warmer localized area (Duke Power Company 1988; Lewis 1990). The increased thermal limit is not expected to substantially affect water quality or aquatic biota in the mixing zone. Following consultation with the North Carolina Department of Health and Natural Resources, the NPDES permit has been modified to allow the higher temperatures [Duke Power Company response to NUMARC survey (NUMARC 1990)]. Modeling reservoir heat budgets allows effects of thermal discharges on stratification to be predicted and used by utilities and regulatory agencies to develop the best heat dissipation scheme. Altered thermal stratification has never been a problem at most plants. At other plants (i.e., McGuire and Oconee), the issue has been periodically re-examined during the initial license period and mitigated as needed by adjusting thermal discharges.

The effects of altered thermal stratification on water quality and distribution of aquatic organisms are monitored during plant operation and are mitigated if necessary through the NPDES permit renewal process. Based on a review of the published literature and operational monitoring reports, operation of the cooling system has not altered thermal stratification at most power plants with once-through cooling systems. At the small number of plants where changes in thermal stratification have occurred, monitoring and modeling studies have been used to adjust the thermal discharges, thereby mitigating adverse impacts. As appropriate, these models take into account other thermal inputs to the receiving waterbody and therefore consider cumulative as well as individual plant effects. Consultation with the utilities and regulatory agencies during preparation of the draft GEIS, as well as their comments on the draft GEIS, revealed no concerns about the individual or cumulative impacts of cooling system operations on thermal stratification. The impacts of altered thermal stratification will continue to be of small significance. No change in operation of the cooling system is expected during the license renewal term, so no change in effects on thermal stratification is anticipated. The effects of thermal stratification could be reduced by changing to a closed-cycle cooling system or by reducing the plants' generation rate. However, these measures would be costly and are not reasonable in light of the small benefits that might be gained from their implementation. Hence, no additional mitigation measures to reduce the impact of cooling system operations on thermal stratification are necessary in the renewal period. For these reasons, the effects of once-through cooling system operation on thermal stratification are a Category 1 issue.

Increased temperature and the resulting decreased viscosity have been hypothesized to change the sediment transport capacity of water, leading to potential sedimentation problems, altered turbidity of rivers, and changes in riverbed configuration. Coutant (1981) discussed the theoretical basis for such possible changes, as well as relevant field investigations, and concluded that there is no indication that this is a significant problem at operating power stations. Examples of altered sediment characteristics are more likely the result of power plant structures (e.g., jetties or canals) or current patterns near intakes and discharges; such alterations are readily mitigated.

Based on review of literature and operational monitoring reports, consultations with utilities and regulatory agencies, and comments on the draft GEIS, there is no evidence that temperature effects on sediment transport capacity have caused adverse environmental effects at any existing nuclear power plant. Regulatory agencies have expressed no concerns regarding the cumulative impacts of temperature effects on sediment transport capacity. Furthermore, because of the small area near the plant affected by increased water temperature, it is not expected that plant operations would have a significant contribution to cumulative impacts. Effects are considered to be of small significance for all plants. No change in the operation of the cooling system is expected during the license renewal term so no change in effects on sediment transport capacity is anticipated. Effects on sediment transport could be reduced by changing to a closed-cycle cooling system or by reducing the plants' generation rate. However, because the effects on sediment transport capacity are considered to be impacts of small significance and because these measures would be costly, the staff does not consider the implementation of these potential mitigation measures to be warranted. This is a Category 1 issue.

Cooling water discharges have the potential for scouring sediments, especially near high-velocity discharge structures, and for changing patterns of sediment deposition. Changes in sediment composition have been observed near operating power plants; for example, the Calvert Cliffs Nuclear Power Plant (MDNR), the Haddam Neck (Connecticut Yankee) Plant (Merriman and Thorpe), and the San Onofre Nuclear Generating Station (MRC). Fine-grained materials near the power plant discharge structure may become suspended by the discharge plume, resulting in localized increases in turbidity and a coarser-grained composition of sediments near the discharge. Depending on site-specific circumstances, changes in sediment composition near the power plant discharge may be regarded as adverse (shading of kelp beds; MRC), beneficial (enhancement of the productivity of benthic animals; MDNR), or inconsequential (Merriman and Thorpe). In all cases, sediment changes are localized.

Review of literature and operational monitoring reports, consultation with utilities and regulatory agencies, and comments on the draft GEIS confirm that sediment scouring has not been a problem at most power plants and has caused only minor localized effects at three plants. The impacts of sediment scouring will continue to be localized and of small significance. Contributions to cumulative impacts are not expected because of the small area near the power plant affected by higher velocity cooling water discharges, and no concerns about cumulative impacts were expressed by the regulatory agencies. The effects of sediment scouring could be reduced by changing to a closed-cycle cooling system or by reducing the plants' generation rate. However, these measures would be costly and are not reasonable in light of the small benefits that might be gained from their implementation. Hence, no additional mitigation measures to reduce sediment scouring effects are necessary in the renewal period. Sediment scouring due to discharge of condenser cooling water is a Category 1 issue.

An early concern about thermal discharges from power plants was that the heat would stimulate biological productivity and speed the process of eutrophication of natural waters. Coutant (1981) examined the evidence for such changes and concluded that, because enhanced mineralization of organic matter by bacteria would offset any thermally induced increases in organic production, significant eutrophication from direct thermal effects at most plants was unlikely. On the other hand, Coutant (1981) hypothesized that power plants that withdraw hypolimnetic water from stratified reservoirs and discharge heated effluents at the surface may (1) lengthen the growing season and (2) transfer previously unavailable nutrients from bottom waters to the surface. A longer growing season and more nutrients in the surface layer could result in more biological production and more organic matter that would settle into the hypolimnion and thus decay and consume oxygen; all of these are symptoms of eutrophication. This chain of events is most likely to be seen in small lakes that were oligotrophic (relatively unproductive) and supported hypolimnetic fisheries. Long-term monitoring of the McGuire Nuclear Station on such a reservoir indicates that operations have not resulted in increased eutrophication (NPDES No. NC0024392, 1988; NPDES No. NC0024392, 1990). Similarly, the operation of Oconee Nuclear Station does not appear to be causing eutrophication in Lake Keowee; long-term studies indicate that nutrient levels in the lake are low and appear to be declining [Duke Power Company, response to NUMARC survey (NUMARC 1990)]. Review of literature and operational monitoring reports, consultation with utilities and regulatory agencies, and review of comments on the draft GEIS indicate that power-plant-induced eutrophication has not been a problem at any existing nuclear power plant. Monitoring studies have not revealed cumulative impacts, and no concerns about nuclear power plants contributing to eutrophication in a cumulative way were expressed by the regulatory agencies. Effects are considered to be of small significance for all plants. No change in operation of the cooling system is expected during the license renewal term, so no change in the effects on eutrophification is anticipated. The eutrophication effects could be reduced by changing to a closed-cycle cooling system or by reducing the plants' generation rate. However, these measures would be costly and are not reasonable in light of the small benefits that might be gained from their implementation. Hence, no additional mitigation measures to reduce eutrophication effects are necessary in the renewal period. Accelerated eutrophication due to discharge of condenser cooling water is a Category 1 issue.

4.2.1.2.4 Chemical Effects

Some of the water quality issues that have been raised are potential chemical effects resulting from discharges of chlorine or other biocides, small-volume discharges of sanitary and other liquid wastes (Chapter 2), chemical spills, and heavy metals leached from cooling system piping and condenser tubing. Impacts of chemical discharges to water quality are considered to be of small significance if discharges are within effluent limitations designed to ensure protection of water quality and if ongoing discharges have not resulted in adverse effects on aquatic biota.

The discharged chemicals, including chlorine and other biocides, are regulated by the NPDES permit of each nuclear power plant. Regulatory concern about toxic effects of chlorine and its combination products, as well as operating experience with control of biofouling, has led many plants to eliminate the use of chlorine or reduce the amount used below those levels that were originally anticipated in the environmental statements associated with issuing the construction permit and operating license. Some power plants use mechanical cleaning methods or, because of the abrasive properties of particulates in the intake water, do not have to clean the condenser cooling system at all. Other plants chlorinate the condenser cooling or service water systems but can isolate certain portions for treatment (e.g., a single unit of a multi-unit plant), thereby allowing dilution to reduce the concentration of chlorine in the discharge. Because of these refinements and the process for modifying NPDES permit conditions as needed, water quality degradation from existing biocide usage at once-through nuclear power plants is not a concern among the regulatory and resource agencies consulted for this GEIS. Based on review of literature and operational monitoring reports, consultations with utilities and regulatory agencies, and comments on the draft GEIS, water quality effects of discharge of chlorine and other biocides are considered to be of small significance for all plants. Small quantities of biocides are readily dissipated and/or chemically altered in the receiving waterbody so that significant cumulative impacts to water quality would not be expected. No change in operation of the cooling system is expected during the license renewal term, so no change in the effects of biocide discharges on receiving water quality is anticipated. Effects of biocide discharges could be reduced by increasing the degree of discharge water treatment, reducing the concentration of biocides, or by treating only a portion of the plants' cooling and service water systems at one time. However, because the effects of biocide discharges on water quality are considered to be impacts of small significance, the staff does not consider the implementation of these potential mitigation measures to be warranted. Discharge of chlorine and other biocides is a Category 1 issue. Discharges of sanitary wastes are regulated by NPDES permit, and discharges that do not violate the permit limits are of small significance.

Minor chemical spills or temporary off-specification discharges from sanitary waste treatment systems and other low-volume effluents (e.g., excessive coliform counts or total suspended solids levels, pH outside of permitted range) were cited as common NPDES permit violations in the utility responses to the NUMARC survey (NUMARC 1990). Such NPDES noncompliances have been variable, random in occurrence, and readily amenable to correction. These minor discharges or spills do not constitute widespread, consistent water quality impacts. Water quality effects of minor chemical discharges and spills are of small significance and do not have significant effects on aquatic biota for all plants and have been mitigated as needed. Significant cumulative impacts to water quality would not be expected because the small amounts of chemicals released by these minor discharges or spills are readily dissipated in the receiving waterbody. Spills and off-specification discharges occur seldom enough that regulatory agencies express no concern about them for operating nuclear power plants. While there may be additional management practices or discharge control devices that could further reduce the frequency of accidental spills and off-specification discharges, they are not warranted because impacts are already small and occur at low frequency and because such mitigation would be costly. The water quality impacts of permitted sanitary waste water and minor, nonradiological chemical discharges and spills are a Category 1 issue.

Heavy metals (e.g., copper, zinc, chromium) may be leached from condenser tubing and other heat exchangers and discharged by power plants as small-volume waste streams or corrosion products. Although all are found in small quantities in natural waters (and many are essential micronutrients), concentrations in the power plant discharge are controlled in the NPDES permit because excessive concentrations of heavy metals can be toxic to aquatic organisms. Discharge of metals and other toxic contaminants may also be subject to individual control strategies developed by the states to control toxic pollutants under the 1987 Amendments to the CWA. These strategies for point source discharges of toxic pollutants are implemented through the NPDES permit program. Langford reviewed the literature concerning heavy metal discharges from power plants and concluded that, during normal operations, concentrations generally are below the levels of detection. However, plant shutdowns for testing and refueling keep stagnant water in contact with condenser tubes and other metal structures for extended periods and could allow abnormally large amounts of metals to be leached. For example, Harrison et al. (DOE/ER-0317) detected elevated copper concentrations in the discharge during startup of Diablo Canyon Nuclear Power Station. Abalone deaths in the discharge area of the Diablo Canyon were attributed to high copper concentrations in the effluent following a shutdown period (Martin et al. 1977).

The ability of aquatic organisms to bioaccumulate heavy metals even at low concentrations has led to concerns about toxicity both to the biota and to humans that consume contaminated fish and shellfish. For example, bioconcentration of copper discharged from the Chalk Point Plant (a fossil-fuel power plant on Chesapeake Bay) resulted in oyster "greening" (Roosenburg 1969). Bioaccumulation of copper released from the H. B. Robinson Plant resulted in malformations and decreased reproductive capacity among bluegill in the cooling reservoir (ASTM STP 854); see Section 4.4.3. In all three of these examples of excessive accumulation of copper (Diablo Canyon, Chalk Point, and H. B. Robinson), replacement of the copper alloy condenser tubes with another material (e.g., titanium) eliminated the problem.

Concentrations of heavy metals in the discharges of once-through nuclear power plants are normally within NPDES permit limits and are quickly diluted or flushed from the area by the large volumes of the receiving water. Discharge of metals and other toxic contaminants may also be subject to individual control strategies developed by the states to control toxic pollutants under the 1987 Amendments to the CWA. These strategies for point source discharges of toxic pollutants are implemented through the NPDES permit program. Excessive discharges of metals have been corrected at the two nuclear power plants (Diablo Canyon and H. B. Robinson) that experienced problems during the original license period. Impacts of heavy metal discharges are considered to be of small significance if water quality criteria (e.g., NPDES permits) are not violated and if aquatic organisms in the vicinity of the plant are not bioaccumulating the metals. Based on review of literature and operational monitoring reports, consultations with utilities and regulatory agencies, and comments on the draft GEIS, discharge of heavy metals leached from the condenser cooling system has been a problem at only Diablo Canyon and H. B.Robinson nuclear power plants, and mitigation was effective in both cases. Although cumulative impacts could result from the long-term accumulation and bioaccumulation of heavy metals, mitigation for individual plant effects has also reduced the potential for contributions to cumulative effects. Monitoring has not revealed a continuing problem with accumulation of heavy metals. No change in operation of the cooling system is expected during the license renewal term, so no change in metal concentrations in the cooling water discharge is anticipated. Effects of elevted metal concentrations could be reduced by replacing condenser tubes with alloys that are less likely to corrode. However, because the effects of metal concentrations on cooling water discharges are considered to be impacts of small significance and because the potential mitigation measures would be costly, the staff does not consider the implementation of these potential mitigation measures to be warranted. Elevated heavy metal concentrations in the condenser cooling water discharge is a Category 1 issue.

4.2.1.3 Water Use/Water Availability

Water use in the United States, as measured by freshwater withdrawals in 1985, averaged 15 million m^3/s (338 billion gal/day) (Carr et al. 1990). Four million m^3/s (ninety-two billion gal/day), or 27 percent of the water withdrawn, was consumed (e.g., by evaporation) and thus was not directly returned to the body of water. The remainder of the withdrawals (73 percent) was return flow available for reuse. In 1985, freshwater withdrawals by steam-electric power plants were approximately 5.7 million m^3/s (132 billion gal/day), which was 39 percent of the total freshwater withdrawals for all uses (Carr et al. 1990). About 2.4 million m^3/s (56 billion gal/day) of saline water was used for cooling by thermoelectric plants in coastal areas. Nuclear power plants accounted for 22 percent of the total thermoelectric withdrawals and fossil-fueled plants for 78 percent.

Consumptive uses remove the water from a stream or river and may or may not impact in-stream and off-stream beneficial uses. Return flows that are discharged to a stream are available to other users; freshwater withdrawals discharged to an estuary are effectively lost to further freshwater use (Carr et al. 1990). On the average, out of 0.4 m^3 (100 gal) withdrawn from surface waters for cooling of steam electric utilities, over 0.37 m^3 (98 gal) is returned almost immediately to the source body of water; less than 0.008 m^3 (2 gal) is consumed through evaporation (Solley et al. 1983). The consumptive loss for once-through cooling systems [0.5 m^3/s (18 ft^3/s) per 1000 MW(e)] is somewhat smaller than that attributed to cooling tower evaporation, which has been estimated to average 0.9 m^3/s (30 ft^3/second) per 1000 MW(e) (Giusti and Meyer 1978).

In those areas experiencing water availability problems, nuclear plant consumption may conflict with either existing or potential downstream municipal water use as well as with in-stream water uses. A shift in human population distribution and associated changes in demand for water could have important implications for the continued supply of cooling water for power generating facilities.

Impacts of power plant water use are considered to be of small significance since conflicts with other offstream or instream water users have not occurred and are not anticipated. The nuclear power plants that use once-through condenser cooling systems are located on large lakes, reservoirs, estuaries, oceans, and rivers, and—except possibly during extended periods of drought—are unlikely to experience problems with the water supply. Because net water consumption by facilities using once-through cooling is negligible compared with the size of the body of water, such plants should have only a limited potential for impacts on water availability for downstream use. Should water-use conflicts arise during operation of existing power plants, local officials who are responsible for allocating water resources would have to weigh the use of water for power generation. Based on review of literature and operational monitoring reports, consultations with utilities and regulatory agencies, and comments on the draft GEIS, water use conflicts are found to be of small significance for all plants and cumulative impacts are not of concern. Net water consumption by facilities using once-through cooling is negligible compared with the size of the body of water. Because of abundant water supply, consumptive water use will have impacts of only small significance on riparian plant and animal communities at sites that use once-through cooling systems. No change in operation of the cooling system is expected during the license renewal term, so no change in effects on consumptive water use or riparian communities is anticipated. Effects on consumptive water use and riparian communities could be reduced by changing to a closed cycle cooling system or by reducing the plant's generation rate. However, because such changes would be costly, and because the effects on consumptive water use and riparian communities are of small significance, the staff does not consider the implementation of these potential mitigation measures to be warranted in light of the small benefit that might be gained. Both of these are Category 1 issues.

4.2.2 Aquatic Ecology

As noted in Section 4.2.1, large amounts of water are withdrawn by once-through cooling systems, passed through the condenser tubes, and discharged back to the body of water with an added load of heat and chemical contaminants. A total of 70 nuclear plants use once-through cooling (see Table 2.2). Initial concerns about effects of thermal effluents on aquatic biota (e.g., Krenkel and Parker 1969) were soon accompanied by concerns about impacts of biocide discharges and losses due to intake effects (i.e., impingement and entrainment). All of these issues have received considerable attention and study from utility and regulatory agency scientists in the past two decades, as exemplified by the numerous books and symposia devoted to resolving them (CONF-750425; Saila 1975; Schubel and Marcy 1978; Jensen 1978, 1981; Barnthouse and Van Winkle 1988). The aquatic resources issues that are considered in this section are entrainment (of fish, shellfish, phytoplankton, and zooplankton), impingement of fish and shellfish, thermal effects (heat shock, cold shock, thermal plume barrier to migratory fish, premature emergence of aquatic insects, enhanced susceptibility to parasitism and disease, stimulation of nuisance organisms, gas bubble disease, lower dissolved oxygen), and chemical effects (biocides and accumulation of contaminants in biota).

The following sections review the past and ongoing impacts on aquatic biota of operation of once-through condenser cooling systems. Any ongoing impacts will probably continue throughout the license renewal term because the cooling system design and operation is not expected to change for most plants. Judgments about the significance of these issues during the license renewal term are based on published information, agency consultation, and information provided by the utilities (Appendix F). These sources represent every nuclear power plant in the United States. In addition, seven case studies (Arkansas, McGuire, Cook, San Onofre, Crystal River, and combined effects of power plants on Lake Michigan and the Hudson River) were evaluated in greater detail. These case studies are examples of large once-through condenser cooling systems that affect a variety of aquatic environments (i.e., large lakes and reservoirs, oceans, and estuaries). Published information about these plants was reviewed to determine whether operation has resulted in demonstrable entrainment, impingement, or thermal impacts. For some of the case studies in Appendix F, cumulative effects of the operation of nuclear power plants in conjunction with other sources of stress to aquatic resources are considered.

4.2.2.1 Analysis of Issues

4.2.2.1.1 Entrainment of Phytoplankton and Zooplankton

As discussed in Section 2.3.5, water that is withdrawn for power plant cooling carries with it a variety of aquatic organisms. Those organisms that are small enough to pass through the debris screens in the intake pass through the entire cooling system and are exposed to heat, mechanical and pressure stresses, and possibly biocides before being discharged to the receiving water. This process, called entrainment, may affect phytoplankton, zooplankton, planktonic larval stages of benthic organisms such as shellfish (i.e., meroplankton), and fish eggs and larvae (ichthyoplankton). Most nuclear power plants have been required to monitor for entrainment effects during the initial years of operation. Entrainment impacts to phytoplankton and zooplankton are considered to be of small significance if there is no evidence of reductions of populations of phytoplankton or zooplankton.

Studies of the effects of entrainment at several nuclear power plants are reviewed in Appendix F. None of the agencies consulted expressed concern about entrainment of phytoplankton or zooplankton (Appendix F). Because of large numbers and short regeneration times of phytoplankton and zooplankton, impacts of entrainment on these organisms have rarely been documented outside the immediate vicinity of the plant and are considered to be of little consequence (Schubel and Marcy 1978; Hesse et al. 1982; Kennish et al. 1984; MDNR 1988; MRC 1989; EPRI EA-1038).

The effects of entrainment at nuclear plants are not expected to cause or contribute to cumulative impacts to populations of zooplankton or phytoplankton. The effects of phytoplankton and zooplankton entrainment are localized (i.e., the affected areas are smaller than the distances between power plants) and are not expected to contribute to cumulative impacts because generation times of plankton are rapid. Review of the literature and operational monitoring reports did not reveal evidence of cumulative impacts from entrainment of phytoplankton and zooplankton. Further, consultation with utilities and agencies during preparation of the draft GEIS, as well as their comments on the draft GEIS (NUREG-1529), revealed no concerns about cumulative impacts of phytoplankton and zooplankton entrainment.

Reviews of the literature, monitoring reports, and consultation with agencies and utilities did not reveal any evidence of mitigation measures that had been required to correct problems with entrainment of phytoplankton and zooplankton. Because cooling system operations are not expected to change during the license renewal term, additional mitigation is not expected to be warranted.

Entrainment of phytoplankton and zooplankton is expected to have a small impact on populations of these organisms in the source body of water at any plant. No change in operation of the cooling system is expected during the license renewal term, so no change in effects on entrainment of phytoplankton and zooplankton is anticipated. Effects on entrainment of phytoplankton and zooplankton could be reduced by changing to a closed cycle cooling system or by reducing the plant's generation rate. However, because the effects on entrainment of phytoplankton and zooplankton are considered to be impacts of small significance and because they would be costly to implement, the staff does not consider the implementation of these potential mitigation measures to be warranted. This is a Category 1 issue.

4.2.2.1.2 Entrainment of Fish and Shellfish

The effects of entrainment on aquatic resources were considered by NRC at the time of original licensing and are periodically reconsidered by EPA or state water quality permitting agencies in the development of NPDES permits and 316(b) demonstrations (Section 4.2.1.1.2). Although significant adverse entrainment effects have not been demonstrated at most facilities, the entrainment of fish and shellfish in early life stages remains an issue at some nuclear power plants with once-through cooling systems. Agencies consulted for this GEIS expressed concerns about the impacts of entrainment at Zion, Salem, Oyster Creek, Indian Point, Calvert Cliffs, Millstone, Yankee Rowe, and Surry. Several licensed nuclear power plants (e.g., Indian Point, Oyster Creek, Comanche Peak, Salem, and Zion) have unresolved 316(b) determinations. At some power plants, fish populations have been restored in the years since issuance of the original license and, as a result, more fish are now susceptible to entrainment. At other nuclear power plants (Beaver Valley, Susquehanna, Three Mile Island, and Peach Bottom), an agency expressed concern about future entrainment during the license renewal period as restoration efforts continue to increase fish populations (James Gillett, Deputy Regional Director, U.S. Fish and Wildlife Service, letter to G. F. Cada, ORNL, Oak Ridge, Tennessee, July 27, 1990).

The impacts of fish and shellfish entrainment are small at many plants, but they may be moderate or even large at a few plants with once-through cooling systems. Further, ongoing restoration efforts may increase the numbers of fish susceptible to intake effects during the license renewal period, so that entrainment studies conducted in support of the original license may no longer be valid. For these reasons, the entrainment of fish and shellfish is a Category 2 issue for plants with once-through cooling systems.

4.2.2.1.3 Impingement of Fish and Shellfish

Aquatic organisms that are drawn into the intake with the cooling water and are too large to pass through the debris screens may be impinged against the screens. Mortality of fish that are impinged is high at many plants because impinged organisms are eventually suffocated by being held against the screen mesh or are abraded, which can result in fatal infection. Impingement can affect large numbers of fish and invertebrates (crabs, shrimp, jellyfish, etc.). As with entrainment, operational monitoring and mitigative measures have allayed concerns about population-level effects at most plants, but impingement mortality continues to be an issue at others. Consultation with resource agencies (Appendix F) revealed that impingement is a frequent concern at once-through power plants, particularly where restoration of anadromous fish may be affected. In several cases, such as Oyster Creek, Salem, Surry, and Prairie Island, significant modifications were made to the intake structure to substantially reduce mortality due to impingement. Impingement is an intake-related effect that is considered by EPA or state water quality permitting agencies in the development of NPDES permits and 316(b) determinations. Appendix F examines studies of the effects of impingement of fish at several nuclear power plants. The impacts of impingement are small at many plants but may be moderate or even large at a few plants with once-through cooling systems. For this reason, the impingement of fish and shellfish is a Category 2 issue.

4.2.2.1.4 Thermal Discharge Effects

The heated effluents of steam-electric power plants can cause mortality among fish and other aquatic organisms from either thermal discharge effects or cold shock. Temperatures high enough to kill organisms are found in the cooling water systems, often in the area nearest the effluent discharge structure. Because thermal effects were among the earliest potential impacts identified for power plant operation, a great deal of research and regulatory effort has been aimed at understanding and controlling thermal discharges. Upper lethal temperatures (and various other expressions of temperature tolerance) have been determined for many important species and life stages. As a result, conditions that can lead to thermal discharge effects are relatively predictable.

Mitigative measures have been employed at many power plants to reduce the potential for thermal discharge effects. They can be minimized by lowering effluent temperature before discharge to natural waters (e.g., with cooling ponds) or by enhancing rapid mixing and heat dissipation (through high-velocity jet diffusers).

Each permitting state has developed mixing zone criteria and thermal discharge limits for steam-electric power plants. If the plant meets these criteria, no 316(a) determination is required. If the facility fails to meet the state temperature limits, the facility must submit data demonstrating that the discharge will ensure the protection and propagation of a balanced indigenous population of shellfish, fish, and wildlife [i.e., a 316(a) demonstration]. For plants within the state limits, the implicit assumption is made that a balanced indigenous population is ensured. The NPDES permit required for each power plant contains discharge temperature limits that are based on either state standards or site-specific studies of thermal effects [i.e., 316(a) demonstrations]. Nevertheless, thermal discharges continue to be an issue at some once-through nuclear power plants (see agency consultation, Appendix F). In some cases, the facility is being extensively modified to minimize thermal-discharge-related effects (e.g., installation of cooling towers at Crystal River). In others, the 316(a) determination has not been approved and is now under review. Studies of thermal discharge effects at selected nuclear power plants that employ once-through cooling systems are described in Appendix F.

Based on the research literature, monitoring reports, and agency consultations, the potential for thermal discharges to cause thermal discharge effect mortalities is considered small for most plants. However, impacts may be moderate or even large at a few plants with once-through cooling systems. For example, thermal discharges at the Crystal River Nuclear Plant are considered by the agencies to have damaged the benthic invertebrate and seagrass communities in the effluent mixing zone around the discharge canal; as a result, helper cooling towers have been installed to reduce the discharge temperatures (Appendix F.4.7). Conversely, at other plants it may become advantageous to increase the temperature of the discharge in order to reduce the volume of water pumped through the plants and thereby reduce entrainment and impingement effects (see discussion of San Onofre Nuclear Generating Station in Appendix F.4.6). Because of continuing concerns about thermal discharge effects and the possible need to modify thermal discharges in the future in response to changing environmental conditions, this is a Category 2 issue for plants with once-through cooling systems.

4.2.2.1.5 Cold Shock

Cold shock occurs when organisms that have been acclimated to warm water (e.g., in a discharge canal in winter) are exposed to sudden temperature decreases when artificial heating ceases. Such situations may occur when a single-unit power plant suddenly shuts down in winter (Coutant 1977) or when winds or currents shift a thermal plume that was occupied by fish or benthic invertebrates seeking warm water. As with heat effects, the conditions that can lead to cold shock are relatively well understood—if it is a function of acclimation temperature, final (cold ambient) temperature, and exposure times—and therefore can be mitigated if needed. Cold shock mortalities have occurred, for example, at the Haddam Neck (Connecticut Yankee) plant (S. W. Gorski, letter to G. F. Cada, ORNL, Oak Ridge, Tennessee, July 18, 1990) and at the Prairie Island and Monticello nuclear generating plants (P. M. Bailey, letter to G. F. Cada, ORNL, Oak Ridge, Tennessee, July 3, 1990). Cold-shock mortalities are relatively rare and usually involve small numbers of fish. Population-level effects have not been demonstrated. Where necessary, the discharge structure or the plant operating procedures have been modified to reduce cold-shock effects. Structural modifications could include constructing a barrier to prevent fish from residing in the discharge canal or designing a high-velocity discharge to encourage rapid mixing and to discourage residence in the plume. Operational measures that could be used to reduce the risk of cold shock by gradually reducing the amount of warm water discharged in winter include gradual shutdowns or shutdowns of only one unit of a multi-unit power plant at a time.

Impacts of cold shock are considered to be of small significance if populations of aquatic organisms in the vicinity of the plant are not reduced. Based on review of literature and operational monitoring reports, consultations with utilities and regulatory agencies, and comments on the draft GEIS, cold-shock-related mortalities of aquatic organisms have been a problem at few existing nuclear power plants. Operational and structural mitigation measures have been effective at the plants that experienced cold shock mortalities. Because mitigation has been effective in those few cases where cold shock has been a problem, effects are considered to be of small significance for all plants. Cold shock is not expected to contribute to cumulative impacts because the potential area of impact is so small and because mitigation to prevent cold shock mortalities at individual power plants also reduces the likelihood that thermal discharges would contribute to cumulative effects. No change in operation of the cooling system is expected during the license renewal term, so no change in potential for cold shock is anticipated. Effects of cold shock could be reduced by changing to a closed cycle cooling system or by reducing the plant's generation rate. However, because the effects of cold shock are considered to be impacts of small significance and these changes would be costly, the staff does not consider the implementation of these potential mitigation measures to be warranted. Cold shock is a Category 1 issue.

4.2.2.1.6 Effects of Movements and Distribution of Aquatic Organisms

Heated effluents can affect aquatic populations in more subtle ways by altering their distribution, growth, or movements. Changes in benthic community composition such as losses of seagrass or other macrophytes can alter the habitat available to aquatic animals. Warm water can increase the metabolic rates of aquatic biota, a method often used in aquaculture to achieve high growth and production rates. However, in the absence of adequate food supplies, elevated metabolic rates can lead to a poor condition of the fish inhabiting heated areas.

It had been suggested that thermal plumes could constitute a barrier to migrating fish if the mixing zone covered a substantial area and exceeded the fish avoidance temperatures. However, studies of effects of heated effluents on Columbia River salmon (Nakatani 1969) and anadromous fish in the Chesapeake Bay (e.g, shad and striped bass) (MDNR 1988) have concluded that fish migration routes were not blocked. Most migrating adult American shad move in the lower half of the water column (Witherell and Kynard 1990) and are therefore unlikely to be deterred by a thermal plume at the surface.

Impacts from potential thermal plume barriers are considered to be of small significance if fish migrations are not blocked and populations of aquatic organisms in the vicinity of the plant are not reduced. Based on review of literature and operational monitoring reports, consultations with utilities and regulatory agencies, and comments on the draft GEIS, thermal plume barriers have not been a problem at any existing nuclear power plants. Heat is rapidly dissipated from power plant discharge plumes, so that effects would only be localized and therefore of small significance for all plants. These effects are not expected to contribute to cumulative impacts. No regulatory agency expressed concerns about cumulative impacts to migrations of aquatic organisms. No change in operation of the cooling system is expected during the license reneqal term, so no change in the potential for a thermal plume barrier to migrating fish is anticipated. Effects of a thermal plume barrier to migrating fish could be reduced by changing to a closed cycle cooling system or by reducing the plant's generation rate. However, because the effects of a thermal plume barrier to migrating fish are considered to be impacts of small significance and because the changes would be costly to implement, the staff does not consider the implementation of these potential mitigation measures to be warranted. Thus thermal plume barriers to migrating fish are a Category 1 issue.

The temperature regime of a body of water is an important component of habitat available to aquatic organisms. By altering the temperature regime, heated effluents can increase or decrease the amount of available habitat. For example, the abundance of coldwater species may be constrained near the southern limits of their distribution by thermal power plant effluents because the heated water exceeds the temperature tolerance of the species. By the same token, heated effluents can extend the northern range of warmwater species by providing thermal refuges during the winter. For example, Stauffer et al. found that blue tilapia, a tropical exotic fish species from Africa and southern Asia, were able to survive low winter water temperatures in the Susquehanna River, Pennsylvania, by congregating in thermal effluents. On a larger scale, the effects of global warming on water temperatures and on the distribution and productivity of aquatic organisms is being studied (Regier et al. 1990). At present, heated discharges from power plants influence a relatively small area of the affected bodies of water so that significant changes to the geographic distribution of a species are unlikely.

Impacts of thermal discharges on geographic distribution of aquatic organisms are considered to be of small significance if populations in the overall region are not reduced. Based on review of literature and operational monitoring reports, consultations with utilities and regulatory agencies, and comments on the draft GEIS, thermal discharges have not been shown to constrain the regional geographic distribution of aquatic organisms at any existing nuclear power plants. Localized reductions in coldwater species or increases in warmwater species are possible, but the effects are limited to small areas and have not altered larger geographic distributions. Effects are considered to be of small significance for all plants. Heat is rapidly dissipated from power plant discharge plumes, and heated plumes are small relative to the size of the waterbody. Consequently, effects would only be localized, and cumulative impacts on geographic distribution would not be expected. No regulatory agency expressed concerns about cumulative impacts on geographic distribution of aquatic organisms. No change in operation of the cooling system is expected during the license renewal term, so no change in effects on geographic distribution of aquatic organisms is anticipated. Effects on geographic distribution of aquatic organisms could be reduced by changing to a closed cycle cooling system or by reducing the plant's generation rate. However, because the effects on geographic distribution of aquatic organisms are considered to be impacts of small significance and because these changes would be costly, the staff does not consider the implementation of these potential mitigation measures to be warranted. Effects of localized thermal discharges on geographic distribution of aquatic organisms are a Category 1 issue.

4.2.2.1.7 Premature Emergence of Aquatic Insects

Heated discharges from power plants can impact aquatic insects that inhabit the bottom areas influenced by the thermal plume. Impacts can range from direct mortality (e.g., when lethal temperatures are exceeded) to sublethal effects (e.g., increases in growth rates; decreases in development times; changes in body size and fecundity). Different species have different tolerances for altered temperature regimes, so that the benthic invertebrate community in the discharge area is rarely eliminated; but it may become dominated by a reduced number of taxa that are tolerant of higher temperatures. Because thermal plumes tend to be buoyant, often the bottom area of the receiving body of water that is affected by elevated temperatures is relatively small, and the effects on the benthic invertebrate community are localized.

Premature emergence of aquatic insects can result from heated effluents coming in contact with benthic habitats (e.g., in the discharge canal or along the shoreline near the discharge) and accelerating the development of immature forms. Adult insects emerge from the water before the normal seasonal cycle and may be unable to reproduce. Although this phenomenon has been observed near power plants, the area likely to be affected by thermal effluents would be a small part of the total lake or river bottom area available for production of aquatic insects. In addition, most aquatic insects have adult upstream migration flights that compensate for normal downstream drift of immature stages (Hynes), so that such localized effects on reproduction through this mechanism are inconsequential (Coutant 1981).

Effects of thermal discharges on premature emergence of aquatic insects are considered to be of small significance if changes are localized and populations in the receiving waterbody are not reduced. Based on reviews of literature and operational monitoring reports, consultations with utilities and regulatory agencies, and comments on the draft GEIS, thermal discharges have not been shown to cause reductions in the overall populations of aquatic insects near any existing nuclear power plants. Localized mortalities among heat-intolerant insect species occur in the thermal mixing zone, but the effects are limited to small areas and do not alter insect communities in larger geographic areas. Because heat in the discharged water is readily dissipated to the atmosphere, effects from this and other heated effluents would not be expected to contribute to cumulative impacts. Effects are considered to be of small significance for all plants. No change in operation of the cooling system is expected during the license renewal term, so no change in effects on emergence of aquatic insects is anticipated. Effects on emergence of aquatic insects could be reduced by changing to a closed cycle cooling system or by reducing the plant's generation rate. However, because the effects on emergence of aquatic insects are considered to be impacts of small significance and because these changes would be costly, the staff does not consider the implementation of these potential mitigation measures to be warranted. Effects of thermal discharges on premature emergence of aquatic insects is a Category 1 issue.

4.2.2.1.8 Gas Bubble Disease

Rapid heating of water in the condenser cooling system decreases the solubility and increases saturation levels of dissolved gases. The supersaturation of nitrogen gas has led to incidents of "gas bubble disease" (GBD) in the discharge areas of steam-electric power plants. The mechanisms by which gas supersaturation and GBD occur at steam-electric power plants (as well as under other conditions such as in the tailwaters of hydroelectric power plants) have been described by Wolke et al. Discharge configurations that do not allow rapid mixing of the effluent with the receiving waters may allow organisms to reside in the supersaturated effluent for long periods (Coutant 1981). As a result of equilibrating with the effluent, the tissues of aquatic organisms become supersaturated as well. Eventually, this unstable condition breaks down, and bubbles form inside the animal, most obviously in the fins and the eyeball (Wolke et al.). Fish mortalities generally occur at gas supersaturation levels above 110 to 115 percent (EPA 440/5-86-001).

GBD in the discharge of a steam-electric power plant (the Marshall Steam Station on Lake Norman) was first reported by DeMont and Miller and has been observed at other power plants since that time. GBD at the Pilgrim Nuclear Power Station caused a loss of 43,000 Atlantic menhaden in 1973, and another 5,000 in 1976 [Boston Edison Company, response to NUMARC survey (NUMARC 1990)]. The problem appears to be greatest at power plants that have discharge canals where fish may reside for extended periods of time (i.e., long enough to equilibrate with supersaturated effluents). The reported incidences of GBD at the Waukegan Generating Station (a coal-fired plant on Lake Michigan; Otto), the Marshall Steam Station (a coal-fired plant on Lake Norman; DeMont and Miller), and the Pilgrim Nuclear Power Station all involved fish residing in discharge canals. Ensuring the rapid mixing of effluents with receiving waters (e.g., with a jet diffuser system) appears to prevent GBD mortalities by inhibiting residence in the thermal plume (Lee 1984). Alternatively, measures to prevent residence of fish in discharge canals may be effective. Emplacement of a barrier net to exclude fishes from the Pilgrim discharge canal has prevented GBD mortalities at that plant since 1976 [Boston Edison Company, response to NUMARC survey (NUMARC 1990)]. The GBD problem has been mitigated at the one nuclear power plant where large numbers of fish were affected.

Impacts of GBD are considered to be of small significance if populations of aquatic organisms in the vicinity of the plant are not reduced. Based on review of literature and operational monitoring reports, consultations with utilities and regulatory agencies, and comments on the draft GEIS, GBD-related mortalities of aquatic organisms have not been a problem at most existing nuclear power plants; and operational and structural mitigation measures have been effective at those plants that experienced GBD mortalities during the initial license period. Effects are considered to be of small significance for all plants. Mitigation to prevent GBD mortalities at individual power plants also reduces the likelihood that thermal discharges would contribute to cumulative effects; no regulatory agency expressed concerns about the contribution of existing nuclear plants to cumulative impacts of GBD. No change in operation of the cooling system is expected during the license renewal term, so no change in effects on GBD is anticipated. Effects on GBD could be reduced by changing to a closed cycle cooling system or by reducing the plant's generation rate. However, because the effects on GBD are considered to be impacts of small significance and because such charges would be costly, the staff does not consider the implementation of these potential mitigation measures to be warranted. Gas bubble disease is a Category 1 issue.

4.2.2.1.9 Low Dissolved Oxygen in the Discharge

A power plant may aggravate the biological effects of low dissolved oxygen (DO) concentrations in the source water by adding a heat load to water with preexisting low DO levels. Aquatic biota below the discharge are then stressed by both higher temperatures (which increase the metabolic rate and the need for oxygen) and preexisting suboptimal oxygen levels. Concern about the effects of low DO concentrations in the heated discharge of the Sequoyah Nuclear Plant on downstream mussel beds and sauger reproduction has been expressed by the Tennessee Division of Water Pollution Control (Ann McGregor, Tennessee Division of Water Pollution Control, telephone interview with G. F. Cada, ORNL, Oak Ridge, Tennessee, May 30, 1990). Cool, hypolimnetic water released from Watts Bar reservoir, upstream from the Sequoyah Nuclear Plant, often had low DO concentrations. The temperature of the condenser cooling water rises approximately 14°C when both units are operating without cooling towers. As a result, a mean net decrease of 0.8 mg/L of DO concentration was measured in the cooling water, which under extreme low flow conditions could reduce the mean water column DO concentration in the Chickamauga reservoir near the Sequoyah Nuclear Plant by approximately 0.5 mg/L (TVA 1990). Water quality modeling indicated that increasing the DO of Watts Bar Dam releases by 2 mg/L would improve DO concentrations through Chickamauga Reservoir by about 1 mg/L. Recent changes in the release schedule of Watts Bar Dam appear to have reduced the stagnation of water near the Sequoyah Nuclear Plant and alleviated concern about low DO effects (Tom Roehm, Tennessee Division of Water Pollution Control, telephone interview with G. F. Cada, ORNL, Oak Ridge, Tennessee, November 16, 1992).

Impacts of low DO concentrations in the discharge are considered to be of small significance if populations of aquatic organisms in the vicinity of the plant are not reduced. Based on review of literature and operational monitoring reports, consultations with utilities and regulatory agencies, and comments on the draft GEIS, low DO concentrations have not been a problem at most existing nuclear power plants, and operational mitigation measures have been effective at the one plant that experienced problems during the initial license period. Effects of low DO concentrations are considered to be of small significance for all plants. Water will be reaerated by turbulent diffusion and/or photosynthesis, so far-field effects are not expected. Mitigation to prevent low DO concentrations in the vicinity of the power plant will also reduce the likelihood of significant cumulative impacts; none of the resource agencies expressed an ongoing concern about the contribution of existing power plants to cumulative impacts of low DO concentrations. No change in operation of the cooling system is expected during the license renewal term, so no change in effects of low DO concentrations is anticipated. Effects of low DO concentrations could be reduced by changing to a closed cycle cooling system or by reducing the plant's generation rate. However, because the effects of low DO concentrations are considered to be impacts of small significance and because these changes would be costly, the staff does not consider the implementation of these potential mitigation measures to be warranted. Low DO concentrations in the thermal discharge are a Category 1 issue.

4.2.2.1.10 Losses from Parasitism, Predation, and Disease

Sublethal power plant stresses may alter predator-prey interactions in the receiving body of water. Aquatic organisms that are stunned but not killed by entrainment, impingement, or thermal effects may still suffer "indirect" mortality through increased susceptibility to predators. Numerous laboratory studies have been carried out to evaluate the level of indirect mortality that might occur following heat and cold shocks or entrainment (reviews in ORNL/TM-7801; Coutant 1981). These studies have commonly demonstrated increased susceptibility to predation, but field evidence of such effects is often limited to anecdotal information such as observations of enhanced feeding activity of seagulls and predatory fish near power plant outfalls. For example, Barkley and Perrin (1971), and CONF-730505 reported increased concentrations of predators feeding on forage fish attracted to thermal plumes. Neither quantification of the levels of stress needed to increase predation rates, nor prediction of the subsequent population- and community-level effects of such changes can be made easily in the field. It is likely that operation of once-through cooling systems will cause some changes in predator-prey relationships, but the best evidence for impacts (or lack of impacts) may come from long-term monitoring of fish populations. Neither the literature reviews nor consultations with agencies and utilities (Appendix F) have revealed studies that demonstrate population- or community-level effects from power-plant-induced alterations of predator-prey relationships.

Elevated water temperatures in power plant discharges have been hypothesized to increase the susceptibility of fish to diseases and parasites. Langford cites a number of factors that could contribute to such an effect, including the tendency for fish to congregate in the heated discharge area in greater than normal concentrations, increased stresses on fish in warmer water that makes them more prone to infection, and the ability of some diseases and parasites to develop faster at higher temperatures. Additionally, it has been suggested that stress and injury from entrainment and impingement contribute to increased susceptibility of fish to disease, parasites, and predation. Coutant (1981) noted that although some studies of increased disease and parasitism in heated waters have found localized effects, most were not adequately designed to determine the significance of the effects to the overall population. The greatest risks appear to be associated with changes in animal concentrations; crowding can occur among fish that are attracted to heated effluents in the winter or that avoid heated water in the summer by occupying limited cool-water refugia. Crowding increases the chances of exposure to infectious diseases and may also lead to other stresses (decreased food supply or reduced oxygen concentrations) that increase susceptibility to disease (Coutant 1987). Despite limited laboratory studies that confirm this phenomenon, population-level effects in the vicinity of plants have not been observed.

Effects of sublethal stresses on the susceptibility of aquatic organisms to predation, parasitism, and disease are considered to be of small significance if changes are localized and populations in the receiving waterbody are not reduced. Based on reviews of literature and operational monitoring reports, consultations with utilities and regulatory agencies, and comments on the draft GEIS, these forms of indirect, power plant-induced mortality have not been shown to cause reductions in the overall populations near any existing nuclear power plants. Effects are considered to be of small significance for all plants. Although sublethal power plant stresses could contribute to cumulative impacts experienced by aquatic biota, monitoring has revealed no evidence for significant effects; the regulatory and resource agencies consulted in the preparation of this GEIS did not express concerns about the contribution of sublethal power plant stresses to cumulative impacts. No change in operation of the cooling system is expected during the license renewal term, so no change in effects of sublethal stresses is anticipated. Effects of sublethal stresses could be reduced by changing to a closed cycle cooling system or by reducing the plant's generation rate. However, because the effects of sublethal stresses are considered to be impacts of small significance and because the changes would be costly, the staff does not consider the implementation of these potential mitigation measures to be warranted. This is a Category 1 issue.

4.2.2.1.11 Stimulation of Nuisance Organisms

A variety of nuisance organisms or nonnative species may become established or proliferate as a result of power plant operations, including fouling organisms such as the Asiatic clam (*Corbicula* sp.) and the recently introduced zebra mussel, *Dreissena polymorpha*. Aspects of the operation of the power plants (e.g., warm temperatures or high flow rates that bring food to filter-feeding organisms) may be conducive to the growth and development of these organisms. *Corbicula* sp. and zebra mussels may become so abundant as to cause operational difficulties for the power plant and may out-compete native clams and mussels in thermally enriched waters. A population of tropical, non-native blue tilapia became established in the Susquehanna River in Pennsylvania by congregating in thermal effluents during the winter. Exposure to rapid temperature decreases (cold shock) killed these fish and eradicated the population from the vicinity of a steam-electric power plant (Stauffer et al.).

Langford (1983) reports a number of instances in which wood-boring crustaceans and mollusks, notably "shipworms," have caused concern in British waters. Although increased abundance of shipworms in the area influenced by heated power plant effluents caused substantial damage to wooden structures, replacement of old wood with concrete or metal structures eliminated the problem. Langford concluded that increased temperatures could enhance the activity and reproduction of wood-boring organisms in enclosed or limited areas but that elevated temperature patterns were not sufficiently stable to cause widespread effects.

In the United States, the influence of the operation of Oyster Creek Nuclear Generating Station on shipworm abundance and distribution has been extensively studied (see summary in Richards et al. 1984). Although numerous studies have varied somewhat in their conclusions, there is agreement that heated effluents from the plant increased the distribution and abundance of the nonnative, tropical-subtropical wood-boring species *Teredo bartschi* (Kennish et al. 1984). This species has not been found in Oyster Creek or Barnegat Bay since 1982, perhaps because of low water temperatures in Oyster Creek during a station outage in the winter of 1981–82 and the pathological effects of a parasite [GPU Nuclear Corporation response to NUMARC survey (NUMARC 1990)]. In addition, the removal of substantial amounts of driftwood and the replacement of untreated structural wood is thought to have contributed to reducing the populations of wood-boring organisms in Oyster Creek. No other concerns about nuisance organisms were cited by the regulatory or resource agencies contacted for this GEIS (Appendix F). Measures taken by licensees to control nuisance species (e.g., increased chlorination or use of molluskicides) may result in impacts on other species. This impact is addressed in Section 4.2.1 and is also controlled by the NPDES permitting procedures.

The effects of stimulating the growth of nuisance organisms are considered to be of small significance to aquatic resources if these organisms are restricted to the condenser cooling system (e.g., Asiatic clam; zebra mussel) or do not proliferate beyond the immediate vicinity of the plant. Based on review of literature and operational monitoring reports, consultations with utilities and regulatory agencies, and comments on the draft GEIS, nuisance organisms such as Asiatic clam may be an operational problem, but they have not impacted aquatic resources near most existing nuclear power plants. Mitigation measures were effective at the one plant that experienced problems with nuisance organisms (shipworms). Effects are considered to be of small significance for all plants. The regulatory and resource agencies consulted in the preparation of this GEIS did not express concerns about the contribution of power plant operations to other activities that might encourage the growth of nuisance organisms (i.e., cumulative effects). No change in operation of the cooling system is expected during the license renewal term, so no change in the growth or distribution of nuisance organisms is anticipated. Effects on nuisance organisms could be reduced by changing to a closed cycle cooling system or by reducing the plant's generation rate. However, because the effects on the growth of nuisance organisms are considered to be impacts of small significance and because such changes would be costly, the staff does not consider the implementation of these potential mitigation measures to be warranted. The stimulation of nuisance aquatic organisms by operation of existing power plants is a Category 1 issue.

4.2.2.2 Summary

The issues and the need for these issues to be addressed in license renewal applications of existing nuclear power plants with once-through cooling systems are summarized in Table 4.1. The operational experience of existing nuclear power plants indicates that many early aquatic resource concerns have not materialized as problems at any facility. Neither the published literature nor the responses of regulatory and resource agencies have revealed concerns about such early issues as phytoplankton and zooplankton entrainment and premature emergence of aquatic insects living in thermal discharges. Although statistically significant localized effects of these stresses have occasionally been demonstrated, long-term or far-field impacts have not been documented. Other issues (e.g., lowered DO concentrations, discharge of heavy metals, cold shock, and stimulation of nuisance organisms) were problems at a few nuclear power plants with once-through cooling systems but have since been mitigated.

Table 4.1 Significance of aquatic resources impacts for license renewal of existing nuclear power plants that use once-through cooling systems

Issue	Impact significance[a]
Water quality, hydrology, and use issues	
Water use conflicts	1
Altered current patterns at intake and discharge structures	1
Altered salinity gradients	1
Temperature effects on sediment transport capacity	1
Altered thermal stratification of lakes	1
Scouring from discharged cooling water	1
Eutrophication	1
Discharge of chlorine or other biocides	1
Discharge of metals in waste water	1
Discharge of sanitary wastes and minor chemical spills	1
Effects of consumptive water use on riparian communities	1
Aquatic ecology	
Impingement of fish and shellfish	2
Entrainment of fish and shellfish early life stages	2
Entrainment of phytoplankton and zooplankton	1
Thermal discharge effects	2
Cold shock	1
Thermal plume barrier to migrating fish	1
Distribution of aquatic organisms	1
Premature emergence of aquatic insects	1
Stimulation of nuisance organisms (e.g., shipworms)	1
Losses from predation, parasitism, and disease among organisms exposed to sublethal stresses	1
Gas supersaturation (gas bubble disease)	1
Low dissolved oxygen in the discharge	1
Accumulation of contaminants in sediments or biota (Section 4.2.1 and 4.2.4)	1

[a]A 1 means impact significance expected to be small at all sites. A 2 means that the impact may be of moderate or large significance at some sites.

Some aquatic resource issues warrant further monitoring and, in some cases, mitigative measures to define and correct adverse impacts. The entrainment and impingement of fish and the discharge of large volumes of heated effluents into small or warm ambient waters were a source of concern at some nuclear power plants. Such issues were examined and resolved through either the NEPA process during the licensing of the facility or the mechanisms of NPDES permitting and associated 316(a) and (b) determinations. They either were found acceptable or mitigated. For some plants with once-through cooling systems, the large volumes of water withdrawn, heated, and discharged back to the receiving water may cause adverse effects to fish and shellfish populations during the license renewal term. Because impacts of entrainment of fish and shellfish, impingement, and thermal discharge effects could be small, moderate, or large, depending on the plant, these are Category 2 issues for plants with once-through cooling systems. These issues will need to be analyzed in the supplemental NEPA document at the time of license renewal.

4.3 COOLING TOWERS

This section introduces cooling towers and their emissions (Section 4.3.1) and then evaluates the impacts of the emissions on surface water and groundwater (Section 4.3.2), aquatic ecology (Section 4.3.3), agricultural crops (Section 4.3.4), terrestrial ecology (Section 4.3.5, which also includes bird collisions with cooling towers), and human health (Section 4.3.6). Impacts of cooling-tower noise are also addressed (Section 4.3.7). Each section that evaluates impacts (Sections 4.3.2–4.3.7) provides a conclusion that defines the significance of the impacts. These conclusions are based on reviews of cooling-tower data available for towers at specific nuclear plants as well as for other cooling towers (e.g., those at coal-fired plants).

4.3.1 Introduction

Mechanical- and natural-draft wet cooling towers transfer waste heat to the atmosphere primarily by evaporating water. Natural-draft towers are generally up to 160 m (520 ft) in height, whereas mechanical-draft towers are generally less than 30 m (100 ft) tall (Roffman and Van Vleck 1974). Because of the large cooling capacity of natural-draft towers, only one such tower is required for each reactor unit; but two or more mechanical-draft towers are required for equivalent cooling.

Most of the water lost from a cooling tower escapes to the atmosphere as water vapor in the exhaust flow. About 10 percent of the vapor recondenses after release, forming the visible part of the plume leaving the tower (Golay et al. 1986). Drift droplets of cooling water are also entrained in the air stream inside the tower and escape directly into the atmosphere. A particulate solid drift material remains after droplet evaporation. The drift contains varying amounts of salts, biocides, and microorganisms.

Natural-draft towers release drift and moisture high into the atmosphere where they are dispersed over long distances. Local impacts are more likely to occur with mechanical-draft towers because the plume is not dispersed over as great an area. The visible moisture plume from a natural-draft cooling tower may be 20 to 30 percent longer than that from comparable mechanical-draft towers (Roffman and Van Vleck 1974). Icing of vegetation and roads can occur near mechanical draft towers when fog is present and temperatures are below freezing. Much of the drift eventually deposits on the earth. The atmospheric transport of drift and the amount of deposition to the earth has been estimated for most nuclear plants through the use of computer models. Actual measurements of drift deposition have been collected at only a few nuclear plants. These measurements indicate that, beyond about 1.5 km (1 mile) from nuclear plant cooling towers, salt deposition is not significantly above natural background levels.

4.3.2 Surface Water Quality and Use

Sections 4.3.2 and 4.3.3 review the past and ongoing impacts on aquatic resources caused by the operation of nuclear power plants with cooling towers. Any ongoing impacts will probably continue into the license renewal term because the cooling system design and operation will not change as a result of license renewal. Judgments about the significance of these issues during the license renewal terms are based on published information, agency consultation, and information provided by the utilities (Appendix F) applicable to every nuclear power plant in the United States. The conclusions drawn in Sections 4.3.2 and 4.3.3 apply to all nuclear power plants with cooling towers.

4.3.2.1 Water Use

Two factors may cause water-use and water-availability issues to become important for some nuclear power plants that use cooling towers. First, the relatively small rates of cooling water withdrawal and discharge allowed some power plants with cooling towers to be located on small bodies of water that are susceptible to droughts or competing water uses. Second, closed-cycle cooling systems evaporate cooling water, and consumptive water losses may represent a substantial proportion of the flows in small rivers. Loss of a substantial portion of flow from a small stream as a result of evaporative losses from a cooling tower will reduce the amount of habitat for fish and aquatic invertebrates. Off-stream water uses, such as power plant consumption, must be regulated to ensure that important in-stream uses, such as habitat for aquatic organisms, boating, angling, and waste assimilation, are not compromised.

Consumptive water use can adversely impact riparian vegetation and associated animal communities by reducing the amount of water in the stream that is available for plant growth, maintenance, and reproduction. Riparian vegetation is defined as streamside vegetation that is structurally and floristically distinct from adjacent upland plant communities (Taylor 1982). Riparian vegetation has important ecological functions; and its importance as a resource has been widely recognized and reviewed (e.g., Brinson et al. 1981; Johnson et al. 1985). Briefly, riparian vegetation stabilizes stream channels and floodplains. It influences biogeochemical cycles, water temperature and quality, and the duration and magnitude of flooding. Riparian vegetation also provides diverse cover, food, water, reproductive habitat, and migration corridors for many aquatic and terrestrial animals. As a result, riparian zones often support a wide variety and high density of wildlife (deer, small mammals, songbirds, raptors, reptiles, and amphibians), especially in arid or urbanized areas. Riparian vegetation may be adversely affected by dewatering in a number of ways (Taylor 1982), including decreases in the width of the riparian corridor, changes in species and community diversity, increased susceptibility to flooding, changes in tree canopy cover, lower tree basal area, and lower seedling densities. Impacts to wildlife occur as a direct or indirect result of degradation of riparian habitats. Such dewatering effects are most apparent in the arid and semi-arid West; in the eastern United States, dewatering effects generally involve more subtle changes in community composition because of the higher precipitation, humidity, and soil moisture and the lower water stress conditions that prevail.

Limerick Generating Station, located on the Schuylkill River at Pottstown, Pennsylvania, is an example of a plant with a closed-cycle cooling system that is subject to water availability constraints because of in-stream-flow requirements in a smaller river, controversy over water use related to interbasin transfer, competing water uses, and water-related agreements between utilities. Aquatic resource issues identified include (1) water quality and low-flow problems in the Schuylkill River; (2) water availability conflicts with downstream water users; (3) increased in-stream flow requirements, particularly with respect to continuing efforts to improve the water quality of the Schuylkill River and to reintroduce American shad into the river; and (4) concerns over saltwater movement upstream in the Delaware River as the result of upstream water use (Margaret A. Reilly, letter to G. F. Cada, ORNL, Oak Ridge, Tennessee May 24, 1990; D. T. Guise, letter to G. F. Cada, ORNL, Oak Ridge, Tennessee, July 3, 1990).

Limerick is in one of the fastest growing regions in Pennsylvania, which is experiencing heavy residential development and water demands for domestic, existing industrial, and developing industrial uses (Joseph Hoffman, letter to V. R. Tolbert, ORNL, Oak Ridge, Tennessee, August 27, 1990). Limerick is permitted to withdraw up to 13 percent of the minimum flow of the Schuylkill River and a major portion of the flow of Perkiomen Creek for cooling tower makeup. Only 5 percent of the 1.8–2.0 m^3/s (65–70 ft^3/s) withdrawn from the Schuylkill River when the flow is greater than 15 m^3/s (530 ft^3/s) is returned to the river. This loss of in-stream flow is viewed as a significant contribution to the water quality and low-flow problems in the Schuylkill River (Dennis T. Guise, letter to G. F. Cada, ORNL, Oak Ridge, Tennessee, July 3, 1990). This water-use issue may be exacerbated as efforts to reintroduce the American shad into the Schuylkill River continue. In addition to the water use from the Schuylkill River, 2 m^3/s (71 ft^3/s) of water is diverted from the Delaware River to the East Branch of Perkiomen Creek via the Point Pleasant Diversion at a rate of 2 m^3/s (71 ft^3/s); this interbasin transfer affects the achievement of the 85 m^3/s (3000 ft^3/s) minimum flow objective in the Delaware River at Trenton. The effects of the diversion are being debated through an NPDES permit appeal before the Pennsylvania Environmental Hearing Board (Dennis T. Guise, letter to G. F. Cada, ORNL, Oak Ridge, Tennessee, July 3, 1990).

The Palo Verde NGS offers another example of competing water uses that may affect continued operation of nuclear facilities that use cooling towers. Palo Verde currently uses treated effluent from the cities of Phoenix and Tolleson for cooling tower makeup water. The blowdown from the cooling towers discharges to on-site lined evaporation ponds [Arizona Public Service Company response to NUMARC survey (NUMARC 1990)]. In the absence of the power plant, part of the municipal effluent would be used for commercial purposes and the remainder discharged to the Gila River, where it would be used for groundwater recharge, irrigation, and support of riparian habitat (Jack Bale, letter to G. F. Cada, ORNL, Oak Ridge, Tennessee, May 31, 1990). According to the Arizona Game and Fish Department (Donald Turner, Arizona Game and Fish Department letter to G. F. Cada, ORNL, Oak Ridge, Tennessee, June 29, 1990), if Palo Verde uses all of its allocation, the flow from the Gila River downstream to Gillespie Dam will be reduced, the water tables will drop significantly, and aquatic habitat and riparian vegetation will be destroyed. Sixty-nine percent of the water flowing in the Gila and Salt rivers downstream from the Ninety-First Avenue treatment plant is discharged by the treatment plant. Most if not all of the water produced by the treatment plant is committed to Palo Verde. When all three units of the plant were operating, flow in the river was significantly reduced, pools and ponds dried up, and numerous fish die-offs occurred (Donald Turner, Arizona Game and Fish Department, letter to G. F. Cada, ORNL, Oak Ridge, Tennessee, June 29, 1990).

Nuclear facilities on small bodies of water may experience water-use constraints related to availability. For example, during temporary drought periods, power plants with cooling towers may have to curtail operations if evaporative water losses exceed the capacity of small, multiple-use source bodies of water. Byron Station in Illinois withdraws water from the Rock River to supply natural-draft cooling towers. By agreement with the Illinois Department of Conservation, the withdrawal for makeup is limited to 3.5 m^3/s (125 ft^3/s) and net water consumption is limited to no more than 9 percent of the flow below 19 m^3/s (679 ft^3/s) [Commonwealth Edison Company response to NUMARC survey (NUMARC 1990)]. Duane Arnold Energy Center on the Cedar River in Iowa uses mechanical-draft cooling towers for condenser cooling and could also experience water availability constraints. The state of Iowa Department of Natural Resources currently has no water-use concerns with operation of Duane Arnold (Larry J. Wilson, letter to G. F. Cada, ORNL, Oak Ridge, Tennessee, May 22, 1990); however, the plant may possibly experience future constraints on the availability of water for consumptive use, because the surface water withdrawals within the state are projected to increase by 19 percent from 1985 to 2005 (Thamke 1990). Within Linn County, where Duane Arnold is located, water use is also projected to increase (Brian Tormee, telephone interview with V. R. Tolbert, ORNL, Oak Ridge, Tennessee, September 4, 1990).

Consultations with regulatory and resources agencies indicate that water use conflicts are already a concern at two closed-cycle nuclear power plants (Limerick and Palo Verde) and may be a problem in the future at Byron Station and the Duane Arnold Energy Center. Because water use conflicts may be small or moderate during the license renewal period, this is a Category 2 issue for nuclear plants with closed-cycle cooling systems. Related to this, the effects of consumptive water use on in-stream and riparian communities could also be small or moderate, depending on the plant, and is also a Category 2 issue.

4.3.2.2 Water Quality

Although cooling towers are considered to be closed-cycle cooling systems, concentration of dissolved salts in the makeup water—which results from evaporative water loss—requires the discharge of a certain percentage of the mineral-rich stream (blowdown) and its replacement with fresh water (makeup). The quantities of blowdown are relatively small compared with the discharges from once-through systems, typically on the order of 10 percent. Water quality impacts could occur from the elevated temperatures of the blowdown or from the concentration and discharge of chemicals added to the recirculating cooling water (to prevent corrosion and biofouling, regulate pH, etc.). A unit of water may reside in the cooling circuit for 3 to 20 cycles before being lost to evaporation or released in the blowdown stream (Coutant 1981). The concentration of total dissolved solids in the cooling tower blowdown averages 500 percent of that in the makeup water, a concentration factor that can be tolerated by most freshwater biota (ORNL/NUREG/TM-226). Dilution of the low-volume blowdown by the receiving water also reduces water quality impacts of heat and contaminants discharged from closed-cycle cooling systems.

Because of strict regulation of chemical discharges from steam-electric power plants (e.g., EPA regulations per 40 CFR Part 423), water treatment systems for cooling tower blowdown have been developed. Many of these systems recapture chemical additives for recycling in the cooling system (Coutant 1981). As noted in Section 4.2, all nuclear power plants are required to obtain an NPDES permit to discharge effluents. These permits are renewed every 5 years by the regulatory agency, either EPA or, more commonly, the state's water quality permitting agency. The periodic NPDES permit renewals provide the opportunity to require modification of power plant discharges or to alter discharge monitoring in response to water quality concerns. Utility responses to the NUMARC survey (Table F.2) indicate that such changes have been made during the plants' operation to correct water quality problems.

Impacts of cooling tower discharges are considered to be of small significance if water quality criteria (e.g., NPDES permits) are not consistently violated. In considering the effects of closed-cycle cooling systems on water quality, the staff evaluated the same issues that were evaluated for open-cycle systems (Table 4.1): altered current patterns, altered salinity gradients, temperature effects on sediment transport capacity, altered thermal stratification of lakes, scouring from discharged cooling water, eutrophication, discharge of chlorine and other biocides, discharge of other chemical contaminants, and discharge of sanitary wastes. Based on review of literature and operational monitoring reports, consultations with utilities and regulatory agencies, and comments on the draft GEIS, discharge of cooling tower effluents has not been a problem at existing nuclear plants. Although occasional violations of NPDES permits have occurred at many plants (e.g., minor spills), water quality impacts have been localized and temporary. Effects are considered to be of small significance for all plants. Cumulative impacts to water quality would not be expected because the small amounts of chemicals released by these low-volume discharges are readily dissipated in the receiving waterbody. No change in operation of the cooling system is expected during the license renewal term, so no change in effects of cooling towers discharges on receiving water quality is anticipated. Effects of cooling tower discharges could be reduced by operating additional wastewater treatment systems, or by reducing the plant's generation rate. However, because the effects of cooling tower discharges on water quality are considered to be impacts of small significance and because the changes would be costly, the staff does not consider the implementation of these potential mitigation measures to be warranted. Effects of cooling tower discharges on water quality are all Category 1 issues.

4.3.3 Aquatic Ecology

Cooling towers have been suggested as mitigative measures to reduce known or predicted entrainment and impingement losses (see, for example, Barnthouse and Van Winkle 1988). The relatively small volumes of makeup and blowdown water needed for closed-cycle cooling systems result in concomitantly low entrainment, impingement, and discharge effects (see Section 4.2.2 for a more complete discussion of these effects regarding once-through cooling systems). Studies of intake and discharge effects of closed-cycle cooling systems have generally judged the impacts to be insignificant (NUREG/0720; NUREG/CR-2337). None of the resource agencies consulted for this GEIS (Appendix F) expressed concerns about the impacts of closed-cycle cooling towers on aquatic resources.

However, even low rates of entrainment and impingement at a closed-cycle cooling system can be a concern when an unusually important resource is affected. Such aquatic resources would include threatened or endangered species or anadromous fish that are undergoing restoration. For example, concern about potential impacts of the Washington Nuclear Project (WNP-2) on chinook salmon has been raised by the Washington Department of Fisheries (Cynthia A. Wilson, Washington Department of Fisheries, letter to G. F. Cada, ORNL, Oak Ridge, Tennessee, July 5, 1990). Although entrainment, impingement, and thermal discharges are not believed to be a problem at WNP-2, the importance of the Columbia River salmon stocks are such that the resource agency feels that monitoring should continue. Similarly, the Pennsylvania Fish Commission has expressed concern about future entrainment and impingement of American shad by the Limerick Generating Station, the Susquehanna Steam Electric Station, Three Mile Island Nuclear Station, and Peach Bottom Atomic Power Station (Dennis T. Guise, Pennsylvania Fish Commission, letter to G. F. Cada, ORNL, Oak Ridge, Tennessee, July 3, 1990). In all cases, losses of American shad at these power plants are minimal or nonexistent, but periodic monitoring has been recommended to ensure that no future problems occur as the anadromous fish restoration efforts continue.

It is unlikely that the small volumes of water withdrawn and discharged by closed-cycle cooling systems would interfere with the future restoration of aquatic biota or their habitats. Effects of operation of closed-cycle cooling systems on aquatic organisms are considered to be of small significance if changes are localized and populations in the receiving waterbody are not reduced. In considering the effects of closed-cycle cooling systems on aquatic ecology, the staff evaluated the same issues that were evaluated for open-cycle systems (Table 4.1): impingement of fish and shellfish, entrainment of fish and shellfish early life stages, entrainment of phytoplankton and zooplankton, thermal discharge effects, cold shock, effects on movement and distribution of aquatic biota, premature emergency of aquatic insects, stimulation of nuisance organisms, losses from predation, parasitism, and disease, gas supersaturation of low dissolved oxygen in the discharge, and accumulation of contaminants in sediments or biota. Based on reviews of literature and operational monitoring reports, consultations with utilities and regulatory agencies, and comments on the draft GEIS, these potential effects have not been shown to cause reductions in the aquatic populations near any existing nuclear power plants. None of the regulatory and resource agencies expressed concerns about the cumulative effects on aquatic resources of closed cycle cooling system operations at this time, although some recommended continued monitoring in view of efforts to restore fish populations. Effects of all of these issues are considered to be of small significance for all plants. No change in operation of the cooling system is expected during the license renewal term, so no change in effects of cooling towers on aquatic biota is anticipated. Effects of entrainment, impingement, and discharges from closed-cycle cooling systems could be reduced by reducing the plant's generation rate, or by operating additional wastewater treatment systems. However, because the effects of cooling tower withdrawals and discharges on aquatic organisms are considered to be impacts of small significance and because the changes would be costly, the staff does not consider the implementation of these potential mitigation measures to be warranted. The effects of closed-cycle cooling system operation on aquatic biota are all Category 1 issues.

4.3.4 Agricultural Crops and Ornamental Vegetation

The issue addressed by this section is the extent to which the productivity of agricultural crops near nuclear plants may be reduced by exposure to salts or other effects (e.g., icing, increased humidity) resulting from cooling-tower operation. The approach to evaluating this issue was as follows: first, based on a literature review, potential impacts of salts in general (whether from cooling towers or other sources such as wind-blown salts near seashores) are described according to the rate of salt deposition to earth and the relative sensitivity of different types of crops (Section 4.3.4.1); then, the data generated by monitoring programs at a representative subset of specific nuclear plants were reviewed (Section 4.3.4.2). The subset includes 10 of the 11 nuclear power plants with mechanical-draft cooling towers. Mechanical-draft towers are the focus of this section because impacts of drift deposition and icing are more likely to occur near these towers than at natural-draft towers. Drift from natural-draft towers is released at greater heights, disperses more widely, and therefore deposits on earth at lower rates or concentrations. Data were also found and reviewed for 8 of the 17 plants with natural-draft cooling towers (Table 4.1). The coal-fired Chalk Point Plant was also included in the analysis because extensive monitoring of cooling-tower-drift effects has been conducted there and because this plant uses brackish water for cooling and represents a case with comparatively high potential for drift impacts from natural-draft towers. The only nuclear plant that has a natural-draft tower and uses brackish water for cooling is Hope Creek in New Jersey. It is included among the plants that were reviewed.

The following standard of significance is applied to the effects of cooling tower operation on agricultural crops and ornamental vegetation. The impact is of small significance if under expected operational conditions measurable productivity losses (either quantity or quality of yield) do not occur for agricultural crops; and measurable damage (either visual or to plant function) does not occur for ornamental vegetation.

4.3.4.1 Overview of Impacts

4.3.4.1.1 Ambient Salts and Cooling-Tower Drift

Agricultural crops can be affected by chemical salts and biocides in cooling tower drift and drift-induced or plume-induced ice formation. Increased fogging, cloud cover, and relative humidity resulting from cooling-tower operation have little potential to affect crops, and adverse effects have not been reported. Generally, drift from cooling towers using fresh water has low salt concentrations and, in the case of mechanical draft towers, falls mostly within the immediate vicinity of the towers (ANL/ES-53), representing little hazard to vegetation off-site. Typical amounts of salt or total dissolved solids in freshwater environments are around 1000 ppm (ANL/ES-53). In arid environments, competition for water resources can result in the use of relatively low-quality or saline water for cooling, and the potential for drift-induced damage to surrounding vegetation may be greater (McBrayer and Oakes 1982). For example, source water for cooling at Palo Verde in Arizona is withdrawn from an onsite reservoir containing treated sewage effluent of relatively high salinity. As a result, cooling tower basin water also had high salinity levels including 10,000 to 26,000 ppm total dissolved solids, 3,400 to 7,000 ppm Cl^-, and 2,700 to 8,600 ppm Na^+ (NUS-5241). High salt levels also occur at plants on the coasts or coastal bays. Brackish cooling water used by the Chalk Point coal-fired plant in Maryland contained 11,000 to 26,000 ppm total soluble salts and 6,600 to 18,000 ppm Cl^- (Mulchi and Armbruster 1983). Nuclear plants with cooling towers use fresh water, except for the Hope Creek Plant in New Jersey, which uses saline water. At the Crystal River Plant, Florida, which currently uses brackish water in once-through cooling, a helper cooling tower has been constructed to cool water in a canal that receives discharge from five fossil and one nuclear units.

Talbot (1979) has concluded that adequate estimates of natural background levels of atmospheric salt loading (naturally occurring drift) and rates of deposition thereof are not available for points remote from oceans. In field measurements at a wet cooling tower, A. Backhaus et al. (1988) estimated that up to 60 percent of the chemical contents in the sample came from atmospheric aerosols and not from the tower. Therefore, observed deposition is not all drift from cooling towers (Talbot 1979). Recent work (ORNL/TM-11121) has quantified background aerosol deposition for a dozen sites throughout the country, but deposition for most locations remains poorly known.

Salts from cooling towers are deposited on vegetation by (1) wind-driven impaction, (2) droplet and particulate fallout, and (3) rainfall (Talbot 1979; CONF-740302, 1975b). In high-salt environments such as a windy seashore, impaction is usually the most important process, delivering 10 times more salt to vegetation than does fallout. Increasing wind speeds and salt concentrations increase impaction, hence increasing vegetation injury (Talbot 1979). In most humid environments, rainwater will wash off salts deposited on vegetation (ANL/ES-53), but exposure can be significant during periods between rainfalls.

4.3.4.1.2 Effects of Salt Drift

Plants damaged by salt drift may have acute symptoms, including necrotic or discolored tissue, stunted growth, or deformities (Talbot 1979; Hoffman et al. 1987). Chronic effects are less obvious but may include some degree of chlorosis and reduced growth (Talbot 1979) or increased susceptibility to disease and insect damage (Hosker and Lindberg 1982).

Climatic conditions affect plants' ability to tolerate salt (Talbot 1979; Maas 1985). The degree of injury is related to the salt content in the leaves, but hot or dry weather conditions and water stress are critical in inducing injury (most crops can tolerate greater salt stress during relatively cool and humid weather) (Maas 1985).

Among the factors that affect the plant's foliar accumulation of salt are physical characteristics of the leaves (Maas 1985; CONF-740302, 1975d; Taylor 1980), type and concentration of salt, ambient temperature and humidity, and length of time the leaf remains wet (Maas 1985). Because salt on foliage is apparently absorbed from solution, high humidity, which retards evaporation, enhances salt uptake (CONF-740302, 1975d; McCune et al. 1977; Talbot 1979; Grattan et al. 1981). Because precipitation and dew affect salt deposition, uptake, and resultant injury, dose exposure is difficult to predict (Talbot 1979; Grattan et al. 1981; McCune et al. 1977; EPA-600/3-76-078).

Plant species and crop varieties vary significantly in their tolerance to drift deposition and to soil salinity (Talbot 1979; Maas 1985). In general, salt uptake, plant injury, and reduction in crop yield have been shown to increase with increasing levels of airborne salt or deposition and with time of exposure (CONF-740302, 1975b; Mulchi and Armbruster 1981; Maas; Grattan et al.; EPA-600/3-76-078). Some plants, however, have shown a slight increase in vegetative productivity [e.g., tobacco at < 4 kg/ha (3.6 lb/acre) per week (Mulchi and Armbruster 1983) and cotton at 8 kg/ha (7 lb/acre per week) (Hoffman et al. 1987)]. Based on experimental exposures, a yield reduction of 10 percent has been estimated for deposition levels as low as 4.7 kg/ha (4.2 lb/acre) per week to corn, a species sensitive to foliar salt injury (Mulchi and Armbruster 1981). Relationships between experimental levels of salt deposition, foliar concentrations of sodium and chloride, and corn yield show that yield may be slightly reduced even at rates as low as 2 kg/ha (1.8 lb/acre) per week (Mulchi and Armbruster 1981). Also, bush beans can have reduced yield depending on the age of plants, with older plants being most sensitive (EPA-600/3-76-078). Deposition rates near nuclear-plant towers, according to available deposition data (Section 4.3.5.1.2), appear to be generally below the rates that would affect sensitive agricultural crops.

Talbot (1979) tabulated salt deposition amounts known to induce acute toxicity symptoms in vegetation (Table 4.2). Corn was the most sensitive crop, showing injury above 1.8 kg/ha (1.6 lb/acre) per week; the least sensitive was pinto beans, showing injury above 253 kg/ha (226 lb/acre) per week. Armbruster and Mulchi (1984) showed that foliar salt deposition of 3.2 to 8.8 kg/ha (2.9 to 7.9 lb/acre) per week increased foliar chloride content and damaged foliage of corn, with the higher deposition reducing the yield of grain by as much as 11 percent. They found similar results for soybeans, with bean yields

 JA00144

Table 4.2 Estimates of salt-drift deposition rates estimated to cause acute injury to vegetation

Species	Deposition above which injury is expected (kg/ha/week)
Crops and ornamental plants	
Zea mays (corn)	1.82
Glycine hispida var York (soybean)	7.28
Gossypium hirsutum (cotton)	8.0
Medicago sativa (alfalfa)	15.7
Forsythia intermedia var spectabilis (forsythia)	189.6
Phaseolus vulgaris var Pinto (pinto bean)	252.8
Albizzia julibrissin rosea (mimosa)	379.2
Koelreutaria paniculata (golden rain tree)	568.8
Native species	
Cornus florida (flowering dogwood)	1.2 (in Maryland) 47.4 (in New York)
Fraxinus americana (white ash)	1.3 (in Maryland) 18.9 (in New York)
Tsuga canadensis (Canadian hemlock)	9.4
Pinus strobus (white pine)	189.6
Quercus prinus (chestnut oak)	379.2
Robinia pseudoacacia (black locust)	379.2
Acer rubrum (red maple)	474.0
Hammamelis virginiana (witch hazel)	1042.8

Note: To convert kg/ha to lb/acre, multiply by 0.8924.

reduced by as much as 7 percent at the highest deposition rate.

W. C. Hoffman et al. (1987) experimentally exposed cotton and cantaloupe in the arid environment near Palo Verde to foliar salt deposition rates of 8 to 415 kg/ha (7 to 370 lb/acre) per year total salt and alfalfa to depositions up to 829 kg/ha (740 lb/acre) per year. They found foliar injury in alfalfa only at the highest deposition level but no injury to cantaloupe or cotton despite increases in foliar Na^{+} and Cl^{-}. Yields of cantaloupe and alfalfa were not reduced, but 415 kg/ha (370 lb/acre) per year reduced cotton boll production and seed cotton yield by approximately 25 percent.

The burning quality of tobacco is known to be adversely affected by elevated Cl^{-}. Experiments have shown that burning quality, or length of time the leaf will burn, is impaired by increasing experimental doses of salt deposition (Mulchi and Armbruster 1983). A 17 percent reduction in burning quality was estimated for a Cl^{-} deposition of 5 kg/ha (4.5 lb/acre) per week, based on regression relationships of deposition, leaf chloride concentration, and leaf burn (Mulchi and Armbruster 1983).

Field studies of the effects of salt drift have been conducted at the Turkey Point plant and the coal-fired Chalk Point plant. Hindawi et al. (EPA-440/5-86-001) investigated field exposures of bean and corn plants to saltwater drift from a test cooling tower and power spray module at the Turkey Point plant. Salt concentrations in tissues of bean and corn plants increased with time during three weeks of exposure and decreased exponentially with distance from the salt drift source. Some injury to leaves was visible at the site of greatest exposure.

The coal-fired Chalk Point plant has a relatively high potential impact from natural-draft cooling towers because brackish water is used for cooling. Other than the Hope Creek plant, all nuclear plants with natural-draft towers use fresh water for cooling. Deposition rates at Chalk Point were measured at 12 monitoring sites at distances of from 1.6 km to 9.6 km (1 to 6 miles) from the towers during their initial 5 years of operation (Mulchi et al. 1982). No increased deposition resulting from cooling-tower operation was detected at these distances. Deposition rates at the sites ranged from about 0.5 to 1.2 kg/ha (0.4 to 1 lb/acre) per month for NaCl, which comprises most of the solids in the brackish cooling water. Monitoring sites, which were established to study effects on agricultural crops, were not located in areas closer to the towers because no active cropland was in these areas and because the plant, located on a peninsula on the Patuxent River, is bounded by water except to the north and north-northwest. Most drift probably deposits in the river.

A study of tobacco plants 3 years after Chalk Point cooling towers began operating failed to find any increase in leaf salt content that could be attributed to drift (Mulchi and Armbruster 1983). Chloride levels in tobacco and chloride and sodium levels in corn and soybeans at 1.6 km (1 mile), the closest distance crops were grown to the Chalk Point towers, were within the range of preoperational values and were no higher than levels found up to 9.6 km (6 miles) from the towers (Mulchi et al. 1982; Mulchi and Armbruster 1983).

4.3.4.1.3 Effects on Soils

Drift deposition also has the potential to damage vegetation by soil salinization. Soil salinization does not usually occur in areas where rainfall is sufficient to leach salts from the soil profile. In arid regions, however, such as at Palo Verde, cooling tower drift has the potential to increase soil salinity and thus affect native and agricultural plants (McBrayer and Oakes 1982). Salinity of irrigated soils in arid regions may also be increased by drift, even though such soils already have a high salinity resulting from salts in irrigation water and high evaporation rates. Responses of crop plants to soil salinity appear to be poorly correlated to their tolerance to foliar-applied salts (Grattan et al. 1981; Maas 1985).

In an experiment in a more humid environment, salts were applied to soils to simulate drift deposition from the Chalk Point coal-fired plant with brackish water cooling towers. One-time applications of 14–112 kg/ha (13–100 lb/acre) NaCl affected leaf Cl^- in corn and soybeans but resulted in no visible damage or reduction in yield (Armbruster and Mulchi 1984). These soil salt treatments also increased soil pH and extractable cations (Armbruster and Mulchi 1984), but leaching by winter precipitation returned soil to pretreatment status.

In humid environments, effects of drift deposition on soils appear transitory if they can be detected at all. Field measurements of the effects of the operating cooling towers at Chalk Point showed no changes in soil chemical elements at distances of 1.6 to 9.6 km (1 to 6 miles) (Mulchi et al. 1982). In a study of five saltwater cooling towers near Galveston Bay, Texas, salt deposition up to 746 kg/ha/year was found within 100 m (328 ft) of the towers, with levels decreasing to <52 kg/ha (46 lb/acre) per year at 434 m (1424 ft) (Wiedenfeld et al. 1978). Weekly deposition ranged from 4.27 kg/ha (3.81 lb/acre) per week to 58.8 kg/ha (52.5 lb/acre) per week. In the survey, salt content of the soil at 104 m (341 ft) from the towers returned to previous levels when towers were shut down during the winter.

4.3.4.2 Plant-Specific Operational Data

Annual reports of environmental monitoring for vegetation damage at nuclear plants were reviewed. Vegetation monitoring included detailed measurements of vegetation structure and composition on permanent plots, aerial infrared photography with subsequent field surveys for vegetation injury, or general surveillance. Vegetation damage ranging from foliar chlorosis to defoliation can be identified on false-color infrared aerial photographs (NUREG/CR-1231). Vegetation monitoring for drift effects has been conducted at 18 nuclear plants. Most of the nuclear plants are not located close to agricultural areas, but six of the plants monitored crops, pasture, orchards, or ornamental vegetation. None reported visible damage to ornamental vegetation or reduction in crop yield (Table 4.3).

A detailed study at Palo Verde in Arizona showed that, after 6 years of operation, no change in agricultural soils attributable to cooling tower emissions occurred. Although significant increases or decreases occurred in some soil parameters at some monitoring locations, these changes appear unrelated to cooling-tower operation and were believed to have been caused by irrigation management, cropping, and fertilizer application. At the conclusion of the 6-year study, no significant effects on

Table 4.3 Results of nuclear facility monitoring for cooling-tower drift effects on terrestrial vegetation

Plant	Vegetation effects	Type of monitoring
	Natural draft	
Arkansas	No visible damage; no foliar chemical changes after one year	Aerial photography; foliar chemistry; orchard, native trees
Beaver Valley	No visible damage	Aerial photography; soil pH and conductivity; native vegetation
Byron	No visible damage	Aerial photography; crops; woody, ornamental, and native vegetation
Callaway	No visible damage	Aerial photography; permanent vegetation plots; native trees
Davis-Besse	No visible damage	Aerial photography; soil chemistry; native vegetation
Hope Creek	No visible damage after one year; no foliar chemical changes after one year	Ground survey; foliar chemistry; soil chemistry; native vegetation
Three Mile Island	No visible damage	Visual inspection; crops and native vegetation
Trojan	No visible damage	Aerial photography; pasture, ornamental and native vegetation
	Mechanical draft	
Catawba	Possible ice damage to loblolly pine < 61 m (200 ft) from towers	Aerial photography; ground survey; native trees
Duane Arnold	No visible damage	Visual inspection; native vegetation
Edwin I. Hatch	No visible damage	Aerial photography; permanent vegetation plots; native vegetation

Table 4.3 (continued)

Plant	Vegetation effects	Type of monitoring
Joseph Farley	No visible damage	Aerial photography; native vegetation
Palisades	Severe ice damage < 61 m (200 ft) from towers; some icing beyond 250 m (820 ft); sulfate injury < 150 m (492 ft) from towers; change in vegetation caused by damage to trees	Aerial photography; permanent vegetation plots; native vegetation
Palo Verde	No visible damage; foliar salt concentrations increased on site	Aerial photography; foliar chemistry; soil chemistry; crops and native vegetation
Prairie Island	Frequent ice damage to oaks adjacent to towers; change in canopy structure caused by ice damage; reduced viability in acorns from oaks near towers	Aerial photography; ground survey; acorn viability survey; native vegetation
River Bend	No visible damage	Aerial photography; permanent vegetation plots; native vegetation
Fort Saint Vrain	No visible damage	Aerial photography; crops; native vegetation
Washington	No foliar chemical changes	Foliar chemistry; soil chemistry; native vegetation

crops or native vegetation had been noted, and the study was discontinued (Halliburton NUS 1992).

At the Palisades plant in Michigan, concern was expressed by owners of nearby fruit orchards about possible effects of elevated humidity on the incidence of disease, particularly apple scab, in their orchards. The concern was that increased humidity could result in the need for increased applications of disease-control sprayings and thus increase orchard operating costs. NRC staff recommended a survey program to assess impacts of cooling-tower moisture on yield, quality, and frequency of disease-control sprayings (NRC 1978). Weather conditions encouraging apple scab are temperatures of 17 to 24°C (63 to 75°F) and

>85 percent relative humidity for 9 h or more. A study was conducted to determine these weather conditions near Palisades cooling towers and in more distant areas (Ryznar et al. 1980). Long-term weather records from weather stations outside the influence of the Palisades cooling towers were analyzed. In addition, a network of meteorological stations was established in the vicinity of the Palisades plant. No increase in weather occurrences favoring apple scab was observed that could be related to Palisades operation.

4.3.4.3 Conclusion

Monitoring results from the sample of nuclear plants and from the coal-fired Chalk Point plant, in conjunction with the literature review and information provided by the natural resource agencies and agricultural agencies in all states with nuclear power plants, have revealed no instances where cooling tower operation has resulted in measurable productivity losses in agricultural crops or measurable damage to ornamental vegetation. Because ongoing operational conditions of cooling towers would remain unchanged, it is expected that there would continue to be no measurable impacts on crops or ornamental vegetation as a result of license renewal. The impact of cooling towers on agricultural crops and ornamental vegetation will therefore be of small significance. Because there is no measurable impact, there is no need to consider mitigation. Cumulative impacts on crops and ornamental vegetation are not a consideration because deposition from cooling tower drift is a localized phenomenon and because of the distance between nuclear power plant sites and other facilities that may have large cooling towers. This is a Category 1 issue.

4.3.5 Terrestrial Ecology

This section addresses the impact of cooling tower drift on natural plant communities (Section 4.3.5.1) and the impact of bird mortality resulting from collisions with natural-draft cooling towers (Section 4.3.5.2).

4.3.5.1 Effects of Cooling-Tower Drift

This section addresses the extent to which natural plant communities near nuclear plants are affected by exposure to salts, icing, or other effects (e.g., fogging and increased humidity) caused by operation of cooling towers. The approach to evaluating this issue is the same as that used for evaluating the impact on agricultural crops in Section 4.3.4.

4.3.5.1.1 Overview of Impacts

The potential impacts of cooling tower operation on native vegetation are similar to those for agricultural crops, including salt-induced leaf damage, growth and seed yield reduction, and ice-induced damage (see Section 4.3.4). In addition, native vegetation may suffer changes in community structure (Talbot 1979) in response to ice damage or differences in species tolerances to drift. Increased fogging and relative humidity near cooling towers have little potential to affect native vegetation, and no such impacts have been reported.

The following standard of significance is applied to the effects of cooling tower operation on natural plant communities. The impact is of small significance if no measurable degradation (not including short-term, minor, and localized impacts) of natural plant communities results from cooling tower operation.

Species vary in their sensitivity to soil salinity and foliar salt deposition, and their tolerances of drift deposition are not well known. Curtis et al. (PPSP) determined that experimental exposure to saline cooling-tower drift for one growing season resulted in foliar damage to vegetation when leaf Cl^- levels were between 3145 and 9000 μg/g dry weight. These investigators also found that several species of trees growing under field conditions were not always as sensitive to salt deposition as they were under greenhouse conditions. Actual sensitivities of native trees may therefore be less than those shown in Table 4.2. Age of leaves also affects sensitivity to deposition. McCune et al. 1977 found that the youngest leaves of deciduous woody species and the year-old needles of conifers were more susceptible than leaves of other ages. Seasonal deposition, therefore, has the potential to affect these species groups differently. The most sensitive native species, flowering dogwood, shows injury from deposition above 1.2 kg/ha (1.1 lb/acre) per week, and the least sensitive species, witch hazel, shows injury above 1042.8 kg/ha (930.6 lb/acre) per week (Talbot 1979). Deposition rates near nuclear plant cooling towers, according to available deposition data, appear to be generally below the rate that would adversely affect dogwood.

Talbot (1979) reviewed studies of vegetation damage at nine industrial cooling tower installations. Three of the six installations having mechanical draft towers (one saltwater and two freshwater) produced some damage to native vegetation within 215 m (705 ft). Natural draft towers at three sites had no reported visible effects on vegetation. Natural draft cooling towers using brackish water at the coal-fired Chalk Point plant resulted in elevated chloride concentrations in vegetation after 1 year of tower operation (PPSP-CPCTP-18), but symptoms of salt toxicity in native trees had not been observed after 2 years of operation (Lauver et al. 1978), after which monitoring was terminated because of the absence of significant effects (C. L. Mulchi, University of Maryland, personal communication with H. Quarles, ORNL, Oak Ridge, Tennessee, March 15, 1995).

Impacts on native vegetation as a result of soil salinization (Section 4.3.4) are not expected except possibly in arid environments. Although according to McBrayer and Oakes (1982), the predicted annual salt deposition of 25 to 50 kg/ha (22 to 51 lb/acre) near the Palo Verde cooling towers could increase soil salinity enough to alter distribution of certain species because natural soil salinity is already close to their salt tolerances, a monitoring study conducted over the first 6 years of cooling tower operation showed no significant effects on native vegetation or crops (Halliburton NUS 1992).

4.3.5.1.2 Plant-Specific Operational Data

Vegetation monitoring at nuclear plants is described in Section 4.3.4. Of the 18 plants reviewed, visible vegetation damage resulting from cooling tower operation was reported for only the Catawba, Palisades, and Prairie Island plants, all with mechanical-draft towers (Table 4.3). At these facilities, damage has been reported primarily within 150 m of the towers. Although no vegetation damage was reported at Palo Verde, increased foliar salt concentrations were found on-site (Halliburton NUS 1992).

At the Catawba Plant a few loblolly pine trees adjacent to the cooling towers were apparently damaged by ice. Damage to the trees consisted of some browning of needles on trees nearest the towers.

At Palisades, monitoring conducted in response to observed vegetation damage included chloride and sulfate deposition and visual observation of damage. Vegetation damage resulted primarily from sulfate and was more extensive than at any other nuclear facility because, at Palisades' unique location, the tops of the cooling towers are lower than the tops of forested dunes on the site. This unique position of the cooling towers contributes to interception of cooling tower emissions by dune vegetation. Vegetation injury ranged from visible signs to severe necrosis of leaves to near-total defoliation in areas with maximum impact. In 1975, severe icing from drift interception also caused extensive damage by breaking branches as well as trunks of trees (Rochow 1978). Approximately 8 ha (20 acres) was affected by sulfates and icing, including about 6 ha (15 acres) of forest. Sulfate damage resulted from addition of sulfuric acid to the cooling water. However, this practice was discontinued, thus significantly reducing the impacts; and the severe icing in 1975 may have resulted from unusual weather conditions combined with a possible cooling tower malfunction (Ryznar et al. 1980).

Vegetation damage was found to correlate with elevated rates of sulfate deposition from the Palisades towers (Rochow 1978); chloride deposition, however, was less than 1.0 g/m^2/month in areas of extensive vegetation damage and did not correlate with the damage. Sulfate deposition rates were 0.61 g/m^2/month between 700 and 1609 m (2296 and 5278 ft) and 9.0 g/m^2/month within 50 m (164 ft) of the tower. About 75 percent of the sulfate fell out within 145 m (129 ft) of the towers (Rochow 1978). Heaviest damage to vegetation was in areas receiving more than 5 g/m^2/month sulfate, but areas receiving 2 to 5 g/m^2/month also were heavily damaged. Areas receiving 1 to 2 g/m^2/month were damaged primarily in the upper portions of trees.

Monitoring at Prairie Island included aerial photography, ground surveys of vegetation, and acorn viability monitoring. Viability of acorns collected from red oak trees located near the mechanical-draft towers was low, although acorn production appeared normal. Icing from plume downwash, which occurred frequently, may have damaged developing embryos in the acorns, which take 2 years to develop (Richardson 1976; Richardson 1978). Ice also damaged some of the trees growing adjacent to the towers. Because the towers at Prairie Island have not been used for cooling during the winter since 1984, icing damage has been eliminated.

Monitoring at Palo Verde included drift deposition, soil chemistry, salt concentrations in vegetation, and aerial photography. Drift deposition up to 95.6 kg/ha (85.3 lb/acre) per year has occurred on the site within 1.6 km (1 mile) of the cooling towers. Amounts of approximately 25 to 50 kg/ha (22 to 45 lb/acre) per year were predicted to alter soil salinity enough to affect vegetation over the long term (McBrayer and Oakes 1982). Increases in soil sodium, potassium, or chloride content have been reported, but increases also occurred in some sites that were distant from the towers (Halliburton NUS 1992). Observed changes in soil chemistry at Palo Verde appeared to be unrelated to cooling tower operation, and no effects on vegetation were reported.

4.3.5.1.3 Conclusion

Monitoring results from the sample of nuclear plants and from the Chalk Point plant, in conjunction with the literature review and information provided by the natural resource agency and agricultural agencies in all states with nuclear power plants, have revealed no instances where cooling tower operation has resulted in measurable degradation of the health of natural plant communities. Observed vegetation damage caused by icing and cooling-tower drift at mechanical draft towers usually is minor and localized in small ares (e.g., Catawba and Prairie Island). Damage to native vegetation has not occurred at Chalk Point coal plant and the Hope Creek nuclear plant, which use brackish water for cooling and represent a comparatively high probability of impact from operation of natural draft towers. Therefore, damage at other nuclear plants with natural draft towers is unlikely. Damage from operation of mechanical-draft towers at Palisades was more extensive than for the other nuclear plants, but was limited to about 8 ha (20 acres) on the site. The damage resulted from Palisades unique location, the addition of sulfuric acid to cooling water, and possibly from a cooling tower malfunction combined with unusual weather conditions. The use of sulfuric acid was discontinued, significantly reducing the impact. Cooling tower drift in the arid environment at Palo Verde has not affected native species through soil salinization: no actual damage was reported over a 6 year study of cooling tower operation (Halliburton NUS 1992). The only potential mitigation measures would be to change to another cooling system or to modify the cooling towers to reduce the amount of drift. Because the impacts of cooling tower drift on native plants are expected to be of small significance at all plants and because the potential mitigation measures would be costly, no mitigation measures beyond those implemented during the current term license would be warranted. Cumulative impacts on natural plant communities are not a consideration because of the distance between nuclear power plant sites and other facilities that may have large cooling towers. This is a Category 1 issue.

4.3.5.2 Bird Collisions with Cooling Towers

This section addresses the significance of avian mortality resulting from collisions of birds with natural-draft cooling towers at nuclear plants. Natural-draft towers, which are tall structures, cause some mortality, whereas mechanical-draft towers cause negligible mortality and are not addressed here. This issue was evaluated by reviewing the general literature for avian collision mortality associated with all types of man-made objects, as well as the monitoring studies conducted at six nuclear plants. The literature review is presented in Section 4.5.6.2. The significance of the mortality caused by cooling towers is determined by examining the actual numbers and species of birds killed and comparing this mortality with the total avian mortality resulting from other man-made objects and with the abundance of bird populations near the towers.

4.3.5.2.1 Overview of Impacts

Throughout the United States, millions of birds are killed annually when they collide with man-made objects, including radio and TV towers, windows, vehicles, smoke stacks, cooling towers, and numerous other objects. An overview of collision mortality for all types of man-made objects is included in the discussion of transmission lines in Section 4.5.6.2.

Avian mortality due to man-made structures is of concern if the stability of the local population of any bird species is threatened or if the reduction in the numbers within any bird population significantly impairs its function within the local ecosystem. Avian mortality resulting from collisions of birds with cooling towers is considered to be of small significance if the losses do not threaten the stability of local populations of any species and if there is no noticeable impairment of its function within the local ecosystem.

4.3.5.2.2 Plant-Specific Analysis

Monitoring of bird collisions has been done at several nuclear plants with natural draft cooling towers, including the Susquehanna plant near Berwick on the Susquehanna River in eastern Pennsylvania, the Davis-Besse plant on the shore of Lake Erie in north central Ohio, the Beaver Valley plant on the Ohio River in extreme western Pennsylvania, the Trojan Plant on the Columbia River in extreme northwestern Oregon, the Three Mile Island plant near Harrisburg in southeastern Pennsylvania, and the Arkansas Nuclear One plant on Dardanelle Lake in northwestern Arkansas. The following information was obtained from nuclear plant annual monitoring reports and from a few other sources, as cited.

At the Susquehanna plant, surveys were conducted on weekdays during spring and fall migration from 1978 through 1986. This plant's natural draft towers are 165 m (540 ft) tall and illuminated at the top with 480-V aircraft warning strobe lights. About 1500 dead birds (total for all survey years) of 63 species were found that had apparently collided with the cooling towers. Others were probably lost in the tower basin water during plant operation. Most of the birds were passerines (songbirds). Fewer collisions seemed to occur during plant operation, when cooling tower plumes and noise may have frightened birds away from the towers. From 1984 through 1986, eight dead bats were also found, including little brown myotis, red bat, and big brown bat.

At Davis-Besse, extensive surveys for dead birds were conducted from fall 1972 to fall 1979. Early morning surveys at the 152-m (499-ft-) tall cooling tower were made almost daily from mid-April to mid-June and from the first of September to late October. After the tower began operating in the fall of 1976, some dead birds were lost through the water outlets of the tower basin. A total of 1554 dead birds were found, an average of 196 per year. The dead birds included 1222 at the cooling tower, 222 around Unit 1 structures, and 110 at the meteorological tower. Most were night-migrating passerines, particularly warblers, vireos, and kinglets. Waterfowl that were abundant in nearby marshes and ponds suffered little collision mortality. Most collision mortalities at the cooling tower occurred during years when the cooling tower was not well illuminated (1974 to spring 1978). After completion of Unit 1 structures and the installation of many safety lights around the buildings in the fall of 1978, collision mortality was significantly reduced (average of 236 per year from 1974 through 1977, 135 in 1978, and 51 in 1979). Diffusion of light from these safety lights may illuminate the cooling tower in such a way that birds can see and avoid it. Lights at nuclear plants may not confuse birds to the extent sometimes caused by lights on radio or TV towers (Section 4.5.6.2). Lights illuminating the Pilgrim Nuclear Station in Massachusetts apparently were not a problem to migrating birds, which were monitored by radar. The orientation, flight speed, and altitude of these birds appeared unaffected by the lights, although on one of nine nights, flight direction at the station was different from that in a control area and flight altitude was higher (Marsden et al. 1980).

At Beaver Valley, surveys were conducted in spring and fall from 1974 through 1978 at the natural draft tower. A total of 27 dead birds were found. At the Trojan Plant, surveys were conducted weekly in 1984 and 1988 at the 152-m 499-ft-) tall cooling tower, meteorological tower, switch yard, and generation building. No dead birds were found. At the 113-m (371-ft-) tall cooling towers at Three Mile Island, a total of 66 dead birds were found from 1973 through 1975 (Temme and Jackson 1979). No dead birds were found at Arkansas Nuclear One, where monitoring at the natural-draft tower was done twice weekly from October 15 through April 15 in 1978–79 and 1979–80.

4.3.5.2.3 Conclusion

Existing data on cooling-tower collision mortality suggest that cooling towers cause only a very small fraction of the total bird collision mortality (see Section 4.5.6.2 for a review of this mortality). The relatively few nuclear plants having natural-draft towers in the United States (approximately 32 units), combined with the relatively low bird mortality at individual natural draft towers, shows that (1) these nuclear plant towers are not greatly affecting bird populations (see Section 4.5.6.2.1) and (2) their contribution to the cumulative effects of bird collision mortalities is very small. Mechanical-draft cooling towers, which are not nearly as tall as natural-draft towers, and other facilities pose little risk to migrating birds.

Local bird populations are apparently not being significantly affected by collision with cooling towers. Waterfowl and other birds that are commonly present as permanent or summer residents around nuclear plants do not frequently collide with the towers. Instead, a very high percentage of the collision mortalities occur during the spring and fall bird migration periods and involve primarily birds migrating at night. Studies that have been conducted at six nuclear plants, in conjunction with literature reporting total collision mortality (Section 4.5.6.2), show that (1) avian mortality associated with cooling towers is a very small part of the total mortality and (2) local bird populations are not being significantly reduced. Data on collision mortality were found for only 6 of the 20 nuclear plants with natural-draft cooling towers. Collision mortality at one or more of these plants may be greater than at the plants where surveys were conducted.

Avian mortality resulting from collisions of birds with cooling towers involves sufficiently small numbers for any species that it is unlikely that the losses would threaten the stability of local populations or result in a noticeable impairment of the function of a species within local ecosystems. There is no reason to believe that the annual mortality rate resulting from collision of birds with any cooling tower would be different during the license renewal term. Thus, avian mortality resulting from collision with cooling towers is of small significance. A potential method of mitigating avian morality would be to illuminate natural draft cooling towers at night. Because it is unlikely that the numbers of birds killed from collision with cooling towers are large enough to affect local population stability or impair the function of a species within the local ecosystem, consideration of further mitigation is not necessary. Because any contributions of cooling tower collisions to overall bird mortality have already been expressed in species populations, it is not expected that there will be any incremental or cumulative impact on bird populations from cooling tower collision mortality due to relicensing of current nuclear plants. The cumulative effect of bird mortality is further considered with transmission lines in Section 4.5.6.2. Avian mortality resulting from collision with cooling towers is a Category 1 issue.

4.3.6 Human Health

Some microorganisms associated with cooling towers and thermal discharges can have deleterious impacts on human health. Their presence can be enhanced by thermal additions. These microorganisms include the enteric pathogens *Salmonella* sp. and *Shigella* sp. as well as *Pseudomonas aeruginosa* and the thermophilic fungi (Appendix D). Tests for these pathogens are well established, and factors germane to their presence in aquatic environs are known and in some cases controllable. Other aquatic microorganisms normally present in surface waters have only recently been recognized as pathogenic for humans. Among these are Legionnaires' disease bacteria (*Legionella* sp.) and free-living amoebae of the genera *Naegleria* and *Acanthamoeba*, the causative agents of various, although rare, human infections. Factors affecting the distribution of *Legionella* sp. and pathogenic free-living amoebae are not well understood. Simple, rapid tests for their detection and procedures for their control are not yet available. The impacts of nuclear plant cooling towers and thermal discharges are considered of small significance if they do not enhance the presence of microorganisms that are detrimental to water and public health.

Potential adverse health effects on workers due to enhancement of microorganisms are an issue for steam-electric plants that use cooling towers. Potential adverse health effects on the public from thermally enhanced microorganisms is an issue for the nuclear plants that use cooling ponds, lakes, or canals and that discharge to small rivers. These plants are all combined in the category of small river (average flow less than 2830 m^3/s (100,000 ft^3/s) in Tables 5.18 and 5.19. These issues were evaluated by reviewing what is known about the organisms that are potentially enhanced by operation of the steam-electric plants.

Because of the reported cases of fatal *Naegleria* infections associated with cooling towers, the distribution of these two pathogens in the power plant environs was studied in some detail (Tyndall et al. 1983; see also Appendix D). In response to these various studies (Appendix D), many electric utilities require respiratory protection for workers when cleaning cooling towers and condensers. However, no Occupational Safety and Health Administration (OSHA) or other legal standards for exposure to microorganisms exist at present. Also, for worker protection, one plant with high concentrations of *Naegleria fowleri* in the circulating water successfully controlled the pathogen through chlorination before its yearly downtime operation (Tyndall et al. 1983).

Changes in the microbial population and in the use of bodies of water may occur after the operating license is issued and the application for license renewal is filed. Ancillary factors may also change, including average temperature of water resulting from climatic conditions. Finally, the long-term presence of a power plant may change the natural dynamics of harmful microorganisms within a body of water by raising the level of *N. fowleri*, which are indigenous to the soils. Increased populations of *N. fowleri* may have significant adverse impacts. On entry into the nasal passage of a susceptible individual, *N. fowleri* will penetrate the nasal mucosa. The ensuing infection results in a rapidly fatal form of encephalitis. Fortunately, humans in general are resistant to infection with *N. fowleri*. Hallenbeck and Brenniman (1989) have estimated individual annual risks for primary amebic meningoencephalitis caused by the free living *N. fowleri* to swimmers in fresh water, to be approximately 4×10^{-6}. Heavily used lakes and other fresh bodies of water may merit special attention and possibly routine monitoring for *N. fowleri*.

Thermophilic organisms may or may not be influenced by the operation of nuclear power plants. The issue is largely unstudied. However, NRC recognizes a potential health problem stemming from heated effluents. Occupational health questions are currently resolved using proven industrial hygiene principles to minimize worker exposures to these organisms in mists of cooling towers. NRC anticipates that all plants will continue to employ proven industrial hygiene principles so that adverse occupational health effects associated with microorganisms will be of small significance at all sites, and no mitigation measures beyond those implemented during the current term license would be warranted. Aside from continued application of accepted industrial hygiene procedures, no additional mitigation measures are expected to be warranted as a result of license renewal. This is a Category 1 issue.

Public health questions require additional consideration for the 25 plants using cooling ponds, lakes, canals, or small rivers (all under the small river category in Tables 5.18 and 5.19) because the operation of these plants may significantly enhance the presence of thermophilic organisms. The data for these sites are not now at hand and it is impossible to predict the level of thermophilic organism enhancement at any given site with current knowledge. Thus the impacts are not known and are site-specific. Therefore, the magnitude of the potential public health impacts associated with thermal enhancement of *N. fowleri* cannot be determined generically. This is a Category 2 issue.

4.3.7 Noise Impacts

When noise levels are below the levels that result in hearing loss, impacts have been judged primarily in terms of adverse public reactions to the noise. Generally, power plant sites do not result in off-site levels more than 10 dB(A) above background. However, some sites have calculated impacts to critical receptors at this level and above. Noise level increases larger than 10 dB(a) would be expected to lead to interference with outdoor speech communication, particularly in rural areas or low-population areas where the day-night background noise level is in the range of 45–55 dB(A). Generally, surveys around major sources of noise such as large highways and airports have found that, when the day-night level increases beyond 60 to 65 dB(A) (FICN 1992), noise complaints increase significantly. Noise levels below 60 to 65 dB(A) are considered to be of small significance.

The principal sources of noise from plant operations are natural-draft and mechanical-draft cooling towers, transformers, and loudspeakers. Other occasional noise sources may include auxiliary equipment such as pumps to supply cooling water from a remote reservoir. Generally, these noise sources are not perceived by a large number of people off-site.

In most cases, the sources of noise are sufficiently distant from critical receptors outside the plant boundaries that the noise is attenuated to nearly ambient levels and is scarcely noticeable. However, during the original license application process, some of the sites identified critical receptors near plant boundaries that would experience noise levels greater than 10 dB above ambient. Those levels would increase the difficulty in outdoor speech communication. (The noise would require that people speak louder to communicate.) In no case is the off-site noise level from a plant sufficient to cause hearing loss.

Natural-draft and mechanical-draft cooling towers emit noise of a broadband nature, whereas transformers emit noise of a specific tonal nature at harmonics of the 60-Hz primary frequency. The frequencies with important intensities are 120, 240, 360, and 480 Hz. Loudspeakers emit noise at audible frequencies, generally below 5000 Hz. Because of the broadband character of the cooling towers, the noise associated with them is largely indistinguishable and less obtrusive than transformer noise or loudspeaker noise. Transformer noise is distinct because of its specific low frequencies. These low frequencies are not attenuated with distance and intervening materials as much as higher frequencies are; thus, low frequencies are more noticeable and obtrusive. However, at most sites employing cooling towers, transformer noise is masked by the broadband cooling tower noise. Loudspeakers would be a more intermittent source of noise.

Cooling tower and transformer noises do not change appreciably with time. No change in noise levels or their attendant impacts would be expected during the license renewal term.

License renewal does not add to the extent of noise impacts, either in frequency distribution or in intensity. No major changes in the noise profile of power plants is anticipated. The only possible source of added impacts would be the result of additional people who build homes near enough to the site that they are affected by noise. At the noise levels anticipated, no cumulative biological impacts are expected.

During the license renewal term, noise impacts will be the same as during the initial license term. These impacts were found to be generally not noticed by the public, thus noise impacts are of small significance. Consideration was given to mitigating these noise impacts. Because the principal sources of noise are cooling towers, transformers, and loudspeakers, these sources would be the focus of noise reduction efforts. Reduction in loudspeaker noise could be accomplished by restricting such use to emergencies only and using personal electronic pagers to contact personnel. Mitigation of the low-frequency noise from cooling towers or transformers is much more difficult and would require shielding by massive concrete structures or earthen berms.

Because these noise reduction methods would be costly and given that there have been few complaints and the noise impacts are so small, no additional mitigation measures are warranted for license renewal. This is a Category 1 issue.

4.4 COOLING PONDS

4.4.1 Introduction

Power plants that use cooling ponds compose a unique subset of closed-cycle systems in that they operate as once-through power plants [i.e., large condenser flow rates (Table 2.1)] that withdraw from and discharge to relatively small bodies of water created for the plant. Cooling ponds reduce the heat load to natural bodies of water from power plant operations without the construction and operational expenses of cooling towers. The natural body of water is not relied on for heat dissipation but is used as a source of makeup water to replace that lost to evaporation and as a receiving stream for discharges from the cooling pond.

4.4.1.1 Types of Cooling Ponds

The range of power plants that use cooling ponds or lakes represents a gradation from closed-cycle power plants sited on small cooling ponds to once-through power plants sited on large, multipurpose reservoirs. For the purpose of this section, a cooling pond will be defined as "a man-made impoundment that does not impede the flow of a navigable system and that is used primarily to remove waste heat from condenser water prior to recirculating the water back to the main condenser" (ORNL/NUREG/TM-226). Under this definition, nine nuclear power plants use cooling ponds: Braidwood, Clinton, Dresden, La Salle, H. B. Robinson, South Texas, Virgil C. Summer, Wolf Creek, and Turkey Point (actually an extensive system of canals for recirculating water). Effects of other power plants located on large, multipurpose reservoirs (e.g., Comanche Peak and William B. McGuire) are included in the analysis of once-through cooling systems in Section 4.2.

The surface areas of the cooling ponds associated with these nine plants range from 629 to 2924 ha (1573 to 7310 acres). Braidwood, Clinton, Dresden, La Salle, and South Texas all use large cooling ponds that rely on nearby rivers for makeup water. Both H. B. Robinson and Clinton recycle their heated effluent in cooling ponds that are impoundments of relatively small creeks. The Virgil C. Summer plant dissipates waste heat to Monticello Reservoir, which in turn receives makeup water from Parr Reservoir. Wolf Creek recycles its condenser cooling water through a cooling pond that receives its makeup water from nearby John Redmond Reservoir. Turkey Point recirculates condenser cooling water through a complex series of canals.

4.4.1.2 Cooling Pond Emissions and Effluents

Power plants sited on cooling ponds do not have unique effluents or emissions. The examples considered in this section represent open-cycle condenser cooling systems that use the man-made pond to recirculate cooling water. Discharges to natural waters are used primarily to control the buildup of dissolved solids, analogous to blowdown from cooling towers, and may or may not have elevated temperatures. The types of emissions and effluents are the same as those considered for once-through cooling systems in Section 4.2.

Also, intake and discharge effects are regulated in the same way as for once-through cooling systems [i.e., through NPDES permits and, if needed, CWA Section 316(a) and (b) determinations (see Section 4.2 for a discussion of these regulatory mechanisms)].

Accelerated evaporation of water from a cooling pond produced by thermal loading from the power plant increases the concentration of total dissolved solids (TDS). Concentrations of TDS in cooling reservoirs average about 1.8 times those in the makeup waters (ORNL/NUREG/TM-226). Contaminants may also accumulate in the pond water and sediments. Accumulation of such water quality constituents as metals (copper or zinc) and chlorinated organic compounds in water, sediments, and aquatic biota has been cited as a potential issue for power plants located on cooling ponds.

4.4.2 Surface Water Use and Quality

This section and Section 4.4.4 review the past and ongoing impacts on aquatic resources of operation of nuclear power plants with cooling ponds. Any ongoing impacts will probably continue into the license renewal term because the cooling system design and operation are not expected to change. Judgments about the significance of these issues during the license renewal term are based on published information, agency consultation, and information provided by the utilities (Appendix F) applicable to every nuclear power plant in the United States. The conclusions reached in these sections apply to all nuclear power plants with cooling ponds.

4.4.2.1 Water Use

Nine nuclear power plants use off-stream ponds or lakes as cooling devices. Although these off-stream bodies of water were specifically designed to serve as cooling systems for temperature reduction before discharge into a river or reservoir, some (e.g., La Salle County Nuclear Station) provide recreational fishing opportunities in addition to cooling. The water-use issue associated with operation of cooling ponds is the availability of adequate streamflows to provide makeup water, particularly during droughts or in the context of increasing in-stream and off-stream uses. Two nuclear power plants, the Braidwood Station and the Wolf Creek Generating Station, have already experienced water-use conflicts.

Braidwood, which withdraws makeup water for its cooling pond from the Kankakee River, will face future water availability conflicts as Joliet, Illinois, becomes a potential downstream water user. Potential use of water upstream for irrigation may also affect the Kankakee River flow and the availability of water for the Braidwood facility. In response to other water-use demands, Braidwood, La Salle County, Dresden, and other nuclear facilities using cooling ponds or lakes, particularly those on the same river system as other thermoelectric generating facilities, may have to reevaluate their overall water requirements and tolerances to drought conditions. For example, Braidwood was forced to cease withdrawal from the Kankakee River during much of July and August 1988 because the flow of the river was below the level at which makeup withdrawals were permitted [Commonwealth Edison Company response to NUMARC survey (NUMARC 1990); Gary Clark, telephone interview with V. R.

Tolbert, ORNL, Oak Ridge, Tennessee, July 5, 1990]. These plants could increase the sizes of their cooling ponds or adopt other measures to compensate for an inability to withdraw makeup water during low flows or because of competing water uses (Gary Clark, Illinois Division of Water Resources, personal communication to V. R. Tolbert, ORNL, Oak Ridge, Tennessee, July 5, 1990).

Probably the most important change in the consideration of water-use impacts since the initial licensing of most of the nuclear generating facilities has been the increased emphasis on in-stream flow for preservation of aquatic habitat, riparian (streamside) habitat, and associated biota. An example of potential water-use conflicts is associated with the withdrawal of makeup water by the Wolf Creek Generating Station in Kansas. Water for the Wolf Creek cooling lake is withdrawn from the Neosho River downstream of John Redmond Reservoir. Riffle (shallow water) areas of this river serve as habitat for a threatened fish species, the Neosho madtom. Makeup water withdrawals during severe drought conditions could affect the riffle habitat of this species (Harold Spiker, letter to G. F. Cada, ORNL, Oak Ridge, Tennessee, June 28, 1990).

Nuclear power plants that withdraw makeup water for cooling ponds from small bodies of water may need to curtail operations during drought periods or may experience future conflicts with other water users (including increasing emphasis on in-stream uses). This potential issue affects only a small number of existing plants, and mechanisms exist for resolving these conflicts (e.g., through derating the plant during temporary drought periods or, if longer-term solutions are required, by the periodic renewals of the plants' NPDES permits). Consultations with regulatory agencies indicate that water use conflicts are already a concern at two of the nine nuclear power plants with cooling ponds (Braidwood and Wolf Creek). Because water use conflicts may be of small or moderate significance during the license renewal period, this is a Category 2 issue for nuclear plants with cooling systems that utilize cooling ponds. The effects of consumptive water use on in-stream and riparian communities could also be of small or moderate significance, depending on the plant, and also are a Category 2 issue.

4.4.2.2 Water Quality

An issue associated with the operation of a cooling pond is potential alteration of the quality of both pond and natural receiving waters as a result of the addition and concentration of a variety of chemicals. As with all other types of condenser cooling systems, chemicals (e.g., chlorine) may be added to control biofouling and to inhibit scaling and corrosion in the condenser tubing. In addition, corrosion products are leached into the circulating water flow and may be concentrated in the recirculating system.

Discharges of heat and chemical contaminants are controlled by the NPDES permits that are issued and periodically renewed for each power plant (Section 4.2). Whereas the volume of water that is discharged to a natural body of water from a cooling pond may be comparable to that discharged as blowdown from a cooling tower, the concentration of dissolved solids is less. In ORNL/NUREG/TM-226, Parkhurst and McLain estimate that the average concentration of TDS is about 400 percent above ambient in the blowdown from cooling towers and about 180 percent above ambient in the discharge from cooling reservoirs. Greater quantities of biocides may also be needed for cooling towers than for cooling ponds because of the additional need to control biofouling on the cooling tower surfaces.

Larimore and McNurney (EPRI EA-1148) compared the water quality of a power plant cooling lake (Lake Sangchris in Illinois) with that of a nearby lake unaffected by power plant discharges. The most obvious differences resulted from the heat input and power-plant-induced circulation, which prevented seasonal thermal stratification in the cooling lake. With the exception of temperature, no water quality differences between the two lakes were attributed to power plant operations.

Becker et al. (EPRI EA-1054) examined available data from 14 cooling impoundments (all associated with fossil-fuel power plants) to identify water quality and ecological effects. These 14 cooling impoundments were selected from a population of 135 steam-electric power plant cooling ponds across the United States as those most likely to provide "worst-case" conditions for identifying impacts from power plant operation. Selection was based on load ratio, that is, impoundment surface area divided by rated plant generating capacity in megawatt (electrical). The authors assumed that cooling impoundments with low load ratios (relatively little dilution of power plant discharges) would be most likely to exhibit discharge-related water quality and ecosystem effects. Neither low DO concentration nor supersaturation of other dissolved gases was a problem, although oxygen deficits occurred in deeper waters of those cooling ponds that stratified.

There was no indication that plant chlorination increased the chloride concentration of closed impoundments. Evaporation from a completely closed pond (no blowdown) resulted in gradual, long-term concentration of inorganic constituents, but levels did not exceed those commonly tolerated by aquatic life.

Potentially more important than the overall increase in TDS is the concentration of specific constituents—for example, heavy metals. The accumulation of heavy metals in cooling ponds via evaporation and bioconcentration has not been identified as a concern by the utilities or regulatory agencies, although specific studies appear to be uncommon. In a survey of 14 cooling impoundments, Becker et al. (EPRI EA-1054) found data on metals for only one. Trace metal concentrations were measured at North Lake, a cooling impoundment in Texas with one of the lowest load ratios in the study. North Lake is a completely enclosed system with essentially no drainage. As a result of high evaporative water losses, water levels cannot be maintained solely by precipitation, so makeup water must be pumped from the nearby Trinity River. In 15 years of operation, the cooling impoundment was refilled about 5.5 times, a situation that should lead to relatively high concentrations of water quality constituents. The North Lake data indicated that trace metals (copper, chromium, iron, lead, manganese, and zinc) were not accumulating in the impoundment, and the levels were too low to be toxic to the ecosystem (Sams 1976). On the other hand, a study of copper concentrations at eight nuclear power plants indicated that the highest chronically elevated concentrations in the discharge waters occurred at the H. B. Robinson Steam Electric Plant Unit 2, a plant with a

 JA00162

cooling impoundment (ASTM STP 854). Examination of a variety of factors, including influent water quality and copper specification, led Harrison (ASTM STP 854) to conclude that elevated levels of copper in the H. B. Robinson plant effluent could be attributed to the low-pH water in the region, which caused relatively high leaching of copper from the condenser tubes. The naturally high corrosivity of the water appeared to be the cause of elevated copper concentrations at this plant. The copper-containing tubing was subsequently replaced because of high leakage, eliminating copper loading to the cooling pond [Carolina Power & Light Company response to NUMARC survey (NUMARC 1990)].

Although power plant chlorination may result in the presence of chlorinated organic compounds, the potential accumulation of these materials appears to have been studied rarely. Sams (1976) investigated the possible buildup of total chlorinated organic compounds in the closed cooling impoundment of a fossil-fueled power plant but detected no quantitative differences between the pond and its makeup water source.

The Illinois Department of Conservation has expressed concern about the adverse influence of discharges from the Dresden Nuclear Power Station cooling pond on the temperature and water quality of the Kankakee River (Mark Frech, letter to G. F. Cada, ORNL, Oak Ridge, Tennessee, July 2, 1990). EPA has also pointed out that Dresden may have difficulty meeting temperature limits in the future as water quality improves and standards become more stringent (Robert Springer, letter to G. F. Cada, ORNL, Oak Ridge, Tennessee, June 29, 1990). With this exception, the effect of operation on water quality is not a concern at the nine nuclear power plants that use cooling ponds as part of their condenser cooling systems. In all cases, the NPDES permits and 316(a) determinations that limit the discharge of heat and other pollutants are periodically reevaluated and renewed by the EPA or state water quality permitting agencies, allowing existing or future water quality issues to be resolved in a timely manner.

The impacts of condenser cooling system discharges on water quality of cooling ponds are considered to be of small significance if water quality criteria (e.g., as contained in NPDES permits) are not violated and if aquatic organisms in the vicinity of the plant are not bioaccumulating metals or other contaminants. Based on review of literature and operational monitoring reports, consultations with utilities and regulatory agencies, and comments on the draft GEIS, degradation of water quality in cooling ponds has not been a problem at most existing nuclear power plants. Mitigation was effective at the one plant that experienced elevated metal levels during the current license period. Effects are considered to be of small significance for all plants. Heat is rapidly dissipated in the vicinity of the power plant so that far-field, cumulative effects would not be expected. No evidence of existing, significant accumulation of contaminants in or near cooling ponds was found in the literature or provided by regulatory agencies. No change in operation of the cooling system is expected during the license renewal term, so no change in effects of discharges on water quality of cooling ponds is anticipated. Effects of discharges to cooling ponds could be reduced by operating additional water treatment systems, greater flushing of the cooling pond/reservoir, or by reducing the plant's generation rate. However, because the effects of discharges on water quality of cooling ponds are considered to be impacts of small significance and because these changes would be costly, the staff does not consider the implementation of these potential mitigation measures to be warranted. Effects of condenser cooling water discharges on water quality of cooling ponds are a Category 1 issue.

4.4.3 Aquatic Ecology

As noted in Section 4.4.2, the concentrations of TDS in cooling ponds averages less than three times that in the makeup water. Such concentrations of most water quality constituents are unlikely to affect aquatic biota. However, elevated levels of particular constituents may be of greater concern. For example, formerly elevated copper concentrations in the effluent from the H. B. Robinson plant (Section 4.4.2) were implicated in increased deformities and reduced reproductive capacity in the bluegill population residing in the cooling pond (NUREG/CR-2822; ASTM STP 854). Harrison and Lam (NUREG/CR-2822) concluded that these sublethal effects were the result of leaching of copper from the condenser tubes by the low-pH water in the pond. Although the highest concentrations of copper in fish tissue were found in bluegills collected in the discharge area, tissue concentrations were also elevated in the intake site compared with an upstream control site. Following replacement of the copper-alloy condenser tubing, fish populations recovered and skeletal deformities disappeared [Carolina Power & Light Company response to NUMARC survey (NUMARC 1990)].

In addition to potential effects from water quality degradation, aquatic biota of cooling ponds may be affected by impingement, entrainment, and thermal discharges. These effects are the same as those considered for once-through cooling systems (Section 4.2.2), except that they mainly influence aquatic communities that did not exist before creation of the cooling pond; natural communities are affected to a lesser extent by the relatively small withdrawals and discharges associated with makeup water and blowdown. In a review of impacts of cooling impoundments of fossil-fuel power plants, Becker et al. (EPRI EA-1054) detected no major detrimental impacts on fish populations from power plant operation. The qualitative effects observed included earlier seasonal spawning and faster growth rates, which the authors attributed to elevated water temperatures. Information was not adequate to determine quantitative power plant effects on fish populations in the 14 impoundments studied. Larimore and McNurney (EPRI EA-1148) compared fish populations of a cooling lake and a nearby noncooling lake. Largemouth bass in the cooling lake spawned earlier, grew faster, were more accessible to anglers in the winter, and had lower rates of parasitic infestation. Parkhurst and McLain (ORNL/NUREG/TM-226) reviewed effects of cooling reservoirs on fish populations. They concluded that (1) effects on game fish populations are generally insignificant or positive but rarely negative, (2) growth rates are generally similar to those of fish from other waters, (3) some species may spawn earlier in the heated environment, (4) many species are attracted to the heated areas during the winter and avoid those areas in the summer, and (5) the thermal tolerances of species inhabiting heated waters are often higher than those for the same species inhabiting ambient-temperature waters.

Consultations with regulatory agencies and nuclear utilities that operate cooling ponds have revealed some site-specific concerns. For example, the Virgil C. Summer Nuclear Station has experienced thermal-discharge-effect-related fish kills in recent summers in and around the heated water discharge bay (James A. Timmerman, Jr., letter to G. F. Cada, ORNL, Oak Ridge, Tennessee, July 2, 1990). These fish kills were localized; they do not appear to have had any adverse effect on the cooling pond population. The utility is investigating the specific causes of the fish kills to implement corrective actions [South Carolina Electric & Gas Company response to NUMARC survey (NUMARC 1990)]. Concerns about biological effects of inadequate in-stream flows below the Wolf Creek Generating Station, particularly during drought years, have been raised (Harold L. Spiker, letter to G. F. Cada, ORNL, Oak Ridge, Tennessee, June 28, 1990). This water-use issue is discussed in Section 4.4.2.1.

The operating experience of nuclear power plants using cooling ponds indicates that impacts on aquatic resources appear to be a function of unique characteristics of the plant or the environment and not generally the result of the cooling system technology. Water-use conflicts (Braidwood, Wolf Creek) and hot weather fish kills (Virgil Summer) could occasionally develop at many fossil-fuel and nuclear power plants. Elevated concentrations of trace metals, which should be most apparent in recirculating cooling ponds, were a concern at only one plant. In this example, elevated copper concentrations in the effluent are believed to have resulted from the leaching of copper from condenser tubing by naturally acidic water; the extent to which buildup of copper in the pond by the recirculation of cooling water also contributed to the subsequent biological effects was not determined. Because effects on the bluegill population have been eliminated by the replacement of the condenser tubing with noncopper alloys, recirculation of residual copper in the cooling pond does not appear to be a problem.

Water quality and aquatic ecology issues for nuclear power plants that use cooling ponds, are summarized in Table 4.4. As noted for power plants with once-through cooling systems in Section 4.2.3.2, operational experience indicates that most early aquatic resource concerns have been found to be of small significance at all sites, and no mitigation measures beyond those implemented during the current term license would be warranted. For the reasons given in Section 4.2.2, these are Category 1 issues. However, entrainment and impingement of fish and thermal discharge effects are of sufficient concern on large cooling ponds that support valued aquatic resources that they continue to be examined in detail as part of CWA Section 316(a) and (b) demonstrations. Section 316(a) or (b) determinations are pending for two of the nine nuclear power plants with cooling ponds (Braidwood and Clinton). Further, changes in aquatic communities of either the cooling ponds or source bodies of water could warrant reexamination of entrainment, impingement, or heat shock effects at any of the plants before the time of license renewal. For some plants, the large volumes of water withdrawn, heated, and discharged back to the receiving water may cause adverse effects to fish populations during the license renewal term. Because impacts of fish entrainment and

Thermal plume barrier to migrating fish	1
Distribution of aquatic organisms	1
Premature emergence of aquatic insects	1
Stimulation of nuisance organisms (e.g., shipworms)	1
Losses from predation, parasitism, and disease among organisms exposed to sublethal stresses	1
Gas supersaturation (gas bubble disease)	1
Low dissolved oxygen in the discharge	1
Accumulation of contaminants in sediments or biota	1

[a]A 1 means that the impact is expected to be of small significance at all sites. A 2 means that the impact may be of moderate or large significance at some sites.

impingement and of thermal discharge effects could be small, moderate, or large, depending on the plant, these are Category 2 issues for nuclear plants that use cooling ponds.

4.4.4 Terrestrial Ecology

The issue evaluated in this section is the extent to which vegetation and wildlife are affected by increased fogging, humidity, and icing near cooling ponds and by water contaminants that may be present in the ponds. The primary impacts of cooling ponds on terrestrial ecological resources occurred when the ponds were constructed and filled, resulting in flooding and loss of terrestrial plant and animal communities. Potential impacts during plant operation include exposure of terrestrial habitats near the ponds to increased levels of humidity, icing, and fog. Also, waterfowl and other wildlife that use the ponds may be exposed to increased levels of dissolved solids and other contaminants released from the power plant. Fogging, humidity, icing, and the presence of dissolved solids and other contaminants that might be present in or at cooling ponds are of concern if they are present at levels that threaten the stability of local wildlife populations or vegetation communities in the vicinity of the cooling ponds. If there is no threat to the stability of local wildlife populations or vegetation communities, then any impact is considered of small significance.

These potential impacts apparently have not been a problem at any plant with cooling ponds. No significant damage to or loss of vegetation has been reported to result from increased humidity, fog, or icing. Without damage to vegetation, wildlife populations should not be affected. Water quality in the ponds is not being degraded to the extent that aquatic life is adversely affected (Sections 4.4.2 and 4.4.4). Therefore, wildlife using these ponds should not be significantly affected by changes in water quality or by loss of aquatic food or prey. Bioaccumulation of contaminants in the bodies of wildlife predators feeding on aquatic biota is not expected to be a problem because of the very low concentrations of contaminants. Because no threat to the stability of local wildlife populations or vegetation communities is found for any cooling pond, the impacts are found to be of small significance. Potential mitigation measures would include excluding wildlife (e.g., birds) from contaminated ponds, converting to a dry cooling system, or reducing plant output during fogging or icing conditions, the impacts are found to be so minor that consideration of additional mitigation measures is not warranted. These effects of cooling ponds are so minor and so localized that cumulative impacts are not a concern. This is a Category 1 issue.

4.5 TRANSMISSION LINES

Impacts of transmission lines result from their maintenance, electromagnetic fields, corona, and rights-of-way (ROW). Their impacts on air quality (Section 4.5.2), land use (Section 4.5.3), human health (Section 4.5.4), surface water quality and aquatic ecology (Section 4.5.5), terrestrial ecology (Section 4.5.6), floodplains and wetlands (Section 4.5.7), and historic and aesthetic resources (Section 4.5.8) are assessed in this section. As at the construction permit stage, the transmission corridor of concern is that which was constructed between the plant switchyard to its connection with the existing transmission system. No new transmission line construction is planned in existing or new corridors. The types of impacts of transmission lines during the license renewal period will be the same as those during the first 40 years of operation.

4.5.1 Introduction

Transmission lines use voltages of about 115 or 138 kV and higher. In contrast, local or area distribution lines use voltages below 115 or 138 kV. Only transmission lines are discussed in this document. Extra-high-voltage transmission lines operate at 345 to 800 kV, whereas ultra-high-voltage (UHV) lines operate at 1000 kV and above. Lines up to 765 kV, a voltage occurring primarily in the eastern United States, are in commercial operation, whereas UHV lines are still in the testing stage of development. The principal advantage of higher-voltage lines is that they can transmit proportionately more power than can lower-voltage lines.

Detailed descriptions of transmission lines and basic electrical concepts are provided by ORNL-6165, DOE/BP-945, and BNWL-1774. Typical transmission line structures, shown in Figure 4.1, range in height from about 20 to 52 m (65 to 170 ft) and provide average spans (the distance between structures) of about 106 to 350 m (350 to 1150 ft). The structures support a three-phase system of conductors and two ground wires above the conductors. The ground wires intercept lightning strikes to prevent the strikes from hitting the conductors and adversely affecting power system operation. The most common structure types are the H-frame and lattice; single-pole and guyed-Y types are less common. The H-frame is usually made of wood and is used for lower-voltage lines. The metal lattice structure is capable of bearing more weight than the H-frame, allowing greater span length, higher-voltage lines, and more circuits for a given width of ROW.

Transmission lines must be inspected periodically to detect any deterioration of or damage to line components. This inspection can be done from the ground but is often done from a helicopter. Maintenance or repairs of power lines may require that vehicles gain access to the lines.

Electric and magnetic fields, collectively referred to as electromagnetic field or EMF, are produced by operating transmission lines. EMF strength at ground level varies greatly under these lines, generally being stronger for higher-voltage lines, a flat configuration of conductors (as opposed to, for example, the delta configuration), relatively flat terrain, terrain with no shielding obstructions (e.g., trees or shrubs), and a closer approach of the lines to the ground. At locations where field strength is maximum, measured values under 500-kV lines often average about 4 kV/m, but sometimes exceed 6 kV/m. Maximum electric field strengths at ground level are 9 kV/m for 500-kV lines and 12 kV/m for 765-kV lines (DOE/BP-945).

Measured magnetic field strengths at the location of maximum values beneath 500-kV lines often average about 70 mG (milligauss). During peak electricity use, when line current is high, the field strength may peak at 140 mG (about 1 percent or less of the time) (DOE/BP-945).

The term "corona" generally refers to the electrical discharges occurring in air subjected to the strong electric fields adjacent to phase conductors. Corona generally is not a problem at voltages below 345 kV. Corona results in audible noise, radio and TV interference, energy losses, and the production of ozone and oxides of nitrogen.

An ROW must be acquired by the utility to prevent certain land uses and vegetation growth from interfering with transmission line operation. To ensure power system reliability, the growth of tall vegetation under the lines must be prevented (by cutting or herbicides) to avoid physical interference with lines or the potential for

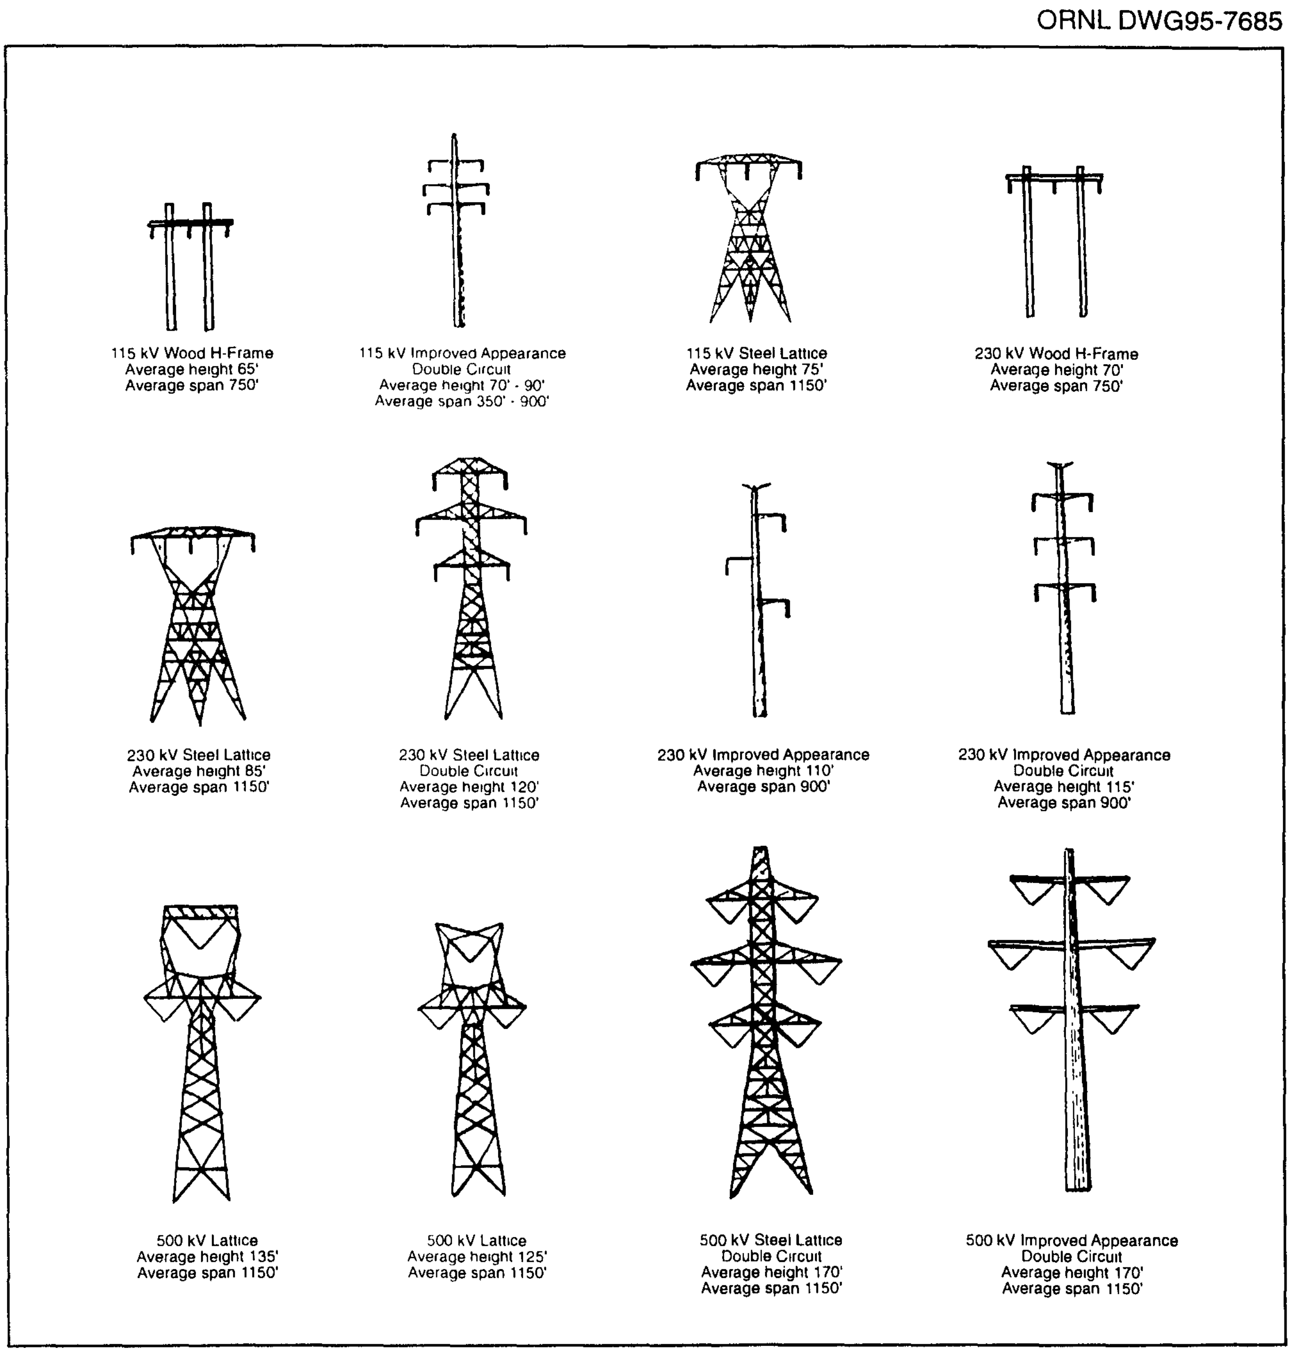

Figure 4.1 Examples of typical transmission line towers. *Source:* DOE/BP-945.

short-circuiting from the line to the vegetation. At the edge of ROW, trees that could topple onto the lines must be removed.

ROW maintenance is described in greater detail by FWS/OBS-79/22, ORNL-6165, BNWL-1774, and Byrnes and Holt (1987).

4.5.2 Air Quality

Small amounts of ozone and substantially smaller amounts of oxides of nitrogen are produced by transmission lines during corona, a phenomenon that occurs when air ionizes near isolated irregularities on the conductor surface such as abrasions, dust particles, raindrops, and insects. Several studies have quantified the amount of ozone generated and concluded that the amount produced by even the largest lines in operation (765 kV) is insignificant (SNYPSC 1978; Scott-Walton et al. 1979; Janes 1980; Varfalvy et al. 1985). Monitoring of ozone levels for 2 years near a Bonneville Power Administration 1200-kV prototype line revealed no increase in ambient ozone levels caused by the line (Bracken and Gabriel 1981; DOE/BP-945). Ozone concentrations generated by transmission lines are therefore too low to cause any significant effects. The minute amounts of oxides of nitrogen produced are similarly insignificant. A finding of small significance is supported by the evidence that production of ozone and oxides of nitrogen are insignificant and does not measurably contribute to ambient levels of those gases. Potential mitigation measures (e.g., burying transmission lines) would be very costly and would not be warranted. This is a Category 1 issue.

4.5.3 Land Use

4.5.3.1 Overview of Impacts

The concerns addressed by this section involve the extent to which license renewal and up to an additional 20 years of plant operation will preclude alternative uses of the transmission line corridor and the relative value that should be placed on such alternative uses. At the time of a license renewal application the transmission corridor and lines will have been in place for well over 20 years, having been initially constructed to furnish power to the site for construction of the plant. Even after cessation of plant operation the transmission line to the site would continue to be used to bring power in to the site during decommissioning. It is likely that a utility would locate new generating capacity on a site and utilize the existing transmission corridor. The site and transmission corridor are valuable assets for the utility. Therefore, the most likely scenario is that regardless of whether a license is renewed it should be anticipated that a transmission corridor will continue in use for the transmission of power indefinitely.

The issue addressed by this section is the extent to which existing transmission lines will, after relicensing, continue to preclude productive use of land or interfere with land uses (e.g., cultivation). Impacts are expected to be no different from those that have occurred during past power line operation. Impacts are described and assessed by reviewing the published literature reporting monitoring data on this topic. No monitoring data on land-use impacts were found that deal with transmission lines specifically associated with nuclear plants. However, because transmission lines associated with nuclear plants are no different from lines associated with other types of generating facilities, literature on any type of transmission line is applicable to the analysis in this section.

The impact of transmission lines on land use resulting from license renewal is considered of small significance if there is no increase in the amount of land committed to the corridor right-of-way and if there are no major changes in the use patterns of the corridor resulting from renewal of the operating license. Alterations in the corridor path could result in impacts of moderate to large significance. Relocating the transmission corridor could result in large land use impacts. There is no basis to believe that any alteration in a transmission corridor would be made in conjunction with license renewal.

The presence of a transmission line and its ROW precludes certain land uses on the ROW that could bring economic gain to the landowner and decreases the profits of forestry, agricultural, orchard, and vineyard operations. However, the landowner has been compensated to some extent for these economic losses by the initial purchase of the ROW easement or, in some cases, by purchase of the land itself.

The construction of buildings or any other permanent structures that could interfere with transmission line operation is usually prohibited on a power line ROW. In contrast, several land uses can occur on ROW without endangering line operation and are usually not restricted by the ROW easement, including hiking, hunting, off-road vehicle use, grazing, agricultural cultivation, irrigation, and roads. Power-line corridors on private property may sometimes increase the frequency of trespassing.

In rural areas, the primary impact on land use is continuing interference with agricultural cultivation, orchards, vineyards, spraying, and irrigation. Some mobile irrigation facilities are very long and may cover an entire field or a large part of the field in one operation (Varner and Patel 1984). The presence of a transmission line structure in such a field may require that the irrigation facility be segmented into two or more independent pieces. Such segmentation increases the labor requirements and the costs of the irrigation facility. Aerial spraying of an agricultural field is restricted by transmission lines; spraying costs may be increased, and the extra maneuvers that the aircraft pilot must make to avoid the lines may lessen the effectiveness of the pesticide coverage.

Impacts on crop production that may have been caused by transmission line interference with aerial spraying have been reported by one field study of cotton, rice, and soybean fields crossed by a 500-kV line in eastern Arkansas (Parsch and Norman 1986). This study hypothesized that crop yields could be reduced either by EMFs (see Section 4.5.6.3) or by inadequate aerial spraying directly under the power lines. Only cotton yields were found to be reduced: 15 percent less lint was produced under the lines than 150 ft from the lines. The resulting loss of income from cotton was estimated as $85.25 per year for an 1100-ft (335-m) span of the lines, based on a 15 percent yield reduction and an average lint yield of 480 lb/acre. The field sampling and statistical analyses were extensive; the observed yield reduction appeared to be real rather than a sampling error. However, the study could not determine whether the EMF or line interference with aerial spraying caused the yield reduction.

The presence of a transmission line structure in any agricultural field, irrigated or not, will continue to exclude land from production and increase the time and money required to perform weed control, cultivation, and harvesting. The major (e.g., 70–90 percent) economic cost results from the exclusion of otherwise productive land from cultivation. The amount of land area affected depends on the structure type and size, the type of crop, and the agricultural practices involved (Grumstrup et al. 1982; EPRI WS-78-141). For lattice-type structures 8 to 9.8 m^2 (26 to 32 ft^2) at the base, the exclusion of productive land varies from about 488 to 976 m^2 (1600 to 3200 ft^2) for each structure. Operations for cultivating some types of crops can be conducted beneath structure bases if the structure is large enough, thus minimizing losses. The presence of guy wires significantly increases the area of land excluded from production, while non-guyed single-pole and H-frame structures have about half as much impact as lattice structures (Grumstrup et al. 1982). Minor additional costs result from the maneuvering necessary for farm machinery to avoid tower legs. Lattice structures and guyed structures interfere more with farming practices than do pole-type structures.

Costs also depend on the relative locations of transmission line structures within fields (Table 4.5). A study of corn, soybean, wheat, oats, buckwheat, and hay fields in Ontario found that the amount of land excluded from production increased in the following order of structure locations: (1) straddling a fence row (minimal impact); (2) adjacent to a fence row; (3) adjoining the headland (the end of the field where the tractor turns) but in the main part of the field; (4) midfield; and (5) within the headland, near, but not adjacent to, a fence row (maximum impact) (EPRI WS-78-141). In tobacco fields, equipment operations differed from those in grain fields, and structures in midfield obstructed cultivation on about twice as much land area as did structures in the headland (Scott 1982). For a variety of grain crops, the economic losses caused by power lines were accounted for by the following factors: time lost—about 30 percent of the costs; land excluded from production—about 60 percent; damaged crop costs—about 2 percent; and material loss—about 8 percent (EPRI WS-78-141). In vineyards, orchards, and tobacco fields, about 75 to 95 percent of the total costs resulted from the continuing exclusion of land from production (EPRI WS-78-141; Scott 1982). In general, the economic losses associated with transmission line structures are closely related to the value of the affected crop, and the percentage of total economic loss resulting from land lost to cultivation is proportionately higher for higher value crops (Scott 1982). Tobacco, orchard, and vineyard crops have relatively high value per acre; grain crops have lower value.

Utilities sometimes locate transmission lines in agricultural areas rather than wooded areas to minimize maintenance costs. Although utilities pay a higher price for ROW on agricultural land, overall costs are minimized by avoiding the higher long-term costs of ROW vegetation maintenance that would be necessary in wooded areas (EPRI WS-78-141).

The potential impact of transmission lines on land use differs among nuclear plants in different geographic regions because land

Table 4.5 Estimated losses in crop profits caused by a lattice structure[a]

Crop	Structure location	
	Midfield	Headland
Tobacco	$356	$132
Peach orchard[b]	95	84
Vineyard[b]	117	53
Wheat	15	—
Soybeans	18	—
Grain corn	25	—
Silage corn	30	—

[a]The currency is the Canadian dollar 1977–1980. The structure is 8.5 × 8.5 m (28 by 28 ft) at the base and its orientation is square to the crop rows as opposed to diagonal to crop rows.
[b]The midfield value is based on not being able to drive equipment under structures and is an average of several midfield variations of structure positioning.
Sources: EPRI WS-78-141; Scott.

uses (e.g., different types of agricultural crops) are different in different regions. The type and extent of the impacts of power lines on land use are relatively well known, and no monitoring of land-use impacts has been done for any specific nuclear plant.

4.5.3.2 Conclusion

There is no basis to believe that the renewal of any operating license will change existing land use in the transmission line corridor either in terms of the amount of land committed or activities taking place within or adjacent to the corridor. For this reason, the staff finds that the impacts of transmission lines on land use attributable to license renewal is of small significance. Ongoing land use impacts would be expected to continue, e.g., constraints on agricultural activity. Although transmission line towers prevent some land from being cultivated or grazed, the amount of land area involved represents only a very small fraction of existing cropland and pasture in the vicinity of transmission lines. Therefore, the reduction in total harvest or livestock production typically has no significant impact on individual farm production or on overall production in larger regions such as townships or counties. The interference with aerial spraying caused by transmission lines can affect an area that is larger than that of the tower site, but the yield in this larger area would not be expected to be reduced by more than a small fraction (e.g., a 15 percent yield reduction in cotton).

The presence of transmission lines does not cause additional permanent loss of farmland (in the sense that farmland is lost, for example, to parking lots and buildings during urban development). Any restrictions on land use within the corridor right-of-way would have been imposed and compensated for as necessary years earlier.

Additional mitigation might require removal of wires, towers, and tower bases so that the entire area previously occupied by towers could be used for farming. Because such mitigation would be costly and would provide little environmental benefit, further consideration of mitigation is not warranted. The significance of any impacts is so minor and localized that cumulative impacts are not an issue. This is a Category 1 issue.

4.5.4 Human Health

The two human health issues related to transmission lines are the acute effect, shock hazard, and the potential for chronic effects from exposure to electric and magnetic fields. As stated previously, the transmission line of concern is that between the plant switchyard and the intertie to the transmission system. Transmission lines are necessary to transfer energy from all types of electrical generating facilities to consumers. Therefore, these issues are generic to the 118 nuclear power plants. Issues are evaluated by referral to the National Electric Safety Code [NESC (1981)] for the shock hazard issue and a review of relevant literature for the issue of potential chronic effects from exposure to the electric and magnetic fields surrounding transmission lines.

EMFs resulting from 60-Hz power transmission lines fall under the category of nonionizing radiation. An example of ionizing radiation is the X-ray. Much of the general population has been exposed to power line fields since near the turn of the century. However, except for the concern about electrical shock from insulated conductors such as fences, there was little concern about health effects from such exposures until the 1960s. A series of events during the 1960s and 1970s heightened public interest in the possibility of non–shock-related health effects from nonionizing radiation exposures and resulted in increased scientific investigation in this area (Wilson et al. 1990). Then, in 1979, results of an epidemiological study suggested a correlation between proximity to high-current wiring configurations and incidence of childhood leukemia (Wertheimer and Leeper 1979). This report resulted in additional interest and scientific research; however, no consistent evidence linking harmful effects with 60-Hz exposures has been presented.

4.5.4.1 Acute Effects (Shock Hazard)

Primary shock currents are produced mainly through direct contact with conductors and have effects ranging from a mild tingling sensation to death by electrocution. Tower designs preclude direct public access to the conductors. Secondary shock currents are produced when humans make contact with (1) capacitively charged bodies such as a vehicle parked near a transmission line or (2) magnetically linked metallic structures such as fences near transmission lines. A person who contacts such an object could receive a shock and experience a painful sensation at the point of contact. The intensity of the shock depends on the EMF strength, the size of the object, and how well the object and the person are insulated from ground.

Design criteria that limit hazards from steady state currents are based on the NESC (1981), adherence to which requires that utility companies design transmission lines so that the short-circuit current to ground, produced from the largest anticipated vehicle or object, is limited to less than 5 mA. In practice, this limits the electric field near roadways to about 7–8 kV/m. No similar code exists for the limitation of the magnetic fields of transmission lines; however, because of concerns about the safety of magnetic fields, several states have created their own regulations. See Nair et al. (1989) for a review of these regulations.)

With respect to shock safety issues and license renewal, three points must be made. First, in the licensing process for the earlier licensed nuclear plants, the issue of electrical shock safety was not addressed. Second, some plants that received operating licenses with a stated transmission line voltage may have chosen to upgrade the line voltage for reasons of efficiency, possibly without reanalysis of induction effects. Third, since the initial NEPA review for those utilities that evaluated potential shock situations under the provision of the NESC, land use may have changed, resulting in the need for a reevaluation of this issue.

The electrical shock issue, which is generic to all types of electrical generating stations, including nuclear plants, is of small significance for transmission lines that are operated in adherence with the NESC. Without review of each nuclear plant transmission line conformance with NESC criteria, it is not possible to determine the significance of the electrical shock potential. This is a Category 2 issue.

4.5.4.2 Chronic Effects

4.5.4.2.1 Results of Ongoing Research

Substantial scientific evidence from laboratory studies funded primarily by DOE and EPRI indicates that extremely low-frequency (ELF) electric and magnetic fields can, under certain conditions, cause biological effects (Wilson et al. 1990; Polk and Postow 1986; Adey and Lawrence 1984; Chiabrera et al. 1985; EPA/600/6-90/005A; Carpenter and Ayraptyan 1994). The importance of these effects for humans who are exposed to transmission line fields is not clear. Perhaps the greatest deficiency in understanding at this time is the lack of a mechanistic theory capable of predicting biological effects from low-level EMF exposures (EPA/600/6-90/005A). Without an understanding of how these EMF fields are interacting with biological functions, the knowledge gained from scientific studies is of limited value both in evaluating the importance of the study results and in devising rational protection strategies for the public and for utility workers.

At exposure levels capable of producing relatively high current densities (10 to 100 mA/m^2), a substantial body of evidence has been accumulated indicating that EMF fields may influence biological function (IRPA/INIRC 1990). Such exposures have been suggested to induce chromosome aberrations, alter the distribution in molecular weights during protein synthesis, inhibit production of melatonin, alter calcium binding in brain tissue, influence RNA transcription, and produce a variety of other effects (OTA-BPA-53 1989). Questions concerning the potential carcinogenic effects of EMF field exposure have been raised as a result of suggestive epidemiological findings and some laboratory experiments. Two currently accepted models of cancer are the initiation-promotion paradigm (Easterly 1981; Stevens et al. 1990). Currently, most investigators conclude that EMF fields are not likely to act as initiators because they have not been shown to cause genetic damage (Aldrich and Easterly 1987). EMF effects on RNA transcription, however, could imply increased reduction of oncogene products, and some investigators consider such data to be indicative of genetic effects (Goodman et al. 1983; Goodman et al. 1987; Goodman and Henderson 1986, 1988). Work is in progress on an attempt to replicate the studies suggesting modification of transcription by EMF. However, attempts thus far have been unsuccessful. Moreover, it has not been shown that EMF fields are cancer promoters, but the presence of some reported EMF bioeffects reveals the need for further study of this issue (Byus et al. 1987; Cain et al. 1986).

The EMF epidemiologic literature has been reviewed extensively (Aldrich and Easterly 1987; Ahlbom; Coleman and Beral 1988; EPA/600/6-90/005A; NRPB 1992). The strongest evidence of an association between certain forms of cancer and exposure to magnetic fields comes from the studies of childhood cancers, namely leukemia, cancer of the central nervous system (CNS), and lymphoma.[1] Several studies have found somewhat elevated, statistically significant risks and elevated nonsignificant risks for these three site-specific cancers in children for whom magnetic fields either have been estimated by the types of wires near their homes or have been measured at 2 mG (0.2 μT) or more. However, there are contradictory results within these same studies, and dose-response relationships could not be substantiated, except in Savitz et al. (1988), based upon limited information on wiring codes. [Savitz and Kaune (1993) have offered an improved analysis of this work.] Furthermore, little information exists on personal exposure and length of residency in the EMFs. Additional but weaker evidence of an association between leukemia, cancer of the CNS, and perhaps cancer of other sites comes from the occupational studies of EMF exposure.

The studies of residential adult exposures to EMFs also provide mixed evidence of a risk of leukemia, mainly because of lack of power or low exposure to levels of EMFs that are hypothesized as being associated with cancer. For the same reasons, these studies cannot be used as support for denying that such an association exists. However, the case control study of cancer in Colorado residents (Wertheimer and Leeper 1982) does support an association with CNS cancer and lymphoma if proximity to high-current electrical wiring configurations is assumed to be an adequate surrogate for exposure.

A careful review of the epidemiological studies involving leukemia, lymphoma, and cancer of the CNS shows a pattern of response that suggests, but does not prove the possibility of, a causal link. Evidence from a large number of biological test systems shows that these fields induce some biological responses in laboratory settings. However, the explanation of which biological processes are involved and the way in which these processes could causally relate to each other and to the induction of malignant tumors is not understood.

4.5.4.2.2 Transmission Line Exposures Relative to Domestic Exposures

An important question regarding regulations is whether transmission line exposures contribute significantly to total EMF field exposures. In most cases, fields produced inside the home by appliances and electrical wiring exceed contributions from transmission line fields. Exceptions to this rule are individuals living adjacent to high-voltage transmission line ROW. Also relevant is the fact that exposures to transmission line fields are considered more continuous than those to appliance fields because transmission line fields permeate large areas (e.g., an entire home). Fields generated by appliances are generally more localized, resulting in intermittent exposures as individuals move around and as the appliances are turned on and off.

Some comparisons (of induced currents) among transmission line exposures, domestic exposures, and exposures used in bioeffects experiments can be made using induced current density as an exposure metric. According to data provided in OTA-BPA-53, field strengths on the ROW of a 500-kV line induce body currents that are higher than those induced by domestic exposures produced by typical electrical appliances. Comparison with bioeffects experiments (OTA-BPA-53) shows that while current densities in many bioeffects experiments are higher than those typically induced by household exposures, some are significantly less. These comparisons are based, however, on average current densities predicted in humans, because EMF dosimetry has not advanced to the point of determining specific current densities in various tissues and organs. Nor has mechanistic understanding identified what field characteristics are important biologically.

4.5.4.2.3 Conclusion

Potential chronic effects are unquantified at this time. Subsequent to the 1992 National Energy Policy Act, a sequence of events relative to ELF research took place. The National Institute of Environmental Health Sciences (NIEHS) was made responsible for directing the EMF biological research funded through the Department of Energy. To oversee policy and general direction of this research, a National EMF Advisory Committee was assembled. Both the EPA and the National Institute for Occupational Safety and Health now maintain EMF hotlines, yet NIEHS has taken the position that the NIEHS has the sole responsibility for declaring whether a hazard exists and the magnitude of that hazard. Federal regulations are not anticipated in the near future, but some states have developed and other states are in the process of developing pertinent ambient field levels at ROW boundaries.

A careful review of the biological and physical studies of 60-Hz EMFs has failed at this time to uncover consistent evidence linking harmful effects with field exposures. EMF fields are unlike other agents that have a toxic effect (e.g., toxic chemicals and ionizing radiation) in that dramatic acute effects cannot be forced and longer-term effects, if real, are subtle. Nonetheless, a wide range of biological responses have been reported to be affected by EMF fields.

Even if clear adverse effects were apparent in the epidemiology literature or with some biological assay, considerable additional work would be required to determine how and what to mitigate, because evidence suggests that some EMF bioeffects do not follow the typical "more intensity is worse" relationship. Furthermore, there may be a subtle relationship between the intensity of the local geomagnetic field and the appearance of effects for some intensities of 60-Hz fields. This complicating evidence points to the fact that, while much experimental and epidemiological evidence has been accrued, the pieces still do not fit together very well.

Because of inconclusive scientific evidence, the chronic effects of EMF could not be categorized as either a Category 1 or 2 issue. NRC will continue to monitor the research initiatives, those within the national EMF program and others internationally, to evaluate the potential carcinogenicity of EMF fields as well as other progress in the EMF study disciplines. If NRC finds that a consensus has been reached by appropriate federal health agencies that there are adverse health effects, all license renewal applicants will have to address the health effects in the license renewal process.

4.5.5 Surface Water Quality and Aquatic Ecology

A basic concern with right-of-way and service road maintenance is the effect that such maintenance activities may have on the health of nearby aquatic ecosystems. The effects are considered of small significance if there is no measurable change in species diversity, abundance or health within the aquatic ecosystem. An effect of moderate significance is defined as one resulting in reduced abundance or health of one or several species that may eventually lead to the demise of the species. An effect of large significance is defined as one resulting in the loss of any species on which a high recreational or commercial value is placed or the collapse of the existing ecosystem.

Potential effects of transmission lines on aquatic resources would arise mainly from water quality impacts associated with maintaining power line ROW and service roads. Where roads cross or border on surface waters, soil erosion could cause elevated turbidity and sedimentation. Appropriate control techniques (e.g., grassed or wooded buffer strips between the road and the body of water) will minimize impacts. Because ROW are normally maintained by mowing or selective application of herbicides (Section 4.5.1.4), soil erosion from power line corridors should not normally be a problem. Potential toxic effects of herbicides that are applied to power line ROW and subsequently transported to surface waters should be considered in the maintenance program. By using herbicides approved for ROW use in accordance with FIFRA, significant adverse effects of herbicides are avoided. Mowing and other activities needed to maintain transmission line corridors are readily controllable to minimize impacts to aquatic resources. These activities are not expected to change during the license renewal term.

Changes in any affected aquatic ecosystem due to construction and maintenance practices will have taken place long before consideration of license renewal. Ongoing management practices with respect to controlling soil erosion and the proper application of herbicides will continue over the term of a renewed license. The aquatic ecosystem is expected to be unaffected by license renewal with no measurable change in species diversity, abundance or health. The effect of transmission lines on surface water quality and aquatic ecology is then of small significance. The continued use of proper management practices with respect to soil erosion and application of herbicides is expected. Impacts of any transmission lines on aquatic ecosystems over a larger geographic area or over time will be stable and not cumulative. The effect of transmission line right-of-way maintenance on surface water quality and aquatic ecology is a Category 1 issue.

4.5.6 Terrestrial Ecology

This section evaluates the impacts of ROW management on wildlife (Section 4.5.6.1); the impacts of bird collisions with transmission lines (Section 4.5.6.2); and the impacts of EMFs on plants, wildlife, and livestock (Section 4.5.6.3).

4.5.6.1 Impacts of ROW Management on Wildlife

The extent to which wildlife populations are affected by vegetation control on transmission line ROW is the issue evaluated by this section. The effects of ROW management in the transmission corridor during the license renewal term are considered of small significance if habitat diversity remains the same as that of the surrounding area, or is increased, while species population declines (if any) in the surrounding habitat are small. The significance of the impact is evaluated by a review of the voluminous published literature on this topic. Numerous scientific papers published mainly during the late 1970s and the 1980s were reviewed for this analysis. Data are not available for lines associated specifically with nuclear plants, but the literature applies to such lines because the same methods for ROW management are used for transmission lines associated with any type of generating facility. This issue was addressed by NRC environmental impact statements for the construction permit stage and the operating license stage.

Most data on the impacts of power line corridors on wildlife are for relatively moist areas of the United States where vegetation growth is rapid and vegetation must be controlled to prevent its interference with the transmission lines. In arid regions, little or no vegetation control is required, and the potential effects on wildlife are small. Potential effects are also small where lines cross croplands, because no vegetation management is required. The following discussion is therefore applicable primarily to forested regions where the utility must conduct vegetation control on transmission line ROW.

Broadcast spraying of herbicides and mowing of the entire corridor have greater periodic impacts on wildlife than do selective cutting or selective application of herbicides. Mowing reduces the vegetation on the ROW to a low stubble, and the remaining vegetation or the regrowth the first year after cutting provides little food or cover for wildlife. As a result of the reduced vegetation, populations of the primary species of birds that nest on a transmission line ROW have been shown to be reduced. Mammal populations may also be reduced, although few data have been collected to show such an impact. Resprouting and regrowth of vegetation on the ROW is usually rapid after cutting. If the vegetation is cut only once every 4 years rather than annually, it usually develops into a dense mixed growth of shrubs, shrub patches, saplings, forbs, and grasses. Bird populations increase along with the vegetation until the next mowing, when the cycle begins again (de Waal Malefyt 1984; Everett et al. 1981; Kroodsma 1982).

Broadcast spraying of herbicides is also done on a periodic basis and causes a cyclic effect on wildlife. However, spraying often kills entire plants, and resprouting is less common. Therefore, after a number of spraying cycles, some plant species are greatly reduced in abundance on the ROW. The resulting plant community consists of herbicide-resistant species and is often not very diverse. Grasses, ferns, and relatively few species of shrubs are usually the dominant vegetation. Correspondingly, the wildlife community has relatively few species and low population densities, and bird-nesting success in grass and forb areas on ROW has been observed to be low. Therefore, from the wildlife perspective, broadcast spraying is usually considered the least desirable vegetation maintenance technique. Annual mowing could have an effect similar to broadcast spraying but is seldom if ever used as a routine management technique for transmission line ROW (Cavanagh et al. 1976; Chasko and Gates 1981, 1982; de Waal Malefyt 1984; Hartley et al. 1984). Broadcast spraying of herbicides on some ROW that currently is mowed may become necessary if woody vegetation becomes too dense, as in ROW through mesophytic forests where forest regeneration is rapid (Luken et al. 1991).

Selective cutting or spraying of vegetation has less impact on wildlife because low-growing shrubs and other vegetation are left undisturbed and provide good wildlife habitat. Selective techniques are labor-intensive and thus may be more expensive than broadcast spraying or mowing. A primary goal of these selective techniques is to eliminate undesirable plant species from the ROW while keeping those that provide good wildlife habitat and that will not interfere with the power lines. Cutting and spraying are often combined because cut stems must often be sprayed to prevent resprouting and thus eliminate the plant. As the desirable plant species begin to dominate the ROW, they gain a competitive advantage and help to prevent the reestablishment of undesirable plants; thus, the long-term vegetation maintenance costs may be reduced (FWS/OBS-79/22, Luken et al. 1994).

Herbicides are generally not highly toxic to wildlife when they are properly applied for ROW management. Therefore, toxic effects of herbicides on wildlife are generally of little concern to wildlife biologists or wildlife managers. Of the many papers reviewed for this analysis, none expressed serious concern for toxic effects.[2] Rather, herbicide effects on wildlife have been shown to result from the vegetation changes that occurred as a result of herbicide application.[3] Changes in vegetation on an ROW or in any other habitat always cause changes in the wildlife community, whether the vegetation is cut or modified by herbicides. As in the case of cutting, herbicide effects on vegetation are usually beneficial to some wildlife species and detrimental to others. The literature referenced above shows that, as long as a diverse plant community remains on herbicide-treated ROW, a diverse wildlife community will also be present.

The maintenance of ROW vegetation as a low-growing plant community results in an ROW wildlife community that is characteristic of such vegetation. This wildlife community has some species of small mammals and birds that are not present in the natural plant communities bounding the ROW. Therefore, the presence of the ROW vegetation adds to the number of wildlife species found in the area. In addition, the ROW provides food and cover for many species of animals that were already present before line construction.[4] Forest edge along the ROW as well as along other open areas may provide some benefit to wildlife, but benefits of such an edge appear to have been overrated (Chasko and Gates 1982; Kroodsma 1984a, 1984b, 1987; Reese and Ratti 1988; Small and Hunter 1989).

The presence of the transmission line and its cleared corridor is apparently not a great disturbance to any wildlife species. Based on all of the literature reviewed, no wildlife species is known to have disappeared from habitats adjoining the corridors after line construction. Some species, however, are less abundant in the forest near the corridor than in the deeper forest, indicating avoidance of the transmission lines and/or the corridor (Kroodsma 1984b, 1984c). Because these species also appear to avoid other types of clearings (e.g., croplands or pasture), the openness of the corridor appears to be the feature being avoided, not the line itself. Predation on eggs and nestlings of forest birds has been observed to be greater near the forest/corridor edge than in the deeper forest and may be one factor responsible for some species appearing to avoid or to be less dense near the corridor (Chasko and Gates 1981, 1982).

The overall effect on wildlife of a transmission line corridor located within a forest appears to be an increase in the number of species present in the total corridor and forest area, while some populations of forest species are slightly lower as a result of the corresponding decrease in amount of forest habitat. Some bird and mammal species that inhabit grassy or brushy habitats are added to the area and are responsible for the increase in the number of species. At the same time, all other forest species remain in the area, and some find improved cover or food resources in the ROW. Population declines in forest species are usually small because the ROW is narrow and occupies only a small fraction of a forested area.

A current concern among ornithologists is the high degree to which forested habitats are being fragmented into smaller and smaller areas as a result of clearing for agriculture and urbanization. This fragmentation appears to be at least partly responsible for significant declines in the populations of many migrant bird species (Small and Hunter 1988; Yahner and Scott 1988). Transmission line corridors, probably because of their narrowness, have not been noted as a significant factor in forest fragmentation impacts on birds.

Where corridors cross particularly important wildlife habitats, impacts may be of greater concern. Impacts on winter habitats of certain big game animals were a particular concern. However, impact studies done for deer wintering yards in the northeastern United States and southeastern Canada (Jackson 1980; Willey and Marion 1980; Doucet et al., 1983, 1987), deer in winter habitats in the Northwest (Loft and Menke 1984), and elk winter habitats in the West (Nelson 1986) showed no significant impact.

Although animal population density is cyclic in response to vegetation changes in ROW, over the long term (i.e., over many cycles) the populations appear relatively stable, with no species being significantly affected. The overall impact of transmission line corridors, based on an extensive literature, appears to be neither significantly adverse nor significantly beneficial. The consensus among wildlife biologists appears to be that cleared transmission line corridors and their maintenance do not have significant adverse impacts and that corridors provide valuable wildlife habitats if properly managed. Of the papers reviewed for this GEIS, none was found that identified any impact of transmission line corridors on wildlife that was of great concern to the authors. The evidence supports a conclusion that continued ROW management during the license renewal term will not lower habitat diversity or cause significant changes in species populations in the surrounding habitat. Thus the impacts are of small significance. The only potential mitigation measure would be relocation of the transmission lines to less sensitive areas, but this would not be warranted due to the small benefit and high capital cost of such actions. No mitigation measures beyond those implemented during the current term license would be warranted and little potential for cumulative impacts is indicated. This is a Category 1 issue.

4.5.6.2 Avian Mortality Resulting from Collisions With Transmission Lines

Numerous studies have been published of avian mortality resulting from collisions with transmission lines and other man-made objects. The issue is whether collision mortality is large enough to cause long-term reductions in bird populations. The analysis of this issue is based on published literature addressing bird collisions with all types of man-made objects and applies to all transmission lines regardless of the type of generating facility. Monitoring data collected at one nuclear plant, Prairie Island, are also summarized.

Avian mortality resulting from collisions with transmission lines is of concern if stability of local populations of any bird species is threatened or if the reduction in the numbers within any bird population significantly impairs its function within the ecosystem. Avian mortality resulting from collisions of birds with transmission lines is considered to be of small significance if there is no threat to the stability of local populations of any species and if there is no noticeable impairment of its functioning within the local ecosystem.

Many millions of birds die each year from natural causes, and millions are killed each year in the United States as a result of colliding with windows of houses and other buildings, radio and TV towers, vehicles, transmission and distribution lines, telephone lines, cooling towers, smokestacks, and many other man-made objects. Numerous papers have reported the more noticeable, sometimes spectacular, kills that have occurred at radio and TV towers and at transmission lines located near lakes or wetlands where birds are concentrated.[5] Large bird kills at radio and TV towers occur at night during spring and fall bird migration and involve primarily passerine birds (songbirds) that appear to be confused by tower lights (Crawford 1981; Larkin 1988; Maehr et al. 1983; Taylor and Kershner 1986). These lights, during conditions of low clouds or fog, create a surrounding area of diffuse light that flying birds are reluctant to leave, with the result that the birds fly in circles around the towers. Thus, these birds run a high risk of colliding with the towers' guy wires. In contrast, kills along transmission lines involve a greater fraction of heavier, less agile birds such as waterfowl and cranes. Inclement weather is often a contributing factor in transmission line kills; lights are not a contributing factor, because they generally are not used to mark transmission lines.

It is unknown to what extent avian populations decline as a result of collision mortality of all types or mortality associated specifically with transmission lines. Several authors have concluded that the mortality caused by transmission lines in their studies did not cause a significant reduction in the bird populations located in their study areas. However, some of these authors expressed concern for cumulative impacts (Beaulaurier et al. 1984; Faanes

1987; Meyer and Lee 1981). Cumulative impacts would accrue as migratory birds such as waterfowl migrate to different areas and are exposed to additional lines, whereupon more collisions occur and total mortality continues to increase.

A few authors have also pointed out that bird mortality along the many thousands of miles of transmission and communication lines in the United States is probably of greater significance than the more noticeable kills in certain transmission line locations where birds are concentrated (Avery 1981; Willard and Willard 1978). The amount of bird mortality in nonwetland areas or in areas of average bird numbers has received little study because the individual bird kills are spread out over long distances and are hard to find. Therefore, accurate estimates of the total bird mortality caused by transmission lines do not exist, and the significance of transmission line collision mortality with regard to long-term population effects cannot be accurately assessed.

Overall, relatively little concern about bird collision mortality has been expressed in the literature. Generally, collision mortality has appeared to be only a small fraction of total mortality and therefore has not been considered to have significant population impacts. Banks (1979) estimated that human activity and bird collisions with man-made structures resulted in the deaths of about 196 million birds per year or 1.9 percent of the total bird mortality (about 10 billion per year) in the continental United States. About 63 million of the estimated 10 billion annual bird deaths (i.e., 0.63 percent) resulted from collision with all types of man-made structures. The transmission line impact would be a fraction of this estimate. Stout and Cornwell (1976) reported on waterfowl mortality. They estimated that about 0.07 percent of the nonhunting waterfowl mortality resulted from collisions with lines, including transmission, distribution, and telephone lines. These estimates, which are essentially all that is available in the literature, suggest that transmission lines do not pose a serious threat to avian populations. Banks (1979) states that most of the human-related mortality is accounted for by relatively few species and that these species maintain large, harvestable populations. This, as Banks pointed out, suggests that human activities do not significantly affect most bird species. Banks concluded that "activities of man that do not necessarily result in the death of birds but rather reduce reproductive potential, such as habitat alteration and environmental contamination, are much more likely to have long-term effects on avian populations."

More recent literature on bird collision mortality has not raised strong concerns that the Banks (1979) and Stout and Cornwell (1976) estimates are too low. However, Avery (1981) pointed out that collision mortality may be significantly higher than Banks' estimate of 63 million. He states that the primary source of collision mortality appears to involve the millions of miles of transmission and communication lines and the billions of glass windows throughout the country. He cites collision mortality estimates higher than Banks' estimates (e.g., 80 million bird deaths annually from collision with windows), but a lack of information prevented him from estimating mortality resulting from collisions with transmission lines. No study reviewed for this GEIS has suggested that collision mortality is a significant factor in reducing the populations of common bird species.

Several reports have suggested that rare species sometimes could be significantly affected by transmission and communication lines, particularly if the lines passed through an area where such species were concentrated (Faanes 1987; ORAU-142, 1978c; Meyer and Lee 1981; Willard and Willard 1978). For example, A. J. Crivelli et al. (1988) surveyed Dalmatian pelican mortality resulting from collision with a line through a pelican wintering area. They concluded that this mortality would result in a 1.3 to 3.5 percent reduction in the number of pelican breeding pairs in Greece and Bulgaria. Whooping cranes, an endangered species in the United States, have collided with power lines on at least 10 occasions according to Faanes (1987). The principal known cause of death for wild fledged whooping cranes is collision with power lines (Morkill and Anderson 1991). Several papers reviewed by Kroodsma (ORAU-142, 1978b) reported that 10 percent of the known mortality of bald eagles from 1960 to 1972 apparently resulted from collisions with some object, frequently a transmission line. Willard and Willard (1978) reported that 4 out of 200 nesting female white pelicans in a small Oregon population died from collisions with transmission lines and considered this mortality to be a significant impact on a small, threatened population.

Several studies have reported on relatively large collision kills where transmission lines crossed wetland areas being used by large concentrations of birds (Anderson 1978; Beaulaurier et al. 1984; Faanes 1987; ORAU-142, 1978c; Malcolm 1982; Meyer and Lee 1981; Rusz et al. 1986). Although the authors were concerned about the mortality, most of them reported that the data indicated the mortality was a small fraction of the number of birds present and that the local bird population was not significantly affected. The case reported by Malcolm (1982) appears to involve the greatest collision mortality.

Two additional studies reported collision-caused deaths of sandhill and whooping cranes, two species that appear particularly susceptible to collision with transmission lines. In the San Luis Valley, Colorado, 78 sandhill cranes and 3 whooping cranes collided with lines during the fall and spring in 1983 and 1984, as reported by W. M. Brown et al. (1985). Whooping cranes were the most frequent casualty in proportion to their abundance (13 to 29 birds observed at various times). These authors also reported that at least eight other whooping cranes in the Rocky Mountain population struck transmission lines from 1977 to 1985. In Idaho, in an area where nine pairs of sandhill cranes were observed nesting, three sandhill cranes and one whooping crane collided with lines during the first year after line construction (Howard et al. 1985).

Sandhill crane mortality in general from 1978 through 1985 was reviewed by Windingstad (1988). Known mortality was as follows: toxins (e.g., from moldy corn and waste peanuts)— approximately 5550 cranes; hail storm (1 occurrence)—600; avian botulism—150; avian cholera— 125; lightning (1 occurrence)—90; collision with transmission lines—5 occurrences reported, the worst resulting in 51 carcasses at a line crossing the Platte River near a crane roost site (numbers in the other four occurrences were not reported); unknown cause—8; lead poisoning—4, avian tuberculosis—1; and predators—1. Despite this extensive mortality in sandhill cranes, their midcontinent population has increased dramatically during the past few decades.

Modification of existing transmission lines has been investigated to reduce collision mortality in localities where relatively large kills occur. The most promising modifications include removal of the ground wires in the most critical locations or placing markers on the ground wires to make them more visible to birds. Such markers include black-and-white ribbons, orange aviation marker balls, plastic spirals, and spiral vibration dampers (Alonso et al. 1994; Brown et al. 1985; Faanes 1987; Morkill and Anderson 1991; ORAU-142, 1978d). For example, Alonso et al. found that colored PVC spirals installed on groundwires reduced bird collisions by 60 percent, and Morkill and Anderson found that yellow aviation balls installed on groundwires reduced sandhill crane collisions by 56 percent.

No relatively high collision mortality is known to occur along transmission lines associated with nuclear power plants in the United States other than the Prairie Island plant in Minnesota. This plant is located on the Mississippi River southeast of Minneapolis and may be the only nuclear plant where surveys were done to find birds that collided with off-site lines. The plant's 1978 annual report presented a 5-year study of bird collisions with transmission lines near the river. Counts were conducted by walking several transects, usually on a weekly basis from April 22 through May 27 from 1974 through 1978. A total of 453 birds were found over the entire 5-year period of observation, primarily passerines (songbirds), mourning doves, ring-necked pheasants, and American coots. Waterbirds included 11 sora rails, 8 wood ducks, 3 mallards, 2 black ducks, 1 great blue heron, 1 ruddy duck, and 1 hooded merganser. No raptors were found. Most collisions apparently occurred during inclement weather. Scavengers probably removed many bird carcasses before they could be found.

Available literature on transmission line collision mortality is insufficient to determine conclusively whether bird populations are being significantly affected. Rather, existing data suggest that transmission lines associated with nuclear plants are probably responsible for only a small fraction of total collision mortality for transmission and distribution lines in general. Also, existing literature suggests that total collision mortality (cumulative impacts) associated with all types of man-made objects is not reducing bird populations significantly.

Based on (1) the fact that existing literature does not show significant impacts of collision mortality on overall species populations and (2) the lack of known instances where nuclear-plant lines are affecting large numbers of individuals in local areas, the staff concludes that the mortality resulting from bird collisions with transmission lines associated with license renewal and an additional 20 years of operation will not cause long-term reduction in bird populations and thus will be of small significance. Further, little potential for significance due to cumulative impacts is indicated. Finally, the modification of transmission lines would not be warranted because the impact is so small and such mitigation measures would be costly. This is a Category 1 issue.

4.5.6.3 Impacts of Electromagnetic Fields on Flora and Fauna

The effects of electromagnetic fields on terrestrial biota are considered to be of small significance if the overall health, productivity and reproduction of individual species appears unaffected.

The EMFs produced by operating transmission lines up to 1100 kV have not been reported to have any biologically or economically significant impact on plants, wildlife, agricultural crops, or livestock (DOE/BP-945; Miller 1983). Areas under and in the vicinity of the lines have been studied numerous times. Vegetation, foliar damage due to EMF-induced corona at leaf margins, agricultural crop production, wildlife population abundance, livestock production, and potential livestock avoidance of the lines have been investigated. Also, many laboratory experiments with plants and laboratory animals have been conducted, often using electric fields much stronger than those occurring under transmission lines.

4.5.6.3.1 Plants

Studies have shown that minor damage to plant foliage and buds can occur in the vicinity of strong electric fields. For example, tree foliage and buds that are close to transmission lines can be damaged and upward or outward growth of branches can be reduced. Damage typically occurs only to the tips and margins of leaves in the uppermost plant parts that are the closest to the lines. The damage in the form of a leaf burn is most prevalent on small pointed leaves and is similar to leaf damage that might occur as a result of drought or other environmental stresses. The damage generally does not interfere with overall plant growth (Miller 1983).

The damage is thought to result from heating caused by induced corona at the leaf tips and margins. The electric field is greatly focused by leaf points or marginal teeth, thus increasing its strength to the point that corona (Section 4.5.1.3) occurs. Night-vision instruments have shown this corona as a glow of light concentrated at leaf tips and margins. The damage apparently does not extend to lower levels of the plant because the electric field weakens with distance from the lines and because the upper plant parts shield the lower parts from the electric field.

In one experiment under an 1100-kV prototype line, the upward growth of alder and Douglas fir trees was reduced by this damage, with the result that the crowns of the trees became somewhat flattened on top and the overall crown developed a broader appearance than usual (Rogers et al. 1984). The growth of the lower parts of the trees and of lower-growing plants such as pasture grass, barley, and peas appeared unaffected (Rogers and Hinds 1983). In another experiment, 50-kV/m fields had no apparent effect on corn germination or the growth of corn seedlings; and the growth of corn, bluegrass, and alfalfa apparently was not affected by fields of 25–50 kV even though minor damage occurred to the outer fringes of the uppermost leaves (Bankoske et al. 1976). Germination of sunflower seeds in a 5-kV/m electric field was reduced by about 5 percent in some cases [4 out of 11 replicates (Marino et al. 1983)]. An experiment with several species of agricultural plants found that a maximum of about 1 percent of the total plant tissue was damaged by exposing the plants to 50-kV/m fields (Poznaniak and Reed 1978).

Lee (DOE/BP-945) reviewed several papers reporting studies in Indiana, Tennessee, and Arkansas. The productivity of corn and other crop plants was not affected by electric fields of 12 to 16 kV/m under a 765-kV line and a UHV test line in Indiana, although plants under the larger line suffered some leaf tip damage from induced corona. Corn production in Tennessee may have been reduced by electric fields up to 8.5 kV/m, but the authors indicated the results were inconclusive. An Arkansas study found normal yields of rice and soybeans but a 15 percent reduced yield of cotton beneath a 500-kV line (see Section 4.5.3). The researchers could not determine whether the reduced cotton yield resulted from electric field or ineffective aerial application of agricultural chemicals beneath the line.

4.5.6.3.2 Honeybees

Several studies have shown that honeybees in hives under transmission lines are affected by EMF (EA-4218; Rogers and Hinds 1983; Warren et al. 1981). Adverse effects include increased propolis (a reddish resinous cement) production, reduced growth, greater irritability, and increased mortality. These effects can be greatly reduced by shielding the hives with a grounded metal screen or by moving the hives away from the lines (Rogers and Hinds 1983; Lee 1980). V. P. Bindokas et al. (1988) showed that these impacts were not caused by direct effects of the electric fields on the bees but by voltage buildup and electric currents within the hives and the resultant shocks to bees. Bees kept in moisture-free nonconductive conditions were not adversely affected, even in electric fields as strong as 100 kV/m.

4.5.6.3.3 Wildlife and Livestock

Chronic exposure to EMF is experienced by small birds and mammals that primarily inhabit ROW corridors and by birds (primarily raptors) that nest in transmission line towers. EMF exposures to larger animals and livestock are usually relatively brief because these animals inhabit relatively large areas instead of small areas beneath the lines. Exposures occur as these larger animals pass beneath the lines or as birds fly by the lines.

The voluminous literature on population studies of small bird and mammal species in transmission line corridors (Section 4.5.6.1) has expressed virtually no concern for possible impacts of EMF. These species apparently thrive underneath the lines, where their abundance appears to depend on habitat quality rather than on the strength of the electric fields to which they are exposed or the size of the line. For example, the density of breeding birds under 500-kV lines in eastern Tennessee is greater than that in adjacent forests (Kroodsma 1984c, 1987) and appears to be greater than bird density in most grassland habitats or agricultural fields. Also, the density of small mammal populations near these lines appears to depend on habitat type rather than on the presence of the lines (Schreiber et al. 1976). A Minnesota study of a 500-kV line found little evidence of either a positive or negative effect of the power line on bird populations (Niemi and Hanowski 1984). Bird and small mammal populations under an 1100-kV line in Oregon were also apparently unaffected by line operations (Rogers and Hinds 1983). Habitat use by elk in western Montana was apparently unaffected by operation of a 500-kV line, as the elk used habitats along the power line in proportion to their availability (DOE/BP-1136).

Raptors, ravens, and some water bird species frequently nest and perch on transmission line towers, particularly in grassland areas where other suitable nest sites are lacking.[6] Thus, the birds are able to use habitats without suitable nest sites—habitats that they otherwise would not have used (Gilmer and Stewart 1983; Williams and Colson 1989). On high-voltage lines supported by metal lattice towers, the birds usually nest on the top (bridge) of the tower where the strength of the electric field is minimal (e.g., 5 kV/m or less) (Lee 1980). Lee found 80 percent of 110 nests on towers to be located on the tower bridge and cited previous studies that showed similar results.

The success of these tower nests in producing young appears to be no different from nests located in areas not exposed to EMF. In central North Dakota, 113 ferruginous hawk nests in high-voltage transmission line towers (18 percent of a total of 628 nests found) had a higher success rate (87 percent) than nests in other locations (however, a hail storm that missed the lines reduced the success of some other nests). The number of fledglings per occupied nest was 2.8 for ground nests (which were larger than tower or tree nests), 2.6 for tower nests, 2.3 for haystack nests, and 2.0 for tree nests (Gilmer and Stewart 1983). In Idaho, Steenhof et al. (1993) studied nesting success of ravens and raptors on a 576-km (370-mile) segment of 500-kV transmission line constructed in 1981. From 1981 through 1989 (the last year reported by Steenhof et al.), the numbers of these species nesting on transmission towers increased to 133 pairs, including roughly 64 percent common ravens, 21 percent red-tailed hawks, 9 percent ferruginous hawks, 6 percent golden eagles, and 0.3 percent great horned owls. Nesting success of these birds averaged 65 percent to 86 percent and was similar to or better than that of the same species nesting on other substrates. Lee (1980) reported finding 110 hawk and raven nests on 260 miles of 230-kV and 500-kV lines of the Bonneville Power Administration. Although the success of these nests was not monitored, the author reported that, based on a literature review, it was unlikely that nesting would be adversely affected by EMF found in most locations in transmission line towers.

Livestock in both field and laboratory studies have shown no significant impacts when exposed to EMF. In DOE/BP-945, J. M. Lee reviewed about 10 reports on effects of transmission lines on livestock in the United States and Sweden. These studies found no evidence that the growth, production, or behavior of beef and dairy cattle, sheep, hogs, or horses were affected by EMF. The studies involved 11 farms along a 765-kV line in Indiana, 55 dairy farms near 765-kV lines in Ohio, 36 herds of cattle near 400-kV lines in Sweden, a mail survey of 106 farms in Sweden, a study of fertility of 58 cows under a 400-kV line in Sweden compared with 58 in a control area, 30 swine raised beneath a 345-kV line in Iowa compared with 30 raised in a control area, and cattle behavior under an 1100-kV prototype line in Oregon. Cattle under the 1100-kV test line in Oregon were startled by the first occurrence of corona noise when the line was reenergized after a shutdown period (Rogers and Hinds 1983). From 1977 through 1981, grazing of cattle in pasture under the line appeared to be unaffected by line operation. In 1980–81, the cattle spent more time near the line during periods when it was deenergized than when it was operating, but spent an increasing amount of time under the line when it was operating as the growing season progressed (Rogers and Hind 1983).

In the Indiana study (Amstutz and Miller 1980), performance of livestock frequently under a 765-kV line on 11 farms was studied during a 2-year period (1977–1979; 9 farms participated for the full 2 years). Animals included 10 horses, 55 sheep, 149 beef cattle, 337 hogs, and 429 dairy cattle. Maximum field voltage levels recorded near ground level were about 9.1 kV/m. General health, behavior, and performance of the animals were not affected by the transmission line EMF.

In the Swedish study of cow fertility, 58 heifers were exposed to a 400-kV, 50-Hz transmission line from June to mid-October 1985 (Algers and Hultgren 1987). The length of exposure was 15 to 20 times longer than the average exposure per year for Swedish dairy herds exposed to 400-kV lines. No effects were observed on the frequency of malformations, the length or variation of the estrous cycle, the midcycle plasma progesterone level, the intensity of estrus, the number of inseminations per pregnancy, the overall conception rate, or the fetal viability. Previous studies of cattle showed no significant effects of EMF on reproduction.

4.5.6.3.4 Conclusion

No significant impacts of EMF on terrestrial biota have been identified. Although foliage very close to lines can be damaged, the overall productivity and reproduction of native and agricultural plants appear unaffected. Also, no evidence suggests significant impacts on individual animals or wildlife populations that are chronically exposed to EMF under transmission lines or in the towers. Livestock behavior and production also appear unaffected by line operation. Therefore, the potential impact of EMF on terrestrial biota is expected to be of small significance for all plants. The only potential mitigation would be to exclude plants and animals from the right of way, a measure with very severe impacts of its own. However, because the impact is of small significance and because mitigation measures could create additional environmental impacts and would be costly, no mitigation measures beyond those implemented during the current term license would be warranted. This is a Category 1 issue.

4.5.7 Floodplains and Wetlands

Transmission lines pass through floodplains and wetlands in many areas. This section evaluates the impacts on floodplains and wetlands that may result from periodic cutting or herbicide treatment of woody vegetation and the occasional use of heavy equipment for line repair. The analysis in this section is based on a literature review and applies to all power lines regardless of the type of generating facility.

Vegetation control is normally required only in forested areas where trees could grow tall enough to interfere with line operation. Marshes, ponds, or other types of wetlands lacking trees generally should not be subjected to vegetation control and thus should not be affected. In forested wetlands, most of which are on floodplains, vegetation may be cut by hand or with a tractor with a rotary blade or may be controlled by herbicides (Section 4.5.1.4). Impacts are generally restricted to the ROW and should have no significant impact on the functions and values that have been identified for floodplains, including storage and slow release of floodwaters, water quality maintenance, groundwater recharge, and support of wildlife populations (Greeson et al. 1979). Herbicides that are often used in prairie wetlands to improve habitat for waterfowl do not appear to have toxic effects on aquatic biota (Solberg and Higgins 1993).

Repair of transmission lines may require access by heavy equipment to tower sites in floodplains or wetlands. This access would damage vegetation and disturb wildlife, having the same types of impacts that occurred during construction of the line. Overall impacts are expected to be relatively minor because (1) line repairs at any one location are rarely required, (2) impacts would be temporary and restricted to relatively small areas, and (3) tower sites often avoid wetlands. Repairs made during winter would generally have less impact than repairs in summer, but often there may be no choice of season because of the necessity for immediate repair.

Studies in Massachusetts indicate that transmission lines and their ROW can be constructed and maintained through wetlands without significant impact (Nickerson and Dobberteen 1987; Thibodeau and Nickerson 1986). The studies were conducted in several areas where 345-kV lines were constructed through cattail marsh, wooded swamp, and shrub swamp/bog. Preconstruction studies were done in 1975 and 1976, and postconstruction studies were done from 1977 to 1982 and again in 1987. The cattail marsh was affected by the placement of heavy oak mats that were required so that heavy construction equipment could enter the marsh. This was done during the winter when the marsh was frozen and aerial parts of plants were dead. The marsh recovered to its original condition in 1 year. Line maintenance or repair using heavy equipment, if required, could be conducted during winter with no greater harm to a marsh.

In a bog, although vegetation was damaged by placement of oak mats and had not fully recovered after 10 years, the number of plant species in affected areas did not differ significantly from that in control areas. The authors recommended that line construction avoid bogs because of their extremely slow recovery.

Wooded swamp dominated by red maple showed significant change in vegetation structure because trees had to be removed from the ROW. After construction, the number of species and individuals returned to normal after 1 year, and a shrub layer became the dominant vegetation. After 10 years, the number of plant species in the ROW was greater than that in undisturbed swamp, even though the ROW vegetation had been mowed once (at a level of 3 ft) 6 years after construction. Because of the rapidity of swamp recovery after construction and the stability of the maintained ROW vegetation, the authors concluded that there was no substantial negative impact on wetland functioning. On swamp ROW cleared for lines from 1936 through 1939, selective cutting and herbicide treatment of cut stumps had been conducted. The numbers of species and individuals were similar to those in adjacent forest, and the ROW showed little evidence of disturbance except where trees had recently been cut (Nickerson and Dobberteen 1987; Thibodeau and Nickerson 1986).

No transmission line associated with a nuclear plant has been identified as being a significant impact on the functions and values of a wetland or floodplain. Only minor impacts of small significance are expected from ROW maintenance or line repair. Because the impact is of small significance and mitigation measures would be costly to implement, none of the mitigation measures identified above (i.e., placement of oak mats in affected areas and avoidance of maintenance during the growing season) would be warranted. This is a Category 1 issue.

4.5.8 Aesthetic Resources

This section evaluates the issue of transmission-line-induced impacts of continued operation of nuclear power plants on historic and aesthetic resources. Transmission lines are probably the most frequently seen equipment associated with power plants, particularly plants such as D. C. Cook or Diablo Canyon that are well hidden from public view. Transmission lines are the least novel in appearance when compared with highly visible nuclear power plant components such as cooling towers and containment vessels. Therefore, they are perceived with less bias than other components of the nuclear power plant complex. People may not even realize that some transmission lines are associated with a particular power plant, especially a nuclear plant.

The definitions of insignificant, noticeable, and significant levels of impact are the same as those described in Section 3.7.8.

The evaluation of past and projected future impacts of transmission lines on aesthetic resources involved staff examination of the experience at the seven selected case study sites, a brief survey of the projected and realized aesthetic impacts at the other operating nuclear power plants, a survey of the professional literature, and a search of recent newspaper and magazine accounts related to these issues.

Nuclear power plants are frequently sited near bodies of water for access to cooling water; their associated transmission lines often intrude into recreation, historic, or scenic areas. Most of the adverse impacts to date from transmission lines center on such incompatibility. Notable examples include Brunswick, Diablo Canyon, Millstone, Nine Mile Point, St. Lucie, and Vogtle. Crossings of major rivers, wetlands, wildlife areas, roads, lakes, cemeteries, and battlefields are the source of the disputes that have arisen. Various design, engineering, siting, construction, and metallic surface treatments have been made available to mitigate these conflicts.

In general, during the license renewal term, continued use of transmission lines and ROW is projected to cause little or no additional impacts beyond those that have already occurred. Some habituation to lines is likely to occur or continue. The problem of erosion of access roads under transmission lines at Diablo Canyon represents a type of impact that could worsen over time if mitigation is not effectively implemented. Proper maintenance of the t ransmission line corridor will help prevent aesthetic degradation. Additional mitigation measures such as replacement of towers or burying the transmission line would be excessively costly and would have additional environmental impacts.

The aesthetic impacts associated with continued operation of transmission lines are of small significance for all plants, and no mitigation measures beyond those implemented during the current term license would be warranted. This is a Category 1 issue.

4.6 RADIOLOGICAL IMPACTS OF NORMAL OPERATION

This section provides an evaluation of the radiological impacts on occupational personnel and members of the public during normal operation following license renewal. This evaluation extends to all 118 nuclear power reactors. Radiation exposures occurring after license renewal are projected based on present levels of exposures. Estimates of additional maintenance, testing, and inspections as a result of a variety of age-related changes in operational procedures were made based on the anticipated changes to current operation and are detailed in Section 2.6 and Appendix B. Added maintenance, testing, and inspection will be accompanied by increased exposure time to members of the work force but are not expected to significantly influence dose to members of the public. Regulatory requirements under which nuclear reactors presently operate are discussed in Section 3.8.1.1.

A detailed discussion is provided in Chapter 6 of the radiological impacts of low-level waste, mixed waste, and spent fuel generated by power reactors during the renewal period; the impacts attributable to the uranium fuel cycle; and the impacts of the transportation of fuel and waste.

In response to comments on the draft GEIS and the proposed rule, the standard defining a small radiological impact has changed from a comparison with background radiation to sustained compliance with the dose and release limits applicable to the activities being reviewed. This change is appropriate and strengthens the criterion used to define a small environmental impact for the reasons that follow. The Atomic Energy Act requires NRC to promulgate, inspect, and enforce standards that provide an adequate level of protection of the public health and safety and the environment. These responsibilities, singly and in the aggregate, provide a margin of safety. The definitions of the significance level of an environmental impact (small, moderate, or large) applied to most other issues addressed in this GEIS are based on an ecological model that is concerned with species preservation, ecological health, and the condition of the attributes of a resource valued by society. Generally, these definitions place little or no weight on the life or health of individual members of a population or an ecosystem. However, health impacts on individual humans are the focus of NRC regulations limiting radiological doses. A review of the regulatory requirements and the performance of facilities provides the bases to project continuation of performance within regulatory standards. For the purposes of assessing radiological impacts, the Commission has concluded that impacts are of small significance if doses and releases do not exceed permissible levels in the Commission's regulations. This definition of "small" applies to occupational doses as well as to doses to individual members of the public. Accidental releases or noncompliance with the standards could conceivably result in releases that would cause moderate or large radiological impacts. Such conditions are beyond the scope of regulations controlling normal operations and providing an adequate level of protection. Given current regulatory activities and past regulatory experience, the Commission has no reason to expect that such noncompliance will occur at a significant frequency. To the contrary, the Commission expects that future radiological impacts from the fuel cycle will represent releases and impacts within applicable regulatory limits.

4.6.1 Public Exposure

During normal operations after license renewal, small quantities of radioactivity (fission, corrosion, and activation products) will continue to be released to the environment in a manner similar to present operation. Analyses of historic effluent data presented in Appendix E have pointed to a systematic reduction in effluents (primarily airborne). While there is no empirical evidence of a leveling off, there will be a practical lower limit of effluent release.

Radioactive-waste management systems are incorporated into each plant and are designed to remove most of the fission-product radioactivity that leaks from the fuel, as well as most of the activation- and corrosion-product radioactivity produced by neutrons in the vicinity of the reactor core (Section 2.2). Improved fuel integrity in the 1980s was an important factor in reducing effluents. In addition, the effectiveness of the gaseous and liquid treatment equipment has increased significantly over the past two decades, as is evidenced by the continuously decreasing levels of effluents (NUREG/CR-2907). The amounts of radioactivity released through vents and discharge points to areas outside the plant boundaries are recorded and published semiannually in the radioactive effluent release reports for each facility. A discussion of the environmental pathways for radioactive effluent releases to the air and water was presented in Section 3.8.1.2. This section will focus on issues more unique to license renewal.

4.6.1.1 Radionuclide Deposition

The concentration of radioactive materials in soils and sediments builds up to an equilibrium value that depends on the rate of deposition and the rate of removal. Removal can take place through radioactive decay or through chemical, biological, or physical processes. For a given rate of release, the concentrations of longer-lived radionuclides and consequently the dose rates attributable to them would continue to increase if license renewal were granted.

In Regulatory Guide 1.109, explicit guidance is provided for calculation of dose for nearly all conceivable pathways. To account for the buildup of radioactive materials, buildup factors of the form $(1 - e^{-\lambda t})$ in the calculations are included, where λ is the radionuclide decay constant, and t is the midpoint of a facility's operational life. Hence, only radioactive decay is used in the removal term. Initially, most of the calculations for construction and operating stage permits used 15 years as the approximate midpoint of facility operating life. This value is now more often taken to be 20 years. The potential license renewal term is an additional 20 years; thus, the effective midlife is 30 years.

At present, most of the radiation dose commitments to the population resulting from atmospheric emissions are from the noble gases (NUREG/CR-2850 1993). The noble gases do not build up in the environment. Iodine-131, of interest because it has the ability to concentrate in the thyroid, achieves equilibrium within weeks. Tritium, cobalt, and cesium normally account for the greatest proportion of the dose from liquid effluents. Tritium is not known to concentrate in sediments or solids and hence does not build up. To determine whether the added period of operation following license renewal would, by virtue of buildup, result in significant (double) added dose, the ratios of buildup factors for midlives of 30 to midlives of 20 years were evaluated. These ratios amount to a 35 percent increase for ^{137}Cs and a 6 percent increase for ^{60}Co. This added increase due to buildup will not significantly change the total dose to members of the public.

One remaining topic about buildup in the environment warrants discussion. Buildup is not explicitly accounted for in the aquatic food pathway (i.e., fish, shellfish, etc.) This pathway relies on the use of bioconcentration factors. A bioconcentration factor for a nuclide is the ratio of the concentration in biota to the radionuclide concentration in water. In certain cases, the bioaccumulation factors may require reexamination. These principally involve fish (in the human food chain) that are bottom feeders. Bottom feeders may ingest worms and other biota that may remobilize radioactive materials accumulated in the sediments.

Accumulation of radioactive materials in the environment is of concern not only to license renewal, but also to operation under present licenses. NRC reporting rules require that pathways that may arise as a result of unique conditions at a specific site considered in licensees' evaluations of radiation exposures. If an exposure pathway is likely to contribute significantly to total dose (10 percent or more to the total dose from all pathways), it must be routinely monitored and evaluated. Environmental monitoring programs are in place at all sites to provide a backup to the calculated doses based on effluent release measurements. Since these programs are ongoing for the duration of the license, locations where unique situations give rise to significant pathways not detailed in NRC Regulatory Guide 1.109 will be identified if and when they become significant. If such pathways result in doses at a plant exceeding the design objectives of Appendix I to 10 CFR Part 50, action will be required.

4.6.1.2 Direct Radiation

Radiation fields are produced around nuclear plants as a result of radioactivity within the reactor and its associated components, low-level storage containers, and components such as steam generators that have been removed from the reactor (as described in Section 3.8). Direct radiation from sources within a light water reactor plant is due primarily to ^{16}N, a radionuclide produced in the reactor core by neutron activation of ^{16}O from the water. Because the primary coolant of an LWR is contained in a heavily shielded area, dose rates in the vicinity of light water reactors are generally undetectable and are less than 1 mrem/year at the site boundary. Some plants [mostly boiling water reactors (BWRs)] do not have completely shielded secondary systems and may contribute some measurable off-site dose. These sources of direct radiation will be unaffected by license renewal.

Original impact statements were reviewed for estimates of off-site dose from radioactive storage containers at both boiling-water reactors and pressurized-water reactors. These estimates suggested small dose contributions at site boundaries (Section 3.8.1.6). Nothing is anticipated to occur during license renewal to significantly change this estimate.

4.6.1.3 Transportation-Related Radiation Doses

The transportation of "cold" (unirradiated) nuclear fuel to the reactor, of spent irradiated fuel from the reactor, and of solid radioactive wastes from the reactor to a waste burial ground represents a source of exposure considered in 10 CFR Part 51.52. The contribution of the environmental effects of such transportation to the environmental costs of license renewal of the nuclear power reactor is set forth in Summary Table S-4 from 10 CFR 51.52. This issue is discussed in Section 6.4.

4.6.1.4 Radiological Monitoring

Background measurements at all sites were obtained during the preoperational phase of the monitoring program. Thus, each facility has characterized the background levels of radioactivity and radiation and their variations among the anticipated important pathways in the areas surrounding the facilities. The operational, off-site radiological monitoring program is conducted to provide data on measurable levels of radiation and radioactive materials in the site environs in accordance with 10 CFR Parts 20 and 50. The program assists and provides backup support to the effluent-monitoring program recommended in NRC Regulatory Guide 1.21, *Measuring, Evaluating, and Reporting Radioactivity in Solid Wastes and Releases of Radioactive Materials in Liquid and Gaseous Effluents from Light-Water-Cooled Nuclear Power Plants*. Such environmental monitoring programs are conducted to augment dose calculations and to ensure that unanticipated buildups of radioactivity will not occur in the environment.

The environmental monitoring programs also identify the existence of effluents from unmonitored release points. An annual survey (land census) identifies changes in the use of unrestricted areas to provide a basis for modifying the monitoring programs.

4.6.2 Public Radiation Doses

Doses to the public during the license renewal term were estimated using current (baseline) levels and trends. For the period after license renewal, two measures of impact are appropriate. They are the dose to the maximally exposed individuals and the population dose. The latter is the average individual dose as a function of distance and sector location multiplied by the population in that sector at that distance.

4.6.2.1 Maximally Exposed Individual

Table 4.6 presents the dose to the maximally exposed individual resulting from airborne effluents as tabulated by NUMARC (1989) for the years 1985 to 1987. Under most circumstances, the dose calculations, made by the reporting utilities, result in an overestimate of dose because of conservative assumptions. The table shows that the greatest dose value for the maximally exposed individual from atmospheric releases (between 1985 and 1987) is 4.3 mrem.[7] On the average, about 5 percent of the sites report an annual dose of 1 mrem or greater to the maximally exposed individual. NRC has recently begun to estimate individual doses for comparison with 10 CFR Part 50, Appendix I objectives (NUREG/CR-2850 1994). Combining air and liquid pathways for calendar year 1990, operation at about 5 percent of the sites resulted in annual

doses of 1–3 mrem to the total body; 32 percent of the sites, 0.1–1.0 mrem; and 63 percent of the sites, less than 0.1 mrem. A comparison of the data from Table 4.6 and from NUREG/CR-2850 (1994) with the design objective doses of Appendix I to 10 CFR Part 50 and the EPA dose limits (Section 3.8.1) shows that existing plants are operating far below allowable limits with respect to effluent control.

Given the conservative nature of the calculations leading to the doses of Table 4.6, the impact on maximally exposed persons around nuclear generating facilities is clearly very small.

4.6.2.2 Average Individual Dose and Population Dose Commitment

4.6.2.2.1 Recent Data

Trends for average individual doses for persons living around nuclear power plants reflect the small radiation dose levels seen in the maximally exposed individuals. Each year, NRC issues a report entitled *Population Dose Commitments Due to Radioactive Releases from Nuclear Power Plant Sites*. The latest publication is for the calendar year 1989 (NUREG/CR-2850, Vol. 11). Methods used in this series are described in Section 3.8.1. The prescribed calculational methods include several basic assumptions to ensure that the results are conservative. Table 4.7 (adapted from

NUREG/CR-2850 and NUREG-0713) presents results obtained for a 15-year period ending in 1989. The numerical entries are person-rem received by those who live within a 50-mile radius of a site; data for individual sites also appear in these reports. The person-rem number is obtained by adding together the individual doses received by this population. For 1988, the cumulative person-rem varied from a low of 0.0015 at Grand Gulf to a high of 16 at McGuire. Seventy-five percent of the total came from 9 of the 67 sites, as shown in Table 4.8. (Information presented in Tables 4.8 and 4.9 was derived from NUREG/CR-2850, Vol. 10,

the most recent volume which presents data summaries with average individual doses.) The arithmetic mean annual radiation dose to people who lived in the vicinity of a U.S. nuclear power plant in 1988 was about 0.0005 mrem. The overall median for 1988 was less than 0.0003 mrem. A histogram shown in Figure 4.1 of NUREG/CR-2850 provided the information shown in Table 4.9.

Note that 97 percent of the individuals received 0.003 mrem or less during 1988. The most recent NCRPM report on this subject gives 300 mrem/year as the U.S. average dose from natural background radiation (NCRPM 1987). The addition of 0.018 mrem at the Hatch site as a result of plant operation is well within and indistinguishable from variations in natural background radiation (see Dudney et al. 1990).

According to the National Council on Radiation Protection and Measurements report, if a person moves from the coast to the Rocky Mountains, the natural annual doses can be increased by as much as 70 mrem. This 70-mrem addition to natural background which occurred because of a personal relocation is 7690 times greater than the average dose from operation of the McGuire nuclear facility during 1988.

4.6.2.2.2 Analysis of Current Trends

Projections into the future can be made on the basis of current trends. On that basis, average individual dose commitments were analyzed. The first objective of the analysis was to determine to what extent known information about all sites could be used to predict what the dose commitment values for each site were for the years 1979–1987. The second objective, if current dose commitments could be predicted adequately, was to use the models to predict future dose commitments for U.S. sites by extrapolating the characteristics used in the model and the population projections for the sites into future years (see Section E.3.2 for more details of this analysis).

A linear model was fitted to the dose data using combinations of independent variables. The independent variables that proved to be most predictive of the log (dose) values included calendar year, year of startup, size in megawatts, vendor (or manufacturer), and status (up or down). The linear model for estimation of air doses resulted in the following conclusions. The manufacturer with the highest air doses is Babcock-Wilcox (B-W) (but highly variable); the next highest is GE; and the lowest is Combustion Engineering (C-E). Air doses are decreasing with calendar year (for 1979 to 87) for all reactor types. The rate of decrease is fastest for GE reactors. The rate of decrease is much smaller for C-E reactors than for others, partly because these are lower to begin with. With the exception of C-E, all types have higher air doses from older reactors. For C-E, newer reactors have higher doses. Larger reactors had higher air doses. This relationship was strong and was a major contributor to the prediction of dose for each reactor site; it held true for all manufacturers but was much less evident in B-W reactors. The increase in air dose with size was largest for GE and for Westinghouse reactors. The overall model accounts for approximately 42 percent of the variation in the air dose values. For all reactor types (manufacturers), air doses decrease significantly when the reactor is operating below 25 percent capacity. This is not necessarily true for doses from liquid sources.

The linear model for estimating liquid dose resulted in the following conclusions: B-W reactors have significantly higher liquid doses than do reactors of other manufacturers, and GE reactors are next highest. Mixed sites (those with multiple reactors and different vendors) have the lowest liquid doses. GE and mixed sites have higher doses from liquid sources when they are operating below 25 percent of theoretical maximum output. Many mixed sites are partly GE reactors. All other manufacturers, all of which are pressurized-water reactors, have lower doses when they are operating below 25 percent capacity. Liquid doses are higher in older reactors only for GE reactors. For others, there is not a significant trend with reactor age. For GE reactors and for Westinghouse reactors, the larger reactors had higher liquid doses. The increase in liquid dose with megawatt capacity was much higher for GE reactors than for the other types. Liquid doses are overall much less predictable than air doses, and the resulting model fit for the liquid doses reflects this unpredictability. For liquid doses, the best-fitting model accounted for only about 20 percent of the overall variability in the model.

Liquid effluents are not decreasing significantly with time for any of the five types, although the coefficients are negative except for the mixed sites. Thus, the general trend with time is for air doses to decrease and for doses from liquid sources to decrease less rapidly. The decreasing trend in total dose commitment results mostly from the lower air dose estimates.

On the basis of the coefficients estimated with this analysis, it is apparent that the dose commitments are being systematically lowered. Results of the analysis were used to plot historical data against predicted doses (see sample figures in Section E.3). These figures portray how each sample reactor has performed with respect to other reactors in its class (i.e., age, size, vendor). Again, the dominant theme is the decline in dose commitment, which is almost universally observed. Even if there were a sudden cessation of the decline in dose to the public, levels are sufficiently low to represent an insignificant impact to humans.

4.6.2.3 Projected Doses for License Renewal

On the basis of information presented in the preceding section, radiation doses to members of the public can be projected into the license renewal period. The three factors upon which judgments can be made are the maximally exposed individual, the average exposed individual, and the cumulative exposure of a population. At present, each of these measures meets the design objectives and regulations. No aspect of future operation was identified that would substantially alter this situation. Rather, evidence presented above suggests that radioactive effluents and hence doses to the public are decreasing.

Maximum individual doses are reported in semiannual effluent release reports, and when these doses exceed Appendix I design objectives, the staff pursues remedial action. Thus these issues are handled on a case-by-case basis. A review of the atmospheric release data sources suggests that, in any given year, up to 5 percent of the power plants produce radiation doses of approximately 20 percent of the Appendix I design objectives (NUMARC 1989). No aging phenomenon has been identified which is expected to increase public radiation doses. Since the design objective provides a point of reference for visibility to the NRC staff, normally operating reactors are not expected to reach regulatory dose limits more often in the period after license renewal than they do at present. For these reasons, impacts to maximally exposed individuals in the public during future operation under license renewal are judged to be radiologically unchanged from present operations.

Similarly, radiation exposure to the average individual and collective dose to the population around a nuclear power plant are not anticipated to increase from present levels in the period after license renewal. Analysis of all available pertinent information suggests that, if anything, radiation doses to the public are decreasing.

Ninety-nine percent of the population within 50 miles of any plant received a dose of 0.003 mrem or less from nuclear power plant effluents in 1988 (Table 4.9). In 1990, the average dose to persons living within an 80-km (50-mile) distance from nuclear power plants was less than 0.001 mrem (NUREG/CR-2850 v. 12). If all 150 million people living within 80 km (50 miles) of nuclear plants receive 0.001 mrem/year for 70 years, the collective dose will be 10,500 person-rem. Using a risk coefficient of 5×10^{-4} cancer fatalities per person-rem, approximately 5 fatalities can be hypothesized. Among the 150 million people, about 30 million will die of spontaneous cancer. Hence, the added risk of cancer fatality is less than 1 in 6 million national cancer fatalities.

From a different perspective, the population of 150 million people would accumulate 45,000,000 person-rem/year from natural background radiation. The annual collective dose from operation of all 118 nuclear power plants, assuming an annual average individual dose as high as 0.002 mrem per person, is 300 person-rem. This is 150,000 times less than the collective dose from naturally occurring radiation. From this perspective, the contribution of nuclear power plants to the radiation dose to members of the public is not significant. Future increases in populations will result in proportional increases in population doses; that is, a doubling of the population around the 118 plants would result in a 600 person-rem annual collective dose. However, the population increase would not change the fact that the collective dose from plant operation is still 150,000 times less than that from naturally occurring radiation.

Cumulative impacts to average individual members of the public can be viewed from the same perspective presented in Section 3.8.1.7. During operation under license renewal, the average annual dose to the public from nuclear power plant operations will remain very small, less than 0.001 mrem/year. Cumulative radiation doses to members of the public will remain about 360 mrem/year and nuclear power plant operation will remain a very small part (less than 0.0003 percent) of the ionizing radiation dose to an average member of the U.S. population.

4.6.2.4 Mitigation

In addition to the regulations within 10 CFR Part 20.1101 (see Section 3.8.1.8) which speak directly to required operation under ALARA principles, 10 CFR Part 50.36a imposes conditions on licensees in the form of technical specifications on effluents from nuclear power reactors. These specifications are intended to keep releases of radioactive materials to unrestricted areas during operations to ALARA levels. Appendix I to 10 CFR Part 50 provides numerical guidance on dose-design objectives and limiting conditions for operation of LWRs to meet the ALARA requirements. These regulations will remain in effect during the period of license renewal.

Evidence presented in Section 3.6, Appendix E, and this section demonstrates that the ALARA process has been effective at controlling and reducing radiation doses to the public. Radiation doses to the public are declining both for average and total doses (Table 4.7) and for individual doses (Tables 4.10 and 4.11). No changes in the operation of power plants under license renewal are expected to increase radiation doses to the public compared with current operation. Because effective mitigation procedures are already in place, there is no need to consider additional mitigation during the period of license renewal.

4.6.2.5 Conclusion

Radiation doses to members of the public from current operation of nuclear power plants have been examined from a variety of perspectives and the impacts were found to be well within design objectives and regulations in each instance. No effect of aging that would significantly affect the radioactive effluents has been identified. Both maximum individual and average doses are expected to remain well within design objectives and regulations. In about 5 percent of the plants, maximum individual doses are approximately 20 percent of the Appendix I design objective. All other plants are operating far below this level.

Because no reason was identified to expect effluents to increase in the period after license renewal, continued operation well within regulatory limits is anticipated. The staff concludes that the significance of radiation exposures to the public attributable to operation after license renewal will be small at all sites. It should also be noted that the estimated cancer risk to the average individual due to plant operations is much less than 1×10^{-6}. No mitigation measures beyond those implemented during the current term license would be warranted because current mitigation practices have resulted in declining public radiation doses and are expected to continue to do so. This is a Category 1 issue.

4.6.3 Occupational Radiation Dose

To determine the significance of the estimated occupational dose during the license renewal term, the staff has examined the baseline trends in cumulative annual occupational dose at pressurized-water reactors and boiling-water reactors and the projected increments to occupational dose due to extended plant operation. These projections were compared with the occupational dose limit requirements of 10 CFR Part 20 and with dose levels now being experienced and were also used as the basis for estimates of cancer risk, which were compared with the spontaneous cancer rate.

4.6.3.1 Baseline Occupational Dose

Occupational radiation protection programs in place at nuclear power plants have maintained an annual average individual dose of only 0.28 rem during 1992 (Table 4.10), compared with an exposure limit of 5 rem. Furthermore, the distribution of individual dose (Table 4.11) indicates that only 3 people received doses at the highest reported level of between 4 and 5 rem and less than 0.5 percent of the workers received doses in excess of 2 rem. (Other supportive historical data can be found in Appendix E.)

Table 4.10 Light-water reactor (LWR) occupational whole-body dose data for boiling-water reactors (BWRs) and pressurized-water reactors (PWRs)

Year	Annual average whole-body dose (rem)		
	All LWRs	All BWRs	All PWRs
1973	0.94	0.85	1.00

As plants age, there will be slight increases in radioactive inventories, resulting in slight increases in occupational radiation doses.

4.6.3.2 Projected Doses for License Renewal

During the license renewal term, the greatest increment to occupational dose over present doses would occur during a 10-year in-service inspection refueling (Table 2.8). The average dose increment related to the 10-year in-service inspection refueling would raise boiling-water reactor averages from a present 360 person-rem (Table 3.12) by 91 person-rem (10-year in-service inspection refueling, Table 2.8) to 451 person-rem and raise pressurized-water reactors from 219 person-rem by 51 person-rem to 270 person-rem. Under the conservative scenario (Table 2.11) these dose increments would add 108 person-rem to BWRs and 66 person-rem to PWRs. These increased levels for a single year are similar to the levels experienced at some plants during the past 2 two reporting years (Table 3.13). After the period of refurbishment, routine operating conditions are expected to cause, industry wide, approximately 32,000 person-rem/year exposure to plant personnel [i.e., 5 percent increase over the currently experienced 30,000 person-mrem/year (Appendix B)]. With the conservative scenario, there is about an 8 percent increase in radiation dose over current operating experience (Tables 2.8 and 2.11).

Within the radiation bioeffects community, one school of thought holds that any radiation exposure is accompanied by a risk of cancer. The other perspective is that below a certain dose and dose rate, no cancer risk is involved. The lowest statistically significant dose associated with excess cancer fatalities among the atomic bomb survivors is considered by ICRP 60 (1991) to be 20 rad. The collective dose to the U.S. population from natural background radiation is approximately 75 million person-rem/year; while not declaring itself on one side or the other on the risk issue, the 1990 BEIR-V report states that there may be no risk from this natural background radiation. If there is no risk from natural background radiation, the annual 32,000 person-rem dose may be of little concern. At the other extreme, if it is assumed that individual doses of less than 20 rem may be included in the collective dose without causing an exaggerated result, the full 32,000 person-rem dose to all workers at nuclear power plants for the typical case may be multiplied by the best estimate risk coefficient for workers (4×10^{-4}); this risk coefficient leads to an annual total of 13 deaths. Of these, 12 would be expected because of normal present-day operation and 1 would be expected to result from aging- and refurbishment-related changes in operation.

This analysis of typically expected conditions provides a range of 0 to 13 deaths induced per year as a result of license renewal, with one of these fatalities resulting from added dose due to aging; very little difference is estimated under the conservative scenario. Thus, radiation doses attributable to plant aging accumulated during the license renewal term might result in a 5 percent increase in the calculated cancer incidence to plant workers, but there may be no increase. The significance of the possible increase depends altogether on the degree of credibility assigned to the risk coefficient derived at high dose and dose rate and applied for low dose and dose rate. In any case, the risk associated with occupational radiation exposures after license renewal is not expected to be significantly different from that during the initial license term.

Currently, occupational radiation doses are on the order of 0.4 rem/year in addition to the 0.36 rem/year received by the typical U.S. resident. If occupational exposure increases by 8 percent as estimated for the conservative scenario, cumulative occupational radiation doses will increase from about 0.76 rem/year to 0.79 rem/year for those working at nuclear plants that operate after the initial license term. Under the typical scenario, occupational doses would increase approximately 5 percent over the currently experienced levels increasing average exposures to 0.78 rem/year.

4.6.3.3 Conclusion

Occupational doses attributable to normal operation during the license renewal term have been examined from several different perspectives. First, projected occupational doses during the period of maximum added dose, the 10-year in-service inspection refueling, are within the range of doses experienced during the past 2 reporting years. Second, the average dose increase of 5 to 8 percent to the typical plant worker would still maintain doses well below regulatory limits. Therefore, occupational radiation exposure during the term of the renewed license meets the standard of small significance. No mitigation measures beyond those implemented during the current term license would be warranted because the ALARA process continues to be effective in reducing radiation doses. This is a Category 1 issue.

4.7 SOCIOECONOMIC IMPACTS

This section reports on the socioeconomic impacts associated with nuclear power plant operations during the license renewal term. The staff reviewed the following socioeconomic issues: (1) changes to local housing caused by plant-induced population growth; (2) the magnitude of all nuclear plant tax payments in relation to total revenues in host communities; (3) disruptions to local public services (i.e., education, transportation, public safety, social services, public utilities, and tourism/recreation); (4) changes to local land use and development patterns resulting from plant-induced population growth and all tax payments; (5) the effects of plant operations on local employment and income levels; (6) plant-related disturbances to historic resources at and around the plant site; and (7) plant-related disturbances to aesthetic resources. Of these socioeconomic impacts only those directly affecting the natural and built environment are carried forward to the decision whether to renew an operating license. The regional economic impact including income, employment, and taxes are not considered in the license renewal decision. As in Chapter 3, plant-induced population growth was studied as a potential influence on a number of the impacts listed above.

The methodological techniques used to evaluate impacts are described briefly in Section 3.7.1 and are detailed in Section C.1; a brief summary of these methods is provided here. For this chapter, past impacts related to plant operations were studied so that the impacts of future operations could be predicted. The impacts projected for the case study sites represent the range of potential impacts at existing nuclear plants because the sample plants were selected to represent the range of nuclear plant sites nationwide. A detailed discussion of site-specific findings is presented in Sections C.4.1 through C.4.7 of Appendix C.

The size of the work force required during the license renewal term is an important determinant of population growth. The permanent license renewal term work force is expected to include those personnel who were on-site during the initial license term, up to 60 additional permanent operations workers per unit, and temporary refueling and maintenance workers during periodic plant outages. Estimates in Chapter 2 and Appendix B of additional work force required during license-renewal-term operations indicate that only one additional worker will be required on a continuous basis for maintenance and inspection activities. The more conservative figure (60 persons per unit) is used in the analysis to account for workers (contractors or rotating utility employees) who are not associated with refueling but may be on-site intermittently. The 60 persons per unit analysis represents an upper bound of the possible socioeconomic impacts.

In addition to those workers previously required during operations-period outages, another 30 workers will be needed for periodic outages during the license renewal term. Potential impacts associated with the presence of periodic outage workers were not systematically evaluated because the duration of these outages will be short (typically 3–4 months). However, evidence about past effects resulting from the temporary influx of refueling/maintenance workers was collected and used in the analysis to predict the impacts of refueling/maintenance during the license renewal term.

The site-specific projections presented here are based on the assumption that no other major construction projects will occur at the same time as refueling and maintenance activities. The potential cumulative population-related impacts during license-renewal-term refueling and maintenance activities would result from the combined populations associated with refueling/maintenance and other concurrent construction activities (not necessarily related to the power plant). Analyses of various refurbishment scenarios (see Appendix C and Chapter 3) suggest the potential magnitude of cumulative impacts resulting from different work force sizes. For example, about 800 refueling/maintenance workers (i.e., about the mean number of workers involved in regularly scheduled outages) combined with another construction work force of about 200, for a total of 1000 workers, would have only small adverse impacts at all but the most remote and sparsely populated sites (e.g., Wolf Creek). Combined work forces of 2,300 could induce large impacts to housing, education, and transportation at some sites. A sensitivity analysis indicates that impact magnitudes would not be increased by a work force as large as 3,400.

The population growth that has resulted from operations at the case study plants has been small, ranging from less than 0.1 percent to 13 percent of a local area's total population (see Table 4.12 and Appendix C). As discussed in Section 3.7.1, the staff believes that Indian Point and Wolf Creek serve as the lower and upper bounds, respectively, of operations-related growth as a percentage of a study area's total population. Thus, population growth that has resulted from worker in-migration is estimated to range at all plants from less than 0.1 percent to 13 percent.

Certain characteristics of the license renewal term work force (e.g., percentage residing in the study area, percentage moving into the study area, percentage of in-migrants accompanied by families) were assumed to be similar to those of the current plant staff and were used to make projections concerning population growth. Information about the impacts that have resulted from population growth during a plant's operation was used to estimate the population-driven impacts that would occur during the plant's license renewal term.

Based on predictions for the case studies, new plant-related population growth resulting from the license renewal term at any nuclear plant would be much smaller than the growth that has resulted from operations thus far. Growth related to increased employment during the license renewal term is expected to represent between less than 0.1 percent and 0.8 percent of the local area's total population for all plants. Because the number of additional permanent workers required at any plant would be relatively small (up to 60 per unit) and because the communities around the plants have already accommodated the existing work force during operations, it is likely that license renewal terms would result in only minimal long-term plant-related population increases for most plants. Therefore, new (incremental) population-driven impacts generally would be minimal, and impacts

Table 4.12 Impact area population growth associated with current and additional permanent plant staff at seven plants in the case study[a]

Plant	Current number of permanent plant staff	Population increase from current staff	Population growth from current staff as a percentage of study area's total population	Projected population increase from additional permanent staff	Population growth from additional staff as a percentage of study area's total population
Arkansas Nuclear One	2205	3418	7.4%	189	0.3%
D. C. Cook					
Bridgman/Lake Township	1252	141	3.0%	15	0.3%

already occurring during current operations would continue with only slight increases during the license renewal term.

4.7.1 Housing

Two types of housing impacts related to workers' demand for housing may occur during license renewal term operations: (1) new housing impacts resulting from the in-migration of additional plant operations workers and (2) the continuing impacts arising from the housing demands of workers involved in periodic plant outages for refueling and maintenance. A third type of impact, unrelated to workers' demands, is the continuing impact of the plant on housing value and marketability.

4.7.1.1 Definition of Significance Levels

Detailed definitions of significance levels of impacts that result from increased housing demand are provided in Section 3.7.2. In summary, small impacts result when no discernible change in housing availability occurs, changes in rental rates and housing values are similar to those occurring statewide, and no housing construction or conversion occurs. Moderate impacts result when there is a discernable reduction in housing availability, rental rates and housing values exceed the inflation rate elsewhere in the state, and minor housing conversions or temporary additions occur. Large impacts occur when project-related demand results in very limited housing availability, considerable increases in rental rates and housing values, and substantial conversion of housing units.

Definitions of the significance of the plant's impacts on the desirability of housing located close to the plant follow. A small impact on housing desirability results when very few or no instances of outmigration occur because of the operation of the nuclear power plant. Also, very few cases of prospective home buyers refusing a home because of its proximity to the plant would occur. Under normal plant operations, housing values should remain within the range of regional fair market prices. Moderate impacts on housing desirability include occasional difficulty in finding a buyer for a house because of its proximity to a nuclear plant. Impacts are also moderate if the proximity of the nuclear plant is cited as a reason for discounting the sale price of the housing units. Impacts on housing desirability are considered large if substantial migration from houses in the vicinity of the plant occurs or if realtors find it difficult or impossible to sell homes in the area. A large impact may also result if a sustained and substantial drop in housing value occurs because of the house's proximity to the plant. Such impacts may be evidenced by a gradual increase in housing value with increasing distance from the plant.

4.7.1.2 Analysis

Housing Demand

The in-migration of plant personnel associated with current operations at each of the seven case study sites has had small impacts on housing. The number of operations workers required at the plants is small relative to original construction work force size, and the operations workers have been introduced gradually to the site so that housing demand has also increased gradually. The demand for housing by refueling workers was found to have a large impact at only one site (Wolf Creek). In that case, approximately 640 additional workers were on-site during the plant outage.

Based on impacts associated with current term operations, population-driven housing impacts resulting from additional permanent workers in the license renewal term would be small at all case study sites. The housing demand resulting from an additional 60 workers per unit would not be large enough to strain the housing markets of communities in which the plants are located and would result in a small impact even in areas where little growth in housing is expected.

Impacts related to the demand for housing resulting from the in-migration of refueling workers are projected to continue to be the same as those currently being experienced—with slight exacerbation due to the additional 30 temporary refueling workers (Section 4.7.1). Thus large impacts may continue at one case study site, Wolf Creek. At other case study plants, these continuing housing impacts associated with in-migrating refueling workers would remain small to moderate.

Housing Marketability

The prevailing belief of realtors and planners in communities surrounding the case study plants is that the plants have had little if any effect on the marketability or value of homes in the vicinity. Housing choices of local residents are rarely affected by the presence of the plant. However, buyers from outside the community are occasionally averse to purchasing properties close to a nuclear power plant. Housing markets have not been affected by this situation because of its infrequency. The value of housing units in close proximity to the plants has experienced only small impacts. A slight negative impact did result because of the accident at Three Mile Island Unit 2; the price of houses in two small subdivisions close to the plant dropped slightly below fair market value after the accident and stayed that way for a brief period following it. At some sites, housing values have increased slightly because of amenities such as sewer systems and improved school systems that were made possible because of tax payments by the nuclear plant.

The license renewal term of the plants will be very much like the original operations period but will include additional safety and maintenance activities. Thus, impacts on housing marketability and values that have occurred during operations will continue during the license renewal term. At all case study sites, only small impacts on housing value and marketability are projected to continue.

4.7.1.3 Conclusion

No demand-related impacts are expected during regular operations, and only small impacts to housing value and marketability are projected. During continuing periodic refueling/maintenance outages, housing demand impacts during refueling/maintenance may range from small to large at various sites. The observed relationship between demographic characteristics and projected housing impacts at the case study sites suggests that large impacts are possible when a work force exceeding 600 persons is required at a site located in a low-population area or in an area that has or recently has had growth control measures that limit housing development. This is a Category 2 issue.

4.7.2 Taxes

This section describes the importance of nuclear plant tax payments as a source of local government revenue. These payments may be made directly to local government jurisdictions or indirectly to local government jurisdictions through state tax and revenue-sharing programs. The tax impacts of operations during the license renewal term were projected based on the current magnitude of tax payments by nuclear plants in relation to total revenues in their local areas (Section C.4.1.3).

4.7.2.1 Definition of Significance Levels

Significance levels during license term renewal operations are considered small if new tax payments are < 10 percent of the taxing jurisdiction's revenue, moderate if payments are 10 to 20 percent, and large if payments represent > 20 percent of revenue. A detailed description of these significance categories is in Section 3.7.3.1. However, the tax payments used to calculate impacts during the license renewal term are all property taxes paid by the nuclear plant, not just the increment due to refurbishment-related improvements.

4.7.2.2 Analysis

The primary taxing authorities for most of the case study plants are the county and city in which the plant is sited and the local school district. The tax-related impacts experienced by those jurisdictions vary widely, depending on the relative size of the taxing jurisdictions and the taxing structure of the state in which the case study is located. The magnitude of current nuclear plant tax payments relative to total local revenues and the associated impact levels is shown in Table 4.13.

The primary tax-related impact expected to occur during the license renewal term at the seven case study plants would be the continuation of tax revenues paid by utilities to local taxing authorities. An additional new tax impact would result from the increase in each plant's assessed value because of refurbishment-based improvements and the associated increase in tax payments. The magnitude of this increase is unknown and may depend on the state's (or other assessing authority's) method of assessment and previous agreements or laws that limit increases in assessed valuation. Generally, the relative importance of tax payments to local jurisdictions during the license renewal term would be similar to that of payments during the current term, although the size of the payments is projected to increase somewhat (see Table 4.13).

4.7.2.3 Conclusion

Tax-related impacts from the continued operation of nuclear plants would range from small to large, as at the case study sites. Tax impacts would consist of the continued effect of direct and indirect tax payments to local jurisdictions, which began before license renewal, in combination with the increase in payments because of refurbishment-related improvements. Impacts of this kind are judged to be beneficial.

4.7.3 Public Services

The approach used to determine past impacts of plant operations and project future public service impacts during the license renewal term is discussed in the introduction to Section 3.7 (also see Section C.4.1.3). For most public services, future impacts were determined based on the projected number of in-migrating workers. To project impacts to local educational systems, however, the number of workers accompanied by their families and the associated family size were also important.

The levels of significance for impacts to public services are the same as those discussed under refurbishment: (1) education, Section 3.7.4.1; (2) transportation, Section 3.7.4.2; (3) public safety, Section 3.7.4.3; (4) social services, Section 3.7.4.4; (5) public utilities, Section 3.7.4.5; and (6) tourism and recreation, Section 3.7.4.6. In general, impacts are small if the existing infrastructure (facilities, programs, and staff) could accommodate any plant-related demand without a noticeable effect on the level of service. Moderate impacts arise when the demand for service or use of the infrastructure is sizeable and would noticeably decrease the level of service or require additional resources to maintain the level of service. Large impacts would result when new programs, upgraded or new facilities, or substantial additional staff are required because of plant-related demand (see Section 3.7.4).

Table 4.13 Current property taxes as percent of total revenues for taxing jurisdiction at seven nuclear power plants in the case study

Plant	Local taxing jurisdiction	Percentage of revenue	Magnitude of beneficial effect
Arkansas Nuclear One	Pope County (study area)	26	Large
	Russellville School District	42	Large

4.7.3.1 Education

Few if any operations-related impacts on education were found at the case study sites. Communities had no substantial problems assimilating the children of the plant staff into local school systems. Educational impacts during the license renewal term would be small at all case-study sites, as has been the case during past operations. The number of new students would be low relative to the size of current school systems. This small impact could be mitigated by hiring additional staff members for the schools, building new educational facilities, or adding modular classrooms to existing facilities. However, because the impact is so small and implementation of these measures would be costly, such measures would not be warranted.

Based on the case-study analysis, educational impacts are projected to be of small significance at all plants. Because no additional teaching staff or classroom space would be needed, no mitigation measures beyond those implemented during the current term license would be warranted. This is a Category 1 issue.

4.7.3.2 Transportation

Transportation impacts related to current operations have been small at most sites but small to moderate at Three Mile Island and Wolf Creek during refueling and maintenance outages. Impacts to transportation during the license renewal term would be similar to those experienced during current operations and would be driven mainly by the workers involved in current plant operations. The 60 additional permanent workers expected during the license renewal term would represent only a small incremental addition to the continuing impacts from past normal operations, while the 30 incremental workers required during periodic refueling/maintenance outages would represent only a small increase in the number of workers typically involved in periodic outages under the original term of the license.

Based on past and projected impacts at the case study sites, transportation impacts would continue to be of small significance at all sites during operations and would be of small or moderate significance during scheduled refueling and maintenance outages. Because impacts are determined primarily by road conditions existing at the time of the project and cannot be easily forecast, a site specific review will be necessary to determine whether impacts are likely to be small or moderate and whether mitigation measures may be warranted.This is a Category 2 issue.

4.7.3.3 Public Safety

Overall, no serious disruptions of services occurred at the case study sites during the operations period. Existing services were adequate to handle the influx of plant staff. Impacts during license renewal would be largely the same as those that occurred during past operations. There would be little or no need for additional police or fire personnel. For this reason impacts would be of small significance at all sites. This small impact could be mitigated by hiring additional police or fire personnel, purchasing additional fire or police vehicles, building police or fire stations, or making improvements and additions to existing facilities. However, because existing services are projected to be adequate to handle plant-related demands and because mitigative measures would be costly, no mitigation measures beyond those implemented during the current term license would be warranted. This is a Category 1 issue.

4.7.3.4 Social Services

Information from case study sites and the literature support a determination of only small impacts on local social services associated with past operations. Impacts to social services during license renewal would be essentially the same as those that have occurred during past operations and would be of small significance at all sites. These impacts could be mitigated by hiring additional staff to administer existing social service programs or establishing new social service programs. However, because no change in the level of services is anticipated and because mitigative measures would be costly, no mitigation measures beyond those implemented during the current term license would be warranted. This is a Category 1 issue.

4.7.3.5 Public Utilities

Overall, there have been minimal impacts to public utilities as a result of plant operations. The existing capacity of public utilities was sufficient to accommodate the small influx of plant staff, and some locales experienced a noticeable decrease in the level of demand for services with the completion of original plant construction. Although impacts to public utilities during license renewal would be very similar to those that occurred during past operations, an increased problem with water availability may occur in conjunction with plant demand and plant-related population growth as a result of current water shortages in some areas. These shortages may result in moderate impacts to public water supplies at sites with limited water availability. This is a Category 2 issue.

4.7.3.6 Tourism and Recreation

Impacts to recreation and tourism during the license renewal term would be largely the same as those that have occurred during operations in the current term. Few or no adverse effects have occurred during current operations at the case-study sites, and some positive effects have resulted because taxes paid by the plants have allowed some municipalities to improve their recreational facilities and programs. Some plants have also increased local tourism. Based on the case study analysis, it is projected that any adverse impacts would be small at all plants and would primarily be the continuation of impacts of past operations. Some positive impact to tourism and recreation also may continue. These impacts could be mitigated by improving existing recreation facilities or adding recreation areas to meet the expanded demand. Because current facilities would be adequate to accommodate local demand and adding new facilities would be costly, no mitigation measures beyond those implemented during the current term license would be warranted. This is a Category 1 issue.

4.7.4 Off-Site Land Use

This section evaluates the impact of plant-induced changes on local land-use and development patterns produced by plant operation during the license renewal term. Detailed definitions of the three magnitudes of land-use change are provided in Section 3.7.5.1. The magnitude of change to off-site land use is considered small if very little new development and minimal changes to an area's land-use pattern result. Moderate change results if considerable new development and some changes to the land-use pattern occur. The magnitude of change is large if large-scale new development and major changes in the land use pattern occur. During the renewal term, new land-use impacts could result from plant-related population growth or from the use by local governments of the plants' tax payments to provide public services that encourage development. This analysis examines the land-use changes associated with past operations to project the potential new impacts of operations during the license renewal term. Conflicts between off-site land use and nuclear plant operations are not expected because federal regulations (10 CFR Part 54) require each licensee to ensure that its nuclear plant remains appropriately protected from any site-related hazards (e.g., airplanes, toxic gases), new or existing at the time the plant was licensed.

4.7.4.1 Analysis

In most cases, the land-use changes that have resulted from operations at the case study plants have been moderate (see Table 4.14 and Appendix C). However, local property tax payments that the utility makes on its nuclear plants have stimulated large indirect land-use changes in one study area because the local jurisdictions has been able to provide the public services (e.g., sewer and water lines, roads) necessary to support substantial industrial development.

For population-driven land-use impacts, the impact predictors are the same as those discussed for refurbishment (Section 3.7.5). The assessment of new tax-driven land-use impacts considered (1) the size of the plant's tax payments relative to the community's total revenues, (2) the nature of the community's existing land-use pattern, and (3) the extent to which the community already has public services in place to support and guide development. In general, if the plant's tax payments are projected to be small relative to the community's total revenue, new tax-driven land-use changes during the plant's license renewal term would be small, especially where the community has preestablished patterns of development and has provided adequate public services to support and guide development. If the plant's tax payments are projected to be medium to large relative to the community's total revenue, new tax-driven land-use changes would be moderate. This is most likely to be true where the community has no preestablished patterns of development (i.e., land use plans or controls) or has not provided adequate public services to support and guide development in the past, especially infrastructure that would allow industrial development. If the plant's tax payments are projected to be a dominant source of the community's total revenue, new tax-driven land-use changes would be large. This would be especially true where the community has no preestablished pattern of development or has not provided adequate public services to support and guide development in the past.

It is projected that population growth related to worker in-migration in the license renewal term would result in small land-use impacts for all of the socioeconomic case study areas (see Appendix C). In contrast, it is projected that new tax-driven land-use impacts would be large at one case study site and moderate at the others during the license renewal term.

4.7.4.2 Conclusion

Based on predictions for the case study plants, it is projected that all new population-driven land-use changes during the license renewal term at all nuclear plants will be small because population growth caused by license renewal will represent a much smaller percentage of the

Table 4.14 Levels of operations-related land-use change at seven case study sites

local area's total population than has operations-related growth. Also, any conflicts between offsite land use and nuclear plant operations are expected to be small. In contrast, it is projected that new *tax-driven* land-use changes may be moderate at a number of sites and large at some others. Because land use changes may be perceived by some community members as adverse and by others as beneficial, the staff is unable to assess generically the potential significance of site-specific off-site land use impacts. This is a Category 2 issue.

4.7.5 Economic Structure

The effects of plant operations during the license renewal term on local employment are predicted by comparing the projected number of direct and indirect jobs created during the license renewal term at a plant with projected total employment for the appropriate study area. Relatively few *new* plant-related jobs would be created during the license renewal term. Nearly all plant-related employment (and associated impacts) expected during that time period would represent a continuation of employment (and impacts) from past operations.

4.7.5.1 Definition of Significance Levels

A detailed explanation of levels of impact significance is in Section 3.7.6.1. Economic effects are small if plant-related employment accounts for <5 percent of total study area employment, moderate if it accounts for 5 to 10 percent, and large if it accounts for more than 10 percent of total study area employment. In summary, the relevant workers are those involved in plant operation, including both new and existing workers. Also, if the magnitude of plant-related employment relative to total study area employment is close to the upper bound for a particular significance level, the impact should be placed in the next higher significance category if the site is remotely located and has a low population density. A site is considered remote if, within a distance of 80 km (50 miles), there is no city with more than 100,000 persons. Low population density is less than 50 persons per 2.6 km^2 (1 square mile). This adjustment factor is necessary to determine the importance of plant employment to the local area in light of its proximity to other areas with competing employment opportunities.

4.7.5.2 Analysis

The economic impacts that have resulted from operating the case study plants range from small to large (see Table 4.15 and Appendix C). Plant-related employment ranges from less than 1 percent to 18 percent of total employment in the communities near the case study plants.

The economic impacts projected to occur during the license renewal term would be primarily a continuation of impacts that already have occurred. At most case study sites, the share of total local employment represented by plant-related employment will be the same as or slightly less than that during current operations (Table 4.15).

4.7.5.3 Conclusion

Based on the findings for the case study sites, economic impacts would be beneficial at all nuclear plant sites. These beneficial impacts would range from small to large.

Table 4.15 Current and projected employment effects of plant operation for the sites in the case study[a]

	Current operations		License renewal term operations

4.7.6 Aesthetic Resources

This section evaluates the impacts on aesthetic resources from continued operation during an extended license renewal period. Significance levels of impacts are the same as those described in Section 3.7.8. The analysis of aesthetic impacts focuses on the visibility and perception of the plants' buildings, particularly containment structures and cooling towers and their associated water vapor plumes. These site features are often visible from neighborhoods, roads, and recreation-based water bodies over a wide area. However, no new visual changes are expected during the renewal term, and impacts primarily would be those that currently exist and would change only as the public's perceptions changed or as new information about affected resources arose.

The evaluation of impacts of past power plant operations and projected future impacts on aesthetic resources involved the following: (1) staff examination of local perceptions at the seven case study sites, as reported by key informants; (2) a brief survey of the original and eventually realized aesthetic impacts at other operating nuclear power plants; (3) a survey of relevant academic literature; and (4) a review of recent newspaper and magazine articles related to these issues. In addition, the staff reviewed several final environmental impact statements prepared by NRC for plants located in areas where aesthetic impacts were perceived to be an important issue: the Indian Point Nuclear Power Plant, located in the lower Hudson River Valley in New York (NUREG-0042, NUREG-0574, Jones and Jones 1975); the Greene County Nuclear Plant in the mid-Hudson River Valley (NUREG-0512); the Montague Nuclear Plant, in north Central Massachusetts (NUREG-0084); and Floating Nuclear Plant, an offshore location (NUREG-0394). Finally, the staff reviewed research sponsored by NRC that developed an econometric model for explaining and predicting visual aesthetic impacts.

4.7.6.1 Analysis

Nuclear power plants—particularly those with natural draft cooling towers—stand out starkly from their backgrounds both physically and symbolically. Their containment buildings and, when present, their hyperbolic cooling towers mark these industrial facilities as decidedly different, although their novelty typically appears to wear off for people who view them repeatedly.

Nuclear plants are usually situated in open areas near bodies of water, rendering cooling towers even more visible. Although they are visible from as far away as 10 miles, the structures are typically partially obscured by trees, buildings, or even slight changes in topography. There are few environments where such structures are perceived as well integrated with surrounding landscapes. Additionally, the visible vapor plumes associated with cooling towers can rise more than 5000 ft above the towers and extend as far as 9 miles downwind. Such a presence, although visible only part of the time under certain meteorological and seasonal conditions, extends the plant-related viewshed considerably beyond that of a tower alone.

At Indian Point, opposition to the plant is difficult to separate from opposition to its effect on aesthetic values, which, according to critics, have been diminished by the plant (K. Kennedy; D. Samson; N. Castro; D. Clyde; L. Gobrecht; K. Sauer telephone interviews with James Saulsbury, June 22, 1990). However, based on a viewshed analysis by landscape architects, the plant is either not visible from or is only insignificantly visible from historical sites in the area (Jones and Jones 1975). The plant is visible from the Peekskill Waterfront, from the Stoney Point Marina, from several established areas in Buchanan and Peekskill, and from approaches on the Hudson River (NUREG-0574). Although opposition to a nuclear facility and aesthetic concerns may both be issues in Westchester County, New York, it appears to be far from the situation in South Carolina (Oconee) and Kansas (Wolf Creek). Structures of the D. C. Cook plant (Michigan) and the Diablo Canyon plant (California) are sufficiently hidden or integrated into the existing landscapes that it is difficult to generalize about the public's attitude toward effects on aesthetic resources. The surrounding community seems generally well accustomed to the Arkansas Nuclear One plant in rural Arkansas and has some reservations only about the cooling tower and plume. The 1979 accident at the Three Mile Island plant (Pennsylvania) illustrates how attitudes seem to have directly affected aesthetic preferences (see Appendix C).

From the analysis of the case study plants (summarized in Table 4.16), perceptions of adverse impacts on aesthetic resources from the continued operation of nuclear power plants are probable in limited circumstances. Such circumstances would include areas that have concentrated aesthetic resources within a plant's viewshed or areas where past associations with a plant could diminish one's enjoyment of the physical environment. But even in these circumstances, the staff has not found clear and widespread evidence of adverse consequences to community institutions and functions that would justify characterizing a site as having a large impact.

Among the case study sites, Wolf Creek, Three Mile Island, Oconee, and Diablo Canyon all have had some impacts on prehistoric sites. At Wolf Creek, the presence of the nuclear power plant was credited as a positive force in local preservation efforts because (1) it brought new people into the area, who in turn influenced local citizens regarding the value and benefits that support of historic preservation could bring to a community, and (2) the increased incomes and expanded work force resulted in some neglected structures becoming occupied and repaired (M. Sirico; M. Reams telephone interviews with James Saulsbury, June 22, 1990).

Historic and archaeological resources can vary widely from site to site. Furthermore, they may have been identified only recently (e.g., an archaeological site) or their historic significance only recently established (e.g., a historic building). For these and other reasons, the National Historic Preservation Act of 1966 requires that the agency undertaking a major action consult with the State Historic Preservation Office to determine whether historic resources exist on or near the site and whether they will be affected by the proposed action.

4.7.6.2 Conclusion

The staff believes that the case studies and the other sources of information consulted have bounded the impacts of continued operation of nuclear power plants on aesthetic resources. Under the proposed provisions of license renewal, no applicant is expected to alter the existing visual intrusiveness of any plant. Certainly, the staff expects that some individuals at nuclear plant sites would perceive the plant structures and vapor plumes negatively. These perceptions will be based on purely

Table 4.16 Summary of past and projected impacts on aesthetic resources from operation of seven nuclear power plants in the case study

Impact predictors	Arkansas Nuclear One	D. C. Cook	Diablo Canyon	Indian Point	Oconee	Three Mile Island	Wolf Creek
Plant located near physical or environmental contexts memorialized in popular or professional media	No	No	No	Yes	No	No	No
Plant viewed as decidedly obtrusive into existing landscape	Somewhat	No	No	Yes	No	Yes	No
Active, widely shared, organized opposition to plant's operation because of plant's decided obtrusiveness	None	None	None	None	None	None	None
Measurable socioeconomic impact resulting from decreased aesthetic enjoyment of environment	No	No	No	Limited	No	Limited	No
Significance of past and projected impacts[a]	Insignificant	Insignificant	Insignificant	Moderate	Insignificant	Moderate	Insignificant

[a]Impacts during the license renewal term are expected to be the same as those experienced during past operations unless new information arises or there is a change in the context in which the plant operates.
Source: Appendix C.

aesthetic considerations (for instance, that the plant is out of character or scale with the community), on environmental and safety concerns, or on an anti-nuclear orientation. Whatever the consideration, the staff believes that these individuals' enjoyment of the environment will be depreciated. However, because license renewal will not alter the visual intrusiveness of any plant, the number of individuals having negative perceptions would probably remain constant. The number of such individuals has not been sufficient to measurably impact community institutions and functions in the past, so the staff believes that the impacts on aesthetic resources would be small in the future. For these individuals, mitigation through the use of nonreflective surfaces and tree plantings would be impractical from both efficiency and cost-benefit perspectives; therefore, no mitigation measures beyond those implemented during the current term license would be warranted. The impact on aesthetic resources is a Category 1 issue.

4.7.7 Historic and Archaeological Resources

This section evaluates potential impacts of license renewal term operations to historic and archaeological resources.

4.7.7.1 Definition of Significance Levels

Sites are considered to have small impacts of historic and archaeological resources (1) if the State Historic Preservation Office (SHPO) identifies no significant resources on or near the site, or (2) if the SHPO identifies (or has previously identified) significant historic resources but determines they will not be affected by plant refurbishment, transmission lines, and license-renewal-term operations and there are no complaints from the affected public about altered historic character, and (3) if the conditions associated with moderate impacts do not occur. Moderate impacts may result if historic resources, determined by the SHPO not to be eligible for the National Register, nonetheless are thought by the SHPO or local historians to have local historic value and to contribute substantially to an area's sense of historic character. Sites are considered to have large impacts to historic resources if resources determined by the SHPO to have significant historic or archaeological value would be disturbed or otherwise have their historic character altered through refurbishment activity, installation of new transmission lines, or any other construction (e.g., for waste storage facility). Determinations of significance of impacts are made through consultation with the state historic preservation officer.

4.7.7.2 Analysis

Impacts to historic and archaeological resources during the license-renewal term would be largely the same as those occurring during the current operations period. At the case-study sites, only small impacts are known to occur. However, any construction activity during the license renewal term, such as building a new waste storage facility or a new access road to a transmission corridor, could induce new impacts. Also, it is possible that previously unknown historic and archaeological resources will be identified or their historic significance will be established in the future. As discussed at length in Section 3.7.7, a determination of impact to historic and archaeological resources must be made through consultation with the SHPO as mandated by the National Historic Preservation Act.

4.7.7.3 Conclusions

Although it is unlikely that historic or archaeological impacts of moderate or large significance would occur during the license-renewal term, determinations of impacts to historic and archaeological resources are site-specific in nature and must be made through consultation with the SHPO. Any mitigation measures must likewise be determined on a case-by-case basis. Because site-specific and activity-specific information is needed to assess the significance of impacts to historic and archaeological resources, this is a Category 2 issue.

4.8 GROUNDWATER USE AND QUALITY

4.8.1 Groundwater Use

Those nuclear plants that use groundwater may affect the utility of groundwater to neighbors. This impact could occur as a direct effect of pumping groundwater, thereby either lowering the water table and reducing the availability or inducing infiltration of water of lesser quality into the ground. Neighboring groundwater users could also be affected indirectly if construction or operation of the power plant were to disrupt the normal recharge of the groundwater aquifer. The impact to neighboring groundwater users is likely to be most significant at a site where water resources are limited. Groundwater usage impact may be important at those sites where a power plant's usage rate exceeds 0.0063 m^3/s (100 gpm). Lower usage rates are not expected to impact sole source or other aquifers significantly.

Groundwater is not used at all nuclear power plants, and where it is used, the rate of usage varies greatly among users. Only Grand Gulf uses groundwater as a source of makeup to the condenser cooling system. This largest user employs a Ranney well collection system to draw groundwater from the Mississippi River alluvial aquifer. Other plants use lesser amounts of groundwater for service water systems or for potable water. Some licensed plants intentionally lower the groundwater table, either by pumping or by a system of drains, in the vicinity of building foundations.

The groundwater-use issue was evaluated by examining the groundwater requirements of appropriate subsets of nuclear power plants. Four subsets were established to encompass the entire scope of groundwater-use issues as described above. One subset consists of sites in regions where the water table or artesian water levels historically have been falling for a number of years (Atlantic and Gulf coastal plains, upper Midwest, Arizona, and California). A second subset consists of sites on both high ground and low-lying areas adjacent to the Great Lakes, the Atlantic and Gulf coasts, and the lower Mississippi River where extensive operational dewatering systems may have been installed. A third subset consists of plants with cooling towers adjacent to small rivers. The fourth subset consists of the only plant using groundwater for cooling tower makeup water.

Data were taken from appropriate final safety analysis reports (FSARs) and final environmental statements (FESs) pertaining to operation of nuclear power plants, and sites having potential groundwater-use conflicts were identified. Appropriate state water-use permitting agency representatives and U.S. Geological Survey (USGS) personnel were interviewed by telephone for additional information. Evaluations and conclusions for each of these groundwater-use scenarios are presented separately in the following discussion.

4.8.1.1 Potable and Service Water

Only one of the upper Midwest sites examined withdraws more than 0.0063 m^3/s (100 gal/min) of groundwater for potable and service water systems [Duane Arnold is permitted to withdraw 0.19 m^3/s (3000 gal/min) by the Water Supply Section, Environmental Protection Division, Iowa Department of Natural Resources]. Other plants (Braidwood, Cook, Dresden, Kewaunee, La Salle, Point Beach, and Zion) in the upper Midwest withdraw small amounts 19×10^{-5} to 536×10^{-5} m^3s (3 to 85 gal/min) of groundwater for potable water systems, or none at all. Except for Duane Arnold, all service water systems are supplied by alternative resources (municipal water systems, lakes, or rivers).

Several Atlantic and Gulf coastal plain sites that are not near municipal water suppliers withdraw larger amounts of groundwater than the upper Midwest sites for potable and service water systems. Withdrawals for these sites (Calvert Cliffs, Crystal River, Hope Creek, Salem, and River Bend) range from 0.025 to 0.050 m^3/s (400 to 800 gal/min). Other coastal sites (Turkey Point, St. Lucie, and Waterford) obtain potable and service water from municipal suppliers.

Only one of the two western sites withdraws groundwater for potable and service water systems. The Palo Verde site in Arizona withdraws 0.063 m^3/s (1000 gal/min) from a confined aquifer.

Many plants use groundwater only for potable water systems and require less than 0.0063 m^3/s (100 gal/min). The cones of depression around such wells generally remain within the plant boundary (typically the case for upper Midwest sites). Where the cone of depression does not extend beyond the site boundary, the plant groundwater use is not expected to contribute to cumulative impacts on groundwater supply. For sites having plant wells that produce more than 0.0063 m^3/s (100 gal/min) (sites that draw both service and potable water from wells), cones of depression may extend beyond the plant boundary. For these sites, a reasonable likelihood exists that off-site private wells will be impacted. The staff considers plant contributions to groundwater use to be of small significance where the plant groundwater consumption is less than 0.0063 m^3/s (100 gal/min).

The effect of groundwater usage on neighboring groundwater users will depend on the rate of usage and the distance to the neighboring well. A neighboring well close to the well field of a plant using a large amount of groundwater could experience some decline in yield. The power plants using groundwater are generally remotely located, and groundwater is not thought to be a limited resource. Conflicts that do arise should be resolvable by taking steps to restore yield of the affected water supply, such as deepening the affected wells.

In conclusion, this is a Category 1 issue for those plants using less than 0.0063 m^3/s (100 gal/min) of groundwater for potable and service water. At this usage rate, there would be no significant depletion of the groundwater supply which could impact other users. Because the cone of depression would not extend beyond the site boundary, mitigation is not warranted. However, if use exceeds 0.0063 m^3/s (100 gal/min), there is a possibility of moderate or large adverse effects, and mitigation may be warranted. Therefore, this is a Category 2 issue for those plants using more than 0.0063 m^3/s (100 gal/min) of groundwater.

4.8.1.2 Operational Dewatering Systems

Operational dewatering systems are in place at the Perry site (on a bluff overlooking Lake Erie) and the Calvert Cliffs site (on a bluff overlooking Chesapeake Bay). The Perry site is actively dewatered by pumping wells, and the water table is depressed by more than 15 m (50 ft). During construction dewatering, the cone of depression extended outward about 150 m (500 ft) (it remained inside the site boundary). Less vigorous pumping is required during operational dewatering, and the cone of depression is reduced. If pumping were discontinued, the water table would rise approximately 6 m (20 ft), groundwater would continue to drain passively through a gravity drain system, and the cone of depression would continue to shrink. The Calvert Cliffs site is passively dewatered by an underdrain system (natural gravity flow). The base of the reactor containment structure at Calvert Cliffs is more than 6 m (20 ft) below sea level, whereas the water table is maintained several feet above sea level. There is no impact to neighboring groundwater users at either of these sites.

None of the sites in low-lying areas of the Atlantic coastal plain had operational dewatering systems (i.e., Hope Creek, Millstone, Oyster Creek, St. Lucie, and Turkey Point). At St. Lucie, a construction site dewatering system [pumped at 0.80 m^3/s (13,000 gal/min)] was decommissioned before the plant was placed in operation. The St. Lucie construction/ operation case history is typical of plants in low-lying areas.

For other sites using active dewatering systems (systems in which groundwater is pumped from the aquifer), the same bounding conditions apply as for groundwater use in potable and service water systems. That is, for operational dewatering systems that do not exceed 0.0063 m^3/s (100 gal/min), impacts would be of only small significance. Because the cone of depression would not extend beyond the site boundaries, no mitigation measures beyond those implemented during the current term license would be warranted. For plants that withdraw more than 0.0063 m^3/s (100 gal/min), the significance of the groundwater withdrawal cannot be determined generically. Groundwater use through operational dewatering is a Category 2 issue.

4.8.1.3 Surface Water Withdrawals for Cooling Towers

Many plants located on small rivers have cooling towers. Rivers often supply alluvial aquifers, and large-scale withdrawals of makeup water for evaporative loss could impact an alluvial aquifer during periods of low flow. However, withdrawal from the river is regulated by local or state agencies.

For example, the withdrawal of water at Duane Arnold is restricted at low flow (Water Use Permit). Under normal flow conditions, Duane Arnold withdraws 1.6 m^3/s (27,000 gal/min) from the Cedar River as cooling tower makeup water. This plant continues to operate, at least temporarily, during low flow by withdrawing water from a standby reservoir on a tributary to Cedar River. This reservoir is used only during emergencies when low-flow conditions exist on the Cedar River.

Indirect groundwater-use conflict resulting from surface water withdrawal from a small river for use in cooling towers is a potentially important concern. Because the significance of these conflicts cannot be determined at this time, this is a Category 2 issue.

4.8.1.4 Use of Groundwater for Cooling Tower Makeup

The Ranney wells at Grand Gulf withdraw groundwater from Mississippi River alluvium at a rate of 1.5 m^3/s [24,000 gal/min (34 million gal/day)] for use as cooling tower makeup water to avoid the aquatic effects of a surface water intake. Groundwater in Mississippi River alluvium is used primarily for irrigation and catfish farming (Jamie Crawford, Mississippi Bureau of Land and Water Resources, telephone interview with W. P. Staub, ORNL, Oak Ridge, Tennessee, December 3, 1990). Generally, groundwater from the alluvial aquifer is too high is iron content to be used for municipal water supplies.

The impact of cooling water intake on groundwater at the Grand Gulf plant (the only plant employing Ranney wells) does not conflict with other groundwater uses in the area. However, conflicts could develop if other uses develop (e.g., additional catfish farms). Because it is not possible to predict whether conflicts will occur at Grand Gulf or the significance of impacts associated with Ranney well use at other plants (if they were to adopt their use), it is not possible to determine the significance of Ranney well use at this time. This is a Category 2 issue.

4.8.2 Groundwater Quality

Impairment of groundwater quality could occur at estuary and ocean site facilities that withdraw groundwater for any purpose (e.g., potable and service water systems, operational dewatering). Long-term pumping of groundwater from coastal plain aquifers by industrial and municipal facilities has contributed to saltwater intrusion in some areas of nearly every Atlantic and Gulf Coast state (USGS 1990). The saltwater intrusion issue was evaluated by examining groundwater use at selected nuclear power plants sited on estuaries and oceanic coastlines. Operational dewatering is not taking place at any of the estuaries or coastal sites.

Groundwater quality could also be impaired at inland sites where groundwater may be replaced by poorer quality river water through induced infiltration (NUREG-0777). Potential impairment of groundwater quality at facilities that have large cooling ponds is discussed in Section 4.8.3.

At this time, no licensed plant is located on a sole-source aquifer (i.e., sole or primary source of water supply for an area). If a site occupied by one of the licensed nuclear plants were in an area designated as a sole-source aquifer, NRC would cooperate with responsible agencies in making required information available. Under the provisions of the SDWA, states must establish demonstration programs for protection of critical aquifers.

Slightly elevated concentrations of tritium have been observed in groundwater adjacent to the Prairie Island plant on the Mississippi River in southern Minnesota (Minnesota Environmental Quality Board 1991; Minnesota Department of Public Service 1992). These elevated concentrations have not altered the current use of groundwater near the site. One off-site privately owned well has reported tritium concentrations ranging between 800 and 1000 pCi/L (dates of measurements are uncertain, but they are no more recent than 1991). By comparison, tritium concentrations in North American streams were about 10 pCi/L prior to the beginning of the nuclear age and about 4000 pCi/L at the end of large-scale atmospheric testing of nuclear weapons in 1963. Radioactive decay of tritium between 1963 and 1992 would produce a concentration of about 715 pCi/L (DOE 1992). If tritium concentrations at Prairie Island were as high as 1000 pCi/L in 1992, then perhaps one-third of the tritium contamination found in local groundwater might be attributable to the Prairie Island plant and the balance would be attributable to atmospheric testing. Future radioactive decay of tritium would further reduce its overall concentration in groundwater. Natural decay and tritium release to the environment at Prairie Island might be expected to reach equilibrium eventually at around 300 pCi/L. This compares with a regulatory limit of 20,000 pCi/L in drinking water.

Data were taken from appropriate FSARs and FESs pertaining to the operation of nuclear power plants. Sites having a potential impact on groundwater quality were identified; appropriate state water-use permitting agency representatives and USGS personnel were interviewed by telephone for additional information. Groundwater quality impacts are considered to be of small significance when the plant does not contribute to changes in groundwater quality that would preclude current and future uses of the groundwater. Hence, the contribution of plant operations (during the license renewal period) to the cumulative impacts of major activities on groundwater quality would be relatively small.

4.8.2.1 Potable and Service Water

Groundwater withdrawals in estuary and oceanic areas can cause saltwater intrusion into freshwater aquifers. Saltwater intrusion, where it occurs, is the cumulative effect of groundwater consumption by users in the affected region and therefore could have a cumulative impact on groundwater quality. Estuary and oceanic sites located in rural areas withdraw groundwater from confined aquifers at rates between 0.025 and 0.063 m^3/s (400 and 1000 gal/min) (e.g., for Calvert Cliffs, Crystal River, and Hope Creek–Salem). In contrast, sites located near urban areas purchase water for their potable and service water systems from municipal suppliers (e.g., Millstone, St. Lucie, and Turkey Point), which themselves use groundwater resources. Directly or indirectly, all nuclear power plants in Florida derive their potable and service water supply from groundwater. The staff considers nuclear plant contributions to saltwater intrusion to have small significance on groundwater quality where the plant's groundwater consumption is less than 10 percent of the regional total.

Withdrawal of potable and service water at nuclear power plants represents a small percentage of county-wide water supplies derived from groundwater in both urban and rural counties of Florida. According to Marella (1988, data for 1985), 2.98 and 21.3 m^3/s (68 and 486 million gal/day) of groundwater were withdrawn for all uses in semi-urban St. Lucie and urban Dade Counties where the St. Lucie and Turkey Point plants are located, respectively. Both of these plants purchase about 0.063 m^3/s [1.4 million gal/day (1000 gal/min)] from municipal sources in these counties. About 1.09 m^3/s (25 million gal/day) of groundwater were withdrawn in rural Citrus County, compared with

1.4 million gal/day withdrawn by Crystal River plant wells in that county. Nuclear plant groundwater consumption at its current rate would not contribute significantly to any future saltwater intrusion that might occur.

Ken Miller (Maryland Water Resources Administration, Water Rights Division, telephone interview with W. P. Staub, ORNL, Oak Ridge, Tennessee, November 28, 1990) believes that saltwater intrusion of the Aquia aquifer, which serves the Calvert Cliffs plant, is unlikely. He bases his conclusion on the fact that this aquifer is confined and changes to an aquitard on its downdip (seaward) side as illustrated in USGS (1988) and Chapelle and Drummond (1983).

Geologic conditions as described above are site specific. The USGS (1988) states that the Raritan-Magothy aquifer in New Jersey is susceptible to saltwater intrusion and is already contaminated in some places. However, based on data for Florida, power plant groundwater consumption ranges from about 0.3 percent to 6 percent of the total in urban and rural regions, respectively. Saltwater intrusion is more likely to occur in urban regions because of the greater demand for water, and electric power generation would be a small contributor.

The potential for inducing saltwater intrusion is considered to be of small significance at all sites because groundwater consumption from confined aquifers for potable and service water uses by nuclear power plants is a small fraction of groundwater use in all cases. Where saltwater intrusion has been a problem, the large uses have been agricultural (irrigation) and municipal groundwater consumption. Mitigation for saltwater intrusion, if needed, would likely take the form of groundwater withdrawal curtailments. Because nuclear plant water consumption represents a small fraction of total consumption, consumption curtailments of large groundwater users (i.e., municipal or agricultural users) are more likely. Consequently, groundwater use curtailments are not expected to be warranted for nuclear plants to mitigate saltwater intrusion impacts. However, even if pro-rata curtailments of groundwater consumption were required of all users, nuclear plants could accommodate most conceivable reductions without adversely affecting their operations. Therefore, this is a Category 1 issue.

4.8.2.2 Groundwater Withdrawal at Inland Sites

Grand Gulf uses large quantities of groundwater from an alluvial aquifer as described in Section 4.8.1.4. Geohydrologic modeling has predicted that groundwater would be replaced by river water of lesser quality by induced infiltration (NUREG-0777). A groundwater monitoring system is currently being installed at Grand Gulf, but no data are currently available to validate the model. Nevertheless, the model's prediction is reasonable.

The net flow of the infiltrating river water will be into the Grand Gulf Ranney well collectors. Thus, water quality change will be largely confined to the plant. Any other users of groundwater from the same formation would induce infiltration in a similar manner. The quality of Mississippi River water would not preclude the current uses of the groundwater from the alluvium. Long-term use of Ranney wells may cause groundwater quality to approach the water quality of the adjoining river. Therefore, the change in water quality resulting from use of Ranney wells would be of small significance at any site. The only possible mitigation for a plant using Ranney wells would be to construct and operate a water intake structure in the nearby water body. However, because the change in groundwater quality would not preclude current and future uses and because building a surface water intake structure would be costly and have adverse environmental effects of its own (Sect. 4.8.1.4), no mitigation measures beyond those implemented during the current term license would be warranted. This is a Category 1 issue. Because groundwater quality level would never be lower than that of the nearby Mississippi River, groundwater withdrawal for Grand Gulf's use would not contribute significantly to the cumulative impacts of water infiltration into the aquifer.

4.8.3 Groundwater Quality Impacts of Cooling Ponds

Alteration of groundwater quality in shallow, unconfined aquifers may occur at the nine nuclear power plant sites that use cooling ponds (Section 4.4.1). Irrigation and private domestic water supplies are the principal off-site uses of these groundwater resources. This issue was evaluated by examining off-site land uses and potential for shallow groundwater utilization at all nine sites. The impact on private uses of groundwater was subdivided into two sets based on current land use: (1) sites surrounded by undeveloped land, including saltwater marshes, and (2) sites adjacent to farmland. Short- and long-term potential for utilization of shallow groundwater resources depends on current land use.

Four plant sites are surrounded by undeveloped land or have large exclusion areas around them. These plants are Clinton (large exclusion area), Dresden (surrounded by undeveloped woodlands), South Texas, and Turkey Point (surrounded by saltwater marshes). Although off-site groundwater is not being used currently near these sites, its long-term use is not necessarily precluded.

The remaining five sites have relatively small exclusion areas and are adjacent to farmland. These plants are Braidwood, La Salle, Robinson, Summer, and Wolf Creek. A limited amount of off-site groundwater is being used currently or could potentially be used at these sites in the near term.

All of the cooling ponds are unlined and have surface areas that range from 637 to 2960 ha (1573 to 7310 acres). Cooling pond water has higher concentrations (than makeup water) of total dissolved solids due to evaporation, heavy metals due to contact of cooling water with plant equipment, and chlorinated organic compounds used to prevent biofouling of equipment. The average concentration of total dissolved solids in continuously recycled cooling pond water is about 2.8 times as large as that in makeup water.

Water seeping from these ponds commingles with underlying shallow groundwater and produces a groundwater mound. Groundwater spreads laterally away from this mound. The commingled groundwater will eventually reach off-site areas. At this point, groundwater quality will be between that of the cooling pond water and the quality of the naturally occurring groundwater. These groundwater contaminant plumes are not expected to alter current groundwater-use categories (as defined by various state regulatory agencies) because contaminant concentrations are not expected to rise significantly. However, groundwater quality is not routinely monitored for contaminants specific to cooling ponds.

Depending on groundwater velocity and adsorption characteristics, some contaminants (diluted by dispersion in natural groundwater) may reach off-site areas during the initial term of the license. As plant operation continues, groundwater quality at points near the site may approach the quality of the cooling pond water. If necessary, mitigation of groundwater contamination due to cooling pond operations might take the form of lining the ponds to reduce infiltration or cleaning groundwater by pumping and treating, both of which would be costly.

The extent of groundwater contamination by cooling ponds has not been documented at this time. Off-site groundwater monitoring is not standard practice at these sites, and there are no data with which to characterize the significance of potential off-site groundwater contamination. For those plants with cooling ponds located in a salt marsh (South Texas and Turkey Point), groundwater quality is not a significant concern because groundwater quality beneath salt marshes is too poor for human use. Because continued infiltration into the shallow aquifer will not change its groundwater use category (which is already restricted to industrial uses only) and because potential mitigation measures would be costly, no mitigation measures beyond those implemented during the current term license would be warranted. Therefore, for plants with cooling ponds located in salt marshes, this is a Category 1 issue. Groundwater in salt marshes is already restricted to industrial use, and there is no mechanism by which cooling pond water infiltrating into the groundwater would change its use category. The impact on groundwater quality for plants with cooling ponds that are not located in salt marshes is a Category 2 issue.

4.9 SUMMARY OF IMPACTS OF OPERATION

The conclusions about the environmental impacts of nuclear power plant operation during a license renewal term are summarized below.

Threatened and Endangered Species

- It is not possible to reach a conclusion about the significance of potential impacts to threatened and endangered species at this time because (1) the significance of impacts on such species cannot be assessed without site- and project-specific information that will not be available until the time of license renewal and (2) additional species that are threatened with extinction and that may be adversely affected by plant operations may be identified between the present and the time of license renewal. This is a Category 2 issue.

Surface Water Quality, Hydrology, and Use

- The staff examined nine aspects of water quality that might be affected by power plant operations: current patterns at intake and discharge structures, salinity gradients, temperature effects on sediment transport, altered thermal stratification of lakes, scouring from discharged cooling water, eutrophication, discharge of biocides, discharge of other chemical contaminants (e.g., metals), and discharge of sanitary wastes. Open-cycle cooling systems are more likely than other cooling systems to have such effects because they withdraw and discharge very large volumes of water; however, the impacts for each of these effects were found to be of small significance for all plants, regardless of cooling system type. For each type of impact, the staff considered potential mitigation measures but found that none were warranted because they would be costly and would have very small environmental benefits. These are Category 1 issues.

- The staff found no potential for water use conflicts or riperian plant and animal community impacts of moderate or large significance for plants with open-cycle cooling systems because they are used on large water bodies. Because the potential mitigation measures are costly and because the potential benefits are small, the staff does not consider mitigation to be warranted. These are Category 1 issues.
- The staff found that water use conflicts and the effects of consumptive water use on in-stream aquatic and riparian terrestrial communities could be of moderate significance at some plants that employ cooling-tower or cooling-pond systems because they are often located near smaller water bodies. For plants with these cooling systems, these are Category 2 issues.

Aquatic Ecology

- The staff examined 12 potential effects that nuclear power plant cooling systems may have on aquatic ecology: (1) impingement of fish; (2) entrainment of fish (early life stages); (3) entrainment of phytoplankton and zooplankton; (4) thermal discharge effects; (5) cold shock; (6) thermal plume barriers to migrating fish; (7) premature emergence of aquatic insects; (8) stimulation of nuisance organisms; (9) losses from predation, parasitism, and disease among organisms exposed to sublethal stresses; (10) gas supersaturation; (11) low dissolved oxygen in the discharge; and (12) accumulation of contaminants in sediments or biota. Except for three potential impacts (entrainment of fish and shellfish, impingement of fish and shellfish, and thermal discharge effects), each of these was found to be of small significance at all plants. Because mitigation would be costly and provide little environmental benefit, no additional mitigation measures beyond those implemented during the current license term are warranted. These are Category 1 issues. The other three impacts would be of small significance at all plants employing cooling-tower cooling systems. Because mitigation would be costly and provide little environmental benefit, no additional mitigation measures beyond those implemented during the current license term are warranted. For those plants, these are Category 1 issues. However, the impacts may be of greater significance at some plants employing open-cycle or cooling-pond systems; and these are Category 2 issues for those plants.

Groundwater Use and Quality

- The staff found that groundwater use of less than 100 gal/min is of small significance because the cone of depression will not extend beyond the site boundary. Conflicts might result from several types of groundwater use by nuclear power plants. If groundwater conflicts arose, they could be resolvable by deepening the affected wells, but no such mitigation is warranted because sites producing less than 0.0063 m^3/s (100 gal/min) would not have a cone of depression that extends beyond the site boundary. This is a Category 1 issue. Plants that extract more than 0.0063 m^3/s (100 gal/min), including plants using Ranney wells, may have groundwater use conflicts of moderate or large significance. Groundwater use is a Category 2 issue for such plants.

- Cooling system makeup water consumption may cause groundwater use conflicts. During times of low flow, surface water withdrawals for cooling tower makeup from small rivers can reduce groundwater recharge. Because the significance of such impacts cannot be determined generically, this is a Category 2 issue.
- Groundwater withdrawals could cause adverse effects on groundwater quality by inducing intrusion of lower-quality groundwater into the aquifer. The staff found that the significance of these potential impacts are of small significance in all cases. Because all plants except Grand Gulf use relatively small quantities of groundwater and surface water intrusion at Grand Gulf would not preclude current water uses, the staff found that mitigation was not warranted. This is a Category 1 issue.
- Cooling ponds leak an undetermined quantity of water through the pond bottom. Because the water in cooling ponds is elevated in salts and metals, such leakage may contaminate groundwater. The staff found that groundwater quality impacts of ponds located in salt marshes would be of small significance in all cases because salt marshes already have poor water quality. This is a Category 1 issue. Cooling ponds that are not located in salt marshes may have groundwater quality impacts of small, moderate, or large significance. This is a Category 2 issue.

Air Quality

- Small amounts of ozone and substantially smaller amounts of oxides of nitrogen are produced by transmission lines; however, ozone concentrations generated by transmission lines are too low to cause any significant effects. The minute amounts of oxides of nitrogen produced are also insignificant. Thus, air quality impacts associated with the operational transmission lines during the renewal term are expected to be of small significance at all sites. Potential mitigation measures would be very costly and are not warranted. This is a Category 1 issue.

Terrestrial Ecology

- The potential impact of cooling tower drift on crops and ornamental vegetation arising from operations during the license renewal term is expected to be of small significance for all nuclear plants. No mitigation measures beyond those implemented during the current license term are warranted because there have been no measurable effects on crops or ornamental vegetation from cooling tower drift. This is a Category 1 issue.
- The impact of cooling towers on natural plant communities would continue to be unmeasurable as a result of license renewal and will therefore be of small significance. Because the impacts of cooling tower drift on native plants are expected to be small and because potential mitigation measures would be costly, no mitigation measures beyond those during the current term license would be warranted. This is a Category 1 issue.

- Bird mortality from collision with power lines associated with nuclear plants is of small significance for all plants because bird mortality is expected to remain a small fraction of total collision mortality associated with all types of man-made objects. Because the numbers of birds killed from collision with cooling towers are not large enough to affect population stability or the ecosystem, consideration of further mitigation is not warranted. Both bird collosion with power lines and bird collision with cooling towers are Category 1 issues.
- Because no threat to the stability of local wildlife populations or vegetation communities is found for any cooling pond, the impacts are found to be of small significance. Potential mitigation measures would include excluding wildlife (e.g., birds) from contaminated ponds, converting to a dry cooling system, or reducing plant output during fogging or icing conditions. The impacts are found to be so minor that consideration of additional mitigation measures is not warranted. These effects of cooling ponds are so minor and so localized that cumulative impacts are not a concern. This is a Category 1 issue.
- Maintaining power-line ROWs causes fluctuations in wildlife populations, but the long-term effects are of small significance. The staff found that bird collision with transmission lines are of small significance. Also, transmission line maintenance and repair would have impacts of only small significance on floodplains and wetlands. In each case, the staff found that potential mitigation measures beyond those implemented during the current license term would be costly and provide little environmental benefit, and thus are not warranted. These are Category 1 issues.
- Wildlife, livestock, and plants residing in power-line EMF apparently grow, survive, and reproduce as well as expected in the absence of EMF. The potential impact of EMF on terrestrial resources during the license renewal term is considered to be of small significance for all plants. Because the impact is of small significance and because mitigation measures could create additional environmental impacts and would be costly, no mitigation measures beyond those implemented during the current term license would be warranted. This is a Category 1 issue.

Land Use

- Land use restrictions are necessary within transmission-line ROWs. The staff found these impacts to be of small significance at all sites. Mitigation beyond that imposed when ROWs were established might include relocating the transmission line. The staff concluded that such mitigation would not be warranted because it would be very costly and provide little environmental benefit. This is a Category 1 issue.

Human Health

- During the license renewal term, the radiation dose commitment to the total worker population is projected to increase less than 5 percent at nuclear power plants under the typical scenario and less than 8 percent at any plant under the conservative scenario. The present operating experience results in about 30,000 person-rem/year for all licensed plants combined. After refurbishment, routine operating conditions are expected to result in 32,000 person-rem/year for all plants combined. The risk associated with occupational radiation exposures after license renewal is expected to be of small significance at all plants. No mitigation measures beyond those implemented during the current license term are warranted because the existing ALARA process continues to be effective in reducing radiation doses. This is a Category 1 issue.

- Among the 150 million people who live within 50 miles of a U.S. nuclear power plant, about 30 million will die of spontaneous cancer unrelated to radiation exposure from nuclear power plants. This number is compared with approximately 5 calculated fatalities associated with potential nuclear-power-plant-induced cancer. The estimated annual cancer risk to the average individual is less than 1×10^{-6}. Public exposure to radiation during the license renewal term is of small significance at all sites, and no mitigation measures beyond those implemented during the current license term are warranted because current mitigation practices have resulted in declining public radiation doses and are expected to continue to do so. This is a Category 1 issue.
- The significance of potential for electrical shock from charges induced by transmission lines that may occur during the license renewal term cannot be evaluated generically because no NESC review was performed for some of the earlier licensed plants. For those that underwent an NESC review, a change in the transmission line voltage may have been made since issuance of the initial operating license, or changes in land use since issuance of the original license could have occurred. This is a Category 2 issue.
- There is no consensus among scientists on whether 60-Hz electromagnetic fields have a measurable human health impact. Because of inconclusive scientific evidence, the chronic effects of electromagnetic fields would be not be categorized as either a Category 1 or 2 issue. If NRC finds that a consensus has been reached that there are adverse health effects, all license renewal applicants will have to address it in the license renewal process.
- Occupational health questions related to thermophilic organisms, like *Legionella* sp., are currently resolved using proven industrial hygiene principles to minimize worker exposures to these organisms in mists of cooling towers. Adverse occupational health effects associated with microorganisms are expected to be of small significance at all sites. Aside from continued application of accepted industrial hygiene procedures, no additional mitigation measures beyond those implemented during the current license term are warranted. This is a Category 1 issue.
- Thermophilic organisms may or may not be influenced by operation of nuclear power plants. The issue is largely unstudied. However, NRC recognizes a potential health problem stemming from heated effluents. Public health questions require additional consideration for the 25 plants using cooling ponds, lakes, canals, or small rivers because the operation of these plants may significantly enhance the presence of thermophilic organisms. The data for these sites is not now at hand and it is impossible with current knowledge to predict the level of thermophilic organism enhancement at any given

site. Thus, the impacts are not known and are site specific. Therefore, the magnitude of the potential public health impacts associated with thermal enhancement of *N. fowleri* cannot be determined generically. This is a Category 2 issue.

Noise

- The principal noise sources at power plants (cooling towers and transformers) do not appreciably change during the aging process. Because noise impacts have been found to be small and generally not noticed by the public, noise impacts are expected to be of small significance at all sites. Because noise reduction methods would be costly, and given that there have been few complaints, no additional mitigation measures are warranted for license renewal. This is a Category 1 issue.

Socioeconomics

- The staff examined socioeconomic effects of nuclear power plant operations during a license renewal period. Five of these would be of small significance at all sites: education, public safety, social services, recreation and tourism, and aesthetics. Because mitigation measures beyond those implemented during the current license term are costly and would offer little benefit, no additional mitigation measures are warranted. These are Category 1 issues. Four of the socioeconomic effects were found to have moderate or large significance at some sites: housing, transportation, public utilities (especially water supply), and off-site land use. These are Category 2 issues. In addition the statutory requirement (National Historic Preservation Act) requires consultation; thus historic and archaeological resources are Category 2 issues.

7. DECOMMISSIONING

7.1 INTRODUCTION

Decommissioning is defined as the safe removal of a nuclear facility from service and the reduction of residual radioactivity to a level that permits release of the property for unrestricted use and termination of the license (10 CFR Part 50.82). Decommissioning must occur because a licensee is not permitted to abandon a facility after ceasing operation. Decommissioning activities do not include the removal of spent fuel, which is considered to be an operational activity; the storage of spent fuel, which is addressed in the Waste Confidence Rule (10 CFR Part 51.23); or the removal and disposal of nonradioactive structures and materials beyond that necessary to terminate the U.S. Nuclear Regulatory Commission (NRC) license. Disposal of the nonradioactive hazardous waste that is not necessary for NRC license termination is not considered part of the decommissioning process for which NRC is responsible.

The purpose of this chapter is to determine whether license renewal of nuclear power plants would change the impacts of decommissioning to such an extent that those impacts would need to be assessed and mitigative measures considered as part of the environmental review for license renewal. Current licenses allow nuclear power plants to operate for as long as 40 years. License renewal would extend the period of operation by as much as 20 years. This chapter addresses incremental impacts of decommissioning after a 20-year license renewal compared with operating for 40 years.

The following potential impacts are addressed: radiation exposures to workers and the public, socioeconomic effects, waste management impacts, air and water quality impacts, and ecological impacts. The principal impacts of decommissioning are expected to result from radiation exposures to workers and from disposal of radioactive materials. Decommissioning is expected to have only minor radiological impacts on the public (primarily as a result of transporting radioactive waste). Socioeconomic impacts of decommissioning would result from the demands on, and contributions to, the community by the workers employed to decommission a power plant. As shown in this chapter, the air quality, water quality, and ecological impacts of decommissioning are all expected to be substantially smaller than those of power plant construction or operation because the level of activity and the releases to the environment are all expected to be smaller during decommissioning than during construction and operation. The effect of license renewal on the costs of decommissioning are also examined because the costs of decommissioning continues to be a public concern; however, no category conclusion is reached because the impact of license renewal on decommissioning cost is not a consideration in the environmental review and the decision to renew a license.

The impacts resulting from decommissioning at 40 years (baseline) are taken from NUREG-0586, the two source documents NUREG/CR-0130 and NUREG/CR-0672, and updates to those source documents such as draft reports NUREG/CR-5884 and NUREG/CR-6174. The same methods used in those documents were used to project the impacts of decommissioning after 60 years of operation. Where the source documents did not address a potential impact, other available data and staff members' professional judgments were used to assess the potential for impacts to change as a result of extended operation. The analysis in this chapter is based on large "reference" pressurized-water reactor (PWR) and boiling-water reactor (BWR) nuclear power plants; consequently, the impacts of decommissioning all U.S. nuclear power plants that reach the end of their operating lives without a serious accident should be encompassed by those described here. The changes in impacts resulting from the extended operation and in the environment at the time of decommissioning were considered. [The discussion is built around a "reference" PWR identified by NUREG/CR-0130, the 1175-MW Trojan Nuclear Plant at Rainier, Oregon, and a "reference" BWR, the 1155-MW(e) Washington Public Power Supply System Nuclear Project 2, which was being built near Richland, Washington (NUREG/CR-0672).]

7.2 THE DECOMMISSIONING PROCESS

This section describes the locations of radioactive materials in nuclear power plants, notes the three commonly discussed decommissioning methods, summarizes experience to date with decommissioning nuclear power plants, and provides information on the wastes generated during decommissioning. Except as noted, the information for this section is from NUREG-0586.

7.2.1 Nuclear Power Plants

Nuclear power plants in the United States use two types of nuclear reactors (Chapter 2); the most common type is the PWR. Most of the 118 licensed power reactors in the United States are PWRs. The other type is the BWR. The locations of radioactive components in these two types of power plants are described briefly to aid the reader's understanding of decommissioning.

7.2.1.1 Pressurized-Water Reactors

Buildings or structures associated with a typical large PWR (Figure 7.1) include (1) the heavily reinforced concrete containment building, which houses the pressure vessel, the steam generators, and the pressurizer system; (2) the turbine building, which contains the turbines and the generator; (3) the cooling water system, which may include the cooling tower and other components; (4) the fuel building, which contains fresh and spent fuel, fuel handling facilities, the spent-fuel storage pool and its cooling system, and the solid radioactive waste system; (5) the auxiliary building, which contains the liquid radioactive waste treatment systems, the filter and ion exchanger vaults, the gaseous radioactive waste treatment system, and the ventilation systems for the containment, fuel, and auxiliary buildings; (6) the control building, which houses the reactor control room and personnel facilities; (7) water intake structures; (8) the administration building; and (9) other structures such as warehouses and nonradioactive shops.

The major radioactive components encountered in decommissioning are associated with the reactor itself—the primary coolant loop, the steam generators, the radioactive waste handling systems, and the concrete biological shield that surrounds the pressure vessel. The reactor core, pressure vessel, steam generators, and piping between the reactor and steam generators are highly radioactive. Because some primary-to-secondary leakage is

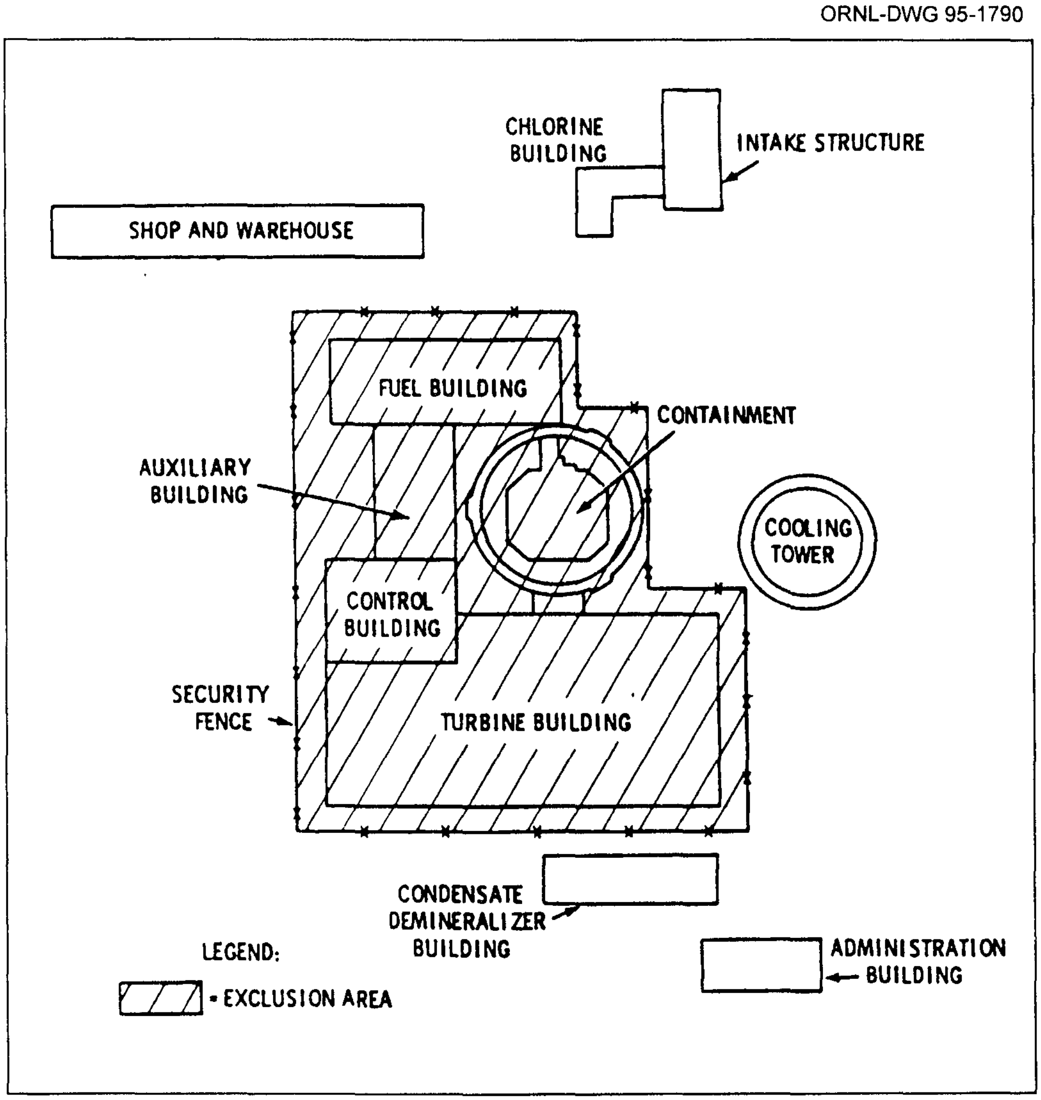

Figure 7.1 Typical pressurized-water reactor generating station layout. Adapted from NUREG/CR-0130.

impossible to avoid, the secondary loop, including the turbines, is slightly contaminated. Because of leakage and blowdown, the cooling water is very slightly contaminated. Much equipment in the auxiliary building is contaminated, as is the spent-fuel storage pool and its associated equipment.

7.2.1.2 Boiling-Water Reactors

Buildings and structures associated with a typical large BWR (Figure 7.2) include (1) the reactor building, which houses the reactor pressure vessel, the containment structure, the biological shield, the spent-fuel pool, and fuel handling equipment; (2) the turbine building, which houses the

ORNL-DWG 95-1756

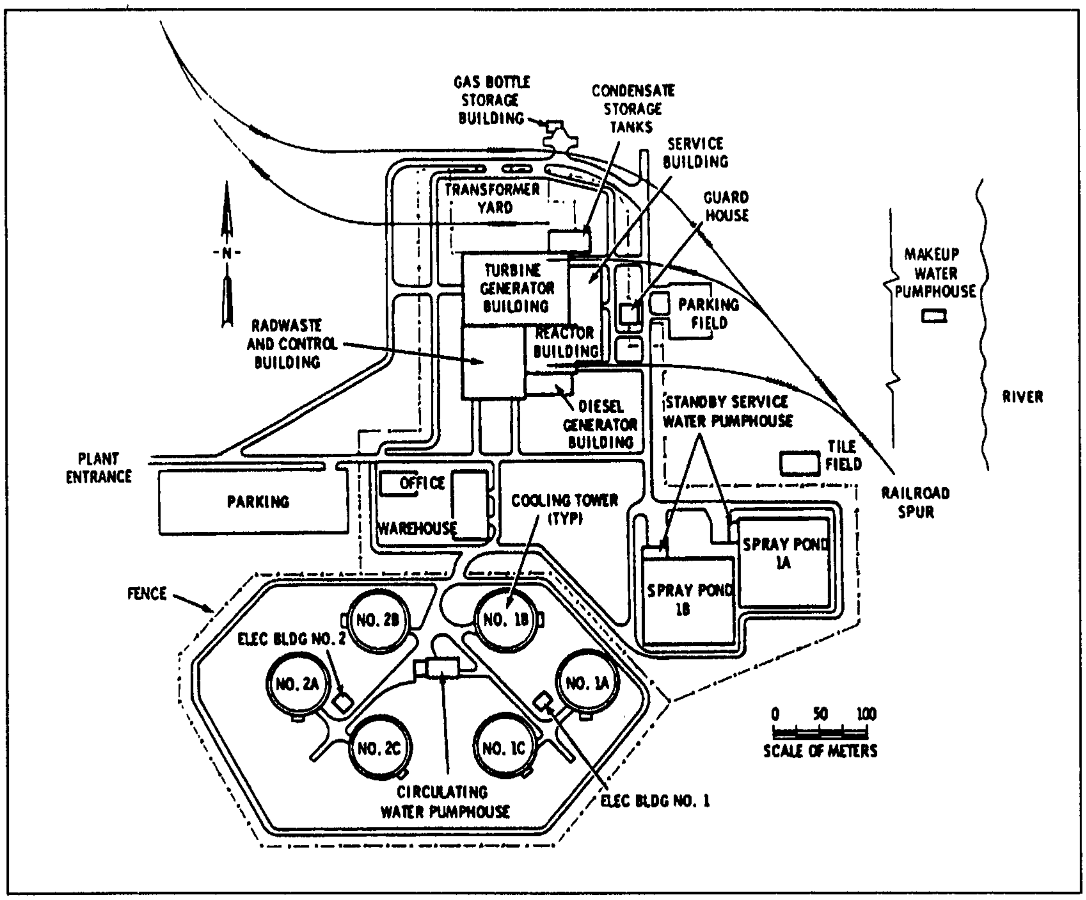

Figure 7.2 Site layout on a typical boiling-water reactor power plant. Adapted from NUREG-0672.

turbine and electric generator; (3) the radioactive waste and control building, which houses the solid, liquid, and gaseous radioactive waste treatment systems and the main control room; (4) the cooling system; (5) water intake structures and pump houses; (6) the service building, which houses the makeup water treatment system, machine shops, and offices; and (7) other minor structures.

The major sources of radiation in decommissioning a BWR are associated with the reactor itself, the containment structure, the concrete biological shield, the primary coolant loop, the turbines, and the radioactive waste handling systems. The reactor building, the turbine generator building, and the radioactive waste building are the only buildings containing radioactive materials. The reactor core and its pressure vessel are highly contaminated, as is the piping to the turbines. The turbines are also contaminated, but the cooling towers and associated piping are not. Much equipment in the radioactive waste building is contaminated, as is the spent-fuel pool in the reactor building.

7.2.2 Decommissioning Methods

In the NRC's original decommissioning studies (NUREG/CR-0130 for PWRs and NUREG/CR-0672 for BWRs), three alternatives were defined: DECON (decontamination/dismantlement as rapidly after reactor shutdown as possible to achieve termination of the nuclear license); SAFSTOR (a period of safe storage of the stabilized and defueled facility followed by final decontamination/dismantlement and license termination); and ENTOMB (immediate removal of the highly activated reactor vessel internals for disposal and relocation of the remainder of the radioactively contaminated materials to the reactor containment building, which is then sealed. With sufficient time, the radioactivity on the entombed materials will have decayed to levels that permit termination of the nuclear license). However, because current regulations require decommissioning to be complete within 60 years, ENTOMB may not be a viable option.

Changes in the industrial and regulatory situation in the United States since the late 1970s have forced revisions to the scenarios of the NRC's original decommissioning alternatives. The most recently revised decommissioning scenarios are described for PWRs in NUREG/CR-5884 and for BWRs in NUREG/CR-6174. There are two principal changes in the revised scenarios. One is the delay of major decommissioning actions for at least 5 to 7 years following reactor shutdown because of a Department of Energy (DOE) requirement to cool the spent fuel in the reactor pool to avoid cladding failures in dry storage. The other is the assumption that decommissioning will be complete within 60 years, as required by current regulations. This delay results in an increase in decommissioning costs during the short safe storage period while the spent fuel pool continues to operate. Changes in cumulative occupational radiation doses also result from the decommissioning scenario changes.

The basic concept of the three alternatives remains unchanged. However, because of the accumulated inventory of spent fuel in the reactor storage pool and the requirement for at least 5 years of storage for the spent fuel before transfer to DOE for disposal, the timing and steps in the process for each alternative have been adjusted to reflect present conditions and possibilities. For the DECON alternative, it is assumed that the owner has strong incentives to decontaminate and dismantle the retired reactor facility as promptly as possible [i.e., future availability and cost of low-level radioactive waste (LLW) disposal and the need to reuse or dispose of the site, necessitating transfer of the stored spent fuel from the pool to a dry storage facility on the reactor site]. Although continued storage of spent fuel in the pool would be acceptable, the modified Part 50 license could not be terminated until the pool was emptied. It is also assumed that an acceptable dry transfer system would be available to remove the spent fuel from the dry storage facility and place it into licensed transport casks when the time came for DOE to accept the spent fuel for disposal. Similar assumptions are made for the SAFSTOR and ENTOMB alternatives for convenience of analysis, even though extended use of the spent fuel pool might be more cost-effective for SAFSTOR.

7.2.2.1 DECON

DECON is the decommissioning method in which the equipment, structures, and portions of the facility and site containing radioactive contaminants are removed or decontaminated to a level that permits the property to be released for unrestricted use shortly after cessation of operations. It is the only decommissioning alternative that leads to termination of the facility license and release of the facility and site for unrestricted use shortly after cessation of facility operations. DECON activities are expected to require about 9 years for large light-water reactors; less time should be required for smaller facilities.

Because DECON operations are expected to be completed within a few years following shutdown, radiation exposures to workers generally are higher than for decommissioning methods that allow for radioactive decay by delaying or extending the work over a longer period. DECON also requires larger commitments of money and commercial waste disposal site space than do other decommissioning methods. The principal advantage of DECON is that the site is available for unrestricted use promptly.

Nonradioactive equipment and structures need not be dismantled or removed for termination of the NRC license and release for unrestricted use. Once the facility's radioactive structures are decontaminated to levels permitting unrestricted use of the facility, nonradioactive facilities may either be put to some other use or demolished at the owner's discretion. [NRC has issued proposed amendments to 10 CFR Part 20 containing radiological criteria for decommissioning of NRC-licensed nuclear facilities (FR 59, 43200, August 22, 1994). Currently, NRC uses, on a case-by-case basis, criteria and practices contained in Regulatory Guide 1.86 and in a letter to Stanford University from J. Miller, Office of Nuclear Reactor Regulation, NRC, dated April 21, 1982.]

DECON, as defined by NUREG/CR-5884 and NUREG/CR-6174, comprises four distinct periods of effort: (1) preshutdown planning/engineering and regulatory reviews, (2) plant deactivation and preparation for storage (no dismantling activities are conducted during this period that would affect the safe operation of the spent fuel pool), (3) plant safe storage with concurrent operations in the spent-fuel pool until the pool inventory is zero, and (4) decontamination and dismantlement of the radioactive portions of the plant, leading to license termination. Because of the delays in development of the federal waste management system, it may be necessary to continue operation of a dry fuel storage facility on the reactor site after the reactor systems have been dismantled and the reactor nuclear license terminated. However, these latter storage costs are considered operations costs under 10 CFR 50.54(b)(b) and are not considered part of decommissioning.

7.2.2.2 SAFSTOR

SAFSTOR is the decommissioning method in which the nuclear facility is placed and maintained in a condition that allows the safe storage of radioactive components of the nuclear plant and subsequent decontamination to levels that permit release for unrestricted use. SAFSTOR was initially conceived of as having three successive stages: (1) a short period of preparation for safe storage (expected to be up to 2 years after final reactor shutdown); (2) a variable safe storage period of continuing care consisting of security, surveillance, and maintenance during which much of the reactor's radioactivity decays; and finally, (3) a relatively short period of decontamination (NUREG-0586). In NUREG/CR-5884 and NUREG/CR-6174, SAFSTOR is described as five distinct periods of effort, with the initial three periods identical to those of DECON. The fourth period is extended safe storage (50 years) with no fuel in the reactor storage pool, and the fifth period is decontamination and dismantlement of the radioactive portions of the plant.

The radioactive or contaminated material must be decontaminated or removed, packaged, and disposed of at a regulated disposal facility. After it has been determined that residual radioactivity is at acceptable levels, the license will be terminated and the facility can be released for unrestricted use. After termination of the NRC license, disassembly or demolition of nonradioactive facilities would be performed at the owner's discretion.

SAFSTOR may be used as a means of satisfying requirements for protection of the public while minimizing the initial commitments of time, money, radiation exposure, and waste disposal capacity. SAFSTOR may also have some advantage where there are other operational nuclear facilities at the same site or where a shortage of radioactive waste disposal capacity occurs. The disadvantages of SAFSTOR are that the site is unavailable for other uses for an extended time; maintenance, security, and surveillance are required until the final decontamination is complete; and few, if any, personnel familiar with the facility are available at the time of decontamination (up to 60 years after plant shutdown).

7.2.2.3 ENTOMB

ENTOMB is the alternative in which radioactive contaminants are encased in a long-lasting material, such as concrete. The entombed structure is maintained and surveillance is performed until the radioactivity decays to a level permitting release of the property for unrestricted use. ENTOMB also comprises five distinct periods of effort, with the initial three periods identical to those of DECON (NUREG/CR-5884 and NUREG/CR-6174). The fourth period is preparation for entombment, when all of the radioactive materials are consolidated within the containment building and entombed. The fifth period is entombed storage for an extended time, between 60 and 300 years.

ENTOMB is intended for use where the residual radioactivity will decay to levels permitting unrestricted release of the facility within reasonable time periods (100 years). However, a few radioactive isotopes produced in nuclear reactors have long half-life periods (Section 7.3.1) that prevent the release of the facilities for unrestricted use within the foreseeable lifetime of any man-made structure. ENTOMB would be a viable alternative only for facilities where radioactive isotopes would be expected to decay to safe levels within the expected lifetime of the entombment structure. This condition likely would not pertain to nuclear power reactors. In addition, the use of the ENTOMB alternative contributes to problems associated with increased numbers of sites dedicated to "interim" storage of radioactive materials for long periods of time.

7.2.3 Decommissioning Experience

U.S. commercial nuclear power reactors that have been shut down through 1992 are listed in Table 7.1. An additional 24 reactors have been or are being decommissioned in France, West Germany, Canada, the United Kingdom, Sweden, and Japan (Gaunt et al. 1990).

7.2.4 Inventory and Disposition of Radioactive Materials

Radioactive materials can be classified as activated or radioactively contaminated materials. Materials become activated when they have been exposed to (irradiated by) high levels of neutron radiation (such as in a reactor). When normal (stable) atoms in

a material absorb neutrons, they become unstable (radioactive) and subsequently emit energy in the form of radiation. Radioactive contamination is radioactive material in the form of fine particles, liquids, or gases that are deposited on the surface of, or mixed with, materials that otherwise are not radioactive. Contaminated materials can generally be decontaminated to various degrees by several techniques. These techniques range from simply washing with soap and water to sandblasting contaminated surfaces. Decontamination techniques for liquids and gases include filtration and chemical ion exchange. Activated materials cannot be decontaminated; they remain radioactive until the radioactive constituents decay to stable isotopes.

Reactor components are generally both activated and contaminated. The principal activated components of a power plant are the reactor internals and the biological shield. Other reactor system components, such as the primary and possibly the secondary coolant loops, the turbines in BWRs, and the radioactive waste handling systems, are not activated but are highly contaminated by the contaminated fluids they contain. The major source of contamination in reactor coolant is the plant corrosion and wear material suspended in the coolant that becomes activated as it passes through the reactor core. Surface contamination can also be found in areas of the plant where leaks from contaminated systems have occurred.

The inventory of radionuclides for PWRs and BWRs is slightly different. A typical large PWR would have a radioactivity level of about 4.8 million Ci (1Ci = 3.7×10^{10} Bq) in the major reactor components, 4800 Ci of radioactive corrosion products in the primary coolant system, and 1200 Ci of radioactivity in the concrete biological shield at the time of shutdown (NUREG/CR-0130). A typical large BWR would have a radioactivity level of about 6.3 million Ci in the major reactor components, 8600 Ci of radioactive corrosion products in the primary coolant system, and 1000 Ci of radioactivity in the concrete biological shield at the time of shutdown (NUREG/CR-0672).

The principal radioactive isotopes from irradiated steel and concrete, with their modes of decay and their half-lives, are listed in Table 7.2. By the end of 40 years of operation, the radionuclides with half-lives of less than about 5 years are at equilibrium, because their rates of decay equal their rates of generation. No matter how much longer a power plant is operated, the concentration of short-half-life radionuclides will not increase. The longer-lived radionuclides are generated much faster than they decay; thus their concentrations increase approximately in proportion to the reactor operating time. Figure 7.3 illustrates the buildup of some important radionuclides as a function of nuclear plant operating life.

Radioactive isotopes that are mainly beta emitters or that have very short half-lives do not contribute significantly to the personnel radiation dose associated with decommissioning. Because beta radiation is weakly penetrating, it can be shielded easily and presents a hazard mainly if ingested or inhaled by operations personnel. Isotopes with very short half-life periods can be allowed to decay to insignificant levels before decommissioning operations begin.

At the time of decommissioning, radioactive materials are found in the reactor building, the auxiliary building, and the fuel building (Section 7.2.1). Immediately after operations are terminated, these parts of the plant are highly radioactive because of short-lived activation products. The highest levels of radioactivity subside very quickly as short-lived radionuclides decay and progressively longer-lived radionuclides dominate the overall radioactivity. After about a year, ^{60}Co dominates the radiation dose to workers. After about 100 years, ^{94}Nb dominates the radiation dose to workers or persons in the vicinity (Figure 7.4). For all practical purposes, the radiation dose to workers will not decrease further because ^{94}Nb has a 20,000-year half-life. Because ^{60}Co and ^{94}Nb dominate the radiation dose during the time of decommissioning, their characteristics affect the decommissioning process.

Both ^{60}Co and ^{94}Nb are activation products—isotopes created when neutrons from nuclear fission convert nonradioactive elements (^{59}Co and ^{93}Nb) in the structural components of the plant into radioactive

isotopes. An important difference is that ^{94}Nb in the steel reactor vessel and components, formed by activation of ^{93}Nb, is not subject to corrosion and movement throughout the primary system to the extent that ^{60}Co is. Consequently, equipment in the reactor containment building that is not exposed to high neutron fluxes and parts of the fuel and auxiliary buildings may be highly contaminated with ^{60}Co but only slightly so with ^{94}Nb.

Extending operations to 60 years would not increase the shutdown radioactivity level of either a PWR or BWR to any appreciable extent. This is because most of the radioactivity at shutdown results from short-half-life radionuclides, such as ^{60}Co, that are already in equilibrium by the time 40 years of operations have transpired. The only change in radioactive inventory resulting from the additional 20 years of operations is the further accumulation of long-half-life radionuclides such as ^{63}Ni and ^{94}Nb, but these long-half-life radionuclides produce only a small fraction of the total radioactivity at shutdown. Of the long-half-life radionuclides, ^{63}Ni contributes most at shutdown but composes less than 3 percent of the total radioactivity. Twenty additional years of operation would increase its contribution to about 4 percent of total shutdown radioactivity. Because ^{63}Ni is a beta emitter, it contributes only a very small part of the dose to workers or the public. Gamma-emitting ^{94}Nb is the most important long-half-life radionuclide with regard to producing external radiation exposure. Based on Figure 7.4, it can be determined that at shutdown ^{94}Nb contributes less than 0.001 percent of the total potential dose. Even though 20 additional years of operation would increase the amount of ^{94}Nb by 50 percent, it would not increase its contribution to the dose much above 0.001 percent.

7.2.5 Waste Generated During Decommissioning

This section summarizes the quantities and types of radioactive waste and emissions generated in decommissioning after 40 and 60 years of operation, respectively. Because the demolition and disposal of nonradioactive parts of nuclear facilities are not considered part of decommissioning, almost all waste generated during decommissioning is radioactive. Although the demolition and disposal of the nonradioactive parts may continue during and after decommissioning, these activities are not regulated by NRC. The impacts of radioactive wastes and emissions are described in Section 7.3. This section does not take into account volume reduction or aggressive processing that could allow release for unrestricted use.

7.2.5.1 Atmospheric Emissions

As shown in Table 7.3, the total atmospheric releases for decommissioning are less than 100 mCi, whereas normal operations average about 3000 Ci/year. Atmospheric releases are expected to consist largely of dust, aerosols, and smokelike particulates produced during the dismantling and handling of reactor components. These releases were estimated by assuming that the airborne concentrations of radionuclides will be a fraction of the contamination level on and in the radioactive components (NUREG/CR-0130 and NUREG/CR-0672). Because the radioactive inventory would be nearly unchanged by operations during a 20-year license renewal term, no difference exists between the base case and 20 years of additional operation.

Table 7.3 Airborne radioactive releases resulting from decommissioning typical pressurized-water reactors (PWRs) and boiling-water reactors (BWRs) with normal operating releases, base case (40 years of operation)[a]

	DECON (mCi)	SAFSTOR (mCi)	ENTOMB (mCi)	Normal operations (Ci/year)
PWR	0.86[b]	0.003[b]	NA[c]	2,600[d]
BWR	87[e]	0.21d[d]	2.25[d]	3,400[d]

[a]Decommissioning releases are for 40 years of operation. Releases for 60 years of operation would be essentially the same.
[b]*Source:* NUREG/CR-0130, Table 11.2-2.
[c]Not available.
[d]*Source:* DOE/EP-0093.
[e]*Source:* NUREG/CR-0672, Tables N.2-12, N.3-4, N.4-4, E.2-11. Decommissioning is assumed to last 5 years.

7.2.5.2 Liquid Effluents

No estimates of liquid waste releases are available for decommissioning nuclear power plants. However, liquids will be produced by decontamination procedures (e.g., some cutting operations and possibly some chemical decontamination procedures) and by disposal of plant fluids (e.g., cooling water and water from fuel storage pools). Filtration and ion exchange methods will be used to decontaminate liquids, as would be done during normal operations. Some liquid effluents may be contaminated with chelating agents and may require further processing. These methods are expected to keep waterborne effluents of most radionuclides within the values of normal operations. Tritium (^3H) is the only radioactive isotope that cannot be removed from waste water by these means.

Tritium is found principally in the primary coolant-loop water. Tritium cannot be removed from water except by extraordinary means and is normally discharged to a surface water body. Normal ^3H discharges from PWRs range from a few hundred to a few thousand curies per year. BWR ^3H discharges are generally only about 10 percent as high as ^3H discharges from PWRs. About 500 Ci of ^3H can be found in PWR primary coolant-loop water. Discharge of the entire volume of primary coolant-loop water over a period of 1 to 5 years after shutdown would be feasible without exceeding normal operating period discharge rates. The amounts or characteristics of liquid effluents discharged during decommissioning would not be changed by operation during a 20-year license renewal term. Discharge of primary coolant water during normal operations limits the accumulation of ^3H in the primary coolant loop; thus ^3H is in equilibrium in the primary coolant water well before 40 years of operation.

7.2.5.3 Solid Waste

Table 7.4 summarizes the quantities of LLW generated by decommissioning of large PWRs and BWRs. The table shows that the largest amount of LLW is

Table 7.4 Estimated burial volume of low-level waste and rubble for large pressurized-water reactor (PWR) and boiling-water reactor (BWR) decommissioning, base case (40 years of operation)

Decommissioning alternative	PWR (m^3)[a]	BWR (m^3)
DECON	6,992	14,282
SAFSTOR 1	763	1,117
SAFSTOR 2	6,992	14,282
ENTOMB 1	305	490
ENTOMB 2	754	1,139
ENTOMB 3	305	490

[a] 1 m^3 = 35.3 ft^3

Source: NUREG/CR-5884, Table ES.1 and NUREG/CR-6174, Table ES.1.

generated by the DECON method and the least is generated by the SAFSTOR method. The quantities listed for the ENTOMB method do not include the volume of the entombing structure or the wastes within.

The decommissioning waste volumes for all three methods of decommissioning also would not be affected by extending the volume of radioactive materials would not increase. (Operational waste quantities would continue, but they do not affect the amount of decommissioning waste.) An additional 20 years of operation would slightly affect the waste characteristics. As discussed in Section 7.2.4, the quantity of long-lived activation products such as ^{94}Nb would continue to increase, essentially in proportion to the additional operational time. As a result, the long-half-life radionuclides in the waste would increase by 50 percent if the plants were operated an additional 20 years. However, as explained earlier, these long-lived radionuclides contribute only a small fraction of the shutdown radioactivity level.

7.3 DECOMMISSIONING IMPACTS AND CHANGES RESULTING FROM LIFE EXTENSION

Estimated decommissioning impacts for 40 years of operation—the base case (taken primarily from NUREG-0586, NUREG/CR-0130, and NUREG/CR-0672)—and the change in impacts caused by continued operations for an additional 20 years under license renewal are reported for each impact area in the following sections. These impacts are estimated for PWRs and BWRs. The per-reactor impacts of decommissioning at multiple-reactor sites are not expected to be significantly different from those at single-reactor sites. [The impacts would be smaller at multiple reactor sites if the reactor decommissionings were staggered and if LLW were stored on the site (NUREG-0586)].

7.3.1 Radiation Dose

The estimated occupational and public radiation doses resulting from the three decommissioning methods after 40 years of operation (base case) are summarized in this section. Occupational dose estimates were presented in draft reports NUREG/CR-5884 and NUREG/CR-6174. These reports do not provide estimates of doses to the public. The Atomic Energy Act requires the Nuclear Regulatory Commission to promulgate, inspect, and enforce standards that provide an adequate level of protection of the public health and safety and the environment. These responsibilities, singly and in the aggregate, provide a margin of safety. For the purposes of assessing radiological impacts, the Commission has concluded that impacts are of small significance if doses and releases do not exceed permissible levels in the Commission's regulations.

7.3.1.1 Occupational Dose

For both PWRs and BWRs, there are substantial differences among the occupational radiation doses for the decommissioning methods (Table 7.5). The DECON method has the highest doses, followed by ENTOMB and then SAFSTOR. Although extending operations 20 years would increase the doses from ^{94}Nb and other less-important long-half-life radionuclides, these doses would not have any appreciable effect on the occupational dose because short-lived radionuclides (primarily ^{60}Co) are the principal sources of worker exposure. For each decommissioning method, the bulk of the dose comes during activities in the first few years after termination of plant operations (period four begins less than 5 years after terminating operations for DECON), when the radioactivity level of ^{60}Co is still significant. At the end of 60 years of SAFSTOR, the dose rate would have decayed to about 0.01 percent of the dose rate at the end of operations, at which time ^{94}Nb would contribute only about 2 percent of the total (Figure 7.4).

An additional 20 years of operation before 60 years of SAFSTOR would increase the amount of ^{94}Nb by approximately 50 percent. During period 5, occupational exposures from SAFSTOR activities would be no more than 10 person-rem. (Section E.A.3 of Appendix E discusses the International System units used in measuring radioactivity and radiation dose. The contribution from ^{94}Nb would be less than 0.2 person-rem. The increase in dose during decommissioning after 20 additional years of operation would be no more than about 0.1 person-rem.

Although total doses to the decommissioning workforce may increase slightly as a result of an additional 20 years of plant operation, the exposure of individual workers will be maintained well below the existing regulatory limits of 10 CRF Part 20. Accordingly, the Commission concludes that radiological impacts to the decontamination workforce as a result of license renewal is of small significance.

The potential increase in total dose to the decommissioning work force may be mitigated by programs that are responsive to 10 CFR 20.1101(b), which requires that "The licensee shall use, to the extent practicable, procedures and engineering controls based upon sound radiation protection principles to achieve occupational doses and doses to members of the public that are as low as is reasonably achievable (ALARA)." The ongoing ALARA programs within the industry already employ measures that would be considered for mitigating the generation or the accumulation of long-lived activation products during 20 additional years of operation. Two examples of mitigation measures that are already in use are (1) replacing components using cobalt alloys with those using low-cobalt or cobalt-free alloys and (2) full system decontamination (e.g., see

Table 7.5 Estimated occupational radiation doses for decommissioning a large reactor (person-rem), base case (40 years of operation)[a]

Decommissioning period[b]	DECON[c,d]	SAFSTOR[c,e]	ENTOMB[c,f]

Moore 1995). No additional mitigation measures warranted. This is a Category 1 issue.

7.3.1.2 Dose to the Public

For both PWRs and BWRs, the radiation dose to the public results primarily from waste shipment (Table 7.6). Furthermore, the dose is almost exclusively caused by shipment of ^{60}Co and shorter-lived radionuclides; for truck shipments, the SAFSTOR 100-years alternative shows negligible dose to the public. Because only the quantities of long-lived radionuclides would increase if plants were operated an additional 20 years, only the dose caused by the long-lived radionuclides would increase. Because the dose to the public from long-lived radionuclides after 40 years

Table 7.6 Estimated radiation dose to the public for decommissioning a large reactor (person-rem), base case (40 years of operation)[a,b]

Totals	10	2	2	5–7[d]

[a]Public radiation exposures are for decommissioning after 40 years of operation (NUREG-0586). Decommissioning exposures after 60 years would be identical, except as noted. Draft reports NUREG/CR-5884 and NUREG/CR-6174 do not provide updates for this information.
[b]NA means not applicable and neg means negligible.
[c]Decommissioning after 60 years of operation would increase occupational and public exposure during (1) decontamination and (2) decontamination truck shipments by only negligible amounts.
[d]Ranges are for removing or leaving internal components or leaving them in place. The higher exposures are associated with removing the internals.
Note: To convert person-rem to person-sievert, multiply by 0.01.

of operation is negligible (see the SAFSTOR 100-years alternative in Table 7.6), an increase of 50 percent of this negligible amount would still remain a negligible dose (less than 0.1 person-rem).

The negligible public radiation exposures for SAFSTOR preparation, continuing care, and decontamination (Table 7.6) include exposures from atmospheric and liquid releases during routine decommissioning operations. There are no historical records of significant releases during decommissioning, and no reliable estimates can be made of the probability and consequences of such events.

However, the probability and consequences of such releases are not expected to be different for decommissioning a base case facility versus decommissioning a facility that has had 20 years of additional operation.

Extending reactor operating life from 40 to 60 years is expected to increase the concentration of long-half-life radionuclides in the facility by up to 50 percent. By the end of the initial 40 years of operation, the radionuclides with half-lives of less than about 5 years are at equilibrium because their rates of decay equal their rates of generation. The release of radioactivity to the atmosphere during decontamination is negligibly small and primarily involves short-lived nuclides. Public exposure even with the increased concentration of long-lived nuclides would remain negligible. The exposure of individual members of the public will be maintained well below existing regulatory limits. Accordingly, the staff concludes that the contribution of license renewal to radiological impacts from decontamination is of small significance. As discussed in Section 7.3.1.1, measures that can reduce possible dose levels to the public are available and are being employed in pursuit of ALARA.

Radiation doses (public and occupational) from decommissioning that are attributable to license renewal are a Category 1 issue.

7.3.2 Waste Management Impacts

An operating 1000-MW(e) reactor generates about 38 m^3 (1300 ft^3) of spent fuel and about 52,000 m^3 (1,800,000 ft^3) of LLW over its 40-year life (NUREG-0586, pp. 2–21). (LLW is defined in Chapter 6.) The reference PWR and BWR are about 15 percent larger, so they would be expected to generate about 15 percent more waste than a 1000-MW(e) plant. As shown by Table 7.4, decommissioning either type of plant after 40 years of operation (base case) would generate less than 15,000 m^3 (530,000 ft^3) of LLW for DECON or short-term SAFSTOR and less than 1,200 m^3 (42,000 ft^3) of LLW for SAFSTOR of 50 years or longer. These waste volumes include spent chelating agent used to decontaminate liquids. The 15,000 m^3 (530,000 ft^3) of decommissioning LLW is about 25 percent, and 1,200 m^3 (42,000 ft^3) is only about 2 percent, of the LLW generated by 40 years of operations. None of these estimates of waste volume includes waste generation during refurbishment.

Extending operations by 20 years would not increase decommissioning waste volumes, so the ratio of decommissioning waste volume to operating waste volume would be even lower. After 60 years of operation, decommissioning LLW would be less than about 20 percent of the operational LLW. If SAFSTOR were used, the decommissioning LLW would be only about 1 percent of the LLW generated by operations.

While the volume of decommissioning waste will not increase with 20 years of additional operating time, the concentration of long-half-life radionuclides will increase. LLW is classified by 10 CFR Part 61 into three waste classes denoted A, B, and C and a category of LLW designated "greater than Class C" (GTCC). Classes A and B are wastes that are contaminated with relatively short-half-life radionuclides and may be safely disposed of near the earth's surface because they will decay to a nonhazardous condition within about 100 years. Class C waste can be disposed of at a moderate depth or near the earth's surface with engineered barriers to prevent inadvertent intrusion into the wastes. GTCC waste cannot safely be disposed of near the earth's surface (Section 6.2.2.2; 10 CFR Part 61.7).

Table 7.7 gives the estimated decommissioning LLW breakdown (DECON scenario) for the base case by waste class per 10 CFR Part 61. Items classified as C and GTCC consist of highly activated metal located in the high-flux neutron field. For the PWR, the GTCC items include the lower core barrel, the thermal shields, the core shroud, and the lower grid plate. The class C items are the upper grid plate and the lower support column. The class B wastes consist of spent resins used during decommissioning, part of the combustible contaminated wastes, and part of the cylindrical pressure vessel wall. The only GTCC wastes from a BWR are the core shroud and top fuel guide. BWR class C wastes are from the control rods and in-core instrumentation, jet pump assemblies, and the top fuel guide. The class B wastes are from the steam separator assembly, the reactor vessel wall, and portions of the clean-up wastes.

Table 7.7 Decommissioning waste volumes for reference pressurized-water reactor (PWR) and boiling-water reactor (BWR) after 40 years of operation[a]

	Class A	Class B/C	GTCC[b]
PWR	6,797 m^3	184 m^3	11 m^3
BWR	13,903 m^3	372 m^3	6.9 m^3

[a]DECON decommissioning method. Other methods would have smaller volumes of Class A and B wastes; Class C and GTCC wastes volumes would not change for other methods. A plant that has operated 60 years would have essentially the same waste volumes and classifications.
[b]GTCC = greater than Class C.
Source: NUREG/CR-5884 and NUREG/CR-6174.
Note: 1 m^3 = 35.3 ft^3.

The radionuclides of most importance for determining the classification of these LLWs are those that have relatively long half-life periods, such as ^{59}Ni and ^{94}Nb. These are also the radionuclides that accumulate in proportion with the length of reactor operation. The estimates in Table 7.7 are made for a plant that has operated 40 years. A plant that has operated 60 years would have essentially the same decommissioning waste volumes and classifications. Because the radionuclide concentration differences among waste classes are large (factors of 10 or more) and because the concentrations of radionuclides increase by no more than 50 percent, few components would be advanced to a higher classification by an additional 20 years of operations. Because the decommissioning waste volumes and classifications are essentially unchanged by an additional 20 years of plant operation, the Commission finds that the environmental impacts of decommissioning waste due to license renewal are of small significance. Measures employed within the context of ALARA, as discussed in Section 7.3.1.1, have the potential to reduce slightly the volume of LLW generated by decommissioning. The impact on decommissioning waste management attributable to license renewal is a Category 1 issue.

7.3.3 Air Quality Impacts

Air quality impacts of decommissioning are expected to be negligible. No major land disturbance for construction laydown or temporary waste storage areas is anticipated. The principal air quality impacts would result from motor vehicles operated by workers for transportation on-site and for movement of people and materials to and from the site. Most decommissioning activities would be conducted inside the containment, the auxiliary building, and the fuel-handling buildings. Because there would be a possibility of airborne releases of radioactivity within these buildings during decommissioning, releases to the ambient environment would be controlled. These impacts would be much smaller than those associated with construction or demolition of the facilities on-site and would not change with 20 additional years of operation. License renewal and an additional 20 years of reactor operation will have no impact on air quality during decommissioning; thus the impact of license renewal on decommissioning air quality impacts is of small significance for all plants. Because license renewal does not affect the level of air pollution during decommissioning, there is no need for the consideration of mitigation as part of the license renewal environmental review. The impact of decommissioning on air quality attributable to license renewal is a Category 1 issue.

7.3.4 Water Quality Impacts

The principal water quality impacts expected from decommissioning are those associated with sanitary sewer operations. Because the decommissioning work force is likely to be smaller than those of construction and certain operational activities (see Section 7.3.7), no increase in water quality impacts is expected. Soil erosion and chemical spills associated with increased site activities during decommissioning have the potential to degrade water quality, but such effects are readily controllable. The potential for significant water quality impacts from erosion or spills is no greater if decommissioning occurs after a 20-year license renewal instead of after the original 40 years of operation. Measures to minimize occupational and public radiation exposure will also protect water quality. License renewal and an additional 20 years of reactor operation will have no impact on water quality during decommissioning; thus the impact is of small significance. Because license renewal does not affect water quality impacts during decommissioning, there is no need for the consideration of mitigation as part of the license renewal environmental review. The impact of decommissioning on water quality impacts attributable to license renewal is a Category 1 issue.

7.3.5 Ecological Impacts

Terrestrial biota impacts, if any, would be associated with land disturbance for laydown or temporary waste storage areas, and no such land disturbance is anticipated. No direct impacts to aquatic biota are expected from routine decommissioning activities. Measures employed to protect water quality will also prevent toxic effects to aquatic organisms from liquid effluents. Therefore, the ecological impacts associated with decommissioning are not expected to vary with the length of time the plant is operated. Decommissioning after a 20-year license renewal would have the same ecological impacts, if any, as decommissioning after 40 years of operation; thus the impact is of small significance. Because license renewal does not affect ecological impacts during decommissioning, there is no need for the consideration of mitigation as part of the license renewal environmental review. The impact of decommissioning on ecological resources attributable to license renewal is a Category 1 issue.

7.3.6 Economic Impacts

In general, the nature of the activities and the elements of the costs associated with decommissioning are well understood, and the necessary skills and equipment should be readily available when needed. Table 7.8 lists percentage estimates of total costs for decommissioning large PWR and BWR reactors by the DECON method.

A 1991 national survey had estimates that averaged $218 million per 1000 MW for a PWR reactor and $283 million per 1000 MW for a BWR. The standard deviation was $74 million for PWRs and $144 million for BWRs. For both types of reactors, the range for plus and minus one standard deviation was $131 million to $350 million (OTA-E-575). These varying estimates reflect the uncertainty of projecting costs well into the future. Additionally, the unique aspects of a plant's design and operating history can affect decommissioning costs (e.g., Three Mile Island Unit 2 and Fort St. Vrain).

The largest cost category is "undistributed"; the largest component of this cost is utility support staff. The timing of decommissioning could influence disposal costs depending on the price of disposal services. The current trend is steeply increasing cost per units of radioactive waste disposal. If this trend continues over the long run, then one effect of license renewal could be to increase decommissioning costs. However, disposal costs should stabilize by the time that most existing plants would be eligible for license renewal. If this is the case, license renewal would have a minimal effect on the undiscounted costs of decommissioning after a 20-year extended operation period, compared with after 40 years of operation.

For the cost estimates included in Table 7.8, doubling the cost per cubic foot of waste disposal would increase total decommissioning costs by about 13 percent for PWRs and 20 percent for BWRs. The assumed rate charged for disposal would have to increase by a factor of about 6 to double the total cost of decommissioning. If the rate of disposal costs turns out to be significantly more than has been assumed in decommissioning cost estimates, there would tend to be significantly more attention devoted to volume reduction; thus, total cost of disposal would tend to increase less than the proportional increase in the rate charged per cubic foot (NUREG/CR-5884, vol. 1, pp. 3.56, 3.57, and NUREG/CR-6174, vol. 1, p. 3.55).

The timing of decommissioning could also affect costs if progress in robotics technology reduces costs and worker radiation exposure. This progress would affect a relatively small part of the decommissioning process and thus is unlikely to reduce the total cost of decommissioning significantly; however, it could result in substantial dose reductions.

The preceding sections show that there is no reason to expect the physical requirements of decommissioning to be materially different when comparing the base case to a 20-year extended operation period. The undiscounted economic costs, although uncertain, should also be relatively stable and thus unaffected by license renewal. However, because of financial considerations, the timing of

[a]Preshutdown period not included in duration total.
[b]Includes direct decommissioning labor and materials for chemical decontamination of systems, cleaning of surfaces, and waste water treatment.
[c]Includes direct labor and materials costs of removal.
[d]Includes direct costs of waste disposal packages.
[e]Includes cask rental costs and transportation costs.
[f]Includes all costs of disposal at the LLW disposal facility.
[g]Includes all costs that are period-dependent—e.g., decommissioning operations contractor (DOC) mobilization/demobilization, utility and DOC overhead staff, nuclear insurance, regulatory costs, plant power usage, taxes, laundry services, environmental monitoring. Most of the undistributed costs are for staffing.
[h]At 3 percent discount rate.
[i]The decommissioning costs have been discounted at a rate of 3 percent real (assumes no inflation). At this rate, delaying decommissioning by the 20-year period of license renewal saves about 45 percent of the decommissioning cost; however, present value total costs have been figured at 2.5 years from final plant shutdown, resulting in savings from license renewal of about 40 percent.
Source: Tables 3.1 and 4.1 and pp. 3.59, 4.13, and 5.13 of NUREG/CR-5884, Vol. 1; Tables 3.1 and 4.1 and pp. 3.58, 4.12, and 5.11 of NUREG/CR-6174, Vol. 1.

decommissioning costs is important. To compare costs of activities that occur at different times, it is necessary to discount these costs to a common point in time. This is accomplished through present worth calculations, which account for the real opportunity cost or time value of money. Delaying decommissioning will allow any funds accumulated for this purpose to earn a return over the additional 20 years of license renewal and thus to reduce the present value of the decommissioning costs. The reduction in the present value is a function of the delay (license renewal period) and the time value of money, so the present value would be reduced by the same amount even if no fund were established and decommissioning were financed with borrowed money at the end of the plant operations. Regardless of how it is financed, the present value of delaying decommissioning costs will result in significant financial cost savings if a positive real discount rate is assumed.

Because total decommissioning costs are uncertain, the amount of financial savings that results from delaying decommissioning is also uncertain. Higher-than-expected decommissioning costs would result in higher cost savings resulting from delaying these costs, and vice versa. At a 3 percent real (i.e., above general inflation) discount rate, the present value savings associated with license renewal is about 40 percent of decommissioning costs (Table 7.8). Real cost increases, which might occur for waste disposal costs, could reduce the cost advantage of license renewal, but waste disposal costs are expected to stabilize before the current licenses of most plants expire. The impact of license renewal on decommissioning costs is not a consideration in the environmental review and decision whether to renew a license.

7.3.7 Socioeconomic Impacts

Socioeconomic impacts associated with decommissioning will be induced by the net change in the labor force as incoming decommissioning workers replace emigrating operations workers. The nature of these impacts will depend on the vitality of local economic activity at the time of decommissioning.

One of the difficulties of attempting to evaluate the socioeconomic impacts of decommissioning in year 40 of a plant's life compared with decommissioning in year 60 relates to the uncertainties about the size of the work force required. The largest nuclear power plant decommissioned to date has been the 150-MW(e) Shippingport Station (Section 7.2.3), which required an average work force during the peak year of approximately 230 workers (DOE/SSDP-0081); this work force was larger than the estimated work forces for very large power plants examined in studies prepared before the Shippingport experience (NUREG/CR-0130, Table 9.1-1; NUREG/CR-0672, Table 9.1-3). Because more-recent manpower estimates for large nuclear power plants are not available, the actual work force required in the future might be substantially larger than currently expected.

If the decommissioning process requires a smaller work force than the on-site operating staff and if the local economy is stable or declining, the result could be economic hardships, including declining property values and business activity, and problems for local government as it adjusts to lower levels of tax revenues. However, even this reduced work force will tend to mitigate temporarily the full adverse socioeconomic effects of terminating operations.

If there is a net reduction in the community work force but the economy is growing, the adverse impacts of this ongoing growth (e.g., housing shortages and school overcrowding) could be reduced.

If the decommissioning work force were substantially larger than the operational work force, the result could be increased demand for housing and public services but also increased tax revenues and higher real estate values. If the economy is characterized by decline, decommissioning could temporarily reverse the adverse economic effects.

In a stable economy, a net increase in the community work force could lead to some shortages in housing and public services, as well as to the higher tax revenues and real estate values mentioned previously. In a growing economy, decommissioning could act as an exacerbating factor to the ongoing shortages that already might exist.

Although the staff cannot project with certainty either the size of the required decommissioning work force or the state of the local economy at the time of decommissioning, the staff has assumed that the baseline conditions will be negligibly different in year 40, compared with year 60. Therefore, the staff expects that the socioeconomic impacts of decommissioning would be essentially similar whether that action were taken in year 60 or in year 40. The impact of license renewal on the socioeconomic impacts of decommissioning are of small significance. Because license renewal does not affect the socioeconomic impacts that will occur at the time of decommissioning, there is no need for the consideration of mitigation as part of the license renewal environmental review. The impact of decommissioning on socioeconomic resources attributable to license renewal is a Category 1 issue.

7.4 CONCLUSIONS

The physical requirements and attendant effects of decommissioning nuclear power plants after a 20-year license renewal are not expected to differ from those of decommissioning at the end of 40 years of operation. Decommissioning after a 20-year license renewal would increase the occupational dose no more than 0.1 person-rem (compared with 7,000 to 14,000 person-rem for DECON decommissioning at 40 years) and the public dose by a negligible amount (Section 7.3.1). License renewal would not increase to any appreciable extent the quantity or classification of LLW generated by decommissioning (Section 7.3.2). Air quality, water quality, and ecological impacts of decommissioning would not change as a result of license renewal (Sections 7.3.3, 7.3.4, and 7.3.5). There is considerable uncertainty about the cost of decommissioning; however, while license renewal would not be expected to change the ultimate cost of decommissioning, it would reduce the present value of the cost (Section 7.3.6). The socioeconomic effects of decommissioning will depend on the magnitude of the decommissioning effort, the size of the community, and the other economic activities at the time, but the impacts will not be increased by decommissioning at the end of a 20-year license renewal instead of at the end of 40 years of operation (Section 7.3.7). Incremental radiation doses, waste management, air quality, water quality, ecological, and socioeconomic impacts of decommissioning due to operations during a 20-year license renewal term would be of small significance. No mitigation measures beyond those provided by ALARA are warranted within the context of the license renewal process. The impacts of license renewal on radiation doses, waste management, air quality, water quality, ecological resources, and socioeconomics impacts from decommissioning are Category 1 issues.

NUCLEAR REGULATORY COMMISSION

10 CFR Part 51

RIN 3150–AD63

Environmental Review for Renewal of Nuclear Power Plant Operating Licenses

AGENCY: Nuclear Regulatory Commission.

ACTION: Final rule.

SUMMARY: The Nuclear Regulatory Commission (NRC) is amending its regulations regarding environmental protection regulations for domestic licensing and related regulatory functions to establish new requirements for the environmental review of applications to renew the operating licenses of nuclear power plants. The amendment defines those environmental impacts for which a generic analysis has been performed that will be adopted in plant-specific reviews for license renewal and those environmental impacts for which plant-specific analyses are to be performed.

The amendment improves regulatory efficiency in environmental reviews for license renewal by drawing on the considerable experience of operating nuclear power reactors to generically assess many of the environmental impacts that are likely to be associated with license renewal. The amendment also eliminates consideration of the need for generating capacity and of utility economics from the environmental reviews because these matters are under the regulatory jurisdiction of the States and are not necessary for the NRC's understanding of the environmental consequences of a license renewal decision.

The increased regulatory efficiency will result in lower costs to both the applicant in preparing a renewal application and to the NRC for reviewing plant-specific applications and better focus of review resources on significant case specific concerns. The results should be a more focused and therefore a more effective NEPA review for each license renewal. The amendment will also provide the NRC with the flexibility to address unreviewed impacts at the site-specific stage of review and allow full consideration of the environmental impacts of license renewal.

The NRC is soliciting public comment on this rule for a period of 30 days. In developing any comment specific attention should be given to the treatment of low-level waste storage and disposal impacts, the cumulative radiological effects from the uranium fuel cycle, and the effects from the disposal of high-level waste and spent fuel.

DATES: Absent a determination by the NRC that the rule should be modified, based on comments received, the final rule shall be effective on August 5, 1996. The comment period expires on July 5, 1996.

ADDRESSES: Send comments to: The Secretary of the Commission, U.S. Nuclear Regulatory Commission, Washington, DC 20555–0001, Attention: Docketing and Services Branch, or hand deliver comments to the Office of the Secretary, One White Flint North, 11555 Rockville Pike, Rockville, Maryland between 7:30 a.m. and 4:15 p.m. on Federal workdays. Copies of comments received and all documents cited in the supplementary information may be examined at the NRC Public Document Room, 2120 L Street NW. (Lower Level), Washington, DC between the hours of 7:45 a.m. and 4:15 p.m. on Federal workdays.

FOR FURTHER INFORMATION CONTACT: Donald P. Cleary, Office of Nuclear Regulatory Research, U.S. Nuclear Regulatory Commission, Washington, DC 20555–0001, telephone: (301) 415–6263; e-mail DPC@nrc.gov.

SUPPLEMENTARY INFORMATION:

I. Introduction

The Commission has amended its environmental protection regulations in 10 CFR part 51 to improve the efficiency of the process of environmental review for applicants seeking to renew an operating license for up to an additional 20 years. The amendments are based on the analyses conducted for and reported in NUREG–1437, ''Generic Environmental Impact Statement for License Renewal of Nuclear Plants'' (May 1996). The Commission's initial decision to undertake a generic assessment of the environmental impacts associated with the renewal of a nuclear power plant operating license was motivated by its beliefs that:

(1) License renewal will involve nuclear power plants for which the

environmental impacts of operation are well understood as a result of data evaluated from operating experience to date;

(2) Activities associated with license renewal are expected to be within this range of operating experience, thus environmental impacts can be reasonably predicted; and

(3) Changes in the environment around nuclear power plants are gradual and predictable with respect to characteristics important to environmental impact analyses.

Although this amendment is consistent with the generic approach and scope of the proposed amendment published on September 17, 1991 (56 FR 47016), several significant modifications have been made in response to the public comments received. The proposed amendment would have codified the findings reached in the draft generic environmental impact statement (GEIS) as well as certain procedural requirements. The draft GEIS established the bounds and significance of potential environmental impacts at 118 light-water nuclear power reactors that, as of 1991, were licensed to operate or were expected to be licensed in the future.

All potential environmental impacts and other matters treated by the NRC in an environmental review of nuclear power plants were identified and combined into 104 discrete issues. For each issue, the NRC staff established generic findings encompassing as many nuclear power plants as possible. These findings would have been codified by the proposed amendment. Of the 104 issues reviewed for the proposed rule, the staff determined that 80 issues could be adequately addressed generically and would not have been reviewed in plant-specific license renewal reviews. For 22 of the issues, it was found that the issue was adequately addressed for some but not all plants. Therefore, a plant-specific review would be required to determine whether the plant is covered by the generic review or whether the issue must be assessed for that plant. The proposed amendment provided guidance on the application of these findings at the site-specific license renewal stage. For the two remaining issues, it was found that the issue was not generically addressed for any plant, and thus a plant-specific review would have been required for all plants.

Other major features of the proposed amendment included a conditional finding of a favorable cost-benefit balance for license renewal and a provision for the use of an environmental assessment that would address only those issues requiring plant-specific review. A finding of no significant impact would have resulted in a favorable cost-benefit balance for that plant. If a finding of no significant impact could not be made for the plant, there would have to have been a determination as to whether the impacts found in the environmental assessment were sufficient to overturn the conditional cost-benefit balance found in the rule.

Although the final amendments to 10 CFR part 51 maintain the same generic approach used in the proposed rule, there are several modifications.The final amendments to 10 CFR part 51 now contain 92 issues. The reduction of the number of issues from 104 in the proposed rule to 92 in the final rule is due to (1) the elimination from the review of the consideration of the need for electric power and associated generating capacity and of the direct economic benefits and costs associated with electric power, (2) removing alternatives as an issue from Table B–1 and addressing review requirements only in the text of the rule, (3) combining the five severe accident issues used in the proposed rule into one issue, (4) eliminating several regional economic issues under socioeconomics that are not directly related to environmental impacts, (5) making minor changes to the grouping of issues under aquatic ecology and groundwater, (6) identifying collective offsite radiological impacts associated with the fuel cycle and all impacts of high level waste and spent fuel disposal as separate issues, and (7) adding environmental justice as an issue for consideration.

Of the 92 issues in the final rule, 68 issues were found to be adequately addressed in the GEIS, and therefore, additional assessment will not be required in a plant-specific review. Twenty-four issues were found to require additional assessment for at least some plants at the time of the license renewal review. In the final rule, the 2 issues in the proposed rule that would have required review for all plants are now included in the set of 24 issues of the final rule.

Public comments on the adequacy of the analysis for each issue were considered by the NRC staff. Any changes to the analyses and findings that were determined to be warranted were made in the final GEIS and incorporated in the rule. Several changes were made to the procedural features of the proposed rule in response to comments by the Council on Environmental Quality, the Environmental Protection Agency, and a number of State agencies. First, the NRC will prepare a supplemental site-specific environmental impact statement (SEIS), rather than an environmental assessment (as initially proposed), for each license renewal application. The SEIS will be issued for public comment as part of the individual plant review process. The NRC will delay any conclusions regarding the acceptability of the overall impacts of the license renewal until completion of the site-specific review. In addition, the SEIS will be prepared in accordance with existing public scoping requirements. The NRC will also review and consider any new and significant information presented during the review of individual license renewal applications. In addition, any person may challenge the validity of the conclusions codified in the rule by filing a petition for rulemaking pursuant to 10 CFR 2.802. Finally, the NRC will review the rule and the GEIS on a schedule that allows revisions, if required, every 10 years. This review will be initiated approximately 7 years after the completion of the previous revision cycle.

In addition to the changes involving public participation, this final rule also contains several changes regarding the scope of analysis and conclusions in the rule and GEIS. The conditional cost-benefit balance has been removed from the GEIS and the rule. In place of the cost-benefit balancing, the NRC will use a new standard that will require a determination of whether or not the adverse environmental impacts of license renewal are so great, compared with the set of alternatives, that preserving the option of license renewal for future decisionmakers would be unreasonable. The final amendment also eliminates NRC's consideration of the need for generating capacity and the preparation of power demand forecasts for license renewal applications. The NRC acknowledges the primacy of State regulators and utility officials in defining energy requirements and determining the energy mix within their jurisdictions. Therefore, the issue of need for power and generating capacity will no longer be considered in NRC's license renewal decisions. The final GEIS has been revised to include an explicit statement of purpose and need for license renewal consistent with this acknowledgment. Lastly, the final rule has eliminated the consideration of utility economics from license renewal reviews under the National Environmental Policy Act (NEPA) except when such benefits and costs are either essential for a determination regarding the inclusion of an alternative in the range of alternatives considered or relevant to mitigation. These and other features of the final rule are explained in detail below.

The NRC is soliciting public comment on this rule for a period of 30 days. In developing any comment specific attention should be given to the treatment of low-level waste storage and disposal impacts, the cumulative radiological effects from the uranium fuel cycle, and the effects from the disposal of high-level waste and spent fuel. Absent a determination by the NRC that the rule should be modified, based on comments received, the final rule shall be effective on August 5, 1996.

II. Rulemaking History

In 1986, the NRC initiated a program to develop license renewal regulations and associated regulatory guidance in anticipation of applications for the renewal of nuclear power plant operating licenses. A solicitation for comments on the development of a policy statement was published in the Federal Register on November 6, 1986 (51 FR 40334). However, the Commission decided to forgo the development of a policy statement and to proceed directly to rulemaking. An advance notice of proposed rulemaking was published on August 29, 1988 (53 FR 32919). Subsequently, the NRC determined that, in addition to the development of license renewal regulations focused on the protection of health and safety, an amendment to its environmental protection regulations in 10 CFR part 51 was warranted.

On October 13, 1989 (54 FR 41980), the NRC published a notice of its intent to hold a public workshop on license renewal on November 13 and 14, 1989. One of the workshop sessions was devoted to the environmental issues associated with license renewal and the possible merit of amending 10 CFR part 51. The workshop is summarized in NUREG/CP–0108, ''Proceedings of the Public Workshop on Nuclear Power Plant License Renewal'' (April 1990). Responses to the public comments submitted after the workshop are summarized in NUREG–1411, ''Response to Public Comments Resulting from the Public Workshop on Nuclear Power Plant License Renewal'' (July 1990).

On July 23, 1990, the NRC published an advance notice of proposed rulemaking (55 FR 29964) and a notice of intent to prepare a generic environmental impact statement (55 FR 29967). The proposed rule was published on September 17, 1991 (56 FR 47016). The same Federal Register notice described the supporting documents that were available and announced a public workshop to be held on November 4–5, 1991. The supporting documents for the proposed rule included:

(1) NUREG–1437, ''Draft Generic Environmental Impact Statement for License Renewal of Nuclear Plants'' (August 1991);

(2) NUREG–1440, ''Regulatory Analysis of Proposed Amendments to Regulations Concerning the Environmental Review for Renewal of Nuclear Power Plant Operating Licenses: Draft Report for Comment'' (August 1991);

(3) Draft Regulatory Guide DG–4002, Proposed Supplement 1 to Regulatory Guide 4.2, ''Guidance for the Preparation of Supplemental Environmental Reports in Support of an Application To Renew a Nuclear Power Station Operating License'' (August 1991); and

(4) NUREG–1429, ''Environmental Standard Review Plan for the Review of License Renewal Applications for Nuclear Power Plants: Draft Report for Comment'' (August 1991).

After the comment period, the NRC exchanged letters with the Council on Environmental Quality (CEQ) and the Environmental Protection Agency (EPA) to address their concerns about procedural aspects of the proposed rule. The Commission also decided that the staff should discuss with the States the concerns raised in comments by a number of States that certain features of the proposed rule conflicted with State regulatory authority over the need for power and utility economics. To facilitate these discussions, the NRC staff developed an options paper entitled ''Addressing the Concerns of States and Others Regarding the Role of Need for Generating Capacity, Alternative Energy Sources, Utility Costs, and Cost-Benefit Analysis in NRC Environmental Reviews for Relicensing Nuclear Power Plants: An NRC Staff Discussion Paper.'' A Federal Register notice published on January 18, 1994 (59 FR 2542) announced the scheduling of three regional workshops during February 1994 and the availability of the options paper. A fourth public meeting on the State concerns was held in May 1994 in order for the NRC staff to better understand written proposals that had been submitted by two industry organizations after the regional workshops. After considering the comments from the workshops and the written comments, the NRC staff issued a proposed supplement to the proposed rule published on July 25, 1994 (59 FR 37724), that it believed would resolve the States' concerns regarding the Commission's consideration of need for power and utility economics. Comments were requested on this proposal. The discussion below contains an analysis of these comments and other comments submitted in response to the proposed rule.

III. Analysis of Public Comments

The analysis of public comments and the NRC's responses to these comments are documented in NUREG–1529, ''Public Comments on the Proposed 10 CFR part 51 Rule for Renewal of Nuclear Power Plant Operating Licenses and Supporting Documents: Review of Concerns and NRC Staff Response'' (May 1996). The extent of comments received during the various stages of the rulemaking process and the principal concerns raised by the commenters, along with the corresponding NRC responses to these concerns, are discussed below.

A. Commenters

In response to the Federal Register notice on the proposed rule published on September 17, 1991 (56 FR 47016), 68 organizations and 49 private citizens submitted written comments. The 68 organizations included 5 Federal agencies; 26 State, regional, and local agencies; 19 nuclear industry organizations and engineering firms; 3 law firms; and 15 public interest groups. Before the close of the initial comment period, the NRC conducted a 2-day workshop on November 4–5, 1991, in Arlington, Virginia, to discuss the proposed rule. Representatives from Federal agencies, State agencies, utilities, engineering firms, law firms, and public interest groups attended the workshop. Workshop panelists included the NRC staff as well as representatives from the Department of Energy (DOE), Department of Interior (DOI), Environmental Protection Agency (EPA), Council on Environmental Quality (CEQ), several State agencies, the nuclear industry, and public interest groups.

In February 1994, the NRC conducted three public meetings to solicit views on the NRC staff's options for addressing the need for generating capacity, alternative energy sources, economic costs, and cost-benefit analysis in the proposed rule. The intent to hold public meetings and the availability of the options paper was noticed in the Federal Register on January 12, 1994 (59 FR 2542). Written comments were also solicited on the options paper. The public meetings were held in Rockville, Maryland; Rosemont, Illinois; and Chicopee, Massachusetts.

Representatives from several States, the National Association of Regulatory Utility Commissioners (NARUC), the nuclear industry, and public interest groups actively participated. Nineteen separate written comments were also submitted, primarily by the States and the nuclear industry. In their submittals, the Nuclear Energy Institute (NEI), formerly known as the Nuclear Management and Resources Council (NUMARC), and Yankee Atomic Electric Company (YAEC) each proposed an approach to handling the issues of need for generating capacity and alternative energy sources in the rule. For the NRC staff to better understand these proposals, an additional public meeting was held with NEI and YAEC on May 16, 1994, in Rockville, Maryland.

After considering the public comments on the NRC staff's options paper, the NRC issued a proposed supplement to the proposed rule; it was published in the Federal Register on July 25, 1994 (59 FR 37724). The proposed supplement set forth the NRC staff's approach to the treatment of need for generating capacity and alternative energy sources, as well as the staff's revision to the purpose of and need for the proposed action (i.e., license renewal), which was intended to satisfy the States' concerns and to meet NEPA requirements. Twenty separate written comments were received in response to this solicitation from Federal and State agencies, the nuclear industry, a public interest group, and two private citizens.

B. Procedural Concerns

The commenters on the proposed rule raised significant concerns regarding the following procedural aspects of the rule:

(1) State and public participation in the license renewal process and the periodic assessment of the GEIS findings;

(2) The use of economic costs and cost-benefit balancing; and

(3) Consideration of the need for generating capacity and alternative energy sources in the environmental review of license renewal applications.

Each of these concerns and the NRC response is discussed below.

1. Public Participation and the Periodic Assessment of the Rule and the GEIS

Concern. Many commenters criticized the draft GEIS finding that 80 of 104 environmental issues could be generically applied to all plants and, therefore, would not be subject to plant-specific review at the time of license renewal. As a consequence, these commenters believe they are being denied the opportunity to participate in the license renewal process. Moreover, they pointed out that the site-specific nature of many important environmental issues does not justify a generic finding, particularly when the finding would have been made 20 years in advance of the decision to renew an operating license. The commenters believe that only a site-specific EIS to support a license renewal decision would satisfy NEPA requirements.

Federal and State agencies questioned how new scientific information could be folded into the GEIS findings because the GEIS would have been performed so far in advance of the actual renewal of an operating license. There were differing views on exactly how the NRC should address this question. A group of commenters, including CEQ and EPA, noted that the rigidity of the proposed rule hampers the NRC's ability to respond to new information or to different environmental issues not listed in the proposed rule. They believe that incorporation of new information can only be achieved through the process of amending the rules. One commenter recommended that, if the NRC decides to pursue the approach of making generic findings based on the GEIS, the frequency of review and update should be specifically stated in the rule. Recommendations on the frequency of the review ranged from 2 years to 5 years.

Response. In SECY–93–032, February 9, 1993, the NRC staff reported to the Commission their discussions with CEQ and EPA regarding the concerns these agencies raised, which were also raised by other commenters, about limiting public comment and the consideration of significant new information in individual license renewal environmental reviews. The focus of the commenters concerns is the limited nature of the site-specific reviews contemplated under the proposed rule. In response, the NRC has reviewed the generic conclusions in the draft rule, expanded the opportunity for site-specific review, and confirmed that what remains as generic is so. Also, the framework for consideration of significant new information has been revised and expanded.

The major changes adopted as a result of these discussions are as follows:

1. The NRC will prepare a supplemental site-specific EIS, rather than an environmental assessment (as initially proposed), for each license renewal application. This SEIS will be a supplement to the GEIS. Additionally, the NRC will review comments on the draft SEIS and determine whether such comments introduce new and significant information not considered in the GEIS analysis. All comments on the applicability of the analyses of impacts codified in the rule and the analysis contained in the draft supplemental EIS will be addressed by NRC in the final supplemental EIS in accordance with 40 CFR 1503.4, regardless of whether the comment is directed to impacts in Category 1 or 2. Such comments will be addressed in the following manner:

a. NRC's response to a comment regarding the applicability of the analysis of an impact codified in the rule to the plant in question may be a statement and explanation of its view that the analysis is adequate including, if applicable, consideration of the significance of new information. A commenter dissatisfied with such a response may file a petition for rulemaking under 10 CFR 2.802. If the commenter is successful in persuading the Commission that the new information does indicate that the analysis of an impact codified in the rule is incorrect in significant respects (either in general or with respect to the particular plant), a rulemaking proceeding will be initiated.

b. If a commenter provides new information which is relevant to the plant and is also relevant to other plants (i.e., generic information) and that information demonstrates that the analysis of an impact codified in the final rule is incorrect, the NRC staff will seek Commission approval to either suspend the application of the rule on a generic basis with respect to the analysis or delay granting the renewal application (and possibly other renewal applications) until the analysis in the GEIS is updated and the rule amended. If the rule is suspended for the analysis, each supplemental EIS would reflect the corrected analysis until such time as the rule is amended.

c. If a commenter provides new, site-specific information which demonstrates that the analysis of an impact codified in the rule is incorrect with respect to the particular plant, the NRC staff will seek Commission approval to waive the application of the rule with respect to that analysis in that specific renewal proceeding. The supplemental EIS would reflect the corrected analysis as appropriate.

2. The final rule and the GEIS will not include conditional cost-benefit conclusions or conclusions about alternatives. Conclusions relative to the overall environmental impacts including cumulative impacts will be left entirely to each site-specific SEIS.

3. After consideration of the changes from the proposed rule to the final rule and further review of the environmental issues, the NRC has concluded that it is

adequate to formally review the rule and the GEIS on a schedule that allows revisions, if required, every 10 years. The NRC believes that 10 years is a suitable period considering the extent of the review and the limited environmental impacts observed thus far, and given that the changes in the environment around nuclear power plants are gradual and predictable with respect to characteristics important to environmental impact analyses. This review will be initiated approximately 7 years after completion of the last cycle. The NRC will conduct this review to determine what, if anything, in the rule requires revision.

Concern. As part of their comments on the July 1994 Federal Register notice, NEI, several utilities, and the DOE asked that the NRC reconsider its understanding with CEQ and EPA regarding the preparation of a site-specific supplemental EIS for each license renewal action. These commenters supported an approach that would allow the preparation of an environmental assessment for reviewing the environmental impacts of license renewal.

Response. The NRC does not agree with this position. The NRC believes that it is reasonable to expect that an assessment of the full set of environmental impacts associated with an additional 20 years of operation of any plant would not result in a ''finding of no significant impact.'' Therefore, the review for any plant would involve an environmental impact statement.

2. Economic Costs and Cost-Benefit Balancing

Concern. State, Federal, and utility representatives expressed concern about the use of economic costs and cost-benefit balancing in the proposed rule and the draft GEIS. Commenters criticized the NRC's heavy emphasis on economic analysis and the use of economic decision criteria. They argued that the regulatory authority over utility economics falls within the States' jurisdiction and to some extent within the jurisdiction of the Federal Energy Regulatory Commission. Commenters also believe that the cost-benefit balancing used in the proposed rule and the draft GEIS went beyond NEPA requirements and CEQ regulations (40 CFR Parts 1500 to 1508). They noted that CEQ regulations interpret NEPA to require only an assessment of the cumulative effects of a proposed Federal action on the natural and man-made environment.

Response. In response to these concerns, the NRC has eliminated the use of cost-benefit analysis and consideration of utility economics in its NEPA review of a license renewal application except when such benefits and costs are either essential for a determination regarding the inclusion of an alternative in the range of alternatives considered or relevant to mitigation. As discussed in more detail in the following section, the NRC recognizes that the determination of the economic viability of continuing the operation of a nuclear power plant is an issue that should be left to appropriate State regulatory and utility officials.

3. Need for Generating Capacity and Alternative Energy Sources

Concern. In their comments on the proposed rule and the draft GEIS, several States expressed concern that the NRC's analysis of need for generating capacity would preempt or prejudice State energy planning decisions. They argued that the determination of need for generating capacity has always been the States' responsibility. Recommendations on how to address this issue ranged from withdrawing the proposed rule to changing the categorization of the issue so that a site-specific review can be performed, thus allowing for meaningful State and public participation. Almost all the concerned States called on the NRC to modify the rule to state explicitly that NRC's analysis does not preempt a State's jurisdiction over the determination of need for generating capacity.

Regarding the issue of alternative energy sources, several commenters contended that the site-specific nature of the alternatives to license renewal did not justify the generic finding in the GEIS. One significant concern about this finding is the States' perception that a generic finding, in effect, preempts the States' responsibility to decide on the appropriate mix of energy alternatives in their respective jurisdictions.

Three regional public meetings were held during the February 1994 to discuss the concerns of the States. At these meetings, and later in written comments, the State of New York proposed an approach to resolve the problem. The approach was endorsed by several other States. This approach had three major conditions:

(1) A statement in the rule that the NRC's findings on need and alternatives are only intended to satisfy the NEPA requirements and do not preclude the States from making their own determination with respect to these issues;

(2) The designation of the need for generating capacity and alternative energy sources as Category 3 (i.e., requiring site-specific evaluation); and

(3) A requirement that all site-specific EISs and relicensing decisions reference State determinations of need for generating capacity and alternative energy sources, and that they defer to those State determinations to the maximum extent possible.

Response. After consideration, the NRC staff did not accept all elements of the States' approach because the approach would have continued to require the NRC to consider the need for generating capacity and utility economics as part of its environmental analysis. In addition, the approach would have required the NRC to develop guidelines for determining the acceptability of State economic analyses, which some States may have viewed as an intrusion on their planning process.

The NRC staff developed and recommended another approach, which was published on July 25, 1994 (59 FR 37724), after consideration of information gathered at the regional meetings and from the written comments. This approach, which borrows some elements from NEI and YAEC proposals, has five major features:

(1) Neither the rule nor the GEIS would contain a consideration of the need for generating capacity or other issues involving the economic costs and benefits of license renewal and of the associated alternatives;

(2) The purpose and need for the proposed action (i.e., license renewal) would be defined as preserving the continued operation of a nuclear power plant as a safe option that State regulators and utility officials may consider in their future planning actions;

(3) The only alternative to the proposed action would be the ''no-action'' alternative, and the environmental consequences of this alternative are the impacts of a range of energy sources that might be used if a nuclear power plant operating license were not renewed;

(4) The environmental review for license renewal would include a comparison of the environmental impacts of license renewal with impacts of the range of energy sources that may be chosen in the case of ''no action''; and

(5) The NRC's NEPA decision standard for license renewal would require the NRC to determine whether the environmental impacts of license renewal are so great that preserving the option of license renewal for future decisionmakers would be unreasonable.

The statement that the use of economic costs will be eliminated in this approach refers to the ultimate NEPA decision regarding the comparison of alternatives and the proposed action. This approach does not preclude a consideration of economic costs if these costs are essential to a determination regarding the inclusion of an alternative in the range of alternatives considered (i.e., an alternative's exorbitant cost could render it nonviable and unworthy of further consideration) or relevant to mitigation of environmental impacts. Also, the two local tax issues and the two economic structure issues under socioeconomics in the table would be removed from consideration when applying the decision standard.

Concern. Comments received from several States on the NRC staff's July 1994 recommended approach ranged from rejection to endorsement. Some States supported the three conditions proposed by the State of New York. Several States were still concerned about whether a meaningful analysis of need for generating capacity and alternative energy sources could be undertaken 20 years ahead of time. One State asked that the proposed rule be withdrawn. Another State wanted the proposed rule to be reissued for public comment. CEQ supported the approach proposed by the State of New York. CEQ believed that the NRC's recommended approach was in conflict with the NEPA process because the proposed statement of purpose and need for the proposed action was too narrow and did not provide for an appropriate range of alternatives to the underlying need for the proposed action. CEQ wanted the NRC to address other energy sources as separate alternatives, rather than as consequences of the no-action alternative. Moreover, CEQ stated that the proposed decision standard places a "weighty and improper burden of proof" on consideration of the alternative. The EPA endorsed CEQ's comments. In general, the nuclear industry was supportive of the recommended approach. However, NEI and the utilities strongly expressed the opinion that, with the redefined statement of purpose and need, alternative energy sources would no longer be alternatives to the proposed action and, therefore, need not be considered.

Response. After consideration of the comments received on the Commission's July 1994 proposal, the Commission has modified and clarified its approach in order to address the concerns of CEQ relative to consideration of appropriate alternatives and the narrow definition of purpose and need. These modifications and clarifications addressed the States' concerns relative to treatment of need for generating capacity and alternatives. Specifically, the Commission has clarified the purpose and need for license renewal in the GEIS as follows:

> The purpose and need for the proposed action (renewal of an operating license) is to provide an option that allows for power generation capability beyond the term of a current nuclear power plant operating license to meet future system generating needs, as such needs may be determined by State, utility, and, where authorized, Federal (other than NRC) decisionmakers.

Using this definition of the purpose of and need for the proposed action, which stresses options for the generation of power, the environmental review will include a characterization of alternative energy sources as being the alternatives to license renewal and not merely the consequences of the no-action alternative and, thus, it addresses CEQ's concern that the scope of the alternatives analysis is unacceptably restricted.

With respect to the States' concerns regarding need for generating capacity analysis, the NRC will neither perform analyses of the need for power nor draw any conclusions about the need for generating capacity in a license renewal review. This definition of purpose and need reflects the Commission's recognition that, absent findings in the safety review required by the Atomic Energy Act of 1954, as amended, or in the NEPA environmental analysis that would lead the NRC to reject a license renewal application, the NRC has no role in the energy planning decisions of State regulators and utility officials. From the perspective of the licensee and the State regulatory authority, the purpose of renewing an operating license is to maintain the availability of the nuclear plant to meet system energy requirements beyond the term of the plant's current license. The underlying need that will be met by the continued availability of the nuclear plant is defined by various operational and investment objectives of the licensee. Each of these objectives may be dictated by State regulatory requirements or strongly influenced by State energy policy and programs. In cases of interstate generation or other special circumstances, Federal agencies such as the Federal Energy Regulatory Commission (FERC) or the Tennessee Valley Authority (TVA) may be involved in making these decisions. The objectives of the various entities involved may include lower energy cost, increased efficiency of energy production and use, reliability in the generation and distribution of electric power, improved fuel diversity within the State, and environmental objectives such as improved air quality and minimized land use.

The consideration of alternatives has been shifted to the site-specific review. The rule contains no information or conclusions regarding the environmental impacts of alternative energy sources, it only indicates that the environmental impact of alternatives will be considered during the individual plant review. However, the GEIS contains a discussion of the environmental impacts of alternative energy sources based on currently available information. The information in the GEIS is available for use by the NRC and the licensee in performing the site-specific analysis of alternatives and will be updated as appropriate. For individual plant reviews, information codified in the rule, information developed in the GEIS, and any significant new information introduced during the plant-specific review, including any information received from the State, will be considered in reaching conclusions in the supplemental EIS. The NRC's site-specific comparison of the impacts of license renewal with impacts of alternative energy sources will involve consideration of information provided by State agencies and other members of the public. This approach should satisfy the States' concerns relative to a meaningful analysis of alternative energy sources.

The Commission disagrees with CEQ's assertion that the new decision standard is inappropriate. Under this decision standard, the NRC must determine if the adverse environmental impacts of license renewal are so great that preserving the option of license renewal for energy planning decisionmakers would be unreasonable. The Commission expects that license renewal would be denied only if the expected environmental effects of license renewal significantly exceed all or almost all alternatives. The Commission believes that this is a reasonable approach to addressing the issue of environmental impacts of license renewal, given NRC's limited role in the area of energy systems planning. The operation of a nuclear power plant beyond its initial license term involves separate regulatory actions, one taken by the utility and the NRC, and the other taken by the utility and the State regulatory authorities. The decision standard would be used by NRC to determine whether, from an environmental perspective, it is reasonable to renew the operating license and allow State and utility decisionmakers the option of considering a currently operating nuclear power plant as an alternative for meeting future energy needs. The test of reasonableness focuses on an analysis of whether the environmental impacts anticipated for continued operation during the term of the renewed license reasonably compare with the impacts that are expected from the set of alternatives considered for meeting generating requirements. The NRC would reject a license renewal application if the analysis demonstrated that the adverse environmental impacts of the individual license renewal were so great that preserving the option of license renewal for energy planning decisionmakers would be unreasonable.

After the NRC makes its decision based on the safety and environmental considerations, the final decision on whether or not to continue operating the nuclear plant will be made by the utility, State, and Federal (non-NRC) decisionmakers. This final decision will be based on economics, energy reliability goals, and other objectives over which the other entities may have jurisdiction. The NRC has no authority or regulatory control over the ultimate selection of future energy alternatives. Likewise, the NRC has no regulatory power to ensure that environmentally superior energy alternatives are used in the future. Given the absence of the NRC's authority in the general area of energy planning, the NRC's rejection of a license renewal application based on the existence of a single superior alternative does not guarantee that such an alternative will be used. In fact, it is conceivable that the rejection of a license renewal application by the NRC in favor of an individual alternative may lead to the implementation of another alternative that has even greater environmental impacts than the proposed action, license renewal.

Given the uncertainties involved and the lack of control that the NRC has in the choice of energy alternatives in the future, the Commission believes that it is reasonable to exercise its NEPA authority to reject license renewal applications only when it has determined that the impacts of license renewal sufficiently exceed the impacts of all or almost all of the alternatives that preserving the option of license renewal for future decision makers would be unreasonable. Because the objectives of the utility and State decisionmakers will ultimately be the determining factors in whether a nuclear power plant will continue to operate, NRC's proposed decision standard is appropriate. The decision standard will not affect the scope or rigor of NRC's analyses, including the consideration of the environmental impacts relevant to the license renewal decision and associated alternatives. The NRC staff believes that, under the circumstances, the decision standard does not place ''a weighty and improper burden of proof'' on other alternatives as CEQ claims.

With respect to the industry's desire to eliminate consideration of alternative energy sources, the Commission does not agree. The Commission does not support the views of NEI and others that alternative energy sources need not be considered in the environmental review for license renewal. The Commission is not prepared to state that no nuclear power plant will fall well outside the range of other reasonably available alternatives far in advance of an actual relicensing decision. Following NEI's suggestion would not lead to a meaningful set of alternatives with which to compare a proposed action. The Commission has always held the view that alternative sources of energy should be compared with license renewal and continued operation of a nuclear power plant.

Lastly, the Commission does not believe it is necessary to reissue this rule for public comment as a State commenter requested. The Commission has taken many measures to involve the public concerning the resolution of public comments on the proposed rule. The Commission has conducted a number of public meetings and published for public comment its recommended procedural revisions to the proposed rule. The Commission believes that modifications made to the proposed rule reflect the logical outgrowth of the proposed rule based on the public comments received by the Commission.

C. Technical Concerns

1. Category and Impact Magnitude Definitions

Concerns. Many commenters expressed concern that the category definitions and the impact-significance definitions were ambiguous and appeared somewhat interconnected. The EPA expressed concern that mitigation of adverse impacts was not addressed adequately.

Commenters expressed a number of concerns about the use of the applicability categories and the magnitude-level categories. With respect to the applicability categories, concerns ranged from a general concern that Category 1 precludes or hinders public involvement in an issue at the time of the plant-specific review to specific concerns about the technical adequacy of the analysis supporting a Category 1 finding for an issue. Several commenters believed that the definitions create confusion, especially as to whether the finding of small impact and Category 1 are interdependent. The GEIS appears to use Category 1 and ''small'' interchangeably. Concern was also expressed that the requirement to consider mitigative actions was inadequately addressed in the draft GEIS and proposed rule.

Response. To reduce potential confusion over the definitions, the use of the categories, and the treatment of mitigation within the context of the categorization scheme, the NRC has revised the definitions to eliminate any ambiguity as to how they are used. Further, the GEIS has been modified to clearly state the reasons behind the category and magnitude findings.

In order to facilitate understanding of the modifications to the GEIS, the previous approach is discussed as follows. In the proposed rule and the draft GEIS, findings about the environmental impact associated with each issue were divided into three categories of applicability to individual plant reviews. These categories were:

- Category 1: A generic conclusion on the impact has been reached for all affected nuclear power plants.
- Category 2: A generic conclusion on the impact has been reached for affected nuclear power plants that fall within defined bounds.
- Category 3: A generic conclusion on the impact was not reached for any affected nuclear power plants.

The significance of the magnitude of the impact for each issue was expressed as one of the three following levels.

- *Small* impacts are so minor that they warrant neither detailed investigation nor consideration of mitigative actions when such impacts are negative.
- *Moderate* impacts are likely to be clearly evident and usually warrant consideration of mitigation alternatives when such impacts are negative.
- *Large* impacts involve either a severe penalty or a major benefit, and mitigation alternatives are always considered when such impacts are negative.

With respect to the categories of applicability, under the proposed rule applicants would have:

(1) Not provided additional analyses of Category 1 issues;

(2) Not provided additional analyses if their plant falls within the bounds

defined in the rule for a Category 2 issue;

(3) Provided additional plant-specific analyses if their plant does not fall within the bounds defined in the rule for a Category 2 issue; and

(4) Provided plant-specific analyses of Category 3 issues.

In order to address the comments on these magnitude and category definitions, the GEIS has been modified to clearly state the reasons behind the category and magnitude findings.

The revised definitions are listed below.

• Category 1: For the issue, the analysis reported in the Generic Environmental Impact Statement has shown:

(1) The environmental impacts associated with the issue have been determined to apply either to all plants or, for some issues, to plants having a specific type of cooling system or other specified plant or site characteristic;

(2) A single significance level (i.e., small, moderate, or large) has been assigned to the impacts (except for collective off site radiological impacts from the fuel cycle and from high level waste and spent fuel disposal); and

(3) Mitigation of adverse impacts associated with the issue has been considered in the analysis and it has been determined that additional plant-specific mitigation measures are likely not to be sufficiently beneficial to warrant implementation.

The generic analysis of the issue may be adopted in each plant-specific review. Issues for which the impact was found to be favorable were also defined to be Category 1 issues.

• Category 2: For the issue, the analysis reported in the GEIS has shown that one or more of the criteria of Category 1 cannot be met and, therefore, additional plant-specific review is required.

If, for an environmental issue, the three Category 1 criteria apply to all plants, that issue is Category 1 and the generic analysis should be used in a license renewal review for all plant applications. If the three Category 1 criteria apply to a subset of plants that are readily defined by a common plant characteristic, notably the type of cooling system, the population of plants is partitioned into the set of plants with the characteristic and the set without the characteristic. For the set of plants with the characteristic, the issue is Category 1 and the generic analysis should be used in the license renewal review for those plants. For the set of plants without the characteristic, the issue is Category 2 and a site-specific analysis for that issue will be performed as part of the license renewal review. The review of a Category 2 issue may focus on the particular aspect of the issue that causes the Category 1 criteria not to be met. For example, severe accident mitigation under the issue ''severe accidents'' is the focus for a plant-specific review because the other aspects of the issue, specifically the offsite consequences, have been adequately addressed in the GEIS. With the revised definitions, the two issues previously designated as Category 3 are now designated Category 2. For an issue to be a Category 1, current mitigation practices and the nature of the impact were considered and a determination was made that it is unlikely that additional measures will be sufficiently beneficial. In the GEIS, in discussing the impacts for each issue, consideration was given to what is known about current mitigation practices.

The definitions of the significance level of an environmental impact have been revised to make the consideration of the potential for mitigating an impact separate from the analysis leading to a conclusion about the significance level of the impact. Further, the significance level of an impact is now more clearly tied to sustaining specific attributes of the affected resource that are important to its viability, health or usefulness. General definitions of small, moderate and large significance levels are given below. These definitions are adapted to accommodate the resource attributes of importance for each of the environmental issues in the GEIS. The definition of ''small'' clarifies the meaning of the term as it applies to radiological impacts. The definition of ''small'' in the proposed rule did not logically apply to such impacts.

The general definitions of significance level are:

• Small: For the issue, environmental effects are not detectable or are so minor that they will neither destabilize nor noticeably alter any important attribute of the resource. For the purposes of assessing radiological impacts, the Commission has concluded that those impacts that do not exceed permissible levels in the Commission's regulations are considered small.

• Moderate: For the issue, environmental effects are sufficient to alter noticeably but not to destabilize important attributes of the resource.

• Large: For the issue, environmental effects are clearly noticeable and are sufficient to destabilize important attributes of the resource.

The discussion of each environmental issue in the GEIS includes an explanation of how the significance category was determined. For issues in which probability of occurrence is a key consideration (i.e., accident consequences), the probability of occurrence has been factored into the determination of significance. The determination of the significance category was made independently of the consideration of the potential benefit of additional mitigation.

The major concerns (organized by topical areas) about the environmental issues examined in the draft GEIS and the NRC staff's response to those concerns are summarized next.

2. Surface Water Quality

Concern. Several commenters expressed concerns related to the National Pollutant Discharge Elimination System (NPDES) permitting process for surface water discharge. They believe that the NRC may have overlooked its legal obligation to comply with Section 401 of the Clean Water Act (CWA). Their recommendations included withholding approval for license renewal until a facility has complied with Section 401 and treating license renewal as an opportunity for a new NEPA review. On the other hand, other commenters recommended decoupling the NRC relicensing process from the NPDES permitting process.

Response. In issuing individual license renewals, the Commission will comply, as has been its practice, with the provisions of Section 401 of the Federal Water Pollution Control Act (see 10 CFR 51.45(d) and 51.71(c)). In addition, pursuant to Section 511(c) of the Federal Water Pollution Control Act of 1972, the Commission cannot question or reexamine the effluent limitations or other requirements in permits issued by the relevant permitting authorities. Nevertheless, compliance with the environmental quality standards and requirements of these permits does not negate the requirement for the Commission to consider all environmental effects of the proposed action. Accordingly, the Commission has not only taken existing permits into account in its analysis of the water quality impacts of license renewal but has also considered information on actual operating impacts collected from individual plants, State and Federal regulatory agencies, and published literature. As a result of this analysis, the Commission has concluded that the environmental impacts on surface water quality are small for those effluents subject to existing permit or certification requirements. A total decoupling of the license renewal process and the NPDES permitting process is not appropriate because, for issues with incomplete Clean Water Act determinations, the NRC cannot complete its weighing and balancing of impacts without independently addressing the issues.

Concern. Several commenters raised concerns that various issues within the Surface Water Quality topic should be Category 2 or 3 issues. These included water use conflicts as experienced in Arizona and the Midwest, thermal stratification and salinity gradients associated with once-through cooling systems, and the toxicity of biofouling compounds.

Response. Regarding the water use conflicts, the NRC has considered the impacts of water use during the renewal period and has concluded that these impacts are small for plants with a once-through cooling system and that this is a Category 1 issue for those plants. However, this issue is designated Category 2 for plants with cooling towers and cooling ponds because, for those plants, the impacts might be moderate (they could also be small). In either case, pursuant to 10 CFR 51.45(d), an applicant for license renewal must identify and indicate in its environmental report the status of State and local approvals regarding water use issues. For those reactor sites where thermal stratification or salinity gradient was found to be the most pronounced, the issues were reviewed during preparation of the GEIS and found to be acceptable by the States within the NPDES process. No change in the categorization in the GEIS would be required. Similarly, the NPDES permit for a facility establishes allowable discharges, including biocides. The NRC has no indication that residual environmental impacts would occur as a result of license renewal activities at any nuclear plant site other than perhaps water use conflicts arising at plants with cooling ponds or cooling towers using make-up water from a small river with low flow. For those plants, this issue is Category 2.

3. Aquatic Ecology

Concern. A number of comments regarding the ecological impact of cooling water withdrawal from aquatic bodies were received. Specific concerns included fish kills associated with the entrainment and impingement of fish within once-through and cooling pond cooling systems, the use of chlorine and molluscicides to control mussel and clam growth, and the long-term effects of heavy metal discharges from plants with copper-nickel condenser tubes. Another commenter noted that license extension affords the opportunity to review the intake and discharge configuration of plant cooling water systems, since the best available technology that is economically available may be different given the additional 20 years of plant operating life.

Response. The Commission has considered the impacts of license renewal on aquatic ecology and, in doing so, has reviewed existing NPDES permits and other information. Based on this analysis, the Commission has concluded that these impacts are small with the exception that plants with once-through cooling and cooling ponds may have larger effects associated with entrainment of fish and shellfish in early life stages, impingement, and heat shock. Agencies responsible for existing permits are not constrained from reexamining the permit issues if they have reason to believe that the basis for their issuance is no longer valid. The Commission does not have authority under NEPA to impose an effluent limitation other than those established in permits issued pursuant to the Clean Water Act. The problem of the long-term effects of heavy metal discharges from plants with copper-nickel condenser tubes has been found at only one plant. The affected condenser tubes have been replaced with tubing of a more corrosion-resistant material.

Concern. A commenter pointed out that the issue of riparian zones should be addressed in the GEIS because the vegetation region along a water course can be affected by water withdrawal and is important in maintaining the habitat.

Response. The NRC agrees with the importance of addressing the impacts of license renewal on the riparian habitat. The final GEIS provides a discussion of the riparian habitat as an important resource and the potential effects of consumptive water use on riparian zones.

4. Groundwater Use and Quality

Concern. Several commenters indicated that groundwater issues should be reviewed on a site-specific basis because of groundwater use conflicts (in particular, the effect on aquifer recharge of using surface water for cooling water), opportunities for saltwater intrusion, and concerns over tritium found in wells at one site. On the other hand, a commenter requested that the issue of groundwater use for cooling tower makeup water be changed from Category 2 to Category 1 because the issue is based solely on data from Ranney wells at the Grand Gulf Nuclear Station, where tests have shown that the elevation of the water plain around Grand Gulf is not dropping.

Response. Based on consideration of comments, the issue of groundwater use conflicts resulting from surface water withdrawals for cooling tower makeup water or cooling ponds is now Category 2 for plants withdrawing surface water from small water bodies during low flow conditions. The GEIS has identified a potential reduction in aquifer recharge as a result of competing water use. These conflicts are already a concern at two closed-cycle nuclear power plants. The NRC does not agree that saltwater intrusion should be considered a Category 2 issue. When saltwater intrusion has been a problem, the major cause has been the large consumption of groundwater by agricultural and municipal users. Groundwater consumption by nuclear power plants is small by comparison and does not contribute significantly to the saltwater intrusion problem. With regard to traces of tritium found in the groundwater at one nuclear power plant, the tritium was attributed to a modification in the plant's inlet and discharge canal that did not take into consideration a unique situation in topology and groundwater flow. The releases were minor and the situation has been corrected.

Regarding the issue of the use of groundwater for cooling water makeup, the NRC has designated this issue as Category 2 even though only the Grand Gulf Nuclear Station is currently using Ranney wells to withdraw groundwater. This water intake does not conflict with other groundwater uses in the area. It is not possible to predict whether or not water use conflicts will occur at the Grand Gulf facility in the future. It is also not possible to determine the significance of the environmental impacts associated with Ranney well use at other nuclear plants that may choose to adopt this method in the future.

5. Terrestrial Ecology

Concern. Several commenters recommended that the issue of bird mortality resulting from collisions with transmission lines, towers, or cooling towers be characterized as a Category 2 issue. Such a characterization would provide for a review of mitigation at those plants with cooling towers that do not have illumination and for power plant transmission lines that transect major flyways or that cross wetlands used by large concentrations of birds.

Response. The NRC does not agree with this recommendation. The GEIS cites several studies that conclude that bird mortalities resulting from collision with transmission lines, towers, or cooling towers are not significantly reducing bird populations. Mitigation measures in place, such as safety lights, were found adequate and additional measures were not warranted. Therefore, the issue remains a Category 1 issue because refurbishment will not involve construction of any additional transmission lines or natural draft cooling towers.

Concern. One commenter expressed concern that the GEIS analysis of land use did not adequately encompass the impact of onsite spent fuel storage on land use and that the Category 1 finding is questionable. A specific concern was the potential need for the construction of additional spent fuel storage facilities associated with the license renewal term, along with their associated impacts on the terrestrial environment.

Response. The NRC does not agree that there is a need to change the Category 1 determination for onsite land use. Waste management operations could require the construction of additional storage facilities and thus adversely affect land use and terrestrial ecology. However, experience has shown that the land requirements would be relatively small (less than 9 acres), impacts to land use and terrestrial ecology would also be relatively small, and the land that may be used is already possessed by the applicant; thus, its basic use would not be altered. Onsite land use is Category 1. Terrestrial ecology with disturbance of sensitive habitat is treated as a separate issue and is Category 2.

6. Human Health

Concern. In the human health section of the GEIS, the radiological impacts of plant refurbishment and continued operations during the license renewal term to workers and the general public were examined. Several commenters indicated that it was inappropriate to compare the radiation exposures associated with license renewal to natural background levels. These commenters believed that the appropriate argument should be that the risks associated with the additional exposures are so small that no additional mitigative measures are required.

Response. The NRC agrees that the assessment of radiation exposure should not be simply a comparison with background radiation. In response to comments on the draft generic environmental impact statement and the proposed rule, the standard defining a small radiological impact has changed from a comparison with background radiation to sustained compliance with the dose and release limits applicable to the various stages of the fuel cycle. This change is appropriate and strengthens the criterion used to define a small environmental impact for the reasons that follow. The Atomic Energy Act requires the Nuclear Regulatory Commission to promulgate, inspect and enforce standards that provide an adequate level of protection of the public health and safety and the environment. The implementation of these regulatory programs provides a margin of safety. A review of the regulatory requirements and the performance of facilities provides the bases to project continuation of performance within regulatory standards. For the purposes of assessing radiological impacts, the Commission has concluded that impacts are of small significance if doses to individuals and releases do not exceed the permissible levels in the Commission's regulations.

With respect to whether additional mitigative measures are required, it should be noted that in 10 CFR parts 20 and 50 there are provisions that radiological impacts associated with plant operation be reduced to levels as low as reasonably achievable (ALARA).

Concern. Several commenters indicated that the GEIS needs a broader treatment of uncertainty as it relates to human health issues.

Response. The NRC agrees that there is considerable uncertainty associated with health effects, especially at low occupational and public dose levels, and particularly with respect to electromagnetic fields. Health effect estimates from radiation exposures are based on the best scientific evidence available and are considered to be conservative estimates. Several sections of the GEIS have been expanded to more thoroughly explain how predicted impacts could be affected by changes in scientific information or standards.

Concern. One commenter indicated that, in the GEIS and the proposed rule, risk coefficients should have been used for chemicals and radiation to obtain upper bound risk estimates of cancer incidence.

Response. The NRC does not agree with this comment. In making comparisons of alternatives, comparisons of the central or best estimates of impacts are consistent with NEPA requirements because they provide the fairest determination. The GEIS is written using current, Commission-approved risk estimators.

Concern. Two commenters expressed concern regarding the GEIS conclusion that the impact of radiation exposure to the public is small, citing a study done by the Massachusetts Department of Public Health (MDPH). This study concluded that adults who live within 10 miles of the Pilgrim Nuclear Power Plant have a risk of contracting leukemia four times greater than other individuals.

Response. The NRC staff reviewed the MDHP study and compared it with various other studies. The results of the study have been contradicted by a National Cancer Institute (NCI) study entitled ''Cancer in Populations Living Near Nuclear Facilities'' (July 1990). The NCI study, which included the Pilgrim plant in its analysis, found no reason to suggest that nuclear facilities may be linked causally with excess deaths from leukemia or from other cancers. The findings of the NCI study are consistent with the findings of several similar epidemiological studies in foreign countries and with the latest conclusions of expert bodies such as the National Research Council's Committee on the Biological Effects of Ionizing Radiation. The NRC continues to base its assessment of the health effects of ionizing radiation on the overall body of scientific knowledge and on the recommendations of expert groups.

7. Socioeconomics

Concern. A commenter concerned with historic preservation pointed out that this issue must be addressed through compliance with the National Historic Preservation Act (NHPA) and cannot be resolved generically.

Response. The NRC agrees with this comment. Historical and archaeological impacts have been changed from a Category 1 to a Category 2 issue (that is, it must be evaluated site-specifically). Consultation with State historical preservation offices and other Government agencies, as required by NHPA, must be undertaken to determine whether protected historical or archaeological resources are in areas that might be disturbed during refurbishment activities and operation during the renewal period.

Concern. Several commenters indicated that transportation issues associated with refurbishment activities should be changed from Category 3 to Category 2 because the impacts will be insignificant in the majority of cases. One recommendation was to use a level of service (LOS) determination for specific plants as the bounding criterion. The analysis would require that LOS be determined for that part of the refurbishment period during which traffic not related to the plant is expected to be the heaviest. Another recommendation was to establish bounding criteria based on past major routine outages.

Response. The NRC agrees that use of the LOS approach may prove to be acceptable. Transportation still must be reviewed on a plant-specific basis, that is, it is a Category 2 issue (based on the revised definition).

Concern. There were recommendations to make the housing impacts during refurbishment a Category 1 issue instead of Category 2. One commenter noted that the construction period data used in the analysis appears to overestimate the impact on housing.

Response. The NRC does not agree that this should be a Category 1 issue. Although negligible housing impacts are anticipated for most license renewals, significant housing impacts have occurred during a periodic plant outage at one of the case plants studied for the analysis. This issue is now a Category 2 issue because moderate and large impacts on housing are possible depending on local conditions (e.g., areas with extremely slow population growth or areas with growth control measures that limit housing development).

8. The Uranium Fuel Cycle and Solid Waste Management

Concern. Wide-ranging concerns were expressed in the comments on the proposed rule and the draft GEIS about the treatment of storage and disposal of low-level waste (LLW), mixed waste, spent fuel, nonradiological waste, and the transportation of fuel and waste to and from nuclear power plants as a consequence of license renewal. Concern was expressed about the uncertain availability of disposal facilities for LLW, mixed waste, and spent fuel; the prospect of generation and onsite storage of an additional 20 years output of waste; and the resulting pressure that would be put on the States to provide LLW disposal facilities. Various commenters expressed concern about the adequacy of the treatment of the cost of waste management and the implications for the economic viability of license renewal. Numerous comments were provided on updating and clarifying data on waste management presented in the draft GEIS. Finally, various questions were raised about the applicability of Table S–3 (10 CFR 51.51 Uranium fuel cycle environmental data—Table S–3, Table of Uranium Fuel Cycle Environmental Data) to the management of waste generated as a result of license renewal.

With regard to spent fuel, several commenters expressed concern that dry cask storage is not a proven technology and that onsite storage of spent fuel from an additional 20 years of plant operation will present environmental and safety problems. Therefore, onsite storage of spent fuel should be considered on a site-specific basis within a plant license renewal review.

Response. The Commission acknowledges that there is uncertainty in the schedule of availability of disposal facilities for LLW, mixed waste, and spent fuel. However, the Commission believes that there is sufficient understanding of and experience with the storage of LLW, mixed waste, and spent fuel to conclude that the waste generated at any plant as a result of license renewal can be stored safely and without significant environmental impacts before permanent disposal. In addition, the Commission concluded that the classification of storage and ultimate disposal as a Category 1 issue is appropriate because States are proceeding, albeit slowly, with the development of new disposal facilities; LLW and mixed waste have been and can be safely stored at reactor sites until new disposal capacity becomes available. Analyses to support this conclusion are presented in Chapter 6 of the final GEIS (NUREG–1437). The following summary of the responses to comments emphasizes the main features of these analyses.

In the draft GEIS, the environmental data in Table S–3 were discussed with respect to applicability during the license renewal period and supplemented with an analysis of the radiological release and dose commitment data for radon-222 and technetium-99. The proposed rule would have had this discussion apply to each plant at the time of its review for license renewal.

Further, in the draft GEIS, Chapter 6, ''Solid Waste Management,'' covered the generation of LLW, mixed waste, spent fuel, and nonradiological waste as a result of license renewal; the transportation of the radiological waste; and the environmental impacts of waste management, including storage and disposal. The findings that were to have been codified in the rule were that, for nonradiological waste, mixed waste, spent fuel, and transportation, the environmental impacts are of small significance and that the analysis in the GEIS applies to each plant (Category 1). For LLW, the finding that would have been codified in the rule was that, if an applicant does not have access to a low-level radioactive waste disposal facility through a low-level waste compact or an unaffiliated State, the applicant must present plans for interim waste storage with an assessment of potential ecological habitat destruction caused by construction activities (Category 2).

In response to the questions about the applicability of Table S–3 to the management of waste associated with license renewal and to the various comments challenging the treatment of the several forms of waste in the draft GEIS and in the proposed rule, the discussion of Table S–3 has been moved from Section 4.8 of the draft GEIS to Chapter 6 of the final GEIS in order to provide a more integrated assessment of the environmental impacts associated with waste management as a consequence of license renewal. Also in response to various comments, the discussion of Table S–3 and of each of the types of waste has been expanded.

Supplemental data are presented in Chapter 6 of the final GEIS in order to extend the coverage of the environmental impacts of the uranium fuel cycle presented in the current Table S–3 and of transportation of radioactive waste presented in the current Table S–4 to radon-222, technetium-99, higher fuel enrichment, and higher fuel burnup. In part, the current Table S–3 and the data supplementing it cover environmental impacts of:

(1) Onsite storage of spent fuel assemblies in pools for 10 years, packaging and transportation to a Federal repository, and permanent disposal; and

(2) Short-term storage onsite of LLW, packaging and transportation to a land-burial facility, and permanent disposal.

The following conclusions have been drawn with regard to the environmental impacts associated with the uranium fuel cycle.

The radiological and nonradiological environmental impacts of the uranium fuel cycle have been reviewed. The review included a discussion of the values presented in Table S–3, an assessment of the release and impact of ^{222}Rn and of ^{99}Tc, and a review of the regulatory standards and experience of fuel cycle facilities. For the purpose of assessing the radiological impacts of license renewal the Commission uses the standard that the impacts are of small significance if doses and releases do not exceed permissible levels in the Commission's regulations. Given the available information regarding the compliance of fuel cycle facilities with applicable regulatory requirements, the Commission has concluded that, other than for the disposal of spent fuel and high-level waste, these impacts on individuals from radioactive gaseous and liquid releases will remain at or below the Commission's regulatory limits. Accordingly, the Commission concludes that offsite radiological impacts of the fuel cycle (individual effects from other than the disposal of spent fuel and high-level waste) are small. ALARA efforts will continue to apply to fuel cycle activities. This is a Category 1 issue.

The radiological impacts of the uranium fuel cycle on human populations over time (collective effects) have been considered within the framework of Table S–3. The 100 year environmental dose commitment to the U.S. population from the fuel cycle, high level waste and spent fuel disposal excepted, is calculated to be about 14,800 man-rem, or 12 cancer fatalities, for each additional 20 year power reactor operating term. Much of this, especially the contribution of radon releases from mines and tailing piles, consists of tiny doses summed over large populations. This same dose calculation can theoretically be extended to include many tiny doses over additional thousands of years as well as doses outside the U.S. The result of such a calculation would be thousands of cancer fatalities from the fuel cycle, but this result assumes that even tiny doses have some statistical adverse health effect which will not ever be mitigated (for example no cancer cure in the next thousand years), and that these dose projections over thousands of years are meaningful. However these assumptions are questionable. In particular, science cannot rule out the possibility that there will be no cancer fatalities from these tiny doses. For perspective, the doses are very small fractions of regulatory limits, and even smaller fractions of natural background exposure to the same populations. No standards exist that can be used to reach a conclusion as to the significance of the magnitude of the collective radiological effects. Nevertheless, some judgement as to the regulatory NEPA implication of this issue should be made and it makes no sense to repeat the same judgement in every case. The Commission concludes that these impacts are acceptable in that these impacts would not be sufficiently large to require the NEPA conclusion, for any plant, that the option of extended operation under 10 CFR part 54 should be eliminated. Accordingly, while the Commission has not assigned a single level of significance for the collective effects of the fuel cycle, this issue is considered Category 1. For other Category 1 issues, the impacts will be considered at the individual renewal stage as a means of judging the total impact of an individual license renewal decision. However, the Commission has already judged the impact of collective effects of the fuel cycle as part of this rule.

There are no current regulatory limits for off-site releases of radionuclides for the current candidate repository site. However if we assume that limits are developed along the lines of the 1995 National Academy of Sciences (NAS) report, and that in accordance with the Commission's Waste Confidence Decision, a repository can and likely will be developed at some site which will comply with such limits, peak doses to virtually all individuals will be 100 millirem per year or less. However, while the Commission has reasonable confidence that these assumptions will prove correct there is considerable uncertainty since the limits are yet to be developed, no repository application has been completed or reviewed, and uncertainty is inherent in the models used to evaluate possible pathways to the human environment. The National Academy report indicated that 100 millirem per year should be considered as a starting point for limits for individual doses, but notes that some measure of consensus exists among national and international bodies that the limits should be a fraction of the 100 millirem per year. The lifetime individual risk from 100 millirem per year dose limit is about 3×10^{-3}. Doses to populations from disposal cannot now (or possibly ever) be estimated without very great uncertainty. Estimating cumulative doses to populations over thousands of years is more problematic. The likelihood and consequences of events that could seriously compromise the integrity of a deep geologic repository were evaluated by the Department of Energy in the ''Final Environmental Impact Statement: Management of Commercially Generated Radioactive Waste,'' October 1980. The evaluation estimated the 70-year whole-body dose commitment to the maximum individual and to the regional population resulting from several modes of breaching a reference repository in the year of closure, after 1,000 years, after 100,000 years, and after 100,000,000 years. The release scenarios covered a wide range of consequences from the limited consequences of humans accidentally drilling into a waste package in the repository to the catastrophic release of the repository inventory by a direct meteor strike. Subsequently, the NRC and other Federal agencies have expended considerable effort to develop models for the design and for the licensing of a high level waste repository, especially for the candidate repository at Yucca Mountain. More meaningful estimates of doses to population may be possible in the future as more is understood about the performance of the proposed Yucca Mountain repository. Such estimates would involve very great uncertainty, especially with respect to cumulative population doses over thousands of years. The standard proposed by the NAS is a limit on maximum individual dose. The relationship of potential new regulatory requirements, based on the NAS report, and cumulative population impacts has not been determined, although the report articulates the view that protection of individuals will adequately protect the population for a repository at Yucca Mountain. However, EPA's generic repository standards in 40 CFR part 191 generally provide an indication of the order of magnitude of cumulative risk to population that could result from the licensing of a Yucca Mountain repository, assuming the ultimate standards will be within the range of standards now under consideration. The standard in 40 CFR part 191 protects the population by imposing ''containment requirements'' that limit the cumulative amount of radioactive material released over 10,000 years. The cumulative release limits are based on EPA's population impact goal of 1,000 premature cancer deaths world-wide for a 100,000 metric tonne (MTHM) repository.

Nevertheless, despite all the uncertainty surrounding the effects of the disposal of spent fuel and high-level waste, some judgement as to the regulatory NEPA implications of these matters should be made and it makes no sense to repeat the same judgement in every case. Even taking the uncertainties into account, the Commission concludes that these impacts are acceptable in that these impacts would not be sufficiently large to require the NEPA conclusion, for any plant, that the option of extended operation under 10 CFR part 54 should be eliminated. Accordingly, while the Commission has not assigned a single level of significance for the impacts of spent fuel and high-level waste disposal, this issue is considered Category 1. Excepting the collective effects previously discussed, for other Category 1 issues, the impacts will be considered at the individual renewal stage as a means of judging the total impact of an individual license renewal decision. However, the Commission has already judged the impacts of high level waste disposal as part of this rule.

With respect to the nonradiological impact of the uranium fuel cycle, data concerning land requirements, water requirements, the use of fossil fuel, gaseous effluent, liquid effluent, and tailings solutions and solids, all listed in Table S–3, have been reviewed to determine the significance of the environmental impacts of a power reactor operating an additional 20 years. The nonradiological impacts attributable to the relicensing of an individual power reactor are found to be of small significance. License renewal of an individual plant is so indirectly connected to the operation of fuel cycle facilities that it is meaningless to address the mitigation of impacts identified above. This is a Category 1 issue.

Table S–3 does not take into account long-term onsite storage of LLW, mixed waste, and storage of spent fuel assemblies onsite for longer than 10 years, nor does it take into account impacts from mixed waste disposal. The environmental impacts of these aspects of onsite storage are also addressed in Chapter 6 of the final GEIS and the findings are included in the final rule in Table B–1 of appendix B to 10 CFR part 51.

Chapter 6 of the GEIS discusses the impacts of offsite disposal of LLW and mixed waste and concludes that impacts will be small. The conclusion that impacts will be small is based on the regulations and regulatory programs in place (e.g., 10 CFR part 61 for LLW and 40 CFR parts 261, 264, and 268 for hazardous waste), experience with existing sites, and the expectation that NRC, EPA, and the States will ensure that disposal will occur in compliance with the applicable regulations.

The Low-Level Radioactive Waste Policy Act of 1980 (LLRWPA) made the States responsible for the disposal of commercially generated LLW. At present, 9 compacts have been formed, representing 42 States. The Texas Compact (Texas, Maine, and Vermont) is pending before the U.S. Congress.

New LLW disposal facilities in the host States of California, North Carolina, and Texas are forecast to be operational between 1997 and 1998. Facilities in the host States of Connecticut, Illinois, Massachusetts, Nebraska, New Jersey, Pennsylvania, and New York are scheduled for operation between 1999 and 2002. Envirocare, in Utah, takes limited types of waste from certain generators.

There are uncertainties in the licensing process and in the length of time needed to resolve technical issues, but in NRC's view there are no unsolvable technical issues that will inevitably preclude successful development of new sites or other off-site disposal capacity for LLW by the time they will be needed. For example, in California, the proposed Ward Valley LLW disposal facility was unexpectedly delayed by the need to resolve technical issues raised by several scientists independent of the project after the license was issued. These issues were recently reviewed and largely resolved by an independent review group. In North Carolina, Texas, and Nebraska, the license application review period has been longer than is required by the LLRWPA, but progress continues to be made.

The State's LLW responsibilities include providing disposal capacity for mixed LLW. Mixed waste disposal facility developers face the same types of challenges as LLW site developers plus difficulties with dual regulation and small volumes. However, in NRC's view there are no technical reasons why offsite disposal capacity for all types of mixed waste should not become available when needed. NRC and EPA have developed guidance on the siting of mixed waste disposal facilities as well as a conceptual design for a mixed waste disposal facility. A disposal facility for certain types of mixed waste is operated by Envirocare in Utah. States have begun discussions with DOE about accepting commercial mixed waste for treatment and disposal at DOE facilities. Although these discussions have yet to result in DOE accepting commercial mixed waste at DOE facilities, it appears that progress is being made toward DOE's eventual acceptance of some portion of commercial mixed waste at its facilities.

While the NRC understands that there have been delays and that uncertainties exist such as those just discussed, the Commission concludes that there is reasonable assurance that sufficient LLW and mixed LLW disposal capacity will be made available when needed so that facilities can be decommissioned consistent with NRC decommissioning requirements. This conclusion, coupled with the expected small impacts from both storage and disposal justify classification of LLW and mixed waste disposal as Category 1 issues.

The GEIS addresses the matter of extended onsite storage of both LLW and mixed waste from refurbishment and operations for a renewal period of up to 20 years. Summary data are provided and radiological and nonradiological environmental impacts are addressed. The analysis considers:

(1) The volumes of LLW and mixed waste that may be generated from license renewal;

(2) Specific requirements under the existing regulatory framework;

(3) The effectiveness of the regulations in maintaining low average doses to members of the public and to workers; and

(4) Nonradiological impacts, including land use, fugitive dust, air quality, erosion, sedimentation, and disturbance of ecosystems.

In addition, under 10 CFR 50.59, licensees are allowed to make changes to their facilities as discussed in the final safety analysis report without NRC permission if the evaluation indicates that a change in the technical specifications is not required or that an unreviewed safety question does not exist. Licensees would have to ensure that any new LLW activities would not represent an unreviewed safety question for routine operations or for conditions that might arise from potential accidents. Both onsite and offsite impacts would have to be considered. If a LLW or mixed waste activity fails either of the two tests in 10 CFR 50.59, a license amendment is required. Subject to the two possible review requirements just noted, the Commission finds that continued onsite storage of both LLW and mixed waste resulting from license renewal will have small environmental impacts and will require no further review within the license renewal proceeding.

The GEIS addresses extended onsite storage of spent fuel during a renewal period of up to 20 years. The Commission has studied the safety and environmental effects of the temporary storage of spent fuel after cessation of reactor operation and has published a generic determination of no significant environmental impact (10 CFR 51.23). The environmental data on storing spent fuel onsite in a fuel pool for 10 years before shipping for offsite disposal have been assessed and reported in NUREG–0116, ''The Environmental Survey of the Reprocessing and Waste Management Portions of the LWR Fuel Cycle'' (October 1976), and published in the Commission's regulations (10 CFR 51.51). Environmental assessments (EA) for expanding the fuel pool storage capacity have been conducted for numerous plants. In each case, a finding of no significant environmental impact was reached.

Radioactive exposures, waste generation, and releases were evaluated and found to be small. The only nonradiological effluent from waste storage is additional heat from the plant that was found to have a negligible effect on the environment. Accidents were evaluated and were found to have insignificant effects on the environment. Dry cask storage at an independent spent fuel storage installation (ISFSI) is another technology used to store under a general license. The environmental impacts of allowing onsite dry cask storage under a general license were assessed in an EA and found to be insignificant. Further, the Commission has conducted EAs for seven specific licensed ISFSIs and has reached a finding of no significant environmental impact for each site. Each EA addressed the impacts of construction, use, and decommissioning. Potential impacts that were assessed include radiological impacts, land use, terrestrial resources, water use, aquatic resources, noise, air quality, socioeconomics, radiological impacts during construction and routine operation, and radiological impacts of off-normal events and accidents. Trends in onsite spent fuel storage capacity and the volume of spent fuel that will be generated during an additional 20 years of operation are considered in the GEIS. Spent fuel storage capacity requirements can be adequately met by ISFSIs without significant environmental impacts. The environmental impacts of onsite storage of spent fuel at all plants have been adequately assessed in the GEIS for the purposes of an environmental review and agency decision on renewal of an operating license; thus, no further review within the license renewal proceeding is required. This provision is relative to the license renewal decision and does not alter existing Commission licensing requirements specific to on-site storage of spent fuel.

The environmental impacts from the transportation of fuel and waste attributable to license renewal are found to be small when they are within the range of impacts of parameters identified in Table S–4. The estimated radiological effects are within regulatory standards. The nonradiological impacts are those from periodic shipments of fuel and waste by individual trucks or rail cars and thus would result in infrequent and localized minor contributions to traffic density. Programs designed to further reduce risk, which are already in place, provide for adequate mitigation. Recent, ongoing efforts by the Department of Energy to study the impacts of waste transportation in the context of the multi-purpose canister (see, 60 FR 45147, August 30, 1995) suggest that there may be unresolved issues regarding the magnitude of cumulative impacts from the use of a single rail line or truck route in the vicinity of the repository to carry all spent fuel from all plants. Accordingly, NRC declines to reach a Category 1 conclusion on this issue at this time. Table S–4 should continue to be the basis for case-by-case evaluation of transportation impacts of fuel and waste until such time as a detailed analysis of the environmental impacts of transportation to the proposed repository at Yucca Mountain becomes available.

9. Accidents

Concern. Several commenters expressed concerns regarding the appropriateness of the severe accident determination in the GEIS and with the treatment of severe accident mitigation design alternatives (SAMDAs) for license renewal. A group of commenters identified areas of concern that they believe justify severe accidents being classified as a Category 3 issue. The areas included seismic risks to nuclear power plants and site-specific evacuation risks. Several commenters questioned whether the analyses of the environmental impacts of accidents were adequate to make a Category 1 determination for the issue of severe accidents. The contention is that a bounding analysis would be established only if plant-specific analyses were performed for every plant, which was not the case. Instead, the GEIS analysis made use of a single generic source term for each of the two plant types.

Response. The Commission believes that its analysis of the impacts of severe accidents is appropriate. The GEIS provides an analysis of the consequences of severe accidents for each site in the country. The analysis adopts standard assumptions about each site for parameters such as evacuation speeds and distances traveled, and uses site-specific estimates for parameters such as population distribution and meteorological conditions. These latter two factors were used to evaluate the exposure indices for these analyses. The methods used result in predictions of risk that are adequate to illustrate the general magnitude and types of risks that may occur from reactor accidents. Regarding site-evacuation risk, the radiological risk to persons as they evacuate is taken into account within the individual plant risk assessments that form the basis for the GEIS. In addition, 10 CFR Part 50 requires that licensees maintain up-to-date emergency plans. This requirement will apply in the license renewal term as well as in the current licensing term.

As was done in the GEIS analysis, the use of generic source terms (one set for PWRs and another for BWRs) is consistent with the past practice that has been used and accepted by the NRC for individual plant Final Environmental Impact Statements (FEISs). The purpose of the source term discussion in the GEIS is to describe whether or not new information on source terms developed after the completion of the most recent FEISs indicates that the source terms used in the past under-predict environmental consequences. The NRC has concluded that analysis of the new source term information developed over the past 10 years indicates that the expected frequency and amounts of radioactive release under severe accident conditions are less than that predicted using the generic source terms. A summary of the evolution of this research is provided in NUREG–1150, ''Severe Accident Risks: An Assessment for Five U.S. Nuclear Power Plants'' (December 1990), and its supporting documentation. Thus, the analyses performed for the GEIS represent adequate, plant-specific estimates of the impacts from severe accidents that would generally over-predict, rather than under-predict, environmental consequences. Therefore, the GEIS analysis of the impacts of severe accidents for license renewal is retained and is considered applicable to all plants.

Based on an evaluation of the comments, the Commission has reconsidered its previous conclusion in the draft GEIS concerning site-specific consideration of severe accident mitigation. The Commission has determined that a site-specific consideration of alternatives to mitigate severe accidents will be required at the time of license renewal unless a previous consideration of such alternatives regarding plant operation has been included in a final environmental impact statement or a related supplement. Because the third criterion required to make a Category 1 designation for an issue requires a generic consideration of mitigation, the issue of severe accidents must be reclassified as a Category 2 issue that requires a consideration of severe accident mitigation alternatives, provided this consideration has not already been completed. The Commission's reconsideration of the issue of severe accident mitigation for license renewal is based on the Commission's NEPA regulations that require a consideration of mitigation alternatives in its environmental impact statements (EISs) and supplements to EISs, as well as a previous court decision that required a review of severe mitigation alternatives (referred to as SAMDAs) at the operating license stage. See, *Limerick Ecology Action* v. *NRC*, 869 F.2d 719 (3d Cir. 1989).

Although the Commission has considered containment improvements for all plants pursuant to its Containment Performance Improvement (CPI) program, which identified potential containment improvements for site-specific consideration by licensees, and the Commission has additional ongoing regulatory programs whereby licensees search for individual plant vulnerabilities to severe accidents and consider cost-beneficial improvements, these programs have not yet been completed. Therefore, a conclusion that severe accident mitigation has been generically considered for license renewal is premature.

The Commission believes it unlikely that any site-specific consideration of severe accident mitigation alternatives for license renewal will identify major plant design changes or modifications that will prove to be cost-beneficial for reducing severe accident frequency or consequences. This Commission expectation regarding severe accident mitigation improvements is based on the analyses performed to date that are discussed below.

The Commission's CPI program examined each of the five U.S. containment types to determine potential failure modes, potential plant improvements, and the cost-effectivenesses of such improvements. As a result of this program, only a few containment improvements were found to be potentially beneficial and were either identified for further NRC research or for individual licensee evaluation.

In response to the *Limerick* decision, an NRC staff consideration of SAMDAs was specifically included in the Final Environmental Impact Statement for the Limerick 1 and 2 and Comanche Peak 1 and 2 operating license reviews, and in the Watts Bar Supplemental Final Environmental Statement for an operating license. The alternatives evaluated in these analyses included the items previously evaluated as part of the CPI Program, as well as improvements identified through other risk studies and analyses. No physical plant modifications were found to be cost-beneficial in any of these severe accident mitigation considerations. Only plant procedural changes were identified as being cost-beneficial. Furthermore, the Limerick analysis was for a high-population site. Because risk is generally proportional to the population around a plant, this analysis suggests that other sites are unlikely to identify significant plant modifications that are cost-beneficial.

Additionally, each licensee is performing an individual plant examination (IPE) to look for plant vulnerabilities to internally initiated events and a separate IPE for externally initiated events (IPEEE). The licensees were requested to report their results to the Commission. Seventy-eight IPE submittals were received and seventy-five IPEEE submittals will be received, covering all operating plants in the United States. These examinations consider potential improvements to reduce the frequency or consequences of severe accidents on a plant-specific basis and essentially constitute a broad search for severe accident mitigation alternatives. The NRC staff is conducting a process review of each plant-specific IPE submittal and IPEEE submittal. To date, all IPE submittals have received a preliminary review by the NRC with 46 out of 78 completed; for the IPEEE submittals, 24 of the 75 are under review. These IPEs have resulted in a number of plant procedural or programmatic improvements and some plant modifications that will further reduce the risk of severe accidents.

In conclusion, the GEIS analysis of severe accident consequences and risk is adequate, and additional plant-specific analysis of these impacts is not required. However, because the ongoing regulatory program related to severe accident mitigation (i.e., IPE and IPEEE) has not been completed for all plants and consideration of severe accident mitigation alternatives has not been included in an EIS or supplemental EIS related to plant operations for all plants, a site-specific consideration of severe accident mitigation alternatives is required at license renewal for those plants for which this consideration has not been performed. The Commission expects that if these reviews identify any changes as being cost beneficial, such changes generally would be procedural and programmatic fixes, with any hardware changes being only minor in nature and few in number. NRC staff considerations of severe accident mitigation alternatives have already been completed and included in an EIS or supplemental EIS for Limerick, Comanche Peak, and Watts Bar. Therefore, severe accident mitigation alternatives need not be reconsidered for these plants for license renewal.

Based on the fact that a generic consideration of mitigation is not performed in the GEIS, a Category 1 designation for severe accidents cannot be made. Therefore, the Commission has reclassified severe accidents as a Category 2 issue, requiring only that alternatives to mitigate severe accidents be considered for those plants that have not included such a consideration in a previous EIS or supplemental EIS. The Commission notes that upon completion of its IPE/IPEEE program, it may review the issue of severe accident mitigation for license renewal and consider, by separate rulemaking, reclassifying severe accidents as a Category 1 issue.

The Commission does not intend to prescribe by rule the scope of an acceptable consideration of severe accident mitigation alternatives for license renewal nor does it intend to mandate consideration of alternatives identical to those evaluated previously. In general, the Commission expects that significant efficiency can be gained by using site-specific IPE and IPEEE results in the consideration of severe accident mitigation alternatives. The IPEs and IPEEEs are essentially site-specific PRAs that identify probabilities of core damage (Level 1 PRA) and include assessments of containment performance under severe accident conditions that identify probabilities of fission product releases (Level 2). As discussed in Generic Letter 88–20, ''Individual Plant Examination for Severe Accident Vulnerabilities'' (November 23, 1988), one of the important goals of the IPE and IPEEE was to reduce the overall probabilities of core damage and fission product releases as necessary by modifying hardware and procedures to help prevent or mitigate severe accidents.

Although Level 3 PRAs have been used in SAMDA analyses to generate site-specific offsite dose estimates so that the cost-benefit of mitigation alternatives could be determined, the Commission does not believe that site-specific Level 3 PRAs are required to determine whether an alternative under consideration will provide sufficient benefit to justify its cost. Licensees can use other quantitative approaches for assigning site-specific risk significance to IPE results and judging whether a mitigation alternative provides a sufficient reduction in core damage frequency (CDF) or release frequency to warrant implementation. For example, a licensee could use information provided in the GEIS analysis (exposure indices, wind frequencies, and demographics) to translate the dominant contributors to CDF and the large release frequencies from the IPE/IPEEE results into dose estimates so that a cost-benefit determination can be performed. In some instances, a consideration of the magnitude of reduction in the site-specific CDF and release frequencies alone (i.e., no conversion to a dose estimate) may be sufficient to conclude that no significant reduction in off-site risk will be provided and, therefore, implementation of a mitigation alternative is not warranted. The Commission will review each severe accident mitigation consideration provided by a license renewal applicant on its merits and determine whether it constitutes a reasonable consideration of severe accident mitigation alternatives.

10. Decommissioning

Concern. Several commenters requested further clarification of the NRC's position regarding decommissioning requirements, especially whether the total impacts address returning the site to green field conditions.

Response. The decommissioning chapter of the GEIS analyzes the impact that an additional 20 years of plant operation would have on ultimate plant decommissioning; it neither serves as the generic analysis of the environmental impacts associated with decommissioning nor establishes decommissioning requirements. An analysis of the expected impacts from plant decommissioning was previously provided in NUREG–0586, ''Final Generic Environmental Impact Statement on Decommissioning of Nuclear Facilities'' (August 1988). The analysis in the GEIS for license renewal examines the physical requirements and attendant effects of decommissioning after a 20-year license renewal compared with decommissioning at the end of 40 years of operation and finds little difference in effects.

With respect to returning a site to green field condition, the Commission defines decommissioning as the safe removal of a nuclear facility from service, the reduction of residual contamination to a level that permits release of the property for unrestricted use, and termination of the license. Therefore, the question of restoring the land to a green field condition, which would require additional demolition and site restoration beyond addressing residual contamination and radiological effects, is outside the current scope of the decommissioning requirements. Moreover, consistent with the Commission's conclusion that license renewal is not expected to affect future decommissioning, any requirement relative to returning a site to a green field and the attendant effects of such a requirement would also not be affected by an additional 20 years of operation. Therefore, the issue of returning a site to pre-construction conditions is beyond the scope of license renewal review.

Concern. Several commenters expressed concern that, because a residual radioactivity rule is still not in place, the LLW estimates should be reexamined.

Response. The NRC does have criteria in place for the release of reactor facilities to unrestricted access following decommissioning. These include the guidance in Regulatory Guide 1.86, ''Termination of Operating Licenses for Nuclear Reactors'' (which provides guidance for surface contamination), dose rate limits from gamma-emitting radionuclides included in plant technical specifications, and requirements for keeping residual contamination as low as reasonably achievable (ALARA) as included in 10 CFR part 20. These criteria were used in developing NUREG–0586, the final GEIS on decommissioning of nuclear facilities, which was published in August of 1988. One conclusion from the analysis conducted for NUREG–0586 was that waste volumes from decommissioning of reactors are not highly sensitive to the radiological criteria. A proposed rule dated August 22, 1994, would codify radiological criteria for unrestricted release of reactors and other nuclear facilities and for termination of a facility license following decommissioning. NUREG–1496, the draft GEIS for the proposed rule on radiological criteria, included analyses of a range of radiological release criteria and confirmed the earlier conclusions that waste volumes from decommissioning of reactors are not sensitive to the residual radiological criteria within the range likely to be selected. This range included residual dose levels comparable to the radiological criteria currently being used for reactor decommissioning. Based on the insensitivity of the waste volume from reactor decommissioning to the radiological criteria, the Commission continues to believe, as concluded in the decommissioning section of the GEIS, that the contribution to environmental impacts of decommissioning from license renewal are small. The Commission further concludes that these impacts are not expected to change significantly as a result of the ongoing rulemaking. Therefore, the determinations in the GEIS remain appropriate.

11. Need for Generating Capacity

Concern. In addition to the major procedural concern discussed earlier about the treatment of need for generating capacity, several commenters raised concerns about the power demand projections used in the GEIS. Some commenters noted that any determination of need quickly becomes dated and, therefore, the demand for and the source of electrical power at the time of license renewal cannot be accurately predicted at this time. Moreover, they believe that the NRC's analysis is not definitive enough to remain unchallenged for 40 years. Another commenter criticized the analysis because it focused only on energy requirements without making appropriate distinctions between energy and peak capacity requirements, plant availability, and capacity factors.

Response. The NRC has determined that a detailed consideration of the need for generating capacity is inappropriate in the context of consideration of the environmental impacts of license renewal. Thus, the NRC will limit its NEPA review of license renewal applications to the consideration of the environmental impacts of license renewal compared with those of other available generating sources. Hence, the concerns regarding demand projections used in the draft GEIS are no longer an issue and they have been removed from the GEIS.

12. Alternatives to License Renewal

Concern. In addition to the procedural concern discussed earlier about the treatment of alternative energy sources as a Category 1 issue, several commenters expressed concerns about the comparison and analysis of alternative energy sources, as well as the economic analysis approach used in the draft GEIS. Consistent with their arguments against the Category 1 designation of alternatives, the commenters questioned the approach adopted in the GEIS of comparing only single alternative energy sources to license renewal. They believe that the NRC's failure to consider a mix of alternatives ignores the potential for other alternative sources of power that are available to different regions of the nation, such as demand-side management, cogeneration, purchased power from Canada, biomass, natural gas, solar energy, and wind power. They also indicated that this approach neglects a utility's ability to serve its customers with a portfolio of supply that is based on load characteristics, cost, geography, and other considerations, and fails to consider the collective impact of the alternatives. Furthermore, the possible technological advances in renewable energy sources over the next 40 years are not addressed.

One commenter argued that designating the issue of alternative energy sources as Category 1 allows a license renewal applicant not to consider the additional requirement of economic threshold analysis. Relative to the economic analysis of the alternatives to license renewal, another commenter questioned the proposed requirement for the license renewal applicant to demonstrate that the ''replacement of equivalent generating capacity by a coal-fired plant has no demonstrated cost advantage over the individual nuclear power plant license renewal.''

According to the commenter, this requirement would force the applicant to perform an economic analysis of an alternative to license renewal. The commenter further argued that NEPA does not require an economic consideration.

Response. In response to these concerns, the final rule no longer requires a cost comparison of alternative energy sources relative to license renewal. Furthermore, the alternative energy sources discussed in the final GEIS include energy conservation and energy imports as well as the other sources discussed by the commenters. An analysis of the environmental impacts of alternative energy sources is included in the GEIS but is not codified in 10 CFR part 51.

The NRC believes that its consideration of alternatives in the GEIS is representative of the technologies available and the associated environmental impacts. With regard to consideration of a mix of alternative sources, the Commission recognizes that combinations of various alternatives may be used to replace power generation from license renewal.

13. License Renewal Scenario

Concern. Several commenters raised concerns related to the license renewal scenario evaluation methodology as implemented in the GEIS. The fundamental issues were the degree of conservatism built into the scenario and the appropriateness of an upper bound type approach in characterizing the refurbishment activities (and associated costs) in light of NEPA requirements to determine reasonable estimates of the environmental impacts of Federal actions.

Regarding the concerns that the refurbishment schedules and scenarios developed for the GEIS were too conservative, several commenters indicated that many of the activities slated for completion during the extended refurbishment before license renewal would actually be completed by many facilities during the course of the current licensing term. The effect of having only one major outage instead of leveling work over three or four outages could lead to an over-estimate of the refurbishment activities and costs that any particular plant would expect to see.

Response. In response to this concern, the NRC has revised the GEIS to include two license renewal program scenarios. The first scenario refers to a ''typical'' license renewal program and is intended to be representative of the type of programs that many plants seeking license renewal might implement. The second scenario retains the original objective of establishing an upper bound of the impacts likely to be generated at any particular plant. The typical scenario is useful for estimating impacts at plants that have been well maintained and have already undertaken most major refurbishment activities necessary for operation beyond the current licensing term. The conservative scenario estimates continue to be useful for estimating the maximum impacts likely to result from license renewal.

The revised approach of providing two separate license renewal scenarios also alleviates the concern about the use of a bounding scenario for license renewal activities. The NRC acknowledges that some applicants for license renewal may not be required to perform certain major refurbishment or replacement activities and, therefore, may have fewer or shorter outages. However, the two scenarios described in the GEIS are neither unrealistic nor overconservative in representing the range of activities that could be expected for license renewal and the possible schedule for performing these activities.

14. Environmental Justice

On February 11, 1994, the President issued Executive Order (E.O.) 12898, ''Federal Actions To Address Environmental Justice in Minority Populations and Low-Income Populations'' (59 FR 7629, February 16, 1994). This order requires each Federal agency to make achieving environmental justice part of its mission by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority and low income populations. The Commission will endeavor to carry out the measures set forth in the executive order by integrating environmental justice into NRC's compliance with the National Environmental Policy of 1969 (NEPA), as amended. E.O. 12898 was issued after publication of the proposed rule and the receipt of comments on the proposed rule. As a result, no comments were received regarding environmental justice reviews for license renewal. Therefore, a brief discussion of this issue relative to license renewal is warranted.

As called for in Section 1–102 of E.O. 12898, the EPA established a Federal interagency working group to, among other things, ''* * * provide guidance to Federal agencies or criteria for identifying disproportionately high and adverse human health or environmental effects on minority populations and low-income populations * * *.'' The CEQ was assigned to provide this guidance to enable agencies to better comply with E.O. 12898. Until the CEQ guidance is received, the Commission intends to consider environmental justice in its evaluations of individual license renewal applications. Greater emphasis will be placed on discussing impacts on minority and low-income populations when preparing NEPA documents such as EISs, supplemental EISs, and, where appropriate, EAs. Commission requirements regarding environmental justice reviews will be reevaluated and may be revised after receipt of the CEQ guidance.

IV. Discussion of Regulatory Requirements

A. General Requirements

In this final rule, the regulatory requirements for performing a NEPA review for a license renewal application are similar to the NEPA review requirements for other major plant licensing actions. Consistent with the current NEPA practice for major plant licensing actions, this amendment to 10 CFR Part 51 requires the applicant to submit an environmental report that analyzes the environmental impacts associated with the proposed action, considers alternatives to the proposed action, and evaluates any alternatives for reducing adverse environmental effects. Additionally, the amendment requires the NRC staff to prepare a supplemental environmental impact statement for the proposed action, issue the statement in draft for public comment, and issue a final statement after considering public comments on the draft.

The amendment deviates from NRC's current NEPA review practice in some areas. First, the amendment codifies certain environmental impacts associated with license renewal that were analyzed in NUREG–1437, ''Generic Environmental Impact Statement for License Renewal at Nuclear Plants'' (xxxx 1996). Accordingly, absent new and significant information, the analyses for certain impacts codified by this rulemaking need only be incorporated by reference in an applicant's environmental report for license renewal and in the Commission's (including NRC staff, adjudicatory officers, and the Commission itself) draft and final SEIS and other environmental documents developed for the proceeding. Secondly, the amendment reflects the Commission's decision to limit its NEPA review for license renewal to a consideration of the environmental effects of the proposed action and alternatives to the proposed action. Finally, the amendment contains the decision standard that the Commission will use in determining the acceptability of the environmental impacts of individual license renewals.

The Commission and the applicant will consider severe accident mitigation alternatives to reduce or mitigate environmental impacts for any plant for which severe accident mitigation alternatives have not been previously considered in an environmental impact statement or related supplement or in an environmental assessment. The Commission has concluded that, for license renewal, the issues of need for power and utility economics should be reserved for State and utility officials to decide. Accordingly, the NRC will not conduct an analysis of these issues in the context of license renewal or perform traditional cost-benefit balancing in license renewal NEPA reviews. Finally, in a departure from the approach presented in the proposed rule, this final rule does not codify any conclusions regarding the subject of alternatives. Consideration of and decisions regarding alternatives will occur at the site-specific stage. The discussion below addresses the specific regulatory requirements of this amendment and any conforming changes to 10 CFR part 51 to implement the Commission's decision to eliminate cost-benefit balancing from license renewal NEPA reviews.

B. The Environmental Report

1. Environmental Impacts of License Renewal

Through this final rule, the NRC has amended 10 CFR 51.53 to require an applicant for license renewal to submit an environmental report with its application. This environmental report must contain an analysis of the environmental impacts of renewing a license, the environmental impacts of alternatives, and mitigation alternatives. In preparing the analysis of environmental impacts contained in the environmental report, the applicant should refer to the data provided in appendix B to 10 CFR part 51, which has been added to NRC's regulations as part of this rulemaking. The applicant is not required to provide an analysis in the environmental report of those issues identified as Category 1 issues in Table B–1 in Appendix B. For those issues identified as Category 2 in Table B–1, the applicant must provide a specified additional analysis beyond that contained in Table B–1. In this final rule, 10 CFR 51.53(c)(3)(ii) specifies the subject areas of the analysis that must be addressed for the Category 2 issues.

Pursuant to 10 CFR 51.45(c), 10 CFR 51.53(c)(2) requires the applicant to consider possible actions to mitigate the adverse impacts associated with the proposed action. This consideration is limited to designated Category 2 matters. Pursuant to 10 CFR 51.45(d), the environmental report must include a discussion of the status of compliance with applicable Federal, State, and local environmental standards. Also, 10 CFR 51.53(c)(2) specifically excludes from consideration in the environmental report the issues of need for power, the economic costs and benefits of the proposed action, economic costs and benefits of alternatives to the proposed action, or other issues not related to environmental effects of the proposed action and associated alternatives. In addition, the requirements in 10 CFR 51.45 are consistent with the exclusion of economic issues in 10 CFR 51.53(c)(2).

2. Consideration of Alternatives

Pursuant to 10 CFR 51.45(c), 10 CFR 51.53(c)(2) requires the applicant to consider the environmental impacts of alternatives to license renewal in the environmental report. The treatment of alternatives in the environmental report should be limited to the environmental impacts of such alternatives.

The amended regulations do not require a discussion of the economic costs and benefits of these alternatives in the environmental report for the operating license renewal stage except as necessary to determine whether an alternative should be included in the range of alternatives considered or whether certain mitigative actions are appropriate. The analysis should demonstrate consideration of a reasonable set of alternatives to license renewal. In preparing the alternatives analysis, the applicant may consider information regarding alternatives in NUREG–1437, ''Generic Environmental Impact Statement for License Renewal of Nuclear Plants'' (xxxx 1996).

The Commission has developed a new decision standard to be applied in environmental impact statements for license renewal as discussed in Section IV.C.2. The amended regulations for license renewal do not require applicants to apply this decision standard to the information generated in their environmental report (although the applicant is not prohibited from doing so if it desires). However, the NRC staff will use the information contained in the environmental report in preparing the environmental impact statement upon which the Commission will base its final decision.

3. Consideration of Mitigation Alternatives

Consistent with the NRC's current NEPA practice, an applicant must include a consideration of alternatives to mitigate adverse environmental impacts in its environmental report. However, for license renewal, the Commission has generically considered mitigation for environmental issues associated with renewal and has concluded that no additional site-specific consideration of mitigation is necessary for many issues. The Commission's consideration of mitigation for each issue included identification of current activities that adequately mitigate impacts and evaluation of other mitigation techniques that might or might not be warranted, depending on such factors as the size of the impact and the cost of the technique. The Commission has considered mitigation for all impacts designated as Category 1 in Table B–1. Therefore, a license renewal applicant need not address mitigation for issues so designated.

C. Supplemental Environmental Impact Statement

This amendment also requires that the Commission prepare a supplemental environmental impact statement (SEIS), consistent with 10 CFR 51.20(b)(2). This statement will serve as the Commission's independent analysis of the environmental impacts of license renewal as well as a comparison of these impacts to the environmental impacts of alternatives. This document will also present the preliminary recommendation by the NRC staff regarding the proposed action. Consistent with the revisions to 10 CFR 51.45 and 51.53 discussed above in regard to the applicant's environmental report, this rulemaking revises portions of 10 CFR 51.71 and 51.95 to reflect the Commission's approach to addressing the environmental impacts of license renewal.

The issues of need for power, the economic costs and benefits of the proposed action, and economic costs and benefits of alternatives to the proposed action are specifically excluded from consideration in the supplemental environmental impact statement for license renewal by 10 CFR 51.95(c), except as these costs and benefits are either essential for a determination regarding the inclusion of an alternative in the range of alternatives considered or relevant to mitigation. The supplemental environmental impact statement does not need to discuss issues other than environmental effects of the proposed action and associated alternatives. This rule amends the requirements in 10 CFR 51.71 (d) and (e) so that they are consistent with the exclusion of economic issues in 10 CFR 51.95(c). Additionally, 10 CFR 51.95 has been amended to allow information from previous NRC site-specific environmental reviews, as well as NRC final generic environmental impact statements, to be referenced in supplemental environmental impact statements.

1. Public Scoping and Public Comments on the SEIS

Consistent with NRC's current NEPA practice, the Commission will hold a public meeting in order to inform the local public of the proposed action and receive comments. In addition, the SEIS will be issued in draft for public comment in accordance with 10 CFR 51.91 and 51.93. In both the public scoping process and the public comment process, the Commission will accept comments on all previously analyzed issues and information codified in Table B–1 of appendix B to 10 CFR part 51 and will determine whether these comments provide any information that is new and significant compared with that previously considered in the GEIS. If the comments are determined to provide new and significant information bearing on the previous analysis in the GEIS, these comments will be considered and appropriately factored into the Commission's analysis in the SEIS. Public comments on the site-specific additional information provided by the applicant regarding Category 2 issues will be considered in the SEIS.

2. Commission's Analysis and Preliminary Recommendation

The Commission's draft SEIS will include its analysis of the environmental impacts of the proposed license renewal action and the environmental impacts of the alternatives to the proposed action. With the exception of offsite radiological impacts for collective effects and the disposal of spent fuel and high level waste, the Commission will integrate the codified environmental impacts of license renewal as provided in Table B–1 of appendix B to 10 CFR part 51 (supplemented by the underlying analyses in the GEIS), the appropriate site-specific analyses of Category 2 issues, and any new issues identified during the scoping and public comment process. The results of this integration process will be utilized to arrive at a conclusion regarding the sum of the environmental impacts associated with license renewal. These impacts will then be compared, quantitatively or qualitatively as appropriate, with the environmental impacts of the considered alternatives. The analysis of alternatives in the SEIS will be limited to the environmental impacts of these alternatives and will be prepared in accordance with 10 CFR 51.71 and subpart A of appendix A to 10 CFR part 51. The analysis of impacts of alternatives provided in the GEIS may be referenced in the SEIS as appropriate. The alternatives discussed in the GEIS include a reasonable range of different methods for power generation. The analysis in the draft SEIS will consider mitigation actions for designated Category 2 matters and will consider the status of compliance with Federal, State, and local environmental requirements as required by 10 CFR 51.71(d). Consistent with 10 CFR 51.71(e), the draft supplemental environmental impact statement must contain a preliminary recommendation regarding license renewal based on consideration of the information on the environmental impacts of license renewal and of alternatives contained in the SEIS. In order to reach its recommendation, the NRC staff must determine whether the adverse environmental impacts of license renewal are so great that preserving the option of license renewal for energy planning decisionmakers would be unreasonable. This decision standard is contained in 10 CFR 51.95(c)(4).

3. Final Supplemental Environmental Impact Statement

The Commission will issue a final supplemental environmental impact statement for a license renewal application in accordance with 10 CFR 51.91 and 51.93 after considering the public comments related to new issues identified from the scoping and public comment process, Category 2 issues, and any new and significant information regarding previously analyzed and codified Category 1 issues. Pursuant to 10 CFR 51.102 and 51.103, the Commission will provide a record of its decision regarding the environmental impacts of the proposed action. In making a final decision, the Commission must determine whether the adverse environmental impacts of license renewal (when compared with the environmental impacts of other energy generating alternatives) are so great that preserving the option of license renewal for energy planning decisionmakers would be unreasonable.

D. NEPA Review for Activities Outside NRC License Renewal Approval Scope

The Commission wishes to clarify that any activity that requires NRC approval and is not specifically required for NRC's action regarding management of the effects of aging on certain passive long-lived structures and components in the period of extended operation must be subject to a separate NEPA review. The actions subject to NRC approval for license renewal are limited to continued operation consistent with the plant design and operating conditions for the current operating license and to the performance of specific activities and programs necessary to manage the effects of aging on the passive, long-lived structures and components identified in accordance with 10 CFR part 54. Accordingly, the GEIS does not serve as the NEPA review for other activities or programs outside the scope of NRC's part 54 license renewal review. The separate NEPA review must be prepared regardless of whether the action is necessary as a consequence of receiving a renewed license, even if the activity were specifically addressed in the GEIS. For example, the environmental impacts of spent fuel pool expansion are addressed in the GEIS in the context of the environmental consequences of approving a renewed operating license, rather than in the context of a specific application to expand spent fuel pool capacity, which would require a separate NEPA review.

These separate NEPA reviews may reference and otherwise use applicable environmental information contained in the GEIS. For example, an EA prepared for a separate spent fuel pool expansion request may use the information in the GEIS to support a finding of no significant impact.

V. Availability of Documents

The principal documents supporting this supplementary information are as follows:

(1) NUREG–1437, ''Generic Environmental Impact Statement for License Renewal of Nuclear Plants'' (May 1996).

(2) NUREG–1529, ''Public Comments on the Proposed 10 CFR part 51 Rule for Renewal of Nuclear Power Plant Operating Licenses and Supporting Documents; Review of Concerns and NRC Staff Response'' (May 1996).

(3) NUREG–1440, ''Regulatory Analysis of Amendments to Regulations Concerning the Environmental Review

for Renewal of Nuclear Power Plant Operating Licenses'' (May 1996).

Copies of all documents cited in the supplementary information are available for inspection and for copying for a fee in the NRC Public Document Room, 2120 L Street NW. (Lower Level), Washington, DC. In addition, copies of NRC final documents cited here may be purchased from the Superintendent of Documents, U.S. Government Printing Office, PO Box 37082, Washington, DC 20013–7082. Copies are also available for purchase from the National Technical Information Service, 5285 Port Royal Road, Springfield, VA 22161.

VI. Submittal of Comments in an Electronic Format

Commenters are encouraged to submit, in addition to the original paper copy, a copy of their letter in an electronic format on IBM PC DOS-compatible 3.5- or 5.25-inch, double-sided, double-density (DS/DD) diskettes. Data files should be provided in Wordperfect 5.1 or later version of Wordperfect. ASCII code is also acceptable or, if formatted text is required, data files should be provided in IBM Revisable-Form Text Document Content Architecture (RFT/DCA) format.

VII. Finding of No Significant Environmental Impact: Availability

The NRC has determined that this final rule is the type of action described as a categorical exclusion in 10 CFR 51.22(c)(3). Therefore, neither an environmental impact statement nor an environmental assessment has been prepared for this regulation. This action is procedural in nature and pertains only to the type of environmental information to be reviewed.

VIII. Paperwork Reduction Act Statement

This final rule amends information collection requirements that are subject to the Paperwork Reduction Act of 1995 (44 U.S.C. 3501 *et seq.*). These requirements were approved by the Office of Management and Budget, approval number 3150–0021.

The public reporting burden for this collection of information is estimated to average 4,200 hours per response, including the time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing the collection of information. Send comments regarding this burden estimate or any other aspect of this collection of information, including suggestions for reducing the burden, to the Information and Records Management Branch (T–6F33), U.S. Nuclear Regulatory Commission, Washington, DC 20555–0001, or by Internet electronic mail at BJS1@nrc.gov; and to the Desk Officer, Office of Information and Regulatory Affairs, NEOB–10202 (3150–0021), Office of Management and Budget, Washington, DC 20503.

Public Protection Notification

The NRC may not conduct or sponsor, and a person is not required to respond to, a collection of information unless it displays a currently valid OMB control number.

IX. Regulatory Analysis

The Commission has prepared a regulatory analysis for this final rule. The analysis examines the costs and benefits of the alternatives considered by the Commission. The two alternatives considered were:

(A) Retaining the existing 10 CFR part 51 review process for license renewal, which requires that all reviews be on a plant-specific basis; and

(B) Amending 10 CFR part 51 to allow a portion of the environmental review to be conducted on a generic basis.

The conclusions of the regulatory analysis show substantial cost savings of alternative (B) over alternative (A). The analysis, NUREG–1440, is available for inspection in the NRC Public Document Room, 2120 L Street NW. (Lower Level), Washington, DC. Copies of the analysis are available as described in Section V.

X. Regulatory Flexibility Act Certification

As required by the Regulatory Flexibility Act of 1980, 5 U.S.C. 605(b), the Commission certifies that this final rule will not have a significant impact on a substantial number of small entities. The final rule states the application procedures and environmental information to be submitted by nuclear power plant licensees to facilitate NRC's obligations under NEPA. Nuclear power plant licensees do not fall within the definition of small businesses as defined in Section 3 of the Small Business Act, 15 U.S.C. 632, or the Commission's Size Standards, April 11, 1995 (60 FR 18344).

XI. Small Business Regulatory Enforcement Fairness Act

In accordance with the Small Business Regulatory Enforcement Fairness Act of 1996, the NRC has determined that this action is not a major rule and has verified this determination with the Office of Information and Regulatory Affairs of OMB.

XII. Backfit Analysis

The NRC has determined that these amendments do not involve any provisions which would impose backfits as defined in 10 CFR 50.109(a)(1); therefore, a backfit analysis need not be prepared.

List of Subjects in 10 CFR Part 51

Administrative practice and procedure, Environmental impact statement, Nuclear materials, Nuclear power plants and reactors, Reporting and recordkeeping requirements.

For the reasons set out in the preamble and under the authority of the Atomic Energy Act of 1954, as amended; the Energy Reorganization Act of 1974, as amended; the National Environmental Policy Act of 1969, as amended; and 5 U.S.C. 552 and 553, the NRC is adopting the following amendments to 10 CFR part 51.

PART 51—ENVIRONMENTAL PROTECTION REGULATIONS FOR DOMESTIC LICENSING AND RELATED REGULATORY FUNCTIONS

1. The authority citation for part 51 continues to read as follows:

Authority: Sec. 161, 68 Stat. 948, as amended, Sec. 1701, 106 Stat. 2951, 2952, 2953 (42 U.S.C. 2201, 2297f); secs. 201, as amended, 202, 88 Stat. 1242, as amended, 1244 (42 U.S.C. 5841, 5842).

Subpart A also issued under National Environmental Policy Act of 1969, secs. 102, 104, 105, 83 Stat. 853–854, as amended (42 U.S.C. 4332, 4334, 4335); and Pub. L. 95–604, Title II, 92 Stat. 3033–3041. Sections 51.20, 51.30, 51.60, 51.61, 51.80, and 51.97 also issued under secs. 135, 141, Pub. L. 97–425, 96 Stat. 2232, 2241, and sec. 148, Pub. L. 100–203, 101 Stat. 1330–223 (42 U.S.C. 10155, 10161, 10168). Section 51.22 also issued under sec. 274, 73 Stat. 688, as amended by 92 Stat. 3036–3038 (42 U.S.C. 2021) and under Nuclear Waste Policy Act of 1982, sec. 121, 96 Stat. 2228 (42 U.S.C. 10141). Sections 51.43, 51.67, and 51.109 also issued under Nuclear Waste Policy Act of 1982, sec. 114(f), 96 Stat. 2216, as amended (42 U.S.C. 10134(f)).

2. Section 51.45 is amended by revising paragraph (c) to read as follows:

§ 51.45 Environmental report.

* * * * *

(c) *Analysis.* The environmental report shall include an analysis that considers and balances the environmental effects of the proposed action, the environmental impacts of alternatives to the proposed action, and alternatives available for reducing or avoiding adverse environmental effects. Except for environmental reports prepared at the license renewal stage pursuant to § 51.53(c), the analysis in the environmental report should also include consideration of the economic, technical, and other benefits and costs of the proposed action and of alternatives. Environmental reports prepared at the license renewal stage pursuant to § 51.53(c) need not discuss the economic or technical benefits and costs of either the proposed action or alternatives except insofar as such benefits and costs are either essential for a determination regarding the inclusion of an alternative in the range of alternatives considered or relevant to mitigation. In addition, environmental reports prepared pursuant to § 51.53(c) need not discuss other issues not related to the environmental effects of the proposed action and alternatives. The analyses for environmental reports shall, to the fullest extent practicable, quantify the various factors considered. To the extent that there are important qualitative considerations or factors that cannot be quantified, those considerations or factors shall be discussed in qualitative terms. The environmental report should contain sufficient data to aid the Commission in its development of an independent analysis.

* * * * *

3. Section 51.53 is revised to read as follows:

§ 51.53 Postconstruction environmental reports.

(a) *General.* Any environmental report prepared under the provisions of this section may incorporate by reference any information contained in a prior environmental report or supplement thereto that relates to the production or utilization facility or any information contained in a final environmental document previously prepared by the NRC staff that relates to the production or utilization facility. Documents that may be referenced include, but are not limited to, the final environmental impact statement; supplements to the final environmental impact statement, including supplements prepared at the license renewal stage; NRC staff-prepared final generic environmental impact statements; and environmental assessments and records of decisions prepared in connection with the construction permit, the operating license, and any license amendment for that facility.

(b) *Operating license stage.* Each applicant for a license to operate a production or utilization facility covered by § 51.20 shall submit with its application the number of copies specified in § 51.55 of a separate document entitled ''Supplement to Applicant's Environmental Report—Operating License Stage,'' which will update ''Applicant's Environmental Report—Construction Permit Stage.'' Unless otherwise required by the Commission, the applicant for an operating license for a nuclear power reactor shall submit this report only in connection with the first licensing action authorizing full-power operation. In this report, the applicant shall discuss the same matters described in §§ 51.45, 51.51, and 51.52, but only to the extent that they differ from those discussed or reflect new information in addition to that discussed in the final environmental impact statement prepared by the Commission in connection with the construction permit. No discussion of need for power, or of alternative energy sources, or of alternative sites for the facility, or of any aspect of the storage of spent fuel for the facility within the scope of the generic determination in § 51.23(a) and in accordance with § 51.23(b) is required in this report.

(c) *Operating license renewal stage.* (1) Each applicant for renewal of a license to operate a nuclear power plant under part 54 of this chapter shall submit with its application the number of copies specified in § 51.55 of a separate document entitled ''Applicant's Environmental Report—Operating License Renewal Stage.''

(2) The report must contain a description of the proposed action, including the applicant's plans to modify the facility or its administrative control procedures as described in accordance with § 54.21 of this chapter. This report must describe in detail the modifications directly affecting the environment or affecting plant effluents that affect the environment. In addition, the applicant shall discuss in this report the environmental impacts of alternatives and any other matters described in § 51.45. The report is not required to include discussion of need for power or the economic costs and economic benefits of the proposed action or of alternatives to the proposed action except insofar as such costs and benefits are either essential for a determination regarding the inclusion of an alternative in the range of alternatives considered or relevant to mitigation. The environmental report need not discuss other issues not related to the environmental effects of the proposed action and the alternatives. In addition, the environmental report need not discuss any aspect of the storage of spent fuel for the facility within the scope of the generic determination in § 51.23(a) and in accordance with § 51.23(b).

(3) For those applicants seeking an initial renewal license and holding either an operating license or construction permit as of June 30, 1995, the environmental report shall include the information required in paragraph (c)(2) of this section subject to the following conditions and considerations:

(i) The environmental report for the operating license renewal stage is not required to contain analyses of the environmental impacts of the license renewal issues identified as Category 1 issues in appendix B to subpart A of this part.

(ii) The environmental report must contain analyses of the environmental impacts of the proposed action, including the impacts of refurbishment activities, if any, associated with license renewal and the impacts of operation during the renewal term, for those issues identified as Category 2 issues in appendix B to subpart A of this part. The required analyses are as follows:

(A) If the applicant's plant utilizes cooling towers or cooling ponds and withdraws make-up water from a river whose annual flow rate is less than 3.15×10^{12} ft^3/year (9×10^{10} m^3/year), an assessment of the impact of the proposed action on the flow of the river and related impacts on instream and riparian ecological communities must be provided. The applicant shall also provide an assessment of the impacts of the withdrawal of water from the river on alluvial aquifers during low flow.

(B) If the applicant's plant utilizes once-through cooling or cooling pond heat dissipation systems, the applicant shall provide a copy of current Clean Water Act 316(b) determinations and, if necessary, a 316(a) variance in accordance with 40 CFR part 125, or equivalent State permits and supporting documentation. If the applicant can not provide these documents, it shall assess the impact of the proposed action on fish and shellfish resources resulting from heat shock and impingement and entrainment.

(C) If the applicant's plant uses Ranney wells or pumps more than 100 gallons of ground water per minute, an assessment of the impact of the proposed action on ground-water use must be provided.

(D) If the applicant's plant is located at an inland site and utilizes cooling ponds, an assessment of the impact of the proposed action on groundwater quality must be provided.

(E) All license renewal applicants shall assess the impact of refurbishment and other license-renewal-related construction activities on important plant and animal habitats. Additionally, the applicant shall assess the impact of the proposed action on threatened or endangered species in accordance with the Endangered Species Act.

(F) If the applicant's plant is located in or near a nonattainment or maintenance area, an assessment of vehicle exhaust emissions anticipated at the time of peak refurbishment workforce must be provided in accordance with the Clean Air Act as amended.

(G) If the applicant's plant uses a cooling pond, lake, or canal or discharges into a river having an annual average flow rate of less than 3.15×10^{12} ft^3/year (9×10^{10} m^3/year), an assessment of the impact of the proposed action on public health from thermophilic organisms in the affected water must be provided.

(H) If the applicant's transmission lines that were constructed for the specific purpose of connecting the plant to the transmission system do not meet the recommendations of the National Electric Safety Code for preventing electric shock from induced currents, an assessment of the impact of the proposed action on the potential shock hazard from the transmission lines must be provided.

(I) An assessment of the impact of the proposed action on housing availability, land-use, and public schools (impacts from refurbishment activities only) within the vicinity of the plant must be provided. Additionally, the applicant shall provide an assessment of the impact of population increases attributable to the proposed project on the public water supply.

(J) All applicants shall assess the impact of the proposed project on local transportation during periods of license renewal refurbishment activities.

(K) All applicants shall assess whether any historic or archaeological properties will be affected by the proposed project.

(L) If the staff has not previously considered severe accident mitigation alternatives for the applicant's plant in an environmental impact statement or related supplement or in an environmental assessment, a consideration of alternatives to mitigate severe accidents must be provided.

(M) The environmental effects of transportation of fuel and waste shall be reviewed in accordance with § 51.52.

(iii) The report must contain a consideration of alternatives for reducing adverse impacts, as required by § 51.45(c), for all Category 2 license renewal issues in Appendix B to Subpart A of this part. No such consideration is required for Category 1 issues in Appendix B to Subpart A of this part.

(iv) The environmental report must contain any new and significant information regarding the environmental impacts of license renewal of which the applicant is aware.

(d) *Postoperating license stage.* Each applicant for a license amendment authorizing the decommissioning of a production or utilization facility covered by § 51.20 and each applicant for a license or license amendment to store spent fuel at a nuclear power plant after expiration of the operating license for the nuclear power plant shall submit with its application the number of copies specified in § 51.55 of a separate document entitled ''Supplement to Applicant's Environmental Report—Post Operating License Stage.'' This supplement will update ''Supplement to Applicant's Environmental Report—Operating License Stage'' and ''Applicant's Environmental Report—Operating License Renewal Stage,'' as appropriate, to reflect any new information or significant environmental change associated with the applicant's proposed decommissioning activities or with the applicant's proposed activities with respect to the planned storage of spent fuel. Unless otherwise required by the Commission, in accordance with the generic determination in § 51.23(a) and the provisions in § 51.23(b), the applicant shall address only the environmental impact of spent fuel storage for the term of the license.

4. In § 51.55, paragraph (a) is revised to read as follows:

§ 51.55 Environmental report—number of copies; distribution.

(a) Each applicant for a license to construct and operate a production or utilization facility covered by paragraphs (b)(1), (b)(2), (b)(3), or (b)(4) of § 51.20, each applicant for renewal of an operating license for a nuclear power plant, each applicant for a license amendment authorizing the decommissioning of a production or utilization facility covered by § 51.20, and each applicant for a license or license amendment to store spent fuel at a nuclear power plant after expiration of the operating license for the nuclear power plant shall submit to the Director of the Office of Nuclear Reactor Regulation or the Director of the Office of Nuclear Material Safety and Safeguards, as appropriate, 41 copies of an environmental report or any supplement to an environmental report. The applicant shall retain an additional 109 copies of the environmental report or any supplement to the environmental report for distribution to parties and Boards in the NRC proceedings; Federal, State, and local officials; and any affected Indian tribes, in accordance with written instructions issued by the Director of the Office of Nuclear Reactor Regulation or the Director of the Office Nuclear Material Safety and Safeguards, as appropriate.

* * * * *

5. In § 51.71, paragraphs (d) and (e) are revised to read as follows:

§ 51.71 Draft environmental impact statement—contents.

* * * * *

(d) *Analysis.* The draft environmental impact statement will include a preliminary analysis that considers and weighs the environmental effects of the proposed action; the environmental impacts of alternatives to the proposed action; and alternatives available for reducing or avoiding adverse environmental effects. Except for supplemental environmental impact statements for the operating license renewal stage prepared pursuant to § 51.95(c), draft environmental impact statements should also include consideration of the economic, technical, and other benefits and costs of the proposed action and alternatives and indicate what other interests and considerations of Federal policy, including factors not related to environmental quality if applicable, are relevant to the consideration of environmental effects of the proposed action identified pursuant to paragraph (a) of this section. Supplemental environmental impact statements prepared at the license renewal stage pursuant to § 51.95(c) need not discuss the economic or technical benefits and costs of either the proposed action or alternatives except insofar as such benefits and costs are either essential for a determination regarding the inclusion of an alternative in the range of alternatives considered or relevant to mitigation. In addition, the supplemental environmental impact statement prepared at the license renewal stage need not discuss other issues not related to the environmental effects of the proposed action and associated alternatives. The draft supplemental environmental impact statement for license renewal prepared pursuant to § 51.95(c) will rely on conclusions as amplified by the supporting information in the GEIS for issues designated as Category 1 in appendix B to subpart A of this part. The draft supplemental environmental impact statement must contain an analysis of those issues identified as Category 2 in appendix B to subpart A of this part that are open for the proposed action. The analysis for all draft environmental impact statements will, to the fullest extent practicable, quantify the various factors considered. To the extent that there are important qualitative considerations or factors that cannot be quantified, these considerations or factors will be discussed in qualitative terms. Due consideration will be given to compliance with environmental quality standards and requirements that have been imposed by Federal, State, regional, and local agencies having responsibility for environmental protection, including applicable zoning and land-use regulations and water pollution limitations or requirements promulgated or imposed pursuant to the Federal Water Pollution Control Act. The environmental impact of the proposed action will be considered in the analysis with respect to matters covered by such standards and requirements irrespective of whether a certification or license from the appropriate authority has been obtained.[3] While satisfaction of Commission standards and criteria pertaining to radiological effects will be necessary to meet the licensing requirements of the Atomic Energy Act, the analysis will, for the purposes of NEPA, consider the radiological effects of the proposed action and alternatives.

(e) *Preliminary recommendation.* The draft environmental impact statement normally will include a preliminary recommendation by the NRC staff respecting the proposed action. This preliminary recommendation will be based on the information and analysis described in paragraphs (a) through (d) of this section and §§ 51.75, 51.76, 51.80, 51.85, and 51.95, as appropriate, and will be reached after considering the environmental effects of the proposed action and reasonable alternatives,[4] and, except for supplemental environmental impact statements for the operating license renewal stage prepared pursuant to § 51.95(c), after weighing the costs and benefits of the proposed action. In lieu of a recommendation, the NRC staff may indicate in the draft statement that two or more alternatives remain under consideration.

[3] Compliance with the environmental quality standards and requirements of the Federal Water Pollution Control Act (imposed by EPA or designated permitting states) is not a substitute for and does not negate the requirement for NRC to weigh all environmental effects of the proposed action, including the degradation, if any, of water quality, and to consider alternatives to the proposed action that are available for reducing adverse effects. Where an environmental assessment of aquatic impact from plant discharges is available from the permitting authority, the NRC will consider the assessment in its determination of the magnitude of environmental impacts for striking an overall cost-benefit balance at the construction permit and operating license stages, and in its determination of whether the adverse environmental impacts of license renewal are so great that preserving the option of license renewal for energy planning decisionmakers would be unreasonable at the license renewal stage. When no such assessment of aquatic impacts is available from the permitting authority, NRC will establish on its own or in conjunction with the permitting authority and other agencies having relevant expertise the magnitude of potential impacts for striking an overall cost-benefit balance for the facility at the construction permit and operating license stages, and in its determination of whether the adverse environmental impacts of license renewal are so great that preserving the option of license renewal for energy planning decisionmakers would be unreasonable at the license renewal stage.

[4] The consideration of reasonable alternatives to a proposed action involving nuclear power reactors (e.g., alternative energy sources) is intended to assist the NRC in meeting its NEPA obligations and does not preclude any State authority from making separate determinations with respect to these alternatives and in no way preempts, displaces, or affects the authority of States or other Federal agencies to address these issues.

§ 51.75 [Amended]

6. In Section 51.75, redesignate footnote 4 as footnote 5.

7. Section 51.95 is revised to read as follows:

§ 51.95 Postconstruction environmental impact statements.

(a) *General.* Any supplement to a final environmental impact statement or any environmental assessment prepared under the provisions of this section may incorporate by reference any information contained in a final environmental document previously prepared by the NRC staff that relates to the same production or utilization facility. Documents that may be referenced include, but are not limited to, the final environmental impact statement; supplements to the final environmental impact statement, including supplements prepared at the operating license stage; NRC staff-prepared final generic environmental impact statements; environmental assessments and records of decisions prepared in connection with the construction permit, the operating license, and any license amendment for that facility. A supplement to a final environmental impact statement will include a request for comments as provided in § 51.73.

(b) *Initial operating license stage.* In connection with the issuance of an operating license for a production or utilization facility, the NRC staff will prepare a supplement to the final environmental impact statement on the construction permit for that facility, which will update the prior environmental review. The supplement will only cover matters that differ from the final environmental impact statement or that reflect significant new information concerning matters discussed in the final environmental impact statement. Unless otherwise determined by the Commission, a supplement on the operation of a nuclear power plant will not include a discussion of need for power, or of alternative energy sources, or of alternative sites, or of any aspect of the storage of spent fuel for the nuclear power plant within the scope of the generic determination in § 51.23(a) and in accordance with § 51.23(b), and will only be prepared in connection with the first licensing action authorizing full-power operation.

(c) *Operating license renewal stage.* In connection with the renewal of an operating license for a nuclear power plant under part 54 of this chapter, the Commission shall prepare a supplement to the Commission's NUREG–1437, ''Generic Environmental Impact Statement for License Renewal of Nuclear Plants'' (xxxx 1996).

(1) The supplemental environmental impact statement for the operating license renewal stage shall address those issues as required by § 51.71. In addition, the NRC staff must comply with 40 CFR 1506.6(b)(3) in conducting the additional scoping process as required by § 51.71(a).

(2) The supplemental environmental impact statement for license renewal is not required to include discussion of need for power or the economic costs and economic benefits of the proposed action or of alternatives to the proposed action except insofar as such benefits and costs are either essential for a determination regarding the inclusion of an alternative in the range of alternatives considered or relevant to mitigation. In addition, the supplemental environmental impact statement prepared at the license renewal stage need not discuss other issues not related to the environmental effects of the proposed action and the alternatives, or any aspect of the storage of spent fuel for the facility within the scope of the generic determination in § 51.23(a) and in accordance with § 51.23(b). The analysis of alternatives in the supplemental environmental impact statement should be limited to the environmental impacts of such alternatives and should otherwise be prepared in accordance with § 51.71 and appendix A to subpart A of this part.

(3) The supplemental environmental impact statement shall be issued as a final impact statement in accordance with §§ 51.91 and 51.93 after considering any significant new information relevant to the proposed

action contained in the supplement or incorporated by reference.

(4) The supplemental environmental impact statement must contain the NRC staff's recommendation regarding the environmental acceptability of the license renewal action. In order to make its recommendation and final conclusion on the proposed action, the NRC staff, adjudicatory officers, and Commission shall integrate the conclusions, as amplified by the supporting information in the generic environmental impact statement for issues designated Category 1 (with the exception of offsite radiological impacts for collective effects and the disposal of spent fuel and high level waste) or resolved Category 2, information developed for those open Category 2 issues applicable to the plant in accordance with § 51.53(c)(3)(ii), and any significant new information. Given this information, the NRC staff, adjudicatory officers, and Commission shall determine whether or not the adverse environmental impacts of license renewal are so great that preserving the option of license renewal for energy planning decisionmakers would be unreasonable.

(d) *Postoperating license stage.* In connection with an amendment to an operating license authorizing the decommissioning of a production or utilization facility covered by § 51.20 or with the issuance, amendment, or renewal of a license to store spent fuel at a nuclear power plant after expiration of the operating license for the nuclear power plant, the NRC staff will prepare a supplemental environmental impact statement for the postoperating license stage or an environmental assessment, as appropriate, which will update the prior environmental review. Unless otherwise required by the Commission, in accordance with the generic determination in § 51.23(a) and the provisions of § 51.23(b), a supplemental environmental impact statement for the postoperating license stage or an environmental assessment, as appropriate, will address the environmental impacts of spent fuel storage only for the term of the license, license amendment, or license renewal applied for.

8. In § 51.103, paragraph (a)(3) is revised and paragraph (a)(5) is added to read as follows:

§ 51.103 Record of decision—General.

(a) * * *

(3) Discuss preferences among alternatives based on relevant factors, including economic and technical considerations where appropriate, the NRC's statutory mission, and any essential considerations of national policy, which were balanced by the Commission in making the decision and state how these considerations entered into the decision.

* * * * *

(5) In making a final decision on a license renewal action pursuant to part 54 of this chapter, the Commission shall determine whether or not the adverse environmental impacts of license renewal are so great that preserving the option of license renewal for energy planning decisionmakers would be unreasonable.

* * * * *

9. Paragraph 4 of appendix A to subpart A of 10 CFR part 51 is revised as follows:

Appendix A to Subpart A—Format for Presentation of Material in Environmental Impact Statements

* * * * *

4. *Purpose of and need for action.* The statement will briefly describe and specify the need for the proposed action. The alternative of no action will be discussed. In the case of nuclear power plant construction or siting, consideration will be given to the potential impact of conservation measures in determining the demand for power and consequent need for additional generating capacity.

* * * * *

10. A new appendix B is added to subpart A of 10 CFR part 51 to read as follows:

Appendix B to Subpart A—Environmental Effect of Renewing the Operating License of a Nuclear Power Plant

The Commission has assessed the environmental impacts associated with granting a renewed operating license for a nuclear power plant to a licensee who holds either an operating license or construction permit as of June 30, 1995. Table B–1 summarizes the Commission's findings on the scope and magnitude of environmental impacts of renewing the operating license for a nuclear power plant as required by section 102(2) of the National Environmental Policy Act of 1969, as amended. Table B–1, subject to an evaluation of those issues identified in Category 2 as requiring further analysis and possible significant new information, represents the analysis of the environmental impacts associated with renewal of any operating license and is to be used in accordance with § 51.95(c). On a 10-year cycle, the Commission intends to review the material in this appendix and update it if necessary. A scoping notice must be published in the Federal Register indicating the results of the NRC's review and inviting public comments and proposals for other areas that should be updated.

TABLE B–1.—SUMMARY OF FINDINGS ON NEPA ISSUES FOR LICENSE RENEWAL OF NUCLEAR POWER PLANTS [1]

Issue	Category [2]	Findings [3]
Surface Water Quality, Hydrology, and Use (for all plants)		
Impacts of refurbishment on surface water quality.	1	SMALL. Impacts are expected to be negligible during refurbishment because best management practices are expected to be employed to control soil erosion and spills.
Impacts of refurbishment on surface water use.	1	SMALL. Water use during refurbishment will not increase appreciably or will be reduced during plant outage.
Altered current patterns at intake and discharge structures.	1	SMALL. Altered current patterns have not been found to be a problem at operating nuclear power plants and are not expected to be a problem during the license renewal term.
Altered salinity gradients	1	SMALL. Salinity gradients have not been found to be a problem at operating nuclear power plants and are not expected to be a problem during the license renewal term.
Altered thermal stratification of lakes.	1	SMALL. Generally, lake stratification has not been found to be a problem at operating nuclear power plants and is not expected to be a problem during the license renewal term.
Temperature effects on sediment transport capacity.	1	SMALL. These effects have not been found to be a problem at operating nuclear power plants and are not expected to be a problem during the license renewal term.
Scouring caused by discharged cooling water.	1	SMALL. Scouring has not been found to be a problem at most operating nuclear power plants and has caused only localized effects at a few plants. It is not expected to be a problem during the license renewal term.
Eutrophication	1	SMALL. Eutrophication has not been found to be a problem at operating nuclear power plants and is not expected to be a problem during the license renewal term.

TABLE B–1.—SUMMARY OF FINDINGS ON NEPA ISSUES FOR LICENSE RENEWAL OF NUCLEAR POWER PLANTS [1]—Continued

Issue	Category [2]	Findings [3]
Discharge of chlorine or other biocides.	1	SMALL. Effects are not a concern among regulatory and resource agencies, and are not expected to be a problem during the license renewal term.
Discharge of sanitary wastes and minor chemical spills.	1	SMALL. Effects are readily controlled through NPDES permit and periodic modifications, if needed, and are not expected to be a problem during the license renewal term.
Discharge of other metals in waste water.	1	SMALL. These discharges have not been found to be a problem at operating nuclear power plants with cooling-tower-based heat dissipation systems and have been satisfactorily mitigated at other plants. They are not expected to be a problem during the license renewal term.
Water use conflicts (plants with once-through cooling systems).	1	SMALL. These conflicts have not been found to be a problem at operating nuclear power plants with once-through heat dissipation systems.
Water use conflicts (plants with cooling ponds or cooling towers using make-up water from a small river with low flow).	2	SMALL OR MODERATE. The issue has been a concern at nuclear power plants with cooling ponds and at plants with cooling towers. Impacts on instream and riparian communities near these plants could be of moderate significance in some situations. See § 51.53(c)(3)(ii)(A).
Aquatic Ecology (for all plants)		
Refurbishment	1	SMALL. During plant shutdown and refurbishment there will be negligible effects on aquatic biota because of a reduction of entrainment and impingement of organisms or a reduced release of chemicals.
Accumulation of contaminants in sediments or biota.	1	SMALL. Accumulation of contaminants has been a concern at a few nuclear power plants but has been satisfactorily mitigated by replacing copper alloy condenser tubes with those of another metal. It is not expected to be a problem during the license renewal term.
Entrainment of phytoplankton and zooplankton.	1	SMALL. Entrainment of phytoplankton and zooplankton has not been found to be a problem at operating nuclear power plants and is not expected to be a problem during the license renewal term.
Cold shock	1	SMALL. Cold shock has been satisfactorily mitigated at operating nuclear plants with once-through cooling systems, has not endangered fish populations or been found to be a problem at operating nuclear power plants with cooling towers or cooling ponds, and is not expected to be a problem during the license renewal term.
Thermal plume barrier to migrating fish.	1	SMALL. Thermal plumes have not been found to be a problem at operating nuclear power plants and are not expected to be a problem during the license renewal term.
Distribution of aquatic organisms	1	SMALL. Thermal discharge may have localized effects but is not expected to affect the larger geographical distribution of aquatic organisms.
Premature emergence of aquatic insects.	1	SMALL. Premature emergence has been found to be a localized effect at some operating nuclear power plants but has not been a problem and is not expected to be a problem during the license renewal term.
Gas supersaturation (gas bubble disease).	1	SMALL. Gas supersaturation was a concern at a small number of operating nuclear power plants with once-through cooling systems but has been satisfactorily mitigated. It has not been found to be a problem at operating nuclear power plants with cooling towers or cooling ponds and is not expected to be a problem during the license renewal term.
Low dissolved oxygen in the discharge.	1	SMALL. Low dissolved oxygen has been a concern at one nuclear power plant with a once-through cooling system but has been effectively mitigated. It has not been found to be a problem at operating nuclear power plants with cooling towers or cooling ponds and is not expected to be a problem during the license renewal term.
Losses from predation, parasitism, and disease among organisms exposed to sublethal stresses.	1	SMALL. These types of losses have not been found to be a problem at operating nuclear power plants and are not expected to be a problem during the license renewal term.
Stimulation of nuisance organisms (e.g., shipworms).	1	SMALL. Stimulation of nuisance organisms has been satisfactorily mitigated at the single nuclear power plant with a once-through cooling system where previously it was a problem. It has not been found to be a problem at operating nuclear power plants with cooling towers or cooling ponds and is not expected to be a problem during the license renewal term.
Aquatic Ecology (for plants with once-through and cooling pond heat dissipation systems)		
Entrainment of fish and shellfish in early life stages.	2	SMALL, MODERATE, OR LARGE. The impacts of entrainment are small at many plants but may be moderate or even large at a few plants with once-through and cooling-pond cooling systems. Further, ongoing efforts in the vicinity of these plants to restore fish populations may increase the numbers of fish susceptible to intake effects during the license renewal period, such that entrainment studies conducted in support of the original license may no longer be valid. See § 51.53(c)(3)(ii)(B).
Impingement of fish and shellfish	2	SMALL, MODERATE, OR LARGE. The impacts of impingement are small at many plants but may be moderate or even large at a few plants with once-through and cooling-pond cooling systems. See § 51.53(c)(3)(ii)(B).
Heat shock	2	SMALL, MODERATE, OR LARGE. Because of continuing concerns about heat shock and the possible need to modify thermal discharges in response to changing environmental conditions, the impacts may be of moderate or large significance at some plants. See § 51.53(c)(3)(ii)(B).

TABLE B–1.—SUMMARY OF FINDINGS ON NEPA ISSUES FOR LICENSE RENEWAL OF NUCLEAR POWER PLANTS [1]—Continued

Issue	Category [2]	Findings [3]
Aquatic Ecology (for plants with cooling-tower-based heat dissipation systems)		
Entrainment of fish and shellfish in early life stages.	1	SMALL. Entrainment of fish has not been found to be a problem at operating nuclear power plants with this type of cooling system and is not expected to be a problem during the license renewal term.
Impingement of fish and shellfish	1	SMALL. The impingement has not been found to be a problem at operating nuclear power plants with this type of cooling system and is not expected to be a problem during the license renewal term.
Heat shock	1	SMALL. Heat shock has not been found to be a problem at operating nuclear power plants with this type of cooling system and is not expected to be a problem during the license renewal term.
Ground-water Use and Quality		
Impacts of refurbishment on ground-water use and quality.	1	SMALL. Extensive dewatering during the original construction on some sites will not be repeated during refurbishment on any sites. Any plant wastes produced during refurbishment will be handled in the same manner as in current operating practices and are not expected to be a problem during the license renewal term.
Ground-water use conflicts (potable and service water; plants that use <100 gpm).	1	SMALL. Plants using less than 100 gpm are not expected to cause any ground-water use conflicts.
Ground-water use conflicts (potable and service water, and dewatering; plants that use >100 gpm).	2	SMALL, MODERATE, OR LARGE. Plants that use more than 100 gpm may cause ground-water use conflicts with nearby ground-water users. See § 51.53(c)(3)(ii)(C).
Ground-water use conflicts (plants using cooling towers withdrawing make-up water from a small river).	2	SMALL, MODERATE, OR LARGE. Water use conflicts may result from surface water withdrawals from small water bodies during low flow conditions which may affect aquifer recharge, especially if other ground-water or upstream surface water users come on line before the time of license renewal. See § 51.53(c)(3)(ii)(A).
Terrestrial Resources		
Refurbishment impacts	2	SMALL, MODERATE, OR LARGE. Refurbishment impacts are insignificant if no loss of important plant and animal habitat occurs. However, it cannot be known whether important plant and animal communities may be affected until the specific proposal is presented with the license renewal application. See § 51.53(c)(3)(ii)(E).
Cooling tower impacts on crops and ornamental vegetation.	1	SMALL. Impacts from salt drift, icing, fogging, or increased humidity associated with cooling tower operation have not been found to be a problem at operating nuclear power plants and are not expected to be a problem during the license renewal term.
Cooling tower impacts on native plants.	1	SMALL. Impacts from salt drift, icing, fogging, or increased humidity associated with cooling tower operation have not been found to be a problem at operating nuclear power plants and are not expected to be a problem during the license renewal term.
Bird collisions with cooling towers.	1	SMALL. These collisions have not been found to be a problem at operating nuclear power plants and are not expected to be a problem during the license renewal term.
Cooling pond impacts on terrestrial resources.	1	SMALL. Impacts of cooling ponds on terrestrial ecological resources are considered to be of small significance at all sites.
Power line right-of-way management (cutting and herbicide application).	1	SMALL. The impacts of right-of-way maintenance on wildlife are expected to be of small significance at all sites.
Bird collision with power lines	1	SMALL. Impacts are expected to be of small significance at all sites.
Impacts of electromagnetic fields on flora and fauna (plants, agricultural crops, honeybees, wildlife, livestock).	1	SMALL. No significant impacts of electromagnetic fields on terrestrial flora and fauna have been identified. Such effects are not expected to be a problem during the license renewal term.
Floodplains and wetland on power line right of way.	1	SMALL. Periodic vegetation control is necessary in forested wetlands underneath power lines and can be achieved with minimal damage to the wetland. No significant impact is expected at any nuclear power plant during the license renewal term.
Threatened or Endangered Species (for all plants)		
Threatened or endangered species.	2	SMALL, MODERATE, OR LARGE. Generally, plant refurbishment and continued operation are not expected to adversely affect threatened or endangered species. However, consultation with appropriate agencies would be needed at the time of license renewal to determine whether threatened or endangered species are present and whether they would be adversely affected. See § 51.53(c)(3)(ii)(E).

TABLE B–1.—SUMMARY OF FINDINGS ON NEPA ISSUES FOR LICENSE RENEWAL OF NUCLEAR POWER PLANTS [1]—Continued

Issue	Category [2]	Findings [3]
Air Quality		
Air quality during refurbishment (nonattainment and maintenance areas).	2	SMALL, MODERATE, OR LARGE. Air quality impacts from plant refurbishment associated with license renewal are expected to be small. However, vehicle exhaust emissions could be cause for concern at locations in or near nonattainment or maintenance areas. The significance of the potential impact cannot be determined without considering the compliance status of each site and the numbers of workers expected to be employed during the outage. See § 51.53(c)(3)(ii)(F).
Air quality effects of transmission lines.	1	SMALL. Production of ozone and oxides of nitrogen is insignificant and does not contribute measurably to ambient levels of these gases.
Land Use		
Onsite land use	1	SMALL. Projected onsite land use changes required during refurbishment and the renewal period would be a small fraction of any nuclear power plant site and would involve land that is controlled by the applicant.
Power line right of way	1	SMALL. Ongoing use of power line right of ways would continue with no change in restrictions. The effects of these restrictions are of small significance.
Human Health		
Radiation exposures to the public during refurbishment.	1	SMALL. During refurbishment, the gaseous effluents would result in doses that are similar to those from current operation. Applicable regulatory dose limits to the public are not expected to be exceeded.
Occupational radiation exposures during refurbishment.	1	SMALL. Occupational doses from refurbishment are expected to be within the range of annual average collective doses experienced for pressurized-water reactors and boiling-water reactors. Occupational mortality risk from all causes including radiation is in the mid-range for industrial settings.
Microbiological organisms (occupational health).	1	SMALL. Occupational health impacts are expected to be controlled by continued application of accepted industrial hygiene practices to minimize worker exposures.
Microbiological organisms (public health) (plants using lakes or canals, or cooling towers or cooling ponds that discharge to a small river).	2	SMALL, MODERATE, OR LARGE. These organisms are not expected to be a problem at most operating plants except possibly at plants using cooling ponds, lakes, or canals that discharge to small rivers. Without site-specific data, it is not possible to predict the effects generically. See § 51.53(c)(3)(ii)(G).
Noise	1	SMALL. Noise has not been found to be a problem at operating plants and is not expected to be a problem at any plant during the license renewal term.
Electromagnetic fields, acute effects (electric shock).	2	SMALL, MODERATE, OR LARGE. Electrical shock resulting from direct access to energized conductors or from induced charges in metallic structures have not been found to be a problem at most operating plants and generally are not expected to be a problem during the license renewal term. However, site-specific review is required to determine the significance of the electric shock potential at the site. See § 51.53(c)(3)(ii)(H).
Electromagnetic fields, chronic effects [5].	NA [4]	UNCERTAIN. Biological and physical studies of 60–Hz electromagnetic fields have not found consistent evidence linking harmful effects with field exposures. However, because the state of the science is currently inadequate, no generic conclusion on human health impacts is possible.[5]
Radiation exposures to public (license renewal term).	1	SMALL. Radiation doses to the public will continue at current levels associated with normal operations.
Occupational radiation exposures (license renewal term).	1	SMALL. Projected maximum occupational doses during the license renewal term are within the range of doses experienced during normal operations and normal maintenance outages, and would be well below regulatory limits.
Socioeconomics		
Housing impacts	2	SMALL, MODERATE, OR LARGE. Housing impacts are expected to be of small significance at plants located in a medium or high population area and not in an area where growth control measures that limit housing development are in effect. Moderate or large housing impacts of the workforce associated with refurbishment may be associated with plants located in sparsely populated areas or in areas with growth control measures that limit housing development. See § 51.53(c)(3)(ii)(I).
Public services: public safety, social services, and tourism and recreation.	1	SMALL. Impacts to public safety, social services, and tourism and recreation are expected to be of small significance at all sites.
Public services: public utilities	2	SMALL OR MODERATE. An increased problem with water shortages at some sites may lead to impacts of moderate significance on public water supply availability. See § 51.53(c)(3)(ii)(I).
Public services, education (refurbishment).	2	SMALL, MODERATE, OR LARGE. Most sites would experience impacts of small significance but larger impacts are possible depending on site- and project-specific factors. See § 51.53(c)(3)(ii)(I).

TABLE B–1.—SUMMARY OF FINDINGS ON NEPA ISSUES FOR LICENSE RENEWAL OF NUCLEAR POWER PLANTS [1]—Continued

Issue	Category [2]	Findings [3]
Public services, education (license renewal term).	1	SMALL. Only impacts of small significance are expected.
Offsite land use (refurbishment)	2	SMALL OR MODERATE. Impacts may be of moderate significance at plants in low population areas. See § 51.53(c)(3)(ii)(I).
Offsite land use (license renewal term).	2	SMALL, MODERATE, OR LARGE. Significant changes in land use may be associated with population and tax revenue changes resulting from license renewal. See § 51.53(c)(3)(ii)(I).
Public services, Transportation	2	SMALL, MODERATE, OR LARGE. Transportation impacts are generally expected to be of small significance. However, the increase in traffic associated with the additional workers and the local road and traffic control conditions may lead to impacts of moderate or large significance at some sites. See § 51.53(c)(3)(ii)(J).
Historic and archaeological resources.	2	SMALL, MODERATE, OR LARGE. Generally, plant refurbishment and continued operation are expected to have no more than small adverse impacts on historic and archaeological resources. However, the National Historic Preservation Act requires the Federal agency to consult with the State Historic Preservation Officer to determine whether there are properties present that require protection. See § 51.53(c)(3)(ii)(K).
Aesthetic impacts (refurbishment).	1	SMALL. No significant impacts are expected during refurbishment.
Aesthetic impacts (license renewal term).	1	SMALL. No significant impacts are expected during the license renewal term.
Aesthetic impacts of transmission lines (license renewal term).	1	SMALL. No significant impacts are expected during the license renewal term.
Postulated Accidents		
Design basis accidents	1	SMALL. The NRC staff has concluded that the environmental impacts of design basis accidents are of small significance for all plants.
Severe accidents	2	SMALL. The probability weighted consequences of atmospheric releases, fallout onto open bodies of water, releases to ground water, and societal and economic impacts from severe accidents are small for all plants. However, alternatives to mitigate severe accidents must be considered for all plants that have not considered such alternatives. See § 51.53(c)(3)(ii)(L).
Uranium Fuel Cycle and Waste Management		
Offsite radiological impacts (individual effects from other than the disposal of spent fuel and high level waste).	1	SMALL. Off-site impacts of the uranium fuel cycle have been considered by the Commission in Table S–3 of this part. Based on information in the GEIS, impacts on individuals from radioactive gaseous and liquid releases including radon-222 and technetium-99 are small.
Offsite radiological impacts (collective effects).	1	The 100 year environmental dose commitment to the U.S. population from the fuel cycle, high level waste and spent fuel disposal is calculated to be about 14,800 person rem, or 12 cancer fatalities, for each additional 20 year power reactor operating term. Much of this, especially the contribution of radon releases from mines and tailing piles, consists of tiny doses summed over large populations. This same dose calculation can theoretically be extended to include many tiny doses over additional thousands of years as well as doses outside the U.S. The result of such a calculation would be thousands of cancer fatalities from the fuel cycle, but this result assumes that even tiny doses have some statistical adverse health effect which will not ever be mitigated (for example, no cancer cure in the next thousand years), and that these does projection over thousands of years are meaningful. However these assumptions are questionable. In particular, science cannot rule out the possibility that there will be no cancer fatalities from these tiny doses. For perspective, the doses are very small fractions of regulatory limits, and even smaller fractions of natural background exposure to the same populations. Nevertheless, despite all the uncertainty, some judgement as to the regulatory NEPA implications of these matters should be made and it makes no sense to repeat the same judgement in every case. Even taking the uncertainties into account, the Commission concludes that these impacts are acceptable in that these impacts would not be sufficiently large to require the NEPA conclusion, for any plant, that the option of extended operation under 10 CFR Part 54 should be eliminated. Accordingly, while the Commission has not assigned a single level of significance for the collective effects of the fuel cycle, this issue is considered Category 1.

TABLE B–1.—SUMMARY OF FINDINGS ON NEPA ISSUES FOR LICENSE RENEWAL OF NUCLEAR POWER PLANTS [1]—Continued

Issue	Category [2]	Findings [3]
Offsite radiological impacts (spent fuel and high level waste disposal).	1	For the high level waste and spent fuel disposal component of the fuel cycle, there are no current regulatory limits for offsite releases of radionuclides for the current candidate repository site. However, if we assume that limits are developed along the lines of the 1995 National Academy of Sciences (NAS) report, ''Technical Bases for Yucca Mountain Standards,'' and that in accordance with the Commission's Waste Confidence Decision, 10 CFR 51.23, a repository can and likely will be developed at some site which will comply with such limits, peak doses to virtually all individuals will be 100 millirem per year or less. However, while the Commission has reasonable confidence that these assumptions will prove correct, there is considerable uncertainty since the limits are yet to be developed, no repository application has been completed or reviewed, and uncertainty is inherent in the models used to evaluate possible pathways to the human environment. The NAS report indicated that 100 millirem per year should be considered as a starting point for limits for individual doses, but notes that some measure of consensus exists among national and international bodies that the limits should be a fraction of the 100 millirem per year. The lifetime individual risk from 100 millirem annual dose limit is about 310^{-3}. Estimating cumulative doses to populations over thousands of years is more problematic. The likelihood and consequences of events that could seriously compromise the integrity of a deep geologic repository were evaluated by the Department of Energy in the ''Final Environmental Impact Statement: Management of Commercially Generated Radioactive Waste,'' October 1980. The evaluation estimated the 70-year whole-body dose commitment to the maximum individual and to the regional population resulting from several modes of breaching a reference repository in the year of closure, after 1,000 years, after 100,000 years, and after 100,000,000 years. Subsequently, the NRC and other federal agencies have expended considerable effort to develop models for the design and for the licensing of a high level waste repository, especially for the candidate repository at Yucca Mountain. More meaningful estimates of doses to population may be possible in the future as more is understood about the performance of the proposed Yucca Mountain repository. Such estimates would involve very great uncertainty, especially with respect to cumulative population doses over thousands of years. The standard proposed by the NAS is a limit on maximum individual dose. The relationship of potential new regulatory requirements, based on the NAS report, and cumulative population impacts has not been determined, although the report articulates the view that protection of individuals will adequately protect the population for a repository at Yucca Mountain. However, EPA's generic repository standards in 40 CFR part 191 generally provide an indication of the order of magnitude of cumulative risk to population that could result from the licensing of a Yucca Mountain repository, assuming the ultimate standards will be within the range of standards now under consideration. The standards in 40 CFR part 191 protect the population by imposing ''containment requirements'' that limit the cumulative amount of radioactive material released over 10,000 years. The cumulative release limits are based on EPA's population impact goal of 1,000 premature cancer deaths world-wide for a 100,000 metric tonne (MTHM) repository. Nevertheless, despite all the uncertainty, some judgement as to the regulatory NEPA implications of these matters should be made and it makes no sense to repeat the same judgement in every case. Even taking the uncertainties into account, the Commission concludes that these impacts are acceptable in that these impacts would not be sufficiently large to require the NEPA conclusion, for any plant, that the option of extended operation under 10 CFR part 54 should be eliminated. Accordingly, while the Commission has not assigned a single level of significance for the impacts of spent fuel and high level waste disposal, this issue is considered Category 1.
Nonradiological impacts of the uranium fuel cycle.	1	SMALL. The nonradiological impacts of the uranium fuel cycle resulting from the renewal of an operating license for any plant are found to be small.
Low-level waste storage and disposal.	1	SMALL. The comprehensive regulatory controls that are in place and the low public doses being achieved at reactors ensure that the radiological impacts to the environment will remain small during the term of a renewed license. The maximum additional on-site land that may be required for low-level waste storage during the term of a renewed license and associated impacts will be small. Nonradiological impacts on air and water will be negligible. The radiological and nonradiological environmental impacts of long-term disposal of low-level waste from any individual plant at licensed sites are small. In addition, the Commission concludes that there is reasonable assurance that sufficient low-level waste disposal capacity will be made available when needed for facilities to be decommissioned consistent with NRC decommissioning requirements.
Mixed waste storage and disposal.	1	SMALL. The comprehensive regulatory controls and the facilities and procedures that are in place ensure proper handling and storage, as well as negligible doses and exposure to toxic materials for the public and the environment at all plants. License renewal will not increase the small, continuing risk to human health and the environment posed by mixed waste at all plants. The radiological and nonradiological environmental impacts of long-term disposal of mixed waste from any individual plant at licensed sites are small. In addition, the Commission concludes that there is reasonable assurance that sufficient mixed waste disposal capacity will be made available when needed for facilities to be decommissioned consistent with NRC decommissioning requirements.

TABLE B–1.—SUMMARY OF FINDINGS ON NEPA ISSUES FOR LICENSE RENEWAL OF NUCLEAR POWER PLANTS [1]—Continued

Issue	Category [2]	Findings [3]
On-site spent fuel	1	SMALL. The expected increase in the volume of spent fuel from an additional 20 years of operation can be safely accommodated on site with small environmental effects through dry or pool storage at all plants if a permanent repository or monitored retrievable storage is not available.
Nonradiological waste	1	SMALL. No changes to generating systems are anticipated for license renewal. Facilities and procedures are in place to ensure continued proper handling and disposal at all plants.
Transportation	2	Table S–4 of this part contains an assessment of impact parameters to be used in evaluating transportation effects in each case. See § 51.53(c)(3)(ii)(M).
Decommissioning		
Radiation doses	1	SMALL. Doses to the public will be well below applicable regulatory standards regardless of which decommissioning method is used. Occupational doses would increase no more than 1 man-rem caused by buildup of long-lived radionuclides during the license renewal term.
Waste management	1	SMALL. Decommissioning at the end of a 20-year license renewal period would generate no more solid wastes than at the end of the current license term. No increase in the quantities of Class C or greater than Class C wastes would be expected.
Air quality	1	SMALL. Air quality impacts of decommissioning are expected to be negligible either at the end of the current operating term or at the end of the license renewal term.
Water quality	1	SMALL. The potential for significant water quality impacts from erosion or spills is no greater whether decommissioning occurs after a 20-year license renewal period or after the original 40-year operation period, and measures are readily available to avoid such impacts.
Ecological resources	1	SMALL. Decommissioning after either the initial operating period or after a 20-year license renewal period is not expected to have any direct ecological impacts.
Socioeconomic impacts	1	SMALL. Decommissioning would have some short-term socioeconomic impacts. The impacts would not be increased by delaying decommissioning until the end of a 20-year relicense period, but they might be decreased by population and economic growth.
Environmental Justice		
Environmental justice [6]	NA [4]	NONE. The need for and the content of an analysis of environmental justice will be addressed in plant-specific reviews. [6]

[1] Data supporting this table are contained in NUREG–1437, ''Generic Environmental Impact Statement for License Renewal of Nuclear Plants'' (xxxx 1996).

[2] The numerical entries in this column are based on the following category definitions:

Category 1: For the issue, the analysis reported in the Generic Environmental Impact Statement has shown:

(1) The environmental impacts associated with the issue have been determined to apply either to all plants or, for some issues, to plants having a specific type of cooling system or other specified plant or site characteristic;

(2) A single significance level (i.e., small, moderate, or large) has been assigned to the impacts (except for collective off site radiological impacts from the fuel cycle and from high level waste and spent fuel disposal); and

(3) Mitigation of adverse impacts associated with the issue has been considered in the analysis, and it has been determined that additional plant-specific mitigation measures are likely not to be sufficiently beneficial to warrant implementation.

The generic analysis of the issue may be adopted in each plant-specific review.

Category 2: For the issue, the analysis reported in the Generic Environmental Impact Statement has shown that one or more of the criteria of Category 1 can not be met, and therefore additional plant-specific review is required.

[3] The impact findings in this column are based on the definitions of three significance levels. Unless the significance level is identified as beneficial, the impact is adverse, or in the case of ''small,'' may be negligible. The definitions of significance follow:

SMALL—For the issue, environmental effects are not detectable or are so minor that they will neither destabilize nor noticeably alter any important attribute of the resource. For the purposes of assessing radiological impacts, the Commission has concluded that those impacts that do not exceed permissible levels in the Commission's regulations are considered small as the term is used in this table.

MODERATE—For the issue, environmental effects are sufficient to alter noticeably, but not to destabilize, important attributes of the resource.

LARGE—For the issue, environmental effects are clearly noticeable and are sufficient to destabilize important attributes of the resource.

For issues where probability is a key consideration (i.e. accident consequences), probability was a factor in determining significance.

[4] NA (not applicable). The categorization and impact finding definitions do not apply to these issues.

[5] Scientific evidence about a chronic biological effect on humans from exposure to transmission line electric and magnetic fields is inconclusive. If the Commission finds that a consensus has been reached by appropriate Federal health agencies that there are adverse health effects, the Commission will require applicants to submit plant-specific reviews of these health effects. Until such time, applicants for license renewal are not required to submit information on this issue.

[6] Environmental Justice was not addressed in NUREG–1437, ''Generic Environmental Impact Statement for License Renewal of Nuclear Plants,'' because guidance for implementing Executive Order 12898 issued on February 11, 1994, was not available prior to completion of NUREG–1437. This issue will be addressed in individual license renewal reviews.

Generic Environmental Impact Statement for License Renewal of Nuclear Plants

Supplement 5

Regarding Turkey Point Units 3 and 4

Final Report

Manuscript Completed: January 2002
Date Published: January 2002

Division of Regulatory Improvement Programs
Office of Nuclear Reactor Regulation
U.S. Nuclear Regulatory Commission
Washington, DC 20555-0001

vicinity of the Turkey Point site, there is a large Hispanic minority population and a smaller Black minority population. In Figure 4-1, there is a large shaded area that covers most of the Florida Everglades in Miami-Dade County. This area, generally lying to the west of the Florida Turnpike, the cities of Homestead, Florida City, and Miami and extending to the boundaries of Broward County on the north and Collier and Monroe counties on the west, is one large census block group. Although the minority population characteristics are similar to other census block groups that are much smaller geographically, this large census block group has a very low population density. It could mistakenly give the impression that there is a large minority population when there is not because of the presence of the Everglades.

Most of the low-income population census block groups (Figure 4-2) in Miami-Dade County are concentrated in central Miami and just outside and to the south of the Miami metropolitan city limits. In Broward County, most of the census block groups are in Fort Lauderdale and along the Miami-Dade/Broward county line.

With the locations of minority and low-income populations identified, the staff proceeded to evaluate whether any of the environmental impacts of the proposed action could affect these populations in a disproportionately high and adverse manner. Based on staff guidance (NRC 1999b), air, land, and water resources within about 80 km (50 mi) of the Turkey Point site were examined. Within that area, a few potential environmental impacts could affect human populations; all of these were considered SMALL for the general population.

The pathways through which the environmental impacts associated with Turkey Point Units 3 and 4 license renewal can affect human populations are discussed in each associated section. The staff evaluated whether minority and low-income populations could be disproportionately affected by these impacts. The staff found no unusual resource dependencies or practices, such as subsistence agriculture, hunting, or fishing, through which the populations could be disproportionately high and adversely affected. In addition, the staff did not identify any location-dependent disproportionately high and adverse impacts affecting these minority and low-income populations. The staff concludes that offsite impacts from Turkey Point Units 3 and 4 to minority and low-income populations would be SMALL, and no special mitigation actions are warranted.

4.5 Groundwater Use and Quality

Category 1 issues in 10 CFR Part 51, Subpart A, Appendix B, Table B-1 that are applicable to Turkey Point Units 3 and 4 groundwater use and quality are listed in Table 4-8. FPL stated in its ER that it is not aware of any new and significant information associated with the renewal of the Turkey Point Units 3 and 4 OLs (FPL 2000a). The staff has not identified any significant new information during its independent review of the FPL ER (FPL 2000a), the staff's site visit, the scoping process, or its evaluation of other available information. Therefore, the staff concludes that there are no impacts related to this issue beyond those discussed in the GEIS. For this

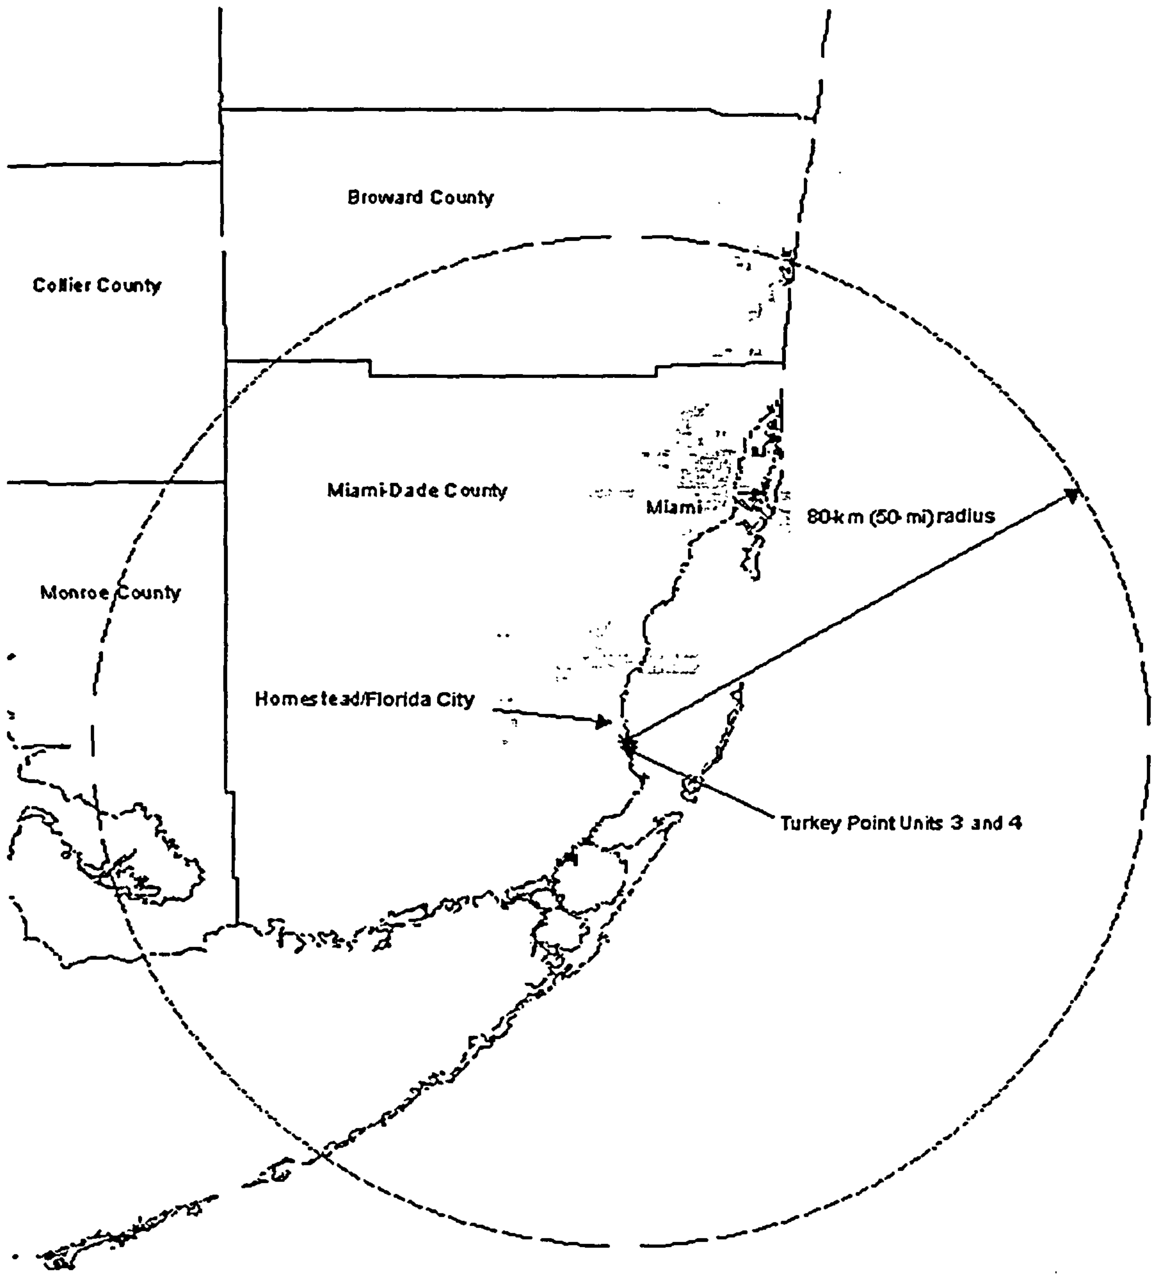

Figure 4-2. Geographic Distribution of Low-Income Populations (shown in shaded areas) Within 80 km (50 mi) of the Turkey Point Site Based on Census Block Group Data[(a)]

(a) Note: Some of the census block groups extend into open water.

Table 4-8. Category 1 Issues Applicable to Groundwater Use and Quality During the Renewal Term

ISSUE—10 CFR Part 51, Subpart A, Appendix B, Table B-1	GEIS Section
GROUNDWATER USE AND QUALITY	
Groundwater use conflicts (potable and service water; plants that use <100 gpm).	4.8.1.1
Groundwater quality degradation (saltwater intrusion)	4.8.2.1
Groundwater quality degradation (cooling ponds in salt marshes)	4.8.3

issue, the GEIS concluded that the impacts are SMALL, and plant-specific mitigation measures are not likely to be sufficiently beneficial to be warranted.

A brief description of the staff's review and the GEIS conclusions, as codified in Table B-1, 10 CFR 51, follows.

- Groundwater use conflicts (potable and service water; plants that use <100 gpm). Based on information in the GEIS, the Commission found that

  "Plants using less than 100 gpm are not expected to cause any ground-water use conflicts."

  As discussed in Section 2.2.2, Turkey Point Units 3 and 4 groundwater use is less than 0.068 m^3/s (100 gpm). The staff has not identified any significant new information during its independent review of the FPL ER, the staff's site visit, the scoping process, or its evaluation of other available information. Therefore, the staff concludes that there are no groundwater use conflicts during the renewal term beyond those discussed in the GEIS.

- Groundwater quality degradation (saltwater intrusion). Based on information in the GEIS, the Commission found that

  "Nuclear power plants do not contribute significantly to saltwater intrusion."

  The staff has not identified any significant new information during its independent review of the FPL ER, the staff's site visit, the scoping process, or its evaluation of other available information. Therefore, the staff concludes that there are no groundwater quality degradation impacts associated with saltwater intrusion during the renewal term beyond those discussed in the GEIS.

- Groundwater quality degradation (cooling ponds in salt marshes). Based on information in the GEIS, the Commission found that

  "Sites with closed-cycle cooling ponds may degrade ground-water quality. Because water in salt marshes is brackish, this is not a concern for plants located in salt marshes."

  The staff has not identified any significant new information during its independent review of the FPL ER, the staff's site visit, the scoping process, or its evaluation of other available information. Therefore, the staff concludes that there are no groundwater quality degradation impacts associated with cooling ponds in salt marshes during the renewal term beyond those discussed in the GEIS.

There are no Category 2 issues related to groundwater use and quality for Turkey Point Units 3 and 4.

4.6 Threatened or Endangered Species

Threatened or endangered species are listed as a Category 2 issue in 10 CFR Part 51, Subpart A, Appendix B, Table B-1. This issue is listed in Table 4-9.

This issue requires consultation with appropriate agencies to determine whether threatened or endangered species are present and whether they would be adversely affected by continued operation of the nuclear plant during the license renewal term. The presence of threatened or endangered species in the vicinity of the Turkey Point site is discussed in Sections 2.2.5 and 2.2.6.

Assessment of potential impacts was initiated by FPL on September 7, 1999 with letters to FWS and National Marine Fisheries Service (NMFS) (Hovey 1999b; 1999c). Assessment of potential impacts on State species of concern was also initiated by FPL on September 7, 1999 with a letter to FFWCC (Hovey 1999d). The three letters requested information on any deficiencies, concerns, or data needed related to the consultation process. In response to FPL's letter, the FWS identified the requirement for consultation by the Federal action agency, identified recent studies by FPL on the American crocodile, described the importance of FPL's conservation activities on American crocodile recovery in south Florida, and provided a table of Federally listed and candidate species and designated critical habitats in south Florida by county (Slack 2000). The NMFS responded to FPL's letter with a conclusion that the proposed action is not p.m. Eastern Standard Time on Tuesday, July 23, 2002. They should be addressed to Director, National Institute of Corrections, 320 First Street, NW., Room 5007, Washington, DC 20534. The NIC application number should be written on the outside of the mail or courier envelope. Applicants are encouraged to use Federal Express, UPS, or similar service to ensure delivery by due date as the mail at the National Institute of Corrections is still being delayed due to recent decontamination procedures implemented after recent events. Applications mailed or express delivery should be sent to: National Institute of Corrections, 320 First Street, NW, Room 5007, Washington, DC 20534, Attn: Director. Hand delivered applications can be brought to 500 First Street, NW, Washignton, DC 20534. The security officer will call our front desk at 307–3106 to come to the security desk for pickup. Faxed or e-mailed applications will not be accepted.

Addresses and Further Information: A copy of this announcement and applications forms may be obtained through the NIC web site: http://www.nicic.org (under ''Additional Opportunities'' click on the title of this cooperative agreement.) Requests for a hard copy of the application forms, and announcement should be directed to Judy Evens, Cooperative Agreement Control Office, National Institute of Corrections, 320 First Street, NW., Room 5007, Washington, DC 20534 or by calling (800) 995–6423, extension 44222 or (202) 307–3106, extension 44222. She can also be contacted by E-mail via *jevens@bop.gov.*

All technical and or programmatic questions concerning this announcement should be directed to BeLinda P. Watson at the above address or by calling (800) 995–6423, extension 30483 or (202) 353–0483, or by E-mail via *bpwatson@bop.gov.*

Eligible Applicants: An eligible applicant is any state or general unit of local government, private agency, educational institution, organization, individuals or team with expertise in requested areas.

Review Considerations: Applications received under this announcement will be subjected to a 3 to 5 person Peer Review Process.

Number of Awards: One (1).

NIC Application Number: 021P11. This number should appear as a reference line in the cover letter and also in box 11 of Standard Form 424 and outside the envelope in which the application is sent.

Executive Order 12372: This program is not subject to the provisions of Executive Order 12372.

The Catalog of Federal Domestic Assistance number is 16.601: Corrections—Training and Staff Development.

Dated: June 7, 2002.

Larry Solomon,

Deputy Director, National Institute of Corrections.

BILLING CODE 4410–36–M

DEPARTMENT OF LABOR

Occupational Safety and Health Administration

Susan Harwood Training Grant Program, FY 2002 Budget; Revised Notice

AGENCY: Occupational Safety and Health Administration (OSHA), Labor.

ACTION: Extension of grant application deadline.

SUMMARY: This notice extends the Susan Harwood Training Grant Program application deadline from June 21, 2002, to July 5, 2002.

The notice of availability of funds and request for grant applications was originally published in the **Federal Register**, 67 FR 36024, May 22, 2002. Organizations interested in submitting a grant application should refer to the May 22 **Federal Register** notice which describes the scope of the grant program and provides information about how to get detailed grant application instructions. Applications should not be submitted without the applicant first obtaining detailed grant application instructions.

DATES: Grant application deadline is Friday, July 5, 2002. Grant applications must be received in the Des Plaines, Illinois, office by 4:30 p.m. Central Time, Friday, July 5, 2002.

ADDRESSES: Submit one signed original and three copies of each grant application to the attention of Grants Officer, U. S. Department of Labor, OSHA Office of Training and Education, Division of Training and Educational Programs, 1555 Times Drive, Des Plaines, Illinois 60018.

FOR FURTHER INFORMATION CONTACT: Ernest Thompson, Chief, Division of Training and Educational Programs, or Cynthia Bencheck, Program Analyst, OSHA Office of Training and Education, 1555 Times Drive, Des Plaines, Illinois 60018, telephone (847) 297–4810. This is not a toll-free number. E-mail *cindy.bencheck@osha.gov.*

The Occupational Safety and Health Act of 1970 and the Departments of Labor, Health and Human Services, and Education, and Related Agencies Appropriation Act, Pub. L. 107–116, authorize this program.

Signed at Washington, DC, this 7th day of June 2002.

John L. Henshaw,

Assistant Secretary of Labor.

[FR Doc. 02–14953 Filed 6–12–02; 8:45 am]

BILLING CODE 4510–26–P

NUCLEAR REGULATORY COMMISSION

[Docket Nos. 50–250 and 50–251]

Florida Power and Light Company, Turkey Point Nuclear Generating Units Nos. 3 and 4; Notice of Issuance of Renewed Facility Operating Licenses Nos. DPR–31 and DPR–41 for an Additional 20-Year Period

Notice is hereby given that the U.S. Nuclear Regulatory Commission (the Commission) has issued Renewed Facility Operating Licenses Nos. DPR–31 and DPR–41 to Florida Power and Light Company (the licensee), the operator of the Turkey Point Nuclear Generating Units Nos. 3 and 4 (Turkey Point Units 3 and 4). Renewed Facility Operating License No. DPR–31 authorizes operation of the Turkey Point Unit 3, by the licensee at reactor core power levels not in excess of 2300 megawatts thermal in accordance with the provisions of the Unit 3 renewed license and its Technical Specifications. Renewed Facility Operating License No. DPR–41 authorizes operation of the Turkey Point Unit 4, by the licensee at reactor core power levels not in excess of 2300 megawatts thermal in accordance with the provisions of the Unit 4 renewed license and its Technical Specifications.

The Turkey Point Units 3 and 4 are pressurized water nuclear reactors located in Miami-Dade County east of Florida City, Florida.

The application for the renewed licenses complied with the standards and requirements of the Atomic Energy Act of 1954, as amended (the Act), and the Commission's regulations. The Commission has made appropriate findings as required by the Act and the Commission's regulations in 10 CFR chapter I, which are set forth in each license. Prior public notice of the action involving the proposed issuance of these renewed licenses and of an opportunity for a hearing regarding the proposed issuance of these renewed licenses was published in the **Federal Register** on October 12, 2000 (65 FR 60693).

For further details with respect to this action, see (1) the Florida Power and Light Company's License Renewal Application for Turkey Point, Units 3 and 4, dated September 8, 2000, as supplemented by letters dated January 19, February 8, February 16, February 26, March 22 (two letters), March 30 (four letters), April 19 (three letters), May 3, May 11 (two letters), May 29 (two letters), June 25, July 18, August 13, November 1, November 7, and December 17, 2001, and April 19, 2002; (2) the Commission's Safety Evaluation Report, dated February 27, 2001, and April 2002 (NUREG–1759), and Supplement 1 thereto, dated May 2002; (3) the licensee's updated final safety analysis report; and (4) the Commission's Final Environmental Impact Statement (NUREG–1437, Supplement 5), dated January 2002. These documents are available at the NRC's Public Document Room, at One White Flint North, 11555 Rockville Pike, first floor, Rockville, Maryland 20852, and can be viewed from the NRC Public Electronic Reading Room at *http://www.nrc.gov/NRC/ADAMS/index.html.*

Copies of Renewed Facility Operating Licenses Nos. DPR–31 and DPR–41 may be obtained by writing to U.S. Nuclear Regulatory Commission, Washington, DC 20555–0001, Attention: Director, Division of Regulatory Improvement Programs. Copies of the Safety Evaluation Report (NUREG–1759), and Supplement 1 thereto, and the Final Environmental Impact Statement (NUREG–1437, Supplement 5) may be purchased from the National Technical Information Service, Springfield, Virginia 22161–0002 at 1–800–553–6847, (*http://www.ntis.gov*), or the Superintendent of Documents, U.S. Government Printing Office, P.O. Box 371954, Pittsburgh, PA 15250–7954 at 202–512–1800, (*http://www.access.gpo.gov/su_docs*). All orders should clearly identify the NRC publication number and the requestor's Government Printing Office deposit account number or VISA or MasterCard number and expiration date.

Dated at Rockville, Maryland, this 6th day of June, 2002.

For the Nuclear Regulatory Commission.

Rajendar Auluck,

Senior Project Manager, License Renewal and Environmental Impacts Program, Division of Regulatory Improvement Programs, Office of Nuclear Reactor Regulation.

BILLING CODE 7590–01–P

OFFICE OF MANAGEMENT AND BUDGET

Guidelines for Ensuring and Maximizing the Quality, Objectivity, Utility, and Integrity of Information Disseminated by the Office of Management and Budget

AGENCY: Office of Management and Budget.

ACTION: Notice of guidelines and request for comments.

SUMMARY: The Office of Management and Budget (OMB) is extending the comment period regarding its draft Information Quality Guidelines from June 14, 2002, to July 1, 2002. OMB is also announcing an extension of the date by which agencies have to submit their draft final information quality guidelines to OMB from no later than July 1, 2002, to no later than August 1, 2002. OMB encourages agencies to use thus extra time to provide the public with additional time to comment on their draft guidelines.

DATES: Written comments regarding OMB's draft Information Quality Guidelines are due by July 1, 2002.

ADDRESSES: Please submit comments to Jefferson B. Hill of the Office of Information and Regulatory Affairs, Office of Management and Budget, Washington, DC 20503. Comments can also be e-mailed to *informationquality@omb.eop.gov.*

FOR FURTHER INFORMATION CONTACT: Jefferson B. Hill, Office of Information and Regulatory Affairs, Office of Management and Budget, Washington, DC 20503. Telephone: (202) 395–3176.

SUPPLEMENTARY INFORMATION: On May 1, 2002 (67 FR 21779), OMB announced it was seeking comments on its draft Information Quality Guidelines by June 14, 2002. OMB is now extending that comment period to July 1, 2002. These Information Quality Guidelines describe OMB's pre-dissemination information quality control and an administrative mechanism for requests for correction of information publicly disseminated by OMB. The draft Information Quality Guidelines are posted on OMB's Web site, *http://www.whitehouse.gov/omb/inforeg/index.html.*

On January 3, 2002 (67 FR 369), with a correction published on February 22, 2002 (67 FR 8452), OMB published government-wide Guidelines for Ensuring and Maximizing the Quality, Objectivity, Utility, and Integrity of Information Disseminated by Federal Agencies. Paragraph IV.5 of these Guidelines calls upon each agency Ano later than July 1, 2002,'' to submit the agency's draft final information quality guidelines to OMB for review regarding the consistency of its guidelines with OMB's January 3 government-wide Guidelines. OMB is extending this deadline to no later than August 1, 2002.

This extension of the July 1 deadline to August 1 provides agencies additional time to seek public comment on their proposed information quality guidelines, and to reconsider their draft guidelines in light of the public comments they do receive.

Dated: June 6, 2002.

John D. Graham,

Administrator, Office of Information and Regulatory Affairs.

BILLING CODE 3110–01–P

SECURITIES AND EXCHANGE COMMISSION

[Rel. No. IC–25606 ; 812–12766]

Touchstone Investment Trust, et al.; Notice of Application

June 6, 2002.

AGENCY: Securities and Exchange Commission (''Commission'').

ACTION: Notice of application for an order under section 6(c) of the Investment Company Act of 1940 (the ''Act'') for an exemption from section 15(a) of the Act and rule 18f-2 under the Act.

Summary of Application: Applicants request an order that would permit them to enter into and materially amend subadvisory agreements without shareholder approval. *Applicants:* Touchstone Investment Trust (''TINT''), Touchstone Strategic Trust (''TST''), Touchstone Tax-Free Trust (''TTFT'') and Touchstone Variable Series Trust (''TVST'') (TINT, TST, TTFT and TVST each a ''Trust'', and collectively, the ''Trusts'') and Touchstone Advisors, Inc. (the ''Adviser'').

Filing Dates: The application was filed on January 29, 2002 and amended on June 5, 2002.

Hearing or Notification of Hearing: An order granting the requested relief will be issued unless the Commission orders a hearing. Interested persons may request a hearing by writing to the Commission's Secretary and serving applicants with a copy of the request, personally or by mail. Hearing requests should be received by the Commission by 5:30 p.m. on July 1, 2002 and should be accompanied by proof of service on applicants, in the form of an affidavit or, for lawyers, a certificate of service.

Proposed Rules

NUCLEAR REGULATORY COMMISSION

10 CFR Part 51

RIN 3150–AI42

[NRC–2008–0608]

Revisions to Environmental Review for Renewal of Nuclear Power Plant Operating Licenses

AGENCY: Nuclear Regulatory Commission.

ACTION: Proposed rule.

SUMMARY: The Nuclear Regulatory Commission (NRC) is proposing to amend its environmental protection regulations by updating the Commission's 1996 findings on the environmental impacts related to the renewal of a nuclear power plant's operating license. The Commission stated that it intends to review the assessment of impacts and update it on a 10-year cycle, if necessary. The proposed rule redefines the number and scope of the environmental impact issues which must be addressed by the Commission in conjunction with the review of applications for license renewal. As part of this 10-year update, the NRC revised the 1996 *Generic Environmental Impact Statement (GEIS) for License Renewal of Nuclear Plants.* Concurrent with the amendments described in this proposed rule, the NRC is publishing for comment the revised GEIS, a revised Regulatory Guide 4.2, Supplement 1, *Preparation of Environmental Reports for Nuclear Power Plant License Renewal Applications,* and a revised Environmental Standard Review Plan, *Standard Review Plans for Environmental Reviews for Nuclear Power Plants, Supplement 1: Operating License Renewal*.

DATES: Comments on this proposed rule, its information collection aspects and its draft regulatory analysis should be submitted by October 14, 2009. Comments on the revised GEIS (NUREG–1437, Revision 1); Regulatory Guide (RG) 4.2, Supplement 1, Revision 1; and Environmental Standard Review Plan (ESRP), Supplement 1, Revision 1 (NUREG–1555), should be submitted by October 14, 2009.

ADDRESSES: Comments may be submitted by letter or electronic mail and will be made available for public inspection. Because comments will not be edited to remove any identification or contact information, such as name, addresses, telephone number, e-mail address, *etc.,* the NRC cautions against including any personal information in your submissions that you do not want to be publicly disclosed. The NRC requests that any party soliciting or aggregating comments received from other persons for submission to the NRC inform these persons that the NRC will not edit their comments to remove any identifying or comment information, and therefore, they should not include any information in their comments that they do not want publicly disclosed.

Federal eRulemaking Portal: Go to *http://www.regulations.gov* and search for documents filed under Docket ID [NRC–2008–0608]. Address questions about NRC dockets to Carol Gallagher, (301) 492–3668; e-mail *Carol.Gallagher@nrc.gov*.

Mail comments to: Secretary, U.S. Nuclear Regulatory Commission, Washington, DC 20555–0001, ATTN: Rulemakings and Adjudications Staff.

E-mail comments to: Rulemaking.Comments@nrc.gov. If you do not receive a reply e-mail confirming that we have received your comments, contact us directly at (301) 415–1677.

Fax comments to: Secretary, U.S. Nuclear Regulatory Commission at (301) 415–1101.

Publicly available documents related to this rulemaking may be accessed using the following methods:

NRC's Public Document Room (PDR): Publicly available documents may be examined at the NRC's PDR, Public File Area O1–F21, One White Flint North, 11555 Rockville Pike, Rockville, Maryland. The PDR reproduction contractor will copy documents for a fee.

NRC's Agencywide Document Access and Management System (ADAMS): Publicly available documents created or received at the NRC are available electronically at the NRC's Electronic Reading Room at *http://www.nrc.gov/reading-rm/adams.html*. From this link, the public can gain entry into ADAMS, which provides text and image files of NRC's public documents. If problems are encountered accessing documents in ADAMS, contact the NRC's PDR reference staff at (800) 397–4209, or (301) 415–4737, or by e-mail to *PDR.resource@nrc.gov*.

FOR FURTHER INFORMATION CONTACT: Mr. Jason Lising, Office of Nuclear Reactor Regulation, U.S. Nuclear Regulatory Commission, Washington, DC 20555–0001; telephone (301) 415–3220; e-mail: *Jason.Lising@nrc.gov*; or Ms. Jennifer Davis, Office of Nuclear Reactor Regulation, U.S. Nuclear Regulatory Commission, Washington, DC 20555–0001; telephone (301) 415–3835; e-mail: *Jennifer.Davis@nrc.gov*.

SUPPLEMENTARY INFORMATION:

I. Introduction

The NRC is proposing to amend Title 10, Part 51, ''Environmental Protection Regulations for Domestic Licensing and Related Regulatory Functions,'' of the *Code of Federal Regulations* (10 CFR Part 51) by updating Table B–1 in Appendix B to Subpart A of ''Summary of Findings on NEPA Issues for License Renewal of Nuclear Power Plants,'' and other related provisions in Part 51 (*e.g.,* § 51.53(c)(3)), which describes the requirements for the license renewal applicant's environmental report. These amendments are based on comments received from the public on NUREG–1437, ''Generic Environmental Impact Statement for License Renewal of Nuclear Plants'' (May 1996), referred to as the ''1996 GEIS,'' and its Addendum 1 (August 1999), a review of plant-specific supplemental environmental impact statements (SEISs) completed since the GEIS was issued in 1996, lessons learned, and knowledge gained from the preparation of these SEISs. The NRC staff has prepared a draft revision to the 1996 GEIS, referred to as the ''revised GEIS,'' which updates the 1996 GEIS based upon consideration of the above described factors. The revised GEIS provides the technical basis for this proposed rule.

In the 1996 GEIS and final rule (61 FR 28467, June 5, 1996), which promulgated Table B–1 and related provisions in Part 51, the Commission determined that certain environmental impacts associated with the renewal of a nuclear power plant operating license were the same or similar for all plants and as such, could be treated on a generic basis. In this way, repetitive reviews of these environmental impacts could be avoided. The Commission based its generic assessment of certain environmental impacts on the following factors:

(1) License renewal will involve nuclear power plants for which the environmental impacts of operation are well understood as a result of lessons learned and knowledge gained from operating experience and completed license renewals.

(2) Activities associated with license renewal are expected to be within this range of operating experience; thus, environmental impacts can be reasonably predicted.

(3) Changes in the environment around nuclear power plants are gradual and predictable.

The 1996 GEIS improved the efficiency of the license renewal process by (1) providing an evaluation of the types of environmental impacts that may occur from renewing commercial nuclear power plant operating licenses; (2) identifying and assessing impacts that are expected to be generic (*i.e.,* the same or similar) at all nuclear plants or plants with specified plant or site characteristics; and (3) defining the number and scope of environmental impacts that need to be addressed in plant-specific SEISs.

As stated in the 1996 final rule that incorporated the findings of the GEIS in Part 51, the NRC recognized that the assessment of the environmental impact issues might change over time, and that additional issues may be identified for consideration. This proposed rule is the result of the 10-year review conducted by the NRC on the information and findings currently presented in Table B–1 of Appendix B to Part 51.

II. Background

Rulemaking History

In 1986, the NRC initiated a program to develop license renewal regulations and associated regulatory guidance in anticipation of applications for the renewal of nuclear power plant operating licenses. A solicitation for comments on the development of a policy statement was published in the **Federal Register** on November 6, 1986 (51 FR 40334). However, the Commission decided to forgo the development of a policy statement and to proceed directly to rulemaking. An advance notice of proposed rulemaking was published on August 29, 1988 (53 FR 32919). Subsequently, in addition to a decision to proceed with the development of license renewal regulations focused on the protection of health and safety, the NRC decided to amend its environmental protection regulations in Part 51.

On October 13, 1989 (54 FR 41980), the NRC published a notice of its intent to hold a public workshop on license renewal on November 13 and 14, 1989. One of the workshop sessions was devoted to the environmental issues associated with license renewal and the possible merit of amending 10 CFR Part 51. The workshop is summarized in NUREG/CP–0108, ''Proceedings of the Public Workshop on Nuclear Power Plant License Renewal'' (April 1990). Responses to the public comments submitted after the workshop are summarized in NUREG–1411, ''Response to Public Comments Resulting from the Public Workshop on Nuclear Power Plant License Renewal'' (July 1990).

On July 23, 1990, the NRC published an advance notice of proposed rulemaking (55 FR 29964) and a notice of intent to prepare a generic environmental impact statement (55 FR 29967). The proposed rule published on September 17, 1991 (56 FR 47016), described the supporting documents that were available and announced a public workshop to be held on November 4 and 5, 1991. The supporting documents for the proposed rule included:

(1) NUREG–1437, ''Draft Generic Environmental Impact Statement for License Renewal of Nuclear Plants'' (August 1991);

(2) NUREG–1440, ''Regulatory Analysis of Proposed Amendments to Regulations Concerning the Environmental Review for Renewal of Nuclear Power Plant Operating Licenses: Draft Report for Comment'' (August 1991);

(3) Draft Regulatory Guide DG–4002, Proposed Supplement 1 to Regulatory Guide 4.2, ''Guidance for the Preparation of Supplemental Environmental Reports in Support of an Application To Renew a Nuclear Power Station Operating License'' (August 1991); and

(4) NUREG–1429, ''Environmental Standard Review Plan for the Review of License Renewal Applications for Nuclear Power Plants: Draft Report for Comment'' (August 1991).

After the comment period, the Commission directed the NRC staff to discuss concerns raised by a number of States that certain features of the proposed rule conflicted with State regulatory authority over the need for power and utility economics. To facilitate these discussions, the NRC developed an options paper entitled, ''Addressing the Concerns of States and Others Regarding the Role of Need for Generating Capacity, Alternative Energy Sources, Utility Costs, and Cost-Benefit Analysis in NRC Environmental Reviews for Relicensing Nuclear Power Plants: An NRC Staff Discussion Paper.'' A **Federal Register** document published on January 18, 1994 (59 FR 2542), announced the scheduling of three regional workshops in February 1994 and the availability of the options paper. A fourth public meeting was held in May 1994 to address proposals that had been submitted after the regional workshops. After consideration of all comments, the NRC issued a supplement to the proposed rule on July 25, 1994 (59 FR 37724), to resolve concerns about the need for power and utility economics.

The NRC published the final rule, ''Environmental Review for Renewal of Nuclear Power Plant Operating Licenses,'' on June 5, 1996 (61 FR 28467). The final rule identified and assessed license renewal environmental impact issues for which a generic analysis had been performed and therefore, did not have to be addressed by a licensee in its environmental report or by the NRC staff in its SEIS. Similarly, the final rule identified and assessed those environmental impacts for which a site-specific analysis was required, both by the licensee in its environmental report and by the NRC staff in its SEIS. The final rule, amongst other amendments to Part 51, added Appendix B to Subpart A of Part 51. Appendix B included Table B–1, which summarizes the findings of NUREG–1437, ''Generic Environmental Impact Statement for License Renewal of Nuclear Plants,'' May 1996 (1996 GEIS).

On December 18, 1996 (61 FR 66537), the NRC amended the final rule published in June 1996 to incorporate minor clarifying and conforming changes and add language omitted from Table B–1. This amendment also analyzed comments received specific to the treatment of low-level waste storage and disposal impacts, the cumulative radiological effects from the uranium fuel cycle, and the effects from the disposal of high-level waste and spent fuel requested in the June 1996 final rule.

On September 3, 1999 (64 FR 48496), the NRC amended the December 1996 final rule to expand the generic findings about the environmental impacts resulting from transportation of fuel and waste to and from a single nuclear power plant. This amendment permitted the NRC to make a generic finding regarding these environmental impacts so that an analysis would not have to be repeated for each license renewal application. The amendment also incorporated rule language consistent with the findings in the 1996 GEIS, which addressed local traffic impacts attributable to continued operations of the nuclear power plant during the license renewal term. The *Generic Environmental Impact Statement for License Renewal of Nuclear Plants: Main Report Section 6.3—''Transportation,'' Table 9.1, ''Summary of Findings on NEPA Issues for License Renewal of Nuclear Power Plants,'' Final Report* (NUREG–1437, Volume 1, Addendum 1), published in August 1999, provides the analysis supporting the amendment.

The current proposed rulemaking began in June 2003 when the NRC issued a notice of intent to update the 1996 GEIS in the **Federal Register** (68 FR 33209). The original comment period began in June 2003 and ended in September 2003. In October 2005 the scoping period was reopened until December 30, 2005 (70 FR 57628).

III. Public Comments

Scoping Process

On June 3, 2003 (68 FR 33209), the NRC solicited public comments which provided the public with an opportunity to participate in the environmental scoping process, as defined in § 51.26. In this notice, the NRC announced the intent to update the 1996 GEIS. The NRC conducted scoping meetings in each of the four NRC regions for the GEIS update. The scoping meetings were held in Atlanta, Georgia (July 8, 2003), Oak Lawn, Illinois (July 10, 2003), Anaheim, California (July 15, 2003), and Boston, Massachusetts (July 17, 2003). The public comment period closed in September 2003 and the project was inactive for the next two years due to limited staff resources and competing demands. On October 3, 2005 (70 FR 57628), the NRC reopened the public comment period and extended it until December 30, 2005. All comments submitted in response to the 2003 scoping request have been considered in preparing the revised GEIS and are publicly available. No comments were received during the 2005 public comment period.

The official transcripts, written comments, and meeting summaries are available electronically for public inspection in the NRC Public Document Room (PDR) or from the Publicly Available Records (PARS) component of NRC's document system under ADAMS Accession Nos. ML032170942, ML032260339, ML032260715, and ML032170934. All comments and suggestions received orally or in writing during the scoping process were considered.

The NRC has prepared a scoping summary report that is available electronically for public inspection in the NRC PDR or from the PARS component of ADAMS under Accession No. ML073450750. Additionally, the scoping summary is located in Appendix A in the revised GEIS.

IV. Discussion

1996 GEIS

Under the NRC's environmental protection regulations in Part 51, which implements Section 102(2) of the National Environmental Policy Act of 1969 (NEPA), renewal of a nuclear power plant operating license requires the preparation of an environmental impact statement (EIS). To help in the preparation of individual operating license renewal EISs, the NRC prepared the 1996 GEIS.

In 1996 and 1999, the Commission amended its environmental protection regulations in Part 51, to improve the efficiency of the environmental review process for applicants seeking to renew a nuclear power plant operating license for up to an additional 20 years. These amendments were based on the analyses reported in the 1996 GEIS.

The 1996 GEIS summarizes the findings of a systematic inquiry into the environmental impacts of continued operations and refurbishment activities associated with license renewal. The NRC identified 92 environmental impact issues. Of the 92 environmental issues analyzed, 69 issues were resolved generically (*i.e.*, Category 1), 21 would require a further plant-specific analysis (*i.e.*, Category 2), and 2 would require a site-specific assessment by the NRC prior to issuance of a renewed license (*i.e.*, uncategorized). As part of a license renewal application, an applicant submits an environmental report to the NRC, and the NRC prepares a plant-specific SEIS to the 1996 GEIS.

The GEIS assigns one of three impact levels (small, moderate, or large) to a given environmental resource (*e.g.*, air, water, or soil). A small impact means that the environmental effects are not detectable, or are so minor that they will neither destabilize, nor noticeably alter, any important attribute of the resource. A moderate impact means that the environmental effects are sufficient to alter noticeably, but not to destabilize, important attributes of the resource. A large impact means that the environmental effects are clearly noticeable, and are sufficient to destabilize important attributes of the resource.

Table B–1 in Appendix B to Part 51, summarizes the findings of the analyses conducted for the 1996 GEIS. Issues and processes common to all nuclear power plants having generic (*i.e.*, the same or similar) environmental impacts are considered Category 1 issues. Category 2 issues are those issues that cannot be generically dispositioned and would require a plant-specific analysis to determine the level of impact.

The 1996 GEIS has been effective in focusing NRC resources on important environmental issues and increased the efficiency of the environmental review process. Currently, 51 nuclear units at 29 plant sites have received renewed licenses.

Revised GEIS

The GEIS revision evaluates the environmental issues and findings of the 1996 GEIS. Lessons learned and knowledge gained during previous license renewal reviews provided a significant source of new information for this assessment. Public comments on previous plant-specific license renewal reviews were analyzed to assess the existing environmental issues and identify new ones. The purpose of this evaluation was to determine if the findings presented in the 1996 GEIS remain valid. In doing so, the NRC considered the need to modify, add to, or delete any of the 92 environmental issues in the 1996 GEIS. After this evaluation, the staff carried forward 78 impact issues for detailed consideration in this GEIS revision. Fifty-eight of these issues were determined to be Category 1 and would not require additional plant-specific analysis. Of the remaining twenty issues, nineteen were determined to be Category 2 and one remained uncategorized. No environmental issues identified in Table B–1 and in the 1996 GEIS were eliminated, but several were combined or regrouped according to similarities.

Environmental issues in the revised GEIS are arranged by resource area. This perspective is a change from the 1996 GEIS in which environmental issues were arranged by power plant systems (*e.g.*, cooling systems, transmission lines) and activities (*e.g.*, refurbishment). The structure of the revised GEIS adopts the NRC's standard format for EISs as established in Part 51, Appendix A to Subpart A of Part 51—''Format for Presentation of Material in Environmental Impact Statements.'' The environmental impacts of license renewal activities, including plant operations and refurbishment along with replacement power alternatives, are addressed in each resource area. The revised GEIS summarizes environmental impact issues under the following resource areas: (1) Land use and visual resources; (2) meteorology, air quality, and noise; (3) geology, seismology, and soils; (4) hydrology (surface water and groundwater); (5) ecology (terrestrial ecology, aquatic ecology, threatened, endangered, and protected species and essential fish habitat); (6) historic and cultural resources; (7) socioeconomics; (8) human health (radiological and nonradiological hazards); (9) environmental justice; and (10) waste management and pollution prevention. The proposed rule revises Table B–1 in Appendix B to Subpart A of Part 51 to follow the organizational format of the revised GEIS.

Environmental impacts of license renewal and the resources that could be affected were identified in the revised GEIS. The general analytical approach for identifying environmental impacts was to (1) describe the nuclear power plant activity that could affect the resource, (2) identify the resource that is affected, (3) evaluate past license renewal reviews and other available information, (4) assess the nature and magnitude of the environmental impact on the affected resource, (5) characterize the significance of the effects, (6) determine whether the results of the analysis apply to all nuclear power plants (whether the impact issue is Category 1 or Category 2), and (7) consider additional mitigation measures for adverse impacts. Identification of environmental impacts (or issues) was conducted in an iterative rather than a stepwise manner. For example, after information was collected and levels of significance were reviewed, impacts were reexamined to determine if any should be removed, added, recombined, or divided.

The Commission would like to emphasize that in complying with the NRC's environmental regulations under § 51.53(c)(3)(iv) applicants are required to provide any new and significant information regarding the environmental impacts of license renewal of which the applicant is aware, even on Category 1 issues. The proposed amendments would not change this requirement.

The revised GEIS retains the 1996 GEIS definitions of a Category 1 and Category 2 issue. The revised GEIS discusses four major types of changes:

(1) *New Category 1 Issue:* These issues would include Category 1 issues not previously listed in the 1996 GEIS or multiple Category 1 issues from the 1996 GEIS that have been combined into a Category 1 issue in the revised GEIS. The applicant does not need to assess this issue in its environmental report. Under § 51.53(c)(3)(iv), however, the applicant is responsible for reporting in the environmental report any ''new and significant information'' of which the applicant is aware. If the applicant is not aware of any new and significant information that would change the conclusion in the revised GEIS, the applicant would be required to state this determination in the environmental report. The NRC has addressed the environmental impacts of these Category 1 issues generically for all plants in the revised GEIS.

(2) *New Category 2 Issue:* These issues would include Category 2 issues not previously listed in the 1996 GEIS or multiple Category 2 issues from the 1996 GEIS that have been combined into a Category 2 issue in the revised GEIS. For each new Category 2 issue, the applicant would have to conduct an assessment of the potential environmental impacts related to that issue and include it in the environmental report. The assessment must include a discussion of (i) the possible actions to mitigate any adverse impacts associated with license renewal and (ii) the environmental impacts of alternatives to license renewal.

(3) *Existing Issue Category Change from Category 2 to Category 1:* These would include issues that were considered as Category 2 in the 1996 GEIS and would now be considered as Category 1 in the revised GEIS. An applicant would no longer be required to conduct an assessment on the environmental impacts associated with these issues. Consistent with the requirements of § 51.53(c)(3)(iv), an applicant would only be required to describe in its environmental report any ''new and significant information'' of which it is aware.

(4) *Existing Issue Category Change from Category 1 to Category 2:* These would include issues that were considered as Category 1 in the 1996 GEIS and would now be considered as Category 2 in the revised GEIS. An applicant that previously did not have to provide an analysis on the environmental impacts associated with these issues would now be required to conduct an assessment of the environmental impacts and include it in the environmental report.

V. Proposed Actions and Basis for Changes to Table B–1

The revised GEIS which is concurrently issued for public comment and publicly available (ADAMS Accession No. ML090220654) provides a summary change table comparing the ninety-two environmental issues in the 1996 GEIS with the seventy-eight environmental issues in the revised GEIS. The proposed rule amends Table B–1 in Appendix B to Subpart A, ''Summary of Findings on NEPA Issues for License Renewal of Nuclear Power Plants,'' to reflect the changes made in the revised GEIS. The changes to Table B–1 are described below:

(i) Land Use

(1) *Onsite Land Use*—''Onsite land use'' remains a Category 1 issue. The proposed rule makes minor clarifying changes to the finding column of Table B–1 for this issue.

(2) *Offsite Land Use*—The proposed rule language combines two Category 2 issues, ''Offsite land use (refurbishment)'' and ''Offsite land use (license renewal term)'' reclassifies this combined issue as a Category 1 issue, and names it, ''Offsite land use.'' The finding column of the current Table B–1 for ''Offsite land use (refurbishment)'' indicates that impacts may be of moderate significance at plants in low population areas. The finding column of the current Table B–1 for ''Offsite land use (license renewal term)'' indicates that significant changes in land use may be associated with population and tax revenue changes resulting from license renewal. As described in the 1996 GEIS, environmental impacts are considered to be small if refurbishment activities were to occur at plants located in high population areas and if population and tax revenues would not change.

Significant impacts on offsite land use are not anticipated. Previous plant-specific license renewal reviews conducted by the NRC have shown no requirement for a substantial number of additional workers during the license renewal term and that refurbishment activities, such as steam generator and vessel head replacement, have not required the large numbers of workers and the months of time that was conservatively estimated in the 1996 GEIS. These reviews support a finding that offsite land use impacts during the license renewal term would be small for all nuclear power plants.

(3) *Offsite Land Use in Transmission Line Rights-of-Way (ROWs)*—The proposed rule renames ''Powerline right of way'' as ''Offsite land use in transmission line rights-of-way (ROWs);'' it remains a Category 1 issue. The proposed rule makes minor clarifying changes to the finding column of Table B–1 for this issue.

(ii) Visual Resources

(4) *Aesthetic Impacts*—The proposed rule language combines three Category 1 issues, ''Aesthetic impacts (refurbishment),'' ''aesthetic impacts (license renewal term),'' and ''aesthetic impacts of transmission lines (license renewal term)'' into one new Category 1 issue, ''Aesthetic impacts.'' The 1996 GEIS concluded that renewal of operating licenses and the refurbishment activities would have no significant aesthetic impact during the license renewal term. Impacts are considered to be small if the visual appearance of plant and transmission line structures would not change. Previous license renewal reviews conducted by the NRC show that the appearance of nuclear plants and transmission line structures do not change significantly over time or because of refurbishment activities. Therefore, aesthetic impacts are not anticipated and the combined issue remains a Category 1 issue.

These three issues are combined into one Category 1 issue as they are similar and combining them would streamline the license renewal process.

(iii) Air Quality

(5) *Air Quality (Non-Attainment and Maintenance Areas)*—The proposed language renames ''Air quality during refurbishment (non-attainment and maintenance areas)'' as ''Air quality (non-attainment and maintenance areas)'' and expands it to include emissions from testing emergency diesel generators, boilers used for facility heating, and particulate emissions from cooling towers. The issue remains a Category 2 issue.

(6) *Air Quality Effects of Transmission Lines*—''Air quality effects of transmission lines'' remains a Category 1 issue. There are no changes for this issue.

(iv) Noise

(7) *Noise Impacts*—The proposed rule renames ''Noise'' as ''Noise impacts''; it remains a Category 1 issue. The proposed rule makes minor clarifying changes to the finding column of Table B–1 for this issue.

(v) Geology and Soils

(8) *Impacts of Nuclear Plants on Geology and Soils*—The proposed language adds a new Category 1 issue, ''Impacts of nuclear plants on geology and soils,'' to the impacts of continued power plant operations and refurbishment activities on geology and soils (*i.e.*, prime farmland) and to determine if there is new or significant information in regard to regional or local seismology. New seismological conditions are limited to the identification of previously unknown geologic faults and are expected to be rare. Geology and soil conditions at all nuclear power plants and associated transmission lines have been well established during the current licensing term and are expected to remain unchanged during the 20-year license renewal term. The impact of continued operations and refurbishment activities during the license renewal term on geologic and soil resources would consist of soil disturbance for construction or renovation projects. Implementing best management practices would reduce soil erosion and subsequent impacts on surface water quality. Best management practices include: (1) Minimizing the amount of disturbed land, (2) stockpiling topsoil before ground disturbance, (3) mulching and seeding in disturbed areas, (4) covering loose materials with geotextiles, (5) using silt fences to reduce sediment loading to surface water, (6) using check dams to minimize the erosive power of drainages, and (7) installing proper culvert outlets to direct flows in streams or drainages.

No information in any plant-specific SEIS prepared to date, or in the referenced documents, has identified these impacts as being significant.

(vi) Surface Water

(9) *Surface-Water Use and Quality*—The proposed rule combines two Category 1 issues, ''Impacts of refurbishment on surface water quality'' and ''Impacts of refurbishment on surface water use,'' and names the combined issue ''Surface-water use and quality.'' These two issues were combined because the impacts of refurbishment on both surface water use and quality are negligible and the effects are closely related.

The NRC expects licensees to use best management practices during the license renewal term for both continuing operations and refurbishment activities. Use of best management practices will minimize soil erosion. In addition, implementation of spill prevention and control plans will reduce the likelihood of any liquid chemical spills. If refurbishment activities take place during a reactor shutdown, the overall water use by the facility will be reduced. Based on this conclusion, the impact on surface water use and quality during a license renewal term will continue to be small for all plants. The combined issue remains a Category 1 issue. The proposed rule makes minor clarifying changes to the finding column of Table B–1 for this issue.

(10) *Altered Current Patterns at Intake and Discharge Structures*, (11) *Altered Salinity Gradients*, (12) *Altered Thermal Stratification of Lakes*, and (13) *Scouring Caused by Discharged Cooling Water*—''Altered current patterns at intake and discharge structures,'' ''Altered salinity gradients,'' ''Altered thermal stratification of lakes,'' and ''Scouring caused by discharged cooling water'' remain Category 1 issues. The proposed rule makes minor clarifying changes to the finding column of Table B–1 for each of these issues.

(14) *Discharge of Metals in Cooling System Effluent*—The proposed language renames ''Discharge of other metals in waste water'' as ''Discharge of metals in cooling system effluent''; it remains a Category 1 issue. The proposed rule makes minor clarifying changes to the finding column of Table B–1 for this issue.

(15) *Discharge of Biocides, Sanitary Wastes, and Minor Chemical Spills*—The proposed rule combines two Category 1 issues, ''Discharge of chlorine or other biocides'' and ''Discharge of sanitary wastes and minor chemical spills'' as ''Discharge of biocides, sanitary wastes, and minor chemical spills.'' The combined issue remains a Category 1 issue. The proposed rule makes minor clarifying changes to the finding column of Table B–1 for this issue.

(16) *Water Use Conflicts (plants with once-through cooling systems)*—''Water use conflicts (plants with once-through cooling systems)'' remains a Category 1 issue. The proposed rule makes a minor clarifying change to the finding column of Table B–1 for this issue.

(17) *Water Use Conflicts (plants with cooling ponds or cooling towers using make-up water from a river with low flow)*—''Water use conflicts (plants with cooling ponds or cooling towers using

make-up water from a river with low flow)'' remains a Category 2 issue. The proposed rule makes minor clarifying changes to the finding column of Table B–1 for this issue.

(18) *Effects of Dredging on Water Quality*—The proposed rule adds a new Category 1 issue, ''Effects of dredging on water quality,'' that evaluates the impacts of dredging to maintain intake and discharge structures at nuclear power plant facilities. The impact of dredging on surface water quality was not considered in the 1996 GEIS and is not listed in the current Table B–1. Most plants have intake and discharge structures that must be maintained by periodic dredging of sediment accumulated in or on the structures.

This dredging, while temporarily increasing turbidity in the source water body, has been shown to have little effect on water quality. In addition to maintaining intake and discharge structures, dredging is often done to keep barge slips and channels open to service the plant. Dredged material is most often disposed on property owned by the applicant and usually contains no hazardous materials. Dredging is performed under a permit issued by the U.S. Army Corps of Engineers and consequently, each dredging action would be subject to a site-specific environmental review conducted by the Corps.

Temporary impacts of dredging are measurable in general water quality terms, but the impacts have been shown to be small.

(19) *Temperature Effects on Sediment Transport Capacity*—''Temperature effects on sediment transport capacity'' remains a Category 1 issue. There are no changes to this issue.

(vii) Groundwater

(20) *Groundwater Use and Quality*—The proposed rule renames ''Impacts of refurbishment on groundwater use and quality'' as ''Groundwater use and quality.'' The issue remains a Category 1 issue. The NRC has concluded that use of best management practices would address any wastes or spills that could affect groundwater quality. The proposed rule updates the finding column of Table B–1 for this issue to include a statement identifying best management practices and makes other minor clarifying changes to the finding column.

(21) *Groundwater Use Conflicts (Plants that Withdraw Less Than 100 Gallons per Minute [gpm])*—The proposed rule renames ''Ground-water use conflicts (potable and service water; plants that use <100 gpm)'' as ''Groundwater use conflicts (plants that withdraw less than 100 gallons per minute [gpm]).'' The issue remains a Category 1 issue. The proposed rule makes minor clarifying changes to the finding column of Table B–1 for this issue.

(22) *Groundwater use conflicts (plants that withdraw more than 100 gpm including those using Ranney Wells)*—The proposed rule combines two Category 2 issues, ''Groundwater use conflicts (potable and service water, and dewatering; plants that use >100 gpm)'' and ''Ground-water use conflicts (Ranney wells)'' and names the combined issue ''Groundwater use conflicts (plants that withdraw more than 100 gpm including those using Ranney wells).'' The combined issue remains a Category 2 issue. Because Ranney wells produce significantly more than 100 gpm, the Ranney wells issue was combined with the general issue of groundwater use conflicts for plants using more than 100 gpm of groundwater. The proposed rule makes clarifying changes to the finding column of Table B–1 for this combined issue.

(23) *Groundwater Use Conflicts (Plants With Closed-Cycle Cooling Systems that Withdraw Makeup Water from a River)*—The proposed rule renames ''Ground-water use conflicts (plants using cooling tower withdrawing make-up water from a small river'' as ''Groundwater use conflicts (plants with closed-cycle cooling systems that withdraw makeup water from a river).'' The combined issue remains a Category 2 issue. The proposed rule makes minor clarifying changes to the finding column of Table B–1 for this issue.

(24) *Groundwater Quality Degradation Resulting from Water Withdrawals*—The proposed rule combines two Category 1 issues, ''Ground-water quality degradation (Ranney wells)'' and ''Ground-water quality degradation (saltwater intrusion)'' and names the combined issue ''Groundwater quality degradation resulting from water withdrawals.'' The combined issue remains a Category 1 issue. The two issues were combined as they both consider the possibility of groundwater quality becoming degraded as a result of the plant drawing water of potentially lower quality into the aquifer. The proposed rule makes clarifying changes to the finding column of Table B–1 for this combined issue.

(25) *Groundwater Quality Degradation (Plants with Cooling Ponds in Salt Marshes)* and (26) *Groundwater Quality Degradation (Plants with Cooling Ponds at Inland Sites)*—''Groundwater quality degradation (plants with cooling ponds in salt marshes)'' and ''Groundwater quality degradation (plants with cooling ponds at inland sites)'' remain, respectively, Category 1 and Category 2 issues. The proposed rule makes clarifying changes to the finding column of Table B–1 for each of these issues.

(27) *Groundwater and Soil Contamination*—The proposed rule adds a new Category 2 issue, ''Groundwater and Soil Contamination,'' to evaluate the impacts of the industrial use of solvents, hydrocarbons, heavy metals, or other chemicals on groundwater, soil, and subsoil at nuclear power plant sites during the license renewal term. Review of license renewal applications has shown the existence of these non-radionuclide contaminants at some plants. This contamination is usually regulated by State environmental regulatory authorities or the Environmental Protection Agency (EPA). In addition, this new Category 2 issue has been added because each specific site has its own program for handling waste and hazardous materials, and no generic evaluation would apply to all nuclear power plants.

Industrial practices at all plants have the potential to contaminate site groundwater and soil through the use and spillage of solvents, hydrocarbons, heavy metals, or other chemicals, especially on sites with unlined wastewater lagoons and storm water lagoons. Any contamination by these substances is subject to characterization and clean-up by State and EPA regulated remediation and monitoring programs.

(28) *Radionuclides Released to Groundwater*—The proposed rule adds a new Category 2 issue, ''Radionuclides released to groundwater,'' to evaluate the potential impact of discharges of radionuclides, such as tritium, from plant systems into groundwater. The issue is relevant to license renewal because virtually all commercial nuclear power plants routinely release radioactive gaseous and liquid materials into the environment. A September 2006 NRC report, ''Liquid Radioactive Release Lessons Learned Task Force Report,'' documented instances of inadvertent releases of radionuclides into groundwater from nuclear power plants (ADAMS Accession No. ML062650312).

NRC regulations in Parts 20 and 50 limit the amount of radioactivity released into the environment to be ''As Low As is Reasonably Achievable'' (ALARA) to ensure that the impact on public health is very low. Most of the inadvertent liquid release events involved tritium, which is a radioactive isotope of hydrogen. However, other radioactive isotopes have been inadvertently released into the environment. An example is leakage from spent fuel pools, where leakage from the stored fuel would allow fission products to be released into the pool water.

The most significant conclusion of the NRC report regards public health impacts. Although there have been a number of events where radionuclides were released inadvertently into groundwater, based on the data available, the NRC did not identify any instances where the health of the public was impacted. The NRC did identify that under the existing regulatory requirements, the potential exists for inadvertent radionuclide releases to migrate offsite into groundwater.

Another factor in adding this new Category 2 issue is the level of public concern associated with such inadvertent releases of radionuclides into groundwater. The NRC concludes that the impact of radionuclide releases to groundwater quality could be small or moderate, depending on the occurrence and frequency of leaks and the ability to respond to leaks in a timely fashion.

(viii) Terrestrial Resources

(29) *Impacts of Continued Plant Operations on Terrestrial Ecosystems*—The proposed rule renames ''Refurbishment impacts'' as ''Impacts of continued plant operations on terrestrial ecosystems;'' it remains a Category 2 issue. The analysis in the revised GEIS expands the scope of this issue to include the environmental impacts associated with continued plant operations and maintenance activities in addition to refurbishment. The proposed rule revises the finding column of Table B–1 for this issue accordingly.

(30) *Exposure of Terrestrial Organisms to Radionuclides*—The proposed rule adds a new Category 1 issue, ''Exposure of terrestrial organisms to radionuclides,'' to evaluate the issue of the potential impact of radionuclides on terrestrial organisms resulting from normal operations of a nuclear power plant during the license renewal term. This issue was not evaluated in the 1996 GEIS. However, the impact of radionuclides on terrestrial organisms has been raised by members of the public as well as Federal and State agencies during previous license renewal reviews.

The revised GEIS evaluates the potential impact of radionuclides on terrestrial biota at nuclear power plants from continued operations during the license renewal term. Site-specific radionuclide concentrations in water, sediment, and soils were obtained from Radiological Environmental Monitoring Operating Reports from 15 nuclear power plants. These 15 plants were selected to represent sites with a range of radionuclide concentrations in the media, including plants with high annual worker dose exposure values for both boiling water reactors and pressurized water reactors. The calculated radiation dose rates to terrestrial biota were compared against radiation-acceptable radiation safety guidelines issued by the U.S. Department of Energy, the International Atomic Energy Agency, the National Council of Radiation Protection and Measurement, and the International Commission on Radiological Protection. The NRC concludes that the impact of radionuclides on terrestrial biota from past and current operations would be small for all nuclear power plants and would not be expected to change appreciably during the license renewal term.

(31) *Cooling System Impacts on Terrestrial Resources (Plants with Once-Through Cooling Systems or Cooling Ponds)*—The proposed rule renames ''Cooling pond impacts on terrestrial resources'' as ''Cooling system impacts on terrestrial resources (plants with once-through cooling systems or cooling ponds).'' This issue remains a Category 1 issue. The analysis in the revised GEIS expands the scope of this issue to include plants with once-through cooling systems. This analysis concludes that the impacts on terrestrial resources from once-through cooling systems, as well as from cooling ponds, is of small significance at all plants. The proposed rule revises the finding column of Table B–1 for this issue accordingly.

(32) *Cooling Tower Impacts on Vegetation (Plants with Cooling Towers)*—The proposed rule combines two Category 1 issues, ''Cooling tower impacts on crops and ornamental vegetation'' and ''Cooling tower impacts on native plants'' and names the combined issue ''Cooling tower impacts on vegetation (plants with cooling towers).'' The combined issue remains a Category 1 issue. The two issues were combined to conform to the resource-based approach used in the revised GEIS and to simplify and streamline the analysis. With the recent trend of replacing lawns with native vegetation, some ornamental plants and crops are native plants, and the original separation into two issues is unnecessary and cumbersome. The proposed rule makes clarifying changes to the finding column of Table B–1 for this combined issue.

(33) *Bird Collisions with Cooling Towers and Transmission Lines*—The proposed rule combines two Category 1 issues, ''Bird collisions with cooling towers'' and ''Bird collision with power lines'' and names the combined issue ''Bird collisions with cooling towers and transmission lines.'' The combined issue remains a Category 1 issue. The two issues were combined to conform to the resource-based approach used in the revised GEIS and to simplify and streamline the analysis. The proposed rule makes clarifying changes to the finding column of Table B–1 for this combined issue.

(34) *Water Use Conflicts with Terrestrial Resources (Plants with Cooling Ponds or Cooling Towers Using Makeup Water from a River with Low Flow)*—The proposed rule adds a new Category 2 issue, ''Water use conflicts with terrestrial resources (plants with cooling ponds or cooling towers using make-up water from a river with low flow)'' to evaluate water use conflict impacts with terrestrial resources in riparian communities. Such impacts could occur when water that supports these resources is diminished either because of decreased availability due to droughts; increased water demand for agricultural, municipal, or industrial usage; or a combination of these factors. The potential range of impact levels at plants, subject to license renewal, with cooling ponds or cooling towers using makeup water from a small river with low flow cannot be generically determined at this time.

(35) *Transmission Line ROW Management Impacts on Terrestrial Resources*—The proposed rule combines two Category 1 issues, ''Power line right-of-way management (cutting and herbicide application)'' and ''Floodplains and wetland on power line right-of-way'' and names the combined issue ''Transmission line ROW management impacts on terrestrial resources.'' The combined issue remains a Category 1 issue. The two issues were combined to simplify and streamline the analysis.

The scope of the evaluation of transmission lines in the revised GEIS is reduced from that of the 1996 GEIS—only those transmission lines currently needed to connect the nuclear power plants to the regional electrical distribution grid are considered within the scope of license renewal. Thus, the number of and length of transmission lines being evaluated are greatly reduced. The revised GEIS analysis indicates that proper management of transmission line ROW areas does not have significant adverse impacts on current wildlife populations, and ROW management can provide valuable wildlife habitats. The proposed rule makes clarifying changes to the finding column of Table B–1 for this combined issue.

(36) *Electromagnetic Fields on Flora and Fauna (Plants, Agricultural Crops, Honeybees, Wildlife, Livestock)*—''Electromagnetic fields on flora and fauna (plants, agricultural crops, honeybees, wildlife, livestock)'' remains a Category 1 issue. There are no changes to this issue.

(ix) Aquatic Resources

(37) *Impingement and Entrainment of Aquatic Organisms (Plants with Once-Through Cooling Systems or Cooling Ponds)*—The proposed rule combines two Category 2 issues, ''Entrainment of fish and shellfish in early life stages (for plants with once-through cooling and cooling pond heat dissipation systems)'' and ''Impingement of fish and shellfish (for plants with once-through cooling and cooling pond heat dissipation systems)'' and one Category 1 issue, ''Entrainment of phytoplankton and zooplankton (for all plants)'' and names the combined issue ''Impingement and entrainment of aquatic organisms (plants with once-through cooling systems or cooling ponds).'' The combined issue is a Category 2 issue.

For the revised GEIS, these issues were combined to simplify the review process in keeping with the resource-based approach and to allow for a more complete analysis of the environmental impact. Nuclear power plants typically conduct separate sampling programs to estimate the numbers of organisms entrained and impinged, which explains the original separation of these issues. However, it is the combined effects of entrainment and impingement that reflect the total impact of the cooling system intake on the resource. Environmental conditions are different to each nuclear plant site and impacts cannot be determined generically. The proposed rule revises the finding column of Table B–1 for this issue accordingly.

(38) *Impingement and Entrainment of Aquatic Organisms (Plants with Cooling Towers)*—The proposed rule combines three Category 1 issues, ''Entrainment of fish and shellfish in early life stages (for plants with cooling tower-based heat dissipation systems),'' ''Impingement of fish and shellfish (for plants with cooling tower-based heat dissipation systems),'' and ''Entrainment of phytoplankton and zooplankton (for all plants)'' and names the combined issue ''Impingement and entrainment of aquatic organisms (plants with cooling towers).'' The combined issue remains a Category 1 issue. The three issues are combined given their similar nature and to simplify and streamline the review process. The proposed rule revises the finding column of Table B–1 for this issue accordingly.

(39) *Thermal Impacts on Aquatic Organisms (Plants with Once-Through Cooling Systems or Cooling Ponds)*—The proposed rule combines four Category 1 issues, ''Cold shock (for all plants),'' ''Thermal plume barrier to migrating fish (for all plants),'' ''Distribution of aquatic organisms (for all plants),'' and ''Premature emergence of aquatic insects (for all plants),'' and one Category 2 issue ''Heat shock (for plants with once-through and cooling pond heat dissipation systems)'' and names the combined issue ''Thermal impacts on aquatic organisms (plants with once-through cooling systems or cooling ponds).'' The combined issue is a Category 2 issue.

The five issues are combined given their similar nature and to simplify and streamline the review process. With the exception of heat shock, previous license renewal reviews conducted by the NRC have shown that the thermal effects of once-through cooling and cooling pond systems have not been a problem at operating nuclear power plants and would not change during the license renewal term, so future impacts are not anticipated. However, it is difficult to differentiate the various thermal effects of once-through cooling and cooling pond systems in the field. Different populations may react differently due to changes in water temperature. For example, if a resident population avoided a heated effluent, the 1996 GEIS would have identified this issue as ''distribution of aquatic organisms;'' however, had this population been migrating, the issue would have been considered under ''thermal plume barrier to migrating fish.'' If individuals had remained in the heated effluent too long, the issue would have been considered under ''heat shock;'' or, if the individuals then left the warm water, the issue would have been considered under ''cold shock.'' Using the resource-based approach in the revised GEIS, each of these issues would be considered a thermal impact from once-through and cooling pond systems. Environmental conditions are different at each nuclear plant site and impacts cannot be determined generically. The proposed rule revises the finding column of Table B–1 for this issue accordingly.

(40) *Thermal Impacts on Aquatic Organisms (Plants with Cooling Towers)*—The proposed rule combines five Category 1 issues, ''Cold shock (for all plants),'' ''Thermal plume barrier to migrating fish (for all plants),'' ''Distribution of aquatic organisms (for all plants),'' ''Premature emergence of aquatic insects (for all plants),'' and ''Heat shock (for plants with cooling-tower-based heat dissipation systems)'' and names the combined issue ''Thermal impacts on aquatic organisms (plants with cooling towers).'' The combined issue is a Category 1 issue.

The five issues are combined given their similar nature and to simplify and streamline the review process. The proposed rule revises the finding column of Table B–1 for this issue accordingly.

(41) *Effects of Cooling Water Discharge on Dissolved Oxygen, Gas Supersaturation, and Eutrophication*—The proposed rule combines three Category 1 issues, ''Eutrophication,'' ''Gas supersaturation (gas bubble disease),'' and ''Low dissolved oxygen in the discharge,'' and names the combined issue ''Effects of cooling water discharge on dissolved oxygen, gas supersaturation, and eutrophication.'' The combined issue is a Category 1 issue.

The three issues are combined given their similar nature and to simplify and streamline the review process. The proposed rule revises the finding column of Table B–1 for this issue accordingly.

(42) *Effects of Non-Radiological Contaminants on Aquatic Organisms*—The proposed rule renames ''Accumulation of contaminants in sediments or biota'' as ''Effects of non-radiological contaminants on aquatic organisms;'' it remains a Category 1 issue. The proposed rule makes clarifying changes to the finding column of Table B–1 for this issue.

(43) *Exposure of Aquatic Organisms to Radionuclides*—The proposed rule adds a new Category 1 issue, ''Exposure of Aquatic Organisms to Radionuclides,'' to evaluate the potential impact of radionuclide discharges upon aquatic organisms. This issue has been raised by members of the public as well as Federal and State agencies during the license renewal process for various plants.

The revised GEIS evaluates the potential impact of radionuclides on aquatic organisms at nuclear power plants from continued operations during the license renewal term. A radiological assessment was performed using effluent release data from 15 NRC-licensed nuclear power plants chosen based on having a range of radionuclide concentrations in environmental media.

Site-specific radionuclide concentrations in water and sediments, as reported in the plant's radioactive effluent and environmental monitoring reports, were used in the calculations. The data is representative of boiling water reactors and pressurized water reactors. The calculated radiation dose rates to aquatic biota were compared against radiation acceptable radiation safety guidelines issued by the U.S. Department of Energy, the International Atomic Energy Agency, the National Council of Radiation Protection and Measurement, and the International Commission on Radiological Protection. The NRC concludes that the impact of radionuclides on aquatic biota from past and current operations would be small for all nuclear power plants, and would not be expected to change appreciably during the license renewal term.

(44) *Effects of Dredging on Aquatic Organisms*—The proposed rule adds a new Category 1 issue, ''Effects of dredging on aquatic organisms,'' to evaluate the impacts of dredging on aquatic organisms. Licensees conduct dredging to maintain intake and discharge structures at nuclear power plant facilities and in some cases, to maintain barge slips. Dredging may disturb or remove benthic communities. In general, maintenance dredging for nuclear power plant operations would occur infrequently, would be of relatively short duration, and would affect relatively small areas. Dredging is performed under a permit issued by the U.S. Army Corps of Engineers and consequently, each dredging action would be subject to a site-specific environmental review conducted by the Corps.

(45) *Water Use Conflicts with Aquatic Resources (Plants with Cooling Ponds or Cooling Towers using Make-Up Water from a River with Low Flow)*—The proposed rule adds a new Category 2 issue, ''Water use conflicts with aquatic resources (plants with cooling ponds or cooling towers using make-up water from a river with low flow)'' to evaluate water use conflict impacts with aquatic resources in instream communities. Such impacts could occur when water that supports these resources is diminished either because of decreased availability due to droughts; increased water demand for agricultural, municipal, or industrial usage; or a combination of these factors. The potential range of impact levels at plants, subject to license renewal, with cooling ponds or cooling towers using makeup water from a small river with low flow cannot be generically determined at this time.

(46) *Refurbishment Impacts on Aquatic Resources*—The proposed rule language renames ''Refurbishment'' as ''Refurbishment impacts on aquatic resources;'' it remains a Category 1 issue. The proposed rule makes minor clarifying changes to the finding column of Table B–1 for this issue.

(47) *Impacts of Transmission Line ROW Management on Aquatic Resources*—The proposed rule adds a new Category 1 issue, ''Impacts of transmission line ROW management on aquatic resources,'' to evaluate the impact of transmission line ROW management on aquatic resources. Impacts on aquatic resources from transmission line ROW maintenance could occur as a result of the direct disturbance of aquatic habitats, soil erosion, changes in water quality (from sedimentation and thermal effects), or inadvertent releases of chemical contaminants from herbicide use. As described in the revised GEIS, any impact on aquatic resources resulting from transmission line ROW management is expected to be small, short term, and localized for all plants.

(48) *Losses from Predation, Parasitism, and Disease Among Organisms Exposed to Sublethal Stresses* and (49) *Stimulation of Aquatic Nuisance Species (e.g., Shipworms)*—''Losses from predation, parasitism, and disease among organisms exposed to sublethal stresses'' and ''Stimulation of aquatic nuisance species (*e.g.*, shipworms)'' remain Category 1 issues. The proposed rule does not change the finding column entries of Table B–1 for these issues.

(x) Threatened, Endangered, and Protected Species and Essential Fish Habitat

(50) *Threatened, Endangered, and Protected Species and Essential Fish Habitat*—The proposed rule renames ''Threatened or endangered species'' as ''Threatened, endangered, and protected species and essential fish habitat'' and expands the scope of the issue to include essential fish habitats protected under the Magnuson-Stevens Fishery Conservation and Management Act. The issue remains a Category 2 issue. The proposed rule makes clarifying changes to the finding column entry of table B–1 for this issue.

(xi) Historic and Cultural Resources

(51) *Historic and Cultural Resources*—The proposed rule language renames ''Historic and archaeological resources'' as ''Historic and cultural resources;'' it remains a Category 2 issue. The proposed rule language more accurately reflects the National Historic Preservation Act requirements that Federal agencies consult with State Historic Preservation Officer and appropriate Native American Tribes to determine the potential impacts and mitigation.

(xii) Socioeconomics

(52) *Employment and Income, Recreation and Tourism*—The proposed rule adds a new Category 1 issue, ''Employment and income,'' and combines it with the ''tourism and recreation'' portion of a current Table B–1 Category 1 issue, ''Public services: public safety, social services, and tourism and recreation.'' These issues are combined given the similar nature and to streamline the review process. The revised GEIS provides an analysis of this issue and concludes that the impacts are generic to all plants undergoing license renewal.

(53) *Tax Revenues*—The proposed rule adds a new Category 1 issue, ''Tax revenues,'' to evaluate the impacts of license renewal on tax revenues. Refurbishment activities, such as steam generator and vessel head replacement, have not had a noticeable effect on the value of nuclear plants, thus changes in tax revenues are not anticipated from future refurbishment activities. Refurbishment activities involve the one-for-one replacement of existing components and are generally not considered a taxable improvement. Also, new property tax assessments; proprietary payments in lieu of tax stipulations, settlements, and agreements; and State tax laws are continually changing the amounts paid to taxing jurisdictions by nuclear plant owners, and these occur independent of license renewal and refurbishment activities.

(54) *Community Services and Education*—The proposed rule language reclassifies two Category 2 issues, ''Public services: Public utilities'' and ''Public services, education (refurbishment)'' as Category 1 issues, and combines them with the Category 1 issue, ''Public services, education (license renewal term),'' and the ''Public safety and social service'' portion of the Category 1 issue, ''Public services: Public safety, social services, and tourism and recreation.'' The combined issue, ''Community services and education,'' is a Category 1 issue.

The four issues are combined as all public services are equally affected by changes in plant operations and refurbishment at nuclear plants. Any changes in the number of workers at a nuclear plant will affect demand for public services from local communities. Nevertheless, past environmental reviews conducted by NRC have shown that the number of workers at relicensed nuclear plants has not changed significantly because of license renewal, so impacts on community services are not anticipated from future license renewals. In addition, refurbishment activities, such as steam generator and vessel head replacement, have not required the large numbers of workers and the months of time that was conservatively analyzed in the 1996 GEIS, so significant impacts on community services are no longer anticipated. Combining the four issues also simplifies and streamlines the NRC review process. The proposed rule revises the finding column of Table B–1 accordingly.

(55) *Population and Housing*—The proposed rule language combines a new Category 1 issue, ''Population,'' and a Category 2 issue, ''Housing impacts,'' and names the combined issue, ''Population and housing.'' The combined issue is a Category 1 issue. The two issues are combined as the availability and value of housing are directly affected by changes in population and to simplify and streamline the NRC review process.

As described in the revised GEIS, the NRC has determined that the impacts of continued operations and refurbishment activities on population and housing, during the license renewal term, would be small, are not dependent on the socioeconomic setting of the nuclear plant, and are generic to all plants. The proposed rule revises the finding column of Table B–1 accordingly.

(56) *Transportation*—The proposed rule reclassifies the Category 2 issue, ''Public services, transportation,'' as a Category 1 issue and renames it ''Transportation.'' As described in the revised GEIS, the NRC has determined that the numbers of workers have not changed significantly due to license renewal, so transportation impacts are no longer anticipated from future license renewals. The proposed rule revises the finding column entry of table B–1 for this issue accordingly.

(xiii) Human Health

(57) *Radiation Exposures to the Public*—The proposed rule combines two Category 1 issues, ''Radiation exposures to the public during refurbishment'' and ''Radiation exposure to public (license renewal term)'' and names the combined issue, ''Radiation exposures to the public.'' The combined issue is a Category 1 issue. These issues are combined given the similar nature and to streamline the review process. The proposed rule revises the finding column of Table B–1 accordingly.

(58) *Radiation Exposures to Occupational Workers*—The proposed rule combines two Category 1 issues, ''Occupational radiation exposures during refurbishment'' and ''Occupational radiation exposures (license renewal term)'' and names the combined issue, ''Radiation exposures to occupational workers.'' The combined issue is a Category 1 issue. These issues are combined given their similar nature and to streamline the review process. The proposed rule revises the finding column of Table B–1 accordingly.

(59) *Human Health Impact from Chemicals*—The proposed rule adds a new Category 1 issue, ''Human health impact from chemicals,'' to evaluate the potential impacts of chemical hazards to workers and chemical releases to the environment.

The evaluation addresses the potential impact of chemicals on human health resulting from normal operations of a nuclear power plant during the license renewal term. Impacts of chemical discharges to human health are considered to be small if the discharges of chemicals to water bodies are within effluent limitations designed to ensure protection of water quality and if ongoing discharges have not resulted in adverse effects on aquatic biota.

The disposal of essentially all of the hazardous chemicals used at nuclear power plants is regulated by Resource Conservation and Recovery Act or National Pollutant Discharge Elimination System (NPDES) permits, thereby minimizing adverse impacts to the environment and on workers and the public. It is anticipated that all plants would continue to operate in compliance with all applicable permits and that no mitigation measures beyond those implemented during the current license term would be warranted as a result of license renewal.

A review of the documents, as referenced in the GEIS; operating monitoring reports; and consultations with utilities and regulatory agencies that were performed for the 1996 GEIS, indicated that the effects of the discharge of chlorine and other biocides on water quality would be of small significance for all power plants. Small quantities of biocides are readily dissipated and/or chemically altered in the body of water receiving them, so significant cumulative impacts to water quality would not be expected. Major changes in the operation of the cooling system are not expected during the license renewal term, so no change in the effects of biocide discharges on the quality of the receiving water is anticipated. Discharges of sanitary wastes and heavy metals are regulated by NPDES. Discharges that do not violate the permit limits are considered to be of small significance. The effects of minor chemical discharges and spills on water quality would be of small significance and mitigated as needed.

(60) *Microbiological Hazards to the Public (Plants with Cooling Ponds or Canals or Cooling Towers that Discharge to a River)*—The proposed rule renames ''Microbiological organisms (public health) (plants using lakes or canals, or cooling towers or cooling ponds that discharge to a small river)'' as ''Microbiological hazards to the public (plants with cooling ponds or canals or cooling towers that discharge to a river);'' it remains a Category 2 issue. The proposed rule makes minor clarifying changes to the Table B–1 finding column entry for this issue.

(61) *Microbiological Hazards to Plant Workers*—The proposed rule renames ''Microbiological organisms (occupational health)'' as ''Microbiological hazards to plant workers;'' it remains a Category 1 issue. There are no changes to the Table B–1 finding column entry for this issue.

(62) *Chronic Effects of Electromagnetic Fields (EMFs)*—The proposed rule renames ''Electromagnetic fields, chronic effects'' as ''Chronic effects of electromagnetic fields (EMFs);'' it remains an uncategorized issue. The proposed rule revises the Table B–1 finding column entry for this issue.

(63) *Physical Occupational Hazards*—The proposed rule adds a new Category 1 issue, ''Physical occupational hazards,'' to evaluate the potential impact of physical occupational hazards on human health resulting from normal nuclear power plant operations during the license renewal term. The impact of physical occupational hazards on human health has been raised by members of the public as well as Federal and State agencies during the license renewal process. Occupational hazards can be minimized when workers adhere to safety standards and use appropriate protective equipment; however, fatalities and injuries from accidents can still occur. Data for occupational injuries in 2005 obtained from the U.S. Bureau of Labor Statistics indicate that the rate of fatal injuries in the utility sector is less than the rate for many sectors (*e.g.*, construction, transportation and warehousing, agriculture, forestry, fishing and hunting, wholesale trade, and mining) and that the incidence rate for nonfatal

occupational injuries and illnesses is the least for electric power generation, followed by electric power transmission control and distribution. It is expected that over the license renewal term, workers would continue to adhere to safety standards and use protective equipment, so adverse occupational impacts would be of small significance at all sites. No mitigation measures beyond those implemented during the current license term would be warranted.

(64) *Electric Shock Hazards*—The proposed rule renames ''Electromagnetic fields, acute effects (electric shock)'' as ''Electric shock hazards;'' it remains a Category 2 issue. The proposed rule revises the Table B–1 finding column entry for this issue by more accurately summarizing the discussion in the GEIS which focuses attention on the potential of electrical shock from transmission lines.

(xiv) Postulated Accidents

(65) *Design-Basis Accidents and (66) Severe Accidents*—''Design-basis accidents'' and ''Severe accidents'' remain Category 1 and 2 issues, respectively. The proposed rule makes minor clarifying changes to the Table B–1 finding column entries for these issues.

(xv) Environmental Justice

(67) *Minority and Low-Income Populations*—The proposed rule adds a new Category 2 issue, ''Minority and low-income populations,'' to evaluate the impacts of nuclear plant operations and refurbishment during the license renewal term on minority and low-income populations living in the vicinity of the plant. This issue is listed in the current Table B–1, but it was not evaluated in the 1996 GEIS. The current Table B–1 finding column entry states that ''[t]he need for and the content of an analysis of environmental justice will be addressed in plant-specific reviews.''

Executive Order 12898 (59 FR 7629; February 16, 1994) initiated the Federal government's environmental justice program. The NRC's ''Policy Statement on the Treatment of Environmental Justice Matters in NRC Regulatory and Licensing Actions'' (69 FR 52040, August 24, 2004) states ''the NRC is committed to the general goals of E.O. 12898, it will strive to meet those goals through its normal and traditional NEPA review process.'' Guidance for implementing Executive Order 12898 was not available prior to the completion of the 1996 GEIS. To accomplish these goals, NRC requires the assistance of applicants in identifying minority and low-income populations and communities residing in the vicinity of the nuclear power plant and determining whether there would be any disproportionately high and adverse human health and environmental impacts on these populations from continued power plant operations and refurbishment activities during the license renewal term.

(xvi) Solid Waste Management

(68) *Low-Level Waste Storage and Disposal*—''Low-level waste storage and disposal'' remains a Category 1 issue. The proposed rule makes clarifying changes to the Table B–1 finding column entry for this issue.

(69) *Onsite Storage of Spent Nuclear Fuel*—The proposed rule renames ''On-site spent fuel'' as ''Onsite storage of spent nuclear fuel;'' it remains a Category 1 issue. The proposed rule does not change the finding column entry of Table B–1 for this issue.

(70) *Offsite Radiological Impacts of Spent Nuclear Fuel and High-Level Waste Disposal*—The proposed rule renames ''Offsite radiological impacts (spent fuel and high level waste disposal)'' as ''Offsite radiological impacts of spent nuclear fuel and high-level waste disposal.'' It remains a Category 1 issue. The proposed rule summarizes the lengthy discussion in the finding column of Table B–1 for this issue, and incorporates specific dose limits obtained from the recent docketing by the NRC of the application for the proposed repository at Yucca Mountain, Nevada.

(71) *Mixed-Waste Storage and Disposal*—''Mixed-waste storage and disposal'' remains a Category 1 issue. The proposed rule revises the Table B–1 finding column entry for this issue by more accurately summarizing the discussion in the GEIS.

(72) *Nonradioactive Waste Storage and Disposal*—The proposed language renames ''Nonradiological waste'' as ''Nonradiological waste storage and disposal;'' it remains a Category 1 issue. The proposed rule makes minor clarifying changes to the finding column of Table B–1 for this issue.

(xvii) Cumulative Impacts

(73) *Cumulative Impacts*—The proposed rule adds a new Category 2 issue, ''Cumulative impacts,'' to evaluate the potential cumulative impacts of license renewal. The term ''cumulative impacts'' is defined in § 51.14(b) by reference to the Council on Environmental Quality (CEQ) regulations, 40 CFR 1508.7, as ''the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions.''

For the purposes of analysis, past actions are considered to be when the nuclear power plant was licensed and constructed, present actions are related to current plant operations, and future actions are those that are reasonably foreseeable through the end of plant operations including the license renewal term. The geographic area over which past, present, and future actions are assessed depends on the affected resource.

The NRC requires the assistance of applicants in identifying other past, present, and reasonably foreseeable future actions, such as the construction and operation of other power plants and other industrial and commercial facilities in the vicinity of the nuclear power plant. Therefore, this environmental impact is considered a Category 2 issue.

(xviii) Uranium Fuel Cycle

(74) *Offsite Radiological Impacts—Individual Impacts from Other than the Disposal of Spent Fuel and High-Level Waste*—''Offsite radiological impacts—individual impacts from other than the disposal of spent fuel and high-level waste'' remains a Category 1 issue. The proposed rule makes minor clarifying changes to the findings column of Table B–1 for this issue.

(75) *Offsite Radiological Impacts—Collective Impacts from Other than the Disposal of Spent Fuel and High-Level Waste*—The proposed rule renames ''Offsite radiological impacts (collective effects)'' as ''Offsite radiological impacts—collective impacts from other than the disposal of spent fuel and high-level waste''; it remains a Category 1 issue. The proposed rule summarizes the discussion in the Table B–1 finding column entry for this issue.

(76) *Nonradiological Impacts of the Uranium Fuel Cycle*—Nonradiological impacts of the uranium fuel cycle'' remains a Category 1 issue. The proposed rule makes minor clarifying changes to the finding column of Table B–1 for this issue.

(77) *Transportation*—''Transportation'' remains a Category 1 issue. The proposed rule revises the Table B–1 finding column entry for this issue by retaining the significance level assigned to this environmental issue as applicable to the uranium fuel cycle. The specific technical discussion supporting these findings is retained in the GEIS.

(xiv) Termination of Nuclear Power Plant Operations and Decommissioning

(78) *Termination of Nuclear Power Plant Operations and Decommissioning*—The proposed rule combines one new Category 1 issue, ''Termination of nuclear power plant operations'' with six other Category 1 issues, ''Radiation doses,'' ''Waste management,'' ''Air quality,'' ''Water quality,'' ''Ecological resources,'' and ''Socioeconomic impacts,'' listed in the 1996 GEIS under the resource area, ''Decommissioning'' and names the combined issue, ''Termination of plant operations and decommissioning.'' This combined issue is a Category 1 issue.

The 1996 GEIS analysis indicates that the six decommissioning issues are expected to be small at all nuclear power plant sites. The new issue addresses the impacts from terminating nuclear power plant operations prior to plant decommissioning. Termination of nuclear power plant operations results in the cessation of activities necessary to maintain the reactor, as well as a significant reduction in plant workforce. It is assumed that termination of plant operations would not lead to the immediate decommissioning and dismantlement of the reactor or other power plant infrastructure.

These environmental issues and the termination of nuclear power plant operations issue would be combined into one Category 1 issue to simplify and streamline the NRC review process. These issues are also addressed in the ''2002 Generic Environmental Impact Statement on Decommissioning of Nuclear Facilities: Regarding the Decommissioning of Nuclear Power Reactors,'' NUREG–0586, which is incorporated by reference in the revised GEIS. The proposed rule revises the findings column of Table B–1 accordingly.

VI. Section-by-Section Analysis

The following section-by-section analysis discusses the proposed modifications to the Part 51 provisions.

Proposed § 51.14(a)

The proposed rule adds to § 51.14(a) a definition for the term ''historic properties.'' The term is intended to be an overarching term that includes those historic, archaeological, and Native American traditional religious and cultural properties (districts, sites, buildings, structures, objects, artifacts) that are covered by the various Federal preservation laws, including the National Historic Preservation Act, and where applicable, the Archaeological Resources Protection Act and the Native American Graves Protection and Repatriation Act.

Proposed § 51.53(c)(2)

The NRC proposes to clarify the required contents of the license renewal environmental report which applicants must submit in accordance with § 54.21 by revising the second sentence in this subparagraph to read, ''This report must describe in detail the affected environment around the plant, the modifications directly affecting the environment or any plant effluents, and any planned refurbishment activities.''

Proposed §§ 51.53(c)(3)(ii)(A), (B), and (E)

For those applicants seeking an initial license renewal and holding either an operating license, construction permit, or combined license as of June 30, 1995, the environmental report shall include the information required in § 51.53(c)(2), but is not required to contain analyses of the environmental impacts of certain license renewal issues identified as Category 1 (generically analyzed) issues in Appendix B to Subpart A of Part 51. The environmental report must contain analyses of the environmental impacts of the proposed action, including the impacts of refurbishment activities, if any, associated with license renewal and the impacts of operation during the renewal term, for those issues identified as Category 2 (plant specific analysis required) issues in Appendix B to Subpart A of Part 51 and must include consideration of alternatives for reducing adverse impacts of Category 2 issues. In addition, the environmental report must contain any new and significant information regarding the environmental impacts of license renewal of which the applicant is aware. The required analyses are listed in §§ 51.53(c)(3)(ii)(A)–(P).

The proposed language for §§ 51.53(c)(3)(ii)(A), (B), and (E) consists of changes to conform to the proposed changes in Table B–1, which in turn, reflects the revised GEIS. The NRC proposes to modify these paragraphs to more accurately reflect the specific information needed in the environmental report that will help the NRC conduct the environmental review of the proposed action.

Section 51.53(c)(3)(ii)(A) is revised to incorporate the findings of the revised GEIS and to require applicants to provide information in their environmental reports regarding water availability and competing water demands and related impacts on instream (aquatic) and riparian (terrestrial) communities.

Section 51.53(c)(3)(ii)(B) is revised to replace ''heat shock'' with ''thermal changes'' to reflect the proposed changes made in the revised Table B–1 as described earlier in this document under ''(ix) Aquatic Resources,'' environmental impact issue, ''(39) Thermal Impacts on Aquatic Organisms (Plants with Once-Through Cooling Systems or Cooling Ponds).''

Section 51.53(c)(3)(ii)(E) is revised to expressly include power plant continued operations within the scope of the impacts to be assessed by license renewal applicants. The paragraph is further revised to expand the scope of the provision to include all Federal wildlife protection laws and essential fish habitat under the Magnuson-Stevens Fishery Conservation and Management Act.

Proposed § 51.53(c)(3)(ii)(I)

The NRC proposes to remove the language in § 51.53(c)(3)(ii)(I) to conform with the proposed changes made in the revised Table B–1 and to reserve the paragraph. These Category 2 issues were changed to Category 1 because significant changes in housing availability, land-use, and increased population demand attributable to the proposed project on the public water supply have not occurred at relicensed nuclear plants. Therefore, impacts to these resources are no longer anticipated from future license renewals. In addition, refurbishment activities, such as steam generator and vessel head replacement, have not required the large numbers of workers and the months of time that was conservatively analyzed in the 1996 GEIS. As such, significant impacts on public schools are no longer anticipated from future refurbishment activities. Applicants would no longer need to assess the impacts of the proposed action on housing availability, land-use, and public schools (impacts from refurbishment activities only) within the vicinity of the plant. Additionally, applicants would no longer need to assess the impact of population increases attributable to the proposed action on the public water supply.

Proposed § 51.53(c)(3)(ii)(J)

The NRC proposes to remove the language in § 51.53(c)(3)(ii)(J) to conform with the proposed changes made in the revised Table B–1 and to reserve the paragraph. This Category 2 issue, ''Public service, Transportation'' was changed to Category 1, ''Transportation,'' and remains under resource area, ''Socioeconomic'' because refurbishment activities, such as steam generator and vessel head replacement, have not required the large numbers of workers and the months of time that was conservatively analyzed in the 1996 GEIS; therefore significant transportation impacts are not anticipated from future refurbishment activities. Applicants would no longer need to assess the impact of the proposed action on local transportation during periods of license renewal refurbishment activities.

Proposed § 51.53(c)(3)(ii)(K)

The proposed language for § 51.53(c)(3)(ii)(K) deletes the phrase, ''or archaeological.'' This term is encompassed by the use of the term ''historical,'' as defined in the proposed rule language under § 51.14, ''Definitions.''

Proposed § 51.53(c)(3)(ii)(N)

The NRC proposes to add a new paragraph (c)(3)(ii)(N) in § 51.53 to conform with the proposed changes made in the revised Table B–1. A new Category 2 issue, ''Minority and low-income populations'' under resource area, ''Environmental Justice'' addresses the issue of determining the effects of nuclear plant operations and refurbishment on minority and low-income populations living in the vicinity of the plant. This issue is listed in the current Table B–1, but was not evaluated in the 1996 GEIS. The finding stated that: ''The need for and the content of an analysis of environmental justice will be addressed in plant-specific reviews.'' Guidance for implementing E.O. No. 12898, ''Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations,'' (Section 1–101) (59 FR 7629) and dated February 16, 1994 was not available before the completion of the 1996 GEIS.

In August 2004, the Commission issued a policy statement on implementation of E.O. 12898: NRC's Policy Statement on the Treatment of Environmental Justice Matters in NRC Regulatory and Licensing Actions (69 FR 52040). As stated therein, ''the NRC is committed to the general goals of E.O. 12898, it will strive to meet those goals through its normal and traditional NEPA review process.'' To accomplish these goals, NRC requires the assistance of applicants in identifying minority and low-income populations and communities residing in the vicinity of the nuclear power plant and determining if there would be any disproportionate and adverse human health and environmental impacts on these populations. The NRC will then assess the information provided by the applicant.

Proposed § 51.53(c)(3)(ii)(O)

The NRC proposes to add a new paragraph (c)(3)(ii)(O) in § 51.53 to conform with the proposed changes made in the revised Table B–1. A new Category 2 issue has been added to the GEIS to evaluate the potential contamination of soil and groundwater from industrial practices at nuclear plants. Industrial practices at all plants have the potential to contaminate site groundwater and soil through the use and spillage of solvents, hydrocarbons, heavy metals, or other chemicals, especially on sites with unlined wastewater lagoons and storm water lagoons. Any contamination by these substances is subject to characterization and clean-up by EPA and State remediation and monitoring programs. NRC requires the assistance of applicants to assess the impact of the industrial practices involving the use of solvents, hydrocarbons, heavy metals, or other chemicals where there is a potential for contamination of site groundwater, soil, and subsoil.

Proposed § 51.53(c)(3)(ii)(P)

The NRC proposes to add a new paragraph (c)(3)(ii)(P) in § 51.53 to conform with the proposed changes made in the revised Table B–1. A new Category 2 issue has been added to the GEIS to evaluate the potential cumulative effects of license renewal and refurbishment at nuclear plants. Cumulative impacts was not addressed in the 1996 GEIS, but is currently being evaluated by the NRC in plant-specific supplements to the GEIS. The Council on Environmental Quality (CEQ), in 40 CFR 1508.7, defines cumulative effects as ''the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions.'' The NRC considers potential cumulative impacts on the environment resulting from the incremental impact of license renewal when added to other past, present, and reasonably foreseeable future actions.

The NRC requires the assistance of applicants in identifying other past, present, and reasonably foreseeable future actions, such as the construction and operation of other power plants and other industrial and commercial facilities in the vicinity of the nuclear power plant.

Proposed § 51.53(c)(3)(ii)(Q)

The NRC proposes to add a new paragraph (c)(3)(ii)(Q) in § 51.53 to conform with the proposed changes made in the revised Table B–1. A new Category 2 issue has been added to the GEIS to evaluate the potential impact of discharges of radionuclides, such as tritium, from plant systems into groundwater. The issue is relevant to license renewal because virtually all commercial nuclear power plants have spent fuel pools, liquid storage tanks, and buried piping that contain liquids with radioactive material that have a potential over time to degrade and release radioactive liquid into the groundwater. The NRC has investigated several cases where radioactive liquids have been inadvertently released into the groundwater in an uncontrolled manner. Any residual activity from these inadvertent releases of radioactive material is subject to characterization and possible remediation by the licensee in order to comply with NRC requirements. NRC requires the assistance of applicants in assessing the impact of any inadvertent releases of radioactive liquids into the groundwater.

Proposed § 51.71(c)

The proposed language for § 51.71(c) deletes the term ''entitlement'' and ''entitlements.'' These terms are not applicable in a license renewal context.

Proposed § 51.71(d)

The proposed language for § 51.71(d) consists of minor conforming word changes to clarify the readability and to include the analysis of cumulative effects. Cumulative impacts were not addressed in the 1996 GEIS, but are currently being evaluated by the NRC in plant-specific supplements to the GEIS. The NRC proposes to modify this paragraph to more accurately reflect the cumulative impacts analysis conducted for environmental reviews of the proposed action.

Proposed § 51.95(c)

The proposed language changes for § 51.95(c) is administrative in nature, and replaces the reference to the 1996 GEIS for license renewal of nuclear plants with a reference to the revised GEIS.

Proposed § 51.95(c)(4)

The proposed language for § 51.95(c)(4) consists of minor grammatical word changes to enhance the readability of the regulation.

VII. Specific Request for Comments

The NRC seeks comments on the proposed Part 51 provisions described in this document and on the regulatory analysis and the information collection aspects of this proposed rule.

The NRC also seeks voluntary information from industry about refurbishment activities and employment trends at nuclear power plants. Information on refurbishment would be used to evaluate the significance of impacts from this type of activity. Information on employment trends would be used to assess the significance of socioeconomic effects of ongoing plant operations on local economies.

Refurbishment

Table B.2 in the 1996 GEIS lists major refurbishment or replacement activities that the NRC used to estimate environmental impacts. The NRC recognizes that the refurbishment impact analysis in the 1996 GEIS may not accurately reflect industry experience performing the activities identified in Table B.2. Please provide (1) the estimated frequency for each activity (*e.g.*, annually, once in the lifetime of a power reactor, as-needed based on inspections, *etc.*), (2) the duration (in weeks), (3) the peak number of project workers in full-time equivalents (FTEs), (4) the timing of these activities (*e.g.*, during planned refueling or maintenance outages), and (5) whether the period of extended operation (*i.e.*, license renewal term) has triggered a need for these activities.

Employment Trends

Please provide data on the annual average number of permanent operations workers (in FTEs by year) after commencement of nuclear plant operations. If possible, the information should include a short non-proprietary discussion about general employment trends and include reasons for any significant changes in employment.

VIII. Guidance Documents

In addition to issuing the revised GEIS for public comment, the NRC is also issuing a revised RG 4.2, Supplement 1, Revision 1 and a revised ESRP, Supplement 1, Revision 1. Both documents are being published concurrently with these proposed amendments. Revised RG 4.2, Supplement 1, Revision 1, provides general procedures for the preparation of environmental reports, which are submitted as part of an application for the renewal of a nuclear power plant operating license in accordance with Title 10, Part 54, ''Requirements for Renewal of Operating Licenses for Nuclear Power Plants,'' of the Code of Federal Regulations (10 CFR Part 54). More specifically, this revised regulatory guide explains the criteria on how Category 2 issues are to be addressed in the environmental report, as specified in the proposed amendments to Part 51.

The revised ESRP, Supplement 1, Revision 1 provides guidance for NRC staff on how to conduct a license renewal environmental review. The ESRP parallels the format in RG 4.2, Supplement 1, Revision 1. The primary purpose of the ESRP is to ensure that these reviews focus on those environmental concerns associated with license renewal as described in Part 51. Additionally, in order to enhance public openness, the NRC committed to issuing for public comment with the proposed rule, the RG 4.2, Supplement 1, Revision 1 and ESRP, Supplement 1, Revision 1.

IX. Agreement State Compatibility

Under the ''Policy Statement on Adequacy and Compatibility of Agreement States Programs,'' approved by the Commission on June 20, 1997, and published in the **Federal Register** (62 FR 46517; September 3, 1997), this rule is classified as compatibility category ''NRC.'' Agreement State Compatibility is not required for Category ''NRC'' regulations. The NRC program elements in this category are those that relate directly to areas of regulation reserved to the NRC by the Atomic Energy Act or the provisions of 10 CFR. Although an Agreement State may not adopt program elements reserved to NRC, it may wish to inform its licensees of certain requirements via a mechanism that is consistent with the particular State's administrative procedure laws, but does not confer regulatory authority on the State.

X. Availability of Documents

The NRC is making the documents identified below available to interested persons through one or more of the following methods, as indicated.

Public Document Room (PDR). The NRC Public Document Room is located at 11555 Rockville Pike, Rockville, Maryland 20852.

Regulations.gov (Web). These documents may be viewed and downloaded electronically through the Federal eRulemaking Portal *http://www.regulations.gov* Docket number NRC–2008–0608.

NRC's Electronic Reading Room (ERR). The NRC's public electronic reading room is located at *http://www.nrc.gov/reading-rm.html.*

XI. Plain Language

The Presidential memorandum dated June 1, 1998, entitled "Plain Language in Government Writing" directed that the Government's writing be in clear and accessible language. This memorandum was published on June 10, 1998 (63 FR 31883). The NRC requests comments on the proposed rule specifically with respect to the clarity and effectiveness of the language used. Comments should be sent to the NRC as explained in the **ADDRESSES** heading of this document.

XII. Voluntary Consensus Standards

The National Technology Transfer and Advancement Act of 1995, Public Law 104–113, requires that Federal agencies use technical standards that are developed or adopted by voluntary consensus standards bodies unless using such a standard is inconsistent with applicable law or is otherwise impractical. The NRC is not aware of any voluntary consensus standard that could be used instead of the proposed Government standards. The NRC will consider using a voluntary consensus standard if an appropriate standard is identified.

XIII. Finding of No Significant Environmental Impact

The NRC has determined that this proposed regulation is the type of action described in categorical exclusion § 51.22(c)(3). Therefore, neither an environmental impact statement nor an environmental assessment has been prepared for this proposed regulation. This action is procedural in nature in that it pertains to the type of environmental information to be reviewed.

XIV. Paperwork Reduction Act Statement

This proposed rule would contain new or amended information collection requirements that are subject to the Paperwork Reduction Act of 1995 (44 U.S.C. 3501, *et seq*). This proposed rule has been submitted to the Office of Management and Budget (OMB) for review and approval of the information collection requirements.

Type of submission, new or revision: Revision.

The title of the information collection: 10 CFR Part 51 Environmental Review for Renewal of Nuclear Power Plant Operating Licenses, Proposed Rule.

The form number if applicable: Not applicable.

How often the collection is required: Once per license renewal.

Who will be required or asked to report: Applicants for license renewal.

An estimate of the number of annual responses: Six.

The estimated number of annual respondents: Six.

An estimate of the total number of hours needed annually to complete the requirement or request (net one-time reporting): 1,944.00 hours

Abstract: 10 CFR Part 51 specifies information to be provided by applicants and licensees so that the NRC can make determinations necessary to adhere to the policies, regulations, and public laws of the United States, which are to be interpreted and administered in accordance with the policies set forth in the National Environmental Policy Act of 1969, as amended.

The NRC is seeking public comment on the potential impact of the information collections contained in this proposed rule and on the following issues:

1. Is the proposed information collection necessary for the NRC to properly perform its functions? Does the information have practical utility?
2. Is the burden estimate accurate?
3. Is there a way to enhance the quality, utility, and clarity of the information to be collected?
4. How can the burden of the information collection be minimized, including the use of automated collection techniques or other forms of information technology?

A copy of the OMB clearance package may be viewed free of charge at the NRC Public Document Room, One White Flint North, 11555 Rockville Pike, Room O–1F21, Rockville, MD 20852. The OMB clearance package and rule are available at the NRC worldwide Web site: *http://www.nrc.gov/public-involve/doc-comment/omb/index.htm* for 60 days after the signature date of this notice.

Send comments on any aspect of these proposed information collections, including suggestions for reducing the burden and on the above issues, by October 14, 2009. Comments received after this date will be considered if it is practical to do so, but assurance of consideration cannot be given to comments received after this date. Comments submitted in writing or in electronic form will be made available for public inspection. Because your comments will not be edited to remove any identifying or contact information, the NRC cautions you against including any information in your submission that you do not want to be publicly disclosed. Comments submitted should reference Docket No. NRC–2008–0608. Comments can be submitted in electronic form via the Federal e-Rulemaking Portal at *http://www.regulations.gov* by search for Docket No. NRC–2008–0608. Comments can be mailed to NRC Clearance Officer, Tremaine Donnell (T–5F52), U.S. Nuclear Regulatory Commission, Washington, DC 20555–0001. Questions about the information collection requirements may be directed to the NRC Clearance Officer, Tremaine Donnell (T–5 F52), U.S. Nuclear Regulatory Commission, Washington, DC 20555–0001, by telephone at (301) 415–5258, or by e-mail to *INFOCOLLECTS.Resource@nrc.gov*. Comments can be mailed to the Desk Officer, Office of Information and Regulatory Affairs, NEOB–10202, (3150–0021), Office of Management and Budget, Washington, DC 20503, or by e-mail to *Christine_J._Kyma@omb.eop.gov* or by telephone at (202) 395–4638.

XV. Regulatory Analysis

The Commission has prepared a regulatory analysis on this proposed regulation. The analysis examines the costs and benefits of the alternatives considered by the NRC. The two alternatives considered (a) No Action—no change to applicable license renewal portions of Part 51 regulations, including Table B–1, which would require applicants seeking license renewal to comply with the existing provisions; or (b) review and update the environmental impact issues and findings and amend applicable license renewal portions of Part 51 and Table B–1. The conclusions of the regulatory analysis show substantial cost savings of alternative (b) over alternative (a).

The NRC requests public comments on this regulatory analysis. Information on availability of the regulatory analysis is provided in Section X of this document. Comments on the regulatory analysis may be submitted to the NRC as indicated under the **ADDRESSES** heading of this document.

XVI. Regulatory Flexibility Act Certification

Under the Regulatory Flexibility Act (5 U.S.C. 605(b)), the Commission certifies that this rule would not, if promulgated, have a significant economic impact on a substantial number of small entities. This proposed rule would only affect nuclear power plant licensees filing license renewal applications. The companies that own these plants do not fall within the scope of the definition of ''small entities'' set forth in the Regulatory Flexibility Act or the size standards established by the NRC (§ 2.810).

XVII. Backfit Analysis

The NRC has determined that the requirements in this proposed rule do not constitute backfitting as defined in § 50.109(a)(1). Therefore, a backfit analysis has not been prepared for this proposed rule.

List of Subjects in 10 CFR Part 51

Administrative practice and procedure, Environmental impact statement, Nuclear materials, Nuclear power plants and reactors, Reporting and recordkeeping requirements.

For the reasons set out in the preamble and under the authority of the Atomic Energy Act of 1954, as amended; the Energy Reorganization Act of 1974, as amended; and 5 U.S.C. 553; the NRC is proposing to adopt the following amendments to 10 CFR Part 51.

PART 51—ENVIRONMENTAL PROTECTION REGULATIONS FOR DOMESTIC LICENSING AND RELATED REGULTORY FUNCTIONS

1. The authority citation for Part 51 continues to read as follows:

Authority: Sec. 161, 68 Stat. 948, as amended, sec. 1701, 106 Stat. 2951, 2952, 2953 (42 U.S.C. 2201, 2297f); secs. 201, as amended, 202, 88 Stat. 1242, as amended, 1244 (42 U.S.C. 5841, 5842); sec. 1704, 112 Stat. 2750 (44 U.S.C. 3504 note). Subpart A also issued under National Environmental Policy Act of 1969, secs. 102, 104, 105, 83 Stat. 853–854, as amended (42 U.S.C. 4332, 4334, 4335); and Pub. L. 95–604, Title II, 92 Stat. 3033–3041; and sec. 193, Pub. L. 101–575, 104 Stat. 2835 (42 U.S.C. 2243). Sections 51.20, 51.30, 51.60, 51.80, and 51.97 also issued under secs. 135, 141, Pub. L. 97–425, 96 Stat. 2232, 2241, and sec. 148, Pub. L. 100–203, 101 Stat. 1330–223 (42 U.S.C. 10155, 10161, 10168). Section 51.22 also issued under sec. 274, 73 Stat. 688, as amended by 92 Stat. 3036–3038 (42 U.S.C. 2021) and under Nuclear Waste Policy Act of 1982, sec. 121, 96 Stat. 2228 (42 U.S.C. 10141). Sections 51.43, 51.67, and 51.109 also issued under Nuclear Waste Policy Act of 1982, sec. 114(f), 96 Stat. 2216, as amended (42 U.S.C. 10134(f)).

2. Section 51.14(a) is amended by adding the term *Historic properties* in alphabetical order to read as follows:

§ 51.14 Definitions.

(a) * * *

Historic properties means any prehistoric or historic districts, sites, buildings, structures, or objects included in, or eligible for inclusion in, the National Register of Historic Places maintained by the Secretary of the Interior. This term includes properties of traditional religious and cultural importance to an Indian Tribe or Native Hawaiian organization and that meet the National Register criteria. The term also includes archaeological resources, such as artifacts, records, and remains, that are related to and located within such prehistoric or historic districts, sites, buildings, or structures.

* * * * *

3. Amend § 51.53 to revise the second sentence of paragraph (c)(2), revise the first sentence of paragraph (c)(3)(ii)(A), revise the second sentence of paragraph (c)(3)(ii)(B), revise paragraph (c)(3)(ii)(E), to remove and reserve paragraphs (c)(3)(ii)(I) and (J), to revise paragraph (c)(3)(ii)(K) and to add paragraphs (c)(3)(ii)(N), (O), (P), and (Q) to read as follows:

§ 51.53 Postconstruction environmental reports.

* * * * *

(c) * * *

(2) * * * This report must describe in detail the affected environment around the plant, the modifications directly affecting the environment or any plant effluents, and any planned refurbishment activities. * * *

(3) * * *

(ii) * * *

(A) If the applicant's plant utilizes cooling towers or cooling ponds and withdraws make-up water from a river whose annual flow rate is less than 3.15×10^{12} ft^3/year (9×10^{10}m^3/year), an assessment of the impact of the proposed action on water availability and competing water demands, the flow of the river, and related impacts on instream (aquatic) and riparian (terrestrial) ecological communities must be provided. * * *

(B) * * * If the applicant can not provide these documents, it shall assess the impact of the proposed action on fish and shellfish resources resulting from thermal changes and impingement and entrainment.

* * * * *

(E) All license renewal applicants shall assess the impact of refurbishment, continued operations, and other license-renewal-related construction activities on important plant and animal habitats. Additionally, the applicant shall assess the impact of the proposed action on threatened or endangered species in accordance with Federal laws protecting wildlife, including but not limited to the Endangered Species Act, and essential fish habitat in accordance with the Magnuson-Stevens Fishery Conservation and Management Act.

* * * * *

(I) [Reserved]

(J) [Reserved]

(K) All applicants shall assess whether any historic properties will be affected by the proposed project.

* * * * *

(N) Applicants shall provide information on the general demographic composition of minority- and low-income populations and communities (by race and ethnicity) residing in the immediate vicinity of the plant that could be affected by the renewal of the plant's operating license, including any planned refurbishment activities, and ongoing and future plant operations.

(O) If the applicant's plant conducts industrial practices involving the use of solvents, hydrocarbons, heavy metals, or other chemicals and has unlined wastewater lagoons, the applicant shall assess the potential for contamination of site groundwater, soil, and subsoil. The applicant shall provide an assessment of dissolved chemical and suspended sediment discharge to the plant's wastewater lagoons in addition to National Pollutant Discharge Elimination System (NPDES) compliance data collected for submittal to the U.S. Environmental Protection Agency (EPA) or designated State agency. A summary of existing reports describing site groundwater and soil contamination should also be included.

(P) Applicants shall provide information about past, present, and reasonably foreseeable future actions occurring in the vicinity of the nuclear plant that may result in a cumulative effect. For example, the applicant should include information about the construction and operation of other power plants and other industrial and commercial facilities in the vicinity of the nuclear plant.

(Q) An applicant shall assess the impact of any inadvertent releases of radionuclides into groundwater. The applicant shall include in its assessment a description of any groundwater protection program for the site, including a description of any monitoring wells, leak detection equipment, or procedures for the surveillance of accessible piping and components containing radioactive materials. The assessment shall also include a description of any past inadvertent releases, including information on the source of the release, the location of the release within the plant site, the types of radionuclides involved, including the quantities, forms, and concentrations of such radionuclides, and the projected impact to the environment during the license renewal term, including the projected transport pathways, concentrations of the radionuclides, and potential receptors (*e.g.*, aquifers, rivers, lakes, ponds, ocean).

* * * * *

4. Amend § 51.71 to revise paragraphs (c) and (d) to read as follows:

§ 51.71 Draft environmental impact statement—contents.

* * * * *

(c) *Status of compliance.* The draft environmental impact statement will list all Federal permits, licenses, and approvals which must be obtained in implementing the proposed action and will describe the status of compliance with those requirements. If it is uncertain whether a Federal permit, license, or approval is necessary, the draft environmental impact statement will so indicate.

(d) *Analysis.* Unless excepted in this paragraph or § 51.75, the draft environmental impact statement will include a preliminary analysis that considers and weighs the environmental effects, including any cumulative effects, of the proposed action; the environmental impacts of alternatives to the proposed action; and alternatives available for reducing or avoiding adverse environmental effects. Additionally, the draft environmental impact statement will include a consideration of the economic, technical, and other benefits and costs of the proposed action and alternatives. The draft environmental impact statement will indicate what other interests and considerations of Federal policy, including factors not related to environmental quality, if applicable, are relevant to the consideration of environmental effects of the proposed action identified under paragraph (a) of this section. The draft supplemental environmental impact statement prepared at the license renewal stage under § 51.95(c) need not discuss the economic or technical benefits and costs of either the proposed action or alternatives except if benefits and costs are either essential for a determination regarding the inclusion of an alternative in the range of alternatives considered or relevant to mitigation. In addition, the supplemental environmental impact statement prepared at the license renewal stage need not discuss other issues not related to the environmental effects of the proposed action and associated alternatives. The draft supplemental environmental impact statement for license renewal prepared under § 51.95(c) will rely on conclusions as amplified by the supporting information in the GEIS for issues designated as Category 1 in appendix B to subpart A of this part. The draft supplemental environmental impact statement must contain an analysis of those issues identified as Category 2 in appendix B to subpart A of this part that are open for the proposed action. The analysis for all draft environmental impact statements will, to the fullest extent practicable, quantify the various factors considered. To the extent that there are important qualitative considerations or factors that cannot be quantified, these considerations or factors will be discussed in qualitative terms. Consideration will be given to compliance with environmental quality standards and requirements that have been imposed by Federal, State, regional, and local agencies having responsibility for environmental protection, including applicable zoning and land-use regulations and water pollution limitations or requirements issued or imposed under the Federal Water Pollution Control Act. The environmental impact of the proposed action will be considered in the analysis with respect to matters covered by environmental quality standards and requirements irrespective of whether a certification or license from the appropriate authority has been obtained.[3] While satisfaction of Commission standards and criteria pertaining to radiological effects will be necessary to meet the licensing requirements of the Atomic Energy Act, the analysis will, for the purposes of NEPA, consider the radiological effects of the proposed action and alternatives.

* * * * *

5. Amend § 51.95 to revise the introductory text of paragraph (c), and the second sentence of paragraph (c)(4) to read as follows:

§ 51.95 Postconstruction environmental impact statements.

* * * * *

(c) *Operating license renewal stage.* In connection with the renewal of an operating license or combined license

[3] Compliance with the environmental quality standards and requirements of the Federal Water Pollution Control Act (imposed by EPA or designated permitting states) is not a substitute for, and does not negate the requirement for NRC to weigh all environmental effects of the proposed action, including the degradation, if any, of water quality, and to consider alternatives to the proposed action that are available for reducing adverse effects. Where an environmental assessment of aquatic impact from plant discharges is available from the permitting authority, the NRC will consider the assessment in its determination of the magnitude of environmental impacts for striking an overall cost-benefit balance at the construction permit and operating license and early site permit and combined license stages, and in its determination of whether the adverse environmental impacts of license renewal are so great that preserving the option of license renewal for energy planning decision-makers would be unreasonable at the license renewal stage. When no such assessment of aquatic impacts is available from the permitting authority, NRC will establish on its own, or in conjunction with the permitting authority and other agencies having relevant expertise, the magnitude of potential impacts for striking an overall cost-benefit balance for the facility at the construction permit and operating license and early site permit and combined license stages, and in its determination of whether the adverse environmental impacts of license renewal are so great that preserving the option of license renewal for energy planning decision-makers would be unreasonable at the license renewal stage.

for a nuclear power plant under parts 52 or 54 of this chapter, the Commission shall prepare an environmental impact statement, which is a supplement to the Commission's NUREG–1437, ''Generic Environmental Impact Statement for License Renewal of Nuclear Plants'' [(Month 20XX)], which is available in the NRC Public Document Room, 11555 Rockville Pike, Rockville, Maryland.

* * * * *

(4) * * * In order to make recommendations and reach a final decision on the proposed action, the NRC staff, adjudicatory officers, and Commission shall integrate the conclusions in the generic environmental impact statement for issues designated Category 1 (with the exception of offsite radiological impacts for collective effects and the disposal of spent fuel and high level waste) with information developed for those open Category 2 issues applicable to the plant under § 51.53(c)(3)(ii), and any new and significant information. * * *

* * * * *

6. In Appendix B to Subpart A of Part 51, Table B–1 is revised to read as follows:

Appendix B to Subpart A—Environmental Effect of Renewing the Operating License of a Nuclear Power Plant

* * * * *

TABLE B–1—SUMMARY OF FINDINGS ON NEPA ISSUES FOR LICENSE RENEWAL OF NUCLEAR POWER PLANTS [1]

Issue	Category [2]	Finding [3]
Land Use		
Onsite land use	1	SMALL. Changes in onsite land use from continued operations and refurbishment associated with the license renewal term would be a small fraction of any nuclear power plant site and would involve only land that is controlled by the licensee.
Offsite land use	1	SMALL. Offsite land use would not be affected from continued operations and refurbishment associated with the license renewal term.
Offsite land use in transmission line rights-of-way (ROWs).	1	SMALL. Use of transmission line ROWs from continued operations and refurbishment associated with the license renewal term would continue with no change in land use restrictions.
Visual Resources		
Aesthetic impacts	1	SMALL. No important changes to the visual appearance of plant structures or transmission lines are expected from continued operations and refurbishment associated with the license renewal term.
Air Quality		
Air quality (non-attainment and maintenance areas).	2	SMALL, MODERATE, or LARGE. Air quality impacts of continued operations and refurbishment activities associated with the license renewal term are expected to be small. However, emissions during these activities could be a cause for concern at locations in or near air quality nonattainment or maintenance areas. The significance of the impact cannot be determined without considering the compliance status of each site and the activities that could occur. These impacts would be short-lived and cease after projects were completed. Emissions from testing emergency diesel generators and fire pumps and from routine operations of boilers used for space heating would not be a concern, even for those plants located in or adjacent to nonattainment areas. Although particulate emissions from cooling towers may be a concern for a very limited number of plants located in States that regulate such emissions, the impacts in even these worst-case situations have been small.
Air quality effects of transmission lines	1	SMALL. Production of ozone and oxides of nitrogen is insignificant and does not contribute measurably to ambient levels of these gases.
Noise		
Noise impacts	1	SMALL. Noise levels would remain below regulatory guidelines for offsite receptors during continued operations and refurbishment associated with the license renewal term.
Geology and Soils		
Impacts of nuclear plants on geology and soils.	1	SMALL. Impacts on geology and soils would be small at all nuclear plants if best management practices were employed to reduce erosion associated with continued operations and refurbishment.
Surface Water		
Surface-water use and quality	1	SMALL. Impacts are expected to be negligible if best management practices are employed to control soil erosion and spills. Water use associated with continued operation and refurbishment projects for license renewal would not increase significantly or would be reduced if a plant outage is necessary to accomplish the action.
Altered current patterns at intake and discharge structures.	1	SMALL. Altered current patterns would be limited to the area in the vicinity of the intake and discharge structures. These impacts have been small at operating nuclear power plants.

TABLE B–1—SUMMARY OF FINDINGS ON NEPA ISSUES FOR LICENSE RENEWAL OF NUCLEAR POWER PLANTS [1]—Continued

Issue	Category [2]	Finding [3]
Altered salinity gradients	1	SMALL. Effects on salinity gradients would be limited to the area in the vicinity of the intake and discharge structures. These impacts have been small at operating nuclear power plants.
Altered thermal stratification of lakes	1	SMALL. Effects on thermal stratification would be limited to the area in the vicinity of the intake and discharge structures. These impacts have been small at operating nuclear power plants.
Scouring caused by discharged cooling water.	1	SMALL. Scouring effects would be limited to the area in the vicinity of the intake and discharge structures. These impacts have been small at operating nuclear power plants.
Discharge of metals in cooling system effluent.	1	SMALL. Discharges of metals have not been found to be a problem at operating nuclear power plants with cooling-tower-based heat dissipation systems and have been satisfactorily mitigated at other plants. Discharges are monitored as part of the National Pollutant Discharge Elimination System (NPDES) permit process.
Discharge of biocides, sanitary wastes, and minor chemical spills.	1	SMALL. The effects of these discharges are regulated by State and Federal environmental agencies. Discharges are monitored as part of the NPDES permit process. These impacts have been small at operating nuclear power plants.
Water use conflicts (plants with once-through cooling systems).	1	SMALL. These conflicts have not been found to be a problem at operating nuclear power plants with once-through heat dissipation systems.
Water use conflicts (plants with cooling ponds or cooling towers using make-up water from a river with low flow).	2	SMALL or MODERATE. Impacts could be of small or moderate significance, depending on makeup water requirements, water availability, and competing water demands.
Effects of dredging on water quality	1	SMALL. Dredging to remove accumulated sediments in the vicinity of intake and discharge structures and to maintain barge shipping has not been found to be a problem for surface water quality. Dredging is performed under permit from the U.S. Army Corps of Engineers.
Temperature effects on sediment transport capacity.	1	SMALL. These effects have not been found to be a problem at operating nuclear power plants and are not expected to be a problem during the license renewal term.
Groundwater		
Groundwater use and quality	1	SMALL. Extensive dewatering is not anticipated from continued operations and refurbishment activities associated with the license renewal term. The application of best management practices for handling any materials produced or used during activities would reduce impacts.
Groundwater use conflicts (plants that withdraw less than 100 gallons per minute [gpm]).	1	SMALL. Plants that withdraw less than 100 gpm are not expected to cause any groundwater use conflicts.
Groundwater use conflicts (plants that withdraw more than 100 gpm including those using Ranney wells).	2	SMALL, MODERATE, or LARGE. Plants that withdraw more than 100 gpm could cause groundwater use conflicts with nearby groundwater users.
Groundwater use conflicts (plants with closed-cycle cooling systems that withdraw makeup water from a river).	2	SMALL, MODERATE, or LARGE. Water use conflicts could result from water withdrawals from rivers during low-flow conditions, which may affect aquifer recharge. The significance of impacts would depend on makeup water requirements, water availability, and competing water demands.
Groundwater quality degradation resulting from water withdrawals.	1	SMALL. Groundwater withdrawals at operating nuclear power plants would not contribute significantly to groundwater quality degradation.
Groundwater quality degradation (plants with cooling ponds in salt marshes).	1	SMALL. Sites with closed-cycle cooling ponds could degrade groundwater quality; however, because groundwater in salt marshes is brackish, this is not a concern for plants located in salt marshes.
Groundwater quality degradation (plants with cooling ponds at inland sites).	2	SMALL, MODERATE, or LARGE. Sites with closed-cycle cooling ponds could degrade groundwater quality. For plants located inland, the quality of the groundwater in the vicinity of the ponds could be affected. The significance of the impact would depend on cooling pond water quality, site hydrogeologic conditions (including the interaction of surface water and groundwater), and the location, depth, and pump rate of water wells.
Groundwater and soil contamination	2	SMALL or MODERATE. Industrial practices involving the use of solvents, hydrocarbons, heavy metals, or other chemicals and unlined wastewater lagoons have the potential to contaminate site groundwater, soil, and subsoil. Contamination is subject to State and Environmental Protection Agency regulated cleanup and monitoring programs.
Radionuclides released to groundwater	2	SMALL or MODERATE. Underground system leaks of process water have been discovered in recent years at several plants. Groundwater protection programs have been established at all operating nuclear power plants.

TABLE B–1—SUMMARY OF FINDINGS ON NEPA ISSUES FOR LICENSE RENEWAL OF NUCLEAR POWER PLANTS [1]—Continued

Issue	Category [2]	Finding [3]
Terrestrial Resources		
Impacts of continued plant operations on terrestrial ecosystems.	2	SMALL, MODERATE, or LARGE. Continued operations, refurbishment, and maintenance activities are expected to keep terrestrial communities in their current condition. Application of best management practices would reduce the potential for impacts. The magnitude of impacts would depend on the nature of the activity, the status of the resources that could be affected, and the effectiveness of mitigation.
Exposure of terrestrial organisms to radionuclides.	1	SMALL. Doses to terrestrial organisms are expected to be well below exposure guidelines developed to protect these organisms.
Cooling system impacts on terrestrial resources (plants with once-through cooling systems or cooling ponds).	1	SMALL. No adverse effects to terrestrial plants or animals have been reported as a result of increased water temperatures, fogging, humidity, or reduced habitat quality. Due to the low concentrations of contaminants in cooling system effluents, uptake and accumulation of contaminants in the tissues of wildlife exposed to the contaminated water or aquatic food sources are not expected to be significant issues.
Cooling tower impacts on vegetation (plants with cooling towers).	1	SMALL. Impacts from salt drift, icing, fogging, or increased humidity associated with cooling tower operation have the potential to affect adjacent vegetation, but these impacts have been small at operating nuclear power plants and are not expected to change over the license renewal term.
Bird collisions with cooling towers and transmission lines.	1	SMALL. Bird collisions with cooling towers and transmission lines occur at rates that are unlikely to affect local or migratory populations.
Water use conflicts with terrestrial resources (plants with cooling ponds or cooling towers using make-up water from a river with low flow).	2	SMALL or MODERATE. Impacts on terrestrial resources in riparian communities affected by water use conflicts could be of moderate significance in some situations.
Transmission line ROW management impacts on terrestrial resources.	1	SMALL. Continued ROW management during the license renewal term is expected to keep terrestrial communities in their current condition. Application of best management practices would reduce the potential for impacts.
Electromagnetic fields on flora and fauna (plants, agricultural crops, honeybees, wildlife, livestock).	1	SMALL. No significant impacts of electromagnetic fields on terrestrial flora and fauna have been identified. Such effects are not expected to be a problem during the license renewal term.
Aquatic Resources		
Impingement and entrainment of aquatic organisms (plants with once-through cooling systems or cooling ponds).	2	SMALL, MODERATE, or LARGE. The impacts of impingement and entrainment are small at many plants but may be moderate or even large at a few plants with once-through and cooling-pond cooling systems, depending on cooling system withdrawal rates and volumes and the aquatic resources at the site.
Impingement and entrainment of aquatic organisms (plants with cooling towers).	1	SMALL. Impingement and entrainment rates are lower at plants that use closed-cycle cooling with cooling towers because the rates and volumes of water withdrawal needed for makeup are minimized.
Thermal impacts on aquatic organisms (plants with once-through cooling systems or cooling ponds).	2	SMALL, MODERATE, or LARGE. Most of the effects associated with thermal discharges are localized and are not expected to affect overall stability of populations or resources. The magnitude of impacts, however, would depend on site-specific thermal plume characteristics and the nature of aquatic resources in the area.
Thermal impacts on aquatic organisms (plants with cooling towers).	1	SMALL. Thermal effects associated with plants that use cooling towers are small because of the reduced amount of heated discharge.
Effects of cooling water discharge on dissolved oxygen, gas supersaturation, and eutrophication.	1	SMALL. Gas supersaturation was a concern at a small number of operating nuclear power plants with once-through cooling systems but has been satisfactorily mitigated. Low dissolved oxygen was a concern at one nuclear power plant with a once-through cooling system but has been effectively mitigated. Eutrophication (nutrient loading) and resulting effects on chemical and biological oxygen demands have not been found to be a problem at operating nuclear power plants.
Effects of non-radiological contaminants on aquatic organisms.	1	SMALL. Best management practices and discharge limitations of NPDES permits are expected to minimize the potential for impacts to aquatic resources. Accumulation of metal contaminants has been a concern at a few nuclear power plants but has been satisfactorily mitigated by replacing copper alloy condenser tubes with those of another metal.
Exposure of aquatic organisms to radionuclides.	1	SMALL. Doses to aquatic organisms are expected to be well below exposure guidelines developed to protect these aquatic organisms.
Effects of dredging on aquatic organisms	1	SMALL. Effects of dredging on aquatic resources tend to be of short duration (years or less) and localized. Dredging requires permits from the U.S. Army Corps of Engineers, State environmental agencies, and other regulatory agencies.
Water use conflicts with aquatic resources (plants with cooling ponds or cooling towers using make-up water from a river with low flow).	2	SMALL or MODERATE. Impacts on aquatic resources in instream communities affected by water use conflicts could be of moderate significance in some situations.
Refurbishment impacts on aquatic resources.	1	SMALL. Refurbishment impacts with appropriate mitigation are not expected to change aquatic communities from their current condition.

TABLE B–1—SUMMARY OF FINDINGS ON NEPA ISSUES FOR LICENSE RENEWAL OF NUCLEAR POWER PLANTS [1]—Continued

Issue	Category [2]	Finding [3]
Impacts of transmission line ROW management on aquatic resources.	1	SMALL. Application of best management practices to ROW near aquatic systems would reduce the potential for impacts.
Losses from predation, parasitism, and disease among organisms exposed to sublethal stresses.	1	SMALL. These types of losses have not been found to be a problem at operating nuclear power plants and are not expected to be a problem during the license renewal term.
Stimulation of aquatic nuisance species (*e.g.*, shipworms).	1	SMALL. Stimulation of nuisance organisms has been satisfactorily mitigated at the single nuclear power plant with a once-through cooling system where previously it was a problem. It has not been found to be a problem at operating nuclear power plants with cooling towers or cooling ponds and is not expected to be a problem during the license renewal term.
Threatened, Endangered, and Protected Species and Essential Fish Habitat		
Threatened, endangered, and protected species and essential fish habitat.	2	SMALL, MODERATE, or LARGE. The magnitude of impacts on threatened, endangered, and protected species and essential fish habitat would depend on the occurrence of listed species and habitats and the effects of power plant systems on them. Consultation with appropriate agencies would be needed to determine whether special status species or habitats are present and whether they would be adversely affected by activities associated with license renewal.
Historic and Cultural Resources		
Historic and cultural resources	2	SMALL, MODERATE, or LARGE. Continued operations and refurbishment associated with the license renewal term are expected to have no more than small impacts on historic and cultural resources located onsite and in the transmission line ROW because most impacts could be mitigated by avoiding those resources. The National Historic Preservation Act (NHPA) requires the Federal agency to consult with the State Historic Preservation Officer (SHPO) and appropriate Native American tribes to determine the potential impacts and mitigation. *See* § 51.14(a).
Socioeconomics		
Employment and income, recreation and tourism.	1	SMALL. Although most nuclear plants have large numbers of employees with higher than average wages and salaries, employment and income impacts from continued operations and refurbishment are expected to be small. Nuclear plant operations, employee spending, power plant expenditures, and tax payments have an effect on local economies. Changes in plant operations, employment and expenditures would have a greater effect on rural economies than on semi-urban economies.
Tax revenues	1	SMALL. Nuclear plants provide tax revenue to local jurisdictions in the form of property tax payments, payments in lieu of tax (PILOT), or tax payments on energy production. The amount of tax revenue paid during the license renewal term from continued operations and refurbishment is not expected to change, since the assessed value of the power plant, payments on energy production and PILOT payments are also not expected to change.
Community services and education	1	SMALL. Changes to local community and educational services would be small from continued operations and refurbishment associated with the license renewal term. With no increase in employment, value of the power plant, payments on energy production, and PILOT payments expected during the license renewal term, community and educational services would not be affected by continued power plant operations. Changes in employment and tax payments would have a greater effect on jurisdictions receiving a large portion of annual revenues from the power plant than on jurisdictions receiving the majority of their revenues from other sources.
Population and housing	1	SMALL. Changes to regional population and housing availability and value would be small from continued operations and refurbishment associated with the license renewal term. With no increase in employment expected during the license renewal term, population and housing availability and values would not be affected by continued power plant operations. Changes in housing availability and value would have a greater effect on sparsely populated areas than areas with higher density populations.
Transportation	1	SMALL. Changes to traffic volumes would be small from continued operations and refurbishment activities associated with the license renewal term. Changes in employment would have a greater effect on rural areas, with less developed local and regional networks. Impacts would be less noticeable in semi-urban areas depending on the quality and extent of local access roads and the timing of plant shift changes when compared to typical local usage.
Human Health		
Radiation exposures to the public	1	SMALL. Radiation doses to the public from continued operations and refurbishment associated with the license renewal term are expected to continue at current levels, and would be well below regulatory limits.

TABLE B–1—SUMMARY OF FINDINGS ON NEPA ISSUES FOR LICENSE RENEWAL OF NUCLEAR POWER PLANTS [1]—Continued

Issue	Category [2]	Finding [3]
Radiation exposures to occupational workers.	1	SMALL. Occupational doses from continued operations and refurbishment associated with the license renewal term are expected to be within the range of doses experienced during the current license term, and would continue to be well below regulatory limits.
Human health impact from chemicals	1	SMALL. Chemical hazards to workers would be minimized by observing good industrial hygiene practices. Chemical releases to the environment and the potential for impacts to the public are minimized by adherence to discharge limitations of NPDES permits.
Microbiological hazards to the public (plants with cooling ponds or canals or cooling towers that discharge to a river).	2	SMALL, MODERATE, or LARGE. These organisms are not expected to be a problem at most operating plants except possibly at plants using cooling ponds, lakes, or canals that discharge to rivers. Impacts would depend on site-specific characteristics.
Microbiological hazards to plant workers	1	SMALL. Occupational health impacts are expected to be controlled by continued application of accepted industrial hygiene practices to minimize worker exposures.
Chronic effects of electromagnetic fields (EMFs) [5].	N/A [4]	Uncertain impact. Studies of 60–Hz EMFs have not uncovered consistent evidence linking harmful effects with field exposures. EMFs are unlike other agents that have a toxic effect (*e.g.*, toxic chemicals and ionizing radiation) in that dramatic acute effects cannot be forced and longer-term effects, if real, are subtle. Because the state of the science is currently inadequate, no generic conclusion on human health impacts is possible.
Physical occupational hazards	1	SMALL. Occupational safety and health hazards are generic to all types of electrical generating stations, including nuclear power plants, and is of small significance if the workers adhere to safety standards and use protective equipment.
Electric shock hazards	2	SMALL, MODERATE, or LARGE. Electrical shock potential is of small significance for transmission lines that are operated in adherence with the National Electrical Safety Code (NESC). Without a review of each nuclear plant transmission line conformance with NESC criteria, it is not possible to determine the significance of the electrical shock potential.
Postulated Accidents		
Design-basis accidents	1	SMALL. The NRC staff has concluded that the environmental impacts of design-basis accidents are of small significance for all plants.
Severe accidents	2	SMALL. The probability-weighted consequences of atmospheric releases, fallout onto open bodies of water, releases to groundwater, and societal and economic impacts from severe accidents are small for all plants. However, alternatives to mitigate severe accidents must be considered for all plants that have not considered such alternatives.
Environmental Justice		
Minority and low-income populations	2	SMALL or MODERATE. Impacts to minority and low-income populations and subsistence consumption will be addressed in plant-specific reviews. *See* NRC Policy Statement on the Treatment of Environmental Justice Matters in NRC Regulatory and Licensing Actions (69 FR 52040).
Solid Waste Management		
Low-level waste storage and disposal	1	SMALL. The comprehensive regulatory controls that are in place and the low public doses being achieved at reactors ensure that the radiological impacts to the environment would remain small during the term of a renewed license.
Onsite storage of spent nuclear fuel	1	SMALL. The expected increase in the volume of spent fuel from an additional 20 years of operation can be safely accommodated onsite with small environmental effects through dry or pool storage at all plants, if a permanent repository or monitored retrievable storage is not available.
Offsite radiological impacts of spent nuclear fuel and high-level waste disposal.	1	For the high-level waste and spent-fuel disposal component of the fuel cycle, the EPA established a dose limit of 15 millirem (0.15 mSv) per year for the first 10,000 years and 100 millirem (1.0 mSv) per year between 10,000 years and 1 million years for offsite releases of radionuclides at the proposed repository at Yucca Mountain, Nevada. The Commission concludes that the impacts would not be sufficiently large to require the NEPA conclusion, for any plant, that the option of extended operation under 10 CFR Part 54 should be eliminated. Accordingly, while the Commission has not assigned a single level of significance for the impacts of spent fuel and high level waste disposal, this issue is considered Category 1.

TABLE B–1—SUMMARY OF FINDINGS ON NEPA ISSUES FOR LICENSE RENEWAL OF NUCLEAR POWER PLANTS [1]—Continued

Issue	Category [2]	Finding [3]
Mixed-waste storage and disposal	1	SMALL. The comprehensive regulatory controls and the facilities and procedures that are in place ensure proper handling and storage, as well as negligible doses and exposure to toxic materials for the public and the environment at all plants. License renewal would not increase the small, continuing risk to human health and the environment posed by mixed waste at all plants. The radiological and nonradiological environmental impacts of long-term disposal of mixed waste from any individual plant at licensed sites are small.
Nonradioactive waste storage and disposal.	1	SMALL. No changes to systems that generate nonradioactive waste are anticipated during the license renewal term. Facilities and procedures are in place to ensure continued proper handling, storage, and disposal, as well as negligible exposure to toxic materials for the public and the environment at all plants.
		Cumulative Impacts
Cumulative impacts	2	Cumulative impacts of license renewal must be considered on a plant-specific basis. Impacts would depend on regional resource characteristics, the resource-specific impacts of license renewal, and the cumulative significance of other factors affecting the resource.
		Uranium Fuel Cycle
Offsite radiological impacts—individual impacts from other than the disposal of spent fuel and high-level waste.	1	SMALL. The impacts to the public from radiological exposures have been considered by the Commission in Table S–3 of this part. Based on information in the GEIS, impacts to individuals from radioactive gaseous and liquid releases, including radon-222 and technetium-99, would remain at or below the NRC's regulatory limits.
Offsite radiological impacts—collective impacts from other than the disposal of spent fuel and high-level waste.	1	There are no regulatory limits applicable to collective doses to the general public from fuel-cycle facilities. The practice of estimating health effects on the basis of collective doses may not be meaningful. All fuel-cycle facilities are designed and operated to meet the applicable regulatory limits and standards. The Commission concludes that the collective impacts are acceptable. The Commission concludes that the impacts would not be sufficiently large to require the NEPA conclusion, for any plant, that the option of extended operation under 10 CFR Part 54 should be eliminated. Accordingly, while the Commission has not assigned a single level of significance for the collective impacts of the uranium fuel cycle, this issue is considered Category 1.
Nonradiological impacts of the uranium fuel cycle.	1	SMALL. The nonradiological impacts of the uranium fuel cycle resulting from the renewal of an operating license for any plant would be small.
Transportation	1	SMALL. The impacts of transporting materials to and from uranium-fuel-cycle facilities on workers, the public, and the environment are expected to be small.
		Termination of Nuclear Power Plant Operations and Decommissioning
Termination of plant operations and decommissioning.	1	SMALL. License renewal is expected to have a negligible effect on the impacts of terminating operations and decommissioning on all resources.

[1] Data supporting this table are contained in NUREG–1437, Revision 1, ''Generic Environmental Impact Statement for License Renewal of Nuclear Plants'' (XX 20XX).

[2] The numerical entries in this column are based on the following category definitions:

Category 1: For the issue, the analysis reported in the Generic Environmental Impact Statement has shown:

(1) The environmental impacts associated with the issue have been determined to apply either to all plants or, for some issues, to plants having a specific type of cooling system or other specified plant or site characteristic;

(2) A single significance level (*i.e.*, small, moderate, or large) has been assigned to the impacts (except for collective off site radiological impacts from the fuel cycle and from high level waste and spent fuel disposal); and

(3) Mitigation of adverse impacts associated with the issue has been considered in the analysis, and it has been determined that additional plant-specific mitigation measures are likely not to be sufficiently beneficial to warrant implementation.

The generic analysis of the issue may be adopted in each plant-specific review.

Category 2: For the issue, the analysis reported in the Generic Environmental Impact Statement has shown that one or more of the criteria of Category 1 cannot be met, and therefore additional plant-specific review is required.

[3] The impact findings in this column are based on the definitions of three significance levels. Unless the significance level is identified as beneficial, the impact is adverse, or in the case of ''small,'' may be negligible. The definitions of significance follow:

SMALL—For the issue, environmental effects are not detectable or are so minor that they will neither destabilize nor noticeably alter any important attribute of the resource. For the purposes of assessing radiological impacts, the Commission has concluded that those impacts that do not exceed permissible levels in the Commission's regulations are considered small as the term is used in this table.

MODERATE—For the issue, environmental effects are sufficient to alter noticeably, but not to destabilize, important attributes of the resource.

LARGE—For the issue, environmental effects are clearly noticeable and are sufficient to destabilize important attributes of the resource.

For issues where probability is a key consideration (*i.e.*, accident consequences), probability was a factor in determining significance.

[4] NA (not applicable). The categorization and impact finding definitions do not apply to these issues.

[5] If, in the future, the Commission finds that, contrary to current indications, a consensus has been reached by appropriate Federal health agencies that there are adverse health effects from electromagnetic fields, the commission will require applicants to submit plant-specific reviews of these health effects as part of their license renewal applications. Until such time, applicants for license renewal are not required to submit information on this issue.

Office of Nuclear Reactor Regulation

Contents

Summary

The Atomic Energy Act of 1954 authorizes the U.S. Nuclear Regulatory Commission (NRC) to issue commercial nuclear power plant operating licenses for up to 40 years and permits the renewal of the licenses as well. NRC regulations allow for the renewal of these operating licenses for up to an additional 20 years, depending on the outcome of safety and environmental reviews. There are no specific limitations in the Atomic Energy Act or the NRC's regulations restricting the number of times a license may be renewed.

The license renewal process is designed to assure safe operation of the nuclear power plant and protection of the environment during the license renewal term. Under the NRC's environmental protection regulations in Title 10, Part 51, of the *Code of Federal Regulations* (10 CFR Part 51), which implement Section 102(2) of the National Environmental Policy Act (NEPA), renewal of a nuclear power plant operating license requires the preparation of an environmental impact statement (EIS).

To support the preparation of these EISs, the NRC issued the *Generic Environmental Impact Statement for License Renewal of Nuclear Plants* (GEIS), NUREG-1437, in 1996. The original 1996 GEIS[(a)] for license renewal was prepared to assess the environmental impacts associated with the continued operation of nuclear power plants during the license renewal term. The NRC also promulgated a rule that codified the findings of the 1996 GEIS into its regulations at 10 CFR Part 51, Subpart A, Appendix B, Table B-1 (61 FR 28467, June 5, 1996). The intent was to determine which environmental impacts would result in essentially the same (generic) impact at all nuclear power plants and which ones could result in different levels of impacts at different plants and would require a plant-specific analysis to determine the impacts. For those issues that could not be generically addressed, the NRC would prepare plant-specific supplemental EISs (SEISs) to the GEIS.

The GEIS is intended to improve the efficiency of the license renewal process by (1) providing an evaluation of the types of environmental impacts that may occur from renewing commercial nuclear power plant operating licenses, (2) identifying and assessing impacts that are expected to be generic (the same or similar) at all nuclear plants (or plants with specific plant or site characteristics), and (3) defining the number and scope of environmental impact issues that need to be addressed in plant-specific EISs.

(a) Any reference in this document to the 1996 GEIS includes the two-volume set published in 1996 and Addendum 1 to the GEIS published in 1999.

As stated in the 1996 final rule that incorporated the findings of the GEIS in 10 CFR Part 51, the NRC recognized that environmental impact issues might change over time, and that additional issues may need to be considered. As further stated in the preamble to Table B-1, the NRC indicated that it intended to review the material in Table B-1 on a 10-year basis.
The NRC began this review on June 3, 2003, by publishing a notice of intent to revise the 1996 GEIS (68 FR 33209). As part of this process and pursuant to 10 CFR 51.29, the NRC conducted scoping and held a series of public meetings (*see* 74 FR 38119 for more details). The original public comment period began in June 2003 and closed in September 2003. The project was inactive for the next two years due to limited NRC staff resources and competing demands. On October 3, 2005 (70 FR 57628), the NRC reopened the public comment period and extended it until December 30, 2005.

On July 31, 2009 (74 FR 38117), the NRC published the proposed rule, "Revisions to Environmental Review for Renewal of Nuclear Power Plant Operating Licenses," for public comment in the *Federal Register*. The proposed rule would amend Table B-1, by updating the Commission's 1996 findings on the environmental impacts related to the renewal of nuclear power plant operating licenses, and other NRC environmental protection regulations (e.g., 10 CFR 51.53, which sets forth the contents of the applicant's environmental report). Together with the proposed rule, the NRC also published a notice of availability of the draft revised GEIS (ADAMS Accession No. ML090220654); a proposed Revision 1 of Regulatory Guide (RG) 4.2, Supplement 1, "Preparation of Environmental Reports for Nuclear Power Plant License Renewal Applications" (ADAMS Accession No. ML091620409); and a proposed Revision 1 to NUREG–1555, Supplement 1, "Standard Review Plans for Environmental Reviews for Nuclear Power Plants" (ADAMS Accession No. ML090230497), in the *Federal Register* (74 FR 38238). All of the documents requested public comments.

The proposed revision to the above documents were based on consideration of 1) comments received from the public during the public scoping period, 2) a review of comments received on plant-specific SEISs completed since the 1996 GEIS was issued, and 3) lessons learned and knowledge gained from previous and ongoing license renewal environmental reviews. The history of this rulemaking is discussed in more detail in the July 31, 2009 (74 FR 38117), proposed rule.

Since publication of the GEIS in 1996, approximately 40 nuclear plant sites (70 reactor units) have been the subject of plant-specific environmental reviews. This revision to the GEIS is intended to incorporate lessons learned and knowledge gained from these plant-specific environmental reviews, as well as changes to Federal laws and new information and research published since the 1996 GEIS.

S.1 Purpose and Need for the Proposed Action

The proposed action is the renewal of commercial nuclear power plant operating licenses. The NRC reviews each application submitted by licensees of operating nuclear power plants. A renewed license is just one of a number of conditions that licensees must meet if the licensee is to continue plant operations during the renewal term.

The purpose and need for NRC's proposed action is to provide an option to continue plant operations beyond the current licensing term to meet future system generating needs, as such needs may be determined by State, utility, system, and, where authorized, Federal (other than NRC) decision-makers. Unless there are findings in the safety review required by the Atomic Energy Act or in the NEPA environmental review that would lead the NRC to reject a license renewal application, the NRC has no role in the energy-planning decisions of power plant owners, State regulators, system operators, and, in some cases other Federal agencies, as to whether the plant should continue to operate.

In addition, the NRC has no authority or regulatory control over the ultimate selection of future replacement power alternatives. The NRC also cannot ensure that environmentally preferable replacement power alternatives are used in the future. While a wide range of replacement power alternatives are discussed in the GEIS, the only alternative to license renewal within NRC's decision-making authority is to not issue a renewed operating license. The impacts of not issuing a renewed operating license are addressed under the no-action alternative.

At some point, all nuclear power plants will terminate operations and undergo decommissioning. Under the no-action alternative, plant operations would be terminated at or before the end of the current license term. The no-action alternative, unlike the other alternatives, does not expressly meet the purpose and need of the proposed action, as it does not provide a means of meeting future electric system needs. No action, on its own, would likely create a need for replacement power, conservation and energy efficiency (demand-side management), purchased power, or some combination of these options.

A full range of replacement power alternatives are evaluated in the GEIS, including fossil fuel, new nuclear, and renewable energy sources. Conservation and power purchasing are also considered as replacement power alternatives to license renewal, because they represent other options for electric system planners.

S.2 Development of the Revised Generic Environmental Impact Statement

The GEIS documents the results of the systematic approach NRC used to evaluate the environmental consequences of renewing the licenses of commercial nuclear power plants and operating the plants for an additional 20 years beyond the current license term. The environmental consequences of license renewal include (1) impacts associated with continued operations and refurbishment activities similar to those that have occurred during the current license term; (2) impacts of various alternatives to the proposed action; (3) impacts from the termination of nuclear power plant operations and decommissioning after the license renewal term (with emphasis on the incremental effect caused by an additional 20 years of operation); (4) impacts associated with the uranium fuel cycle; (5) impacts of postulated accidents (design-basis accidents and severe accidents); (6) cumulative impacts of the proposed action; and (7) resource commitments associated with the proposed action, including unavoidable adverse impacts, the relationship between short-term use and long-term productivity, and irreversible and irretrievable commitment of resources. The environmental consequences of these activities are discussed in the GEIS.

In the 1996 GEIS, the NRC identified and assessed 92 environmental issues. This GEIS revision reviews and reevaluates the environmental impact issues and findings in the original GEIS. Experience gained from license renewal reviews conducted since the 1996 GEIS was published provides a source of new information for the evaluation presented in this revision. In addition, new research, findings, and other information were considered in evaluating the significance of impacts associated with license renewal. The purpose of the evaluation was to determine if the findings presented in the 1996 GEIS remain valid. In doing so, the NRC considered the need to modify, add to, group, or delete any of the 92 issues evaluated in the 1996 GEIS.

In a Notice of Intent published in the *Federal Register* on June 3, 2003, the NRC notified the public of its plan to revise the GEIS and to give people an opportunity to participate in the environmental scoping process. This step was the initial opportunity for public participation in the GEIS revision. In July 2003, the NRC held public scoping meetings in four locations (one in each of the four NRC regions)—Atlanta, Georgia; Oak Lawn, Illinois; Anaheim, California; and Boston, Massachusetts.

Participation in the scoping process by members of the public and local, State, Tribal, and Federal government agencies was encouraged and used to (1) determine the scope of the GEIS revision and identify whether there are any significant new issues that should be analyzed in depth; (2) identify and eliminate from detailed study those issues that are peripheral, are not significant, or have been covered by prior environmental reviews; (3) identify any environmental assessments and other EISs that are being or will be prepared that are related to, but are not part of, the scope of the proposed action; and (4) identify other environmental review and consultation requirements related to the proposed action.

The initial scoping period for this GEIS revision was from June 3, 2003, to September 17, 2003, but scoping was reopened between September 27, 2005, and December 30, 2005. The NRC staff reviewed the transcripts and all written material received during the scoping periods and identified individual comments. All comments and suggestions received orally during the scoping meetings or in writing were considered.

In evaluating the impacts of the proposed action and considering comments received from the public, agencies and other entities during the scoping period, the NRC identified 78 impact issues: 70 impact issues were associated with continued operations, refurbishment, and other supporting activities; 2 with postulated accidents; 1 with termination of plant operations and decommissioning; 4 with the uranium fuel cycle; and 1 with cumulative impacts. For all of these issues, the incremental effect of license renewal was the focus of the evaluation.

For each potential environmental impact issue, the revised GEIS (1) describes the nuclear power plant activity that could affect the resource, (2) identifies the resource that is affected, (3) evaluates past license renewal reviews and other available information, (4) assesses the nature and magnitude of the environmental impact on the affected resource, (5) characterizes the significance of the effect, (6) determines whether the results of the analysis apply to all nuclear power plants (whether the impact issue is Category 1, Category 2, or uncategorized), and (7) considers additional mitigation measures for adverse impacts.

The scope of the revised GEIS also evaluates the impacts of alternatives to license renewal, including replacement power generation (using fossil fuels, nuclear, and/or renewable energy), conservation and energy efficiency (demand-side management), and purchased power. It also evaluates the impacts from the no-action alternative (not renewing the operating license). This GEIS includes the NRC's evaluation of construction, operation, postulated accidents, decommissioning, and fuel cycles for these alternatives.

The NRC issued the revised GEIS as a draft on July 31, 2009; the NRC published a notice of the issuance in the *Federal Register* (34 FR 38238, July 31, 2009). The NRC also issued a proposed rule, which would codify the findings of the revised GEIS in Table B-1 of 10 CFR Part 51 as well as amend related 10 CFR Part 51 regulations (34 FR 38117, July 31, 2009). Both the notice issuing the draft revised GEIS and the proposed rule asked for public comments. The public comment period ran from July 31, 2009 to January 12, 2010. The NRC received several comment submissions (e.g., letters, e-mails), which contained, in aggregate, several hundred written comments. During the public comment period, the NRC also held six public meetings, which were transcribed (see ML093070141 for a summary of the public meetings).

All in-scope comments, both written and those received during the public meetings, were considered in preparing this revised GEIS.

S.3 Impact Definitions and Categories

The NRC's standard of significance for impacts uses the Council on Environmental Quality (CEQ) terminology for "significantly" (40 CFR 1508.27), which requires consideration of both "context" and "intensity." Based on this, the NRC established three levels of significance for potential impacts: SMALL, MODERATE, and LARGE. The definitions of the three significance levels, which are presented in the footnotes to Table B-1 of 10 CFR Part 51, Subpart A, Appendix B, follow:

- SMALL impact: Environmental effects are not detectable or are so minor that they will neither destabilize nor noticeably alter any important attribute of the resource. For the purposes of assessing radiological impacts, the Commission has concluded that those impacts that do not exceed permissible levels in the Commission's regulations are considered SMALL.

- MODERATE impact: Environmental effects are sufficient to alter noticeably, but not to destabilize, important attributes of the resource.

- LARGE impact: Environmental effects are clearly noticeable and are sufficient to destabilize important attributes of the resource.

In addition to a determination of significance of environmental impacts associated with an issue, a determination was made whether the analysis in the GEIS could be applied to all nuclear plants (as well as to all plants with certain plant or site characteristics). Issues were assigned a Category 1 or Category 2 designation as follows:

Category 1 issues are those that meet all of the following criteria:

(1) The environmental impacts associated with the issue have been determined to apply either to all plants or, for some issues, to plants having a specific type of cooling system or other specified plant or site characteristics;

(2) A single significance level (i.e., SMALL, MODERATE, or LARGE) has been assigned to the impacts (except for offsite radiological impacts—collective impacts from other than the disposal of spent fuel and high-level waste);

(3) Mitigation of adverse impacts associated with the issue has been considered in the analysis, and it has been determined that additional plant-specific mitigation measures are not likely to be sufficiently beneficial to warrant implementation.

For issues that meet the three Category 1 criteria, no additional plant-specific analysis is required in future SEISs unless new and significant information is identified.

Category 2 issues are those that do not meet one or more of the criteria of Category 1, and therefore, require additional plant-specific review.

S.4 Affected Environment

For purposes of the evaluation in this GEIS revision, the “affected environment” is the environment currently existing around operating commercial nuclear power plants. Current conditions in the affected environment are the result of past construction and operations at the plants. The NRC has considered the effects of these past and ongoing impacts and how they have shaped the environment. The NRC evaluated impacts of license renewal that are incremental to existing conditions. These existing conditions serve as the baseline for the evaluation and include the effects of past and present actions at the plants. It is this existing affected environment that comprises the environmental baseline against which potential environmental impacts of license renewal are evaluated.

The NRC described the affected environment in terms of the following resource areas and activities: (1) land use and visual resources; (2) meteorology, air quality, and noise; (3) geologic environment; (4) water resources (surface water and groundwater resources); (5) ecological resources (terrestrial resources, aquatic resources, special status species and habitats); (6) historic and cultural resources; (7) socioeconomics; (8) human health (radiological and nonradiological hazards); (9) environmental justice; and (10) waste management and pollution prevention. The affected environments of the operating plant sites represent diverse environmental conditions.

S.5 Impacts from Continued Operations and Refurbishment Activities Associated with License Renewal

NRC identified 78 impact issues from continued operations and refurbishment associated with license renewal. Seventeen of these issues were identified as Category 2 issues and would require plant-specific evaluations in future SEISs. The conclusions in each resource topical area are summarized here.

Land Use

- The impacts of continued operations and refurbishment on onsite land use would be SMALL. Changes in onsite land use from continued operations and refurbishment would be a small fraction of the nuclear power plant site and would only involve land that is controlled by the licensee. This is a Category 1 issue.

- The impacts of continued operations and refurbishment on offsite land use would be SMALL. Offsite land use would not be affected from continued operations and refurbishment associated with license renewal. This is a Category 1 issue.

- Use of transmission line right-of-ways (ROWs) would continue with no change in offsite land use restrictions. This is a Category 1 issue.

Visual Resources

- No important changes to the visual appearance (aesthetics) of plant structures or transmission lines are expected from continued operations and refurbishment. This is a Category 1 issue.

Air Quality

- Air quality impacts from continued operations and refurbishment activities would be SMALL. Emissions from refurbishment activities at locations in or near air quality nonattainment or maintenance areas would be short-lived and would cease once the activities are completed. Operating experience has shown that the scale of refurbishment activities has not resulted in exceedances in the *de minimis* thresholds for criteria pollutants. Best management practices, including fugitive dust controls and the imposition of permit conditions in State and local air emissions permits, would ensure conformance with applicable State or Tribal Implementation Plans. Emissions from emergency diesel generators and fire pumps and routine operations of boilers used for space heating would not be a concern, even for plants located in or adjacent to nonattainment areas. Impacts from cooling tower particulate emissions even under the worst-case situations have been SMALL. This is a Category 1 issue.

- Production of ozone and oxides of nitrogen from transmission lines is insignificant and does not contribute measurably to ambient levels of these gases. This is a Category 1 issue.

Noise Impacts

- The impacts of continued operations and refurbishment on offsite noise levels would be SMALL. Noise levels would remain below regulatory guidelines for offsite receptors. This is a Category 1 issue.

Geology and Soils

- The effect of geologic and soil conditions on plant operations and the impact of continued operations and refurbishment activities on geology and soils would be SMALL and would not change appreciably during the license renewal term. This is a Category 1 issue.

Surface Water Resources

- The non-cooling system impacts of continued operations and refurbishment on surface water use and quality would be SMALL if best management practices are employed to control soil erosion and spills. Surface water use would not increase significantly or would be reduced if refurbishment occurs during a plant outage. This is a Category 1 issue.

- Altered current patterns would be limited to the area in the vicinity of the intake and discharge structures. These impacts have been SMALL at operating nuclear power plants. This is a Category 1 issue.

- Effects on salinity gradients would be limited to the area in the vicinity of the intake and discharge structures. These impacts have been SMALL at operating nuclear power plants. This is a Category 1 issue.

- Effects on thermal stratification in lakes would be limited to the area in the vicinity of the intake and discharge structures. These impacts have been SMALL at operating nuclear power plants. This is a Category 1 issue.

- Scouring effects would be limited to the area in the vicinity of the intake and discharge structures. These impacts have been SMALL at operating nuclear power plants. This is a Category 1 issue.

- Discharges of metals in cooling system effluent have not been found to be a problem at operating nuclear power plants with cooling-tower-based heat dissipation systems and have been mitigated at other plants. Discharges are monitored as part of the National Pollutant Discharge Elimination System (NPDES) permit process. This is a Category 1 issue.

- The discharge and effects of biocides, sanitary wastes, and minor chemical spills are regulated by State and Federal environmental agencies. Discharges are monitored and controlled as part of the NPDES permit process. These impacts have been SMALL at operating nuclear power plants. This is a Category 1 issue.

- Surface water use conflicts have not been found to be a problem at operating nuclear power plants with once-through heat dissipation systems. This is a Category 1 issue.

- Surface water use conflicts could occur with nuclear power plants that rely on cooling ponds or cooling towers using makeup water from a river. Impacts could be SMALL or MODERATE, depending on makeup water requirements, water availability, and competing water demands. This is a Category 2 issue.

- Dredging to remove accumulated sediments in the vicinity of intake and discharge structures and to maintain barge shipping has not been found to be a problem for surface water quality. Dredging is performed under permit from the U.S. Army Corps of Engineers, and possibly, from State or local agencies. This is a Category 1 issue.

- Temperature effects on sediment capacity have not been found to be a problem at operating nuclear power plants and are not expected to be a problem during the license renewal term. This is a Category 1 issue.

Groundwater Resources

- The non-cooling system impacts of continued operations and refurbishment on groundwater would be SMALL. Extensive dewatering is not anticipated during continued operations. Industrial practices involving the use of solvents, hydrocarbons, heavy metals, or other chemicals and/or the use of wastewater ponds or lagoons have the potential to contaminate site groundwater, soil, and subsoil. Contamination is subject to State or U.S. Environmental Protection Agency (EPA)-regulated cleanup and monitoring programs. The application of best management practices for handling any materials produced or used during these activities would reduce impacts. This is a Category 1 issue.

- Groundwater use conflicts are not anticipated for nuclear power plants that withdraw less than 100 gallons per minute. This is a Category 1 issue.

- Groundwater use conflicts with nearby groundwater users could occur with nuclear power plants that withdraw more than 100 gallons per minute. Impacts could be SMALL, MODERATE, or LARGE. This is a Category 2 issue.

- For plants with closed-cycle cooling systems that withdraw makeup water from a river, groundwater use conflicts could result from water withdrawals from rivers during low-flow conditions, which may affect aquifer recharge. The significance of impacts would depend on makeup water requirements, water availability, and competing water demands. The impacts on groundwater quality could be SMALL, MODERATE, or LARGE. This is a Category 2 issue.

- Groundwater withdrawals at operating nuclear power plants would not significantly degrade groundwater quality. This is a Category 1 issue.

- For plants with closed-cycle cooling ponds in salt marshes, groundwater quality could be degraded; the impact would be SMALL. However, groundwater in salt marshes is naturally brackish and thus, not potable. Consequently, the human use of such groundwater is limited to industrial purposes. This is a Category 1 issue.

- For plants with closed-cycle cooling ponds at inland sites, the impacts on groundwater quality could be SMALL, MODERATE, or LARGE. The significance of the impact would depend on cooling pond water quality; site hydrogeologic conditions (including the interaction of surface water and groundwater); and the location, depth, and pump rate of water wells. This is a Category 2 issue.

- Radionuclides released to groundwater, particularly tritium, due to inadvertent leaks of radioactive liquids from plant components and pipes could result in SMALL or MODERATE groundwater quality impacts. Such leaks have occurred at numerous plants. Groundwater protection programs have been established at all operating nuclear power plants to minimize the potential impact from any inadvertent releases. This is a Category 2 issue.

Terrestrial Resources

- Non-cooling system impacts of continued operations and refurbishment may affect terrestrial communities. Application of best management practices would reduce the potential for impacts. The magnitude of impacts (SMALL, MODERATE, or LARGE) would depend on the nature of the activity, the status of the resources that could be affected, and the effectiveness of mitigation. This is a Category 2 issue.

- The impacts of the exposure of terrestrial organisms to radionuclides would be SMALL. Doses to terrestrial organisms are expected to be well below exposure guidelines developed to protect these organisms. This is a Category 1 issue.

- Cooling system impacts on terrestrial resources would be SMALL for all nuclear plants with once-through cooling systems or cooling ponds. No adverse effects to terrestrial plants or animals have been reported as a result of increased water temperatures, fogging, humidity, or reduced habitat quality. Due to the low concentrations of contaminants in cooling system effluents, uptake and accumulation of contaminants are not expected to be significant. This is a Category 1 issue.

- Cooling tower operations and the impacts from salt drift, icing, fogging, or increased humidity associated with cooling tower operation have the potential to affect adjacent vegetation. However, these impacts have been SMALL at operating nuclear power plants and are not expected to change over the license renewal term. This is a Category 1 issue.

- Bird collisions with cooling towers and other plant structures and transmission lines occur at rates that are unlikely to affect local or migratory populations, and the rates are not expected to change during the license renewal term. This is a Category 1 issue.

- Water use conflicts with terrestrial resources for plants with cooling ponds or cooling towers using makeup water from a river could be SMALL or MODERATE. Impacts on terrestrial resources in riparian communities affected by water use conflicts could be of moderate significance in some situations. This is a Category 2 issue.

- Transmission line ROW management impacts on terrestrial resources would be SMALL. Continued ROW management is expected to keep terrestrial communities in their current condition. Application of best management practices would reduce the potential for impacts. This is a Category 1 issue.

- Impacts of electromagnetic fields on flora and fauna would be SMALL. No significant impacts of electromagnetic fields on terrestrial flora and fauna have been identified. Such effects are not expected to be a problem during the license renewal term. This is a Category 1 issue.

Aquatic Resources

- The impacts of impingement and entrainment of aquatic organisms could be SMALL, MODERATE, or LARGE at nuclear plants with once-through cooling systems or cooling ponds. The impacts are SMALL at many plants but may be MODERATE or even LARGE at a few plants, depending on cooling system withdrawal rates and volumes and the aquatic resources at the site. This is a Category 2 issue.

- The impacts of impingement and entrainment of aquatic organisms would be SMALL at plants with cooling towers. Impingement and entrainment rates are lower at plants that use closed-cycle cooling with cooling towers because the rates and volumes of water withdrawal needed for makeup are minimized. This is a Category 1 issue.

- Entrainment of phytoplankton and zooplankton has not been found to be a problem at operating nuclear power plants and is not expected to be a problem during the license renewal term. This is a Category 1 issue.

- Thermal impacts on aquatic organisms could be SMALL, MODERATE, or LARGE at nuclear plants with once-through cooling systems or cooling ponds. Most of the effects associated with thermal discharges are localized and are not expected to affect overall stability of populations or resources. The magnitude of impacts would depend on site-specific thermal plume characteristics and the nature of aquatic resources in the area. This is a Category 2 issue.

- Thermal impacts on aquatic organisms associated with plants that use cooling towers would be SMALL because of the reduced amount of heated discharge. This is a Category 1 issue.

- Infrequently reported thermal impacts would be SMALL for all nuclear plants during the license renewal term. Cold shock has been satisfactorily mitigated at operating nuclear plants with once-through cooling systems, has not endangered fish populations or been found to be a problem at operating nuclear power plants with cooling towers or cooling ponds, and is not expected to be a problem. Thermal plumes have not been found to be a problem at operating nuclear power plants and are not expected to be a problem. Thermal discharge may have localized effects but is not expected to affect the larger geographical distribution of aquatic organisms. Premature emergence has been found to be a localized effect at some operating nuclear power plants but has not been a problem and is not expected to be a problem. Stimulation of nuisance organisms has been mitigated at the single nuclear power plant with a once-through cooling system where previously it was a problem. It has not been found to be a problem at operating nuclear power plants with cooling towers or cooling ponds and is not expected to be a problem. This is a Category 1 issue.

- The effects of cooling water discharge on dissolved oxygen, gas supersaturation, and eutrophication are expected to result in SMALL impacts at all nuclear plants. Gas supersaturation was a concern at a small number of operating nuclear power plants with once-through cooling systems but has been satisfactorily mitigated. Low dissolved oxygen was a concern at one nuclear power plant with a once-through cooling system, but the problem has been effectively mitigated. Eutrophication (nutrient loading) and resulting effects on chemical and biological oxygen demands have not been found to be a problem at operating nuclear power plants. This is a Category 1 issue.

- The impacts of nonradiological contaminants on aquatic organisms would be SMALL. Best management practices and discharge limitations of NPDES permits are expected to minimize the potential for impacts to aquatic resources. Accumulation of metal contaminants has been a concern at a few nuclear power plants, but has been satisfactorily mitigated by replacing copper alloy condenser tubes with those of another metal. This is a Category 1 issue.

- The impacts of radionuclides on aquatic organisms would be SMALL. Doses to aquatic organisms are expected to be well below exposure guidelines developed to protect these organisms. This is a Category 1 issue.

- The effects of dredging on aquatic resources would be SMALL. Dredging at nuclear power plants is expected to occur infrequently, would be of relatively short duration, and would affect relatively small areas. Dredging is performed under permit from the U.S. Army Corps of Engineers, and possibly, from other State or local agencies. This is a Category 1 issue.

- Water use conflicts with aquatic resources for plants with cooling ponds or cooling towers using makeup water from a river could be SMALL or MODERATE. Impacts on aquatic resources in stream communities affected by water use conflicts could be of moderate significance in some situations. This is a Category 2 issue.

- The non-cooling system impacts of continued operations and refurbishment activities on aquatic resources would be SMALL. Licensee application of appropriate mitigation measures is expected to result in no more than small changes to aquatic communities from their current condition. This is a Category 1 issue.

- The impacts of transmission line ROW management on aquatic resources would be SMALL. Licensee application of best management practices to ROW maintenance is expected to result in no more than small impacts to aquatic resources. This is a Category 1 issue.

- Losses from predation, parasitism, and disease among organisms exposed to sublethal stresses would be SMALL. These types of losses have not been found to be a problem at operating nuclear power plants and are not expected to be a problem during the license renewal term. This is a Category 1 issue.

Special Status Species and Habitats

- The magnitude of impacts on threatened, endangered, and protected species, critical habitat, and essential fish habitat would depend on the occurrence of listed species and habitats and the effects of power plant systems on them. Consultation with appropriate agencies would be needed to determine whether special status species or habitats are present and whether they would be adversely affected by continued operations and refurbishment associated with license renewal. This is a Category 2 issue.

Historic and Cultural Resources

- Continued operations and refurbishment associated with license renewal are expected to have no more than small impacts on historic and cultural resources located onsite and in the transmission line ROWs because most impacts could be mitigated by avoiding those resources. The National Historic Preservation Act (NHPA) requires the Federal agency to consult with the State Historic Preservation Officer (SHPO) and Native American Tribes to determine the potential effects on historic properties and mitigation, if necessary. This is a Category 2 issue.

Socioeconomics

- Although most nuclear plants have large numbers of employees with higher than average wages and salaries, employment, income, recreation, and tourism, impacts from continued operations and refurbishment associated with license renewal are expected to be SMALL. This is a Category 1 issue.

- Impacts on tax revenues would be SMALL. Nuclear plants provide tax revenue to local jurisdictions in the form of property tax payments, payments in lieu of tax (PILOT) payments, or tax payments on energy production. The amount of tax revenue paid during the license renewal term as a result of continued operations and refurbishment associated with license renewal is not expected to change. This is a Category 1 issue.

- Changes to community services and education resulting from continued operations and refurbishment associated with license renewal would be SMALL. With little or no change in (1) employment at the licensee's plant, (2) value of the power plant, (3) payments on energy production, and (4) PILOT payments expected during the renewal term, community and educational services would not be affected by continued power plant operations. This is a Category 1 issue.

- Population and housing impacts would be SMALL as changes resulting from continued operations and refurbishment associated with license renewal to regional population and housing availability and value would be SMALL. With little or no change in employment at the licensee's plant expected during the license renewal term, population and housing availability and values would not be affected by continued power plant operations. This is a Category 1 issue.

- Transportation impacts would be SMALL as changes resulting from continued operations and refurbishment associated with license renewal to traffic volumes would be SMALL. This is a Category 1 issue.

Human Health

- Radiation doses to the public from continued operations and refurbishment associated with the license renewal term are expected to continue at current levels and would be well below regulatory limits. The impacts from radiation doses to the public would be SMALL. This is a Category 1 issue.

- Radiation doses to plant workers from continued operations and refurbishment associated with license renewal are expected to be within the range of doses experienced during the current license term and would continue to be well below regulatory limits. The impacts from radiation doses to plant workers would be SMALL. This is a Category 1 issue.

- Chemical hazards to plant workers resulting from continued operations and refurbishment associated with license renewal are expected to be minimized by the licensee implementing good industrial hygiene practices as required by permits and Federal and State regulations. Chemical releases to the environment and the potential for impacts to the public are expected to be minimized by adherence to discharge limitations of NPDES and other permits. The impacts from chemical hazards to plant workers would be SMALL. This is a Category 1 issue.

- Microbiological hazards to the public are not expected to be a problem at most operating plants but could result in SMALL, MODERATE, or LARGE impacts at plants with cooling ponds, lakes, canals, or that discharge to a river. Impacts would depend on site-specific characteristics. This is a Category 2 issue.

- Microbiological hazards to plant workers would be SMALL. Occupational health impacts are expected to be controlled by continued application of accepted industrial hygiene practices to minimize worker exposures as required by permits and Federal and State regulations. This is a Category 1 issue.

- The chronic effects of electromagnetic fields (EMFs) associated with nuclear plants and associated transmission lines are uncertain. Studies of 60-Hz EMFs have not uncovered consistent evidence linking harmful effects with field exposures. EMFs are unlike other agents that have a toxic effect (e.g., toxic chemicals and ionizing radiation) in that dramatic acute effects cannot be forced and longer-term effects, if real, are subtle. Because the state of the science is currently inadequate, no generic conclusion on human health impacts is possible. This issue has not been categorized.

- Physical occupational safety and health hazards are generic to all types of electrical generating stations, including nuclear power plants, and are of small significance if the workers adhere to safety standards and use personal protective equipment as required by Federal and State regulations. This is a Category 1 issue.

- Electric shock hazards could result in SMALL, MODERATE, or LARGE impacts. Electrical shock potential is of small significance for transmission lines that are operated in adherence with the National Electrical Safety Code (NESC). Without a review of conformance with NESC criteria of each nuclear power plant's in-scope transmission lines, it is not possible to determine the generic significance of the electrical shock potential. This is a Category 2 issue.

Postulated Accidents

- The environmental impacts of design-basis accidents are SMALL for all nuclear plants. Due to the requirements for nuclear plants to maintain their licensing basis and implement aging management programs during the license renewal term, the environmental impacts during a license renewal term should not differ significantly from those calculated for the design-basis accident assessments conducted as part of the initial plant licensing process. This is a Category 1 issue.

- For severe accidents, the probability-weighted consequences of atmospheric releases, fallout onto open bodies of water, releases to groundwater, and societal and economic impacts from severe accidents are SMALL for all plants. However, alternatives to mitigate severe accidents must be considered for all plants that have not considered such alternatives. This is a Category 2 issue.

Environmental Justice

- Impacts to minority and low-income populations and subsistence consumption resulting from continued operations and refurbishment associated with license renewal will be addressed in plant-specific reviews. See NRC Policy Statement on the Treatment of Environmental Justice Matters in NRC Regulatory and Licensing Actions (69 FR 52040, August 24, 2004). This is a Category 2 issue.

Waste Management and Pollution Prevention

- The impacts from low-level waste (LLW) storage and disposal would be SMALL. The comprehensive regulatory controls that are in place and the low public doses being achieved at reactors ensure that the radiological impacts on the environment would remain SMALL during the license renewal term. This is a Category 1 issue.

- The impacts from onsite storage of spent nuclear fuel would be SMALL. The expected increase in the volume of spent fuel from an additional 20 years of operation can be safely accommodated onsite during the license renewal term with small environmental effects through dry or pool storage at all plants. This is a Category 1 issue.

- The impacts from offsite radiological impacts of spent nuclear fuel and high-level waste (HLW) disposal are uncertain. The issue is not categorized.

- The impacts from mixed-waste storage and disposal would be SMALL. The comprehensive regulatory controls and the facilities and procedures that are in place ensure proper handling and storage, as well as negligible doses and exposure to toxic materials for the public and the environment at all plants. License renewal would not increase the small continuing risk to human health and the environment posed by mixed waste at all plants. The radiological and nonradiological environmental impacts of long-term disposal of mixed waste from any individual plant at licensed sites are SMALL. This is a Category 1 issue.

- The impacts from nonradioactive waste storage and disposal would be SMALL. No changes to systems that generate nonradioactive waste are anticipated during the license renewal term. Facilities and procedures are in place to ensure continued proper handling, storage, and disposal, as well as negligible exposure to toxic materials for the public and the environment at all plants. This is a Category 1 issue.

Cumulative Impacts

- Cumulative impacts are those impacts on the environment that result from the incremental impact of the proposed action when added to other past, present, and reasonably foreseeable future actions, regardless of what agency (Federal or non-Federal) or person undertakes such other actions. The cumulative impacts of continued operations and refurbishment associated with license renewal must be considered on a plant-specific basis. Impacts would depend on regional resource characteristics, the resource-specific impacts of license renewal, and the cumulative significance of other factors affecting the resource. This is a Category 2 issue.

Uranium Fuel Cycle

- The individual offsite radiological impacts resulting from portions of the uranium fuel cycle, other than the disposal of spent fuel and HLW, would be SMALL. The impacts on individuals from radioactive gaseous and liquid releases during the license renewal term would remain at or below the NRC's regulatory limits. This is a Category 1 issue.

- With respect to the collective offsite radiological impacts from the uranium fuel cycle other than the disposal of spent fuel and HLW, there are no regulatory limits applicable to collective doses to the general public from fuel-cycle facilities. The practice of estimating health effects based on collective doses may not be meaningful. All fuel-cycle facilities are designed and operated to meet the applicable regulatory dose limits and standards. Accordingly, the Commission concludes that the collective impacts are acceptable. This is a Category 1 issue.

- The nonradiological impacts of the uranium fuel cycle resulting from the renewal of an operating license for any plant would be SMALL. This is a Category 1 issue.

- The impacts of transporting materials to and from uranium-fuel-cycle facilities on workers, the public, and the environment are expected to be SMALL. This is a Category 1 issue.

Termination of Nuclear Power Plant Operations and Decommissioning

- Termination of plant operations and decommissioning would occur eventually regardless of license renewal. The additional 20-year period of operation under the license renewal term would not affect the impacts of shutdown and decommissioning on any resource or at any plant. This is a Category 1 issue.

S.6 Comparison of Alternatives

The GEIS also evaluates the impacts of the proposed action (license renewal) and alternatives to license renewal, including the no-action alternative (not renewing the operating license). It also evaluates the impacts of replacement power alternatives (fossil fuels, nuclear, and renewable energy), conservation and energy efficiency (demand-side management), and purchased power. The impacts of renewing the operating license of a nuclear power plant are comparable to the impacts of energy alternatives. Replacement power alternatives would require the construction of a new power plant or modification of the electric transmission grid. The new power plants would also have operational impacts. Conversely, license renewal does not require major construction and operational impacts, which would not change beyond what is currently being experienced. Other alternatives that would not have construction or operational impacts include conservation and energy efficiency (demand-side management), delayed retirement, repowering, and purchased power.

Operational impacts of license renewal are comparable to replacement power alternatives and some renewable alternatives in some resource areas (socioeconomics) but quite different in other resource areas (air emissions, fuel cycle, land use, and water consumption). Renewable energy alternatives (wind, ocean wave, and ocean current alternatives) have very few operational impacts, while others (biomass combustion and conventional hydropower) can have considerable impacts. Some renewable energy alternatives (wind and solar) have relatively low but regionally variable capacity factors.

License renewal and alternatives differ in other respects, including the consequences of accidents. License renewal and new nuclear energy alternatives may have low-probability but potentially high-consequence accidents. In addition, fuel cycle impacts vary across alternatives. Some, like fossil fuel, require large amounts of land for fuel extraction.

Impacts from terminating power plant operations and decommissioning would vary between license renewal and the alternatives. License renewal delays the date of reactor shutdown and decommissioning but does not alter the impact levels. Impacts would be SMALL in all resource areas. In comparison, impacts from terminating operations and decommissioning of most alternatives would be larger than impacts from license renewal.

Under NEPA, the NRC has the obligation to consider reasonable alternatives to the proposed action of renewing the license for a nuclear reactor. The GEIS facilitates that alternative analysis by providing NRC review teams with empirical evidence of the performance, environmental impacts, and resource demands and impacts of those potential replacement power alternatives current as of the time this GEIS was prepared. A site-specific analysis of alternatives will be performed for each SEIS, taking into account changes in technology and science since the preparation of this GEIS.

1 Introduction

Contents of Chapter 1

The Atomic Energy Act of 1954 authorizes the U.S. Nuclear Regulatory Commission (NRC) to issue commercial nuclear power plant operating licenses for up to 40 years. The 40-year length of the original license period was imposed for economic and antitrust reasons rather than the technical limitations of the nuclear power plant. NRC regulations allow for the renewal of these operating licenses for up to an additional 20 years, depending on the outcome of an assessment determining whether the nuclear power plant can continue to operate safely and protect the environment during the 20-year period of extended operation. There are no specific limitations in the Atomic Energy Act or the NRC's regulations restricting the number of times a license may be renewed.

The license renewal process is designed to assure the safe operation of the nuclear power plant and protection of the environment for up to an additional 20 years. Under the NRC's environmental protection regulations in Title 10, Part 51 of the *Code of Federal Regulations* (10 CFR Part 51), which implement the National Environmental Policy Act (NEPA), renewal of a nuclear power plant operating license requires the preparation of an environmental impact statement (EIS).

To support the preparation of these EISs, the NRC prepared the *Generic Environmental Impact Statement for License Renewal of Nuclear Plants* (GEIS), NUREG-1437 (NRC 1996, 1999). The original 1996 GEIS[a] for license renewal was prepared to assess the environmental impacts associated with the continued operation of nuclear power plants during the license

(a) Any reference in this document to the 1996 GEIS includes the two-volume set published in 1996 and Addendum 1 to the GEIS published in 1999.

renewal term. The intent of the GEIS is to determine which impacts would essentially be the same at all nuclear power plants and which ones could be different at different plants and would require a plant-specific analysis to determine the impacts.

1.1 Purpose of the GEIS

Generic Environmental Impact Statement (GEIS)

A GEIS is an environmental impact statement that assesses the scope and impact of the environmental effects that would be associated with an action (such as license renewal) at numerous sites.

Supplemental Environmental Impact Statement (SEIS)

A SEIS updates or supplements an existing EIS (such as the GEIS). The Commission directed the NRC staff to issue plant-specific supplements to the GEIS for each license renewal application.

The GEIS for license renewal of nuclear power plants assesses the environmental impacts that could be associated with license renewal and an additional 20 years of power plant operation. This assessment is summarized in this GEIS. This GEIS also provides the technical basis for license renewal amendments to the Commission's regulations, 10 CFR Part 51, "Environmental Protection Regulations for Domestic Licensing and Related Regulatory Functions." In the 1996 GEIS and related rulemaking, the Commission determined that certain impacts associated with the renewal of a nuclear power plant operating license were the same or similar for all plants and could be treated on a generic basis. In this way, repetitive reviews of these impacts could be avoided. The Commission based its generic assessment of certain environmental impacts on the following factors:

(1) License renewal will involve nuclear power plants for which the environmental impacts of operation are well understood as a result of lessons learned and knowledge gained from operating experience and completed license renewals.

(2) Activities associated with license renewal are expected to be within this range of operating experience; thus, environmental impacts can be reasonably predicted.

(3) Changes in the environment around nuclear power plants are gradual and predictable.

The GEIS is intended to improve the efficiency of the license renewal process by (1) providing an evaluation of the types of environmental impacts that may occur from renewing commercial nuclear power plant operating licenses, (2) identifying and assessing impacts that are expected to be generic (the same or similar) at all nuclear plants (or plants with specified plant or site characteristics), and (3) defining the number and scope of environmental impact issues that need to be addressed in plant-specific EISs. The GEIS provides information that will aid the preparation of plant-specific EISs.

1.2 Description of the Proposed Action

> ***The Proposed Action***
>
> To renew commercial nuclear power plant operating licenses.
>
> ***Purpose and Need for the Proposed Action***
>
> To provide an option to continue plant operations beyond the current licensing term to meet future system generating needs.

Under NRC's environmental protection regulations in 10 CFR 51.20, renewal of a nuclear power plant operating license is identified as a major Federal action that requires the preparation of an EIS to address the impacts of renewing a plant's operating license. The EIS requirements for a plant-specific license renewal review are specified in 10 CFR 51.71 and 51.95. NRC's public health and safety and other technical requirements for the renewal of operating licenses are found in 10 CFR Part 54. Part 54 requires applicants to perform safety evaluations and assessments of nuclear power plants and provide the NRC with sufficient information to analyze the impacts of continued operation for the requested renewal term. Applicants are required to assess the effects of aging on passive and long-lived systems, structures, and components.

Most utilities are expected to begin preparation for license renewal about 10 to 20 years before expiration of their current operating licenses. Inspection, surveillance, test, and maintenance programs to support continued plant operations during the license renewal term would be integrated gradually over a period of years. Any refurbishment-type activities undertaken for the purposes of license renewal have generally been completed during normal plant refueling or maintenance outages before the original license expires. Activities associated with license renewal and operation of a plant for an additional 20 years are discussed in Chapter 2.

1.3 Purpose and Need for the Proposed Action

The Commission acts on each application submitted by a licensee for the renewal of commercial nuclear power plant operating licenses per Section 103 of the Atomic Energy Act. A renewed license is just one of a number of conditions that licensees must meet to operate its nuclear plant during the license renewal term. State regulators, system operators, and in some cases, other Federal agencies, ultimately decide whether the plant will continue to operate based on factors such as need for power or other factors within the State's jurisdiction or owner's control. Economic considerations play a primary role in this decision.

The purpose and need for the proposed action (issuance of a renewed license) is to provide an option that allows for baseload power generation capability beyond the term of the current nuclear power plant operating license to meet future system generating needs. Such needs may be determined by other energy-planning decision-makers, such as State, utility, and, where authorized, Federal agencies (other than the NRC). Unless there are findings in the safety review required by the Atomic Energy Act or the NEPA environmental review that would lead the NRC to reject a license renewal application, the NRC does not have a role in the energy-planning decisions of whether a particular nuclear power plant should continue to operate.

From the perspective of the licensee and the State regulatory authority, the purpose of renewing an operating license is to maintain the availability of the nuclear power plant to meet system energy requirements beyond the term of the plant's current license. In cases of interstate generation or other special circumstances, Federal agencies such as the Federal Energy Regulatory Commission (FERC) or the Tennessee Valley Authority (TVA) may be involved in making these decisions.

1.4 Alternatives to the Proposed Action

In license renewal environmental reviews, the NRC considers the environmental consequences of the proposed action, the no-action alternative (i.e., not renewing the operating license), and the environmental consequences of various alternatives for replacing the nuclear power plant's generating capacity. No conclusions are made in the GEIS about the relative environmental consequences of license renewal, the no-action alternative, and the construction and operation of alternative facilities for generating electric energy. However, information presented in the GEIS can be used by the NRC and applicants in performing the plant-specific analysis of alternatives.

In plant-specific environmental reviews, the NRC compares the environmental impacts of license renewal with those of the no-action alternative and replacement power alternatives to determine whether the adverse environmental impacts of license renewal are great enough to deny the option of license renewal for energy-planning decision-makers.

1.5 Analytical Approach Used in the GEIS

1.5.1 Objectives

The GEIS serves to facilitate NRC's environmental review process by identifying and evaluating environmental impacts that are considered generic and common to all nuclear power plants. Plant-specific impact issues will be addressed in separate supplemental EISs (SEISs) to the GEIS. Generic impacts will be reconsidered in SEISs only if there is new and significant information that would change the conclusions in the GEIS.

1.5.2 Methodology

Environmental impacts of license renewal and the resources that could be affected by continued operation and refurbishment were identified. The general analytical approach for identifying environmental impacts was to (1) describe the nuclear power plant activity that could affect the resource, (2) identify the resource that is affected, (3) evaluate past license renewal reviews and other available information, (4) assess the nature and magnitude of the environmental impact on the affected resource, (5) characterize the significance of the effects, and (6) determine whether the results of the analysis apply to all nuclear power plants (whether the environmental impact issue is Category 1 or Category 2, as described below). Identifying environmental impacts (or issues) was conducted in an iterative rather than a stepwise manner. For example, after information was collected and levels of significance were reviewed, impacts were reexamined to determine if any should be removed, added, consolidated, or divided.

1.5.2.1 Defining Environmental Issues

The 1996 GEIS presents the findings of a systematic inquiry into the environmental impacts of license renewal resulting in the identification of 92 environmental issues (or impacts), which were evaluated in the GEIS. Public and stakeholder comments on previous plant-specific license renewal reviews were analyzed in an effort to reevaluate the existing environmental issues and identify new issues. Environmental issues in this GEIS are arranged by resource area. This perspective is a change from the 1996 GEIS in which environmental issues were arranged by power plant systems.

1.5.2.2 Collecting Information

Information from completed license renewal environmental reviews was collected and reviewed. Searches of the open scientific literature, databases, and Web sites were conducted for each resource area. This information was collected and evaluated to determine if the environmental issues and findings in the 1996 GEIS needed to be revised.

1.5.2.3 Determining Significance Levels for Issues

A standard of significance was established for each license renewal environmental impact issue evaluated in the 1996 GEIS based on the Council on Environmental Quality (CEQ) terminology for “significantly” (see 40 CFR 1508.27). Since the significance and severity of an impact can vary with the setting of the proposed action, both “context” and “intensity,” as defined in CEQ regulations 40 CFR 1508.27, were considered. Context is the geographic, biophysical, and social context in which the effects will occur. In the case of license renewal, the context is the environment surrounding the nuclear power plant. Intensity refers to the severity of the impact in whatever context it occurs. Based on this, the NRC established three levels of significance for potential impacts: SMALL, MODERATE, and LARGE. The definitions of these three significance levels, which are presented in the footnotes to Table B–1 in Appendix B to Subpart A of 10 CFR Part 51, follow:

- SMALL—environmental effects are not detectable or are so minor that they will neither destabilize nor noticeably alter any important attribute of the resource. For the purposes of assessing radiological impacts, the Commission has concluded that those impacts that do not exceed permissible levels in the Commission's regulations are considered SMALL.

- MODERATE—environmental effects are sufficient to alter noticeably, but not to destabilize, important attributes of the resource.

- LARGE—environmental effects are clearly noticeable and are sufficient to destabilize important attributes of the resource.

The discussion of each environmental impact issue in the GEIS includes an explanation of how the significance category was determined. For issues in which the probability of occurrence is a key consideration (i.e., postulated accidents), the probability of occurrence has been factored into the determination of significance. Possible mitigation measures that could be used to avoid, minimize, rectify, reduce, eliminate, or compensate for adverse impacts are discussed where appropriate.

In addition to determining the significance of environmental impacts associated with an issue, a determination was made whether the analysis in the GEIS could be applied to all nuclear power plants. The categories to which an issue may be assigned are presented below.

- **Category 1**—the analysis reported in the GEIS has shown the following:

  (1) The environmental impacts associated with the issue have been determined to apply either to all plants or, for some issues, to plants having a specific type of cooling system or other specified plant or site characteristics;

  (2) A single significance level (i.e., SMALL, MODERATE, or LARGE) has been assigned to the impacts (except for collective offsite radiological impacts from the fuel cycle and from high-level waste and spent fuel); and

  (3) Mitigation of adverse impacts associated with the issue has been considered in the analysis, and it has been determined that additional plant-specific mitigation measures are not likely to be sufficiently beneficial to warrant implementation.

- **Category 2**—the analysis reported in the GEIS has shown that one or more of the criteria of Category 1 cannot be met, and therefore, additional plant-specific review is required.

If all three Category 1 criteria apply to a particular issue, then the generic impact analysis presented in this GEIS is relied upon by the NRC in evaluating license renewal applications and plant-specific SEISs provided there is no new and significant information requiring further analysis. For issues that do not meet all three Category 1 criteria, the issue is considered a Category 2 issue, and a plant-specific impact analysis is required for that issue.

1.6 Scope of the GEIS Revision

The NRC assessed the impact of license renewal on 92 environmental issues for the 1996 GEIS. Impacts associated with 69 of these issues were determined to be generic (i.e., the same or similar at all plants), or Category 1. These issues are addressed in the 1996 GEIS and do not require a plant-specific assessment unless new and significant information is found that would change the conclusions in the GEIS. Guidance on plant-specific analyses required for the other 23 issues is provided in 10 CFR Part 51. Findings on the scope and magnitude of environmental impacts of renewing a nuclear power plant operating license in the GEIS as required by section 102(2) of NEPA are summarized in Table B–1 in Appendix B to Subpart A of 10 CFR Part 51 (Table B–1).

This GEIS reviews and reevaluates the issues and findings of the 1996 GEIS in compliance with the requirement to review the material in Appendix B to Subpart A of 10 CFR Part 51 and update it on a 10-year cycle, if necessary. Lessons learned and knowledge gained during previous license renewal reviews provided a significant source of new information for this review. Public comments received during previous license renewal environmental reviews were re-examined to validate existing environmental issues and identify new ones. Since 1996, over 40 commercial nuclear power plants have undergone a license renewal environmental review. The purpose of the review for this GEIS was to determine if the findings presented in the 1996 GEIS remain valid. In doing so, the NRC considered the need to modify, add, group, or delete any of the 92 environmental impact issues evaluated in the 1996 GEIS. In addition, new research, findings, and other information were considered when the significance of impacts associated with license renewal was being evaluated. After this review, the NRC carried forward 78 environmental impact issues for detailed consideration in this GEIS.

1.7 Decisions to Be Supported by the GEIS

The decisions to be to be supported by the GEIS are whether or not to renew the operating licenses of individual commercial nuclear power plants for an additional 20 years. The GEIS was developed to support these decisions and to serve as a basis from which future NEPA analyses for the license renewal of individual nuclear power plants would tier. According to CEQ guidelines (40 CFR 1508.28), tiering refers to "the coverage of general matters in broader environmental impact statements (such as national program or policy statements) with subsequent narrower statements or environmental analyses (such as regional or basinwide program statements or ultimately site-specific statements) incorporating by reference the general discussions and concentrating solely on the issues specific to the statement subsequently prepared…. Tiering in such cases is appropriate when it helps the lead agency to focus on the issues which are ripe for decision and exclude from consideration issues already decided or not yet ripe." The GEIS provides the NRC decision-maker with important environmental information considered common to all nuclear power plants and allows greater focus to be placed on plant-specific (i.e., Category 2) issues.

The scope of the environmental review for license renewal consists of the range of actions, alternatives, and impacts to be considered in an EIS. The purpose of scoping is to identify significant issues related to the proposed action. Scoping also identifies and eliminates from detailed study issues that are not significant or have been covered by a prior environmental review. Having a defined scope for the environmental review allows the NRC to concentrate on the essential issues resulting from the actions being considered rather than on issues that may have been or are being evaluated in different regulatory review processes, such as the license renewal safety review (NRC 2006).

The NEPA process focuses on environmental impacts rather than on issues related to safety. Safety issues become important to the environmental review when they could result in environmental impacts, which is why the environmental effects of postulated accidents are considered in the GEIS and in plant-specific supplements to the GEIS. Since NEPA regulations do not provide for a safety review, the license renewal process includes an environmental review that is distinct and separate from the safety review. Since the two reviews are separate, operational safety issues and safety issues related to nuclear power plant aging are considered outside the scope for the environmental review, just as the environmental issues are not considered as part of the safety review. However, safety issues that are raised during the environmental review are forwarded to the appropriate NRC organization for consideration and appropriate action (NRC 2006).

Actions subject to NRC approval for license renewal are limited to continued nuclear power plant operation consistent with the plant design and operating conditions for the current operating license and to the performance of specific activities and programs necessary to manage the effects of aging on the passive, long-lived structures and components identified in accordance with 10 CFR Part 54. Accordingly, the GEIS does not serve as the NEPA review for other activities or programs outside the scope of NRC's 10 CFR Part 54 license renewal review.

> ***Environmental Impact Statements***
>
> 10 CFR 51.70(b): The draft environmental impact statement … will state how alternatives considered in it and decisions based on it will or will not achieve the requirements of Sections 101 and 102(1) of NEPA. (See also the Council on Environmental Quality (CEQ) Regulations for Implementing NEPA, 40 CFR 1502.2(d).)

Separate NEPA reviews must be prepared regardless of whether the action is necessary as a consequence of receiving a renewed license, even if the activity were specifically addressed in the GEIS. For example, the environmental impacts of spent fuel pool expansion are addressed in the GEIS in the context of the environmental consequences of approving a renewed operating license. However, any specific application submitted to the NRC to expand spent fuel pool capacity at a given facility would still require its own separate NEPA review. These separate NEPA reviews may reference and otherwise use applicable environmental information contained in the GEIS. For example, an environmental assessment prepared for a separate spent fuel pool expansion request may use the information in the GEIS to support a finding of no significant impact (see June 5, 1996 Final Rule [61 FR 28467]).

There are many factors that NRC takes into consideration when deciding whether to renew the operating license of a nuclear power plant. The analyses of environmental impacts evaluated in this GEIS will provide NRC's decision-maker (in this case, the Commission) with important environmental information for use in the overall decision-making process. There are also decisions outside the regulatory scope of license renewal that cannot be made on the basis of the final GEIS analysis. These decisions include the following issues.

1.7.1 Changes to Plant Cooling Systems

The NRC will not make a decision or any recommendations on the basis of information presented in this GEIS regarding changes to nuclear power plant cooling systems, other than those involving safety-related issues, to mitigate adverse impacts under the jurisdiction of State or other Federal agencies. Implementation of the provisions of the Clean Water Act, including those regarding cooling system operations and design specifications, is the responsibility of the U.S. Environmental Protection Agency (EPA). In many cases, the EPA delegates such authority to the individual States. To operate a nuclear power plant, licensees must comply with the Clean Water Act, including associated requirements imposed by the EPA or the State, as part of the National Pollutant Discharge Elimination System (NPDES) permitting system under Section 402 of the Clean Water Act and State water quality certification requirements under Section 401 of the Clean Water Act. The EPA or the State, not the NRC, sets the limits of effluents and operational parameters in plant-specific NPDES permits. Nuclear power plants cannot operate without a valid[b] NPDES permit and a Section 401 Water Quality Certification.

1.7.2 Disposition of Spent Nuclear Fuel

The NRC will not make a decision or any recommendations on the basis of the information presented in this GEIS regarding the disposition of spent nuclear fuel at nuclear power plants. Within the context of a license renewal environmental review, the NRC concluded that the storage of spent nuclear fuel can be accomplished safely and without significant environmental impacts. The radiological impacts from the onsite storage of spent nuclear fuel to human health during the term of license renewal continue to be well within regulatory limits, and therefore, meet the standard for a conclusion of SMALL impact. Nonradiological environmental impacts also continue to be SMALL. The overall conclusion for onsite storage of spent nuclear fuel during the license renewal term is that the environmental impacts will be SMALL for each plant. Within the context of renewal, the NRC concludes that its regulatory requirements for spent nuclear fuel provide adequate protection of plant workers, the public, and the environment.

In 1982, the Congress enacted the Nuclear Waste Policy Act (NWPA), and on January 7, 1983, the President signed it into law. The NWPA defined the Federal Government's responsibility to provide permanent disposal in a deep geologic repository for spent fuel and high-level radioactive waste from commercial and defense activities. Under amended provisions (1987) of this Act, the U.S. Department of Energy (DOE) has the responsibility to locate, build, and operate a repository for such wastes. The NRC has the responsibility to establish regulations governing the construction, operation, and closure of the repository, consistent with environmental standards established by the EPA.

The 1987 amendments required DOE to evaluate only the suitability of the site at Yucca Mountain, Nevada, for a geologic disposal facility. In addition, the amendments outlined a detailed approach for the disposal of high-level radioactive waste involving review by the President, Congress, State and Tribal governments, NRC, and other Federal agencies. In February 2002, after many years of studying the suitability of the site, DOE recommended to the President that the Yucca Mountain site be developed as a long-term geologic repository for high-level waste. In April 2002, the Governor of Nevada notified Congress of his State's

(b) A valid NPDES permit is considered to be one that is either current (i.e., within its current effective date) or one that has expired but has been "administratively continued" by the permitting authority upon the timely submission of an applicant for renewal pursuant to the provisions of 40 CFR 122.6.

objection to the proposed repository. Subsequently, Congress voted to override the objection of the State.

DOE submitted a license application to the NRC for construction authorization for a repository at Yucca Mountain in June 2008. Upon acceptance of the application, the NRC started its technical evaluation. However, on March 3, 2010, the U.S. Department of Energy (DOE) filed a motion with the Atomic Safety and Licensing Board (Board) seeking permission to withdraw its application for authorization to construct a high-level waste geological repository at Yucca Mountain, Nevada. The Board denied that request on June 29, 2010, in LBP-10-11, and the parties filed petitions asking the Commission to uphold or reverse this decision. On October 1, 2010, the Commission directed the staff to perform an orderly closure of its Yucca Mountain activities. As part of the orderly closure, the NRC staff prepared three technical evaluation reports documenting its work.

On September 9, 2011, the Commission issued Memorandum and Order CLI-11-07, stating that it found itself evenly divided on whether to take the affirmative action of overturning or upholding the Board's June 29, 2010, decision. Exercising its inherent supervisory authority, the Commission directed the Board to complete all necessary and appropriate case management activities by September 30, 2011. On September 30, 2011, the Board issued a Memorandum and Order suspending the proceeding.

The NRC's non-sensitive Yucca Mountain-related documents are being preserved and made available to the public as part of the NRC staff's activities to retain the accumulated knowledge and experience gained as a result of its Yucca Mountain-related activities. These documents can be viewed on the NRC's public website (http://www.NRC.gov).

DOE decisions and recommendations concerning the ultimate disposition of spent nuclear fuel are ongoing and outside the regulatory scope of this GEIS.

Further, for the offsite disposal of spent nuclear fuel, the NRC's Waste Confidence Decision and Rule represented the Commission's generic determination that spent nuclear fuel can continue to be stored safely and without significant environmental impacts for a period of time after the end of the licensed life for operation of a nuclear power plant. This generic determination meant that the NRC did not need to consider the storage of spent nuclear fuel after the end of a reactor's licensed life for operation in the NEPA documents that support its reactor and spent-fuel storage license application reviews.

The NRC first adopted the Waste Confidence Decision and Rule in 1984. The NRC amended the decision and rule in 1990, reviewed them in 1999, and amended them again in 2010 (49 FR 34694 (August 31, 1984); 55 FR 38474 (September 18, 1990); 64 FR 68005 (December 6, 1999); and 75 FR 81032 and 81037 (December 23, 2010)). The NRC made a minor amendment to the rule in 2007 to clarify that it applies to combined licenses (72 FR 49509 (August 28, 2007)). The Waste Confidence Decision and Rule are codified in the NRC regulation 10 CFR 51.23.

On December 23, 2010, the Commission published in the *Federal Register* a revision of the Waste Confidence Decision and Rule to reflect information gained from experience in the storage of spent nuclear fuel and the increased uncertainty in the siting and construction of a permanent geologic repository for the disposal of spent nuclear fuel and high-level waste (75 FR 81032 and 81037). In response to the 2010 Waste Confidence Decision and Rule, the states of New York, New Jersey, Connecticut, and Vermont, along with several other parties challenged the Commission's NEPA analysis in the decision, which provided the regulatory basis for the rule. On June 8, 2012, the United States Court of Appeals, District of Columbia Circuit, in *New York v. NRC*, 681 F.3d 471 (D.C. Cir. 2012), vacated the NRC's Waste Confidence Decision and Rule, after finding that it did not comply with NEPA.

In response to the court's ruling, the Commission issued CLI-12-16 on August 7, 2012, in which the Commission determined that it would not issue licenses that rely upon the Waste Confidence Decision and Rule until the issues identified in the court's decision are appropriately addressed by the Commission. CLI-12-16 provided, however, that the decision not to issue licenses only applied to final license issuance; all licensing reviews and proceedings should continue to move forward. In SRM-COMSECY-12-0016, dated September 6, 2012, the Commission directed the NRC staff to proceed with a rulemaking that includes the development of a generic EIS to support a revised Waste Confidence Decision and Rule and to publish both the EIS and the revised decision and rule in the *Federal Register* within 24 months (by September 6, 2014). The Commission indicated that both the EIS and the revised Waste Confidence Decision and Rule should build on the information already documented in various NRC studies and reports, including the existing environmental assessment that the NRC developed as part of the 2010 Waste Confidence Decision and Rule. The Commission directed that any additional analyses should focus on the issues identified in the court's decision. The Commission also directed that the NRC staff provide ample opportunity for public comment on both the draft EIS and the proposed Waste Confidence Decision and Rule.

In accordance with CLI-12-16, the NRC will not approve any site-specific license renewal applications until the deficiencies identified in the court's decision have been resolved. Two license renewal GEIS issues that rely, wholly or in part, upon the Waste Confidence Decision and Rule are the "onsite storage of spent nuclear fuel" and "offsite radiological impacts of spent nuclear fuel and high-level waste disposal." Both of these issues were classified as Category 1 in the 10 CFR Part 51 rule that was promulgated in 1996; the 2009 proposed rule continued the Category 1 classification for both of these issues. As part of its response to the *New York v. NRC* decision, the NRC revised these two issues accordingly. Specifically, the NRC revised the Category 1 "Onsite storage of spent nuclear fuel" issue to narrow the period of onsite storage to the license renewal term. In both the 1996 rule (in which this issue was named "onsite spent fuel") and the 2009 proposed rule, the NRC relied upon the 1990 Waste Confidence Decision and Rule to make a generic finding that spent nuclear fuel could be stored safely onsite with no more than a small environmental impact for the term of the extended license (from approval of the license renewal application to the expiration of the operating license) plus a 30 year period following the permanent shutdown of the power reactor and expiration of the operating license.

The 1990 Waste Confidence Decision and Rule provided the basis for the 30 year period following the permanent shutdown of the reactor and expiration of the operating license. The 2010 Waste Confidence Decision and Rule extended this post-reactor shutdown onsite storage period from 30 years to 60 years. Given the *New York v. NRC* decision, and pending the issuance of a generic EIS and revised Waste Confidence Decision and Rule (as directed by SRM-COMSECY-12-0016), the period of onsite storage of spent nuclear fuel following the permanent shutdown of the power reactor and expiration of the operating license is now excluded from this GEIS issue. As revised, this issue now covers the onsite storage of spent fuel for the term of the extended license only.

Similarly, the NRC revised the Category 1 issue, "Offsite radiological impacts of spent nuclear fuel and high-level waste disposal" (this issue was named "offsite radiological impacts (spent fuel and high level waste disposal)" in the 1996 rule and GEIS). This issue pertains to the long-term disposal of spent nuclear fuel and high-level waste, including possible disposal in a deep geologic repository. Although the Waste Confidence Decision and Rule did not assess the impacts associated with disposal of spent nuclear fuel and high-level waste in a repository, it did reflect the Commission's confidence, at the time, in the technical feasibility of a repository and when that repository could have been expected to become available. Without the analysis in the Waste Confidence Decision, the NRC cannot assess how long the spent fuel will need to be stored onsite. Therefore, the NRC reclassifies this GEIS issue from a Category 1 issue with no assigned impact level to an uncategorized issue with an impact level of uncertain.

1.7.3 Emergency Preparedness

The NRC will not make a decision or any recommendations on the basis of information presented in this GEIS regarding emergency preparedness at nuclear power plants. Nuclear power plant owners, government agencies, and State and local officials work together to create a system for emergency preparedness and response that will serve the public in the unlikely event of an emergency. The emergency plans for nuclear power plants cover preparations for evacuation, sheltering, and other actions to protect residents near plants in the event of a serious incident.

In the United States, 104 commercial nuclear power reactors are licensed to operate at 65 sites in 31 States. For each site, there are onsite and offsite emergency plans to assure that adequate protective measures can be taken to protect the public in the event of a radiological emergency. Federal oversight of emergency preparedness for licensed nuclear power plants is shared by the NRC and Federal Emergency Management Agency (FEMA). The NRC and FEMA have a Memorandum of Understanding (44 CFR Appendix A to Part 353), under which FEMA has the lead in overseeing offsite planning and response, and the NRC assists FEMA in carrying out this role. The NRC has statutory responsibility for the radiological health and safety of the public and retains the lead for oversight of onsite preparedness.

Before a plant is licensed to operate, the NRC must have reasonable assurance that adequate protective measures can and will be taken in the event of a radiological emergency. The NRC's decision of reasonable assurance is based on licensees complying with NRC regulations and guidance. In addition, licensees and area response organizations must demonstrate they can effectively implement emergency plans and procedures during periodic evaluated exercises. As part of the reactor oversight process, the NRC reviews licensees' emergency planning procedures and training. These reviews include regular drills and exercises that assist licensees in identifying areas for improvement, such as in the interface of security operations and emergency preparedness. Each plant owner is required to exercise its emergency plan with the NRC, FEMA, and offsite authorities at least once every two years to ensure that State and local officials remain proficient in implementing their emergency plans. Licensees also self-test their emergency plans regularly by conducting drills.

FEMA findings and determinations as to the adequacy and capability of implementing offsite plans are communicated to the NRC. The NRC reviews the FEMA findings and determinations as well as the onsite findings. The NRC then makes a determination on the overall state of emergency preparedness. These overall findings and determinations are used by the NRC to make radiological health and safety decisions before issuing licenses and in the continuing oversight of operating reactors. The NRC has the authority to take action, including shutting down any reactor deemed not to provide reasonable assurance of the protection of public health and safety.

The Commission considered the need for a review of emergency planning issues in the context of license renewal during its rulemaking proceedings on 10 CFR Part 54, which included public notice and comment. As discussed in the statement of consideration for rulemaking (56 FR 64966), the programs for emergency preparedness at nuclear power facilities apply to all nuclear power facility licensees and require the specified levels of protection from each licensee regardless of plant design, construction, or license date. Requirements related to emergency planning are in the regulations at 10 CFR 50.47 and Appendix E to 10 CFR Part 50. These requirements apply to all operating licenses and will continue to apply to facilities with renewed licenses. Through its standards and required exercises, the Commission reviews existing emergency preparedness plans throughout the life of any facility, keeping up with changing demographics and other site-related factors.

Therefore, the Commission has determined that there is no need for a special review of emergency planning issues in the context of an environmental review for license renewal (NRC 2006). Thus, decisions and recommendations concerning emergency preparedness at nuclear plants are ongoing and outside the regulatory scope of license renewal.

1.7.4 Safeguards and Security

The NRC requires that nuclear power plants be both safe and secure. Safety refers to operating the plant in a manner that protects the public and the environment. Security refers to protecting the plant (using people, equipment, and fortifications) from intruders who wish to damage or destroy it in order to harm people and the environment.

Security issues such as safeguards planning are not tied to a license renewal action but are considered to be issues that need to be dealt with continuously as a part of a nuclear power plant's current (and renewed) operating license. Security issues are periodically reviewed and updated at every operating plant. These reviews continue throughout the period of an operating license, whether it is the original or renewed license. If issues related to security are discovered at a nuclear plant, they are addressed immediately, and any necessary changes are reviewed and incorporated under the operating license (NRC 2006). As such, decisions and recommendations concerning safeguards and security at nuclear power plants are ongoing and outside the regulatory scope of this GEIS.

1.7.5 Need for Power

The NRC will not make a decision or any recommendations on the basis of information presented in this GEIS regarding the need for power at nuclear power plants. The regulatory authority over licensee economics (including the need for power) falls within the jurisdiction of the States and, to some extent, within the jurisdiction of FERC. The proposed rule for license renewal published on September 17, 1991 (56 FR 47016), had originally included a cost-benefit analysis and consideration of licensee economics as part of the NEPA review. However, during the comment period, State, Federal, and licensee representatives expressed concern about the use of economic costs and cost-benefit balancing in the proposed rule and the 1996 GEIS. They noted that CEQ regulations interpret NEPA to require only an assessment of the cumulative effects of a proposed Federal action on the natural and man-made environment and that the determination of the need for generating capacity has always been a State responsibility. For this reason, the purpose and need for license renewal was defined by the Commission in the June 5, 1996, final rule as follows (61 FR 28467):

> The purpose and need for the proposed action (renewal of an operating license) is to provide an option that allows for power generation capability beyond the term of a current nuclear power plant operating license to meet future system generating needs, as such needs may be determined by State, utility, and, where authorized, Federal (other than NRC) decision-makers.

10 CFR 51.95(c)(2) states:

> The supplemental environmental impact statement (SEIS) for license renewal is not required to include discussion of need for power or the economic costs and economic benefits of the proposed action or of alternatives to the proposed action except insofar as such benefits and costs are either essential for a determination regarding the inclusion of an alternative in the range of alternatives considered or relevant to mitigation.

1.7.6 Seismicity and Flooding

The NRC will not make a decision or any recommendations on the basis of information presented in this GEIS regarding seismic risk and flooding at nuclear power plants. The NRC's assessment of seismic and flood hazards for existing nuclear power plants is a separate and distinct process from license renewal reviews. Seismic and flood hazard issues are addressed by the NRC on an ongoing basis at all licensed nuclear facilities. As such, decisions and recommendations concerning seismic risk and flooding at nuclear power plants are outside the regulatory scope of this GEIS. Nevertheless, following the accident at the Fukushima Dai-ichi nuclear power plant resulting from the March 11, 2011, Great Tohoku Earthquake and subsequent tsunami, the NRC established the Near-Term Task Force as directed by the Commission on March 23, 2011, in COMGBJ-11-0002. The Japan Near-Term Task Force assessment resulted in the issuance of 10 CFR 50.54 (f) letters on March 12, 2012, directing that seismic and flooding reevaluations be conducted at existing nuclear power plants (NRC 2012).

1.8 Implementation of the Rule (10 CFR Part 51)

1.8.1 General Requirements

The regulatory requirements for conducting a NEPA review for license renewal are similar to the NEPA review requirements for other major plant licensing actions. Consistent with the current NEPA practice for major plant licensing actions, an applicant is required to submit an environmental report that assesses the environmental impacts associated with the proposed action, considers alternatives to the proposed action, and evaluates any alternatives for reducing adverse environmental effects. For license renewal, the NRC prepares a draft SEIS to the GEIS for public comment and issues a final SEIS after considering public comments on the draft.

1.8.2 Applicant's Environmental Report

The applicant's environmental report must contain an assessment of the environmental impacts of renewing a license, the environmental impacts of alternatives, and mitigation alternatives. In preparing the analysis of environmental impacts contained in the environmental report, the applicant should refer to the information provided in Table B-1 of 10 CFR Part 51. The applicant is not required to assess the environmental impacts of Category 1 issues listed in Table B-1 unless the applicant is aware of new and significant information that would change the conclusions in the GEIS. For Category 2 issues listed in Table B-1, the applicant must provide a plant-specific assessment of the impacts. 10 CFR 51.53(c)(3)(ii) specifies the areas that must be addressed for the Category 2 issues in the environmental report.

10 CFR 51.45(c) and 10 CFR 51.53(c)(2) require the applicant to consider alternatives available for reducing or avoiding adverse environmental effects associated with the proposed action. This consideration is limited to designated Category 2 issues. Pursuant to 10 CFR 51.45(d), the environmental report must include a discussion of the status of compliance with applicable Federal, State, and local environmental standards. Also, 10 CFR 51.53(c)(2) specifically excludes from consideration in the environmental report the issues of need for power, the economic costs and benefits of the proposed action, economic costs and benefits of alternatives to the proposed action, or other issues not related to environmental effects of the proposed action and associated alternatives. NRC regulations do not require a discussion of the economic costs and benefits of these alternatives in the environmental report for license renewal, except as necessary to determine whether an alternative should be included in the range of alternatives considered or whether certain mitigative actions are appropriate. The analysis should also demonstrate consideration of a range (set) of reasonable alternatives to license renewal. In preparing the alternatives analysis, the applicant is not limited to the technologies presented in this GEIS. Information provided in the applicant's environmental report will be used in preparing the NRC's SEIS.

1.8.3 NRC's SEIS

As required by 10 CFR 51.20(b)(2), the NRC is required to prepare a SEIS to the GEIS for each license renewal application. The SEIS will serve as the NRC's analysis of the environmental impacts of license renewal as well as a comparison of these impacts to the environmental impacts of alternatives. This document will also present the NRC's recommendation as to the environmental impact of license renewal. SEISs for license renewal do not need to include a discussion of the need for power or the economic costs and economic benefits of the proposed action or of alternatives to the proposed action (10 CFR 51.95(c)(2)).

1.8.4 Public Scoping and Public Comments

NRC conducts public scoping meetings in order to inform the public about the license renewal process and receive comments on the scope of the NRC's plant-specific environmental review. At the conclusion of the scoping period, NRC reviews and addresses public comments in a scoping summary report. In addition, the draft SEIS is issued for public comment (see 10 CFR 51.73). In both the scoping and the public comment process, the NRC will consider comments and will determine whether these comments provide any information that is new and significant compared with that previously considered in the GEIS (for Category 1 issues). If the comments are determined to provide new and significant information that could change the conclusions in the GEIS, these comments will be considered and addressed in the SEIS.

1.8.5 NRC's Draft SEIS

The NRC's draft SEIS will include its analysis of the environmental impacts of the proposed license renewal action and the environmental impacts of the alternatives to the proposed action. The NRC will utilize and integrate (1) the environmental impacts of license renewal as provided in Table B-1 of 10 CFR Part 51 for Category 1 issues, (2) the appropriate plant-specific analyses of Category 2 issues, and (3) any new and significant information identified in the applicant's environmental report or during the scoping and public comment process to arrive at a conclusion regarding the environmental impacts of license renewal. These impacts are compared to the environmental impacts of the alternatives presented in the SEIS.

1.8.6 NRC's Final SEIS

The NRC will issue a final SEIS in accordance with 10 CFR 51.91 and 51.93 after considering (1) the public comments, (2) the analysis of Category 2 issues, and (3) any new and significant information involving Category 1 issues. The NRC will provide a record of its decision regarding the environmental impacts of the proposed license renewal action (see 10 CFR 51.102 and 51.103). All comments on the draft SEIS will be addressed by the NRC in the final SEIS in accordance with 10 CFR 51.91(a)(1). Comments will be addressed in the following manner:

(a) NRC's response to a comment regarding the applicability of the analysis of an impact codified in the rule (i.e., 10 CFR Part 51) to the plant in question may be a statement and explanation of its view that the analysis is adequate including, if applicable, consideration of the significance of new information. A commenter dissatisfied with such a response may file a petition for rulemaking under 10 CFR 2.802. Procedures for the submission of petitions for rulemaking are explained in 10 CFR Part 2. If a commenter is successful in persuading the Commission that the new information does indicate that the analysis of an impact codified in the rule is incorrect in significant respects (either in general or with respect to the particular plant), then a rulemaking proceeding will be initiated.

(b) If a commenter provides new information that is relevant to the plant and is also relevant to other plants (i.e., generic information) and that information demonstrates that the analysis of an impact codified in the rule is incorrect, the NRC will seek Commission approval either to suspend the application of the rule on a generic basis with respect to the analysis or to delay granting the renewal application (and possibly other renewal applications) until the rule can be amended. This GEIS would reflect the corrected analysis and any additional consideration of alternatives as appropriate.

(c) If a commenter provides new, site-specific information that demonstrates that the analysis of an impact codified in the rule is incorrect with respect to the particular plant, then the NRC staff will seek Commission approval to waive the application of the rule with respect to that analysis in that specific renewal proceeding. The SEIS would reflect the corrected analysis as appropriate.

1.9 Public Comments on the Draft GEIS

The public comment process for the GEIS was similar to that used for SEISs and other NRC NEPA documents. In July 2009, NRC distributed the draft GEIS to Federal, State, and local government agencies; American Indian Tribes; environmental interest groups; and members of the public who requested copies. As part of the process to solicit public comments on the draft GEIS, the NRC:

- Placed a copy of the draft GEIS into the NRC's Public Electronic Reading Room and on its license renewal Web site;
- Sent copies of the draft GEIS to members of the public and environmental interest groups, representatives of American Indian Tribes, and Federal, State, and local agencies;
- Published a notice of availability of the draft GEIS in the *Federal Register* (74 FR 38239);
- Published a notice of an extension to the comment period from 75 to 165 days (74 FR 51522);

- Issued public announcements, such as advertisements in local newspapers and postings in public places, of the availability of the draft GEIS;

- Announced and held public meetings in (1) Atlanta, Georgia, on September 15, 2009; (2) Newton, Massachusetts, on September 17, 2009; (3) Oak Brook, Illinois, on September 24, 2009; (4) Rockville, Maryland, on October 1, 2009; (5) Pismo Beach, California, on October 20, 2009; and (6) Dana Point, California, on October 22, 2009, to receive public comments on the draft GEIS;

- Issued public service announcements and press releases announcing the issuance of the draft GEIS, the public meetings, and instructions on how to comment on the draft GEIS; and

- Established several methods for the submittal of comments on the draft GEIS, including an e-mail address to receive comments through the Internet.

During the public comment period, the NRC received a total of 32 comment letters, e-mails, and Web submissions in addition to comments received during the public meetings. The NRC reviewed public meeting transcripts and comment letters, which have been incorporated by reference in this GEIS. The public meeting transcripts and comment letters have also been made available online in the Agencywide Documents Access and Management System (ADAMS) (see GEIS Appendix A).

The NRC used public comments gathered during the meetings and comment period when developing the final GEIS. NRC responses to comments are included in GEIS Volume 2, Appendix A, Section A.2. Comments were received on a variety of topics, including (1) land use and visual impacts; (2) air quality, meteorology, and climatology; (3) soils, geology, and seismology; (4) water quality, hydrology, and use; (5) aquatic ecology, terrestrial ecology, and threatened and endangered species; (6) historic and cultural resources; (7) socioeconomics; (8) human health; (9) uranium fuel cycle and waste management; (10) cumulative impacts; (11) alternatives to license renewal; (12) postulated accidents; and (13) decommissioning. In addition, comments were received on the overall license renewal process and in opposition to nuclear power. Some comments received were editorial in nature or were considered outside of the scope of the license renewal environmental review process.

Some of the more frequently mentioned issues and their disposition in the final GEIS are described in the following paragraphs. Note that these issues are not presented in any particular order.

Seismic issues. Many commenters wanted seismic issues to be included in the rule and pointed out the importance of reassessing seismic conditions in determining the safety of operating nuclear power plants. Industry commenters disagreed and argued that seismology should not be considered part of the issue of "Impacts of nuclear plants on geology and soils" in the proposed rule because it is an ongoing safety issue that is being addressed at all plants.

The NRC agrees with the commenters that consideration of seismic conditions is an ongoing safety issue. Although seismic conditions at nuclear power plants are generically discussed in the GEIS as part of the geologic environment, seismology is not identified as a separate issue in the GEIS because the NRC considered historical earthquake data for each nuclear power plant when that plant was first licensed. The NRC requires all licensees to take seismic activity into account in order to maintain safe operating conditions at all nuclear power plants. When new seismic hazard information becomes available, the NRC evaluates the new data and models to determine if any changes are needed at existing plants regardless of whether or not a plant has renewed its license. This reactor oversight process, which includes seismic safety, remains separate from license renewal.

Unrelated to license renewal, the NRC completed the Generic Issues Program Safety/Risk Assessment Stage for Generic Issue 199 in August 2010, "Implications of Updated Probabilistic Seismic Hazard Estimates in Central and Eastern United States on Existing Plants," which evaluated recent updates to estimates of the seismic hazard in the central and eastern United States (NRC 2010a,b). The results of the Generic Issue 199 Safety/Risk Assessment indicated that the currently operating nuclear power plants have adequate safety margin for seismic issues. The NRC's assessment indicated that overall seismic risk estimates remain SMALL, and adequate protection is maintained. The NRC's path forward for Generic Issue 199 is described in NRC Information Notice 2010–18 (NRC 2010b). It provided notice of NRC's intent to follow the appropriate regulatory process to request that operating nuclear power plants and independent spent fuel storage installations provide specific information relating to their facilities to enable the NRC staff to complete the appropriate backfit analyses (see 10 CFR 50.109) where candidate backfits would be identified and evaluated. NRC then developed a draft generic letter to request needed data from power reactor licensees. However, following the accident at the Fukushima Dai-ichi nuclear power plant resulting from the March 11, 2011 Great Tohoku Earthquake and subsequent tsunami, the NRC established the Near-Term Task Force as directed by the Commission. The Japan Near-Term Task Force assessment resulted in the issuance of 10 CFR 50.54(f) letters on March 12, 2012, that addressed GI-199 in its entirety in recommendations 2.1 and 2.3 regarding seismic and flooding reevaluations, respectively (NRC 2012). The NRC's Japan Lessons Learned Project Directorate has now assumed the work of GI-199, including the evaluation of information received and actions taken by power reactor licensees in response to the March 12, 2012 10 CFR 50.54(f) letters.

The NRC's assessment of seismic hazards for existing nuclear power plants is a separate and distinct process from license renewal reviews. Seismic hazard issues are being addressed by the NRC on an ongoing basis at all licensed nuclear facilities. Sections 3.4 and 4.4.1 of the

GEIS explain that geologic and seismic conditions were considered in the original design of nuclear power plants and are part of the license bases for operating plants. Seismic conditions are attributes of the geologic environment that are not affected by continued plant operations and refurbishment and are not expected to change appreciably during the license renewal term for all nuclear power plants.

Air quality impacts. Several commenters objected to the issue "Air quality (non-attainment and maintenance areas)" being listed as a Category 2 issue in the proposed rule. The commenters argued that air quality impacts would be SMALL even in worst-case situations because licensees are required to operate within State air permit requirements.

The NRC agrees with the commenters. Operating experience has shown that the potential impact from emergency generators and boilers on air quality would be SMALL for all plants and, given the infrequency and short duration of maintenance testing, would not be an air quality concern even at plants located in or adjacent to nonattainment areas. Based on these comments, NRC technical staff re-evaluated this issue and determined that air quality impacts would be SMALL for all plants, and the issue should be Category 1. The GEIS was revised to explain this determination.

In addition, recent analysis has shown that the worst-case emissions from cooling tower drift and particulate emissions at operating plants were also SMALL. Air quality impacts from vehicle, equipment, and fugitive dust emissions associated with refurbishment would be SMALL for most plants, but could be a cause for concern for plants located in or near air quality nonattainment or maintenance areas. However, the impacts would be temporary and would cease once projects were completed. In addition, operating experience has shown that refurbishment activities have not required the large numbers of workers and extended durations conservatively predicted and analyzed in the 1996 GEIS, nor have such activities resulted in exceedances in the *de minimis* thresholds for criteria pollutants in nonattainment and maintenance areas. Consequently, the NRC agrees with the commenters' arguments that air quality impacts would be SMALL for all plants and should be a Category 1 issue.

Groundwater and soil contamination. Several commenters objected to the new Category 2 issue, "Groundwater and soil contamination," in the proposed rule and draft GEIS and asserted that contamination from industrial practices is addressed by U.S. Environmental Protection Agency (EPA) and State regulations that monitor and address these impacts. Specifically, the use, storage, disposal, release, and/or cleanup of spilled or leaked solvents, hydrocarbons, and other potentially hazardous materials are governed by the Resource Conservation and Recovery Act (RCRA), Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), Toxic Substances Control Act (TSCA), Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA), and the Clean Water Act (CWA).

While classified as a Category 2 issue in the draft GEIS and proposed rule, further consideration of the "Groundwater and soil contamination" issue and public comments revealed that the potential impacts on groundwater and soil quality from common industrial practices (e.g., the use, handling, storage, and disposal of chemicals, petroleum products, waste, and hazardous material) can be addressed generically, as industrial practices employed by nuclear power plants are not unique but common to all industrial facilities. The NRC concludes that the overall impact of industrial practices on groundwater use and quality from past and current operations is SMALL for all nuclear power plants and not expected to change appreciably during the license renewal term. NRC agrees with the commenters to the extent that clarification was needed and that common industrial practices which can cause groundwater or soil contamination can be addressed generically as a Category 1 issue.

Further, the final rule and GEIS combine the re-classified "Groundwater and soil contamination" issue with the Category 1 "Groundwater use and quality" issue and renames the consolidated Category 1 issue as "Groundwater contamination and use (non-cooling system impacts)." These issues were consolidated because they both consider the impact of industrial activities associated with the continued operations of a nuclear power plant (not directly related to cooling system effects) on groundwater use and quality. Consolidating these issues also conforms to the resource-based approach used in this revised GEIS and serves to facilitate the license renewal environmental review process.

The previous findings for "Groundwater use and quality," as analyzed in the 1996 GEIS, indicated that impacts of continued operations and refurbishment on groundwater use and quality would be SMALL, as extensive dewatering is not anticipated, and the application of best management practices for handling any materials produced or used during activities would reduce impacts. These findings were re-evaluated in the draft GEIS and are retained in this final GEIS.

This new consolidated issue also considers the impacts on groundwater, soil, and subsoil from the industrial use of solvents, hydrocarbons, heavy metals, or other chemicals at nuclear power plant sites during the license renewal term, including the impacts resulting from the use of wastewater disposal ponds or lagoons (both lined or unlined). Industrial practices at all nuclear plants have the potential to contaminate groundwater and soil, especially on sites with unlined wastewater and storm water lagoons. Contaminants have been found in groundwater and soil samples at some nuclear power plants during previous license renewal environmental reviews.

Any groundwater and soil contamination at operating nuclear power plants is subject to characterization and cleanup under EPA and State-regulated remediation and monitoring programs. In addition, wastewater disposal ponds and lagoons are subject to discharge authorizations under NPDES and related State wastewater discharge permit programs. Each operating nuclear power plant must comply with these EPA and State regulatory requirements.

As such, each site has an established program for handling chemicals, waste, and other hazardous materials. Moreover, nuclear power plant licensees are expected to employ best management practices, both in minimizing effluents and in remediation. Thus, this new consolidated issue, as explained in the final GEIS and rule, is a Category 1 issue.

Radionuclides in groundwater. Several commenters expressed opposition to the inclusion of a new Category 2 issue "Radionuclides released to groundwater," with an impact estimate of SMALL to MODERATE in the proposed rule and draft GEIS. Some commenters indicated that the issue category should be changed to Category 1; others suggested that the levels of significance should range from SMALL to LARGE. The argument for changing the issue to Category 1 was based on the voluntary industry-wide initiative (NEI 07-07, *Industry Ground Water Protection Initiative—Final Guidance Document*; NEI 2007) designed to protect groundwater.

This new Category 2 issue evaluates the potential contamination and degradation of groundwater resources resulting from inadvertent discharges of radionuclides into groundwater from nuclear power plants. Within the past several years, there have been numerous events at power reactor sites which involved unknown, uncontrolled, and unmonitored releases of radionuclides into the groundwater. The number of these events and the high level of public controversy have made this issue one that the NRC believes needs a "hard look" as required by NEPA.

As a voluntary action, NEI 07–07 cannot be enforced by the NRC. As such, no violations can be issued against a licensee who fails to comply with the guidance in NEI 07-07. Furthermore, the NRC cannot rely on a voluntary initiative as a basis to ensure that the nuclear power industry will have adequate information available for the NRC to determine whether a documented leak or spill does or does not have an adverse impact on groundwater resources. Regarding the magnitude of impact, the NRC bases its determination of SMALL to MODERATE impact on a review of existing plants have had inadvertent releases of radioactive liquids. Even though the NRC expects impacts for all plants to be within this range, a conclusion of LARGE impact would not be precluded for a future license renewal review based on new and significant information if the data support such a conclusion. As reflected in the final GEIS and rule, "Radionuclides released to groundwater" remains a Category 2 issue.

Radiation exposure to the public. Many commenters identified recent studies that claim an association between cancer risk and proximity to nuclear power facilities.

The NRC's primary mission is to protect the public health and safety and the environment from the effects of radiation from nuclear reactors, materials, and waste facilities. The NRC's regulatory limits for radiological protection are set to protect workers and the public from the harmful health effects (i.e., cancer and other biological impacts) of radiation to humans. The limits are based on the recommendations of scientific standards-setting organizations. These radiation standards reflect extensive scientific study by national and international organizations. The NRC actively participates in and monitors the work of these organizations to remain current on the latest trends in radiation protection. If the NRC determines that there is a need to revise its radiation protection regulations, it will initiate a separate rulemaking. The models recognized by the NRC for use by licensees to calculate dose incorporate conservative assumptions to ensure that workers and members of the public are adequately protected from radiation.

On April 7, 2010, the NRC announced that it asked the National Academy of Sciences (NAS) to perform a state-of-the-art study on cancer risk for populations surrounding nuclear power facilities (ADAMS Accession No. ML100970142). The NAS has a broad range of medical and scientific experts who can provide the best available analysis of the complex issues involved in discussing cancer risk and commercial nuclear power plants. The NAS is a nongovernmental organization chartered by the U.S. Congress to advise the nation on issues of science, technology, and medicine. Through the National Research Council and Institute of Medicine, it carries out studies independently of the government, using processes designed to promote transparency, objectivity, and technical rigor. More information on its methods for performing studies is available at http://www.nationalacademies.org/studycommitteprocess.pdf.

The NAS study will update the 1990 U.S. National Institutes of Health National Cancer Institute (NCI) report, "Cancer in Populations Living Near Nuclear Facilities" (Jablon et al. 1991), which concluded there was no evidence that nuclear facilities may be linked casually with excess death from leukemia or from other cancers in populations living nearby. The study's objectives are to (1) evaluate whether cancer risk is different for populations living near nuclear power facilities; (2) include cancer occurrence; (3) develop an approach to assess cancer risk in geographic areas that are smaller than the county level; and (4) evaluate the study results in the context of offsite doses from normal reactor operations. The study began in the summer of 2010 and is expected to be completed within three years. A discussion about NRC's sponsorship of this follow-up study is in Section 3.9.1.3 of the GEIS.

Onsite storage of spent nuclear fuel, waste disposal, and Yucca Mountain. Please see section 1.7.2, "Disposition of Spent Nuclear Fuel," above.

Postulated accidents. Numerous comments were received on the NRC's evaluation and classification of postulated accidents. One commenter disagreed with the GEIS's conclusion that environmental impact from design basis accidents (DBAs) is SMALL. Also, several commenters disagreed with the GEIS conclusion that the environmental impact from severe accidents is SMALL, and further, that the evaluation is not adequate because of its use of probability-weighted risk assessments. Their position is that for severe accidents, the revised GEIS should also evaluate the consequences of reactor accidents and expand the evaluation to include spent fuel pool accidents and accidents due to age-related plant component degradation. In addition, some of the commenters stated that the NRC has gained enough information from the many plant licenses it has renewed to make a determination, on a generic basis, that the “Severe accidents” issue should be reclassified as Category 1.

Design Basis Accidents. The NRC does not agree that the GEIS’s evaluation of DBAs is incorrect. The NRC evaluates and presents the potential consequences of DBAs in nuclear power plant licensing documents and considers them in the GEIS for license renewal. In order to receive NRC approval for an initial operating license, an applicant must submit a final safety analysis report (FSAR) as part of its application. The FSAR presents the applicable design criteria and design information for the proposed reactor, as well as comprehensive data on the proposed site. The FSAR also discusses hypothetical reactor accident situations and addresses the safety features that prevent and mitigate those accidents. During the initial licensing process for a power reactor, the NRC reviews the FSAR to determine whether or not the plant design meets the NRC’s regulations.

At initial licensing, the NRC also considered the environmental impact of DBAs at each operating nuclear power plant. DBAs are those events that both the applicant and the NRC evaluate to ensure that the plant can withstand normal and abnormal transients (e.g., rapid changes in reactor power) without undue risk to the health and safety of the public. Although the NRC does not expect that all of these postulated events will occur during the life of the plant, the NRC evaluates them to establish the basis for the preventive and mitigative safety systems of the facility. The acceptance criteria for DBAs are described in 10 CFR Part 50, “Domestic Licensing of Production and Utilization Facilities,” and 10 CFR Part 100, “Reactor Site Criteria.” Compliance with these regulations provides reasonable assurance of adequate protection of public health and safety.

During operations, the NRC requires that each power plant licensee maintains acceptable design and performance criteria in accordance with the NRC regulations, including during any license renewal period. Therefore, the calculated releases from DBAs will remain within the NRC regulatory limits.

The 1996 GEIS, in Section 5.2, discusses the impacts of potential accidents. It contains a discussion of plant accidents and consequences. This discussion addresses general characteristics of design basis (and severe) accidents, characteristics of fission products, meteorological considerations, possible exposure pathways, potential adverse health effects, avoiding adverse health effects, accident experience and observed impacts, and emergency preparedness. This GEIS reexamined the information from the 1996 GEIS and concluded that it is still valid. Because the information on DBAs is valid and has not changed, this GEIS does not repeat the information from the 1996 GEIS.

Severe Accidents. The NRC does not agree with the comments that the GEIS evaluation is inadequate regarding the impacts from severe accidents because it uses probability-weighted risk assessments. Severe accidents (i.e., beyond design-basis accidents) are those that could result in substantial damage to the reactor core, whether or not there are serious off-site consequences. The 1996 GEIS estimated and considered the potential impacts on human health and economic factors from full-power severe reactor accidents initiated by internal events at different types of nuclear facilities located in different types of settings. That evaluation included modeling the release of radioactive materials into the environment and modeling the pathways (i.e., exposure to the radioactive plume, inhalation of radioactivity, consumption of contaminated food) through which members of the public could potentially be exposed to doses of radiation. Based on the calculated doses, the 1996 GEIS reported the consequences (i.e., potential early and latent fatalities) from such accidents. In developing a potential impact level, however, the NRC took into account the very low probability of such events, as well as their potential consequences, and concluded that the likely impact from individual nuclear power plants is small.

In this GEIS, the NRC expanded the scope of the severe accident evaluations and used more recent technical information that included both internal and external event core-damage frequency, as well as improved severe accident source terms, spent fuel pool accidents, low power and reactor shutdown events, new radiation risk-coefficients from the National Academy of Sciences, "Health Risks from Exposure to Low Levels of Ionizing Radiation: Biological Effects of Ionizing Radiation (BEIR) VII report," and risk impacts of reactor power uprates and higher fuel burn-up levels. As a result, this GEIS considers updated information in determining the potential consequences of a reactor accident. Considering this updated information and that severe reactor accidents remain unlikely, this GEIS concludes that the environmental impacts of a severe accident remain small.

The NRC notes, however, that the GEIS is not the primary vehicle the NRC uses to address and regulate risks from severe accidents. The NRC's regulations and regulatory practices employ safety standards in the design, construction, and operation of nuclear power plants as well as risk models to ensure the public is adequately protected on an on-going basis. The NRC 's ongoing oversight addresses the public's risk from nuclear power plant accidents, accounts for the effects of proposed changes that may be made as part of power plant operations, and considers new information about the facility or its environment when necessary.

Although the NRC has determined that impacts from severe accidents are small for all facilities, the NRC continues to maintain that severe accidents cannot be a Category 1 issue because plant-specific mitigation measures vary greatly based on plant designs, safety systems, fuel type, operating procedures, local environment, population, and siting characteristics. Thus, severe accidents remain a Category 2 issue. Accordingly, the NRC has not changed the requirements in 10 CFR 51.53(c)(3)(ii)(L) that an applicant's environmental report must contain a discussion that considers alternatives to mitigate severe accidents if the NRC has not previously considered this issue in an environmental impact statement or environmental assessment for the facility.

Spent Fuel Pool Accidents. The 1996 GEIS included a quantitative analysis of a severe accident involving a reactor operating at full power. A qualitative evaluation of SFP accidents is presented in Appendix E of this GEIS. Based on this evaluation, this GEIS concludes that the environmental impacts from accidents involving SFPs are comparable to those from the reactor accidents at full power that were evaluated in the 1996 GEIS, and as such, SFP accidents do not warrant separate evaluation. Based on the continued validity of conclusions from the 1996 GEIS, as affirmed by the Commission (see following paragraph), this GEIS does not contain a quantitative evaluation of SFP accidents.

The issue of an accident involving the spent fuel was specifically addressed by the NRC in response to two Petitions for Rulemaking (PRM), PRM-51-10 and PRM-51-12, submitted by the Attorney General of the Commonwealth of Massachusetts in 2006 and the Attorney General of California in 2007, respectively (collectively, the Petitioners). The Petitioners challenged the 1996 GEIS Category 1 classification for this issue.[c] The Petitioners requested that the NRC initiate a rulemaking concerning the environmental impacts of the high-density storage of spent nuclear fuel in spent fuel pools (SFPs). The Petitioners asserted that ‘‘new and significant information’’ showed that the NRC incorrectly characterized the environmental impacts of high-density spent fuel storage as ‘‘insignificant’’ in the 1996 GEIS for the renewal of nuclear power plant licenses. Specifically, the Petitioners asserted that spent fuel stored in high-density SFPs is more vulnerable to a zirconium fire than the NRC concluded in its NEPA analysis.

On August 8, 2008 (73 FR 46204), the Commission denied the petitions, stating:

> Based upon its review of the petitions, the NRC has determined that the studies upon which the Petitioners rely do not constitute new and significant information. The NRC has further determined that its findings related to the storage of spent nuclear fuel in pools, as set forth in NUREG-1437 and in Table B-1, of Appendix B to Subpart A of 10 CFR Part 51, remain valid. Thus, the NRC has met and continues to meet its obligations under NEPA. For the reasons discussed previously, the Commission denies PRM-51-10 and PRM-51-12.[d]

(c) The details of the petitions and the NRC’s evaluations of those petitions are available to the public through the ADAMS electronic reading room (at www.nrc.gov using ADAMS accession number ML073310115) and in the Federal e-Rulemaking Portal (http://www.regulations.gov, Docket ID [NRC-2006-0022] (PRM-51-10), and [NRC-2007-0019] (PRM-51-12)).

(d) 73 FR 46204, 46212 (August 8, 2008). The NRC decision to deny the two rulemaking petitions was upheld by the United States Court of Appeals for the Second Circuit. *New York v. the Nuclear Regulatory Commission*, 589 F.3d 551 (2nd Cir. 2009).

Based on the continued validity of conclusions from the 1996 GEIS, and as affirmed by the Commission in its denial of PRM-51-10 and PRM-51-12, the NRC concludes that the onsite storage of spent fuel is properly classified as Category 1.

Aging-Related Degradation. Issues related to age-related plant component degradation are addressed in the NRC's safety evaluation of the plant's license renewal application. The regulations covering the safety review for license renewal are in 10 CFR Part 54.

The 1996 GEIS discusses the potential effects of age on the physical plant and notes that such deterioration could result in an increased likelihood of component or structure failure that could increase the rate of plant accidents. The GEIS notes that the NRC requires an applicant for license renewal address the issue of age-related degradation by identifying, in an integrated plant assessment process, those passive, long-lived structures and components that are susceptible to age-related degradation and whose functions are necessary to ensure that the facility's current licensing basis will be maintained in the license renewal period. The GEIS found that the safety evaluation performed by the NRC as part of the license renewal process provides reasonable assurance that age-related degradation will be managed and adequate protection of the health and safety of the public will be maintained during the license renewal period. Therefore, the 1996 GEIS concluded "the probability of any radioactive releases from accidents will not increase over the license renewal period." Based on nuclear power plants' continued compliance with 10 CFR Part 54 to manage age-related degradation, this GEIS did not alter or revise this conclusion.

Climate change. Several commenters discussed the need to include a discussion of the effects of climate change on plant operations and the effect of continued operations during the license renewal period on environmental resources affected by climate change.

Like other Federal agencies, the NRC has begun to evaluate the effects of greenhouse gas (GHG) emissions and its implications for global climate change in its environmental reviews for both new reactor and license renewal applications. Changes in climate have the potential to affect air and water resources, ecological resources, and human health, and should be taken into account when evaluating cumulative impacts over the license renewal term.

Subsequent to the publication of the proposed rule and during the public comment period, the Commission issued a memorandum and order concerning two combined license applications for new reactor units at the Tennessee Valley Authority Bellefonte site in Alabama and the Duke Energy Carolinas Lee site in South Carolina (CLI–09–21, November 3, 2009). The memorandum and order stated:

> [B]ecause the Staff is currently addressing the emerging issues surrounding greenhouse gas emissions in environmental reviews required for the licensing of nuclear facilities, we believe it is prudent to provide the following guidance to the Staff. We expect the Staff to include consideration of carbon dioxide and other greenhouse gas emissions in its environmental reviews for major licensing actions under the National Environmental Policy Act. The Staff's analysis for reactor applications should encompass emissions from the uranium fuel cycle as well as from construction and operation of the facility to be licensed. The Staff should ensure that these issues are addressed consistently in agency NEPA evaluations and, as appropriate, update Staff guidance documents to address greenhouse gas emissions.[e]

Presently, insufficient data exists to support an impact level on a generic basis. The NRC only has direct emission data for a handful of facilities. Although some States have varying reporting requirements, GHG emissions reporting nationwide is in its infancy. The EPA promulgated its GHG emissions reporting rule on October 30, 2009 (74 FR 56260). In accordance with this rule, the first industry reporting date was March 31, 2011.[f] Moreover, the 25,000 annual metric ton reporting threshold EPA established in the above final rule are not an indication of what EPA considers to be a significant (or insignificant) level of GHG emissions on a scientific basis, but a threshold chosen by EPA for policy evaluation purposes.[g]

In order to comply with the Commission's direction in CLI–09–21 and in response to the comments received, a new section, "GHG Emissions and Climate Change" (Chapter 4, Section 4.12.3.2), summarizing the potential cumulative impacts of GHG emissions and global climate change, has been added to the final GEIS. The NRC will also include within each SEIS a plant-specific analysis of any impacts caused by GHG emissions over the course of the license renewal term as well as any cumulative impacts caused by potential climate change upon the affected resources during the license renewal term. The final rule was not revised to include any reference to GHG emissions or climate change.

Recent advances in (replacement power alternatives. Several commenters asserted that much of the information describing replacement power alternatives did not reflect the state-of-

(e) In the matter of Duke Energy Carolinas, LLC (Combined License Application for William States Lee III Nuclear Station, Units 1 and 2); in the matter of Tennessee Valley Authority (Bellefonte Nuclear Power Plant, Units 3 and 4), CLI–09–21 (NRC November 3, 2009).

(f) 74 FR 56260, 56267 (October 30, 2009), codified at 40 CFR 98.3(b) ("The annual GHG report must be submitted no later than March 31 of each calendar year for GHG emissions in the previous calendar year").

(g) EPA concluded for policy evaluation purposes, the 25,000 metric ton threshold more effectively targets large industrial emitters and suppliers, covers approximately 85 percent of U.S. emissions, and minimizes the burden on smaller facilities.

the-science. In some cases, commenters noted facts and events that occurred after the publication date of the draft GEIS.

The NRC has updated the final GEIS to incorporate the latest information on replacement power alternatives, but it is inevitable that rapidly evolving technologies will outpace information presented in the GEIS. Incorporation of this information is more appropriately made in the context of plant-specific license renewal reviews, rather than in the GEIS. As with renewable energy technologies, energy policies are evolving rapidly. While the NRC acknowledges that legislation, technological advancements, and public policy can underlie a fundamental paradigm shift in energy portfolios, the NRC cannot make decisions based on anticipated or speculative changes. Instead, the NRC considers the status of alternatives and energy policies when conducting plant-specific environmental reviews. The introduction to GEIS Section 2.3.4 has been revised to clarify NRC's approach to evaluating replacement power alternatives.

Emergency preparedness and security. Many commenters expressed concern with emergency preparedness, evacuation, and safety and security planning at nuclear power plants. Commenters stated that these concerns were not adequately covered in the draft GEIS and should be included in the scope of plant-specific license renewal supplements to the GEIS.

As explained in GEIS Section 1.7.3, emergency preparedness and planning are part of a nuclear power plant's current operating license. Before a nuclear power plant is licensed to operate, the NRC must have "reasonable assurance that adequate protective measures can and will be taken in the event of a radiological emergency" (10 CFR 50.47). Therefore, the Commission determined that decisions and recommendations concerning emergency preparedness at nuclear plants are ongoing and outside the regulatory scope of license renewal.

The Commission considered the need for a review of emergency planning issues in the context of license renewal during its rulemaking proceedings on 10 CFR Part 54, "Requirements for Renewal of Operating Licenses for Nuclear Power Plants," which included public notice and comment. As discussed in the Statement of Consideration for rulemaking (56 FR 64966; December 13, 1991), the programs for emergency preparedness at nuclear power facilities apply to all nuclear power facility licensees and require the specified levels of protection from each licensee regardless of plant design, construction, or license date. NRC requirements related to emergency planning are in the regulations at 10 CFR 50.47 and Appendix E to 10 CFR Part 50, "Emergency Planning and Preparedness for Production and Utilization Facilities." These requirements apply to all operating licenses and will continue to apply to facilities with renewed licenses. Through its standards and required exercises, the Commission reviews existing emergency preparedness plans throughout the life of any facility, keeping up with changing demographics and other site-related factors.

Further, the NRC actively reviews its regulatory framework to ensure that the emergency preparedness regulations are current and effective. The agency began a major review of its emergency preparedness framework in 2005, including a comprehensive review of the emergency preparedness regulations and guidance, the issuance of generic communications regarding the integration of emergency preparedness and security, and outreach efforts to interested persons to discuss emergency preparedness issues. In 2011, these activities culminated in the issuance of a final rule that enhances a nuclear power plant's response to possible hostile action events by making drill and exercise programs more challenging, changing the criteria for declaring emergencies, and taking additional steps to protect workers. The rule also includes other new requirements such as when updates to evacuation time estimates are required.

As explained in GEIS Section 1.7.4, security issues are not tied to a license renewal action but are considered to be issues that need to be dealt with continuously as a part of the current (and renewed) operating license. If issues related to security are discovered at a nuclear plant, they are addressed immediately, and any necessary changes are reviewed and incorporated under the current operating license (NRC 2006). For example, after the terrorist attacks of September 2001, the NRC issued security-related orders and guidance to nuclear power plants. These orders and guidance included interim measures for emergency planning. Nuclear industry groups and Federal, State, and local government agencies assisted in the prompt implementation of these measures and participated in drills and exercises to test these new planning elements. The NRC reviewed licensees' commitments to address these requirements and verified their implementation through inspections to ensure public health and safety.

In summary, the issue of security (and risk from terrorist acts against nuclear power plants) is not unique to facilities requesting license renewal. The NRC routinely assesses threats and other information provided by other Federal agencies and sources. The NRC also ensures that licensees meet their security requirements through its ongoing regulatory process (routine inspections) as a current and generic regulatory issue that affects all nuclear power plants. Therefore, as discussed in the Statements of Consideration for the 10 CFR Part 54 rulemaking, the Commission has determined that there is no need for a special review of security issues in the context of an environmental review for license renewal.

Fukushima earthquake and tsunami. On March 11, 2011, a massive earthquake off the east coast of Honshu, Japan, produced a devastating tsunami that struck the coastal town of Fukushima. The six-unit Fukushima Dai-ichi nuclear power plant was directly impacted by these events. The resulting damage caused the failure of several of the units' safety systems needed to maintain cooling water flow to the reactors. As a result of the loss of cooling, the fuel overheated, and there was a partial meltdown of the fuel contained in several of the reactors. Damage to the systems and structures containing reactor fuel resulted in the release of radioactive material to the surrounding environment.

In response to the earthquake, tsunami, and resulting reactor accidents at Fukushima Dai-ichi (hereafter referred to as the “Fukushima events”), the Commission directed the staff to convene an agency taskforce (Japan Near-Term Task Force) of senior leaders and experts to conduct a methodical and systematic review of the relevant NRC regulatory requirements, programs, and processes, including their implementation, and to recommend whether the agency should make near-term improvements to its regulatory system. As part of the short-term review, the taskforce concluded that, while improvements are expected to be made as a result of the lessons learned from the Fukushima events, the continued operation of nuclear power plants and licensing activities for new plants do not pose an imminent risk to public health and safety (NRC 2011).

During the time that the taskforce was conducting its review, groups of individuals and non-governmental organizations petitioned the Commission to suspend all licensing decisions in order to conduct a separate, generic NEPA analysis to determine whether the Fukushima events constituted “new and significant information” under NEPA that must be analyzed as part of environmental reviews. The Commission found the request premature and noted, “In short, we do not know today the full implications of the [Fukushima] events for U.S. facilities.”[h] However, the Commission found that if “new and significant information comes to light that requires consideration as part of the ongoing preparation of application-specific NEPA documents, the agency will assess the significance of that information, as appropriate.”[i] The Federal courts of appeal and the Commission have interpreted NEPA such that an EIS must be updated to include new information only when that new information provides “a seriously different picture of the environmental impact of the proposed project from what was previously envisioned.”[j]

In the context of the GEIS, the Fukushima events are considered a severe accident (i.e., a type of accident that may challenge a plant’s safety systems at a level much higher than expected) and more specifically, a severe accident initiated by an event external to the plant. The 1996 GEIS concluded that risks from severe accidents initiated by external events (such as an earthquake) could have potentially high consequences but found that external events are adequately addressed through a consideration of a severe accident initiated by an internal event (such as a loss of cooling water). Therefore, an applicant for license renewal need only analyze

(h) *Union Electric Co. d/b/a Ameren Missouri* (Callaway Plant, Unit 2), CLI-11-05, 74 NRC __, __ (slip op. at 30) (Sept. 9, 2011).

(i) *Id.* at 30-31.

(j) *Id*. at 31 (quoting *Hydro Resources, Inc.* (2929 Coors Road, Suite 101, Albuquerque, NM 87120), CLI-99-22, 50 NRC 3, 14 (1999) (citing *Marsh v. Oregon Natural Resources Council*, 490 U.S. 360, 373 (1989))). The Commission also noted that it can modify a facility’s operating license outside of a renewal proceeding and made clear that “it will use the information from these activities to impose any requirement it deems necessary, irrespective of whether a plant is applying for or has been granted a renewed operating license.” *Id.* at 26-27.

the environmental impacts from an internal event in order to adequately characterize the environmental impacts from either type of event. Prior to the Fukushima events, this GEIS examined more recent and up-to-date information regarding external events and concluded that the analysis in the 1996 GEIS remains valid.

Meanwhile, the Japan Near-Term Task Force assessment resulted in the issuance of 10 CFR 50.54(f) letters on March 12, 2012, to address seismic and flooding reevaluations (NRC 2012). As of the publication date of this GEIS, the NRC's evaluation of the consequences of the Fukushima events is ongoing under the direction of the NRC's Japan Lessons Learned Project Directorate. As such, the NRC will continue to evaluate the need to make improvements to existing regulatory requirements based on the task force report and additional studies and analyses of the Fukushima events as more information is learned. To the extent that any revisions are made to NRC regulatory requirements, they would be made applicable to nuclear power reactors regardless of whether or not they have a renewed license. Therefore, no additional analyses have been performed in this GEIS as a result of the Fukushima events. In the event that the NRC identifies information from the Fukushima events that constitutes new and significant information with respect to the environmental impacts of license renewal, the NRC will discuss that information in its site-specific SEISs to the GEIS, as it does with all such new and significant information.

1.10 Changes from the Draft GEIS

In response to public comments on the proposed rule (74 FR 38117, July 21, 2009) and draft GEIS and as a result of information that was unavailable at the time of the issuance of the draft GEIS, the final GEIS contains revisions and new information. Volume 2, Appendix A, Section A.2 presents the comments received during the public comment period on the proposed rule and draft GEIS and NRC's responses to those comments. A brief discussion of the most important changes is provided in this section.

1.10.1 General Overview of Rule-Related Changes

Based on public comments and direction from the Commission, a number of the environmental impact issues identified in Table B-1 of the proposed rule and the associated technical basis for the findings in the draft GEIS were re-evaluated for the final GEIS and rule. Some of these environmental impact issues are discussed in the Section 1.9, "Public Comments on the Draft GEIS." These changes are discussed in detail in Chapter 4 in this final GEIS and are briefly summarized as follows:

- "Air quality (non-attainment and maintenance areas)" issue was changed from a Category 2 to a Category 1 issue and renamed, "Air quality impacts (all plants)."

- “Groundwater and soil contamination,” was changed from a Category 2 to a Category 1 issue and consolidated with “Groundwater use and quality” into a single renamed Category 1 issue, “Groundwater contamination and use.”

- “Thermal impacts on aquatic organisms” issues were reorganized to separate out several Category 1 thermal impact issues (grouped together with a Category 2 thermal impact issue in the proposed rule) to create a new separate combined Category 1 issue, “Infrequently reported thermal impacts (all plants),” which also includes the previously separate “Stimulation of aquatic nuisance species (e.g., shipworms)” Category 1 thermal impact issue. Like Category 1 issues had been grouped together within the larger context of the Category 2 issue in the proposed rule to facilitate the environmental review process consistent with the resource-based approach in this GEIS.

- “Impingement and entrainment of aquatic organisms” issues were reorganized to separate out a single impingement and entrainment Category 1 issue (grouped with other impingement and entrainment issues in the proposed rule) to create a new separate Category 1 issue, “Entrainment of phytoplankton and zooplankton (all plants).” Like impingement and entrainment issues had been grouped together within the larger context of the Category 2 issue, “Impingement and entrainment of aquatic organisms (plants with once-through cooling systems or cooling ponds)” in the proposed rule to facilitate the environmental review process consistent with the resource-based approach in this GEIS.

- The NRC revised the Category 1 “Onsite storage of spent nuclear fuel”[(k)] issue to narrow the period of onsite storage to the license renewal term as a result of the 2012 D.C. Circuit decision in *New York v. NRC*, and the Commission’s subsequent direction. As described in section 1.7.2, “Disposition of spent nuclear fuel,” above, pending the issuance of a generic EIS and revised Waste Confidence Decision and Rule, the period of onsite storage of spent nuclear fuel following the permanent shutdown of the power reactor and expiration of the operating license is now excluded from this GEIS issue. As revised, this issue now covers the onsite storage of spent fuel for the term of the extended license only; it remains classified as a Category 1 issue.

- The “Offsite radiological impacts of spent nuclear fuel and high-level waste disposal” issue[(l)] was determined to be a Category 1 issue in the 1996 GEIS, but given the 2012

(k) The issue was named “On-site spent fuel” in the 1996 rule and GEIS.
(l) The issue was named “Offsite radiological impacts (spent fuel and high level waste disposal)” in the 1996 rule and GEIS.

> D.C. Circuit decision in *New York v. NRC*, and the Commission's subsequent direction, the NRC reclassified the issue to uncategorized in the final GEIS. As the NRC has now determined that this issue is uncategorized, pending further action by the Commission to address the issues raised in *New York v. NRC*, an applicant is not required to conduct a plant-specific assessment of the environmental impacts associated with this issue in its environmental report.

As a result, 59 environmental impact issues were determined to be Category 1 and would not require additional plant-specific analysis unless new and significant information is identified during a plant-specific license renewal environmental review that would change the conclusions in the GEIS. Of the remaining 19 issues, 17 were determined to be Category 2, and two are uncategorized. These 78 issues are evaluated in the final GEIS. No environmental issues evaluated in the 1996 GEIS were eliminated, but certain issues have been consolidated or grouped due to the related nature of the impacts.

1.10.2 Greenhouse Gas Emissions and Climate Change

A discussion of greenhouse gas emissions and climate change has been added to the final GEIS.

1.10.3 Miscellaneous Revisions and Editorial Changes

Several sections in the final GEIS were revised to reflect the availability of more recent information or to include corrections, fix erroneous information, improve the presentation, and to make other editorial changes. Sections of the GEIS were also revised in response to the Plain Writing Act of 2010, which directs Federal agencies to write all new publications, forms, and publicly distributed documents in a clear, concise, organized manner and to follow other best practices appropriate to writing for the public. None of these revisions and editorial changes affect the assessment of environmental impacts to the 78 environmental issues addressed in the final GEIS.

1.11 Lessons Learned

As previously discussed, the NRC reviewed and reevaluated the impacts of license renewal on the 92 environmental issues addressed in the 1996 GEIS. Over 40 nuclear plants (70 reactor units) have since undergone license renewal environmental reviews. Lessons learned and knowledge gained from these license renewal environmental reviews have provided a significant source of new information for this GEIS revision.

The purpose of this review and reevaluation was to determine if the findings presented in the 1996 GEIS remain valid. In doing so, the NRC considered the need to modify, add, group, or delete any of the 92 issues in the 1996 GEIS. After this review and reevaluation, the NRC carried forward 78 impact issues for detailed consideration in this GEIS revision. The issues identified in the 1996 GEIS have served to accurately categorize most environmental impacts associated with license renewal, and there have been no cases where new and significant information called into question the original findings of the GEIS. There have been a number of instances where new (but not significant) information was discovered during a license renewal review. In most cases, the new information identified did not fit into one of the 92 environmental issues addressed in the 1996 GEIS but still warranted review in the plant-specific SEIS. For example, the environmental review for license renewal at the D.C. Cook plant in Michigan considered the effects of sanitary sewage lagoons on groundwater quality as a new issue. The review for the Oyster Creek plant considered the effects of a small dam built to impound water for fire-fighting purposes. The license renewal environmental review process established in 10 CFR Part 51 has proven to be robust because it allows new information and lessons learned to be addressed in subsequent plant-specific license renewal environmental reviews.

1.12 New Organization of the GEIS

This GEIS revision adopts the NRC's standard format for EISs as established in 10 CFR Part 51, Subpart A, Appendix A. Consequently, the organizational structure of this GEIS is quite different from that of the 1996 GEIS. The 1996 GEIS presented impacts organized around plant systems (e.g., cooling systems, transmission lines) and activities (e.g., refurbishment). This GEIS takes a more typical NEPA resource-based approach to presenting impacts where all components of the proposed action and alternatives are presented for each resource area. The following list describes the contents of each chapter of GEIS:

- **Chapter 2** presents brief descriptions of the proposed action (including nuclear plant operations, refurbishment, and termination of operations and decommissioning) during the license renewal term and summary of impacts; the no-action alternative; and replacement power alternatives.

- **Chapter 3** presents a general description of the affected environment in the vicinity of operating commercial nuclear power plants in the United States. Included are descriptions of nuclear power plant facilities and operations followed by general descriptions of existing conditions in the following topical areas: (1) land use and visual resources; (2) meteorology, air quality, and noise; (3) geologic environment; (4) water resources (surface water and groundwater resources); (5) ecological resources (terrestrial resources, aquatic resources, special status species and habitats); (6) historic and cultural resources; (7) socioeconomics; (8) human health (radiological and nonradiological hazards); (9) environmental justice; and (10) waste management.

- **Chapter 4** presents the environmental consequences associated with the proposed action (license renewal) and replacement power alternatives (including the effects of construction and operations) on each of the topical areas presented in Chapter 3. Impacts common to all alternatives (including the environmental consequences of fuel cycles and terminating power plant operations), cumulative impacts, and resource commitments associated with the proposed action are also discussed.

- **Chapter 5** presents a list of the preparers of this GEIS, their affiliations, authorship responsibilities, and qualifications.

- **Chapter 6** provides a list of the agencies, organizations, and persons receiving copies of the GEIS.

- **Chapter 7** provides for a glossary of terms used in the GEIS.

4 Environmental Consequences and Mitigating Actions

4.1 Introduction

The U.S. Nuclear Regulatory Commission (NRC) evaluated the environmental consequences of the proposed action (i.e., license renewal) including the (1) impacts associated with continued operations and refurbishment activities similar to those that have occurred during the current license term; (2) impacts of various alternatives to the proposed action; (3) impacts from the termination of nuclear power plant operations and decommissioning after the license renewal term (with emphasis on the incremental effect caused by an additional 20 years of operation); (4) impacts associated with the uranium fuel cycle; (5) impacts of postulated accidents (design-basis accidents and severe accidents); (6) cumulative impacts of the proposed action; and (7) resource commitments associated with the proposed action, including unavoidable adverse impacts, the relationship between short-term use and long-term productivity, and irreversible and irretrievable commitment of resources.

Contents of Chapter 4

In evaluating impacts for this revision of the *Generic Environmental Impact Statement for License Renewal of Nuclear Plants* (NRC 1996, referred to in this document as the "1996 GEIS"), the NRC used a standard of significance based on the Council on Environmental Quality (CEQ) terminology for "significantly" (see Title 40, Section 1508.27 in the *Code of Federal Regulations* [40 CFR 1508.27]), which considers both "context" and "intensity." The NRC established three significance levels—SMALL, MODERATE, and LARGE—and has used these levels and associated definitions as standard practice in preparing its supplemental environmental impact statements (SEISs) to the GEIS. As indicated in Section 1.5, the definitions of the three significance levels are as follows:

- **SMALL:** Environmental effects are not detectable or are so minor that they will neither destabilize nor noticeably alter any important attribute of the resource.

- **MODERATE:** Environmental effects are sufficient to alter noticeably, but not to destabilize, important attributes of the resource.

- **LARGE:** Environmental effects are clearly noticeable and are sufficient to destabilize important attributes of the resource.

These levels are used for describing the impacts of most aspects of the proposed action as well as the impacts of alternatives to the proposed action. Resource-specific definitions are provided where applicable.

4.1.1 Environmental Consequences of the Proposed Action

As described in Section 2.1, a number of activities associated with the proposed action could have environmental consequences. The proposed action includes the activities associated with normal operations during the license renewal term, including (1) plant operation, (2) activities needed to support operations and meet infrastructure requirements (e.g., road improvements, new parking lots, waste storage facilities, and new ancillary buildings), and (3) refurbishment actions needed to replace and/or repair critical portions of reactor systems.

The assessment includes a determination of the magnitude of the impact (SMALL, MODERATE, or LARGE, as defined above) and whether or not the analysis of the environmental issue could be applied to all or a category of plants. Issues are assigned a Category 1 or a Category 2 designation as follows:

Category 1 issues are those that meet all of the following criteria:

- The environmental impacts associated with the issue were determined to apply either to all plants or, for some issues, to plants having a specific type of cooling system or other specified plant or site characteristics.

- A single significance level (i.e., SMALL, MODERATE, or LARGE) was assigned to the impacts (except for offsite radiological impacts—collective impacts from other than the disposal of spent fuel and high-level waste).

- The mitigation of adverse impacts associated with the issue was considered in the analysis, and it was determined that additional plant-specific mitigation measures are not likely to be sufficiently beneficial to warrant implementation.

For issues that meet the three Category 1 criteria, no additional plant-specific analysis is required in future supplemental EISs (SEISs) unless new and significant information is identified.

Category 2 issues are those that do not meet one or more of the criteria of Category 1 and for which, therefore, an additional plant-specific review is required.

A total of 78 impact issues that are related to the proposed action were identified (summarized in Table 2.1-1). For each potential environmental impact issue identified, the GEIS revision (1) describes the nuclear power plant activity that could affect the resource, (2) identifies the resource that is affected, (3) evaluates past license renewal reviews and other available information, (4) assesses the nature and magnitude of the environmental impact on the affected resource, (5) characterizes the significance of the effect, (6) determines whether the results of the analysis apply to all nuclear power plants (i.e., whether the impact issue is Category 1 or Category 2), and (7) considers additional mitigation measures for adverse impacts. In cases for which the issue differs from that presented in the 1996 GEIS, the rationale for the new treatment is presented.

4.1.2 Environmental Consequences of Continued Operations and Refurbishment Activities during the License Renewal Term

> In most cases, the impacts of continued operations and refurbishment activities during the license renewal term are similar to the impacts that have resulted from the operation of licensed nuclear power plants during the current license term.

The activities that would occur during normal operations of the license renewal term and that are thus the subject of this evaluation are discussed in Section 2.1. It is important to note that the impacts of the original construction of the nuclear power plants and past operational impacts are not the focus of this evaluation of environmental consequences. Both the impacts of original construction and the impacts of past operations have affected and, in many cases, established the current conditions at each plant and vicinity. These conditions serve as the baseline for the impact analyses presented in this section. Past impacts are presented in the description of the affected environment in Chapter 3. In these cases, the impacts of continued operations and refurbishment activities during the license renewal term are similar to the impacts that have resulted from the operation of licensed nuclear power plants during the current license term. In most cases, impacts of the proposed action would not represent a change from current conditions and are considered SMALL. In other cases, the proposed action could result in a change from current conditions, and the impacts could be considered MODERATE or LARGE.

A total of 78 impact issues (including 5 issues related to waste management at both nuclear power plants and other nuclear fuel cycle facilities) that are related to continued operations and refurbishment activities during the license renewal term were identified and evaluated; they are summarized in Table 2.1-1. This revised GEIS provides the technical basis for the issues presented in Table B-1 in Appendix B, Subpart A, of 10 CFR Part 51. The identified impact issues are discussed by resource topic in the remainder of this section. The assessment approaches specific to each resource area are described in Appendix D.

4.1.3 Environmental Consequences of the No-Action Alternative

The no-action alternative represents a decision by the NRC not to issue a renewed operating license. If a license is not renewed, the licensee would have to shut the plant down. At some point in time, all plants eventually would be required to shut down and undergo decommissioning. Under the no-action alternative, these eventualities would occur sooner than if the NRC issued a renewed license.

Denying license renewal and ceasing operation under the no-action alternative may lead to a variety of potential outcomes, but these are essentially the same as the ones that would eventually occur once plant operations ceased after license renewal (see Section 4.12.2 for a discussion of these effects). Reactor shutdown would result in a net reduction in power production capacity. The power not generated by the nuclear plant during a license renewal term would likely be replaced by (1) generating alternatives other than the nuclear power plant, (2) demand-side management, (3) power purchased from other electricity providers, or (4) some combination of these options. Note that NRC's consideration of the no-action alternative does not involve the determination of whether any power is needed or should be generated. The decision to generate power and the determination of how much power is needed are at the discretion of State, Federal (non-NRC), and utility officials.

4.1.4 Environmental Consequences of Replacement Power Alternatives

Replacement power alternatives consider the potential environmental impacts from the construction and operation of alternative power generating technologies (including a new nuclear reactor) that could replace the power from an existing nuclear power plant. Each resource area in this chapter assesses the environmental effects of constructing and operating various replacement power alternatives. Alternatives were selected on the basis of reviews of energy technologies that are either currently commercially viable on a utility scale and operational prior to the expiration of a reactor's operating license or can be expected to become commercially viable on a utility scale and operational prior to the expiration of a reactor's operating license. Other energy technologies that hold promise for becoming part of a bulk electricity portfolio sometime in the future are identified but not evaluated in detail. Should the need arise to replace the electrical power generating capacity of a reactor, either because its operating license will not be renewed or because of changes in strategies to meet changing regional or local demand, the necessary replacement power is likely to be provided by a suite or portfolio of electrical energy producing technologies, including, perhaps, expansions of the capacities of one or more existing power-generating facilities within the region. The number of possible combinations of energy producing technologies to replace lost electrical power generating capacity is quite large. An evaluation of even a small fraction of these combinations would not significantly advance the knowledge base supporting the license renewal decision. Consequently, individual technologies rather than combinations are evaluated as replacement power alternatives in this GEIS. Data on commercial products or services are included for information purposes only. No endorsement is implied. The NRC does not engage in energy-planning decisions and makes no judgment as to which of the replacement power alternatives would be chosen in any given case.

In addition to the installation of electrical energy producing technologies, replacement power could also be provided by importing power over the bulk electricity grid. Power replaced through energy purchases would likely have similar characteristics to some of the replacement power alternatives being considered, and would be dependent on available energy sources at the time of the purchase. At the time of publication, coal, natural gas, and nuclear-fueled power plants are the most-prevalent sources of purchased replacement power, though an increasing number of renewable power sources are emerging. As such, the effects of purchased power are likely to be similar to the effects of operating a combination of electrical energy producing technologies or similar to the fossil or nuclear-fueled alternatives. Impacts overall are likely to be lower for purchased power (if existing power generation and transmission capacity is also available) since no construction is necessary. On the other hand, since existing plants are likely to have less-stringent emissions controls, operational impacts to air quality and human health may be slightly greater for purchased power than for new construction.

4.1.5 Environmental Consequences of Terminating Nuclear Power Plant Operations and Decommissioning

All operating nuclear power plants will terminate operations and be decommissioned at some point after the end of their operating licenses or after a decision is made to cease operations. License renewal could potentially delay this eventuality for an additional 20 years beyond the current license period. The impacts of decommissioning nuclear plants were evaluated in the *Generic Environmental Impact Statement for Decommissioning Nuclear Facilities: Supplement 1, Regarding the Decommissioning of Nuclear Power Reactors*, NUREG-0586 (NRC 2002a). The effects of license renewal on the impacts of terminating nuclear power plant operations and decommissioning are considered a single environmental issue. Because the impacts are expected to be SMALL at all plants and for all environmental resources, it is considered a Category 1 issue. The impacts of terminating nuclear power plant operations and decommissioning for each resource area are discussed in Section 4.12.2.

4.2 Land Use and Visual Resources

4.2.1 Environmental Consequences of the Proposed Action—Continued Operations and Refurbishment Activities

Since September 11, 2001, changes in onsite land use have occurred at nuclear power plants across the nation, with increased restrictions on site access and changes in barricades and landscaping to enhance security. Generally, land use conditions are expected to continue unchanged until plant decommissioning. Similarly, the use of transmission line ROWs is projected to continue with few, if any, changes in restrictions and easements.

In addition, the presence and visual profiles of operating nuclear power plants and transmission lines have been well established during the current licensing term. These conditions would remain unchanged during the 20-year license renewal term.

4.2.1.1 Land Use

In the 1996 GEIS, the impacts of nuclear power plant operations on onsite land use, power line right of way, and offsite land use (license renewal term and refurbishment) were evaluated separately. While it was concluded that impacts to onsite land use and power line right of ways would be small at all plants, anticipated changes in population and tax revenues attributed to license renewal and power plant refurbishment were predicted to have SMALL to MODERATE impacts on offsite land use. Subsequent license renewal reviews have shown, however, that license renewal and power plant refurbishment have had little or no effect on offsite land use.

Land use impact issues evaluated for this GEIS revision include the impacts of continued plant operations and refurbishment activities on (1) onsite land use (evaluated in the 1996 GEIS); (2) offsite land use (consolidation and reclassification of two 1996 GEIS issues: (1) offsite land use (refurbishment) and (2) offsite land use (license renewal term)); and (3) offsite land use in transmission line ROWs (issue was renamed from the 1996 GEIS issue, “Power line right-of-ways”).

Onsite Land Use

Operational activities at a nuclear power plant during the license renewal term would be similar to those occurring during the current license term. Generally, onsite land use conditions would remain unchanged. However, additional spent nuclear fuel and low-level radioactive waste generated during the license renewal term could require the construction of new or expansion of existing onsite storage facilities. Should additional storage facilities be required, this action would be addressed in separate license reviews conducted by the NRC. The NRC has not identified any information or situations during previous license renewal reviews that would alter the conclusion that impacts from continued plant operations and refurbishment would be SMALL for all commercial nuclear power plants. Refurbishment activities, such as steam generator and vessel head replacement, have not permanently changed onsite land use conditions.

On the basis of these considerations, the NRC concludes that the impact of continued plant operations during the license renewal term and refurbishment on onsite land use would be SMALL for all nuclear plants and remains a Category 1 issue.

Offsite Land Use

The impacts of continued plant operations during the license renewal term and refurbishment on offsite land use were evaluated separately in the 1996 GEIS. It was predicted that impacts associated with refurbishment and changes in population and tax revenue on offsite land use could range from SMALL to MODERATE. Subsequent license renewal reviews, however, have shown no power plant-related population changes or significant tax revenue changes due to license renewal. Non-outage employment levels at nuclear power plants have remained relatively unchanged or have decreased. With no increase in the number of workers, there has been no increase in housing, infrastructure, or demand for services beyond what has already occurred. Operational activities during the license renewal term would be similar to those occurring during the current license term and would not affect offsite land use beyond what has already been affected. The NRC has not identified any information or situations, including low population areas or population and tax revenue changes resulting from license renewal that would alter the conclusion that impacts on offsite land use would be SMALL for all nuclear power plants.

For plants that have the potential to impact a coastal zone or coastal watershed, as defined by each State participating in the National Coastal Zone Management Program, applicants for license renewal must submit to the affected State a certification that the proposed license renewal is consistent with the State Coastal Zone Management Program. Applicants must coordinate with the State agency that manages the State Coastal Zone Management Program to obtain a determination that the proposed nuclear plant license renewal would be consistent with the State program. Consistency with State Coastal Zone Management Programs assures that impacts in State coastal zones will be SMALL.

On the basis of these considerations, the NRC concludes that the impact of continued plant operations during the license renewal term and refurbishment on offsite land use would be SMALL at all plants and is considered a Category 1 issue.

Offsite Land Use in Transmission Line ROWs

As previously discussed in Section 3.1.6.5, in most cases, transmission lines originating at power plant substations are no longer owned or managed by nuclear power plant licensees. Accordingly, only those transmission lines that connect the plant to the switchyard where electricity is fed into the regional power distribution system (encompassing those lines that connect the plant to the first substation of the regional electric power grid) and power lines that feed the plant from the grid during outages are considered within the scope of license renewal environmental reviews. Operational activities in offsite transmission line ROWs, within this scope of review, during the license renewal term, would be similar to those occurring during the current license term and would not affect offsite land use in transmission line ROWs beyond what has already been affected.

Certain land use activity in the ROW is usually restricted. Land cover is generally managed through a variety of maintenance procedures so that vegetation growth and building construction do not interfere with power line operation and access. Land use within ROWs are limited to activities that do not endanger power line operation; these include recreation, off-road vehicle use, grazing, agricultural cultivation, irrigation, roads, environmental conservation, and wildlife areas.

Impacts on crop production that may have been caused by transmission line interference with aerial spraying have been reported by one field study of cotton, rice, and soybean fields crossed by a 500-kV line in eastern Arkansas (Parsch and Norman 1986). This study hypothesized that crop yields could be reduced either by electromagnetic fields (EMFs) or by inadequate aerial spraying directly under the power lines. Only cotton yields were found to be reduced; 15 percent less lint was produced under the lines than 150 ft (46 m) from the lines. The resulting loss of income from cotton was estimated as $85.25 per year for an 1,100-ft (335-m) span of the lines, based on a 15 percent yield reduction and an average lint yield of 480 lb/acre (538 kg/hectare). The field sampling and statistical analyses were extensive; the observed yield reduction appeared to be real rather than a sampling error. However, the study could not determine whether the EMF or line interference with aerial spraying caused the yield reduction.

Transmission lines do not preclude the use of the land for farming or environmental and recreational use. Transmission lines connecting nuclear power plants to the electrical grid are no different from transmission lines connecting any other power plant.

The impact of transmission lines on offsite land use during the license renewal term was considered to be SMALL for all plants and was designated as a Category 1 issue in the 1996 GEIS. No new information that would alter that conclusion has been identified in subsequent license renewal reviews.

On the basis of these considerations, the NRC concludes that the impact of transmission line ROWs on offsite land use during the license renewal term would be SMALL for all plants and remains a Category 1 issue.

4.2.1.2 Visual Resources

In the 1996 GEIS, the NRC considered the visual resource impacts of continued plant operations, refurbishment, and transmission lines separately as follows: (1) aesthetic impacts (refurbishment); (2) aesthetic impacts (license renewal term); and (3) aesthetic impacts of transmission lines (license renewal term). Subsequent license renewal environmental reviews conducted by the NRC have shown that nuclear power plants and transmission lines have not changed in appearance significantly over time, so aesthetic impacts are not anticipated. The three issues identified in the 1996 GEIS were combined and are evaluated as a single issue.

Aesthetic Impacts

As previously discussed, the NRC considered the impacts of continued plant operations during the license renewal term and refurbishment on visual resources separately in the 1996 GEIS. The NRC concluded that for both issues the impacts on visual resources would be SMALL for all plants and both were determined to be Category 1 issues, because the existing visual profiles of nuclear power plants were not expected to change during the license renewal term. A case study performed for the 1996 GEIS found a limited number of situations where nuclear power plants had a negative effect on visual resources. Negative perceptions were based on aesthetic considerations (for instance, the plant is out of character or scale with the community or the viewshed), physical environmental concerns, safety and perceived risk issues, an anti-plant attitude, or an anti-nuclear orientation. It is believed that these negative perceptions would persist regardless of mitigation measures. Subsequent license renewal reviews have not revealed any new information that would change this perception.

In addition, the visual appearance of transmission lines is not expected to change during the license renewal term. After the containment building and cooling towers, transmission line towers are probably the most frequently observed structure associated with nuclear power plants. Transmission lines from nuclear power plants are generally indistinguishable from those from other power plants. Since electrical transmission lines are common throughout the United States, they are generally perceived with less prejudice than the nuclear power plant itself. Also, the visual impact of transmission lines tends to wear off when viewed repeatedly. Replacing or moving towers or burying cables to reduce the visual impact would be impractical from both an efficiency and cost-benefit perspective. The impact of transmission lines during the license renewal term on visual resources was considered to be SMALL for all plants and designated as a Category 1 issue in the 1996 GEIS. No new information that would alter that conclusion has been identified in subsequent license renewal environmental reviews.

On the basis of these considerations, the NRC concludes that the aesthetic impacts of continued plant operations during the license renewal term, refurbishment, and transmission lines, within this scope of review, on visual resources would be SMALL for all plants and remains a Category 1 issue.

4.2.2 Environmental Consequences of Alternatives to the Proposed Action

Construction—Construction of a new power plant would involve the permanent commitment of land for the power plant, plant intake and discharge structures, water treatment facilities, and cooling towers. Other construction-related land use impacts would include land clearing, excavations, drilling of monitoring wells, and the installation of temporary support facilities. Material laydown areas and onsite concrete batch plants would also represent additional temporary land use and visual impacts. These would be removed after the power plant is completed. Depending on location, construction of electrical substation, switchyards, transmission lines, railroad spurs, access roads may also be required. Some of these facilities could affect offsite land use.

Construction at an existing nuclear power plant site or brownfield site would have less of an impact on land use and visual resources than a greenfield site. Construction at an existing nuclear power plant site would have the least impact on land use, because the plant could make use of existing intake and discharge structures, substations, transmission lines, office buildings, parking lots, and access roads. Constructing a power plant at a greenfield site would remove land from other productive uses such as agriculture. It could convert potential prime farmland to industrial use. In addition, construction at a greenfield site would have a more dramatic impact on visual resources, since the industrial power plant would likely be significantly different from the surrounding landscape. Constructing at a brownfield site would have less of an impact on the land use than a greenfield site.

The increase in traffic to and from the construction site could require changes to existing transportation infrastructure and traffic patterns resulting in offsite land use impacts and visual impacts. These impacts would cease at the end of construction.

Operations—Land would be in use throughout the period of power plant operation. Visual resources would also be affected. Visual impacts would be similar to other industrial activities at an existing nuclear power plant site or brownfield site. However, the height of new buildings structures as well as transmission line, meteorological, and cooling towers could add to the visual impact. Condensate plumes during plant operations may be visible for some distance during certain weather conditions.

4.2.2.1 Fossil Energy Alternatives

Construction and Operations—Impacts on land use from constructing coal- or natural gas-fired power plants would be similar. However, a coal-fired power plant would need more land than a natural gas-fired plant due to the need for coal fuel delivery and waste storage facilities. As a result, the coal-fired power plant would also have a higher visual impact.

4.2.2.2 New Nuclear Alternatives

Construction and Operations—Land would be required for the construction of spent nuclear fuel and low-level radioactive waste storage facilities. The appearance of the reactor containment and turbine buildings would add to the visual impact.

4.2.2.3 Renewable Alternatives

Construction—Land requirements for renewable energy facilities vary greatly. Biomass fueled energy facilities with utility-scale capacities could require at least 300 ac (122 ha). Flat plate solar photovoltaic systems would require approximately 6.2 ac (2.5 ha)/MW; however, improvements in photovoltaic cell efficiency could reduce the amount of land required to 0.68 ac (0.28 ha)/MW by 2030. Solar thermal facilities with concentrators would require substantial land area. Projected land requirements for advanced power tower facilities generating 200 MWe in the year 2030 would be 612 ac (247 ha). Given the expected capacity factor of advanced power tower facilities, the land requirements equate to 1.1×10^{-3} ha/MWh/yr (EERE 1997). Land area required for an advanced solar power trough facility operating in 2030 with a rated capacity of 320 MW would be 792 ac (320 ha) (EERE 1997).

Wind energy facilities would require approximately 0.3 ac (0.12 ha)/MW. Utility-scale wind farms would require relatively large areas. However, unlike solar technologies, once construction is completed, land areas between the turbines can be put to other beneficial (nonintrusive) use. Substantially lesser amounts of land area would be required for geothermal facilities (estimated at 173 ac [70 ha] for a 49 MW facility) (BLM 1999), and very small amounts of land (for cable landings and substations, estimated at 100 ac [40.4 ha] for utility-scale offshore energy facilities) would be required for offshore wind and current facilities.

For renewable energy technologies that utilize combustion and/or steam cycles, the appearance of buildings, height and prominence of smokestacks, and condensate plumes, would have a visual impact.

Operations—The operational impacts of alternative energy technologies on land use and visual resources are presented in the following subsections.

Hydroelectric Energy Sources

Hydroelectric dams and reservoirs capable of generating utility-scale power would be substantial in scale and prominence and have a visual impact. Large dams that also serve as flood control could significantly affect land use patterns upstream and downstream beyond the decommissioning of the facility.

Geothermal

Geothermal facilities would be less prominent, typically located in remote areas and may generate a steam plume that is visible from long distances. Visual resources would be affected by wellheads, exposed transfer piping, and power plant structures, and could have a dramatic impact on a remote area. The intermittent creation of steam condensate plumes would be visible from great distances.

Wind

A relatively large area of land would be required for wind energy; however, only about 5 to 10 percent of the land area would be utilized by turbines, power collection and conditioning systems, and other support facilities. Land affected by the installation of buried power and communication cables interconnecting each turbine with a power substation would be minimally intrusive. Wind farms, although less complex than combustion-based facilities in their visual appearance, would have a visual impact due to the height of the turbines. Offshore wind farms could be sufficiently distant from the shore to attenuate most, if not all, of the visual impacts on onshore observers.

Biomass

The physical appearance of a biomass fuel-fired energy facility would be similar to that of a fossil fuel fired facility. The industrial footprint would be less. Additional land would be required, however, for growing biomass crops.

Municipal Solid Waste, Refuse-Derived Fuel, and Landfill Gas

The physical appearance of a municipal solid waste, refuse-derived and landfill gas-fired energy facility would be similar to that of a fossil fuel fired facility, but the amount of land needed for the energy production facilities would be less. Some additional land would be required, however, for fuel handling facilities (e.g., storage piles, hammermills, grinders, bucket conveyors, blowers, and pneumatic conveyance systems). Buildings, smokestacks, cooling towers, and condensate plumes would have a visual impact, but would be comparable to a fossil fuel-fired facility.

Solar Thermal

Land would be required for the powerblock (steam cycle, turbine/generator building, substation, cooling towers, condensate plume, and support equipment). Visual impacts would occur if a power tower technology is employed as well as the array of solar collectors.

Solar Photovoltaic

Utility-scale facility would require a very large area of land. Visual resources would be affected by the size of the facility.

Ocean Wave and Current

Land use would be only slightly affected by land-based support systems (cable landing, substation, and warehouse and repair facility); existing piers and docks are expected to be sufficient to support the offshore facility during operation. Above-water components are expected to be relatively inconspicuous, even when equipped with marker lights; their relatively small height above the water, their distance from shore, and the curvature of the earth may serve to partially or completely conceal them from onshore observers.

4.3 Air Quality and Noise

4.3.1 Environmental Consequences of the Proposed Action—Continued Operations and Refurbishment Activities

Ambient air quality and noise conditions at all nuclear power plants and associated transmission lines have been well established during the current licensing term. Notwithstanding significant changes to the nature and type of industrial activities in the area, these conditions are expected to remain unchanged during the 20-year license renewal term.

The focus of this section is the impacts of continued operations and refurbishment activities during the license renewal term on air quality and noise. Refurbishment and associated construction activities can affect air quality (e.g., fugitive dust, vehicle and equipment exhaust emissions, and automobile exhaust from commuter traffic). Baseline meteorological, climatological, and ambient air quality and noise conditions at operating plants are discussed in Sections 3.3.1 and 3.3.2, respectively. License renewal is expected to result in a continuation of similar conditions for an extended period commensurate with the license renewal term, typically 20 years. As a result, the criteria air pollutants emitted and the noise generated during normal continued plant operations over the license renewal term are not expected to change substantially and thus should remain SMALL.

4.3.1.1 Air Quality

Two issues related to impacts on air quality during the license renewal term are considered in this section:

- Air quality impacts (all plants); issue encompasses impacts of continued operations (not considered in the 1996 GEIS) and refurbishment activities on air quality, including nonattainment or maintenance area conformity (issue was modified, reclassified, and renamed from the 1996 GEIS); and

- Air quality effects of transmission lines. This issue was evaluated in the 1996 GEIS.

Air Quality Impacts (All Plants)

Continued Operations—The impact of continued plant operations during the license renewal term on air quality was not identified as an issue in the 1996 GEIS. It is evaluated here because of the potential for air quality to be affected by the operations of fossil-fuel-fired equipment needed for normal operations and by the operations of cooling towers in plants that use a closed-cycle cooling system. These potential impacts are discussed below.

Impacts on air quality during normal plant operations can result from operations of fossil-fuel-fired equipment needed for various plant functions (see Section 3.3.2). Each licensed plant typically employs emergency diesel generators for use as a backup power source. Emergency diesel generators and fire pumps typically require State or local operating permits. These generators provide a standby source of electric power for essential equipment required during plant upset or an emergency event. They also provide for safe reactor shutdown and for the maintenance of safe conditions at the power station during such an event. These diesel generators are typically tested once a month with several test burns of various durations (e.g., 1 to several hours). In addition to these maintenance tests, longer-running endurance tests are also typically conducted at each plant. Each generator is typically tested for 24 hours on a staggered test schedule (e.g., once every refueling outage). Plants with nonelectric fire pumps, typically also diesel-fired, usually employ test protocols identical or similar to those used for emergency generators. Maintenance procedures during these tests would include, for example, checks for leaks of lubricating oil or fuel from equipment, and pumps would be replaced as required. Most State air pollution regulations provide exemptions for air pollution sources that are not routinely operated, which can be defined as sources with insignificant activity meeting specified operating criteria (e.g., so many hours of continuous operation over specified periods or so many hours of operation per year).

In addition to the emergency diesel generators, fossil fuel (i.e., diesel-, oil-, or natural-gas-fired) boilers are used primarily for evaporator heating, plant space heating, and/or feed water purification. These units typically operate at a variable load on a continuous basis throughout the year unless end use is restricted to one application, such as space heating. Air emissions include carbon monoxide (CO), nitrogen oxides (NO_x), carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), particulate matter (PM), and volatile organic compounds (VOCs) for diesel-, natural-gas-, and oil-fired units. Natural-gas-fired units emit only trace amounts of VOCs and PM that has an aerodynamic diameter of 10 μm or less (PM_{10}). The utility boilers at commercial plants are relatively small when compared with most industrial boilers and are typically regulated through State-level operating permits.

The potential impact from emergency generators and boilers on air quality would be expected to be SMALL for all plants, and, given the infrequency and short duration of maintenance testing, it would not be an air quality concern even at those plants located in or adjacent to nonattainment areas. The locations of the currently designated nonattainment areas near nuclear plants are shown in Section 3.3.2.

As discussed in Section 3.3, cooling tower drift can increase downwind PM concentrations, impair visibility, ice roadways, cause drift deposition, and damage vegetation and painted surfaces. There are currently 24 licensed nuclear power plants that use wet cooling towers in closed-cycle cooling systems. Most of the plants use two or more towers for reactor heat removal. Of the 47 operating towers, 24 are natural draft cooling towers and 23 are mechanical draft cooling towers. There are currently no dry or hybrid (combinations incorporating elements of both dry and wet design) systems being used at operating nuclear plants. Only 1 of the 47 towers (a natural draft cooling tower at the Hope Creek plant in New Jersey) is operating at a plant that uses high-salinity water for cooling system makeup. An air quality impact analysis performed in support of an extended power uprate request for Hope Creek assessed emissions related to cooling tower drift droplets and PM for this worst-case situation and found that the impacts of cooling tower operations on air quality were small, as summarized in Section 3.3.2.

Thus, although there is the potential for some air quality impacts to occur as a result of equipment and cooling tower operations, even in the worst-case situation (Hope Creek), the impacts have been small, and licensees would be required to operate within State permit requirements.

Refurbishment Activities—Potential sources of impacts on air quality during refurbishment activities associated with continued operations during the license renewal term include (1) fugitive dust from site excavation and grading and (2) emissions from motorized equipment, construction vehicles, and workers' vehicles. Some refurbishment activities would be performed on equipment inside existing buildings and would not generate air emissions.

With application of adequate controls or mitigation measures and best practices, the air quality impacts from these air pollution sources would be small and of relatively short duration. The disturbed area for refurbishment actions, if required, is expected to be 10 ac (4 ha) or less, based on assumptions from the 1996 GEIS. During site excavation and grading, some PM in the form of fugitive dust would be released into the atmosphere. Because of the (1) small size of the disturbed area, (2) relatively short construction period, (3) availability of paved roadways at existing facilities, and (4) use of best management practices (BMPs) (such as watering, chemical stabilization, and seeding), fugitive dust resulting from these construction activities would likely be minimal.

Construction vehicles and other motorized equipment would generate exhaust emissions that include small amounts of CO, NO_x, VOCs, and PM. These emissions would be temporary (restricted to the construction period) and localized (occurring only in the immediate vicinity of construction areas). Emissions impacts from construction equipment and vehicles (e.g., CO, hydrocarbons, and PM from use of diesel fuels) and from fugitive dust emissions from ground-clearing and grading activities could be SMALL or MODERATE. For refurbishment occurring in geographical areas with poor or marginal air quality, the emissions generated from these activities could be cause for concern in a few cases (e.g., building demolition, debris removal, and new construction). However, the 1990 Clean Air Act Amendments include a provision that no Federal agency shall support any activity that does not conform to a State Implementation Plan designed to achieve the National Ambient Air Quality Standards (NAAQS) for criteria pollutants (sulfur dioxide [SO_2], nitrogen dioxide [NO_2], CO, ozone [O_3,], lead [Pb], PM_{10}, and PM with a mean aerodynamic diameter of 2.5 μm or less [$PM_{2.5}$]).

On April 5, 2010, the U.S. Environmental Protection Agency (EPA) issued its 40 CFR Part 51 and 93 revisions to the General Conformity Regulations in the *Federal Register* (75 FR 17254) These regulations revised and updated the general conformity regulations published on November 30, 1993, in 58 FR 63214. General conformity requires Federal agencies to ensure that a proposed Federal action in air quality nonattainment or maintenance areas conforms to the applicable State Implementation Plan. A conformity analysis must be completed before the action is taken. A conformity analysis begins with an applicability analysis to determine whether the action is exempt or has total net direct and indirect emissions below the *de minimis* levels. The *de minimis* emission levels (40 CFR 93.153(b)) serve as screening values to determine whether a conformity determination must be undertaken for a proposed Federal action. The applicability analysis must be documented. If conformity applies, the agency must prepare a written conformity analysis and determination for each pollutant for which the emissions caused by a proposed Federal action would exceed the *de minimis* levels. An area is designated as nonattainment for a criteria pollutant if it does not meet NAAQS for the pollutant. A maintenance area is one that a State has redesignated from nonattainment to attainment. The current nationwide designations of nonattainment and maintenance areas are identified in Section 3.3.2.

The *de minimis* levels for air emissions vary depending on air quality conditions in the area where the plant is located. In most cases, the *de minimis* levels are established at 100 tons per year. Exceptions include:

- NO_x or VOC emissions of 10, 25, and 50 tons per year in extreme, severe, and serious ozone nonattainment areas, respectively;

- VOC emissions of 50 tons per year in ozone nonattainment areas inside an ozone transport region stretching from Virginia to Maine;

- PM_{10} emissions of 70 tons per year in serious PM_{10} nonattainment areas; and

- Lead emissions of 25 tons per year in lead nonattainment areas.

None of the operating nuclear plants are located in extreme, severe, or serious ozone nonattainment areas; in serious PM_{10} nonattainment areas; or in lead nonattainment areas. Therefore, the *de minimis* levels applied to plants in the nonattainment areas are 100 tons per year for all criteria pollutants except VOC emissions of 50 tons per year for plants within the ozone transport region.

In maintenance areas, the *de minimis* levels are 100 tons per year for all pollutants, except for 50 tons per year for VOCs inside the ozone transport region. The *de minimis* levels of 25 tons per year apply in maintenance areas, but no plants are located in these areas.

In addition to the above, *de minimis* levels of 100 tons per year applies to SO_2 and NO_x emissions in $PM_{2.5}$ nonattainment and maintenance areas unless NO_x is determined not to be a significant $PM_{2.5}$ precursor. Levels of 100 tons per year may apply to emissions of VOCs and ammonia if either is determined to be a significant precursor. The regulations require that direct construction emissions including construction vehicle and equipment exhaust and fugitive dust and indirect emissions such as those from worker and delivery vehicles be included in the conformity analysis.

Emissions from construction equipment and vehicles are expected to be small for anticipated refurbishment projects on the basis of activities that have occurred to date; however, larger projects may require a sizeable workforce that could contribute vehicle exhaust emissions that could exceed the *de minimis* thresholds for CO, NO_x, and VOCs (the latter two contribute to the formation of O_3) in nonattainment and maintenance areas. In addition, the amount of fugitive dust generated by dust resuspension from larger projects involving construction vehicle use onsite or vehicle use in the vicinity of construction activities may approach or exceed the threshold for PM_{10} and $PM_{2.5}$ in nonattainment and maintenance areas. Dust suppression measures could be implemented in areas of concern. In summary, emissions from equipment and vehicle exhaust and fugitive dust could result in impacts, but could be mitigated through appropriate fugitive dust control measures.

In the 1996 GEIS, the NRC concluded that the impacts from plant refurbishment associated with license renewal on air quality could range from SMALL to LARGE, although these impacts were expected to be SMALL for most plants. However, findings from license renewal SEISs published since the 1996 GEIS have shown that refurbishment activities, such as steam generator and vessel head replacement, have not required the large numbers of workers and months of time, as well as the degree of land disturbance, that was conservatively estimated in the 1996 GEIS. Presumed air pollutant emissions, including levels of fugitive dust, have therefore not been realized. The NRC concludes that the impact of refurbishment activities on air quality during the license renewal term would be SMALL for most plants, but could be cause for concern at plants located in or near air quality nonattainment or maintenance areas, depending on the nature of the planned activity. Still, the impacts would be temporary and cease once projects were completed and implementation of BMPs including fugitive dust controls and the imposition of new and/or revised conditions in State and local air emissions permits would ensure conformance with applicable State or Tribal Implementation Plans.

On the basis of these considerations, the NRC concludes that the air quality impact of continued nuclear plant operations during the license renewal term and refurbishment would be SMALL for all plants, and that the impacts of license renewal on air quality should be considered a Category 1 issue.

Air Quality Effects of Transmission Lines

Small amounts of ozone and substantially smaller amounts of oxides of nitrogen are produced by transmission lines during corona, a phenomenon that occurs when air ionizes near isolated irregularities on the conductor surface such as abrasions, dust particles, raindrops, and insects. Several studies have quantified the amount of ozone generated and concluded that the amount produced by even the largest lines in operation (765 kilovolt [kV]) is insignificant (SNYPSC 1978; Scott-Walton et al. 1979; Janes 1980; Varfalvy et al. 1985). Monitoring of ozone levels for two years near a Bonneville Power Administration 1,200-kV prototype line revealed no increase in ambient ozone levels caused by the line (Bracken and Gabriel 1981; Lee et al. 1989). Ozone concentrations generated by transmission lines are therefore too low to cause any significant effects. The minute amounts of oxides of nitrogen produced are similarly insignificant. A finding of SMALL significance for transmission lines, within this scope of review (see Sections 3.1.1 and 3.1.6.5 in this GEIS), is supported by the evidence that production of ozone and oxides of nitrogen are insignificant and does not measurably contribute to ambient levels of those gases. Potential mitigation measures (e.g., burying transmission lines) would be very costly and would not be warranted. This is a Category 1 issue.

4.3.1.2 Noise

One issue related to noise impacts during the license renewal term and refurbishment is considered in this section:

- Noise impacts of continued operations and refurbishment activities. This issue was evaluated in the 1996 GEIS.

Noise Impacts

Noise from nuclear plant operations can often be detected offsite relatively close to the plant site boundary. Sources of noise and the relative magnitude of impacts during normal nuclear power plant operations are discussed in Section 3.3.3. Major sources of noise at operating nuclear power plants are cooling towers, turbines, transformers, large pumps, and cooling water system motors. Nuclear plant operations have not changed appreciably with time, and no change in noise levels or noise-related impacts are expected during the license renewal term. Since no change is expected in the amount of noise generated during the license renewal term, the only issue of concern is the number of people now living close to the nuclear power plant who are exposed to operational noise.

Given the industrial nature of the power plant and the number of years of plant operation, noise from a nuclear plant is generally nothing more than a continuous minor nuisance. However, noise levels may sometimes exceed the 55 dBA level that the EPA uses as a threshold level to protect against excess noise during outdoor activities (EPA 1974). However, according to the EPA this threshold does “not constitute a standard, specification, or regulation,” but was intended to provide a basis for State and local governments establishing noise standards. Nevertheless, noise levels at the site boundary are expected to remain well below regulatory standards for offsite residents.

Noise would also be generated by construction-related activities and equipment used during refurbishment. However this noise would occur for relatively short periods of time (several weeks) and is not expected to be distinguishable from other operational noises at the site boundary nor create an adverse impact on nearby residents.

In the 1996 GEIS, the NRC concluded that noise was not a problem at operating plants and was not expected to be a problem at any nuclear plant during the license renewal term. The magnitude of noise impacts was therefore determined to be SMALL for all plants, and the issue was designated as Category 1. No new information altering this conclusion has been identified in subsequent license renewal reviews.

On the basis of these considerations, the NRC concludes that the noise impact of continued nuclear plant operations during the license renewal term and refurbishment would be SMALL for all plants, and remains a Category 1 issue.

4.3.2 Environmental Consequences of Alternatives to the Proposed Action

Construction—Air quality impacts would include criteria pollutants from construction vehicles and equipment and dust from land clearing and grading. VOCs could be released from organic solvents used in cleaning, during the application of protective coatings, and the onsite storage and use of petroleum-based fuels. Construction vehicles and equipment would also generate noise. Impacts, however, would be temporary, and both air quality and noise impacts would return to pre-construction levels after construction was completed.

Air quality and noise impacts from construction activities would be similar whether occurring at a greenfield site, brownfield site, or at an existing nuclear power plant. The impacts would be greatest, however, at a greenfield site because of cleaner ambient air quality and noise conditions, even though greenfield sites may also be found in NAAQS nonattainment areas. Onsite concrete batch plants, if required, would also contribute to construction-related dust and noise.

Operations—Air quality would be affected during operations by cooling tower drift; auxiliary power equipment, building heating, ventilation, and air conditioning (HVAC) systems; and vehicle emissions. Auxiliary power equipment could include standby diesel generators and power systems for emergency power and auxiliary steam.

Ambient noise levels would be affected by cooling towers (water pumps, cascading water, or fans), transformers, turbines, pumps, compressors, loudspeakers, other auxiliary equipment such as standby generators, and vehicles. Air quality and noise impacts would be the greatest at greenfield sites.

4.3.2.1 Fossil Energy Alternatives

Construction—Air quality and noise impacts would be the same as described in Section 4.3.2. The impact analysis for fossil energy alternatives is based on projected impacts of facilities studied by the U.S. Department of Energy's (DOE's) National Energy Technology Laboratory (NETL). Baseline performance and cost data for 12 technologies are presented in a report issued by NETL (NETL 2007).

An independent study conducted by the EPA on some of the technologies in the NETL report provides additional environmental impact data (EPA 2006). However, due to different power plant designs and fuel used in the NETL and EPA studies the data are not directly comparable.

Nevertheless, data from both studies are presented to provide a range of environmental impacts. Most of the data presented in the following sections are extracted from those two reports.

Operations—Fossil fuel power plants can have a significant impact on air quality. The burning of fossil fuels is a major source of criteria pollutants and greenhouse gases, primarily CO_2, as well as other hazardous air pollutants. The exact nature of these pollutants depends on the chemical constituency of the fuel, combustion technology, air pollution control devices, and onsite management of fuel (e.g., coal) and waste material. Sources of noise include coal delivery, coal crushing, and fuel and waste handling activities.

The EPA has identified 13 trace elements likely to be emitted from an integrated gasification combined cycle (IGCC) facility, including arsenic, cadmium, lead, mercury, and selenium. The average concentrations of trace elements emitted in pounds emitted per million Btu input (lb/10^6 Btu) are as follows: antimony (4), arsenic (2.1), beryllium (0.09), cadmium (2.9), chloride (740), chromium (2.7), cobalt (0.57), fluoride (38), lead (2.9), manganese (3.1), mercury (1.7), nickel (3.9), and selenium (2.9) (EPA 2006).

Table 4.3-1 displays some of the anticipated air quality impacts of coal-burning technologies (EPA 2006). Table 4.3-2 shows projected emissions of criteria and hazardous air pollutants from fossil fuel plants (NETL 2007). The values presented in the two tables represent the possible range of operational emissions that could result from fossil-fuel-fired power plants.

Fossil fueled power plants not equipped with carbon capture and storage devices will emit large amounts of CO_2 and lesser amounts of other greenhouse gases. EPA projections of CO_2 emissions from a 500-MW integrated gasification combined cycle facility burning bituminous, sub-bituminous, and lignite coals are 1,441 lb/MWh (or 199 lb/MBtu), 1,541 lb/MWh (208 lb/MBtu), and 1,584 lb/MWh (211 lb/MBtu), respectively (EPA 2006). However, as can be seen from the data presented in Table 4.3-2, CO_2 emissions can be reduced by as much as 90 percent with the installation of carbon capture and storage devices.

4.3.2.2 New Nuclear Alternatives

Construction—Air quality and noise impacts for the construction of a new nuclear power plant would be the same as described in Section 4.3.2.

Operations—An operating nuclear plant would have minor air emissions associated with diesel generators and other small-scale intermittent sources. Air quality and noise impacts would be the same as described in Section 4.3.2.

Table 4.3-1. Projected Air Quality Impacts for Selected Power Production Technologies Burning Various Ranks of Coal[(a)]

Fuel	Technology[(b)]	Projected Air Quality Impacts (lb/MWh)							SO_2 Removal Percent	NO_x Removal Basis[(f)]
		NO_x (NO_2)	SO_2	CO	Particulate[(c)]	VOCs	Lead[(d)]	Mercury[(e)]		
Bituminous coal	IGCC	0.355	0.311	0.217	0.051	–	1.0×10^{-6} to 2.4×10^{-6}	5.50×10^{-6}	99	15 ppmvd @ 15 percent O_2

	Ultra-supercritical PC	0.498	0.714	0.830	0.100	0.022	16.6×10^{-5} to 21×10^{-5}	6.06×10^{-6}	95.8	0.06 lb/MBtu

Footnotes on next page.

Table 4.3–1. (cont.)

(a) Proximate analyses values (weight percent) for bituminous/sub-bituminous/lignite study coals include: weight percent ash: 9.70/4.50/17.92; moisture: 11.12/27.40/31.24; fixed carbon: 44.19/36.70/22.96; volatiles: 34.99/31.40/28.08. Higher heating values (Btu/lb) for study coals are: 11,667/8,800/6,312.

(b) None of the technologies represented in this table is equipped with carbon capture and storage (CCS) capability. The EPA study (EPA 2006) on which data in this table are based included only coal combustion technologies. IGCC = integrated gasification combined cycle. PC = pulverized coal.

(c) Particulate removal is 99.9 percent or greater for IGCC cases and 99.8 percent for bituminous coal, 99.7 percent for sub-bituminous coal, and 99.9 percent for lignite coal in the PC cases. Particulate matter emission rates shown include the overall filterable particulate matter only.

(d) Little empirical evidence exists on the behavior of lead in IGCC facilities. The EPA anticipates that approximately 5 percent of the lead in the input coal will be emitted to the air, while the remaining lead will remain with gasifier slag and other solid wastes generated in other gas cleaning units.

(e) As with lead, the behavior of mercury in IGCC systems is not well understood. It is anticipated that as much as 60 percent of coal-derived mercury will be potentially emitted to the atmosphere; however, fabric filters and scrubbers installed for particulate and SO_2 controls may effectively capture as much as 98 percent of the mercury present in exhaust gases. With the advent of mercury emission regulations and the installation of other devices specifically designed to capture mercury, the EPA expects that a larger fraction of mercury contained in the coal will ultimately be found in solid wastes generated in those mercury capture devices.

(f) A percent removal for NO_x cannot be calculated with a basis (i.e., an uncontrolled unit), for comparison. Also, the PC and IGCC technologies use multiple technologies (e.g., combustion controls, selective catalytic reduction [SCR]) to control NO_x. NO_x emission comparisons are based on emission levels expressed in parts per million volume (dry basis) (ppmvd) at 15 percent oxygen for IGCC and lb/MBtu for PC cases.

(g) A relatively low SO_2 removal efficiency of 87 percent results from a relatively low sulfur content in sub-bituminous coal of only 0.22 percent. Higher removal efficiencies occur with higher sulfur-content coals.

4.3.2.3 Renewable Alternatives

Construction—Air quality and noise impacts for the construction of land-based alternative energy technologies would be the same as described in Section 4.3.2. Air quality impacts associated with the construction of offshore power generating facilities and support structures include the emission of criteria pollutants from construction barges and equipment (e.g., cranes, compressors) and vehicles delivering materials and crews to embarkation locations on the shore, and dust from the construction of onshore facilities (e.g., cable landings, substations).

Construction-related noise impacts would be substantially different offshore than those associated with onshore construction since these activities would be distant from most human receptors and because noise propagates much greater distances in water. Marine animals that use noise for navigation (e.g., echolocation) would be affected by construction-related noise. Sources of noise would include crew vessels and construction and equipment barges; seismic technologies used to characterize the site; explosives or pile driving to construct foundations for offshore wind turbines or anchoring devices for wave, tidal, and current energy capturing equipment; and excavation of sea bottoms for installation of buried power and communication cables. Construction-related impacts on air quality and noise would generally be temporary.

Operations—The operational impacts of alternative energy technologies on air quality and noise are presented in the following subsections.

Hydroelectric Energy Sources

Air quality would be affected by minor emissions of criteria pollutants during plant operations, primarily from workforce vehicles and internal combustion engines on pumps, air compressors, emergency power generators, and other support equipment.

Geothermal

Air quality would be affected by the release of criteria pollutants from vehicles and equipment utilizing internal combustion engines. Air quality would be affected by the release of dissolved hydrogen sulfide from geothermal fluids during well operation; installation of hydrogen sulfide control/capture devices on wellheads would be required to regulate release to acceptable levels. Air quality would be affected by the release of greenhouse gases, estimated to be 1,570 lb/hr of greenhouse gases (carbon dioxide 92.3 percent, methane 0.1 percent) during operation. Greenhouse gas emission rate is approximately 26 times less than the rate of release from a fossil fuel-fired power plant. Air quality could also be affected by the release of small amounts of acid rain precursors (NO_x, SO_2).

During winter months, air quality and visibility would be affected by ground-level fogging/icing that could occur from cooling towers. Ambient noise levels would be affected by cooling towers, compressors, and internal combustion engines and manipulation of fluids under high pressure. Noise could be as much as 45 dB above background at offsite locations.

Wind

Wind farms would have no discernible impacts on air quality. Noise impacts would include aerodynamic noise from the turbine rotor and mechanical noise from turbine drivetrain components.

Noise from offshore wind farms consisting of aerodynamic and mechanical noise from the wind turbine transmitted underwater via the tower could affect marine species, especially those that use echolocation to navigate. Onshore components of offshore wind facilities would affect land animals when located at or near important habitats. Because of water density, noise travels proportionally greater distances under water; thus, the area over which noise impacts may occur would be much greater for offshore wind farms.

Biomass

Air impacts would result from feedstock handling activities (storage, crushing/grinding, loading conveyors, etc.) and combustion. Combustion of biomass generally results in smaller amounts of greenhouse gas (primarily CO_2) than combustion of fossil fuel. For some biomass sources such as energy crops, the amount of CO_2 released during their combustion is roughly equivalent to the amount absorbed by the plants during their growing cycle. Except for greenhouse gas emissions of vehicles and equipment used to plant, cultivate, and harvest, energy crops are considered to be greenhouse gas-neutral with respect to their application in electrical energy production. Conversion to energy of biomass that would otherwise be managed as a solid waste represents a net greenhouse gas “sink” since combustion for energy production avoids the greenhouse gas emissions (primarily methane) that would have resulted from the landfilling and decomposition of such materials. Example criteria pollutant impacts (in lb/MWh; NREL 2003) include:

SO_x	Wood waste burned in stoker boiler	0.08
	Fluidized bed combustion	0.08
	Energy crops combusted in IGCC system	0.05
NO_x	Wood waste burned in stoker boiler	2.1
	Fluidized bed combustion	0.9
	Energy crops combusted in IGCC system	2.2

CO	Wood waste burned in stoker boiler	12.2
	Fluidized bed combustion	0.17
	Energy crops combusted in IGCC system	0.23
PM_{10}	Wood waste burned in stoker boiler	0.50
	Fluidized bed combustion	0.3
	Energy crops combusted in IGCC system	0.01

A 200-MW co-firing wood biomass coal facility (where biomass is 15 percent of the total heat input) operating in 2030 with an 80 percent capacity factor providing 771 GWh/yr electricity would have the following air emissions (EERE 1997):

SO_2 40,544 T/yr (36,200 MT/yr)

CO_2 3,248,224 T/yr (2,900,200 MT/yr)

Noise impacts from biomass combustion facilities would be similar in nature and magnitude to coal-fired plants of equivalent size and capacity.

Municipal Solid Waste, Refuse-Derived Fuel, and Landfill Gas

Air impacts from combustion of refuse-derived fuel would depend on the quality of the fuel. Criteria and hazardous air pollutants could be released if not removed during refuse-derived fuel production. Air pollutants of concern include hydrochloric acid, nitric oxide (NO), sulfuric acid, arsenic, cadmium, chromium (VI), dioxins/furans, various polycyclic aromatic hydrocarbons (PAHs), chlorinated benzenes, dienes, phenols, and polychlorinated biphenyls (PCBs). Air quality could be affected by the release of dioxins and other PAHs from the incomplete combustion of fuel. Noise impacts from municipal solid waste, refuse-derived fuel, and landfill gas combustion facilities would be similar in nature and intensity to coal-fired and natural gas-fired power plants. Noise sources would include municipal solid waste feedstock preparation activities (cutting grinding, etc., to produce a feedstock of uniform size) and pump and compressor noise from the collection and transfer of landfill gas.

Solar Thermal

Dust could be released due to the removal of vegetation. Noise during operations would include mechanical noise from operation of powerblock components (steam cycle and cooling system pumps, turbines, and generators), and pump noise from circulation of heat transfer fluids, cooling tower noise (fans, cascading water).

Solar Photovoltaic

Dust could be released from the plant site due to the removal of vegetation. Individual photovoltaic cells could release toxic heavy metals to the atmosphere (primarily cadmium, selenium, and arsenic) in the event of fire. Virtually no discernible noise or air quality impacts would result from the routine operation of the facility.

Ocean Wave and Current

Air quality would be only minimally affected by facility operation; air quality would be affected by the release of criteria pollutants during periodic inspection, maintenance, and repair; vessels are expected to burn low-sulfur diesel fuel. Onshore air quality would be affected by the release of criteria pollutants from workforce vehicles and the possible release of fugitive dust from onshore support facilities. Mechanical noise from moving parts and hydrodynamic noise from the interaction of turbine blades with water would minimally affect the ambient above-water noise environment; underwater noise sources (primarily turbine blades, mechanical noise from other moving parts, and vessel propellers) could travel great distances and could affect marine organisms, especially those utilizing echolocation.

4.4 Geologic Environment

4.4.1 Environmental Consequences of the Proposed Action—Continued Operations and Refurbishment Activities

Geology and Soils

The impacts on geology and soils during the license renewal term were not considered in the 1996 GEIS. Geologic and soils conditions at all nuclear power plants and associated transmission lines have been well established during the current licensing term. These conditions are expected to remain unchanged during the 20-year license renewal term.

The impact of continued operations and refurbishment associated with license renewal on geologic and soil resources would consist of soil disturbance, including sediment and/or any associated bedrock, for projects, such as replacing or adding buildings, roads, parking lots, and belowground and aboveground utility structures. Implementing BMPs would reduce soil erosion and subsequent impacts on surface water quality. These practices include, but are not limited to, minimizing the amount of disturbed land, stockpiling topsoil before ground disturbance, mulching and seeding in disturbed areas, covering loose materials with geotextiles, using silt fences to reduce sediment loading to surface water, using check dams to minimize the erosive power of drainages, and installing proper culvert outlets to direct flows in streams or drainages.

Detailed geotechnical analyses would be required to address the stability of excavations, foundation footings, and slope cuts for building construction, road creation, or other refurbishment-related construction projects. Depending on the plant location and design, riverbank or coastline protection might need to be upgraded, especially at water intake or discharge structures, if natural flows, such as storm surges, cause an increase in erosion. In addition, the Farmland Protection Policy Act (7 USC 4201 et seq.) requires Federal agencies to take into account agency actions affecting the preservation of farmland including prime and other important farmland soils, as described in Section 3.4. While the Farmland Protection Policy Act could apply in some circumstances at nuclear power plant sites (e.g., development of renewable energy resources as an alternative to license renewal, other projects completed with Federal assistance including funding), it does not apply to Federal permitting or licensing actions for activities on private or non-Federal lands (7 CFR 658.2).

Plant-specific environmental reviews conducted by the NRC to date have not identified any significant impact issues related to geology and soils.

As discussed in Section 3.4, nuclear power plants were originally sited, designed, and licensed in consideration of the geologic and seismic criteria set forth in 10 CFR 100.10(c)(1) and 10 CFR Part 100, Appendix A, and constructed in accordance with 10 CFR Part 50, Appendix A. In its license renewal environmental reviews, the NRC considers the risk to reactors from seismicity in the evaluation of severe accident mitigation alternatives. Where appropriate, seismic issues are also assessed in the site-specific safety review that is performed for license renewals.

Further, the NRC requires all licensees to take seismic activity into account in order to maintain safe operating conditions at all nuclear power plants. When new seismic hazard information becomes available, the NRC evaluates the new information to determine if any changes are needed at existing plants. This reactor oversight process, which includes seismic safety, is separate and distinct from license renewal.

Consequently, the impact of continued operations during the license renewal term and refurbishment activities relative to the geologic environment would be SMALL for all nuclear plants and a Category 1 issue.

4.4.2 Environmental Consequences of Alternatives to the Proposed Action

Construction—For all alternatives (including fossil energy, new nuclear, and renewable alternatives) discussed in this section, the impacts of construction on geology and soils would be similar. Land would be cleared of vegetation during construction. Soils would be stored onsite for redistribution at the end of construction. Land clearing during construction and the installation of power plant structures and impervious pavements would alter surface drainage.

Natural drainage patterns at brownfield sites have been previously altered. Sources of aggregate such as crushed stone and sand and gravel would be required for construction of buildings, foundations, roads, and parking lots.

4.4.2.1 Fossil Energy Alternatives

Operations—Impacts on soil and geologic resources during power plant operations would be limited to the extraction of fossil fuel, typically at existing mining and drilling locations far from the power plant. Surface mining or underground mining for coal would result in various degrees of overburden clearing, soil stockpiling, waste rock disposal, re-routing of drainages, and management of any co-located geologic resources. Eventual mine closure would require proper restoration efforts to reduce the impact of erosion of replaced topsoil. Drilling for petroleum resources would involve clearing and grading for drill pads and construction of underground pipelines with associated soil disturbance. Proper design of surface water crossings would be needed to manage the potential for erosion at these locations.

4.4.2.2 New Nuclear Alternatives

Operations—Impacts on soil and geologic resources during operation would be limited to the extraction of ore material used to make nuclear fuel, typically at existing mining locations far from the power plant. The extraction could involve mining techniques similar to those used for fossil fuels, along with management of ore tailings. An alternative method is solution mining, which would involve the construction of drilling pads, similar to those used for the extraction of petroleum.

4.4.2.3 Renewable Alternatives

Operations—The operational impacts of alternative energy technologies on geology and soils are presented in the following subsections.

Hydroelectric Energy Sources

Geology and soils in the immediate area of a dam and reservoir would be affected by sedimentation in the reservoir basin and changes in upstream and downstream erosion patterns. Dams would induce downstream impacts such as low and high flow conditions, changes in sediment transport and deposition patterns, and channel erosion or scouring.

Geothermal

The injection of cooled geothermal fluids might induce microseismic activity. The removal of large quantities of groundwater could result in land subsidence. The alternative of engineered geothermal systems applied to hot, dry rock resources would avoid the possibility of subsidence.

Biomass

Soils would be affected by contaminants potentially present in runoff from unprotected piles of feedstock materials, fly ash and bottom ash, and scrubber sludge. Farming could result in soil erosion and the release of pesticides and fertilizers to nearby water bodies or to shallow groundwater aquifers.

Solar Thermal and Photovoltaic

This alternative requires a large amount of land. To avoid a fire hazard, solar collection devices would need to be kept free of vegetation. This practice could result in soil erosion in cleared areas by wind and precipitation runoff.

4.5 Water Resources

Hydrologic and water quality conditions at all nuclear power plants and associated transmission lines have been well established during the current licensing term. However, continued operations and refurbishment activities could have an impact on water resources during the license renewal term. This section describes the potential impact of these proposed activities and alternatives to these proposed activities on surface water and groundwater resources.

4.5.1 Environmental Consequences of the Proposed Action—Continued Operations and Refurbishment Activities

Continued operations and refurbishment activities during the license renewal term could affect surface water and groundwater resources in a manner similar to what has occurred during the current license term (see Sections 3.5.1 and 3.5.2, respectively).

4.5.1.1 Surface Water Resources

For the most part, no significant surface water impacts are anticipated during the license renewal term that would be different from those occurring during the current license term. Certain operational changes (such as a power uprate) affecting surface water would be evaluated by the NRC in a separate environmental assessment. For potential impacts to water resources, the use of surface water is of greatest concern because of the high volumetric flow rates required for condenser cooling at power plants. Withdrawals from surface water bodies are high for both once-through and closed-cycle cooling systems. Consumptive water use occurs through evaporation and drift, especially from cooling towers, and may affect water availability downstream from plants along rivers. Associated impacts on surface water quality may result from the discharge of thermal effluent containing chemical additives. Other potential impacts on surface water are the result of normal industrial plant activities during the license renewal term.

The following issues concern impacts on surface water that may occur during the license renewal term:

- Surface water use and quality (non-cooling system impacts) (consolidation and expansion of two issues evaluated in the 1996 GEIS: (1) impacts of refurbishment on surface water quality and (2) impacts of refurbishment on surface water use);
- Altered current patterns at intake and discharge structures (evaluated in the 1996 GEIS);
- Altered salinity gradients (evaluated in the 1996 GEIS);
- Altered thermal stratification of lakes (evaluated in the 1996 GEIS);
- Scouring caused by discharged cooling water (evaluated in the 1996 GEIS);
- Discharge of metals in cooling system effluent (evaluated in the 1996 GEIS);
- Discharge of biocides, sanitary wastes, and minor chemical spills (consolidation of two issues evaluated in the 1996 GEIS: (1) discharge of chlorine or other biocides and (2) discharge of sanitary wastes and minor chemical spills);
- Surface water use conflicts (plants with once-through cooling systems) (evaluated in the 1996 GEIS);
- Surface water use conflicts (plants with cooling ponds or cooling towers using makeup water from a river) (issue was modified from the 1996 GEIS to include all rivers);
- Effects of dredging on surface water quality (new issue not considered in the 1996 GEIS); and
- Temperature effects on sediment transport capacity (evaluated in the 1996 GEIS).

Surface Water Use and Quality (Non-Cooling System Impacts)

This issue is a consolidation and expansion of two 1996 GEIS issues (impacts of refurbishment on surface water quality and impacts of refurbishment on surface water use). Continued operations and refurbishment activities could result in the degradation of water quality within the receiving watershed. Power plant sites and land-disturbing activities can increase the variety and quantity of pollutants entering receiving water bodies such as streams, rivers, and lakes. Pollutants within stormwater runoff from plant sites can include suspended sediment; pesticides and nutrients from landscaped areas; oil, grease, and toxic chemicals from motor vehicles; spills of hydrocarbon fuels; paints; road salts; heavy metals from roof shingles and motor vehicles; and thermal pollution from impervious surfaces. These pollutants could potentially harm aquatic and terrestrial species, contaminate recreational areas, and degrade drinking water supplies.

In an effort to minimize or eliminate impacts to the water quality of receiving water bodies, BMPs are typically included as conditions within NPDES permits. BMPs are measures used to control the adverse stormwater-related effects of land disturbance and development. They include structural devices designed to remove pollutants, reduce runoff rates and volumes, and protect aquatic habitats. BMPs also include nonstructural or administrative approaches, such as training to educate staff on the proper handling and disposal of potential pollutants.

Permanent BMPs are designed to control pollutants to the maximum extent practicable during continued operations of the power plant. Extended detention and infiltration basins are examples of pollutant removal features designed to remove pollutants based on volume. Hydrodynamic separator systems (hydrodynamic devices, baffle boxes, swirl concentrators, or cyclone separators) and other devices are examples of pollutant removal devices that are typically designed based on flow rate.

Refurbishment activities involving construction-related land disturbance are expected to be managed by an approved Stormwater Pollution Prevention Plan (SWPPP). The SWPPP would indicate the structural and non-structural BMPs that must be implemented for the duration of the refurbishment activity. Examples of construction BMPs include use of sediment (silt) fences, check dams, staked hay bales, sediment ponds, and mulching and geotextile matting of disturbed areas.

BMPs and conformance to plant site NPDES permits, encompassing those covering stormwater discharges associated with construction and industrial activity, are expected to be followed during continued operations and refurbishment activities. Implementation of spill prevention and control plans would further reduce the likelihood of any liquid chemical spills.

Continued operations and refurbishment activities will require water for non-cooling-related purposes, including some consumptive use (i.e., water that is used but not returned to the source and effectively lost). The water source is dependent on the nuclear power plant site, water availability, and the nature of any refurbishment activities. Typical water sources at nuclear plants are surface water, groundwater, and public domestic (potable) water.

Water may be used during refurbishment activities for concrete production, dust control, washing stations, facility and equipment cleaning, and soil compaction and excavation backfilling. However, the impacts due to the volume of water consumed from a surface water source would be insignificant when compared with that used and consumed by a plant's cooling system.

The use of groundwater for non-cooling system uses would have a similar, minimal impact on the surface water source as a direct surface water withdrawal, assuming an interconnection between the groundwater source and surface water body. Groundwater withdrawal near a water body with a disconnected groundwater table would have no effect on the surface water resource.

The use of public domestic water would reduce the direct consumptive use impacts on surface water resources. Still, domestic water runoff and water main breaks have the potential to introduce an additional pollutant (residual chlorine), which could impact water quality. It is expected that such occurrences would be rare and would be identified and corrected as piped domestic water is metered at the point of interconnection with a plant's water distribution system. Any such occurrences are not expected to present a significant water quality concern over the license renewal term.

Surface water consumption for non-cooling water-related operational activities is anticipated to be negligible and limited to such uses as facility and equipment cleaning. As a result, no surface use conflicts would be expected.

The impacts of refurbishment on surface water use and quality during the license renewal term were considered to be SMALL for all plants and were designated as Category 1 issues in the 1996 GEIS, and non-cooling system operational impacts on water use and quality are expected to be SMALL, as described above. In addition, if refurbishment took place during a reactor shutdown, the overall water use by the facility would be greatly reduced. No new information in plant-specific SEISs or associated literature has been identified that would change this conclusion. On the basis of these considerations, the non-cooling system impacts of continued operations and refurbishment activities on surface water resources would be SMALL for all nuclear plants. This is a Category 1 issue.

Altered Current Patterns at Intake and Discharge Structures

The large flow rates associated with cooling system water use have the potential to alter current patterns. The degree of influence depends on the design and location of the intake and discharge structures and the characteristics of the surface water body. The effect on currents near the intake and discharge locations is expected to be localized, and any problems would have been mitigated during the early operational period of a plant (NRC 1996). Most nuclear power plants are sited on large bodies of water to make use of the water for cooling purposes. The size of large rivers, lakes, or reservoirs precludes significant current alterations except in the vicinity of the structures. For ocean shore or bay settings, the effect is further reduced when compared with the strong natural water movement patterns. For example, current patterns have been modified at the Oyster Creek plant, which is located inland from Barnegat Bay in New Jersey. The once-through cooling system for this plant was created by modifying two small rivers originally flowing parallel into the bay. On the north side of the plant, the South Branch of the Forked River was enlarged between the plant and the bay to serve as an intake canal. On the south side of the plant, Oyster Creek was enlarged between the plant and the bay for use as a discharge canal. Near the plant, the two waterways were joined. Bay water is pulled from the bay through the intake canal to the plant, against the original flow direction of the lowest reach of the South Branch of the Forked River. Flow at the mouth of this river is therefore both reversed and significantly increased, while flow at the mouth of the Oyster Creek discharge canal is significantly increased. While current patterns in Barnegat Bay in the immediate vicinity of the intake and discharge canals are affected by operations, the effect is minor on the overall Barnegat Bay system (NRC 1996, 2007b).

This issue has no relevance to plants relying on cooling ponds because they are man-made features without natural currents.

Impacts from altered current patterns at intake and discharge structures during the license renewal term were considered to be SMALL for all plants and were designated as a Category 1 issue in the 1996 GEIS. No new information has been identified in plant-specific SEISs or associated literature that would change this conclusion. On the basis of these considerations, the impact of altered current patterns at intake and discharge structures would be SMALL for all nuclear plants and remains a Category 1 issue.

Altered Salinity Gradients

This issue relates to plants located on estuaries and addresses changes in salinity caused by cooling system water withdrawals and discharges. Using the same example site as for the current patterns issue, the Oyster Creek plant's construction included modification of the lower reaches of two creeks. These portions of the creeks were originally brackish, with a mix of freshwater from their upper reaches and tidally influenced bay water. Because of the cooling system operations, the water quality of these lower reaches now essentially matches that of Barnegat Bay, with contributions of freshwater from their upper reaches being relatively minor. These lower reaches are also affected by occasional dredging activities, and the discharge canal receives water to which heat and chemicals have been added. The salinity changes do not affect the upper portions of these streams. In the 1996 GEIS, only minor effects had been noted in Barnegat Bay.

As documented in the 1996 GEIS and Calvert Cliffs SEIS (NRC 1999b), the NRC found that the Calvert Cliffs plant on the Chesapeake Bay has not had significant effects on bay salinity. Altered salinity gradients are expected to be noticeable only in the immediate vicinity of intake and discharge structures.

Impacts from altered salinity gradients at intake and discharge structures during the license renewal term were considered to be SMALL for all plants and were designated as Category 1 issues in the 1996 GEIS. No new information has been identified in plant-specific SEISs or associated literature that would alter this conclusion. On the basis of these considerations, the impact of altered salinity gradients would be SMALL for all nuclear plants and remains a Category 1 issue.

Altered Thermal Stratification of Lakes

Because cooling systems typically withdraw from the deeper, cooler portion of the water column of lakes or reservoirs and discharge to the surface, they have the ability to alter the thermal stratification of the surface water. This is not considered an issue for rivers or oceans because of mixing caused by natural turbulence.

A thermal plume of discharge water loses heat to the atmosphere and to the receiving surface water body. It also undergoes mixing with the surface water. In the 1996 GEIS, examples included the Oconee plant in South Carolina, where the withdrawal of cool, deep water for cooling purposes favors warmwater fish species at the expense of coolwater fish. Mitigation of this effect is possible by modifying the allowable discharge water temperature. In an example from the McGuire power plant in North Carolina, a modeling study indicated that increasing the permitted discharge temperature would reduce the withdrawal of cool, deep water and conserve coolwater species habitat.

Thermal plumes may be studied through field measurements and modeling studies. For plants on lakes or reservoirs, the thermal effect on stratification is examined periodically through the National Pollutant Discharge Elimination System (NPDES) permit renewal process. Problems with thermal stratification due to nuclear power plant operations have not been encountered.

Impacts from altered thermal stratification of lakes and reservoirs during the license renewal term were considered to be SMALL for all plants and were designated as Category 1 issues in the 1996 GEIS. No new information has been identified in plant-specific SEISs or associated literature that would alter this conclusion. On the basis of these considerations, the impact of altered thermal stratification of lakes would be SMALL for all nuclear plants and remains a Category 1 issue.

Scouring Caused by Discharged Cooling Water

The high flow rate of water from a cooling system discharge structure has the potential to scour sediments and redeposit them elsewhere. The scouring will remove fine-grained sediments, resulting in turbidity, and leave behind coarse-grained sediments.

The degree of scouring depends on the design of the discharge structure and the character of the sediments. Scouring is expected to occur only in the vicinity of the discharge structure where flow rates are high. While scouring is possible during reactor startup, operational periods would typically have negligible scouring. Natural sediment transport processes could bring fresh sediment into the discharge flow area. These processes include transport due to ocean currents, tides, river meandering, and storm events.

In the 1996 GEIS, scouring had not been noted as a problem at most plants and had been observed at only three nuclear power plants (Calvert Cliffs, Connecticut Yankee [no longer operating], and San Onofre). The effects at these plants were localized and minor.

Impacts from scouring caused by discharged cooling water during the license renewal term were considered to be SMALL for all plants and were designated as a Category 1 issue in the 1996 GEIS. No new information has been identified in plant-specific SEISs or associated literature that would alter this conclusion. On the basis of these considerations, the impact of scouring caused by discharged cooling water is SMALL for all nuclear plants and remains a Category 1 issue.

Discharge of Metals in Cooling System Effluent

Heavy metals such as copper, zinc, and chromium can be leached from condenser tubing and other components of the heat exchange system by circulating cooling water. These metals are normally addressed in NPDES permits because high concentrations of them can be toxic to aquatic organisms. During normal operations, concentrations are normally below laboratory detection levels. However, plants occasionally undergo planned outages for refueling, with stagnant water remaining in the heat exchange system. During an outage at the Diablo Canyon plant in California, the longer residence time of water in the cooling system resulted in elevated copper levels in the discharge when operations resumed; abalone (*Haliotis* spp.) deaths were attributed to the increased copper (NRC 1996). At the Robinson plant in South Carolina, the gradual accumulation of copper in its reservoir resulted in impacts on the bluegill (*Lepomis macrochirus*) population. In both cases, copper condenser tubes were replaced with titanium ones, and the problem was eliminated (NRC 1996). Impacts from the discharge of metals in cooling system effluent during the license renewal term were considered to be SMALL for all plants and were designated as a Category 1 issue in the 1996 GEIS. No new information has been identified in plant-specific SEISs or associated literature that would alter this conclusion. On the basis of these considerations, the impact of the discharge of metals in cooling system effluent would be SMALL for all nuclear plants and remains a Category 1 issue.

Discharge of Biocides, Sanitary Wastes, and Minor Chemical Spills

The use of biocides is common and is required to control biofouling and nuisance organisms in plant cooling systems. However, the types of chemicals, their amounts or concentrations, and the frequency of their use may vary. The use of biocides at nuclear power plants was discussed generally in Section 3.5.1. Ultimately, any biocides used in the cooling system are discharged to surface water bodies. The discharge of treated sanitary waste also occurs at plants. Discharge may occur via onsite wastewater treatment facilities, via an onsite septic field, or through a connection to a municipal sewage system. Minor chemical spills collected in floor drains are associated with industry in general and are a possibility at all plants. Each of these factors represents a potential impact on surface water quality. In the 1996 GEIS, the impacts of these releases were evaluated as two issues: (1) discharge of chlorine or other biocides and (2) discharge of sanitary wastes and minor chemical spills. Here they are treated as a single issue.

Discharges of cooling water and other plant wastewaters are monitored through the NPDES program administered by the EPA, or, where delegated, individual States. The NPDES permit contains requirements that limit the flow rates and pollutant concentrations that may be discharged at permitted outfalls. The permit may also include biological monitoring parameters that are primarily associated with the discharge of cooling water. Wastewater discharge is also covered through NPDES permitting, and it includes biochemical monitoring parameters. Discharge from building drains is also addressed in the NPDES permit. Because of Federal or State regulatory involvement, and because regulatory and resource agencies have not found significant problems with outfall monitoring, the impacts from the discharge of chlorine and other biocides and minor spills of sanitary wastes and chemicals during license renewal and refurbishment were considered to be SMALL for all plants and designated as Category 1 issues in the 1996 GEIS. No new information has been identified in plant-specific SEISs or associated literature that would alter this conclusion. On the basis of these considerations, the discharge of biocides, sanitary wastes, and minor chemical spills would be SMALL for all nuclear plants and remains a Category 1 issue.

Surface Water Use Conflicts (Plants with Once-Through Cooling Systems)

Nuclear power plant cooling systems may compete with other users relying on surface water resources, including downstream municipal, agricultural, or industrial users. Once-through and closed-cycle cooling systems have different water consumption rates. Once-through cooling systems return most of their withdrawn water to the same surface water body, with evaporative losses of less than 3 percent (Solley et al. 1998). Consumptive use by plants with once-through cooling systems during the license renewal term is not expected to change unless power uprates, with associated increases in water use, are proposed. Such uprates would require an environmental assessment by the NRC.

Future scenarios for water availability focus on climate change and associated changes in precipitation and temperature patterns. Increased temperatures and/or decreased rainfall would result in lower river flows, increased cooling pond evaporation, and lowered water levels in the Great Lakes or reservoirs. While weather will vary from year to year, the results of climate change models and the projected changes to surface water runoff in the 21st century (NETL 2006) predicted increases in runoff in the eastern United States and decreases in runoff in the western United States, where water is currently less available. Regardless of overall climate change, droughts could result in problems with water supplies and allocations. Because future agricultural, municipal, and industrial users would continue to share their demands for surface water with power plants, conflicts might arise if the availability of this resource decreased. This situation would then necessitate decisions by local, State, and regional water planning officials.

Population growth around nuclear power plants has caused increased demand on municipal water systems, including systems that rely on surface water. Municipal intakes located downstream of a nuclear power plant could experience water shortages, especially in times of drought. Water demands upstream of a plant could impact the water availability at the plant's intake.

In the 1996 GEIS, impacts of continued operations and refurbishment on water use conflicts associated with once-through cooling systems were considered to be SMALL and were designated as a Category 1 issue. No new information has been identified in plant-specific SEISs or associated literature that would alter this conclusion. On the basis of these considerations, the NRC concludes that the impact on water use conflicts from the continued operation and refurbishment activities would be SMALL for plants that utilize once-through cooling and remains a Category 1 issue.

Surface Water Use Conflicts (Plants with Cooling Ponds or Cooling Towers Using Makeup Water from a River)

Nuclear power plant cooling systems may compete with other users relying on surface water resources, including downstream municipal, agricultural, or industrial users. Closed-cycle cooling is not completely closed, because the system discharges blowdown water to a surface water body and withdraws water for makeup of both the consumptive water loss due to evaporation and drift (for cooling towers) and blowdown discharge. For plants using cooling towers, the makeup water needed to replenish the consumptive loss of water to evaporation can be significant and is reported at 60 percent or more of the condenser flow rate by Solley et al. (1998). Cooling ponds will also require makeup water as a result of naturally occurring evaporation, evaporation of the warm effluent, and possible seepage to groundwater.

Consumptive use by plants with cooling ponds or cooling towers using makeup water from a river during the license renewal term is not expected to change unless power uprates, with associated increases in water use, are proposed. Such uprates would require an environmental assessment by the NRC. In the 1996 GEIS, application of this issue applied only to rivers with low flow[(a)] so as to define the difference between plants located on “small” versus “large” rivers. However, any river, regardless of size, can experience low flow conditions of varying severity during periods of drought and changing conditions in the affected watershed such as upstream diversions and use of river water. NRC has subsequently determined that use of the term “low flow” in categorizing river flow is of little value considering that all rivers can experience low flow conditions.

Further and as stated earlier, increased temperatures and/or decreased rainfall would result in lower river flows, increased cooling pond evaporation, and lowered water levels in the Great Lakes or reservoirs. Regardless of overall climate change, droughts could result in problems with water supplies and allocations. Conflicts might arise due to competing agricultural, municipal, and industrial user demands for surface water with power plants. Closed cooling systems are more susceptible to these issues than once-through cooling systems because they consume more water. For this reason, climate change is more of a potential concern for water use conflicts among closed systems.

Population growth around nuclear power plants has caused increased demand on municipal water systems, including systems that rely on surface water. Municipal intakes located downstream from a nuclear power plant could experience water shortages, especially in times of drought. Similarly, water demands upstream from a plant could impact the water availability at the plant’s intake.

(a) A river with low flow was previously defined in 10 CFR 51.53(c)(3)(ii)(A) and in the 1996 GEIS as one with an annual flow rate that is less than 3.15×10^{12} ft^3/yr (9×10^{10} m^3/yr).

As discussed in the 1996 GEIS, water use conflicts have also been observed for plants with closed-cycle cooling systems. The Limerick plant on the Schuylkill River in Pennsylvania is cited as an example of a plant on which limits were imposed on the rate of withdrawal from a river for the purpose of avoiding water use conflicts, including downstream water availability and water quality. Availability problems for downstream habitat and users may be anticipated at other plants.

Water use conflicts associated with plants with cooling ponds or cooling towers using makeup water from a river with low flow were considered to vary among sites because of differing site-specific factors, such as makeup water requirements, water availability (especially in terms of varying river flow rates), changing or anticipated changes in population distributions, or changes in agricultural or industrial demands. No new information has been identified in plant-specific SEISs or associated literature has been identified that would alter this conclusion.

On the basis of these considerations, the impact of water use conflicts from the continued operation of nuclear power plants with cooling ponds or cooling towers using makeup water from a river could be SMALL or MODERATE, depending on factors such as plant-specific design characteristics affecting consumptive water use, the characteristics of the water body serving as the source for makeup water, and the amount of competing use for that water. Because the impact could vary among nuclear plants, the issue continues to be Category 2.

Effects of Dredging on Surface Water Quality

Dredging in the vicinity of surface water intakes, canals, and discharge structures takes place in order to remove deposited sediment and maintain the function of plant cooling systems. Dredging may also be needed to maintain barge shipping lanes. Whether accomplished by mechanical, suction, or other methods, dredging disturbs sediments in the surface water body and affects surface water quality by temporarily increasing the turbidity of the water column. In areas affected by industries, dredging can also mobilize heavy metals, PCBs, or other contaminants in the sediments.

The frequency of dredging depends on the rate of sedimentation. At the Oyster Creek plant in New Jersey, dredging took place during site construction to create canals for the once-through cooling system (NRC 2007b). Depth measurements are performed there every two years, and dredging has taken place on portions of the canal system since construction. At the Susquehanna plant in Pennsylvania, the plant's river intake and diffuser pipe are dredged annually (NRC 2008b).

In general, maintenance dredging affects localized areas for a brief period of time. Dredging operations are performed under permits issued by the U.S. Army Corps of Engineers (USACE), and possibly from State or local agencies. The physical alteration of water bodies is regulated by Federal and State statutes under Section 401 (Certification) and Section 404 (Permits) of the Clean Water Act. The USACE regulates the discharge of dredged and/or fill material under Section 404, while Section 401 requires the applicant for a Section 404 permit to also obtain a Water Quality Certification from the State in order to confirm that the discharge of fill materials will be in compliance with applicable State water quality standards. If dredging could affect threatened or endangered species or critical habitat, as established under the Endangered Species Act, the USACE must consult with the U.S. Fish and Wildlife Service or the National Marine Fisheries Service (NMFS) before it makes a permit decision. In issuing a Section 404 permit, the USACE also considers other potential impacts on aquatic resources, archaeological resources, Tribal concerns, and the permitting requirements of State and local agencies. The permitting process may include planning for the sampling and disposal of the dredged sediments.

The impact of dredging has not been found to be a problem at operating nuclear power plants. Dredging has localized effects on water quality that tend to be short-lived. The impact of dredging on water quality would be SMALL for all nuclear plants and is considered a Category 1 issue.

Temperature Effects on Sediment Transport Capacity

Increased temperature and the resulting decreased viscosity have been hypothesized to change the sediment transport capacity of water, leading to potential sedimentation problems, altered turbidity of rivers, and changes in riverbed configuration. Coutant (1981) discussed the theoretical basis for such possible changes, as well as relevant field investigations, and concluded that there is no indication that this is a significant problem at operating power stations. Examples of altered sediment characteristics are more likely the result of power plant structures (e.g., jetties or canals) or current patterns near intakes and discharges; such alterations are readily mitigated.

Based on review of literature and operational monitoring reports, consultations with utilities and regulatory agencies, and public comments on previous license renewal reviews, there is no evidence that temperature effects on sediment transport capacity have caused adverse environmental effects at any existing nuclear power plant. Regulatory agencies have expressed no concerns regarding the impacts of temperature on sediment transport capacity. Furthermore, because of the small area near a nuclear power plant affected by increased water temperature, it is not expected that plant operations would have a significant impact. Effects are considered to be of SMALL significance for all plants. No change in the operation of the cooling system is expected during the license renewal term so no change in effects on sediment transport capacity is anticipated. This issue remains Category 1.

4.5.1.2 Groundwater Resources

Operational activities during the license renewal term would be similar to those occurring during the current license term. The impact issues of concern are availability of groundwater and the effect of nuclear plant operations on groundwater quality.

The following eight issues concern impacts on groundwater that may occur during the license renewal term:

- Groundwater contamination and use (non-cooling system impacts) (issue was modified and expanded from the 1996 GEIS issue, "Impacts of refurbishment on groundwater use and quality," to include the impacts of continued operations including potential groundwater contamination);

- Groundwater use conflicts (plants that withdraw less than 100 gallons per minute [gpm]) (evaluated in the 1996 GEIS);

- Groundwater use conflicts (plants that withdraw more than 100 gallons per minute [gpm]) (consolidation of two issues from the 1996 GEIS: (1) groundwater use conflicts (potable and service water and dewatering; plants that use >100 gpm) and (2) groundwater use conflicts (Ranney wells));

- Groundwater use conflicts (plants with closed-cycle cooling systems that withdraw makeup water from a river) (issue was modified from the 1996 GEIS to include all rivers);

- Groundwater quality degradation resulting from water withdrawals (consolidation of two issues from the 1996 GEIS: (1) groundwater quality degradation (Ranney wells) and (2) groundwater quality degradation (saltwater intrusion));

- Groundwater quality degradation (plants with cooling ponds in salt marshes) (evaluated in the 1996 GEIS);

- Groundwater quality degradation (plants with cooling ponds at inland sites) (evaluated in the 1996 GEIS); and

- Radionuclides released to groundwater (new issue not considered in the 1996 GEIS).

Groundwater Contamination and Use (Non-Cooling System Impacts)

This renamed issue is an expansion of the issue “Impacts of refurbishment on groundwater use and quality” from the 1996 GEIS with the addition of the impacts of industrial activities associated with continued operations on groundwater use and quality.

As mentioned in Section 3.5.2, the original construction of some plants required dewatering of a shallow aquifer, and operational dewatering takes place at some plants including for groundwater contaminant plume control. This is accomplished by systems of pumping wells or drain tiles. Continued operations and refurbishment activities during the license renewal term are not expected to require any significant dewatering that would have an incremental effect on groundwater availability over that which has already taken place. Such dewatering impacts are expected to remain SMALL and confined to the boundaries of operating plants.

In the 1996 GEIS, the groundwater impacts associated with refurbishment activities were considered to be SMALL for all nuclear plants. No new information has been identified in plant-specific SEISs or associated literature that would alter this conclusion.

The contamination of groundwater and soil can result from general industrial practices at any site and is not limited to those occurring at nuclear power plants. Such industrial practices can be evaluated generically, as they are common to industrial facilities and nuclear power plants. Activities that result in contamination may include the use of solvents, hydrocarbon fuels (diesel and gasoline), heavy metals, or other chemicals. These materials all have the potential to affect groundwater and soil if released. Furthermore, contaminants present in the soil can act as long-term sources of contamination to underlying groundwater depending on the severity of the spill.

Based on previous plant-specific reviews, these types of groundwater and soil contamination problems have occurred at some operating plants. Release of contaminants into groundwater and soil degrades the quality of these resources, even if applicable groundwater quality standards are not exceeded. This includes *de minimis* quantities of contaminants that do not typically require reporting to regulatory agencies because they are below applicable threshold quantities and/or have been promptly remediated and would not otherwise pose a long-term threat to human health and the environment.

Examples of the types of contamination that may be present at a plant include hydrocarbon leaks or spills at a storage tank, leaked or spilled solvents from barrels, and a hydraulic oil line break (NRC 2006d), thallium in soil at a seepage pit, heavy metals in soil at a sand blasting site, a diesel fuel line leak, methyl tertiary butyl ether (MTBE) from spills of a gasoline storage tank, PCBs in soil as a result of former dielectric fluid use (NRC 2007b), and hydrocarbon spills and sulphuric acid leaks (NRC 2008b). These situations have required regulatory involvement by State agencies during both monitoring and remediation phases. Remediation has taken place in the form of excavation and recovery wells. In these instances, all contamination was either remediated with no further action required by regulatory agencies or has been confined to the plant site with remediation continuing, as with the ongoing recovery of diesel fuel at the Oyster Creek plant. Nevertheless, the number of occurrences of such problems can be minimized by means of proper chemical storage, secondary containment, and leak detection equipment. In addition, nuclear plants have their own programs for handling chemicals, waste, and other hazardous and toxic materials in accordance with Federal and State regulations and permits generally require the use of BMPs to prevent releases to the environment. Continued implementation of such programs and procedures such as pollution and spill prevention and control plans including BMPs (e.g., good housekeeping of the plant site, preventive maintenance, routine inspections, etc.) would reduce the likelihood of any inadvertent releases to soils and/or groundwater.

An additional source of groundwater contamination can be the use of wastewater ponds or lagoons. At the Cook plant in Michigan, permitted wastewater ponds are used for receiving treated sanitary wastewater and for process wastes from the turbine room sump. Groundwater monitoring has shown that concentrations of water quality parameters have increased to levels above background but below drinking water standards (NRC 2005a). As a result, in an arrangement with the county, the use of groundwater by other users in a designated area has been restricted with the affected groundwater limited to the southwestern portion of the plant property.

Contaminants in wastewater disposal ponds and lagoons, whether lined or unlined, at a plant have the potential to enter groundwater and soils. However, the use of wastewater disposal ponds and lagoons is subject to discharge authorizations under National Pollutant Discharge Elimination System (NPDES) and State wastewater discharge permit programs and monitoring.

Remediation of groundwater contamination can involve long-duration cleanup processes that depend on the types, properties, and concentrations of the contaminants; aquifer properties; groundwater flow field characteristics; and remedial objectives. Contaminants may be able to migrate to onsite potable wells or to the wells of offsite groundwater users. Groundwater monitoring programs, including monitoring of onsite drinking water quality in accordance with safe drinking water regulations, would be expected to identify problems before contaminated groundwater reached receptors; however, monitoring wells need to be present and in proper locations in order to detect contaminants.

On the basis of these considerations, the impact of continued operations during the renewal period and refurbishment activities on groundwater use would be SMALL for all nuclear plants. Further, the impact of plant industrial practices and their impact on groundwater quality associated with continued operations and refurbishment activities would continue to be SMALL. This issue is considered Category 1.

Groundwater Use Conflicts (Plants That Withdraw Less Than 100 Gallons per Minute [gpm])

Water wells are commonly used at sites to provide water for the potable water system, although municipal water is available at some nuclear plants. Groundwater may also be used for landscaping (see Section 3.5.2). At some sites, groundwater is the source for the makeup and service water systems. In this case, the water undergoes treatment to prepare it for the intended use.

The pumping of groundwater creates a cone of depression in the potentiometric surface around the pumping well. The amount the water table or potentiometric surface declines and the overall extent of the cone depend on the pumping rate, characteristics of the aquifer (e.g., its permeability), whether the aquifer is confined or unconfined, and certain boundary conditions (including the nearby presence of a hydrologically connected surface water body). Generally, plants with a peak withdrawal rate of less than 100 gpm (378 L/min) do not have a significant cone of depression. Their potential for causing conflict with other groundwater users would depend largely on the proximity of the other wells. As stated in the 1996 GEIS, cones of depression usually do not extend past the property boundary, reducing the possibility of a groundwater use conflict.

In the 1996 GEIS, the groundwater impacts associated with continued operations during the license renewal term were considered to be SMALL for all nuclear plants and designated as Category 1. No new information has been identified in plant-specific SEISs or associated literature that would alter this conclusion. On the basis of these considerations, the impact on groundwater use conflicts from continued operations during the license renewal term for all nuclear plants that withdraw less than 100 gpm (378 L/min) would be SMALL and remains a Category 1 issue.

Groundwater Use Conflicts (Plants That Withdraw More Than 100 Gallons per Minute [gpm])

This issue is a consolidation of two issues in the 1996 GEIS: (1) groundwater use conflicts (potable and service water and dewatering; plants that use >100 gpm) and (2) groundwater use conflicts (Ranney wells).

Nuclear power plants withdraw groundwater for various purposes. Most plants use groundwater to supply their potable water and service water needs. In some cases, groundwater is pumped to intentionally lower high water tables. At the Grand Gulf plant in Mississippi, Ranney wells in the Mississippi River alluvium are used to provide cooling system makeup water (see Section 3.5.2).

As described in the section above, the pumping of groundwater is expected to create a cone of depression around the well, with the degree of aquifer dewatering dependent on various factors. A nuclear plant may have several wells, with combined pumping in excess of 100 gpm (378 L/min). Overall site pumping rates of this magnitude have the potential to create conflicts with other local groundwater users if the cone of depression extends to the offsite well(s). Large offsite pumping rates for municipal, industrial, or agricultural purposes may, in turn, lower the water level at power plant wells. For any user, allocation is normally determined though a State-issued permit.

Groundwater use conflicts have not been observed at any nuclear power plants, and no significant change in water well systems is expected over the license renewal term. If a conflict did occur, it might be possible to resolve it if the power plant relocated its well or wellfield to a different part of the property. The siting of new wells would be determined through a hydrogeologic assessment.

In the 1996 GEIS, groundwater use conflicts were considered for plants that withdraw more than 100 gpm (378 L/min) or plants that use Ranney wells. The NRC concluded that the impacts of continued operations and refurbishment would not necessarily be the same at all nuclear plant sites (i.e., a Category 2 issue) because of site-specific factors (e.g., well pump rates, well locations, and hydrogeologic factors) and that the impacts could be SMALL, MODERATE, or LARGE. No new information has been identified in plant-specific SEISs or associated literature that would alter this conclusion. On the basis of these considerations, groundwater use conflicts for plants that withdraw more than 100 gpm (378 L/min) could be SMALL, MODERATE, or LARGE, depending on the plant-specific characteristics described above and remains a Category 2 issue.

Groundwater Use Conflicts (Plants with Closed-Cycle Cooling Systems That Withdraw Makeup Water from a River)

In the case of plants with cooling towers or cooling ponds that rely on a river for makeup of consumed (evaporated) cooling water, it is possible water withdrawals from the river could lead to groundwater use conflicts with other users. This situation could occur because of the interaction between groundwater and surface water, especially in the setting of an alluvial aquifer in a river valley. Consumptive use of the river water, if significant enough to lower the river's water level, would also influence water levels in the alluvial aquifer. Shallow wells of nearby groundwater users could therefore have reduced water availability or go dry. During times of drought, the effect would be occurring naturally, although withdrawals for makeup water would increase the effect. In the 1996 GEIS, a situation at the Duane Arnold plant in Iowa was described in which a reservoir on a small tributary is used as a secondary supply of makeup water for the plant's cooling towers. During low-flow conditions in the plant's usual source of water, the Cedar River, the plant is not allowed to withdraw river water. Instead, it uses the reservoir temporarily. Because the high rate of water usage can lower the water level in the reservoir significantly, local users of shallow groundwater may be affected. As described for other issues above, this situation is highly dependent on the area's hydrogeologic framework and the locations, depths, and pump rates of wells, in addition to the amount that the surface water level declines.

In the 1996 GEIS, groundwater use conflicts were evaluated for plants that use cooling towers withdrawing makeup water from a river during continued operations and refurbishment. NRC found that conflicts would not necessarily be the same at all nuclear plant sites because of site-specific factors (e.g., the amount of surface water decline, well pump rates, well locations, and hydrogeologic factors). The resulting impact could be SMALL, MODERATE, or LARGE. Therefore, this issue was considered Category 2. No new information has been identified in plant-specific SEISs or associated literature that would alter this conclusion. On the basis of these considerations, groundwater use conflicts for nuclear plants that use closed-cycle cooling systems that withdraw makeup water from a river could have SMALL, MODERATE, or LARGE impacts depending on the plant-specific characteristics of surrounding areas described above and remains a Category 2 issue.

Groundwater Quality Degradation Resulting from Water Withdrawals

This issue is a consolidation of two related issues in the 1996 GEIS: (1) groundwater quality degradation (Ranney wells) and (2) groundwater quality degradation (saltwater intrusion). These two issues both consider the possibility of groundwater quality becoming degraded as a result of drawing water of potentially lower quality into an aquifer. For this reason, they are discussed here as a single issue.

A well near a river may draw lower-quality river water into the aquifer as a function of the interaction between groundwater and surface water. An example of Ranney wells (see Section 3.5.2) at the Grand Gulf plant in Mississippi causing induced infiltration of Mississippi River water into the alluvial aquifer was discussed in the 1996 GEIS. While site-specific hydrogeologic factors and well design may provide some control on the flow of surface water to the well, the bulk of the groundwater pumped by a well in an alluvial aquifer near a river is expected to be induced surface water, with a smaller component of groundwater from the direction opposite the river. If well pumping is continuous, the only portion of the shallow aquifer significantly affected by induced infiltration remains in the capture zone of the well(s). Therefore, the portion of the aquifer with water quality parameters approaching those of the river water would usually be located on the power plant's property.

Wells in a coastal setting (e.g., ocean shore or estuary) have the potential to cause saltwater intrusion into the aquifer. This water quality problem is a common concern for large pumping centers associated with municipal or industrial users. The degree of saltwater intrusion depends on the cumulative pumping rates of wells, their screen depths, and hydrogeologic conditions. Deep, confined aquifers, for example, may be separated from saline aquifers closer to the surface. However, as evaluated in the 1996 GEIS, the potential for inducing saltwater intrusion was considered to be of SMALL significance at all sites because groundwater consumption from confined aquifers for potable and service water uses by nuclear power plants is a small fraction of groundwater use in all cases. Where saltwater intrusion has been a problem, the large users have been for agricultural (irrigation) and municipal water supply uses.

Impacts related to groundwater quality degradation for nuclear plants that use Ranney wells and groundwater quality degradation (saltwater intrusion) were designated as Category 1 issues in the 1996 GEIS. No new information has been identified in plant-specific SEISs or associated literature that would alter this conclusion. On the basis of these considerations, groundwater quality degradation resulting from water withdrawals would be SMALL for all nuclear plants and remains a Category 1 issue.

Groundwater Quality Degradation (Plants with Cooling Ponds in Salt Marshes)

Nuclear plants that use cooling ponds as part of their cooling water system discharge effluent to the pond. The effluent's concentration of contaminants and other solids increases relative to that of the makeup water as it passes through the cooling system. These changes include increased total dissolved solids (or TDS), since they concentrate as a result of evaporation, increased heavy metals (because cooling water contacts the cooling system components), and increased chemical additives to prevent biofouling. Because all the ponds are unlined (NRC 1996), the water discharged to them can interact with the shallow groundwater system and may create a groundwater mound. In this case, groundwater below the pond can flow radially outward, and this groundwater would have some of the characteristics of the cooling system effluent.

In salt marsh locations, the groundwater is naturally brackish (i.e., with a TDS concentration of about 1,000 to more than 10,000 milligrams per liter [mg/L]) and, thus, is already limited in its uses. As such, this issue concerns only the potential for changing the groundwater use category of the underlying shallow and brackish groundwater due to the introduction of cooling water contaminants. Two nuclear plants, South Texas in Texas and Turkey Point in Florida, have cooling systems (man-made cooling pond and cooling canal system, respectively) located relatively near or constructed in salt marshes. Plants relying on brackish water cooling systems would not further degrade the quality of the shallow aquifer relative to its use classification. This is because groundwater quality beneath salt marshes is already too poor for human use (i.e., it is non-potable water) and is only suitable for industrial use. Plants relying on cooling ponds in salt marsh settings are expected to have a SMALL impact on groundwater quality. This is the same conclusion reached in the 1996 GEIS. No new information has been identified in plant-specific SEISs or associated literature that would alter this conclusion. On the basis of these considerations, the impact of groundwater quality degradation for nuclear plants using cooling ponds in salt marshes would be SMALL and it remains a Category 1 issue.

Groundwater Quality Degradation (Plants with Cooling Ponds at Inland Sites)

The above discussion on cooling ponds relates to this issue. Some nuclear power plants that rely on unlined cooling ponds are located at inland sites surrounded by farmland or forest or undeveloped open land. Degraded groundwater has the potential to flow radially from the ponds and reach offsite groundwater wells. The degree to which this occurs depends on the water quality of the cooling pond; site hydrogeologic conditions (including the interaction of surface water and groundwater); and the location, depth, and pump rate of water wells. Mitigation of significant problems stemming from this issue could include lining existing ponds, constructing new lined ponds, or installing subsurface flow barrier walls. Groundwater monitoring networks would be necessary to detect and evaluate groundwater quality degradation. The degradation of groundwater quality associated with cooling ponds has not been reported for any inland nuclear plant sites.

The 1996 GEIS considered the impacts of this issue during continued operations and concluded that the impact would not necessarily be the same at all sites (i.e., a Category 2 issue) and could be SMALL, MODERATE, or LARGE. No new information has been identified in plant-specific SEISs or associated literature that would alter this conclusion.

On the basis of these considerations, the impacts of groundwater quality degradation for plants using cooling ponds at inland sites could be SMALL, MODERATE, or LARGE, depending on site-specific differences in the cooling pond's water quality; site hydrogeologic conditions (including the interaction of surface water and groundwater); and the location, depth, and pump rate of water wells. This issue remains Category 2.

Radionuclides Released to Groundwater

This is a new Category 2 issue. It has been added to the GEIS in order to evaluate the potential contamination of groundwater from the release of radioactive liquids from plant systems into the environment.

This issue was added because there were numerous instances of inadvertent releases of liquids containing radioactive material into the groundwater at nuclear power plants. The issue is relevant to license renewal because all commercial nuclear power plants routinely release radioactive gaseous and liquid materials into the environment. These radioactive releases are designed to be planned, monitored, documented, and released into the environment at designated discharge points. However, within the past several years, there have been numerous events at power reactor sites which involved unknown, uncontrolled, and unmonitored release of liquids containing radioactive material into the groundwater. NRC regulations in 10 CFR Part 20 and in 10 CFR Part 50 limit the amount of radioactive material, from all sources at a nuclear power plant, released into the environment to levels that are as low as is reasonably achievable (ALARA). The regulations are designed to protect the public and the environment.

The majority of the inadvertent liquid release events involved tritium, which is a radioactive isotope of hydrogen. However, other radioactive isotopes, such as cesium and strontium, have also been inadvertently released into the groundwater. The types of events include leakage from spent fuel pools, buried piping, and failed pressure relief valves on an effluent discharge line.

In 2006, the NRC's Executive Director for Operations chartered a task force to conduct a lessons-learned review of these incidents. On September 1, 2006, the task force issued its report: *Liquid Radioactive Release Lessons Learned Task Force Report* (NRC 2006a).

The most significant conclusion dealt with the potential health impacts on the public from the inadvertent releases. Although there were numerous events where radioactive liquid was released to the groundwater in an unplanned, uncontrolled, and unmonitored fashion, based on the data available, the task force did not identify any instances where public health and safety was adversely impacted.

Specific examples from NRC (2006a) focus on tritium releases at 15 plants. Concentrations of tritium in sampled onsite groundwater at many of these plants ranged well above the EPA drinking water standard of 20,000 pCi/L. Examples include onsite monitoring well samples of up to 250,000 pCi/L at the Braidwood plant in Illinois, up to 211,000 pCi/L at the Indian Point plant in New York (NRC 2008c), up to 486,000 pCi/L at the Dresden plant in Illinois, more than 30,000 pCi/L at the Watts Bar plant in Tennessee, and 71,400 pCi/L at the Palo Verde plant in Arizona. Examples of samples taken either directly from the source of the leak or from nearby onsite monitoring wells include samples with up to 200,000 pCi/L of tritium at the Callaway plant in Missouri, up to 15,000,000 pCi/L at the Salem plant in New Jersey, and up to 750,000 pCi/L at the Seabrook plant in New Hampshire. At the Byron plant in Illinois, tritium in monitoring wells was above the background level but below drinking water standards (up to 3,800 pCi/L). The location and construction of the monitoring wells relative to potential leak locations have not been evaluated. For each example, it is possible that a different well placement could detect higher or lower activity concentrations.

Other reported instances (NRC 2006a) of tritium above background levels have been a result of operator error, licensed discharge, or leaks or discharges to drain systems. At the Oyster Creek plant in New Jersey, a mistake involving a valve allowed tritium-contaminated water to flow to the discharge canal. Sampling of this water showed levels of 16,000 pCi/L. At the Wolf Creek plant in Kansas, an onsite lake receiving liquid effluent was found to have a tritium activity concentration of 13,000 pCi/L (NRC 2008a). The Perry plant in Ohio had water samples in its drainage system with an activity concentration of 60,000 pCi/L. In each of these cases, the tritium present at the surface could infiltrate or seep into the groundwater system.

The NRC does not consider the referenced tritium releases to be a health risk to the public or onsite workers (NRC 2006a) because the tritiated groundwater is expected to remain onsite. However, an exception is the event at Braidwood, which resulted in detectable concentrations of tritium at an offsite location. Sampling of an offsite residential well at Braidwood showed 1,600 pCi/L of tritium which is above the background level but well below EPA's drinking water standard. There would be no potential for risk to workers unless onsite wells were used for the potable water system and if the leak was in the capture zone of the well. However, the NRC requires that the onsite potable well water be monitored for radioactivity to protect plant workers.

The task force identified that under current NRC regulations the potential exists for unplanned, uncontrolled, and unmonitored releases of radioactive liquids to migrate offsite into the public domain. The following elements collectively contribute to this conclusion:

- Some of the power plant components that contain radioactive fluids that have leaked were constructed to commercial standards, in contrast to plant safety systems that are typically fabricated to more stringent requirements. The result is a lower level of assurance that these types of components will be leak proof over the life of the plant.

- Some of the components that have leaked were not required by NRC requirements to be subject to surveillance, maintenance, or inspection activities by the licensee. This increases the likelihood that leakage in such components can go undetected. Additionally, relatively low leakage rates may not be detected by plant operators, even over an extended period of time.

- Portions of some components or structures are physically not visible to operators, thereby reducing the likelihood that leakage will be identified. Examples of such components include buried pipes and spent fuel pools.

- Leakage that enters the ground below the plant may be undetected because there are generally no NRC requirements to monitor the groundwater onsite for radioactive contamination unless an onsite well is used for drinking water or irrigation.

- Contamination in groundwater onsite may migrate offsite undetected. Although the power plant operator is required by NRC regulations to perform offsite environmental monitoring, the sampling locations are typically in the vicinity of the routine effluent discharge point into the environment, not around plant systems, piping, and tanks containing radioactive liquids.

Another aspect encountered by the NRC due to the inadvertent releases was the high level of concern from the public, even at the very low radiation levels caused by the events. There has also been significant media coverage and demands by State and local government officials and members of Congress for the NRC to take action to stop these events.

On the basis of the information and experience with these leaks, the NRC concludes that the impact to groundwater quality from the release of radionuclides could be SMALL or MODERATE, depending on the magnitude of the leak, radionuclides involved, hydrogeologic factors, the distance to receptors, and the response time of plant personnel to identify and stop the leak in a timely fashion. Since the leaks are not planned and there are currently no NRC regulations that would require the timely identification and termination of a leak, there is no information available to make a generic assessment. Therefore, a site-specific evaluation in the Environmental Report is needed for each application for license renewal, and this issue is considered Category 2.

4.5.2 Environmental Consequences of Alternatives to the Proposed Action

Construction—For all alternatives discussed in this section, the impacts of construction on water resources would be similar. Construction-related impacts on hydrology (land clearing and impervious pavements) would alter surface drainage patterns and groundwater recharge zones. Surface water runoff over disturbed ground and material stockpiles could increase levels of dissolved and suspended solids and other contaminants. Groundwater withdrawn from onsite wells and dewatering systems could depress the water table and possibly change the direction of groundwater flow near the plant. Concrete production and wetting of ground surfaces and unpaved roadways for fugitive dust control could require substantial amounts of water. Appropriate permits, including a Clean Water Act Section 404 permit, Section 401 certification, and Section 402(p) NPDES general stormwater permit, would be required prior to construction. These impacts would apply generally to the construction phase of each of the alternatives discussed below. Differences among alternatives would depend not only on the selected technology but also on site-specific factors, which cannot be evaluated here. Discussion of such differences is outside the scope of this GEIS.

Operation—Most electrical power plants require water for cooling. As a result, fossil-fueled and nuclear power plants are generally located near large surface water bodies, including lakes, rivers, or oceans. Water cooling systems at power plants use either once-through or closed-cycle systems. Potable water can be purchased from municipalities or commercial water providers or obtained from onsite wells or a combination of the above.

Potential operational impacts to surface waters could occur from blowdown and evaporative losses in the steam cycle and cooling system and from drift of chemically treated cooling water from the cooling tower. Releases of industrial wastewaters would be controlled by an NPDES permit. The operational impacts of alternative energy technologies on land use and visual resources are presented in the following subsections.

4.5.2.1 Fossil Energy Alternatives

Operation—Fossil fuel power plants require a continuous supply of water to operate. Water demands vary greatly among technologies, ranging from a low of 3,760 gpm (14,222 L/min) for an IGCC technology without carbon capture and storage to more than 14,000 gpm (53,000 L/min) for a subcritical pulverized coal unit with carbon capture and storage. EPA estimates of raw water usage for various coal-burning technologies, normalized to a nominal generating capacity of 500 MWe, appear in Table 4.5-1. Water resources would be affected not only by water withdrawals but by reintroduction of water from steam cycle, cooling tower, and gasifier blowdown water. Hydrology would also be affected by wastewater generated by coal and exhaust-gas cleaning devices that may be operating and by other ancillary industrial activities.

Water usage is a function of the coal combustion technology, heating value of the coal being consumed, the design of the primary cooling systems (e.g., once-through versus closed-cycle, mechanical versus natural draft, dry cooling, and wet/dry hybrid cooling), and the operation of various other devices, such as gasifiers and gas-cleaning units (including flue gas desulfurization), all of which require water.

Table 4.5-1. Raw Water Usage Estimates for Fossil Fuel Electric Power Technologies

Technology[a]	Coal Rank[b]		
	Bituminous	**Sub-bituminous**	**Lignite**
IGCC	4,960 (685) [4,950][c]	5,010 (676) [5,000][c]	5,270 (700) [5,259][d]
Subcritical PC[e]	9,260 (1,050) [9,241]	9,520 (1,050) [9,501]	9,960 (1,050) [9,940]
Supercritical PC[e]	8,460 (1,050) [8,443]	8,830 (1,060) [8,812]	9,200 (1,055) [9,182]
Ultra-supercritical PC[e]	7,730 (1,050) [7,717]	7,870 (1,050) [7,857]	8,710 (1,050) [8,695]

(a) IGCC = integrated gasification combined cycle; PC = pulverized coal.
(b) Water usage expressed as lb/MWh (lb/MBtu input) [gal/min].

4.5.2.2 New Nuclear Alternatives

Water resources would be affected by operation of the cooling system and by discharges of blowdown water from the cooling system and steam cycle, both of which can introduce chemical contaminants and heat to the receiving surface water body. Operation of these systems could also affect hydrology by reducing available surface water volume, altering current patterns at intake and discharge structures, altering salinity gradients, scouring and increases in sediment caused by discharges of treated cooling water, and increasing water temperature. Hydrologic impacts would vary, depending on the surface water source used for cooling as well as the cooling water system employed. Hydrology can also be affected by the plant's service water system, which provides water for turbine and reactor auxiliary equipment cooling, reactor shutdown cooling, and other services. Surface water and groundwater can also be affected by discharges authorized under permits and by accidental spills and leaks of radionuclides, chemicals, and fuels to the ground surface. Overall, impacts on water resources at a greenfield site could be significant and depend highly on local circumstances and factors such as other dependencies on the hydrologic resources. Hydrologic impacts at a brownfield site or an existing nuclear facility could also be significant, depending on whether or not the new nuclear plant could use the existing cooling water system.

4.5.2.3 Renewable Alternatives

The operational impacts of alternative energy technologies on water resources are presented in the following subsections.

Hydroelectric Energy Sources

Reservoirs could be affected by changes in water temperature and amounts of dissolved oxygen. Surface water temperatures in the reservoir could be affected when water flow is reduced. Warm water released from the top of the dam and cooler water released from the lower portions of the dam could affect river water temperatures downstream. Additionally, both low- and high-flow conditions would alter sediment transport and deposition patterns.

Geothermal

Hydrology would be affected by water consumed by the facility; the project could consume up to 6.8 ac-ft/yr (i.e., about 2.2 million gal [8,390 m^3]) of water during operation. Degradation and loss of integrity of geothermal wells could affect shallow groundwater quality through the release of contaminants. Liners installed on any surface impoundments should be sufficient to protect surface water resources from contamination by industrial fluids (including geothermal fluids) during routine operation.

Wind

No impacts on water resources are expected to result from routine operation of either onshore or offshore wind farms.

Biomass

Water demands for cooling and steam would be similar to those of fossil fuel-fired power plants. Water demand could equal evaporative water loss from cooling tower and flue gas scrubbers, and blowdown waters discharged from steam cycle and cooling water systems. Water demand could range from 3,000 to 5,000 gpm (11,400 to 18,900 L/min). Water quality would be affected by contaminants released in runoff from piles of feedstock materials, fly and bottom ash, and scrubber sludge.

Solar Thermal

There is a potential for contamination from accidental release of working fluids (heat transfer fluids) or thermal storage media (molten salts) contained in binary systems. For an advanced power tower facility operating in 2030 and using a wet mechanical cooling tower, projected water demands (i.e., consumptive use as a result of water lost to evaporation) would be about 630 gal (2.4 m^3)/MWh (EERE 1997).

4.6 Ecological Resources

4.6.1 Environmental Consequences of the Proposed Action—Continued Operations and Refurbishment

Environmental conditions at all nuclear power plants and associated transmission lines have been well established during the current licensing term. These conditions are expected to remain unchanged during the 20-year license renewal term. The following section describes the effects of continued operations and refurbishment activities on terrestrial and aquatic resources over the license renewal term.

Continued operations and refurbishment are not expected to change substantially over the license renewal term. Therefore, license renewal generally represents a continuation of current environmental stresses that have existed over many years of operation. However, due to the ever-changing nature of biological communities, the impacts of continued operation may change. These conditions are described in Sections 3.6.1 (Terrestrial Resources), 3.6.2 (Aquatic Resources), and 3.6.3 (Special Status Species and Habitats). The factors associated with continued operations and refurbishment activities that could affect these resources over the 20-year license renewal term are presented in the following sections.

4.6.1.1 Terrestrial Resources

Continued operations of the nuclear power plants during the 20-year license renewal term are expected to include operation of cooling towers, operation of once-through cooling systems and cooling ponds, management of transmission line ROWs, maintenance of site facilities, releases of gaseous and liquid effluents, and potentially, and refurbishment-related construction activities. Terrestrial habitats and wildlife would continue to be exposed to cooling tower drift; maintenance activities associated with ROWs, cooling systems, and site facilities; and chemical and radiological releases. Cooling towers and transmission lines would continue to be potential collision hazards for birds, wildlife near the site would be exposed to elevated noise levels, and refurbishment-related construction activities could result in habitat loss and disturbance of wildlife. Details regarding these impacting factors are presented in Section 3.6.1.

This section considers the following issues related to terrestrial resources:

- Effects on terrestrial resources (non-cooling system impacts) (issue was modified from the 1996 GEIS to encompass the impacts of continued operations and refurbishment);

- Exposure of terrestrial organisms to radionuclides (new issue not considered in the 1996 GEIS);

- Cooling system impacts on terrestrial resources (plants with once-through cooling systems or cooling ponds) (issue was modified and renamed from the 1996 GEIS issue, “Cooling pond impacts on terrestrial resources”);

- Cooling tower impacts on vegetation (plants with cooling towers) (consolidation of two issues from the 1996 GEIS: (1) cooling tower impacts on crops and ornamental vegetation, and (2) cooling tower impacts on native plants);

- Bird collisions with plant structures and transmission lines (consolidation of two issues in the 1996 GEIS: (1) bird collisions with cooling towers and (2) bird collision with transmission lines);

- Water use conflicts with terrestrial resources (plants with cooling ponds or cooling towers using makeup water from a river) (new issue not specifically considered in the 1996 GEIS);

- Transmission line ROW management impacts on terrestrial resources (consolidation of two issues from the 1996 GEIS: (1) power line ROW management (cutting and herbicide application) and (2) floodplains and wetland on power line ROW)). This issue includes impacts on upland plant communities; and

- Electromagnetic fields on flora and fauna (plants, agricultural crops, honeybees, wildlife, livestock) (issue from the 1996 GEIS).

Effects on Terrestrial Resources (Non-Cooling System Impacts)

Continued operations and refurbishment activities could continue to affect onsite terrestrial resources during the license renewal term at all operating nuclear power plants. Factors that could potentially result in impacts include landscape maintenance activities, stormwater management, and elevated noise levels. These impacts would, for the most part, be similar to past and ongoing impacts. The 1996 GEIS did not evaluate the impact of continued operations and maintenance on onsite biota, but this issue has been identified by the NRC for consideration in this GEIS revision on the basis of environmental reviews performed for plant-specific SEISs.

Nuclear power plant sites are typically maintained as modified habitats with lawns and other landscaped areas; however, they may also include disturbed early successional habitats or even small areas of relatively undisturbed habitat. Onsite developed areas are generally maintained by mowing and the application of herbicides or pesticides. The diversity of plant species in these areas is generally kept at a reduced level. Plant species often consist of cultivated varieties or weedy species tolerant of disturbance. Areas of the nuclear plant site outside the security fence may include natural areas, such as forests or shrublands, in various degrees of disturbance. Onsite wetlands may be affected by stormwater management. Effects may include changes in plant community characteristics, altered hydrology, decreased water quality, and sedimentation (EPA 1993, 1996; Wright et al. 2006). Impervious surfaces within the watershed generally result in increased runoff and reduced infiltration, causing changes in the frequency or duration of inundation or soil saturation and greater fluctuations in wetland water levels. Runoff may contain sediments, contaminants from road and parking surfaces, or herbicides. Erosion of wetland substrates and plants can result from increased flow velocities from impervious surfaces. Onsite wildlife near transformers or cooling towers are exposed to elevated noise levels that could disrupt behavioral patterns. Maintenance of landscaped areas generally keeps wildlife diversity lower than in surrounding habitats. Wildlife species occurring on sites within the security areas are typically limited by low habitat quality and generally include common species adapted to industrial sites.

The characteristics of terrestrial habitats and wildlife communities currently on nuclear power plant sites have generally developed in response to many years of typical operations and maintenance programs. While some may have reached a relatively stable condition, some habitats and populations of some species may have continued to change gradually over time. Operations and maintenance activities during the license renewal term are expected to be similar to current activities (see Section 2.1). Because the species and habitats present on the sites (i.e., weedy species and habitats they make up) are generally tolerant of disturbance, it is expected that continued operations during the license renewal term would maintain these habitats and wildlife communities in their current State, or maintain current trends of change.

Terrestrial habitats and wildlife could be affected by ground disturbance from refurbishment-related construction activities. Land disturbed during the construction of new independent spent fuel storage installations (ISFSIs) would range from about 2.5 to 10 ac (1 to 4 ha). Other activities may include new parking areas for plant employees, access roads, buildings, and facilities. Temporary project support areas for equipment storage, worker parking, and material laydown areas could also result in the disturbance of habitat and wildlife. In the 1996 GEIS, the NRC considered only the impacts of refurbishment on terrestrial habitats and concluded that the impacts would not necessarily be the same at all sites (i.e., a Category 2 issue) and could range from SMALL to LARGE.

Operational activities occurring in undeveloped portions of the site would affect terrestrial habitats and wildlife. Some wildlife would be displaced to nearby available habitats. However, competition would increase for many species, reducing the likelihood of survival of displaced individuals. Indirect effects could include fugitive dust, alteration of hydrology from changes in surface water flow patterns and infiltration to shallow groundwater, water quality degradation, or establishment of invasive species. Species that are more sensitive to disturbance may be displaced by more tolerant species. Affected habitats may include uplands or wetlands on or near the activity as well as wetlands within the watershed. Alterations in vegetative cover, the compaction of upland soils, or the development of impervious surfaces within the watershed generally result in more runoff and less infiltration to shallow groundwater, causing an increase or decrease in the hydrologic input to nearby wetlands (EPA 1993, 1996; Wright et al. 2006). Effects include changes in the frequency or duration of inundation or soil saturation and greater fluctuations in wetland water levels. Runoff often contains sediments, contaminants from road and parking surfaces, or herbicides used in managing ROW or site vegetation (EPA 1993, 1996; Wright et al. 2006). The erosion of wetland substrates and plants can result from increased flow velocities. Actions that result in the discharge of dredge or fill material into wetlands that are under the jurisdiction of the Clean Water Act (CWA) require a Section 404 permit from the USACE. Actions that could potentially affect threatened or endangered species would require consultation with the U.S. Fish and Wildlife Service (USFWS) under Section 7 of the Endangered Species Act (ESA), or with State resource agencies. Rare or unique plant communities, sensitive habitats such as wetlands or rookeries, or high-quality undisturbed habitats may occur in or near potentially affected areas. Impacts on such habitats could be considered LARGE if they caused the destabilization of a resource. Impacts would be considered SMALL if only previously disturbed or other lower-quality habitats were affected.

Successful application of environmental review procedures, employed by the licensees at many of the operating nuclear plant sites, would result in the identification and avoidance of important terrestrial habitats. In addition, the application of BMPs to minimize the area affected; to control fugitive dust, runoff, and erosion from project sites; to reduce the spread of invasive nonnative plant species; and to reduce disturbance of wildlife in adjacent habitats could greatly reduce the impacts of continued operations and refurbishment activities.

Site-specific factors related to refurbishment activities may vary considerably among nuclear power plant sites. The habitats present on or in the vicinity of nuclear power plants also vary greatly. Therefore, a generic determination of potential impacts on terrestrial resources from refurbishment or other activities is not possible. Impacts on terrestrial habitats and wildlife would depend on site-specific factors, and impact assessments would need to be conducted on a site-specific basis prior to license renewal. Consistent with this finding, the NRC concluded in the 1996 GEIS that the impacts of refurbishment actions could be significant if important resources are affected, depending on site-specific conditions.

On the basis of these considerations, the NRC concludes that the impact of continued operations and refurbishment activities similar to those occurring during the current license term on terrestrial resources could be SMALL, MODERATE, or LARGE, depending on site-specific differences in the terrestrial resources present, project-specific activities, and the effectiveness of mitigation measures. The issue is therefore considered Category 2.

Exposure of Terrestrial Organisms to Radionuclides

This section addresses the issue of potential impacts of radionuclides on terrestrial organisms resulting from normal operations of a nuclear power plant during the license renewal term. This issue was not evaluated in the 1996 GEIS. However, public concerns about the impacts of radionuclides on terrestrial organisms at some nuclear power plants have led to an evaluation of the issue in this GEIS revision.

Radionuclides may be released from nuclear power plants into the environment via a number of pathways. Releases into terrestrial environments often result from deposition of small amounts of radioactive particulates released from power plant vents during normal operations. typically include krypton, xenon, and argon (which do not contain radioactive particles), tritium, isotopes of iodine, and cesium, and they may also include strontium, cobalt, and chromium. Radionuclides may also be released into the aquatic environment from the liquid effluent discharge line. Radionuclides that enter shallow groundwater from cooling ponds can be taken up by terrestrial plant species, including both upland species and wetland species, where wetlands receive groundwater discharge. Terrestrial biota may be exposed to ionizing radiation from radionuclides through direct contact with water or other media, inhalation, or ingestion of food, water, or soil.

The uptake of radionuclides from soil and water by many plant species and their incorporation into plant tissues have been well demonstrated (Bell et al. 1988; Hinton et al. 1996; Hinton et al. 1999; Hitchcock et al. 2005; Kaplan et al. 2005; Sahr et al. 2005; NCRP 2006; Pinder et al. 2006). The degree of uptake varies according to the degree to which the radionuclide binds to the sediment particles (the partition coefficient [Kd] of the nuclide and sediment constituents, such as clay particles) as well as other environmental factors, such as pH or the concentrations of other elements such as potassium (NCRP 2006). The effects on plants of chronic exposure to radionuclides range from reduced trunk growth, canopy cover, stem growth, photosynthetic capacity, seed production and germination in trees, and reduced reproductive potential in herbaceous plants, to chromosome damage as well as mortality in both groups (IAEA 1992; Real et al. 2004; Sahr et al. 2005). Growth effects have been observed at dose rates above 0.01 rad/hr (100 μGy/hr), while chromosome effects have occurred at 2.0×10^{-6} rad/hr (0.02 μGy/hr) (Real et al. 2004). Radionuclides are transferred to herbivores and subsequently to higher trophic levels, such as predators (Meyers-Schone and Walton 1990; Kelsey-Wall et al. 2005; Beresford et al. 2005; NCRP 2006).

The DOE guideline for radiation dose rates from environmental media recommends limiting the radiation dose to riparian and terrestrial mammals to less than 0.1 rad/d (0.001 Gy/d) and limiting the dose to terrestrial plants to less than 1.0 rad/d (0.01 Gy/d) (DOE 2002). These guidelines were developed on the basis of experimental evidence that negative effects would not occur at these doses. The effects of ionizing radiation on populations of terrestrial organisms have been given considerable attention in the literature. A report by the International Atomic Energy Agency (IAEA 1992) described invertebrate organisms as being less sensitive to ionizing radiation than are vertebrates. There is additional evidence indicating that some terrestrial wildlife species may be more resistant to ionizing radiation than are humans. For instance, Ulsh et al. (2000) examined the effects of cesium-137 radiation on cellular processes of wild turtles and humans. They discovered that human fibroblasts were 1.7 times more sensitive to ionizing radiation than the fibroblasts of wild turtles.

Eisler (1994) summarized studies examining the effects of ionizing radiation on aquatic and terrestrial organisms and reported that chronic doses at the minimum treatment dose of 90 rad/d (0.9 Gy/d) reduced the growth of some bird species. Few studies examine the effects of ionizing radiation on birds at doses lower than 90 rad/d (0.9 Gy/d), and none of them observed any adverse effects. For example, Zach et al. (1993) found no negative effects on the breeding performance of adults or the growth of nestling tree swallows (*Tachycineta bicolor*) at doses as low as 0.014 rad/d (1.4×10^{-4} Gy/d). Eisler (1994) also reported that an acute exposure of 1.1 rad (0.011 Gy) was demonstrably harmful to small mammals. In a summary by Real et al.

(2004), radiological dose rates as low as 1 rad/d (0.01 Gy/d) could be potentially harmful to some terrestrial plant species, although most effects were observed at doses greater than 100 rad/d (1 Gy/d). Furthermore, IAEA (1992) concluded that irradiation at chronic dose rates of 1 rad/d (0.01 Gy/d) or less are not likely to negatively affect plant populations.

Genetic effects of ionizing radiation on terrestrial biota have not been demonstrated at doses below the DOE guidelines. Turner et al. (1971) found that doses as low as 4 rad/d (0.04 Gy/d) adversely affect the reproductive capabilities of the leopard lizard (*Crotaphytus wislizenii*), and Nagasawa et al. (1990) observed chromosomal aberrations in the cells of hamsters at acute radiation doses as low as 2 rad (0.02 Gy). The European Committee on Radiation Risk (ECRR) reviewed studies concerning the effects of low-level radiation exposures on a variety of animal species. Although study details were not provided, the ECRR noted that a wide range of animal studies show juvenile mortality effects from internal irradiation, which have not been addressed by the International Commission on Radiological Protection (ICRP) or other risk agencies (ECRR 2003).

The NRC conducted a review of all operating nuclear power plants to evaluate the potential impacts of radionuclides on terrestrial biota from continued operations. Site-specific radionuclide concentrations in water, sediment, and soils were obtained from Radiological Environmental Monitoring Program (REMP) reports for 15 nuclear plants. These 15 plants were selected to represent sites with a range of radionuclide concentrations in the media, including plants with high annual worker total effective dose equivalent (TEDE) values (Tables 3.9-5 and 3.9-6) or public exposures (Tables 3.9-9, 3.9-10, and 3.9-11) for both boiling water reactors (BWRs) and pressurized water reactors (PWRs). The RESRAD-BIOTA dose evaluation model (DOE 2004e) was used to calculate estimated dose rates for terrestrial biota by using the media concentrations presented in the REMP reports (see Section D.5 in Appendix D for further details on the approach used).

Results of the RESRAD-BIOTA dose modeling are presented in Table 4.6-1, showing the total dose estimates for three different terrestrial ecological receptors: riparian animal (an animal that was assumed to spend approximately 50 percent of its time in aquatic environments and 50 percent of its time in terrestrial environments), terrestrial animal, and terrestrial plant. The maximum estimated dose rate calculated for any of the nuclear power plants is 0.0354 rad/d (3.54×10^{-4} Gy/d) (riparian animal at the Browns Ferry plant), which is below the guideline value of 0.1 rad/d (0.001 Gy/d) for a riparian animal receptor. It is unlikely that the normal operations of these power plants would have adverse effects on terrestrial biota resulting from radionuclide releases because the calculated doses are below protective guidelines and thus would not significantly affect populations.

On the basis of these calculations and a review of the available literature, the NRC concludes that the impact of routine radionuclide releases from past and current operations and

Table 4.6-1. Estimated Radiation Dose Rates to Terrestrial Ecological Receptors from Radionuclides Measured in Water, Sediment, and Soils at U.S. Nuclear Power Plants

	Sum of Total Dose (rad/d) for Receptor [(a)]			
Power Plant	**Riparian Animal**	**Terrestrial Animal**	**Terrestrial Plant**	**Source**
Arkansas Nuclear	4.62×10^{-4}	3.37×10^{-7}	1.04×10^{-7}	Entergy 2006a

Columbia	2.62×10^{-3}	4.45×10^{-4}	2.82×10^{-5}	Energy Northwest 2005
Comanche Peak	1.50×10^{-2}	2.89×10^{-6}	9.37×10^{-7}	TXU 2004
Cook	2.48×10^{-3}	2.22×10^{-3}	2.44×10^{-4}	IMP 2006
Hatch	2.39×10^{-3}	1.82×10^{-6}	5.19×10^{-7}	Southern Company 2003
Fort Calhoun	5.26×10^{-4}	3.41×10^{-7}	1.06×10^{-7}	OPPD 2004
Indian Point	2.30×10^{-3}	2.22×10^{-3}	2.44×10^{-4}	Entergy 2006b
Millstone	3.31×10^{-3}	2.20×10^{-3}	2.20×10^{-4}	DNC 2004
Nine Mile Point	2.40×10^{-3}	1.83×10^{-6}	5.24×10^{-7}	CEG 2004
Palisades	6.00×10^{-6}	2.89×10^{-7}	9.48×10^{-8}	NMC 2004
Point Beach	7.79×10^{-3}	2.48×10^{-2}	2.12×10^{-2}	EIML 2005
San Onofre	7.79×10^{-3}	2.48×10^{-2}	2.12×10^{-2}	SCE 2005
Vermont Yankee	7.56×10^{-3}	1.85×10^{-6}	5.30×10^{-7}	Entergy 2003

(a) Dose rates were estimated with RESRAD-BIOTA (DOE 2004e) by using site-specific radionuclide concentrations in water, sediment, and soils obtained from the REMP reports.

refurbishment activities on terrestrial biota would be SMALL for all nuclear plants and would not be expected to appreciably change during the renewal period. It is considered a Category 1 issue.

Cooling System Impacts on Terrestrial Resources (Plants with Once-Through Cooling Systems or Cooling Ponds)

Terrestrial vegetation and wildlife could be affected by the continued operation of cooling systems at nuclear power plants during the 20-year license renewal term. This issue applies to nuclear power plants with once-through cooling systems and cooling ponds typically with low levels of consumptive use. In the 1996 GEIS, the NRC evaluated the impacts to terrestrial ecology from cooling ponds but not the impacts from once-through cooling systems. Impacts of cooling ponds on terrestrial resources were considered to be SMALL for all plants that used cooling ponds and were designated as Category 1 issues in the 1996 GEIS. The impact on terrestrial resources from the operations of other cooling systems has been identified by the NRC for consideration in this GEIS revision. The impacts of cooling tower operations are considered as a separate issue elsewhere in this section.

Primary impacts of continued operation of the cooling systems at nuclear power plants include alterations of the physical environment that terrestrial organisms inhabit. Such changes to the physical environment may include increased water temperatures; humidity and fogging; contaminants in surface water or groundwater; and disturbance of wetlands from maintenance dredging of onsite cooling ponds, disposal of dredged material from such dredging, and erosion of shoreline wetlands. Unlike dredging of navigable waterways discussed in other GEIS issues, maintenance dredging of onsite cooling ponds and onsite disposal of dredged material (e.g., mud) typically do not require permits. Water temperatures in cooling ponds, canals, and reservoirs may increase as warm water effluent is discharged from the power plants. The elevated water temperatures associated with the cooling system may affect the distributions of some terrestrial plant and animal species associated with riparian or wetland communities. For example, the growth of plants along the cooling pond shoreline is restricted by the thermal effluent at the H.B. Robinson plant in South Carolina (NRC 2003b). Increased humidity and fogging around the cooling system discharge resulting from elevated water temperatures may alter the distributions of some vegetation communities. The cooling system may also transport contaminants generated during normal power plant operations to animal and plant receptors. Terrestrial biota may be exposed to contaminants released from the power plant's cooling system, either by direct contact with the cooling system effluent or through uptake from aquatic food sources near the cooling system. Terrestrial plants and wildlife associated with wetland or riparian communities along the receiving water body may be exposed, as well as wildlife that forage in these waters, such as waterfowl. In these cases, contaminants associated with the cooling system may have adverse impacts on terrestrial organisms. Maintenance dredging near cooling system intakes or outfalls may disturb wetland habitats along with accumulated sediments, and sedimentation from dredging disposal may indirectly affect wetlands. Shoreline wetlands or riparian habitats may be affected by erosion resulting from high-velocity effluent discharges or altered current patterns. The impacts of the cooling system are of concern if water temperature, humidity and fogging levels, contaminants associated within the discharged effluent, maintenance activities, or discharge flows have adverse effects on local plant and animal populations.

The NRC examined the potential impacts of the operation of nuclear power plant cooling systems on terrestrial resources during the 20-year license renewal term by reviewing published site-specific radiological effluent release (RER) reports, site environmental reports (ERs), and SEISs. For this analysis, a total of eight nuclear power plants with different types of cooling systems were investigated to determine the effects of cooling system operation on terrestrial resources. The type of cooling system that operated at each of the eight power plants reviewed, and a summary of the contaminants evaluated in the aquatic effluent, is shown in Table 4.6-2.

Contaminants investigated to be of potential concern in the liquid effluent associated with cooling systems at nuclear power plants include chlorine and other biocides, tritium, heavy metals, VOCs, oil products, and strontium. The concentrations of these contaminants have been found to be low within the liquid effluent discharged from the nuclear power plants.

Although water screening guidelines have not been established for terrestrial biota, compliance with NPDES permits should ensure that nonradioactive contaminant concentrations discharged from the cooling system are low enough to have only SMALL impacts on water quality and aquatic communities.

From a review of the 2006 RER reports for the power plants, quarterly tritium releases in liquid effluent may be as high as 1.69×10^{-5} µCi/mL. These concentrations do not exceed the public health-regulated tritium concentrations specified in 10 CFR Part 20, Appendix B, Table 2, which is set at 0.001 µCi/mL for water effluent concentrations. Tritium concentrations discharged in liquid effluent are much lower than those reported to have adverse effects on terrestrial wildlife. For example, Cahill et al. (1975) exposed rats to 1, 10, 50, or 100 µCi/mL of tritium in drinking water per day. They found that rats exposed to the higher doses (50 and 100 µCi/mL) experienced shorter life spans, whereas no adverse chronic effects were observed in rats at the two lower doses (1 and 10 µCi/mL). Therefore, the discharge of contaminants on terrestrial resources during the license renewal term is considered to be of SMALL significance.

Table 4.6-2. Contaminants Evaluated in Cooling Systems at Selected Power Plants

Power Plant	Cooling System	Contaminants	References
Dresden	Cooling lake and spray canal	Chlorine, tritium, heavy metals	NRC 2004a; Exelon 2003
Oyster Creek	Once-through cooling	Chlorine, tritium, VOCs	NRC 2007b
Palisades	Mechanical draft cooling tower	Chlorine, tritium, bromine, oil	NRC 2006d
Peach Bottom	Once-through cooling with towers	Chlorine, tritium, strontium	NRC 2003a; Exelon 2001a
Pilgrim	Once-through cooling	Chlorine, tritium, heavy metals	NRC 2007c
Turkey Point	Closed-cycle canal	Chlorine, tritium	NRC 2002b; FPL 2000
Vermont Yankee	Once-through cooling and towers	Chlorine, copper, iron, zinc	NRC 2007a
Wolf Creek	Closed-cycle cooling pond	Chlorine, tritium	WCNOC 2002; WCGS 2003

In the operation of the cooling system, contaminants (e.g., heavy metals) may be leached from condenser tubing and discharged by the power plant's cooling system. Elevated concentrations of these contaminants are toxic to aquatic and terrestrial organisms. In the past, the use of copper alloy condenser tubes in the cooling systems at the H.B. Robinson plant in South Carolina and Diablo Canyon plant in California resulted in the discharge of copper in the liquid effluent, which was observed to have adverse effects on the morphology and reproduction of resident bluegill populations at the Robinson plant (Harrison 1985), and abalone (*Haliotis* spp.) deaths were attributed to the increased copper levels discharged after a resumption of operations at Diablo Canyon (NRC 1996). Terrestrial wildlife that feed on these fish in the receiving waters could have been exposed to elevated copper levels. Also, potential reductions in populations of prey species could affect predator species. However, the replacement of the copper alloy condenser tubes with tubes made of different materials (e.g., titanium) has rectified this problem.

Thermal impacts on terrestrial habitats or wildlife exposed to elevated temperatures have not been identified at the nuclear power plants; however, as noted above, the growth of plants along portions of cooling pond shorelines may be restricted by high-temperature effluents. Temperature increases in receiving water bodies due to effluent discharges are regulated through NPDES permits to limit the extent of temperature increases for the protection of biota. In addition, because the plant communities present have been influenced by many years of facility operation, the elevated temperatures are unlikely to result in mortality of wetland and riparian plants that may be exposed to the discharges because species that are intolerant of elevated temperatures are unlikely to be growing near the outfall. The heated effluents could lengthen the growing season for wetland or riparian plant communities present. A potentially beneficial effect of the heated discharges at the Turkey Point plant in Florida has been the development of suitable habitat for the American crocodile (*Crocodylus acutus*), an established population of which occupies the cooling canal system. In addition, ice-free open water areas that provide foraging opportunities for the bald eagle (*Haliaeetus leucocephalus*) and various waterfowl species are often maintained by heated discharges during winter months at a number of nuclear plants in northern States. These benefits would be expected to continue during the license renewal term.

The impingement of waterfowl at the cooling water intakes has been observed at some nuclear plants, such as the Cook plant in Michigan, the Nine Mile Point plant in New York, and the Point Beach plant in Wisconsin. About 400 ducks, primarily lesser scaup (*Aythya affinis*), were impinged at the D.C. Cook plant in December 1991 (Mitchell and Carlson 1993); about 100 ducks, both greater scaup (*Aythya marila*) and lesser scaup, were impinged in January 2000 at the Nine Mile Point plant (NRC 2006e). At Point Beach, a number of double-crested cormorants (*Phalacrocorax auritus*) were impinged in September 1990, and 33 birds (mostly gulls) were impinged from June 2001 through December 2003 (NRC 2005b). Changes in operational procedures, such as the periodic cleaning of zebra mussels off intake structures, and changes in intake structure design, have been implemented to minimize the impacts on waterfowl. It is likely that any impingement over the license renewal term would result in only minor effects on waterfowl populations.

Groundwater quality can be degraded by contaminants present in cooling ponds and cooling canals. Deep-rooted terrestrial plants could be exposed to these contaminants. In addition, biota could be exposed to contaminants at locations of groundwater discharge, such as wetlands or riparian areas. However, as noted above, contaminant concentrations are typically very low, and any effects on terrestrial plants would be expected to be SMALL. Mitigation may also be implemented where sensitive resources could be affected. At the Turkey Point plant in Florida, for example, the flow of hypersaline groundwater from the cooling canals toward the Everglades to the west is prevented by an interceptor ditch, located along the west side of the canal system, from which groundwater inflow is extracted (NRC 2002b).

Surface water or groundwater that is withdrawn by nuclear power plants may potentially reduce the availability of water to terrestrial biota, such as those associated with wetlands or riparian areas along surface water bodies used as sources of cooling water, or those supported by groundwater discharges to wetlands or riparian areas. For once-through cooling systems, flow reductions from consumptive use generally represent a small decrease in water availability and have not resulted in water use conflicts for terrestrial resources. For example, losses due to the operation of the cooling system at the Peach Bottom plant in Pennsylvania, which operates as a once-through system with helper cooling towers, represent less than 2 percent of the minimum monthly average river flow of the cooling water source (NRC 2003a). In contrast, however, for some closed-cycle systems, consumptive water use may result in conflicts with requirements for the protection of riparian, wetland, or other communities, primarily where the nuclear plants are located on small bodies of water or small streams. Although water withdrawal rates are much lower for closed-cycle systems (which require makeup water as a result of evaporative losses) than for once-through systems, consumptive losses may be relatively high. Because of restrictions imposed at some plants on water withdrawal and consumption rates, which are protective of biotic resources, reductions in plant operations may be required under certain conditions when there are low water levels, such as during droughts. During extensive droughts, temporary impacts on riparian and wetland communities could occur.

Impacts on terrestrial biota associated with the operation of the cooling system have not been reported as a problem at any of the nuclear power plants evaluated. No adverse effects on terrestrial plants or animals have been reported as a result of increased water temperatures, fogging, humidity, or reduced habitat quality. Because of the low concentrations of contaminants within the liquid effluents associated with the cooling systems, the uptake and accumulation of contaminants in the tissues of wildlife exposed to the contaminated water or aquatic food sources are not expected to be a significant issue, and the impacts are expected to be SMALL for all plants. Potential mitigation measures would include regular monitoring of the cooling systems for water quality and measures to exclude wildlife from contaminated ponds. On the basis of these considerations, the NRC concludes that the impact of continued operation of the cooling systems on terrestrial resources would be SMALL for all nuclear plants and is considered a Category 1 issue.

Cooling Tower Impacts on Vegetation (Plants with Cooling Towers)

Continued operation of cooling towers could affect vegetation during the license renewal term. This issue applies only to operating nuclear power plants with cooling towers. The issue is a consolidation of two issues evaluated in the 1996 GEIS: (1) cooling tower impacts on crops and ornamental vegetation and (2) cooling tower impacts on native plants. Impacts of cooling tower emissions on these resources were considered to be SMALL for all plants and were designated as Category 1 issues in the 1996 GEIS.

As discussed in Section 3.6.1, terrestrial habitats in the vicinity of nuclear power plant cooling towers have been exposed to deposition of cooling tower drift particulates (including salt), deposition of water droplets on vegetation from drift, structural damage from freezing vapor plumes, and increased humidity. Drift contains small amounts of particulates that are dispersed from cooling towers over a wide area, with particulates from natural draft towers dispersing over a larger area and at a lower deposition rate than from mechanical draft towers (NRC 1996). However, most of the deposition from cooling towers occurs in relatively close proximity to the towers. Generally, deposition rates from these cooling towers have been below those that are known to result in measurable adverse impacts on plants, and no deposition effects on agricultural crops or plant communities have been observed at most of the nuclear power plants (NRC 1996). Exceptions have been observed at some nuclear plants; however, the impacts have been addressed by changes to cooling tower operations. For example, high levels of sulfate deposition, along with temporary excessive icing conditions at the Palisades plant on the southeast shoreline of Lake Michigan, resulted in the loss of about 5 ac (2 ha) of dune forest near the cooling towers and its replacement with a dense scrub-shrub community within several years of the startup of operations (NRC 2006b). These conditions were subsequently resolved by changes made to the cooling system.

Salt deposition from cooling tower drift is a potential impacting factor that can affect coastal power plants that use high-salinity water for cooling. The only such nuclear plant is the Hope Creek plant in New Jersey, which has natural draft cooling towers and withdraws cooling water from the Delaware River estuary (see Section 3.3.2 for a discussion of Hope Creek cooling tower drift emissions). High rates of deposition on plants or soil can result in injury to plants from acute effects and may result in changes to plant communities from chronic effects (Talbot 1979). Salt-tolerant species may increase in abundance, while sensitive species may decrease. Some salt-tolerant species are invasive and may become dominant in affected areas. However, no measurable effects from cooling tower drift on plant communities in the vicinity of Hope Creek have been observed (NRC 1996). The Palo Verde plant in Arizona uses cooling water with somewhat elevated salt concentrations. Studies have detected elevated levels of salt in plant leaves near the plant; however, the studies showed that no changes to native plants or crop production occurred (see Section 3.3.2 for a discussion of cooling tower drift emissions from the Palo Verde plant).

Impacts from icing have been rare, minor, and localized near nuclear power plant cooling towers and have been corrected by changes in tower operation at the plants where they occurred. For example, icing damaged oak trees adjacent to the cooling towers at the Prairie Island plant in Minnesota, changing the tree canopy structure and reducing acorn viability. Changes in tower operations eliminated the impacts (NRC 1996). Impacts from increased humidity have not been observed at nuclear power plants.

The continued operation of nuclear power plants would not be expected to result in increases in deposition rates from cooling towers or the accumulation of deposition constituents in soils. Because of the solubility of these materials, they are generally removed through precipitation. Plant communities in the vicinity of cooling towers have been exposed to many years of cooling tower operations, and are unlikely to change during the license renewal term. Any effects of icing during the renewal period would continue to be rare, minor, and localized. On the basis of these considerations, the NRC concludes that the impact of continued operation of cooling towers on plant communities would be SMALL for all nuclear plants and is considered a Category 1 issue.

Bird Collisions with Plant Structures and Transmission Lines

This section addresses the issue of avian mortality resulting from collisions of birds with natural draft cooling towers and transmission lines, within this scope of review (see Sections 3.1.1 and 3.1.6.5 in this GEIS), and other plant structures at nuclear power plants. Natural draft towers, which are tall structures (usually taller than 330 ft [100 m]), cause some mortality, whereas mechanical draft towers, which are smaller (usually shorter than 100 ft [30 m]), cause negligible mortality (NRC 1996). Because of these facts, mechanical draft towers are not addressed here. The impacts from birds colliding with cooling towers and transmission lines were evaluated by reviewing the primary literature for avian collision mortality associated with all types of man-made objects, as well as the results of monitoring studies conducted at six nuclear plants. The magnitude of the impact of the mortality caused by cooling towers is determined by examining the actual numbers and species of birds killed and comparing this mortality with the total avian mortality resulting from other man-made objects relative to bird population size.

Throughout the United States, it has been estimated that millions of birds are killed each year when they collide with man-made objects, including cooling towers, radio and television towers, buildings, vehicles, wind generation facilities, transmission lines, and numerous other objects

(Erickson et al. 2001). Many of these deaths can be considered unlawful take under the Endangered Species Act or the Migratory Bird Treaty Act. Bird mortality resulting from collisions with man-made structures is of concern if the stability of the local or migratory population of any bird species is threatened or if the reduction in numbers within any bird population significantly impairs its function within the ecosystem.

The number of collision-related bird deaths varies, depending on the type of man-made object. For example, Table 4.6-3 shows the estimated annual bird collision mortality in the United States. Collisions with buildings and windows account for the greatest number of collision mortalities annually, whereas wind generation facilities account for the least number of collision- related deaths (Table 4.6-3; Erickson et al. 2001). These estimates differ largely as a result of the density of the man-made structures in the study areas. It is estimated that more than 98 million commercial and residential buildings exist across the United States (Klem 1990; Erickson et al. 2001); compare this number with the number of wind turbines, which is less than 20,000 in 29 States (Manville 2005).

There are nearly 100,000 communication towers registered with the Federal Communications Commission (68 FR 53696 k), some of which have been observed to cause a large number of avian collision mortalities (Able 1973; Kemper 1996; Crawford and Engstrom 2001). Most of these large mortality events at communication towers occur at night during spring and fall migration periods involving songbirds that appear to become confused by tower lights (Taylor and Kershner 1986; Larkin and Frase 1988; Manville 2005). For example, a single television tower in northern Florida, Crawford and Engstrom (2001) reported more than 44,000 bird

Table 4.6-3. Estimated Annual Bird Collision Mortality in the United States

Source	Annual Mortality[a]
Vehicles[b]	60 million to 80 million
Buildings and windows[c]	98 million to 980 million
Power lines[d]	10,000 to 174 million
Communication towers[e]	4 million to 50 million
Wind generation facilities[f]	10,000 to 40,000

(a) Estimated annual mortality was extrapolated from literature reviews.
(b) Includes automobiles, trains, and airplanes.
(c) Includes buildings and attached structures such as smokestacks and windows.
(d) Includes all electric communication lines and transmission lines.
(e) Includes radio, television, cellular, microwave, and public safety towers.
(f) Includes wind turbines and supporting structures.
Source: Erickson et al. 2001

collision mortalities over a 29-year period. Communication towers involved with the most bird collisions are tall (exceeding 1,000 ft [305 m]), illuminated at night with incandescent lights, guyed, and located near wetlands and bird migration pathways (Manville 2005). During nights of heavy cloud cover or fog, the incandescent lights illuminating the communication towers may attract migrating songbirds to the towers, increasing the likelihood of collisions. Compared to communication towers, cooling towers at nuclear power plants are shorter (less than 650 ft [200 m]) and are illuminated with low-intensity light sources (1.0 ft-candle or less), such that migrating birds may not be as attracted to them, thus decreasing the likelihood of collision.

Natural draft cooling towers and transmission lines create collision hazards for migratory and local bird species. Monitoring of bird collisions has been done at several nuclear plants with natural draft cooling towers, including the Susquehanna plant on the Susquehanna River near Berwick in eastern Pennsylvania, the Davis-Besse plant on the shore of Lake Erie in north central Ohio, the Beaver Valley plant on the Ohio River in extreme western Pennsylvania, the former Trojan plant on the Columbia River in extreme northwestern Oregon, the Three Mile Island plant near Harrisburg in southeastern Pennsylvania, and the Arkansas plant on Dardanelle Lake in northwestern Arkansas. The following information regarding those plants was obtained from nuclear plant annual monitoring reports and from Temme and Jackson (1979).

At the Susquehanna plant, surveys were conducted on weekdays during the spring and fall bird migrations from 1978 through 1986. (Unit 1 began operating in 1983 and Unit 2 came online in 1985.) The plant's natural draft towers are 165-m (540-ft) tall and illuminated at the top with 480-V aircraft warning strobe lights. About 1,500 dead birds (total for all survey years, an average of 166 per year) representing 63 species were found; they had apparently collided with the cooling towers. Other birds were probably lost in the tower basin water during plant operation. Most of the birds were songbirds. Fewer collisions seemed to occur during plant operation, when cooling tower plumes and noise may have frightened birds away from the towers.

At Davis-Besse, extensive surveys for dead birds were conducted from fall 1972 to fall 1979. Early morning surveys at the 152-m-tall (499-ft-tall) cooling tower were made almost daily from mid-April to mid-June and from the first of September to late October. After the tower began operating in the fall of 1976, some dead birds were lost through the water outlets of the tower basin. A total of 1,561 dead birds were found, an average of 195 per year. The dead birds included 1,229 at the cooling tower, 224 around Unit 1 structures, and 108 at the meteorological tower. Most were night-migrating songbirds, particularly wood-warblers (family Parulidae), vireos (*Vireo* spp.), and kinglets (*Regulus* spp.). Waterfowl that were abundant in nearby marshes and ponds suffered little collision mortality. Most collision mortalities at the cooling tower occurred during years when the cooling tower was not well illuminated (1974 to spring 1978). After the completion of Unit 1 structures and installation of many safety lights around the buildings in the fall of 1978, collision mortality was significantly reduced (average of 236 per year from 1974 through 1977, 135 in 1978, and 51 in 1979). This reduction was accomplished by installing low-intensity light sources (1.0 ft-candle or less) to illuminate the cooling tower, which allowed birds to see and avoid it. It appears that the lights at nuclear plants do not confuse birds to the extent that lights on radio or TV towers sometimes do.

At Beaver Valley, surveys were conducted at the natural draft tower in the spring and fall seasons from 1974 through 1978. A total of 27 dead birds were found. At the Trojan plant, surveys were conducted weekly in 1984 and 1988 at the 499-ft-tall (152-m-tall) cooling tower, meteorological tower, switchyard, and generation building. No dead birds were found. At the 371-ft-tall (113-m-tall) cooling towers at Three Mile Island, 66 dead birds were found from 1973 through 1975. No dead birds were found at the Arkansas plant, where monitoring at the natural draft tower was done twice weekly from October 15 through April 15 in 1978–79 and 1979–80.

The available data on cooling-tower collision mortality suggest that cooling towers at nuclear power plants cause only a very small fraction of the total annual bird collision mortality from all sources. A very high percentage of all collision mortalities occur during the spring and fall bird migration periods and involve primarily songbirds migrating at night. The relatively few nuclear power plants in the United States that have natural draft towers (24 towers at operating nuclear power plants), combined with the relatively low bird mortality at individual natural draft towers, indicates that (1) bird populations are not greatly affected by collisions with nuclear power plant cooling towers and (2) the contribution of cooling towers to the cumulative effects of bird collision mortalities is very small. Mechanical draft cooling towers, which are not nearly as tall as natural draft towers, pose little risk to migrating birds.

Because the frequency of avian mortality resulting from collisions with cooling towers is small for any species, it is unlikely that the losses would threaten the stability of local migratory bird populations or result in a noticeable impairment of the function of a species within local ecosystems. There is no reason to believe that the annual mortality rate resulting from collision of birds with any cooling tower would be different during the license renewal term. Mitigation measures may include illuminating the natural draft cooling towers at night with low-intensity lights so birds can see the towers and avoid collisions. Because cooling towers represent only a small part of total bird collision mortality, it is not expected that there will be any incremental impact on bird populations from cooling tower collision mortality as a result of license renewal. The impact from bird collisions with cooling towers during the license renewal term was considered to be SMALL for all nuclear plants and was designated as a Category 1 issue in the 1996 GEIS. No new information has been identified in the plant-specific SEISs prepared to date or the literature that would alter that conclusion.

The potential for birds to collide with transmission lines depends on a number of factors, such as bird species, migration behavior, and location and physical characteristics of the transmission line (Bevanger 1988; Janss 2000; Manville 2005). Larger-bodied bird species such as raptors are more likely to collide with transmission lines (Harness and Wilson 2001; Manville 2005), whereas smaller-bodied birds such as migrating songbirds are more likely to collide with towers (Temme and Jackson 1979). This difference is most likely the result of differences in the behavior of raptors and songbirds. Raptors are known to use utility structures as perch locations and nest sites more often than do songbirds (Blue 1996; Manville 2005), whereas nocturnal migrating songbirds may become confused by the lights on communication towers (Crawford and Engstrom 2001). Lights are not a contributing factor in bird collisions at transmission lines because lights are not generally used to mark transmission lines.

It is unknown to what extent bird populations are negatively affected by deaths caused by collisions with transmission lines. Generally, bird mortality resulting from collisions with transmission lines has appeared to be only a small fraction of total mortality; therefore, it has not been considered to have significant population impacts (Stout and Cornwell 1976; Banks 1979). However, rare, threatened, or endangered species may be affected by transmission lines, particularly if the lines pass through areas where such species are concentrated (Sergio et al. 2004; Sundar and Choudhury 2005). There are no reports of relatively high collision mortality occurring at the transmission lines associated with nuclear power plants in the United States. As described in Section 3.1.6.5 and further in 3.1.1, in-scope transmission lines include only those lines that connect the plant to the first substation that feeds into the regional power distribution system. This substation is frequently, but not always, located on the plant property. The length of transmission lines associated with nuclear plants is considerably less than the total 500,000 mi (800,000 km) of transmission lines estimated within the United States (Manville 2005). Therefore, transmission lines associated with nuclear power plants are likely responsible for only a small fraction of total bird collision mortality.

Because the literature does not indicate there is a significant impact from collision mortality on overall species populations and because there are no known instances in which nuclear plant transmission lines have affected local bird populations, it is not expected that the mortality resulting from bird collisions with transmission lines associated with nuclear plants and an additional 20 years of plant operation would cause long-term reductions in bird populations.

The impact of bird collisions with transmission lines during the license renewal term was considered to be SMALL for all plants and was designated as a Category 1 issue in the 1996 GEIS. No new information was identified in the site-specific SEISs prepared to date or the literature that would alter that conclusion. On the basis of these considerations, the NRC concludes that the impact of bird collisions with plant structures and transmission lines during the license renewal term would be SMALL for all nuclear plants and remains a Category 1 issue.

Water Use Conflicts with Terrestrial Resources (Plants with Cooling Ponds or Cooling Towers Using Makeup Water from a River)

In the 1996 GEIS, water use conflicts included ecological impacts on aquatic and riparian communities. The NRC separated out the ecological impacts in this revised GEIS to specifically address the effects of water use conflict on terrestrial resources in riparian communities. This new issue specifically applies to nuclear power plants with cooling ponds or cooling towers, typically with high levels of consumptive use and that use makeup water from a river. Water use conflicts with terrestrial resources in riparian communities could occur when water that supports these resources is diminished either because of decreased availability due to droughts; increased water demand for agricultural, municipal, or industrial usage; or a combination of such factors. For example, Wolf Creek uses Coffee County Lake for cooling (NRC 2008a). Makeup water for the lake is withdrawn from the Neosho River downstream of John Redmond Reservoir. The Neosho River is a small river with especially low water flow during drought conditions. The riparian communities downstream of this reservoir may be affected by the plant’s water use during periods when the lake level is low and makeup water is obtained from the Neosho River. For the Wolf Creek plant, the water use conflict impact is SMALL to MODERATE and a site-specific condition. For future license renewals, the potential range of impact levels at plants with cooling ponds or cooling towers using makeup water from a river cannot be determined at this time. The NRC concludes that the impact of water use conflicts with riparian communities is a plant-specific Category 2 issue.

Transmission Line ROW Management Impacts on Terrestrial Resources

This section evaluates the extent to which plant communities and wildlife populations could be affected by transmission line ROW management during the license renewal term at all nuclear power plants. This issue is a consolidation of two issues that were evaluated in the 1996 GEIS: (1) power line ROW management (cutting and herbicide application) and (2) floodplains and wetland on power line ROW. Impacts on these resources were considered to be SMALL for all plants and were designated as Category 1 issues in the 1996 GEIS. As described in Section 3.1.6.5 and further in 3.1.1, in-scope transmission lines include only those lines that connect the plant to the first substation that feeds into the regional power distribution system. This substation is frequently, but not always, located on the plant property.

Generally, ROW management involves clearcutting, selective cutting of tall woody vegetation, mowing, or herbicide application. These activities alter the physical features of vegetation communities by reducing vegetation height, density, and species diversity, which may impact wildlife populations inhabiting those areas. The cutting of woody vegetation is usually not needed in grassland, desert, or shrub habitats, so associated impacts are not an issue there. Habitat quality in the ROW and nearby areas may be affected, and ROW management may affect local wildlife populations. Data on the effects of maintenance of transmission line ROWs specifically associated with nuclear power plants are not available, but the literature applies to such transmission lines because the methods used to maintain transmission line ROWs are similar for any transmission line ROW at any facility.

Plant communities are affected by the presence of maintained ROWs as well as other ongoing maintenance activities. The principal impacts associated with transmission line ROWs occur as a result of the initial clearing activities during transmission line installation. During installation, forested upland and wetland habitats in ROWs are typically converted to scrub-shrub communities, herbaceous upland, or emergent wetland types when trees are removed. Effects are less extensive where ROWs are established in grassland, desert, or shrub habitats. ROW effects extend beyond the area of direct disturbance. Transmission line ROWs established in otherwise undeveloped areas contribute to habitat fragmentation and affect the distribution of species in undisturbed areas along the corridors. The effects of habitat fragmentation associated with clearings and the creation of edges may continue to develop over a considerable period of time, since some species are lost while others become established (Saunders et al. 1991). Clearings in wooded areas tend to contribute to an increase in deer populations and increased access to forest interior areas (Alverson et al. 1988). The gradual loss of some plant species from these areas due to browsing may extend over many decades.

The operation of heavy equipment during ROW maintenance activities can result in soil compaction, affecting the establishment of some native plant species. ROW corridors occasionally provide a route for the introduction or expansion of invasive species populations into new areas. Significant changes in vegetation cover, such as removal of the tree canopy, and compaction of upland soils within the watershed of a wetland generally result in increased runoff and reduced infiltration to shallow groundwater, causing an increase or decrease in hydrologic input to nearby wetlands (EPA 1993, 1996; Wright et al. 2006). Effects include changes in the frequency or duration of inundation or soil saturation and greater fluctuations in wetland water levels. Runoff often contains sediments, contaminants from road and parking surfaces, or herbicides used in ROW or site vegetation management. Erosion of wetland substrates and plants can result from increased flow velocities that result from the changes in runoff and surface drainage patterns.

The presence of the ROWs would continue to affect the habitats within and adjacent to the transmission line corridors during the license renewal term; there would be more light and less soil moisture than found in undisturbed habitats. The plant communities that became established during the years of the initial operating license would generally remain altered communities, with a different species composition and community structure than undisturbed habitats. In many areas, ROW management would prevent the development of mature plant communities. Plant species that are typically associated with high-quality, undisturbed native habitats and are intolerant of disturbed conditions would generally continue to be excluded from ROWs. Although species diversity may be high in these disturbed habitats, many of the species may be common or weedy native species or non-natives. However, in some areas, rare or protected species that require open canopies, such as the golden sedge (*Carex lutea*), Cooley's meadowrue (*Thalictrum cooleyi*), and rough-leaf loosestrife (*Lysimachia asperulaefolia*), which occur within the Brunswick Steam Electric Plant ROWs in North Carolina, would continue to occur under the conditions existing within the ROWs. Invasive upland or wetland species that became established within the ROWs during the initial operating license would continue to exclude native species and reduce species diversity (BPA 2000). Invasive species populations may continue to expand unless aggressive management efforts are implemented.

Plant communities in and along ROWs are generally maintained in a modified condition for safe and efficient operation of the transmission lines. To protect the electric conductors, ROW management typically includes the periodic cutting of tall trees and application of herbicides. Tree cutting is a minor management activity in regions where tree growth in ROWs is limited, such as in grasslands, desert, or shrubland areas. Mowing is also frequently used as a management method to control the growth of woody species and promote the establishment of grassland or other herbaceous habitat types. Management activities and transmission line repair occasionally result in the erosion of exposed soils where vegetation has been removed or where soils are disturbed by equipment. Management activities that result in the disturbance, compaction, or exposure of soils may promote the establishment of invasive species (BPA 2000). Erosion of upland soils may result in sedimentation or increased turbidity in wetlands within the watershed. Herbicides used to manage undesirable species may drift onto nontarget species or affect wetland communities through runoff from treated areas (BLM 2007). The operation of heavy equipment in wetlands during ROW maintenance or transmission line repair can damage or compact wetland soils and vegetation.

Many of the nuclear power plants incorporate mitigation into their ROW management plans to protect wetlands or other sensitive or high-quality habitats. For example, within the ROWs of the Millstone plant in Connecticut, precautions are taken to protect and promote quality habitats. Herbicide use is prohibited within 10 ft of wetlands or surface water, and mowing is conducted only from November through April to protect saturated soils and minimize loss of fruit and seeds (NRC 2005c). ROW maintenance practices used at the Brunswick plant in North Carolina, such as methods of herbicide use, are designed to preserve and protect rare and listed plant species and sensitive natural areas known to occur within the ROWs. Established procedures are in place to protect rare and listed plant species if they are encountered by maintenance crews (NRC 2006b). At the Browns Ferry plant in Alabama, field studies are conducted to inventory and protect listed plant species and sensitive habitats. Species populations are monitored, and habitats are managed and maintained. In the most sensitive areas, vehicles and equipment are prohibited, and all vegetation clearing is done by hand (NRC 2005d).

Most data on the impacts of transmission line ROWs on wildlife are for relatively moist areas of the United States where vegetation growth is rapid and vegetation must be controlled to prevent its interference with the transmission lines. In arid regions, little or no vegetation control is required, and the potential effects on wildlife are small. Potential effects are also small where lines cross croplands, because no vegetation management is required. The following discussion is therefore applicable primarily to forested regions where the utility must control vegetation on transmission line ROWs.

The maintenance of a transmission line ROW could directly affect wildlife as the result of (1) continued habitat loss or alteration; (2) displacement due to noise during maintenance activities; (3) mortality from maintenance equipment, conductors, or wires; (4) reduced mobility of some species, such as amphibians, across the cleared ROW; and (5) toxicity from herbicide or fuel spills. ROW creation establishes, and maintenance activities maintain, a new habitat type that divides a pre-existing and usually much larger habitat type, such as a forest (Yahner et al. 2004). The increased amount of edge along the boundary of the two habitats may affect wildlife by (1) increasing rates of predation among nesting birds, (2) restricting wildlife dispersal and migration patterns, (3) negatively affecting wildlife species that require large undisturbed areas, or (4) increasing local wildlife abundance and diversity.

Many studies identify the potential effects of ROW maintenance on wildlife populations. Transmission line ROWs may represent a barrier for species, such as large mammalian carnivores, that require large tracts of contiguous forested habitat (Crooks 2002). ROW maintenance may also have negative effects on smaller, less mobile wildlife species. For example, studies have shown that some amphibian species have difficulty crossing disturbed habitat and may experience increased rates of mortality as a result of physiological stress (Gibbs 1998; Rothermel 2004).

Traditionally, habitat edges have been considered to be beneficial to wildlife because species diversity is usually greater there (Yahner 1988). However, some species such as neotropical migrating songbirds that prefer interior forest habitat may be adversely affected by the increase in edge habitat associated with ROW clearings. These species require large blocks of forest for successful reproduction and survival (Wilcove 1988). Studies have found that nests of these bird species placed near edges are more likely to fail as a result of predation or nest parasitism than nests located near the forest interior (Paton 1994; Robinson et al. 1995). This failure is often due to an increase in the abundance of predators (e.g., skunks and raccoons) and nest parasites (e.g., brown-headed cowbirds [*Molothrus ater*] that lay their eggs in the nests of other birds), which are capable of proliferating in disturbed areas and edge habitats (Evans and Gates 1997; Crooks and Soulé 1999). Increased predation and nest parasitism rates along edge habitats have reduced the populations of some neotropical bird species to the point where they have become locally extinct (Crooks and Soulé 1999).

Numerous studies indicate that wildlife populations can benefit from ROW management. Ongoing research on the effects of ROW management on wildlife has been conducted for more than 50 years at the State Game Lands 33 Research Project in Pennsylvania (Yahner 2004). Results of the studies conducted at that site indicate that long-term management of the ROW may provide an essential food source and cover habitat for insects, amphibians and reptiles, numerous bird species, and mammals such as black bear (*Ursus americanus*) and white-tailed deer (*Odocoileus virginianus*). Even species of concern, such as neotropical migrant birds, have been commonly observed using the brushy habitats provided by the ROW. Yahner et al. (2002, 2004) found that herbicide treatments in the ROW did not have any adverse effects on the nesting success of neotropical migrating bird species like the eastern towhee (*Pipilo erythrophthalmus*). King and Byers (2002) discovered that songbird nesting success was greater within the brushy ROW habitat than in nearby vegetation communities.

In a study of rodent populations in Oregon, Wolff et al. (1997) found higher densities of gray-tailed voles (*Microtus canicaudus*) in disturbed open habitats than in other habitats. They also found no effect of habitat disturbance on vole survival, reproductive success, or population size. Johnson et al. (1979) found that the diversity of small mammals was greater in ROW habitats than in adjacent forest habitats. There is also evidence that ROW maintenance can provide suitable habitat for some important insect populations, such as butterflies (Bramble et al. 1999). Thus, the management of ROW habitats may provide suitable habitat for a number of wildlife species, including some sensitive species such as neotropical migrant songbirds.

An important aspect of ROW management is the consideration of management strategies that limit the adverse effects on wildlife species. Herbicides are generally not highly toxic to wildlife when they are properly applied for ROW management. Therefore, toxic effects of herbicides on wildlife are generally of little concern to wildlife biologists or wildlife managers. Of the papers reviewed for this analysis, none expressed serious concern about toxic effects. In fact, some management techniques using herbicides have been proposed to maintain the function of the ROW and maximize the amount of suitable habitat for wildlife species. Yahner et al. (2002) proposed a phased approach to control the growth of undesirable plants, such as large trees, and maintain an early successional shrub-like plant community along the ROW. This objective could be accomplished through a combination of mechanical treatments (e.g., mowing) and selective herbicide applications. This approach could minimize the costs associated with vegetation management along a ROW and might be an important conservation tool for numerous wildlife species (Marshall and Vandruff 2002; Yahner et al. 2002).

The overall impact of transmission line ROW areas appears to be neither significantly adverse nor significantly beneficial. The consensus among wildlife biologists appears to be that although the initial habitat destruction associated with ROW clearing can have numerous consequences on wildlife populations, the proper management of transmission line ROW areas does not have significant adverse impacts on current wildlife populations, and ROW management can provide valuable wildlife habitats. Of the papers reviewed for this evaluation, none identified any significant impact of transmission line corridors on wildlife. The evidence supports a conclusion that continued ROW management during the license renewal term will not lower habitat quality or cause significant changes in wildlife populations in the surrounding habitat. On the basis of these considerations, the NRC concludes that the impact of continued transmission line ROW management on terrestrial resources is SMALL for all nuclear plants and remains a Category 1 issue.

Electromagnetic Fields on Flora and Fauna (Plants, Agricultural Crops, Honeybees, Wildlife, Livestock)

As described in Section 3.1.6.5 and further in 3.1.1, in-scope transmission lines include only those lines that connect the plant to the first substation that feeds into the regional power distribution system. This substation is frequently, but not always, located on the plant property. The effects of electromagnetic fields on terrestrial biota are considered to be of SMALL significance if the overall health, productivity, and reproduction of individual species appear unaffected.

The EMFs produced by operating transmission lines up to 1,100 kV have not been reported to have any biologically or economically significant impact on plants, wildlife, agricultural crops, or livestock (Lee et al. 1989; Miller 1983). Areas under and in the vicinity of the lines have been studied numerous times. Vegetation, foliar damage due to EMF-induced corona at leaf margins, agricultural crop production, wildlife population abundance, livestock production, and potential livestock avoidance of the lines have been investigated. Also, many laboratory experiments with plants and laboratory animals have been conducted, often using electric fields much stronger than those occurring under transmission lines.

Plants—Studies have shown that minor damage to plant foliage and buds can occur in the vicinity of strong electric fields. For example, tree foliage and buds that are close to transmission lines can be damaged and upward or outward growth of branches can be reduced. Damage typically occurs only to the tips and margins of leaves in the uppermost plant parts that are the closest to the lines. The damage in the form of a leaf burn is most prevalent on small pointed leaves and is similar to leaf damage that might occur as a result of drought or other environmental stresses. The damage generally does not interfere with overall plant growth (Miller 1983).

The damage is thought to result from heating caused by induced corona at the leaf tips and margins. The electric field is greatly focused by leaf points or marginal teeth, thus increasing its strength to the point that corona (Section 4.6.1.3) occurs. Night-vision instruments have shown this corona as a glow of light concentrated at leaf tips and margins. The damage apparently does not extend to lower levels of the plant because the electric field weakens with distance from the lines and because the upper plant parts shield the lower parts from the electric field.

In one experiment under an 1,100-kV prototype line, the upward growth of alder and Douglas fir trees was reduced by this damage, with the result that the crowns of the trees became somewhat flattened on top and the overall crown developed a broader appearance than usual (Rogers et al. 1984). The growth of the lower parts of the trees and of lower-growing plants such as pasture grass, barley, and peas appeared unaffected (Rogers and Hinds 1983). In another experiment, 50-kV/m fields had no apparent effect on corn germination or the growth of corn seedlings; and the growth of corn, bluegrass, and alfalfa apparently was not affected by fields of 25–50 kV even though minor damage occurred to the outer fringes of the uppermost leaves (Bankoske et al. 1976). Germination of sunflower seeds in a 5-kV/m electric field was reduced by about 5 percent in some cases [4 out of 11 replicates (Marino et al. 1983)]. An experiment with several species of agricultural plants found that a maximum of about 1 percent of the total plant tissue was damaged by exposing the plants to 50-kV/m fields (Poznaniak and Reed 1978).

Lee et al. (1989) reviewed several papers reporting studies in Indiana, Tennessee, and Arkansas. The productivity of corn and other crop plants was not affected by electric fields of 12 to 16 kV/m under a 765-kV line and a UHV test line in Indiana, although plants under the larger line suffered some leaf tip damage from induced corona. Corn production in Tennessee may have been reduced by electric fields up to 8.5 kV/m, but the authors indicated the results were inconclusive. An Arkansas study found normal yields of rice and soybeans, but a 15 percent reduced yield of cotton beneath a 500-kV line (see Section 4.3.1.1). The researchers could not determine whether the reduced cotton yield resulted from electric field or ineffective aerial application of agricultural chemicals beneath the line.

Honeybees—Several studies have shown that honeybees in hives under transmission lines are affected by EMF (Greenburg et al. 1985; Rogers and Hinds 1983; Warren et al. 1981). Adverse effects include increased propolis (a reddish resinous cement) production, reduced growth, greater irritability, and increased mortality. These effects can be greatly reduced by shielding the hives with a grounded metal screen or by moving the hives away from the lines (Rogers and Hinds 1983; Lee 1980). Bindokas et al. (1988) showed that these impacts were not caused by direct effects of the electric fields on the bees but by voltage buildup and electric currents within the hives and the resultant shocks to bees. Bees kept in moisture-free nonconductive conditions were not adversely affected, even in electric fields as strong as 100 kV/m.

Wildlife and Livestock—Chronic exposure to EMF is experienced by small birds and mammals that primarily inhabit ROW corridors and by birds (primarily raptors) that nest in transmission line towers. EMF exposures to larger animals and livestock are usually relatively brief because these animals inhabit relatively large areas instead of small areas beneath the lines. Exposures occur as these larger animals pass beneath the lines or as birds fly by the lines.

The voluminous literature on population studies of small bird and mammal species in transmission line corridors (presented earlier in this section) has expressed virtually no concern for possible impacts of EMFs. These species apparently thrive underneath the lines, where their abundance appears to depend on habitat quality rather than on the strength of the electric fields to which they are exposed or the size of the line. For example, the density of breeding birds under 500-kV lines in eastern Tennessee is greater than that in adjacent forests (Kroodsma 1984, 1987) and appears to be greater than bird density in most grassland habitats or agricultural fields. Also, the density of small mammal populations near these lines appears to depend on habitat type rather than on the presence of the lines (Schreiber et al. 1976). A Minnesota study of a 500-kV line found little evidence of either a positive or negative effect of the power line on bird populations (Niemi and Hanowski 1984). Bird and small mammal populations under an 1,100-kV line in Oregon were also apparently unaffected by line operations (Rogers and Hinds 1983). Habitat use by elk in western Montana was apparently unaffected by operation of a 500-kV line, as the elk used habitats along the power line in proportion to their availability (Canfield 1988).

Raptors, ravens, and some water bird species frequently nest and perch on transmission line towers, particularly in grassland areas where other suitable nest sites are lacking. Thus, the birds are able to use habitats without suitable nest sites—habitats that they otherwise would not have used (Gilmer and Stewart 1983; Williams and Colson 1989). On high-voltage lines supported by metal lattice towers, the birds usually nest on the top (bridge) of the tower where the strength of the electric field is minimal (e.g., 5 kV/m or less) (Lee 1980). Lee found 80 percent of 110 nests on towers to be located on the tower bridge and cited previous studies that showed similar results.

The success of these tower nests in producing young appears to be no different from nests located in areas not exposed to EMF. In central North Dakota, 113 ferruginous hawk nests in high-voltage transmission line towers (18 percent of a total of 628 nests found) had a higher success rate (87 percent) than nests in other locations (however, a hail storm that missed the lines reduced the success of some other nests). The number of fledglings per occupied nest was 2.8 for ground nests (which were larger than tower or tree nests), 2.6 for tower nests, 2.3 for haystack nests, and 2.0 for tree nests (Gilmer and Stewart 1983). In Idaho, Steenhof et al. (1993) studied nesting success of ravens and raptors on a 370-mile (576-km) segment of 500-kV transmission line constructed in 1981. From 1981 through 1989 (the last year reported by Steenhof et al. 1993), the numbers of these species nesting on transmission towers increased to 133 pairs, including roughly 64 percent common ravens, 21 percent red-tailed hawks, 9 percent ferruginous hawks, 6 percent golden eagles, and 0.3 percent great horned owls. Nesting success of these birds averaged 65 percent to 86 percent and was similar to or better than that of the same species nesting on other structures. Lee (1980) reported finding 110 hawk and raven nests on 260 miles (418 km) of 230-kV and 500-kV lines of the Bonneville Power Administration. Although the success of these nests was not monitored, the author reported that, based on a literature review, it was unlikely that nesting would be adversely affected by EMF found in most locations in transmission line towers.

Livestock in both field and laboratory studies have shown no significant impacts when exposed to EMF. Lee et al. (1989) reviewed about 10 reports on effects of transmission lines on livestock in the United States and Sweden. These studies found no evidence that the growth, production, or behavior of beef and dairy cattle, sheep, hogs, or horses were affected by EMFs. The studies involved 11 farms along a 765-kV line in Indiana, 55 dairy farms near 765-kV lines in Ohio, 36 herds of cattle near 400-kV lines in Sweden, a mail survey of 106 farms in Sweden, a study of fertility of 58 cows under a 400-kV line in Sweden compared with 58 in a control area, 30 swine raised beneath a 345-kV line in Iowa compared with 30 raised in a control area, and cattle behavior under an 1,100-kV prototype line in Oregon. Cattle under the 1,100-kV test line in Oregon were startled by the first occurrence of corona noise when the line was re-energized after a reactor shutdown period (Rogers and Hinds 1983). From 1977 through 1981, grazing of cattle in pasture under the line appeared to be unaffected by line operation. In 1980–1981, the cattle spent more time near the line during periods when it was de-energized than when it was operating, but spent an increasing amount of time under the line when it was operating as the growing season progressed (Rogers and Hinds 1983).

In the Indiana study (Amstutz and Miller 1980), performance of livestock frequently under a 765-kV line on 11 farms was studied during a 2-year period (1977–1979; 9 farms participated for the full 2 years). Animals included 10 horses, 55 sheep, 149 beef cattle, 337 hogs, and 429 dairy cattle. Maximum field voltage levels recorded near ground level were about 9.1 kV/m. General health, behavior, and performance of the animals were not affected by the transmission line EMF.

In the Swedish study of cow fertility, 58 heifers were exposed to a 400-kV, 50-Hz transmission line from June to mid-October 1985 (Algers and Hultgren 1987). The length of exposure was 15 to 20 times longer than the average exposure per year for Swedish dairy herds exposed to 400-kV lines. No effects were observed on the frequency of malformations, the length or variation of the estrous cycle, the mid-cycle plasma progesterone level, the intensity of estrus, the number of inseminations per pregnancy, the overall conception rate, or the fetal viability. Previous studies of cattle showed no significant effects of EMFs on reproduction.

Conclusion—No significant impacts of EMFs on terrestrial biota have been identified. Although foliage very close to lines can be damaged, the overall productivity and reproduction of native and agricultural plants appear unaffected. Also, no evidence suggests significant impacts on individual animals or wildlife populations that are chronically exposed to EMFs under transmission lines or in the towers. Livestock behavior and production also appear unaffected by line operation. Therefore, the potential impact of EMFs on terrestrial biota is expected to be of SMALL significance for all plants. The only potential mitigation would be to exclude plants and animals from the right of way, a measure with very severe impacts of its own. However, because the impact is of small significance and because mitigation measures could create additional environmental impacts and would be costly, no mitigation measures beyond those implemented during the current term license would be warranted. This remains a Category 1 issue.

4.6.1.2 Aquatic Resources

Continued operations of the nuclear power plants during the 20-year license renewal term includes the operation of the cooling system (once-through, cooling ponds, or cooling towers), transmission line ROW maintenance, releases of gaseous and liquid effluents, facility maintenance, and refurbishment-related construction activities. Aquatic organisms would continue to be subject to impingement, entrainment, thermal discharges, chemical and radiological contaminants, and erosion and sedimentation. This section considers eleven issues concerning impacts of the proposed action on aquatic resources:

- Impingement and entrainment of aquatic organisms (plants with once-through cooling systems or cooling ponds) (consolidation of two issues from the 1996 GEIS: (1) entrainment of fish and shellfish in early life stages and (2) impingement of fish and shellfish (for plants with once-through cooling and cooling pond heat dissipation systems)).

- Impingement and entrainment of aquatic organisms (plants with cooling towers) (consolidation of two issues from the 1996 GEIS: (1) entrainment of fish and shellfish in early life stages and (2) impingement of fish and shellfish (for plants with cooling tower-based heat dissipation systems)).

- Entrainment of phytoplankton and zooplankton (all plants) (issue in the 1996 GEIS);

- Thermal impacts on aquatic organisms (plants with once-through cooling systems or cooling ponds) (issue was modified and renamed from the 1996 GEIS issue, “Heat shock (for plants with once-through and cooling pond heat dissipation systems)”);

- Thermal impacts on aquatic organisms (plants with cooling towers) (issue was modified and renamed from the 1996 GEIS issue, “Heat shock (for plants with cooling-tower-based heat dissipation systems)”);

- Infrequently reported thermal impacts (all plants) (consolidation of five issues from the 1996 GEIS: (1) cold shock, (2) thermal plume barrier to migrating fish, (3) distribution of aquatic organisms, (4) premature emergence of aquatic insects; and (5) stimulation of nuisance organisms (e.g., shipworms));

- Effects of cooling water discharge on dissolved oxygen, gas supersaturation, and eutrophication (consolidation of three issues from the 1996 GEIS: (1) eutrophication, (2) gas supersaturation (gas bubble disease), and (3) low dissolved oxygen in the discharge);
- Effects of nonradiological contaminants on aquatic organisms (issue was modified and renamed from the 1996 GEIS issue, accumulation of contaminants in sediments or biota, to include contaminant effects other than just accumulation);
- Exposure of aquatic organisms to radionuclides (new issue not considered in the 1996 GEIS);
- Effects of dredging on aquatic organisms (new issue not considered in the 1996 GEIS);
- Water use conflicts with aquatic resources (plants with cooling ponds or cooling towers using makeup water from a river) (new issue not considered in the 1996 GEIS);
- Effects on aquatic resources (non-cooling system impacts) (issue was modified and renamed from the 1996 GEIS issue, "Refurbishment," to include non-refurbishment impacts);
- Impacts of transmission line ROW management on aquatic resources (new issue not considered in the 1996 GEIS);
- Losses from predation, parasitism, and disease among organisms exposed to sublethal stresses (issue in the 1996 GEIS).

Overview of Impingement and Entrainment

Impingement occurs when organisms are held against the intake screen or netting placed within intake canals. Most impingement involves fish and shellfish. Table 4.6-4 lists some of the fish species commonly impinged at power plants. At some nuclear power plants, other vertebrate species may also be impinged on the traveling screens or on intake netting placed within intake canals. These include five species of sea turtle: loggerhead (*Caretta caretta*), green (*Chelonia mydas*), Kemp's

Impingement

Impingement is the entrapment of all life stages of fish and shellfish on the outer part of an intake structure or against a screening device during periods of water withdrawal (40 CFR 125.83).

Entrainment

Entrainment is incorporation of all life stages of fish and shellfish with intake water flow entering and passing through a cooling-water intake structure and into a cooling water system (40 CFR 125.83).

Table 4.6-4. Fish Species Commonly Impinged or Entrained at Power Plants

Ecosystem Type	Fish Species
Rivers	Alewife (*Alosa pseudoharengus*)
	Gizzard shad (*Dorosoma cepedianum*)
	Common carp (*Cyprinus carpio*)
	White bass (*Morone chrysops*)
	Sunfish (*Lepomis* spp.)
	Crappie (*Pomoxis* spp.)
	Yellow perch (*Perca flavescens*)
	Freshwater drum (*Aplodinotus grunniens*)
Great Lakes	Alewife (*Alosa pseudoharengus*)
	Gizzard shad (*Dorosoma cepedianum*)
	Yellow perch (*Perca flavescens*)
	Rainbow smelt (*Osmerus mordax*)
Estuaries	Bay anchovy (*Anchoa mitchilli*)
	Tautog (*Tautoga onitis*)
	Atlantic menhaden (*Brevoortia tyrannus*)
	Gulf menhaden (*Brevoortia patronus*)
	Winter flounder (*Pleuronectes americanus*)
	Weakfish (*Cynoscion regalis*)
Oceans	Bay anchovy (*Anchoa mitchilli*)
	Striped anchovy (*Anchoa hepsetus*)
	Silver perch (*Bairdiella chrysura*)
	Cunner (*Tautogolabrus adspersus*)
	Scaled sardine (*Harengula jaquana*)
	Queenfish (*Seriphus politus*)

ridley (*Lepidochelys kempi*), leatherback (*Dermochelys coriacea*), and hawksbill (*Eretmochelys imbricata*). Impingement of these sea turtles has occurred at the Diablo Canyon and San Onofre plants on the Pacific coast; at the Salem, Oyster Creek, Brunswick, and St. Lucie plants on the Atlantic coast; and at the Crystal River plant on the Gulf coast on the either Atlantic and Gulf of Mexico coasts or east coast (Gunter et al. 2001). Waterfowl have also been impinged at several plants; examples are double-crested cormorants (*Phalacrocorax auritus*) at Point Beach plant in Wisconsin (NRC 2005b), lesser scaup (*Aythya affinis*) at Cook in Michigan (Mitchell and Carlson 1993), and lesser scaup and greater scaup (*A. marila*) at Nine Mile Point in New York (NRC 2006d). Isolated incidents of impingement or other impacts from power plants have been reported for other vertebrates, such as the American crocodile (*Crocodylus acutus*) at Turkey Point in Florida and the West Indian manatee (*Trichechus manatus*) at Turkey Point and St. Lucie in Florida (Gunter et al. 2001). Small numbers of harbor (*Phoca vitulina*), gray (*Halichoerus grypus*), harp (*Pagophilus groenlandicus*), and hooded (*Cystophora cristata*) seals have been impinged at Seabrook in New Hampshire (67 FR 61). Impingement impacts are expected to continue during the license renewal term. The impacts of impingement are different for once-through and closed-cycle cooling systems and are therefore discussed separately below.

Entrainment occurs when organisms pass through the intake screens and travel through the condenser cooling system. Aquatic organisms typically entrained include ichthyoplankton (fish eggs and larvae), larval stages of shellfish and other macroinvertebrates, zooplankton, and phytoplankton. Juveniles and adults of some species may also be entrained if they are small enough to pass through the intake screen openings, which are commonly 0.38 in. (1 cm) at the widest point. Table 4.6-4 lists fish species commonly entrained at power plants.

<u>Impingement and Entrainment of Aquatic Organisms (Plants with Once-Through Cooling Systems and Cooling Ponds)</u>

In the 1996 GEIS, the NRC considered that for plants with a once-through cooling systems or cooling ponds, the impacts of impingement and entrainment of aquatic organisms were SMALL at many plants but MODERATE to LARGE at a few nuclear plants. Therefore, impingement and entrainment were considered Category 2 issues. For plants that operate in a hybrid mode, impingement and entrainment would be SMALL at most nuclear plants, but could be MODERATE or LARGE at a few plants, and were also considered Category 2 issues.

Impingement is more of a concern at nuclear plants that have once-through cooling because these plants require a larger amount of water than plants that operate under closed-cycle (NRC 1996). Impingement monitoring at the Palisades nuclear power plant in Michigan demonstrated this difference. In 1972, when the plant used once-through cooling, 654,000 fish were impinged yearly at a water withdrawal rate of 400,000 gpm. In 1976, cooling towers were added to the plant, and it began operating as a closed-cycle plant. Intake withdrawal rate was reduced to

78,000 gpm, and impingement dropped to 7,200 fish per year (Consumers Energy Company and Nuclear Management Company 2001). McLean et al. (2002) reported that the magnitude of impingement at Maryland power plants with similar intake designs within Chesapeake Bay differed greatly according to the location of the intake.

Impingement at the Quad Cities plant in Illinois is often an order of magnitude higher from February through April than during summer and fall, even though the cooling water intake flow is only half that of the rest of the year (Bodensteiner and Lewis 1992). Impingement at Quad Cities was primarily composed of young-of-year and juveniles; in the case of gizzard shad (*Dorosoma cepedianum*) and freshwater drum (*Aplodinotus grunniens*), fish of these ages cannot tolerate near-freezing to freezing temperatures during winter and early spring. Other species, such as the bluegill (*Lepomis macrochirus*), channel catfish (*Ictalurus punctatus*), and white bass (*Morone chrysops*), are also prominent in winter impingement collections (Bodensteiner and Lewis 1992, 1994; LaJeone and Monzingo 2000). Although the number of fish impinged at Quad Cities was relatively high (e.g., nearly 3 million in 1989), most (up to 90 percent) of the fishes that entered the intake forebay were dead or moribund. Therefore, even if these fish were not impinged, they would have still been lost from the fishery (LaJeone and Monzingo 2000). Similar results have been noted for impingement of threadfin shad (*Dorosoma petenense*) at the McGuire plant in North Carolina (NRC 2002c) and gizzard shad at the Summer plant in South Carolina (NRC 2004b).

For the Pilgrim plant in Massachusetts, the NRC concluded that impingement during continued operation of the plant would have a MODERATE impact on the Jones River population of the rainbow smelt (*Osmerus mordax*) on the basis of an observed decline of that population, uncertainty about the stock's status, impingement rates, and low impingement survivability. Impingement had a SMALL to MODERATE impact on all other species (NRC 2007c).

For the Wolf Creek plant in Kansas, the NRC concluded that impingement during continued operation of the plant could have SMALL to MODERATE impacts at the makeup water screen house during periods when river water levels were low, because fish would have less available habitat to use as a refuge and would likely be exposed to greater pumping frequency and volume removals from the Neosho River. During most of the license renewal term, the impacts of impingement would be SMALL (NRC 2008a).

Various methods that have been used to reduce impingement include returning impinged fish to the water source, bypassing fish at the intake screens, and preventing the approach of fish to the intake area (Lieberman and Muessio 1978). Various deflection methods that have been used at power plants to reduce impingement include physical barriers, visual stimuli (e.g., air-bubble screens and static or strobe lights), water velocity and pressure changes, electrical shocks, and sound (Maes et al. 2004). These methods have variable effectiveness. For example, sound has been most effective at plants that primarily impinge clupeids

(Maes et al. 2004; Ross et al. 1993, 1996; NRC 2005a,b). Stocking, restoring habitat, and installing cooling towers are also mitigation options.

At the Surry plant in Virginia, about 94 percent of all fish impinged were returned alive to the river through the fish return system. Only five species had less than 80 percent survival. These were the spot (*Leiostomus xanthurus*), Atlantic menhaden (*Brevvortia tyrannus*), blueback herring (*Alosa aestivalis*), threadfin shad, and bay anchovy (*Anchoa mitchilli*) (NRC 2002d). These species generally are susceptible to physical injuries while impinged (e.g., because of their delicate scales). A mitigation program at St. Lucie involves Florida Power and Light Company periodically trapping fish from the intake canal, tagging them, and releasing them in the ocean. The goal is to tag and release 1000 fish per year (NRC 2003a). At the Calvert Cliffs plant in Maryland, about 5.25 million blue crabs (*Callinectes sapidus*) were impinged between 1975 and 1982, but impingement survival was 99 percent (NRC 1999b).

Physical stresses experienced by organisms during impingement are affected by screen wash frequency, screen rotation speed, and screen modifications intended to reduce stress associated with fish separation and handling. Low pressure spray is often used to return organisms to a water body, whereas high pressure spray is used for debris removal. When screens are infrequently washed, impinged organisms may become moribund from repeated attempts to free themselves and may suffocate against the screen (Jinks 2005). Generally, species with heavier skeletal structures, thick scales or bony scutes, thick protective slimes, or hard exoskeletons are most likely to resist physical injury and desiccation during impingement (Jinks 2005).

Although fish return systems can decrease impingement mortality, some stressed and injured fish returned to the water body may take a number of days to die. Even those with minor damage may develop a bacterial or fungal infection that eventually leads to mortality. Also, returned fish may be exhausted, disoriented, and damaged, which makes them more susceptible to predation (Henderson et al. 2003). Replacing conventional intake screens with Ristroph screens is unlikely to result in a significant reduction in impingement mortality at localities where clupeid and sciaenid species predominate (Henderson et al. 2003).

While planktonic organisms are generally not uniformly distributed throughout a water body, it is often assumed that withdrawal of a certain percentage of the source water would result in entrainment of that percentage of the planktonic organisms that pass by a plant (EPA 2002). At Browns Ferry in Alabama, the portion of the river flow that passed through the plant was found to be higher than the percentage of larval fishes in the river that were entrained (NRC 2005c). Fish species with free-floating early life stages are those most susceptible to entrainment (EPA 2002). For power plants (nuclear and fossil) located in the Great Lakes, the number of fish entrained increased with increasing power capacity (Kelso and Milburn 1979).

Entrained organisms are exposed to heat, mechanical, pressure, and chemical stresses (NRC 1996). Entrained organisms are exposed to a rapid temperature rise that is essentially equivalent to the temperature rise across the condensers during their passage through the plant (Schubel et al. 1977). It has been conservatively concluded that mortality of planktonic organisms is assumed to be 100 percent. For ichthyoplankton, this assumption is based on the extreme delicacy of eggs and the fact that their skeleton, musculature, and integument are soft, thereby providing only a minimal amount of protection for vital organs (EPA 2002). Nevertheless, these killed organisms provide food for consumers and decomposers in the receiving water body (Fox and Moyer 1973). Conversely, bacteria and other microorganisms that are entrained may increase in number as a result of prolonged exposure to increased heat (Fox and Moyer 1973; see Section 3.9.3). At the Quad Cities plant in Illinois, LaJeone and Monzingo (2000) concluded that as long as discharge temperatures do not exceed 100°F (37.8°C), some entrainment survival would occur.

Fish eggs and larvae have a high natural mortality rate; thus, the number of entrained ichthyoplankton that would have survived to become adult fish is much lower than the number of eggs and larvae entrained (EPA 2002). In a laboratory study on the exposure of larval common shrimp (*Crangon crangon*) and lobster (*Homarus gammarus*) and adult copepods (*Acartia tonsa*) to simulated entrainment stresses (i.e., thermal, mechanical, chlorine, and pressure effects, both alone and in combination), it was concluded that most individuals of each species would survive passage through a nuclear power station under normal operating conditions. Since the experiments on these crustaceans demonstrated that each species has different responses to different stressors, the only generalization that could be made is that mortality from the totality of entrainment passage would be 10 to 20 percent (Bamber and Seaby 2004).

Mitigation has been used to minimize entrainment losses. This includes several measures that also minimize impingement impacts (e.g., using closed-cycle cooling and designing intakes to minimize velocities through the intake screens). At the McGuire plant in North Carolina, about 45 percent of the cooling water is obtained from the low-level intake, which pulls water from the hypolimnion at a depth of about 100 ft (30 m), where few planktonic organisms occur. Therefore, entrainment is minimized (NRC 2002c). Skimmer walls inside the intake bays at the Robinson plant in South Carolina similarly reduce entrainment (NRC 2003b). At the Millstone plant, potential mitigation measures that were identified included reducing intake flows during the winter flounder (*Pleuronectes americanus*) spawning season; conducting regular inspections, maintenance, or refueling during the spawning season; importing fish into the areas; installing fine mesh screens on the intakes; or installing cooling towers (NRC 2005c).[b]

Section 316(b) of the CWA requires that the location, design, construction, and capacity of cooling water intake structures reflect the best technology available for minimizing impingement and entrainment of aquatic organisms. Section 316(b) is regulated under the NPDES program. Two rulemaking phases initiated by EPA associated with Section 316(b) are relevant to nuclear power plant cooling water intake structures. Phase I (enacted in December 2001) is for new facilities (40 CFR 125.83) with a design intake flow greater than 2 million gpd (7.6 million L/d) and that use at least 25 percent of water withdrawn used for cooling purposes (40 CFR Part 125, Subpart I). Phase II (enacted in July 2004) applies to existing large electric generating facilities with a design intake flow of 50 million gpd (189 million L/d) or more and that use at least 25 percent of the water withdrawn for cooling purposes (40 CFR Part 125, Subpart J). The Phase II Rule was suspended on July 9, 2007, after several of its key provisions were remanded by the U.S. Court of Appeals.

As of late 2012, existing nuclear power plant facilities with a cooling water intake structure that are not currently subject to a national rule require Section 316(b) NPDES permit conditions that reflect best technology available for minimizing adverse environmental impact on a case-by-case, best professional judgment basis (40 CFR 125.90(b) and 401.14). The NRC expects that any site-specific mitigation required under the NPDES permitting process should result in a reduction in the impacts of continued plant operations.

In the 1996 GEIS, the NRC categorized the impacts of license renewal on impingement and entrainment of aquatic organisms to be SMALL, MODERATE, or LARGE at plants with once-through cooling or cooling ponds (i.e., a Category 2 issue). No new information has been identified in the plant-specific SEISs prepared to date or in the literature that would alter those conclusions.

On the basis of these considerations, the NRC concludes that the impingement and entrainment of aquatic organisms over the license renewal term at nuclear plants with once-through cooling or cooling ponds could be SMALL, MODERATE, or LARGE and remains a Category 2 issue. The magnitude of the impact would depend on plant-specific characteristics of the cooling system (including location, intake velocities, screening technologies, and withdrawal rates) and

(b) The NRC cannot impose water quality mitigation requirements on licensees. The Atomic Safety and Licensing Appeal Board, in the “Yellow Creek” case, determined that the EPA has sole jurisdiction over the regulation of water quality with respect to the withdrawal and discharge of waters for nuclear power stations, and it also determined that the NRC is prohibited from placing any restrictions or requirements on the licensees of those facilities with regard to water quality (Tennessee Valley Authority [Yellow Creek Nuclear Plant, Units 1 and 2], ALAB-515, 8 NRC 702, 712-13 [1978]).

characteristics of the aquatic resource (including population distribution, status, management objectives, and life history).

Impingement and Entrainment of Aquatic Organisms (Plants with Cooling Towers)

Removal of any substantial volume of water from a natural body of water by a cooling system will likely also remove or kill some of the aquatic organisms that live there through impingement or entrainment. However, the number of individuals that could be removed from a population before detectable negative effects would occur is often not known. The potential for impingement and entrainment of aquatic organisms is influenced by a variety of factors such as:

- Amount of water withdrawn relative to the size of the cooling water source,
- Location and configuration of intake structures,
- Type of water body from which water is withdrawn and the conditions within that water body,
- Proximity of withdrawal structures to sensitive biological habitats (e.g., spawning and nursery habitats),
- Sensitivity of populations of impinged and entrained organisms to potential losses of individuals, and
- Mitigation measures in place to reduce impingement and entrainment.

Of these factors, the volume of water withdrawn relative to the size of the water source appears to be the best predictor of the number of organisms that would be impinged or entrained within a given aquatic system (Henderson and Seaby 2000). Because the volume of water withdrawn by a power plant is minimized when a closed-cycle cooling system is employed, the impacts to aquatic organisms from impingement and entrainment would be smaller than the impacts from impingement and entrainment that would occur if that plant employed a once-through cooling system instead.

In the 1996 GEIS, the NRC determined that impingement and entrainment of fish and shellfish was a Category 1 issue for plants with cooling towers, because the level of impingement and entrainment of fish and shellfish with this type of cooling system was not found to be a problem at operating plants, and was not expected to be a problem during the license renewal term (NRC 1996). This finding was also based on the lower rates of water withdrawal required for plants with cooling towers when operating in a closed-cycle mode. Withdrawal rates would not be reduced in situations where cooling towers are used in a helper mode to cool discharge temperatures under once-through operating conditions. These types of systems are included under the evaluation of once-through systems above.

In considering the impingement and entrainment effects of closed-cycle cooling systems on aquatic ecology, the NRC evaluated the same issues that were evaluated for plants with once-through cooling systems or cooling ponds. On the basis of reviews of the literature and license renewal SEISs published to date, reduced populations of aquatic biota attributable to occurrences of impingement and entrainment have not been reported for any existing nuclear power plants with cooling towers operated in closed-cycle mode.

On the basis of these considerations, the NRC concludes that the impingement and entrainment of aquatic organisms at plants with cooling towers operating as a closed-cycle cooling system over the license renewal term would be SMALL and remains a Category 1 issue.

Entrainment of Phytoplankton and Zooplankton (All Plants)

In addition to the entrainment of fish and shellfish in early life stages, the entrainment of phytoplankton and zooplankton was evaluated in the 1996 GEIS, and entrainment was categorized as a Category 1 issue for all cooling systems.

As described in the previous sections, water that is withdrawn for power plant cooling carries with it a variety of aquatic organisms. Those organisms that are small enough to pass through the debris screens in the intake pass through the entire cooling system and are exposed to heat, mechanical and pressure stresses, and possibly biocides before being discharged to the receiving water. This process, called entrainment, may affect phytoplankton and zooplankton, as well as planktonic larval stages of benthic organisms such as shellfish (i.e., meroplankton), and fish eggs and larvae (ichthyoplankton), as separately evaluated above. Most nuclear power plants have been required to monitor for entrainment effects during the initial years of operation. Entrainment impacts to phytoplankton and zooplankton are considered to be of SMALL significance if there is no evidence of reductions of populations of phytoplankton or zooplankton.

For example, about 70 percent of the copepod entrained at the Millstone plant in Connecticut suffered mortality, but this loss only represented 0.1 to 0.3 percent of the copepod production of eastern Long Island Sound (Carpenter et al. 1974). At the Calvert Cliffs plant in Maryland, entrainment survival for the five most abundant zooplankton species was 65 to 100 percent (NRC 1999b). Except for one sample (when discharge temperatures at the Cook plant in Michigan exceeded 95°F [35°C] and resulted in a 14 to 22 percent mortality difference in zooplankton), there was no relationship between zooplankton mortality and discharge water temperatures, suggesting that mechanical stress was the major cause of zooplankton entrainment mortality. During the period of the study, chlorination was infrequent because entrained sand provided sufficient scouring action to negate the need for biocides. The sand may have added to the mechanical stress experienced by entrained zooplankton. Zooplankton mortality was significantly greater in the discharge waters than the intake waters, but differences averaged less than 3 percent. Such small losses due to entrainment cannot be detected in the lake. It was concluded that fish predation rather than entrainment was the major source of zooplankton mortality in inshore waters during most of the year (Evans et al. 1986).

Entrainment of phytoplankton and zooplankton is expected to have a SMALL impact on populations of these organisms in source water bodies for all plants. No change in operation of the cooling system is expected during the license renewal term, so no change in effects on entrainment of phytoplankton and zooplankton is anticipated. Effects on entrainment of phytoplankton and zooplankton could be reduced by changing to a closed cycle cooling system or by reducing the plant's generation rate. However, because the effects on entrainment of phytoplankton and zooplankton are considered to be impacts of SMALL significance, this issue continues to be Category 1.

Effects of Thermal Discharges on Aquatic Organisms

During the license renewal term, thermal discharges from the cooling system would continue to affect aquatic resources. The potential impacts of thermal discharges are different for once-through and closed-cycle cooling systems as discussed below.

<u>Thermal Impacts on Aquatic Organisms (Plants with Once-Through Cooling Systems or Cooling Ponds)</u>

In the 1996 GEIS, the NRC found that for plants with a once-through cooling system or cooling ponds, the level of impact for thermal discharge on aquatic biota (primarily due to heat shock) was SMALL at many plants and MODERATE or LARGE at some nuclear plants. Because characteristics of both the thermal discharges and the affected aquatic resources are specific to each site, NRC classified heat shock as a Category 2 issue that required a site-specific assessment for license renewal. The NRC (1996) found the potential for thermal discharge impacts to be greatest at plants with once-through cooling systems (NRC 1996), primarily because of the higher discharge temperatures and larger thermal plume area compared to plants with cooling towers.

In the revised GEIS, the NRC assessed potential impacts of thermal discharges during the renewal term (the remaining years of the original license plus 20 additional years) by reviewing published applicant’s Environmental Reports, NRC’s license renewal SEISs, and the relevant scientific literature. For most nuclear plants involved in license renewal, NRC projected that the impact levels of thermal discharges during the license renewal term would be SMALL. The NRC found impact levels at the Crystal River plant, for example, to be SMALL to MODERATE. According to York et al. (2005), thermal discharges from the Diablo Canyon and San Onofre plants, both located on the California coast and employing once-through cooling systems, have had significant impacts on aquatic habitats. The NRC is reviewing the Diablo Canyon plant's application for license renewal, and the San Onofre plant has not submitted an application at the time of this review, so NRC has neither completely assessed impacts at these two plants nor assigned impact levels. Other site-specific considerations for thermal discharges during the license renewal term for plants with once-through cooling systems can occur for plants located in areas where restoration efforts are under way to increase natural resource populations or reestablish migratory fish species or where thermal discharge plumes could encompass otherwise high-quality habitats. Site-specific design features, such as locating the discharge structures in areas where warmer water would be rapidly diluted, may mitigate adverse thermal effects (Beitinger et al. 2000). Hall et al.'s (1978) finding that the potential for thermal discharge impacts is greatest in shallow, enclosed, and poorly mixed water bodies illustrates the site-specific influence of receiving water body characteristics on environmental impact.

One form of thermal impact is heat shock, which NRC defines as occurring when the water temperature meets or exceeds the thermal tolerance of a species for some duration of exposure (NRC 2007d). In most situations, fish are capable of moving out of an area that exceeds their thermal tolerance limits, although many aquatic resource species lack such mobility. Heat shock is typically observable only for fish species, particularly those that float when dead, so the following discussion emphasizes fish.

Some nuclear plants have reported occasional fish kills from heat shock. At the Pilgrim plant in Massachusetts, only two fish mortality incidents have been attributed to heat shock. In 1975, about 3,000 Atlantic menhaden (*Brevoortia tyrannus*) were killed, and in 1978, about 2,300 clupeids (schooling fish such as menhaden sardines, and shad (*Alosa* spp.)) were killed (NRC 2007d). At the McGuire plant in North Carolina, five dead striped bass (*Morone saxatilis*) were found in and near the discharge, although their deaths may or may not have been related to heat shock (NRC 2002c). Over 94,000 dead fish, mostly bluefill (*Lepomis macrochirus*), were killed when cooling lake temperatures near the La Salle County Station in Illinois exceeded upper lethal temperatures for most species (Exelon 2001c). Similar heat shock kills happened at the Braidwood Nuclear Station's cooling lake when about 1,000 fish, mostly gizzard shad (*Dorosoma cepedianum*), died (NRC 2005e); on July 22, 2001, when about 700 unidentified fish were killed (Exelon 2001b); and on June 28, 2005, when about 10,000 unidentified fish were killed (Exelon 2005).

Another form of thermal impact involves the sublethal effects from thermal discharges (e.g., stunning or disorientation) that could alter predator-prey interactions by increasing the susceptibility of affected individuals to predation. Schubel et al. (1977) concluded that the exposure of fish larvae (e.g., blueback herring (*Alosa aestvalis*), American shad (*A. sapidissima*), striped bass) to an excess of 59°F (15°C) would significantly increase their vulnerability to predation. However, the 1996 GEIS did not report population- or community-level effects from power plant influences on predator-prey relationships in the field, and such effects are difficult to prove from field studies. Organisms overwintering within thermal plumes can also experience chronic malnutrition (Hall et al. 1978). Thermal discharges can also increase the susceptibility of fishes to diseases and parasites as a result of a combination of the increased density of fish within the thermal plume (potentially leading to increased exposure to infectious diseases or other stresses), the fish being more prone to infection in warmer water, and the ability of diseases and parasites to develop faster at higher temperatures. Examples of other temperature-related impacts on aquatic resources could include the loss of smolt characteristics in salmon (McCormick et al. 1999) and premature spawning (Hall et al. 1978).

A number of mitigative measures can reduce thermal discharge effects. These include lowering the effluent temperatures before discharges reach the receiving water body (e.g., the cooling pond at the Dresden plant in Illinois or the cooling canal system at the Turkey Point plant in Florida) or enhancing rapid mixing and heat dissipation (e.g., high-velocity jet diffusers at FitzPatrick in New York) (NRC 1996). At the Surry plant in Virginia, the thermal discharge lies about 6 mi (9.7 km) upstream of the intake structure to protect downstream oyster beds from potential thermal discharge impacts (NRC 2002d). After several fish kills at the Summer plant in the 1980s, South Caroline Electric & Gas Co. removed a hump in the discharge canal, limited reservoir drawdowns, and dredged the discharge canal to reduce the likelihood of future fish kills (NRC 2004b).

The NRC (1996) concluded that the impact levels of heat shock on aquatic biota during the license renewal term could be SMALL, MODERATE, or LARGE at plants with once-through cooling or cooling ponds (i.e., a Category 2 issue). The present review identified no new information that would alter those conclusions for effects of thermal discharges in the plant-specific SEISs prepared to date or in other literature. Based on these considerations, the NRC concludes that the issue of thermal discharges on aquatic organisms at nuclear plants with once-through cooling systems or cooling ponds over the license renewal term could have SMALL, MODERATE, or LARGE impact levels and is a Category 2 issue. The impact level at any plant depends on the characteristics of its cooling system (including location and type of discharge structure, discharge velocity and volume, and three-dimensional characteristics of the thermal plume) and characteristics of the affected aquatic resources (including the species present and their physiology, habitat, population distribution, status, management objectives, and life history).

<u>Thermal Impacts on Aquatic Organisms (Plants with Cooling Towers)</u>

In the 1996 GEIS, the NRC determined that for plants with cooling towers, the effects of thermal discharges with respect to heat shock (i.e., the potential for heated effluents to directly kill aquatic organisms) was a Category 1 issue. This determination was made because thermal effects associated with this type of cooling system were not found to be a problem at operating plants and are not expected to be a problem during the license renewal term (NRC 1996). This finding was based, in part, on the presence of smaller thermal plumes at plants with closed-cycle cooling towers than would occur if a once-through cooling system was used at those plants. Other sublethal effects of thermal discharges are discussed and evaluated separately below (see Infrequency Reported Thermal Impacts (All Plants)).

In the 1996 GEIS, the NRC considered the impacts of thermal discharges on aquatic organisms during the license renewal term to be SMALL at nuclear plants with cooling towers (i.e., a Category 1 issue). No new information has been identified in the plant-specific SEISs prepared to date or in the literature that would alter those conclusions. On the basis of these considerations, the NRC concludes that the direct impact of thermal discharges on aquatic organisms at nuclear plants with cooling towers over the license renewal term would be SMALL and remains a Category 1 issue.

Infrequently Reported Thermal Impacts (All Plants)

In addition to the effects of heat shock as described above for plants with once-through cooling systems or cooling ponds and those using cooling towers, other potential effects common to the operation of plant cooling systems include cold shock, the creation of thermal plume migration barriers, changes in the distribution of aquatic organisms, accelerated development of aquatic insect maturation, and stimulation of the growth of aquatic nuisance species. The 1996 GEIS addressed these uncommon impacts individually; this revised GEIS consolidates them. The components of the consolidated issue are further described below.

Cold shock can occur when organisms acclimated to the elevated temperatures of a thermal plume are abruptly exposed to temperature decreases when the artificial source of heating stops. Such events are most likely to occur during winter. Cold shock events have only rarely occurred at nuclear plants (e.g., Haddam Neck [no longer operating], Prairie Island, Monticello, and Oyster Creek). Fish mortalities usually involved only a few fish and did not result in population-level effects (NRC 1996). Gradual shutdown of plant operations generally precludes cold shock events.

The potential exists for thermal plumes to create a barrier to migrating fishes if the mixing zone covers an extensive cross-sectional area of a river and exceeds the fish avoidance temperature (NRC 1996). For example, concerns were expressed that thermal discharge from the Vermont Yankee plant could affect both spawning and outmigration of American shad (*Alosa sapidissima*) and Atlantic salmon (*Salmo salar*) and potentially cause a reduction in Atlantic salmon smoltification, particularly since a hydroelectric facility was located immediately downstream of the plant and because the fish passage facility and thermal discharge were located on the same side of the river (NRC 2007a). In the 316(b) demonstration to support increased discharge temperature limits at the Vermont Yankee plant, it was determined that the smolts would not be delayed because the thermal plume covered only a small cross section of the Connecticut River. To date, significant impacts on migratory fishes have not been reported for nuclear power plants.

Impacts of thermal discharges on the geographic distribution of aquatic organisms are considered to be of SMALL significance if populations in the overall region are not reduced. Based on review of literature, operational monitoring reports, consultations with utilities and regulatory agencies, and license renewal SEISs published to date, thermal discharges have not been shown to constrain the regional geographic distribution of aquatic organisms at any existing nuclear power plant. This is because heat is usually dissipated rapidly from power plant discharge plumes, and heated plumes are often small relative to the size of the receiving water body.

Heated effluents could accelerate the development of immature stages of aquatic insects in freshwater systems, resulting in premature emergence. If adults emerge before the normal seasonal cycle, they may be unable to feed or reproduce. Premature emergence has been observed in laboratory investigations (e.g., Nebeker 1971) but not in field investigations (e.g., Langford 1975). Heated effluents could also stimulate population growth of macroinvertebrates. Thermal discharges from the Oconee plant in South Carolina stimulated the population growth of oligochaetes (aquatic worms) in the immediate vicinity of the power plant (less than 5 percent of the total cooling reservoir surface). However, the local changes in oligochaete populations could not be linked to the direct increases in water temperatures, but they may have been directly or indirectly affected by increases in zooplankton, vegetation, and current velocities in the area of the discharge (Nichols 1981).

An aquatic nuisance species is “a nonindigenous species that threatens the diversity or abundance of native species or the ecological stability of infested waters, or commercial, agricultural, aquacultural or recreational activities dependent on such waters” (Nonindigenous Aquatic Nuisance Prevention and Control Act of 1990). A wide variety of nuisance or non-native species may become established or proliferate as a result of power plant operations, including fouling organisms such as the Asiatic clam and the recently introduced zebra mussel. Aspects of the operation of the power plants (e.g., warm temperatures or high flow rates that bring food to filter-feeding organisms) may be conducive to the growth and development of these organisms. *Asiatic clams* and zebra mussels may become so abundant as to cause operational difficulties for the power plant and may out-compete native clams and mussels in thermally enriched waters. A population of tropical, nonnative blue tilapia (*Oreochromis aureus*) became established in the Susquehanna River in Pennsylvania by congregating in thermal effluents during the winter. Exposure to rapid temperature decreases (cold shock) killed these fish and eradicated the population from the vicinity of the plant.

Langford (1983) reports a number of instances in which wood-boring crustaceans and mollusks, notably “shipworms,” have caused concern in British waters. Although increased abundance of shipworms in the area influenced by heated power plant effluents caused substantial damage to wooden structures, replacement of old wood with concrete or metal structures eliminated the problem. Langford concluded that increased temperatures could enhance the activity and reproduction of wood-boring organisms in enclosed or limited areas but that elevated temperature patterns were not sufficiently stable to cause widespread effects.

Thermal discharges can allow nuisance species, such as the Asiatic clam (*Corbicula fluminea*) and zebra mussel (*Dreissena polymorpha*), to become established or proliferate (NRC 1996). At the North Anna plant in Virginia, the higher water discharges related to plant operation were found to increase the growing season of the water hyacinth (*Hydrilla verticillata*). Nuisance levels of this plant resulted. The water hyacinth was brought under control by stocking triploid (sterile) herbivorous grass carp (*Ctenopharyngodon idella*) (NRC 2002e).

The influence of the operation of Oyster Creek Nuclear Generating Station on abundance and distribution of a nonnative, tropical-subtropical, wood-boring shipworm (*Teredo bartschi*) has been extensively studied (see summary in Richards et al. 1984). Although numerous studies have varied somewhat in their conclusions, there is agreement that heated effluents from the plant increased the distribution and abundance of shipworms (Kennish et al. 1984). This species has not been found in Oyster Creek or Barnegat Bay since 1982, perhaps because of low water temperatures in Oyster Creek during a station outage in the winter of 1981–82 and the pathological effects of a parasite (GPU Nuclear Corporation response to a Nuclear Management and Resources Council [NUMARC] survey [NUMARC 1990]). In addition, the removal of substantial amounts of driftwood and the replacement of untreated structural wood is thought to have contributed to reducing the populations of wood-boring organisms in Oyster Creek. No other concerns about nuisance organisms were cited by the regulatory or resource agencies contacted for this GEIS revision (Appendix F). Measures taken by licensees to control nuisance species (e.g., increased chlorination or use of molluscicides) may result in impacts on other species. This impact is also controlled by NPDES permitting procedures.

The effects of stimulating the growth of nuisance organisms are considered to be of SMALL significance to aquatic resources if these organisms are restricted to the condenser cooling system (e.g., Asiatic clam; zebra mussel) or do not proliferate beyond the immediate vicinity of the plant. Mitigation measures were effective at the one plant that experienced problems with nuisance organisms (e.g., shipworms). Effects on nuisance organisms could be reduced by changing to a closed-cycle cooling system or by reducing the plant’s generation rate, but, based on the review conducted by NRC for this GEIS revision, NRC categorizes the impact level as SMALL and would expect it to be SMALL for all plants.

The NRC's review revealed only small levels of impact in the aquatic resources due to the infrequently reported thermal impacts and expects the same at all plants. As a result, NRC classifies this combined issue as Category 1.

Effects of Cooling Water Discharge on Dissolved Oxygen, Gas Supersaturation, and Eutrophication

The potential effects on aquatic biota from low dissolved oxygen levels, gas supersaturation (gas bubble disease), and eutrophication in the cooling water discharge of nuclear power plants were identified as Category 1 issues in the 1996 GEIS. These three issues are combined and discussed together here.

The availability of oxygen is a requirement for the metabolism of aerobic organisms. It also influences inorganic chemical reactions. For aquatic organisms with gills, the concentration of dissolved oxygen in the water is one of the most important parameters to consider for evaluating water quality. In general, dissolved oxygen concentrations of less than 3 ppm in warmwater habitats or less than 5 ppm in coldwater habitats can adversely affect fish (Morrow and Fischenich 2000). Oxygen dissolves into water via diffusion from the surrounding air, by aeration (i.e., mixing with atmospheric air due to turbulent movement of the water), and as a product of photosynthesis. The level of dissolved oxygen in water is highly dependent on temperature, and the amount of oxygen that can dissolve in a given volume of water (i.e., the saturation point) is inversely proportional to the temperature of the water. Thus, when other chemical and physical conditions are equal, the warmer the water is, the less dissolved oxygen it can hold. An increase in water temperature also affects the amount of oxygen that aquatic organisms need by increasing the chemical reaction rates and metabolic rates. The rates of many chemical reactions in water approximately double for every 18°F (10°C) increase in temperature. Thus, the addition of a heat load to an aquatic ecosystem via the discharge of cooling water has the potential to stress aquatic biota by simultaneously increasing metabolic rates and the need for oxygen and by reducing dissolved oxygen concentrations to suboptimal levels.

The potential for effects on biota from a reduction in the dissolved oxygen concentration is greater in ecosystems where dissolved oxygen levels are already approaching suboptimal levels as a result of other factors that affect the environment. Thus, organisms in ecosystems where (1) the biological demand for dissolved oxygen is elevated as a result of increased levels of detritus or nutrients (e.g., eutrophication from runoff containing fertilizers or manure or from the release of dead, entrained organisms in the discharge of once-through cooling systems) or (2) low flow levels and high ambient temperatures already exist (e.g., as a result of drought conditions or hot weather) may be more susceptible to negative effects if dissolved oxygen levels are reduced further. For this reason, the EPA and States often regulate dissolved oxygen to ensure that minimum levels will be maintained. The following discussion focuses on dissolved oxygen because it directly affects aquatic resources rather than focusing on the contributing causes of low dissolved oxygen levels associated with cooling water system operation (e.g., eutrophication due to increased temperature, lower dissolved oxygen capacity with increased temperature, higher biological oxygen demand (BOD), and chemical oxygen demand (COD) with increased temperature, etc.).

After cooling water is discharged, additional oxygen dissolves in the water as a result of diffusion and the introduction of oxygen released by aquatic plants and algae as a by-product of photosynthesis (during daylight hours only). The saturation point for the water increases as it cools, and aeration due to turbulent movement can further increase the rate of oxygenation. For these reasons, effects on aquatic biota due to low dissolved oxygen levels are not expected to extend beyond the thermal mixing zone. Thus, even in cases where dissolved oxygen levels in the immediate vicinity of the discharge structures of power plants may be too low to support some aquatic biota, the amount of aquatic habitat affected is typically small relative to that available in the receiving water body as a whole. Discharge systems are typically designed to minimize the affected area by promoting mixing of introduced warmer water with ambient water from the receiving system, by increasing turbulence near the discharge point, or by introducing air into the water.

The impacts of low dissolved oxygen concentrations in the discharge are considered to be of SMALL significance if populations of aquatic organisms in the vicinity of the plant are not reduced. On the basis of reviews of literature and operational monitoring reports, dissolved oxygen concentrations have been adequate for maintaining aquatic ecosystems in the water bodies that receive cooling water from currently operating nuclear power plants. Operational mitigation measures (increasing the oxygenation of water released from an upstream dam) have been effective at the one plant (Sequoyah plant in Tennessee) for which periodic low dissolved oxygen levels in the receiving water (Chickamauga Reservoir) were identified as potentially affecting downstream mussel beds and sauger (*Sander canadensis*) reproduction during the initial license term.

In addition to the effects of cooling systems on dissolved oxygen described above, rapid heating of water in the condenser cooling system also decreases the solubility and saturation point for other dissolved gases. Thus, as the water passing through the cooling system is heated, the water becomes supersaturated with gases. Although the levels of dissolved gases will equilibrate to normal values as the water cools and mixes with ambient waters, tissues of aquatic organisms that remain in the supersaturated effluent for extended periods can become equilibrated to the increased partial pressures of gases within the effluent. If these organisms are subsequently exposed to water with lower partial pressures (which occurs when the water cools or when the organisms move to water in other locations or at other depths), dissolved gas (especially nitrogen) within the tissues may come out of solution and form embolisms (bubbles) within the affected tissues, most noticeably the eyes and fins. The resulting condition is known as gas bubble disease. Swelling and hemorrhages in tissues can cause behavioral abnormalities or death, depending on the number of bubbles that form and the tissues that are affected (Noga 2000). Fish mortalities generally occur at gas supersaturation levels above 110 to 115 percent (EPA 1986). Aquatic insects and crustaceans appear to be more tolerant of supersaturated water than fish (Nebeker et al. 1981).

The ability to detect and avoid supersaturated waters varies among species. A fish can avoid supersaturated waters by either not entering the affected area or by diving to avoid the onset of supersaturated conditions near the surface. Some species, however, may not avoid supersaturated waters until symptoms of gas bubble disease occur; at that point, some fish may already have been lethally exposed. Other species may be attracted to supersaturated waters due to stimuli such as warmwater discharges (Gray et al. 1983).

Gas supersaturation and gas bubble disease have resulted in the death of fish in the discharge of some steam-electric power plants, as has been reported in the past from the Pilgrim plant in Massachusetts (NRC 1996, 2007c). Gas supersaturation and gas bubble disease are also commonly associated with hydroelectric dams, typically resulting when water that is mixed with air while traveling over spillways is subsequently pushed to depth within stilling basins (Parametrix, Inc. 1975). The death of organisms due to gas supersaturation in heated effluents from power plants appears to be most likely at plants that have discharge canals where fish may reside for extended periods of time (i.e., long enough to equilibrate with supersaturated effluents). Gas solubility tends to increase with decreases in water temperatures; therefore, gas bubble disease at steam-electric stations would be most likely to occur during winter months (McInerny 1990). As reported in the 1996 GEIS, observed incidences of gas bubble disease at the Waukegan Generating Station (a coal-fired plant on Lake Michigan), Marshall Steam Station (a coal-fired plant on Lake Norman), and the Pilgrim plant involved fish residing in discharge canals. At the Pilgrim plant, the loss of approximately 43,000 Atlantic menhaden in 1973 was attributed to gas bubble disease (McInerny 1990), and other species of fish may also have been affected (Fairbanks and Lawton 1977). Promoting the rapid mixing of effluents with receiving waters (e.g., with jet diffuser systems) appears to effectively prevent such mortalities by inhibiting residence of organisms in the thermal plume (Lee and Martin 1975) and by limiting the extent of the area where supersaturated conditions may occur. Restricting entry of fish into discharge canals may also be effective at controlling mortality. A fish barrier net was installed in the discharge canal at the Pilgrim plant after the mortality events observed during the 1970s, although subsequent implementation of engineering controls have mitigated conditions so that the use of the net has not been required since then.

Impacts from gas supersaturation are considered to be of SMALL significance if populations of aquatic organisms in the vicinity of the plant are not reduced. On the basis of reviews of the available scientific literature, plant-specific ERs, and the SEISs that have been completed to date, deaths of aquatic organisms attributable to gas supersaturation have not been a concern at most existing nuclear power plants. Operational and structural mitigation measures have been effective at controlling effects on fish at the Pilgrim plant, where fish kills attributable to gas supersaturation occurred during the initial license period. In no case has a substantial effect on populations of aquatic organisms been observed. Use of engineering controls (e.g., use of jet diffusers for cooling water discharge systems) that prevent the occurrence of mortality due to gas bubble disease at individual power plants also reduces the likelihood that discharges from cooling systems would contribute to cumulative effects.

Unless the operation of the cooling system or the ambient conditions that affect levels of dissolved oxygen or gas supersaturation in the receiving waters were to change substantially, it is anticipated that there would be no change in effects of low dissolved oxygen concentrations or gas supersaturation on aquatic biota during the license renewal term. Overall, effects of low dissolved oxygen concentrations and gas supersaturation attributable to cooling water discharges are considered to be of SMALL significance for all plants.

For some plants, the potential for effects of low dissolved oxygen concentrations or gas supersaturation on aquatic resources could be further reduced by changing from a once-through cooling system to a closed-cycle cooling system or by reducing the plant's generation rate. However, because the continued effects of operations on dissolved oxygen concentrations and gas supersaturation are considered to be of SMALL overall significance to populations of aquatic resources and because implementation of these changes would be costly, it is believed that such changes are not warranted on the basis of controlling levels of dissolved gases. Impacts of license renewal on dissolved oxygen levels and on the incidence of gas bubble disease were considered to be SMALL for all nuclear plants and were designated as Category 1 issues in the 1996 GEIS. No new information has been identified in the plant-specific SEISs prepared to date or in the literature that would alter those conclusions.

On the basis of these considerations, the NRC concludes that the impact on aquatic biota from the alteration of dissolved oxygen levels and gas supersaturation associated with continued operations over the license renewal term would be SMALL for all nuclear plants and remains a Category 1 issue.

Effects of Nonradiological Contaminants on Aquatic Organisms

The potential for nonradiological contaminants to accumulate in sediments or aquatic biota was identified as a Category 1 issue in the 1996 GEIS. This was originally raised as an issue of concern at a few power plants that used copper alloy condenser tubes, but this concern has been successfully mitigated by replacing copper alloy tubes with those made from other metals (e.g., titanium). An operating nuclear power plant can contribute other contaminants by concentrating existing constituents from the water body (e.g., in blowdown at closed-cycle plants) or by the addition of chemicals to cooling water during plant operations (e.g., biocides).

Biocides are used in cooling water systems to prevent the buildup of microorganisms that can impede heat transfer across heat exchange surfaces. Biocides are also used to prevent excessive growth of algae or other organisms that attach to structures, which can reduce cooling water flow by blocking pipes, tubing, and other water conveyances. For example, zebra mussels and Asiatic clams within the intakes or cooling systems of power plants can cause partial to total blockage of grates and pipes or cause damage to pipes and facilities, requiring the plants to temporarily suspend operations in order to remove the blockage or repair the damage. To prevent this from happening, plants in areas where these mollusks occur generally use nonoxidizing molluscicides (e.g., quaternary ammonium salts, glutaraldehyde, isothiazoline, triazine, and carbamates). The amount of a biocide that is applied to the cooling waters is controlled so that the concentrations that are discharged from the cooling system are too low to cause adverse effects to native mussels in the receiving water body. Allowable concentrations for biocides in discharged cooling waters are governed by NPDES permit restrictions to reduce the potential for toxic effects on nontargeted organisms (e.g., native mussels and fishes). At the Browns Ferry plant in Alabama, small sponge rubber balls are continuously recirculated through the condenser tubes to keep them clear of Asiatic clams and thus reduce the use of molluscicides (NRC 2005c). Also, various means can be used to minimize the discharged concentrations of biocides in the blowdown, including closing the blowdown valve before biocides are added, discharging blowdown to large sediment or retention ponds, and dechlorination (Veil et al. 1997).

As reported in the 1996 GEIS, heavy or toxic metals (e.g., copper, zinc, and chromium) may be leached from condenser tubing and other heat exchangers and discharged by power plants as small-volume waste streams or corrosion products. Although heavy metals are found in small quantities in natural waters (and many are essential micronutrients), concentrations in the power plant discharge are typically controlled in the NPDES permit because excessive concentrations of heavy metals can be toxic to aquatic organisms. Discharge of metal and other toxic contaminants may also be subject to individual control strategies developed by the States to control toxic pollutants under the CWA. These strategies for point source discharges of toxic pollutants are implemented through the NPDES permit program. Heavy metal concentrations in discharges during normal operations are generally low. However, reactor shutdowns for testing and refueling keep stagnant water in contact with condenser tubes and other metal structures for extended periods and may allow abnormally large amounts of metals to be leached into the water.

The ability of aquatic organisms to bioaccumulate heavy metals, even at low concentrations, has led to concerns about toxicity both to the humans and biota that consume contaminated fish and shellfish. For example, the bioconcentration of copper discharged from the Chalk Point plant (a fossil fuel power plant on Chesapeake Bay) resulted in discoloration (“greening”) effects on eastern oysters (*Crassotrea virginica*) (Roosenburg 1969), and the bioaccumulation of copper released from the Robinson plant in South Carolina resulted in malformations and decreased reproductive capacity among bluegill in the cooling reservoir. Replacement of copper alloy tubes with tubes made from other metals (e.g., titanium) alleviated the elevated copper levels in both of these cases (NRC 1996, 2003b).

Concentrations of heavy metals and other contaminants in the discharges of nuclear power plants are normally quickly diluted or flushed from the area by the large volumes of the receiving water. The discharge of metals and other toxic contaminants may also be subject to controls implemented by State or Federal agencies through the NPDES permit process. Impacts of contaminant discharges are considered to be of SMALL significance if water quality criteria (e.g., NPDES permits) are not violated and if aquatic organisms in the vicinity of the plant are not bioaccumulating the contaminants.

The accumulation of contaminants in sediments and biota was designated as a Category 1 issue in the 1996 GEIS. No new information has been identified in plant-specific SEISs prepared to date or in the reviewed literature that would alter those conclusions. However, this issue has been modified to look at contaminant effects other than accumulation. As long as changes to the cooling system, such as during refurbishment, do not occur during the license renewal term and the discharge requirements of the NPDES permit are met, no impact of contaminants on aquatic biota would be anticipated. On the basis of these considerations, the NRC concludes that the impact of contaminants on aquatic organisms associated with continued operations and refurbishment would be SMALL for all nuclear plants and remains a Category 1 issue.

Exposure of Aquatic Organisms to Radionuclides

The potential impact of radionuclides on aquatic organisms from normal operations of a nuclear power plant during the license renewal term was not identified as an issue in the 1996 GEIS. However, the impact of radionuclides on aquatic organisms has been raised as an issue by the public for several of the plants that have undergone license renewal, and that issue is reviewed here.

Aquatic biota can be exposed externally to ionizing radiation from radionuclides in water, sediment, and other biota, and aquatic biota can be exposed internally via ingested food and water and, in certain situations, absorption through the skin and respiratory organs (Blaylock et al. 1993). No evidence of significant differences in sensitivity to radionuclides between marine and freshwater organisms has been reported (Blaylock et al. 1993). Some radionuclides tend to follow pathways similar to their nutrient analogs and can therefore be transferred rapidly through the food chain. These include (1) radionuclides such as strontium-90, barium-140, radon-226, and calcium-46 that behave like calcium and are therefore accumulated in bony tissues; (2) radionuclides such as iodine-129 and iodine-131 that act like stable iodine and accumulate in thyroid tissue; (3) radionuclides such as potassium-40, cesium-137, and rubidium-86 that follow the general movement of potassium and can be distributed throughout the body; and (4) radionuclides such as tritium, which resembles stable hydrogen, that are distributed throughout the body of an organism (Ahier and Tracy 1995).

Fish, especially developing eggs and young, appear to be the aquatic organisms that are the most sensitive to the effects of ionizing radiation, while phytoplankton and zooplankton are relatively resistant to effects from exposure (NCRP 1991; Blaylock et al. 1993). DOE's guideline for radiation dose rates from environmental sources recommends limiting the radiation dose to aquatic biota to no more than 1 rad/d (0.01 Gy/d). As described in Blaylock et al. (1993), this guideline was derived by reviewing the results of experimental data (NCRP 1991) that indicated there would not be any negative population-level effects on aquatic biota at doses up to 1 rad/d (0.01 Gy/d). That review reported that significant histological effects on the gonads of small tropical fish were detected at a dose of 1 rad/d (0.01 Gy/d), although the majority of controlled studies that examined the potential chronic effects of ionizing radiation on aquatic organisms did not find significant effects unless the dose was much greater than 1 rad/d (0.01 Gy/d) (NCRP 1991). Real et al. (2004) summarized several chronic irradiation studies on fish (mostly from gamma radiation at dose rates of 0.2 to 120 rad/d [0.02 to 1.2 Gy/d]) that reported effects, such as lowered fecundity, delayed spawning, reduced testis mass and sperm production, reduced immune response, reduced larval survival, and increased vertebral anomalies. They concluded that dose rates of less than approximately 10 rad/d (0.1 Gy/d) to any life stage are unlikely to affect survival (Real et al. 2004). Kryshev and Sazykina (1998) reported that ecological effects of ionizing radiation on aquatic biota occur at dose rates between 0.2 and 80,000 rad/d (0.002 and 800 Gy/d)]. For comparison, Brown et al. (2004) used models to estimate doses to aquatic biota from naturally occurring radionuclides as ranging from 0.00024 to 0.11 rad/d (2.4×10^{-6} to 1.1×10^{-3} Gy/d) for European freshwater ecosystems and 0.00024 to 0.06 rad/d (2.4×10^{-6} to 6.0×10^{-4} Gy/d) for European marine waters.

Dose rates for aquatic biota were calculated with the RESRAD-BIOTA dose evaluation model (DOE 2004e) using site-specific radionuclide concentrations in water and sediments reported in the REMP reports for 15 NRC-licensed power plants (Table 4.6-5). (See Section D.5 in Appendix D for a description of the methodology used.) These 15 plants represent plants with a range of radionuclide concentrations in environmental media. The total estimated dose rates for aquatic biota for these plants were all less than 0.2 rad/d (0.002 Gy/d), considerably less than the guideline value of 1 rad/d (0.01 Gy/d). Thus, it is anticipated that normal operations of these facilities would not result in negative effects on aquatic biota. Effects on populations of aquatic biota from such doses would be SMALL. A 25-year study of gamma-ray-emitting radionuclide levels near the Susquehanna plant in Pennsylvania indicated that there have been no known environmental impacts on aquatic resources (Patrick et al. 2007). On the basis of the reviewed literature and the dose rates that have been estimated for aquatic biota from site-specific data, the NRC concludes that the impact of radionuclides on aquatic biota from past operations would be SMALL for all plants, and it would not be expected to change appreciably during the renewal

Table 4.6-5. Estimated Radiation Dose Rates to Aquatic Animals from Radionuclides Measured in Water and Sediments at U.S. Nuclear Power Plants

	Estimated Dose Rates (rad/d)[a]		
Plant	**Water**	**Sediment**	**Total**
Arkansas Nuclear	1.87×10^{-4}	1.98×10^{-6}	1.89×10^{-4}
Browns Ferry	1.43×10^{-2}	2.88×10^{-5}	1.43×10^{-2}
Calvert Cliffs	1.53×10^{-7}	1.09×10^{-10}	1.54×10^{-7}
Columbia	5.01×10^{-2}	2.17×10^{-5}	5.01×10^{-2}
Comanche Peak	5.82×10^{-2}	1.03×10^{-4}	5.83×10^{-2}
D.C. Cook	5.01×10^{-2}	1.46×10^{-4}	5.02×10^{-2}
Hatch	5.02×10^{-2}	1.22×10^{-5}	5.02×10^{-2}
Fort Calhoun	1.06×10^{-1}	5.71×10^{-6}	1.06×10^{-1}
Indian Point	5.01×10^{-2}	2.03×10^{-5}	5.01×10^{-2}
Millstone	5.02×10^{-2}	5.73×10^{-4}	5.08×10^{-2}
Nine Mile Point	5.02×10^{-2}	1.02×10^{-5}	5.02×10^{-2}
Palisades	1.34×10^{-7}	3.65×10^{-6}	3.78×10^{-6}
Point Beach	2.67×10^{-3}	2.73×10^{-4}	2.95×10^{-3}
San Onofre	1.12×10^{-2}	3.00×10^{-4}	1.15×10^{-2}
Vermont Yankee	5.02×10^{-2}	1.11×10^{-3}	5.13×10^{-2}

(a) Dose rates were estimated with RESRAD-BIOTA (DOE 2004e) by using site-specific radionuclide concentrations in water and sediments obtained from REMP reports.

period. Therefore, the impact of radionuclides on aquatic biota that would result from continued operations is considered a Category 1 issue.

Effects of Dredging on Aquatic Organisms

Dredging is an activity that is performed at some power plants to remove accumulated sediments from intake and discharge areas (or, more rarely, to maintain barge slips) and may have localized impacts on aquatic biota. The impacts of dredging were not evaluated in the 1996 GEIS.

Sediment (especially sand and silt) that enters water bodies through the process of erosion can accumulate and gradually fill in some areas. Because of this, maintenance dredging may be required at some power plants to keep cooling water intakes and discharges clear of sediment

(Allen et al. 2004; NRC 2007b,c). Dredging may also occur as part of power plant operation to maintain appropriate water circulation in water bodies that provide cooling water (e.g., at the Millstone plant; NRC 2005c) or to maintain access for barges (e.g., at the Calvert Cliffs plant in Maryland; NRC 1999b). Dredging can be accomplished in a number of ways (e.g., using various types of mechanical or hydraulic dredges), but it generally entails excavating a layer of sediment from the affected areas and transporting it to onshore or offshore areas for disposal.

Dredging can affect aquatic biota in a variety of ways. Except for some deep-burrowing animals or motile animals, such as larger crustaceans and fish, that may survive dredging through avoidance, it is assumed that organisms living on or in the affected sediments will be killed. Sediments suspended in the water column during dredging activities may settle onto and bury adjacent habitats, clog the feeding structures of filter-feeding organisms, or reduce light penetration. The potential for impacts on aquatic organisms as a result of direct effects of suspended sediment depends on the types of organisms present in the affected area, the amount and particle sizes of the sediment, and the duration of dredging activities (Nichols et al. 1990; Wilber and Clarke 2001).

The recovery of benthic communities in habitats disturbed by dredging depends, in part, on the characteristics of the remaining sediments (Diaz 1994; Haynes and Makarewicz 1982), the sources and types of organisms available to recolonize from surrounding areas, and the size of the disturbed area (Whitlatch et al. 1998). In soft-sediment environments, such as those that are most likely to require dredging in the vicinity of power plant intakes, recovery of animal communities generally occurs relatively quickly (sometimes within weeks) especially if the dredged areas are relatively small (e.g., Diaz 1994). In some cases, however, recovery of benthic communities may take several years (e.g., Kaplan et al. 1975; Guerra-García et al. 2003). Recovery of benthic communities following dredging also tends to be faster in areas exposed to periodic disturbances, such as tidally influenced habitats (Diaz 1994).

Sediments in and around cities and industrial areas are often contaminated with a variety of pollutants. These pollutants are introduced to waterways from point sources such as combined sewer overflows, municipal and industrial discharges and spills, or may be introduced from nonpoint sources such as surface runoff and atmospheric deposition. Contaminants that have accumulated in buried layers of sediment are often less readily bioavailable or less chemically active (EPA 2004). Depending on the concentrations of specific contaminants in accumulated sediments, there could be increased bioavailability and increased toxicity of those contaminants if they are resuspended in the water column due to dredging activities (Petersen et al. 1997; Su et al. 2002; EPA 2004). On the basis of a review of the information in the ERs and SEISs that have been prepared for previous renewal applications, the levels of chemical and radionuclide contamination of sediments in the areas near power plant intakes and discharges that would need to be dredged are likely to be relatively low. For example, as reported in the

SEIS for license renewal for the Pilgrim Nuclear Power Station in Massachusetts, the toxicity of sediments to marine organisms, which was evaluated prior to dredging the intake channel, was found to be low (NRC 2007c).

In general, maintenance dredging for nuclear power plant operations would occur infrequently, would be of relatively short duration, and would affect relatively small areas. For example, at the Peach Bottom Atomic Power Station in Pennsylvania, it is estimated that dredging of the intake basins is performed approximately once every 20 years and a total area of approximately 6 ac (2.4 ha) would need to be dredged (NRC 2003a). Portions of either the intake or the discharge canals at the Oyster Creek Nuclear Generating Station in New Jersey have been dredged approximately every 10 years (NRC 2007b), and the intake area for the Monticello Nuclear Generating Plant in Minnesota requires dredging every 6 to 8 years (NRC 2006c). It is anticipated that maintenance dredging would be primarily undertaken in areas containing soft sediments that would be recolonized fairly rapidly by benthic organisms in surrounding areas. In addition, permits from the USACE, State environmental agencies, or other applicable regulatory authorities would be required prior to initiating dredging. Site-specific evaluation of potential environmental impacts, including potential impacts on listed species of aquatic organisms, would be considered as part of the permitting process, and appropriate mitigation measures, if needed, could be identified and implemented.

Available scientific literature, plant-specific ERs, and the SEISs that were reviewed indicate that the effects of these dredging activities on populations or communities of aquatic organisms would likely be SMALL at all plants where they occur. On the basis of these considerations, the NRC concludes that the impact of dredging on aquatic resources would be SMALL for all nuclear plants and is considered a Category 1 issue.

Water Use Conflicts with Aquatic Resources (Plants with Cooling Ponds or Cooling Towers Using Makeup Water from a River)

In the 1996 GEIS, water use conflicts was listed as a site-specific, surface water quantity issue that included within it ecological impacts on aquatic and riparian communities. The NRC separated out the ecological impacts in this revised GEIS because the effects of water use conflicts on aquatic resources in stream communities could occur under many scenarios.

Increased temperatures and/or decreased rainfall would result in lower river flows, increased cooling pond evaporation, and lowered water levels in the Great Lakes or reservoirs. Regardless of overall climate change, droughts could result in problems with water supplies and allocations. Because future agricultural, municipal, and industrial users would continue to share their demands for surface water with power plants, conflicts might arise if the availability of this resource decreased.

Water use conflicts with aquatic resources could occur when water to support these resources is diminished either because of decreased water availability due to droughts; increased demand for agricultural, municipal, or industrial usage; or due to a combination of such factors. Water use conflicts with biological resources in stream communities is a concern due to the duration of license renewal and potentially increasing demands on surface water.

For example, Wolf Creek uses Coffee County Lake for cooling (NRC 2008a). Makeup water for the lake is withdrawn from the Neosho River downstream of John Redmond Reservoir. The Neosho River is a river with low water flow during drought conditions. The aquatic communities in the Neosho River downstream include an endangered fish species, the Neosho madtom (*Noturus placidus*), that may be affected by the plant's water use during periods when the lake level is low and makeup water is obtained from the Neosho River. For the Wolf Creek plant, the water use conflict impact is SMALL to MODERATE and a site-specific condition. For future license renewals, the potential range of impact levels at plants with cooling ponds or cooling towers using makeup water from a river with low flow cannot be determined at this time. The impact of water use conflicts with stream communities is considered a plant-specific Category 2 issue.

Effects on Aquatic Resources (Non-Cooling System Impacts)

Impacts on aquatic resources from continued operations and refurbishment activities could occur at all operating nuclear power plants during the license renewal term as a result of (1) direct disturbance of aquatic habitats within project areas, (2) sedimentation of nearby aquatic habitats as a consequence of soil erosion, (3) changes in water quantity or water quality (e.g., grading that affects surface runoff patterns or depletions or discharges of water into aquatic habitats), or (4) releases of chemical contaminants into nearby aquatic systems. In some cases, impacts have a potential to continue to occur throughout the period covered by license renewal. In the 1996 GEIS, the NRC considered only the impact of refurbishment on aquatic habitats and concluded that the impact would be SMALL for all nuclear plants (i.e., a Category 1 issue).

The surface area disturbed during construction of new waste storage facilities (e.g., ISFSIs) would be expected to range from about 2.5 to 10 ac (1 to 4 ha). Other supporting activities that could occur at specific sites may include the construction of new parking areas for plant employees, utility corridors, access roads, or new buildings or facilities, or the demolition of existing buildings. Land used for equipment storage, worker parking, and material laydown areas could result in disturbance to aquatic resources within the plant boundaries. Surface water habitats could also be affected by draining ponds, blocking or redirecting streams, or placing rip-rap along shorelines. Depending on the size and nature of the water body, and other project-specific aspects, organisms within the affected habitats could be displaced or killed, or the community structure within the water body could be altered.

The potential for soil erosion and sediment loading of nearby aquatic habitats is typically proportional to the amount of surface disturbance, erosion potential of the soil, slope, condition of disturbed areas at any given time, and proximity to aquatic habitats. Ground-disturbing activities have a higher erosion potential. Mitigation measures include controlling surface runoff with ditches, berms, and sedimentation basins; prompt revegetation to control erosion; stockpiling and reusing excavated topsoil; and various other techniques used to control soil erosion and water pollution. These mitigation measures (often referred to as BMPs) are expected to be implemented as part of project activities undertaken during the license renewal term to minimize impacts on surface water quality and aquatic resources.

During refurbishment, effluent discharges from the cooling system of a nuclear power plant would either remain similar to those occurring during normal operations during refurbishment or would decrease if the plant was partially or totally shut down. Consequently, effects of changes in water withdrawals and discharges during refurbishment would be of SMALL significance. The impact on aquatic biota from water use would not be expected to substantially change during refurbishment or maintenance activities from the impact during existing operations.

During ground-disturbing activities, contaminants could enter aquatic habitats as a result of runoff from project sites or from accidental releases of fuels or lubricants. The level of impacts from releases of toxicants would depend on the type and volume of chemicals entering the waterway, the location of the release, the nature of the water body (e.g., size, volume, flow rates, and water chemistry), and the types and life stages of organisms present in the affected area. In general, lubricants and fuel would not be expected to enter waterways as long as construction machinery and fuel storage areas and fueling locations were located away from water bodies, and spill prevention and control measures are in place.

Obstructions to fish movement could occur in streams with low flows. Restrictions on fish movement would likely be most significant if they occurred in streams that supported species that need to move to specific areas in order to reproduce.

The impact of refurbishment on aquatic habitats was evaluated in the 1996 GEIS and considered a Category 1 issue. Permits from various Federal, State, and local governmental authorities are typically required for ground-disturbing activities. For example, refurbishment may require the issuance of permits under Section 404 of the CWA if the activities were to directly affect aquatic habitats. With proper application of environmental reviews, permitting processes, and BMPs, impacts on sensitive aquatic habitats would likely be avoided. The NRC concludes that the impact of continued operations and refurbishment activities on aquatic resources is SMALL and is considered a Category 1 issue.

Impacts of Transmission Line ROW Management on Aquatic Resources

Impacts on aquatic resources from transmission line ROW management could occur as a result of the direct disturbance of aquatic habitats, soil erosion, changes in water quality (from sedimentation and thermal effects), or inadvertent releases of chemical contaminants from herbicide use. These impacts could occur throughout the license renewal term. The NRC did not evaluate the impact of transmission line ROW maintenance on aquatic biota in the 1996 GEIS, but this issue has been identified by the NRC for consideration in this GEIS revision on the basis of past environmental reviews conducted for plant-specific SEISs.

Water quality impacts could result from maintaining transmission line ROWs and, as necessary, service roads. Where access roads cross or border on surface waters, soil erosion could cause elevated turbidity and sedimentation. Application of appropriate control techniques (e.g., establishing and maintaining vegetated buffer strips between the road and the body of water) would reduce impacts. Because ROWs are normally maintained by mowing, selective cutting, and/or selective application of herbicides, soil erosion from transmission line corridors should not normally be a problem. Potential toxic effects of herbicides that are applied to transmission line ROWs and subsequently transported to surface waters should be considered in the ROW maintenance program. By using herbicides approved for ROW use in accordance with the Federal Insecticide, Fungicide, and Rodenticide Act, significant adverse effects of herbicides on aquatic ecosystems should be minimized. Maintenance activities in the vicinity of stream and river crossings employ procedures to minimize erosion and shoreline disturbance (e.g., control of vegetation within streamside buffer zones is generally accomplished by manual techniques) while encouraging small tree, shrub, and other low-growth vegetative cover. The nature or frequency of these activities is not expected to change substantially during the license renewal term.

For small streams in particular, trees may have grown sufficiently between cutting cycles to provide stream shading. Removal of these trees to maintain required conductor clearance could increase water temperature. Coldwater species may avoid such areas. The normal reaction of fish exposed to stressful temperatures is to move along the temperature gradient until preferred temperatures are encountered. Fish could avoid elevated temperatures within the opened ROW by swimming upstream or downstream to areas of groundwater inflow, to deep holes, or to shaded areas. However, effects that result in avoidance of specific areas by some species could represent a partial loss of available habitat. Thermal conditions of larger streams (e.g., those that are 10 ft [3 m] wide or wider) would be generally unaltered, since they are mostly unshaded.

Most transmission line ROWs are maintained on a 3- to 6-year cycle, so impacts on a water body would be infrequent. Any adverse impacts would be localized and temporary and would occur primarily on small streams. To minimize potential impacts from siltation and sedimentation, herbicide application, and stream warming, the licensee or owner of the transmission line typically adheres to standard mitigation practices (application of herbicides according to label instructions and by licensed personnel) listed in the vegetation management plan. Most operators establish stream buffer setbacks within which herbicides cannot be applied, and most widely used herbicides (e.g., glyphosate, fosamine, and imazapyr) pose minimal risks to aquatic organisms.

Changes in aquatic species diversity, abundance, or health from transmission line ROW maintenance are likely to be SMALL. The continued use of proper management practices with respect to soil erosion and application of herbicides is expected. Consequently, it is anticipated that the impact of transmission lines on surface water quality and aquatic resources would be SMALL. The decision to renew the license for a specific plant would affect only the portion of the transmission line that connects the power plant to the first substation. In many cases, the first substation is within or near the boundary of the plant property, and only a short distance of transmission line would be affected by the license renewal decision. Consequently, the amount of aquatic habitat crossed by this portion of a transmission line is also likely to be SMALL.

The impact on aquatic resources of maintaining transmission line ROWs was not identified as an issue in the 1996 GEIS. However, the impact is expected to be SMALL, short term, and localized. The NRC concludes that the impact of transmission line ROW maintenance on aquatic resources would be SMALL for all nuclear plants and is considered a Category 1 issue.

Losses from Predation, Parasitism, and Disease Among Organisms Exposed to Sublethal Stresses

Sublethal power plant stresses may alter predator-prey interactions in the receiving body of water, as evaluated in the 1996 GEIS. Aquatic organisms that are stunned but not killed by entrainment, impingement, or thermal effects may still suffer “indirect” mortality through increased susceptibility to predators. Numerous laboratory studies have been carried out to evaluate the level of indirect mortality that might occur following heat and cold shocks or entrainment (reviews in Cada et al. 1981; Coutant 1981). These studies have commonly demonstrated increased susceptibility to predation, but field evidence of such effects is often limited to anecdotal information such as observations of enhanced feeding activity of seagulls and predatory fish near power plant outfalls. For example, Barkley and Perrin (1971) and Romberg et al. (1974) reported increased concentrations of predators feeding on forage fish attracted to thermal plumes. Neither quantification of the levels of stress needed to increase predation rates, nor prediction of the subsequent population- and community-level effects of such changes can be made easily in the field. It is likely that operation of once-through cooling systems will cause some changes in predator-prey relationships, but the best evidence for impacts (or lack of impacts) may come from long-term monitoring of fish populations. Neither the literature reviews nor consultations with agencies and utilities (Appendix F) have revealed studies that demonstrate population- or community-level effects from power-plant-induced alterations of predator-prey relationships.

Elevated water temperatures in power plant discharges have been hypothesized to increase the susceptibility of fish to diseases and parasites. Langford (1983) cites a number of factors that could contribute to such an effect, including the tendency for fish to congregate in the heated discharge area in greater than normal concentrations, increased stresses on fish in warmer water that makes them more prone to infection, and the ability of some diseases and parasites to develop faster at higher temperatures. Additionally, it has been suggested that stress and injury from entrainment and impingement contribute to increased susceptibility of fish to disease, parasites, and predation. Coutant (1981) noted that although some studies of increased disease and parasitism in heated waters have found localized effects, most were not adequately designed to determine the significance of the effects to the overall population. The greatest risks appear to be associated with changes in animal concentrations; crowding can occur among fish that are attracted to heated effluents in the winter or that avoid heated water in the summer by occupying limited cool-water refugia. Crowding increases the chances of exposure to infectious diseases and may also lead to other stresses (decreased food supply or reduced oxygen concentrations) that increase susceptibility to disease (Coutant 1987). Despite limited laboratory studies that confirm this phenomenon, population-level effects in the vicinity of plants have not been observed.

Impact levels due to sublethal stresses on the susceptibility of aquatic organisms to predation, parasitism, and disease are considered to be of SMALL significance if changes are localized and populations in the receiving water body are not reduced. Based on reviews of literature and operational monitoring reports, consultations with utilities and regulatory agencies, and comments on the draft GEIS, these forms of indirect, power plant-induced mortality have not been shown to cause reductions in the overall populations near any existing nuclear power plants. Levels of impact are SMALL for all plants reviewed. Although sublethal power plant stresses contribute to cumulative impacts experienced by aquatic biota, monitoring has revealed no evidence for significant effects; the regulatory and resource agencies consulted in the preparation of this GEIS did not express concerns about the contribution of sublethal power plant stresses to cumulative impacts.

On the basis of its review, the NRC concludes that the level of impact due to sublethal stresses has been SMALL at plants reviewed and expects it to be SMALL for all nuclear plants. The issue remains Category 1.

4.6.1.3 Special Status Species and Habitats

Threatened, Endangered, and Protected Species and Essential Fish Habitat

The impacts associated with continued nuclear power plant operations and refurbishment activities during the license renewal term that could affect threatened, endangered, and protected species, critical habitat, and essential fish habitat (EFH) are similar to those described for terrestrial resources (Section 4.6.1.1) and aquatic resources (Section 4.6.1.2). Continued operations during the license renewal term would be expected to include such stressors as operation of cooling towers, operation of once-through cooling systems and cooling ponds, transmission line ROW management, maintenance of site facilities, releases of gaseous and liquid effluents, withdrawal of surface water, and potentially refurbishment activities. Details are presented in Section 3.6.3. There are several Federal Acts that provide protection to certain species and habitats that are treated here under a single issue. The issue includes impacts to biological resources such as threatened and endangered species and their critical habitat under the ESA, EFH as protected under the Magnuson-Stevens Fishery Conservation and Management Act (MSA), and impacts to mammalian species protected under the Marine Mammal Protection Act.

Terrestrial Species

Continued operations and refurbishment activities at all nuclear plants could have an impact on Federally or State-listed threatened and endangered species during the license renewal term. Factors that could potentially result in impacts on listed terrestrial species include habitat disturbance, cooling tower drift, operation and maintenance of cooling systems, transmission line ROW maintenance, collisions with cooling towers and transmission lines, and exposure to radionuclides. In the 1996 GEIS, the NRC considered the impacts of refurbishment and continued operation on threatened and endangered terrestrial species and concluded that the impacts would not necessarily be the same at all sites (i.e., a Category 2 issue) and could range from SMALL to LARGE.

Federally listed threatened and endangered terrestrial species are protected under the ESA, while State-listed species are protected under provisions of various State regulations. Prior to license renewal, the NRC must consult with the USFWS to determine the presence of any Federally listed species or critical habitat at or near the site and assess the potential for impacts from continued operation of the plant or associated transmission lines. The impacts of refurbishment activities on threatened or endangered species must also be considered during project planning, and consultation with the USFWS must be initiated if the possibility for impacts exists. Guidance for the consultation process is provided in the *Endangered Species Consultation Handbook* (USFWS and NMFS 1998).

Site-specific factors related to continued operations and refurbishment activities may vary widely among nuclear power plants. The listed species on or in the vicinity of nuclear power plants also range widely, depending on numerous factors such as the plant location and habitat types present (see Section 3.6.3.1). In addition, the list of threatened and endangered species is not static and is frequently modified by the USFWS and NMFS, with new listings being added as some species are determined to be eligible, other species being delisted (removed from the list), or the listing category of some species being changed because of changes in the status of or threats to the species population. Therefore, a generic determination of potential impacts on listed species during a nuclear power plant's license renewal term is not possible. Impacts on threatened and endangered species would depend on site-specific factors, and impact assessments would need to be conducted on a site-specific basis. Nuclear plants known to support terrestrial listed species on the site or along transmission line ROWs generally have monitoring programs to identify changes in populations and report impacts to the USFWS and State agencies. Monitoring provides information that can be used for developing or adjusting mitigation during the license renewal term.

Aquatic Species and Essential Fish Habitats

Potential impacts of continued operations and refurbishment activities on Federally or State-listed threatened and endangered species, protected marine mammals, and EFH could occur during the license renewal term. This issue applies to all operating nuclear power plants. Factors that could potentially result in impacts to these species and habitats include impacts of refurbishment, other ground-disturbing activities, release of contaminants, effects of cooling water discharge on dissolved oxygen, gas supersaturation, eutrophication, thermal discharges, entrainment, impingement, reduction in water levels due to the cooling system operations, dredging, radionuclides, and transmission line ROW maintenance. In the 1996 GEIS, the NRC considered potential impacts on threatened and endangered aquatic species from the operation of all nuclear power plants as a Category 2 issue and concluded that the impacts could range from SMALL to LARGE.

Power plants (nuclear and otherwise) that use estuarine or marine waters for cooling could entrain or impinge sea turtles (National Research Council 1990). The impingement mortality of sea turtles (all of which are Federally listed) has received the most attention to date with regard to the effects of nuclear power plant operations on listed species. Sea turtles are commonly encountered at some coastal nuclear plants, including the St. Lucie plant in Florida, the Oyster Creek plant in New Jersey, and the Brunswick plant in North Carolina. Between 1977 and 1997, the average number of sea turtles removed from the intake canal at the St. Lucie plant was 266 per year (Gunter et al. 2001). These included loggerhead, green, leatherback, hawksbill, and Kemp's ridley sea turtles. Most were loggerhead and green sea turtles, with an average of 150 and 103 removed per year, respectively. Among the sea turtles removed, about 4 percent of the loggerheads, 2 percent of the green, and 13 percent of the Kemp's ridley sea turtles were dead (Gunter et al. 2001). Sixty-eight sea turtles were impinged on intake screens at the Oyster Creek plant between 1992 and 2005, and 28 (41 percent) of those individuals died (NRC 2007c). The incidental take limit established by the NMFS for Kemp's ridley sea turtles was exceeded at the Oyster Creek plant in 2004, which required re-initiation of ESA Section 7 consultation with the NMFS (NRC 2007c). All three sea turtle species have been collected, as recently as 2004, in the vicinity of the Brunswick plant intake canal in North Carolina (NRC 2006e). Seventy-five percent of these turtles were released unharmed to the ocean or transported to a sea turtle facility for rehabilitation. Special panels have been installed at the diversion structure of the Brunswick plant, located at the entrance to the intake canal, to minimize the potential for sea turtles to enter the intake canal (NRC 2006e).

The licensees of the St. Lucie, Oyster Creek, and Brunswick plants have also implemented programs to monitor the intake canals for sea turtles and to capture and release to the wild any sea turtles observed in the intake canals (NRC 2003a, 2007c, 2006e). In addition, the licensee of the St. Lucie plant has initiated programs to monitor turtle nests on nearby beaches and has implemented facility lighting restrictions (NRC 2003a). Incidental takes of sea turtles have also been recorded for other plants that use estuarine or marine waters for cooling, including the Crystal River and Salem plants (Sackschewsky 2004). Sea turtles also have the potential to occur in the vicinity of other nuclear power plants located near estuarine or marine ecosystems, including the Calvert Cliffs, Diablo Canyon, Hope Creek, and Millstone plants (Sackschewsky 2004). In the SEISs prepared for the Calvert Cliffs plant (NRC 1999b) and the Millstone plant (NRC 2005c), it was determined that continued operations would not adversely affect endangered sea turtles.

Many nuclear plants whose operations are known to affect special status aquatic species have been required to establish monitoring programs and implemented mitigations in consultation with the USFWS or NMFS. For some plants, NMFS or FWS have developed incidental take limits to ensure that effects on species do not exceed specific levels. If takes exceed these incidental take limits, the NRC would be required to reinitiate consultation with USFWS or NMFS. Continued implementation of these actions would reduce the potential for adverse impacts to listed species during the license renewal term.

Prior to license renewal, the NRC consults with the USFWS and NMFS to determine the presence of and possible impacts on any ESA-listed aquatic species. Guidance for the ESA consultation process is provided in the *Endangered Species Consultation Handbook* (USFWS and NMFS 1998). The NRC also contacts the NMFS for license renewal applications for plants located in areas that may contain EFH for Federally managed marine or anadromous fisheries or for plants that may have an effect on protected marine mammals. In addition, the appropriate State agencies are contacted to determine the potential for State-listed species to be affected by continued operations and refurbishment activities during the license renewal term.

Subsequent consultation could be required for specific maintenance or refurbishment activities undertaken at a plant during the license renewal term.

Site-specific factors related to operations and refurbishment varies widely among nuclear power plants. The special status aquatic species and habitats in the vicinity of nuclear power plants and their transmission lines also vary widely, depending on numerous factors such as the plant location and habitat types present (see Section 3.6.3.2). In addition, the lists of special status species and habitats are not static and are frequently modified by the USFWS, NMFS, and State agencies, with new listings being added as some species are determined to be eligible, other species being delisted (removed from the list), or the listing category of some species being changed because of changes in the status of or threats to the species population. EFH designations and status also can change through time. Therefore, a generic determination of potential impacts on species and habitats during a nuclear power plant's license renewal term is not possible. Impacts on special status species and habitats would depend on site-specific factors, and impact assessments would need to be conducted on a site-specific basis in the plant-specific SEISs prepared for license renewal applications.

In preparing this revised GEIS, the NRC staff has determined that the levels of impact that it developed to implement the National Environmental Policy Act (NEPA) (i.e., SMALL, MODERATE, or LARGE) are not sufficiently clear with respect to the ESA and MSA, as these laws define and require other findings. So, in complying with the ESA, the NRC will report in its plant-specific environmental reviews and future SEISs the effects of continued operations and refurbishment in terms of its ESA findings of (1) no effect, (2) not likely to adversely affect, (3) likely to adversely affect, or (4) is likely to jeopardize the listed species or adversely modify the designated critical habitat of Federally listed species populations or their critical habitat. For listed species where the NRC has found that its action is "likely to adversely affect" the species or habitat, the NRC may further characterize the effects as "is [or is not] likely to jeopardize listed species or adversely modify designated critical habitat." Similarly, in complying with the MSA, the NRC will report the effects of continued operations and refurbishment in terms of its MSA findings of (1) no adverse impact, (2) minimal adverse impact, or (3) substantial adverse impact to the essential habitat of Federally managed fish populations during the license renewal term.

On the basis of these considerations, the NRC concludes that the impact of continued operations and refurbishment activities on threatened, endangered, and protected species and habitats as well as essential fish habitat would depend on plant-specific design and operating characteristics, environmental review procedures established for ground-disturbing activities, the occurrence of species and habitats, and other site-specific considerations. Consequently, this issue remains a plant-specific, or Category 2, issue.

4.6.2 Environmental Consequences of Alternatives to the Proposed Action

Construction—For all alternatives discussed in this section, the impacts of construction on ecological resources would be qualitatively similar. Ecological impacts are site-dependent. Impacts would depend on the type and location of a proposed facility, the technologies to be employed, the size of the area affected, and the specific ecological characteristics of the area to be developed. Vegetation would be removed from construction and material storage areas, and along utility pathways. Some disturbed areas would be re-vegetated after plant construction. Native vegetation could be displaced by invasive species in areas disturbed by construction. Some areas near access roads may be affected by the release of fugitive dust.

Construction-related noise could disturb wildlife. Permanent habitat loss could occur for some species. Despite reclamation efforts, a certain amount of natural habitat at greenfield sites could be permanently lost. Industrial development at brownfield and existing nuclear power plant sites have already affected or altered the natural habitat.

Operations—Various impacts on ecological resources can be anticipated throughout the operating period of an electrical power plant. Impacts include fugitive dust; impingement and entrainment of fish and other aquatic organisms; heated effluent from cooling water discharge and blowdown; gasifier and boiler blowdowns; steam water treatment; cooling tower drift (fogging and ice); salt deposition; maintenance of transmission line ROWs; bird collisions; and wildlife avoidance behavior due to operational activities and noise. Aquatic ecosystems would be affected by cooling water discharge, steam-cycle blowdown, and other (NPDES-permitted) wastewater. Onsite maintenance, accumulation of contaminants in sediment or biota, changes in levels of dissolved oxygen in surface water, dredging, and possible deposition of radionuclides would also impact aquatic resources. The magnitude of potential impacts from a proposed facility could be greater than or less than renewing the license for an existing facility depending upon site-specific and project-specific factors.

4.6.2.1 Fossil Energy Alternatives

Operations—Many of the potential ecological impacts from operations of a fossil energy facility (coal- or gas-fired) would essentially be similar to those for a nuclear facility.

Unique features of a coal-fired power plant that could impact ecological resources include:

- Coal delivery, cleaning and storage—periodic maintenance dredging (if coal is delivered by barge), noise, dust, loss of habitat, sedimentation and turbidity, and introduction of minerals and terrace elements (including contaminants that can cause impacts similar to acid mine drainage);

- Limestone preparation and storage—dust and runoff can affect soil and vegetation and increase water hardness and turbidity;

- Air emissions—most notably, acid precipitation can cause direct and indirect effects on terrestrial and aquatic organisms including injury to foliage, leaching of nutrients, decreased biodiversity, and elimination of certain fish species from lakes and streams; and

- Disposal of combustion wastes—habitat loss and potential seepage of trace and other elements into groundwater, soils, and surface waters.

The unique feature of a gas-fired power plant that could impact ecological resources would be the need for a gas pipeline. The main impact of a pipeline would be the loss, modification, and fragmentation of habitat.

Overall, ecological impacts from a fossil energy facility would depend on whether it would be located at a new site or replace an existing energy facility and whether the fossil energy facility would use once-through or closed-cycle cooling. The range of ecological impacts would be SMALL to MODERATE at an existing industrial site using closed-cycle cooling to MODERATE to LARGE at a new location using open-cycle cooling.

4.6.2.2 New Nuclear Alternatives

Operations—Since 1997, the NRC has certified four new standard designs for light-water nuclear power plants under 10 CFR Part 52, Subpart B. Therefore, impacts on ecological resources from construction and operation of a new nuclear power plant are considered in this section. The NRC assumes that the new nuclear reactor would have a 40-year lifetime. The extent of ecological impacts would depend on the location of the facility. A new nuclear plant located at the site of the existing nuclear facility would limit the amount of habitat disturbance that would be required (e.g., a new reactor at an alternative site would require about 500 to 1,000 acres [202 to 405 ha]). Additionally, existing transmission facilities, roads, parking areas, and possibly cooling system could be used if the new nuclear facility is located at the site of the existing facility. Ecological communities would experience reduced productivity and biological diversity from land disturbance. Regardless of whether a new reactor was constructed at an existing or alternative site, the amount of habitat disturbance would be greater than for license renewal of an existing nuclear facility.

Operational impacts on terrestrial ecology from a new nuclear reactor would be similar to those for the existing facility (Section 4.6.1.1). It is expected that a new nuclear reactor facility would use a closed-cycle cooling system. If the existing nuclear facility had once-through cooling, then impacts on aquatic resources for the new nuclear reactor would be reduced. Otherwise, operational impacts on aquatic ecology would be similar.

Overall, the ecological impacts of the nuclear alternative would be SMALL to MODERATE at an existing site and MODERATE to LARGE at an alternative site.

4.6.2.3 Renewable Alternatives

Construction—Dams and reservoirs would alter river flow and temperature, which could affect aquatic and terrestrial resources downstream. Dams create a barrier to fish migration if fish passages are not installed. Aquatic and terrestrial resources would have to adapt to the newly created reservoir. Disruptions to the sea bottom for installation of power and communication cables would affect benthic populations and other species that rely on benthic organisms for food. Unique ecological impacts could result from construction of offshore facilities from boat traffic to and from the construction site. Other impacts include underwater noise, alteration of sediment transport and deposition patterns, and possible disruption of onshore and nearshore nesting areas.

Operations—The operational impacts of alternative energy technologies on terrestrial and aquatic ecology are summarized in the following subsections.

Hydroelectric Energy Sources

Downstream conditions could be affected by dam operations (store-and-release of water) that could vary river flow conditions. Aquatic and terrestrial resources would be affected by fluctuating water levels downstream of the dam. Aquatic organisms could become stranded temporarily when river levels are lowered. Temperature and nutrient stratification in the reservoir and reduced levels of dissolved oxygen could result in hypotoxic or anoxic conditions for aquatic organisms. Aquatic and riparian ecosystems downstream would be affected by a variety of dam-induced conditions, such as changes in sediment transport and deposition patterns, and channel erosion or scouring. Hydropower operations could enhance populations of nonnative aquatic biota and riparian plants.

Geothermal

Birds and bats could be affected by contact with geothermal fluids temporarily stored in surface impoundments.

Wind

Aerodynamic and mechanical noise from wind turbines would affect wildlife. Collisions with wind turbines would increase bird and bat mortality. However technological advances allow rotors to turn at lower speeds, thus reducing the potential for bird and bat strikes. Underwater noise impacts from offshore facilities would extend to great distances due to the density of water. Offshore facilities could impact threatened and endangered species, marine mammals, birds, or sea turtles. Other impacts include disturbance of nesting areas, alteration of key habitat, underwater noise, or fuel spills.

Biomass

Habitat loss could occur from the cultivation of energy crops. Deposition of toxic constituents from municipal solid waste feedstock could affect aquatic and terrestrial ecosystems.

Solar Thermal and Photovoltaic

Solar fields occupy large areas of land that could reduce or preclude natural vegetation communities and wildlife use. Synthetic organic heat transfer fluids could affect surrounding vegetation. Misalignment of mirrors could also increase fire risk.

Ocean Wave and Current

Boat traffic, noise, navigation safety lights, inspection and maintenance activities could affect marine mammals, fish, and sea turtles. Sea turtles could be affected by wave-topping devices. Onshore nesting areas could be affected. Fish, sea turtles, and marine mammals could collide with underwater turbines.

4.7 Historic and Cultural Resources

4.7.1 Environmental Consequences of the Proposed Action—Continued Operations and Refurbishment

Section 106 of the National Historic Preservation Act requires Federal agencies to take into account the effects of their undertakings (license renewal) on historic properties. As discussed in Section 3.7.1, the NRC fulfills its Section 106 requirements through the NEPA process (see 36 CFR 800.8). In license renewal, only one impact issue is evaluated:

- Historic and cultural resources; issue encompasses the impact of continued operations and refurbishment activities on historic properties located onsite and in transmission line

ROWs (issue was modified and renamed from the1996 GEIS issue, “Historic and archaeological resources”).

This issue was addressed in the 1996 GEIS; however, the process for considering historic properties has been updated, and the range of historic properties has been expanded to include traditional cultural properties.

Many facilities were constructed prior to the implementation of Section 106 regulations; therefore, many nuclear plant sites were not investigated for the presence of historic and cultural resources prior to construction. As most licensees are not aware of the presence or status of historic and cultural resources on their site, a review of the site and plant activities since construction should be conducted by qualified cultural resource professionals and approved by the appropriate State Historic Preservation Office (SHPO). A variety of historic and cultural resources can be found at plant sites. Archaeological sites are generally identifiable only through field investigations. Traditional cultural properties (TCPs), historic and cultural resources that are important for a community to maintain its cultural heritage, can also be found in the immediate environs of a nuclear power plant. In some cases, the nuclear power plant itself may be considered a historic property for its design or engineering. Ultimately, historic and cultural resources at each site can be quite different and must be assessed at a plant-specific level and in consultation with SHPOs, Tribal representatives, and other interested parties.

The NRC will identify historic and cultural resources within a defined Area of Potential Effect (APE). The license renewal APE is the area that may be impacted by land-disturbing, or other operational, activities associated with continued plant operations and maintenance during the license renewal term and/or refurbishment. The APE typically encompasses the nuclear power plant site, its immediate environs including viewshed, and the transmission lines within this scope of review (see Sections 3.1.1 and 3.1.6.5 in this GEIS). The APE may extend beyond the nuclear plant site and transmission lines when these activities may affect historic and cultural resources. This determination is made irrespective of land ownership or control. If any historic properties are present, their significance is determined through application of the *National Register of Historic Places* (NRHP) criteria.

Continued operations during the license renewal term and refurbishment activities at a nuclear power plant can affect historic and cultural resources through (1) ground-disturbing activities associated with plant operations and ongoing maintenance (e.g., construction of new parking lots or buildings), landscaping, agricultural or other use of plant property, (2) activities associated with transmission line maintenance (e.g., maintenance of access roads or removal of danger trees), and (3) changes to the appearance of nuclear power plants and transmission lines. Licensee renewal environmental reviews have shown that the appearance of nuclear power plants and transmission lines have not changed significantly over time; therefore additional viewshed impacts to historic and cultural resources are not anticipated.

Extensive ground-disturbing activities occurred during nuclear power plant construction at nuclear power plant sites, and much of the land immediately surrounding the power block was disturbed down to bedrock. This activity would have eliminated any potential for historic or cultural resources to be present in this portion of the power plant site. However, to effectively determine areas that could potentially contain historic and cultural resources, a survey of any area which may be disturbed by continued operations during the license renewal term or by refurbishment associated with license renewal, including previously disturbed areas of the nuclear power plant site (other than the land immediately surrounding the power block), should be conducted by qualified professionals and in consultation with the appropriate SHPO and other consulting parties.

In the 1996 GEIS, the NRC considered the impact of continued operations and refurbishment on historic and archaeological resources at nuclear power plants and concluded that impacts would not be the same at all plants (i.e., a Category 2 issue) and could range from SMALL to LARGE. Subsequent license renewal environmental reviews conducted by the NRC support the Category 2 designation.

The National Historic Preservation Act of 1966 (NHPA) requires the NRC to conduct a site-specific assessment to determine whether historic properties are present in the APE, and if so, whether the license renewal decision would result in any adverse effect upon such properties. Thus, the NRC concludes that it is more appropriate to make one of the following determinations in its plant-specific environmental reviews instead of assigning a significance level (i.e., SMALL, MODERATE, or LARGE): (1) no historic properties present; (2) historic properties are present, but not adversely affected; or (3) there is an adverse effect on a historic property. On the basis of these considerations, the impact of continued operations and refurbishment activities on historic properties (and cultural resources) remains a Category 2 issue.

4.7.2 Environmental Consequences of Alternatives to the Proposed Action

Construction—Impacts to historic and cultural resources from the construction of a replacement power facility are primarily related to ground disturbance and are dependent on the location of the power plant. Before constructing a new replacement power plant or a facility at a greenfield, brownfield, or existing nuclear power plant site, a historic and cultural resource inventory would need to be performed by a qualified cultural resource professional. Any land needed to support the replacement power plant including roads, transmission corridors, rail lines, or other ROWs would also need to be surveyed for historic properties.

4.7.2.1 Fossil Fuel Alternatives

Operations—Ground-disturbing activities during power plant operations and maintenance could impact historic and cultural resources at the power plant site. Other ongoing activities at the power plant site could also affect historic and cultural resources. These activities include, but are not limited to, grading, excavating, landscaping, and operating large vehicles over previously undisturbed portions of the site.

4.7.2.2 New Nuclear Alternatives

Operations—Ground-disturbing activities during power plant operations and maintenance could impact historic and cultural resources at the power plant site. Other ongoing activities at the power plant site could also affect historic and cultural resources. These activities include, but are not limited to, grading, excavating, landscaping, and operating large vehicles over previously undisturbed portions of the site.

4.7.2.3 Renewable Alternatives

Hydroelectric Energy Sources

Operations—Fluctuations of river flow could erode embankments affecting downstream historic properties. Ground-disturbing activities during power plant operations and maintenance could impact historic and cultural resources at the dam site. It is assumed that impacts to historic properties would have been addressed prior to construction.

Wind

Operations—Historic properties would be affected by the presence of wind turbines in the viewshed. Ground-disturbing activities during power plant operations and maintenance could impact historic and cultural resources at the wind farm site. It is assumed that impacts to historic properties would have been addressed prior to construction.

Ocean Wave and Current

Operations—Historic properties located offshore could be affected by kinetic energy by ocean wave and/or current-energy-capturing devices. Ground-disturbing activities during power plant operations and maintenance could impact historic and cultural resources on the ocean floor. It is assumed that impacts to historic properties would have been addressed prior to construction.

Geothermal, Biomass, and Solar Thermal and Photovoltaic

Operations – Ground-disturbing activities during power facility operations and maintenance could impact historic and cultural resources at the power plant site. Other ongoing activities at the power facility site could also affect historic and cultural resources. These activities include, but are not limited to, grading, excavating, landscaping, operating large vehicles over previously undisturbed portions of the site.

4.8 Socioeconomics

4.8.1 Environmental Consequences of the Proposed Action—Continued Operations and Refurbishment Activities

The socioeconomic impact of ongoing power plant operations has become well established during the current license term for all nuclear power plants. Changes in employment and tax payments caused by license renewal and associated refurbishment activities can have a direct and indirect effect on community services and housing demand, as well as traffic volumes in the communities around each nuclear power plant.

A review of license renewal applications provides no evidence that the number of permanent power plant operations workers would increase during the license renewal term. This differs from the conservative assumption that up to 60 additional workers per reactor unit (upper bound) could be needed to support aging management-related maintenance and inspection activities (see 1996 GEIS). Licensees, however, indicated that they had no plans to add non-outage workers during the license renewal term and that increased maintenance and inspection activities could be managed using the current workforce. This review also revealed that refurbishment activities, such as steam generator and vessel head replacement, have not required the large numbers of workers and months of time that was conservatively predicted in the 1996 GEIS. Therefore, people living in the vicinity of a nuclear power plant are not likely to experience any changes in socioeconomic conditions during the license renewal term beyond what is currently being experienced. In addition, refurbishment impacts are expected to be similar to what has been experienced during regularly scheduled power plant refueling and maintenance outages.

The environmental review conducted for this GEIS revision identified five socioeconomic impact issues, which include all of the original socioeconomic license renewal term and refurbishment impact issues addressed in the 1996 GEIS. These five issues are:

- Employment and income, recreation and tourism (new, consolidated issue that adds impacts on employment and income that were not addressed in the 1996 GEIS). Also included in this issue are the impacts on recreation and tourism (impacts on tourism and recreation were addressed in the 1996 GEIS as part of the issue, "Public services: public safety, social services, and tourism and recreation");

- Tax revenues (new issue; issue was considered and discussed in the 1996 GEIS, but not identified as a separate environmental review issue);

- Community services and education (consolidation and reclassification of the following issues in the 1996 GEIS: (1) public services: public safety, social services [excluding public services: tourism and recreation]; (2) public services: public utilities; (3) public services: education [license renewal term]; and (4) public services: education [refurbishment]);

- Population and housing (issue was reclassified and renamed from the 1996 GEIS issue, "Housing impacts"; these impacts were considered in the 1996 GEIS, although the population impacts component was not identified as a separate issue); and

- Transportation (issue was reclassified and renamed from the 1996 GEIS issue, "Public services: transportation").

4.8.1.1 Employment and Income, Recreation, and Tourism

As discussed in Chapter 3, the nuclear power plant and the communities that support it can be described as a dynamic socioeconomic system. The communities provide the people, goods, and services required to operate the nuclear power plant. Power plant operations, in turn, provides employment and income and pays for goods and services from the communities.

Employees receive income from the nuclear power plant in the form of wages, salaries, and benefits. Employees and their families, in turn, spend this income on goods and services within the community thereby creating additional opportunities for employment and income. In addition, people and businesses in the community receive income for the goods and services sold to the power plant. Payments for these goods and services create additional employment and income opportunities in the community. The measure of a communities' ability to support the operational demands of a power plant depends on the ability of the community to respond to changing socioeconomic conditions.

As previously discussed, it is unlikely that the number of power plant operations workers would change at a nuclear power plant during the license renewal term. While it was conservatively estimated in the 1996 GEIS that up to 60 additional workers per unit could be required during the license renewal term, subsequent license renewal environmental reviews have shown little or no need to hire additional operations workers. In addition, refurbishment activities, such as steam generator and vessel head replacement, have not required the numbers of workers and the months of time conservatively estimated in the 1996 GEIS. Consequently, employment levels at a nuclear power plant are not expected to change as a result of license renewal.

Some communities experience seasonal transient population growth due to local tourism and recreational activities. Income from tourism and recreational activities creates employment and income opportunities in the communities around nuclear power plants. Communities located near nuclear power plants in coastal regions, notably Pilgrim near Plymouth and Cape Cod, Massachusetts; the D.C. Cook and Palisades plants on the eastern shore of Lake Michigan, and the Oyster Creek plant on the New Jersey shore north of Atlantic City, experience summer, weekend, and retirement population increases due to the recreational and tourism activities that attract visitors. Some communities, such as those located in the region around the Vermont Yankee plant in Vermont, attract visitors interested in outdoor recreational activities, such as camping, hiking, and skiing.

As discussed in Section 4.2.1.2, the NRC considered the impacts of continued plant operations during the license renewal term and refurbishment on visual resources, which could affect tourism and recreational business interests. The NRC concluded in the 1996 GEIS that the impacts on visual resources would be SMALL for all plants and was a Category 1 issue, primarily because the impact had already occurred and the visual profile of nuclear power plants were not expected to change as a result of license renewal. Also, visual impacts tend to wear off over time when viewed repeatedly.

However, a case study performed for the 1996 GEIS found situations where nuclear power plants have had a negative effect on visual resources. Negative perceptions were based on aesthetic considerations (for instance, the plant is out of character or scale with the community or the viewshed), physical environmental concerns, safety and perceived risk issues, an anti-power plant (or utility) attitude, or an anti-nuclear orientation. It is believed that some of these negative perceptions would persist regardless of mitigation measures. Subsequent license renewal reviews have not revealed any new information that would change this perception.

Nevertheless, the effects of power plant operations on employment, income, recreation, and tourism are ongoing and have become well-established during the current license term for all nuclear power plants. The impacts from power plant operations during the license renewal term on employment and income in the region around each nuclear power plant are not expected to change from what are currently being experienced. In addition, tourism and recreational activities in the vicinity of nuclear plants are not expected to change as a result of license renewal. On the basis of these considerations, the NRC concludes that the impact of continued nuclear plant operations and refurbishment activities on employment, income, recreation, and tourism would be SMALL and is therefore considered a Category 1 issue.

4.8.1.2 Tax Revenues

Nuclear power plants and the workers who operate them are an important source of tax revenue for many local governments and public school systems. Tax revenues from nuclear power plants mostly come from property tax payments or other forms of payments such as payments in lieu of (property) taxes, or PILOT payments, although taxes on energy production have also been collected from a number of nuclear power plants. County and municipal governments and public school districts receive tax revenue either directly or indirectly through State tax and revenue-sharing programs.

Counties and municipal governments in the vicinity of a nuclear power plant also receive tax revenue from sales taxes and fees from the power plant and its employees. Changes in the number of workers and the amount of taxes paid to county, municipal governments, and public schools can affect socioeconomic conditions in the counties and communities around the nuclear power plant.

A review of license renewal applications received by the NRC since the 1996 GEIS has shown that refurbishment activities, such as steam generator and vessel head replacement, have not had a noticeable effect on the assessed value of nuclear plants, thus changes in tax revenues are not anticipated from future refurbishment activities. Refurbishment activities involving the one-for-one replacement of existing components and equipment are generally not considered a taxable improvement. Also, property tax assessments; proprietary payments in lieu of tax stipulations, settlements, and agreements; and State tax laws are continually changing the amount of taxes paid to taxing jurisdictions by nuclear plant owners. These changes are independent of license renewal and refurbishment activities.

The primary impact of license renewal would be the continuation or change in the amount of taxes paid by nuclear power plant owners to local governments and public school systems. The impact of nuclear plant operations on tax revenues in local communities and the impact that the expenditure of tax revenues has on the region are not expected to change appreciably from the amount of taxes paid during the current license term. Tax payments during the license renewal term would be similar to those currently being paid by each nuclear plant. On the basis of these considerations, the NRC concludes that the impact of continued nuclear plant operations and refurbishment on tax revenue would be SMALL and is therefore considered a Category 1 issue.

4.8.1.3 Community Services and Education

In the 1996 GEIS, impacts on public (community) services and education were evaluated based on the projected number of “in-migrating” workers accompanied by their families. In addition, impacts on (1) public services: public safety, social services…; (2) public services: public utilities; (3) public services, education (license renewal term); and (4) public services, education (refurbishment) were considered as separate impact issues in the 1996 GEIS but have been consolidated and reclassified under this issue. All but the “public services: tourism and recreation” component of the 1996 GEIS issue, “Public services: public safety, social services, and tourism and recreation” are considered here.

The four 1996 GEIS issues have been consolidated because all public services are equally affected by changes in nuclear power plant operations and refurbishment activities. Any changes in the number of workers at a nuclear plant will affect the demand for public services from local communities. Environmental reviews conducted by NRC since the 1996 GEIS have shown, however, that the number of workers at relicensed nuclear plants has not changed significantly because of license renewal, so demand-related impacts on community services, including public utilities, are no longer anticipated from future license renewals.

In addition, refurbishment activities, such as steam generator and vessel head replacement, have not required the large numbers of workers and the months of time that was conservatively analyzed in the 1996 GEIS, so significant impacts on community services are no longer anticipated. Because of the relatively short duration of refurbishment-related activities, workers are not expected to bring families and school-age children with them; therefore, impacts from refurbishment on educational services are also no longer anticipated.

Taxes paid by nuclear power plant owners support a range of community services, including public water, safety, fire protection, health, and judicial, social, and educational services. In some communities, tax revenues from power plants can have a noticeable impact on the quality of services available to local residents. Although many of the community services paid for by tax revenues from power plants are used by plant workers and their families, the impact of nuclear plant operations on the availability and quality of community services and education is SMALL and is not expected to change as a result of license renewal. On the basis of these considerations, the NRC concludes that the impact of continued nuclear plant operations and refurbishment activities on community services and education would be SMALL and is therefore considered a Category 1 issue.

4.8.1.4 Population and Housing

Socioeconomic impact analyses of resources (e.g., housing) affected by changes in regional population are based on employment trends at nuclear power plants. Population growth from increased employment and spending at a nuclear power plant is important because it is one of the main drivers of socioeconomic impacts. Plant-induced population growth, while not an impact itself, was studied as a potential influence on a number of impact issues analyzed in the 1996 GEIS. As previously discussed, however, employment levels at nuclear power plants are expected to remain relatively constant with little or no population growth or increased demand for permanent housing during the license renewal term. The operational effects on population and housing values and availability in the vicinity of nuclear power plants are not expected to change from what is currently being experienced, and no demand-related impacts are expected during the license renewal term.

The increased number of workers at nuclear power plants during regularly scheduled plant refueling and maintenance outages does create a short-term increase in the demand for temporary (rental) housing units in the region around each plant. However, because of the short duration and the repeated nature of these scheduled outages and the general availability of rental housing units (including portable trailers) in the vicinity of nuclear power plants, employment-related housing impacts have had little or no long-term impact on the price and availability of rental housing. Refurbishment impacts would be similar to what is experienced during routine plant refueling and maintenance outages.

License renewal reviews conducted since the 1996 GEIS have shown that housing has not been an issue at relicensed nuclear plants including those plants located in "sparsely populated areas." Therefore, impacts to these resources are no longer anticipated from future license renewals. On the basis of these considerations, the NRC concludes that the impact of continued nuclear plant operations and refurbishment activities on population and housing would be SMALL and is therefore considered a Category 1 issue.

4.8.1.5 Transportation

Transportation impacts depend on the size of the workforce, the capacity of the local road network, traffic patterns, and the availability of alternate commuting routes to and from the plant. Because most sites have only a single access road, there is often congestion on these roads during shift changes.

Nevertheless, license renewal is not likely to affect local transportation conditions in the vicinity of a nuclear power plant beyond what is currently being experienced. Transportation impacts are ongoing and have become well established during the current licensing term for all nuclear power plants. As previously discussed, it is unlikely that the number of permanent operations workers would increase at a nuclear power plant during the license renewal term. While it was estimated in the 1996 GEIS that up to 60 additional workers per unit could be required during the license renewal term, subsequent environmental reviews have shown little or no need for additional operations workers. In addition, refurbishment activities, such as steam generator and vessel head replacement, have not required the numbers of workers and the months of time conservatively estimated in the 1996 GEIS. Consequently, employment at nuclear power plants during the license renewal term is expected to remain unchanged. Refurbishment impacts would be similar to what has been experienced during routine plant refueling and maintenance outages.

The increased number of workers at nuclear power plants during regularly scheduled plant refueling and maintenance outages have caused short-term increases in traffic volumes on roads in the vicinity of each plant. However, because of the relative short duration of these outages, increased traffic volumes have had little or no lasting impact. Therefore, there would be no transportation impacts during the license renewal term beyond those already being experienced. On the basis of these considerations, the NRC concludes that the impact of continued operations and refurbishment activities on local transportation would be SMALL and is therefore considered a Category 1 issue.

4.8.2 Environmental Consequences of Alternatives to the Proposed Action

The impacts of power plant development on local and regional socioeconomic conditions would be qualitatively similar for all alternatives discussed in this section. Local economies have the potential to be directly or indirectly affected by power plant construction and operation. The power plant and the communities that support it can be described as a dynamic socioeconomic system. The communities provide the people, goods, and services required by power plant construction and operation. Activities at the plant, in turn, create the demand and pay for the people, goods, and services in the form of wages, salaries, and benefits for jobs and dollar expenditures for goods and services. The measure of the communities' ability to support the demands of the power plant depends on their ability to respond to changing environmental, social, economic, and demographic conditions.

Construction—The scale of the socioeconomic impacts of construction activities associated with each alternative would be related to the cost and complexity of the facility and the size of the workforce. The duration of the impact would be determined by the time required to complete construction. The impacts of the construction of power plants on employment and income in the local area and region around a new plant would vary depending on the location of major equipment suppliers and local labor availability. Impacts may be more dramatic and larger at greenfield sites located in rural areas than areas on the periphery of larger urban areas. Overall, construction is expected to have a temporary effect on the local economy.

While some construction workers would be local, additional workers may be required from outside the immediate area depending on the local availability of appropriate trades and occupational groups. At plants in rural locations, a larger number of construction workers would come from outside the local area, while most of the workforce in semi-urban locations would likely commute to the job site rather than relocate. Construction is likely to have some impact on local services such as public utilities, public safety, tourism, and recreation, depending on the number of workers required to in-migrate into the area around each plant. Materials needed for construction (e.g., sand, gravel, fill, etc.) are expected to be provided locally. However, the majority of construction materials and technology components are expected to be purchased in other parts of the United States or overseas. Transportation impacts during construction would include commuter and truck material and equipment delivery traffic to and from the construction site.

Operations—Operations of a new power plant would have an ongoing effect on the local economy, which would be directly or indirectly affected by power plant operation. As would be the case for construction, the impacts of the operation of power plants on employment and income in the local area and region around a new plant would vary depending on the location of major equipment suppliers and the availability of local labor. In addition, operations impacts may have a larger relative impact on communities in rural locations, with smaller relative impacts in semi-urban locations. The operations workforce would increase demand for social services, depending on the number of workers required to migrate into the area around each plant. Property values for nearby private residences could be affected positively if plant workers were to live locally. Property values could also be affected negatively, if there were impacts associated with noise, traffic, or if there were visual impacts associated with the plant.

Declining property values may mean increased local taxes to support existing levels of service in local public and educational services, which combined with declining quality of life, may lead to some population out-migration. The loss of recreational opportunity could mean the loss of employment and income in local communities hosting recreational suppliers and providing temporary accommodation. Transportation impacts would include increased commuter traffic during shift changes and deliveries of materials and equipment to the power plant.

The following sections briefly highlight socioeconomic impacts that would be characteristics of particular energy alternatives.

4.8.2.1 Fossil Fuel Alternatives

A relatively large workforce would be required to construct and operate fossil-fuel alternative-technology power plants, and, as a consequence, impacts on local employment and income and the local public and educational services that would be needed with the in-migration of workers during each phase could be large. Fossil-fuel alternatives, including natural gas- and coal-fired plants, could have substantial impacts, depending on various key aspects of each technology. Differences in stack heights and emissions between the two technologies and the transportation impacts associated with coal deliveries to the power plant (primarily by rail) and the removal of wastes and byproducts may affect property values and recreation and tourism opportunities in the vicinity of plants.

4.8.2.2 New Nuclear Alternatives

A relatively large workforce would be required to construct and operate new nuclear power plants, and, as a consequence, impacts on local employment and income and the local public and educational services that would be needed with the in-migration of workers during each phase could be large. Impacts of the construction and operation of new nuclear plants would also depend on key features of these plants. In addition to the heights of cooling towers and other tall or large structures, the existence of a nuclear power plant could affect property values and recreation and tourism through the perception of risk that people may have related to nuclear technology itself, and also the presence and visibility of nuclear waste storage facilities.

4.8.2.3 Renewable Alternatives

Operations –The impacts of alternative energy technologies on socioeconomics are presented in the following subsections. A relatively small workforce would be required to operate renewable alternative technology power plants and, as a consequence, impacts on employment and income and the local public and educational services that would occur with the in-migration of workers during each phase for each alternative technology would be SMALL.

Hydroelectric Energy Sources

Although there may be economic losses in the local area and region associated with development of hydroelectric resources, notably with the loss of agricultural land, transportation infrastructure, and recreational opportunities, the reservoir would create new recreational opportunities including parks, campgrounds, and boat ramps. Traffic in the vicinity of the dam and reservoir, typically a rural agricultural area, could increase as a result of recreational opportunities created by the reservoir.

Geothermal

Depending on the location of geothermal plants and the amount of land required for power plant development, recreation and property values in the area could be adversely affected by noise, sights, and odors from plant operations. Transportation impacts are expected to be limited, although large vehicle traffic could be required for the deployment and replacement of equipment.

Wind

Depending on the location of wind energy development, the visual impact of wind turbines, and to a lesser extent the associated noise, may have adverse impacts on recreation in the local area and on property values and quality of life in local rural communities. Transportation impacts are expected to be limited. Large vehicles could be required for the deployment and replacement of equipment.

Biomass

Truck and rail traffic bringing biomass fuel to the facility and removing solid wastes to offsite disposal facilities could impact local transportation networks and may affect property values and recreation and tourism opportunities in the vicinity of plants.

Ocean Wave and Current

Tourist and recreational activities on coastal beaches could be affected by the visual and noise impacts of helicopter and boat traffic. Wave energy devices that float on the ocean surface could affect navigation and water-borne recreational activities.

4.9 Human Health

4.9.1 Environmental Consequences of the Proposed Action—Continued Operations and Refurbishment Activities

Human health conditions at all nuclear power plants and associated transmission lines have been well established during the current licensing term. These conditions are expected to remain unchanged during the 20-year license renewal term.

4.9.1.1 Environmental Consequences of Normal Operating Conditions

This section provides an evaluation of the impacts of radiological, chemical, microbiological, EMFs, and other hazards on occupational personnel and members of the public from continued operation and refurbishment activities during the license renewal term. This evaluation extends to all U.S. commercial nuclear power reactors. For safe and reliable operation of a nuclear power plant, it is necessary to perform routine maintenance on plant systems and components. Maintenance activities conducted at nuclear power plants include inspection, surveillance, and repair and/or replacement of material and equipment to maintain the current licensing basis of the plant and ensure compliance with environmental and public safety requirements. Certain activities can be performed while the reactor is operating, and others require that the reactor be shut down. Long-term outages are scheduled for refueling and for certain types of repairs or maintenance activities, such as the replacement of steam generators for PWRs.

4.9.1.1.1 Radiological Impacts

Two environmental issues related to radiological exposure and risk are reviewed here: (1) radiation exposures to plant workers and (2) radiation exposures to the public, both of which would result from continued operation and refurbishment activities during the license renewal term. All aspects of these consolidated issues were evaluated in the 1996 GEIS, but the impacts of refurbishment were considered separately from those of operations.

For the purposes of assessing radiological impacts, impacts are considered to be SMALL if releases and doses do not exceed permissible levels in the NRC's regulations. This definition of SMALL applies to occupational doses as well as to doses to individual members of the public. Accidental releases or noncompliance with the standards could conceivably result in releases that would cause MODERATE or LARGE radiological impacts. Such conditions are beyond the scope of regulations for controlling normal operations and providing an adequate level of protection. Environmental consequences and human health effects of potential accidents are addressed in Section 4.9.1.2.

Radiation Exposures to Plant Workers

The occupational radiological exposures from current operations at nuclear power plants are discussed in Section 3.9.1.2, and the risk estimates from this radiation exposure are discussed in Section 3.9.1.4.

In the 1996 GEIS, the impacts from occupational radiological exposure from refurbishment and continued operations were evaluated separately. To estimate radiation-related impacts on workers over the license renewal term, occupational radiation exposure was used as the environmental impact initiator that was quantified. It was assumed that occupational radiation exposure would change relative to current nuclear plant operations as a result of actions taken to support license renewal. To evaluate the impacts, two types of license renewal programs were considered: a "typical" or "mid-stream" license renewal program, and a "conservative" or "bounding" program (NRC 1996). Each program applied to both PWRs and BWRs. Thus, in all, four scenarios were considered. It was assumed that activities carried out in support of license renewal would be performed primarily during selected outages. Five types of outages were considered: normal refuelings, 5-year in-service inspection (ISI) outages, 10-year ISI outages, current-term refurbishment outages, and major refurbishment outages. The potential actions and activities that would be undertaken during these outages were identified. All of the rules and regulations, in particular, the Maintenance Rule (10 CFR 50.65, "Requirements for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants"), were taken into account in developing typical license renewal or plant-life extension (NRC 1996). The occupational exposure for each of the five types of outages was estimated for all four scenarios (see Table 4.9-1).

For refurbishment efforts, dose estimates for activities during each of the four current-term refurbishment outages were 11 and 10 person-rem for PWRs and BWRs, respectively, for the typical case; and 200 and 191 person-rem, respectively, for the conservative case. Dose estimates for the assumed single period of major refurbishment were 79 and 153 person-rem for

Table 4.9-1. Additional Collective Occupational Dose (person-rem) for Different Actions under Typical and Conservative Scenarios during the License Renewal Term

Outage Type	Typical BWR	Conservative BWR	Typical PWR	Conservative PWR
Normal refueling[(a)]	4	10	3	7
5-yr ISI[(b)] refueling[(c)]	71	27	30	35
10-yr ISI refueling[(d)]	91	108	51	66
Current-term refurbishment[(e)]	10	191	11	200
Major refurbishment outage[(f)]	153	1,561	79	1,380
Total all occurrences	457	2,666	261	2,374

(a) 8 occurrences, 2-month duration each.
(b) ISI = in service inspection.
(c) 2 occurrences, 3-month duration each.
(d) 1 occurrence, 4-month duration for conservative and 3-month duration for typical scenario.
(e) 4 occurrences, 4-month duration for conservative and 3-month duration for typical scenario.
(f) 1 occurrence, 9-month for conservative and 4-month duration for typical scenario.
Source: Tables 2.8 and 2.11 in the 1996 GEIS

PWRs and BWRs, respectively, for the typical case; and 1380 and 1561 person-rem, respectively, for the conservative case. The issue was designated as a Category 1 issue in the 1996 GEIS.

For continued operations during the license renewal term, the NRC observed in the 1996 GEIS that the greatest increment to occupational dose over the present dose would occur during a 10-year ISI refueling. In a typical case, the occupational dose would increase over the present dose by 91 person-rem for a BWR and by 51 person-rem for a PWR. In a conservative case, the occupational dose would increase over the present dose by 108 person-rem and 66 person-rem, respectively, for BWRs and PWRs. It was noted that there is about an 8 percent increase in collective radiation dose over current operating experience. The individual occupational doses would be well below regulatory limits (i.e., the impact would be SMALL), and the issue was designated as a Category 1 issue.

For estimating the impacts from continued operation and refurbishment activities during the license renewal term in this GEIS revision, the occupational exposure histories for all commercial nuclear power plants were evaluated for trends.

Throughout the nuclear power industry, modification and upgrade activities have continued at each operating plant. They have included a broad range of activities in response to NRC requirements and industry initiatives, including post-Three Mile Island upgrades, radioactive waste system modifications, and spent fuel storage upgrades. In addition, several nuclear power plants have undergone major refurbishment efforts, such as PWR steam generator replacement and the replacement of coolant recirculation piping in BWRs. These activities offered a significant potential for occupational exposure. Thus, occupational exposure histories accumulated to date reflect normal operation plus modifications and additions to existing systems. This information forms the basis for evaluating the occupational doses that result from refurbishment and continued operations during the license renewal term. The data in Tables 3.9-8 and 3.9-9 show that there are variations in occupational dose from year to year, but there is no consistent trend that shows that occupational doses are increasing over time.

Since 1996, over 70 operating reactors at over 40 nuclear power plant sites have undergone an environmental review for license renewal. Many nuclear power plants have already replaced major components like steam generators during their current license term. Moreover, as part of the license renewal application, the plants have conducted an aging management review. All of the plants expect to conduct the activities related to managing impacts from aging during plant operation or normal refueling and other outages, but they do not plan any outage specifically for the purpose of refurbishment. The applicants have indicated that the activities conducted during the license renewal term are expected to be within the bounds of normal operations; thus, even the typical scenario in the 1996 GEIS can be considered conservative.

Overall, data presented in Tables 3.9-3 to 3.9-13 provide ample evidence that occupational doses at all commercial power plants are far below the occupational dose limit of 5 rem/yr established by 10 CFR Part 20 and that the continuing efforts to maintain doses at ALARA levels have been successful.

The wide range of annual collective doses experienced at PWRs and BWRs in the United States results from a number of factors, such as the reactor design, amount of required maintenance, and amount of reactor operations and in-plant surveillance. Because these factors can vary widely and unpredictably, it is very difficult to determine in advance a specific year-to-year annual occupational radiation dose for a particular plant throughout its operating lifetime. On occasion, relatively high collective occupational doses (as compared with the average annual collective dose) may be unavoidable, even at plants with radiation protection programs designed to ensure that occupational doses will be kept to ALARA levels.

During 2005, with occupational radiation protection programs in place, nuclear power plants maintained an annual average individual dose of 0.12 rem and 0.18 rem for PWRs and BWRs, respectively (Table 3.9-11), compared with an exposure limit of 5 rem. For all nuclear power plants combined, the occupational doses to individual workers are estimated to average 0.15 rem/yr (Table 3.9-4). At these dose levels, the average increase in fatal individual cancer risk to a worker is approximately 6×10^{-5}/yr (using the ICRP risk coefficient of 4×10^{-4}/rem from Table 3.9-20). If the reactor operates for 60 years, the cumulative increase in fatal cancer to an individual worker is estimated to be 3.6×10^{-3} (a 50 percent increase over the baseline of 40 years of operations). However, it is very unlikely that the same worker would be employed for all 60 years of plant operations.

The average collective occupational exposure for the year 2005 was roughly 171 person-rem per plant at BWRs and about 79 person-rem per plant at PWRs (Table 3.9-10). For 2005, 50 percent of the PWRs reported collective doses between 44 and 107 person-rem, while 50 percent of the BWRs reported collective doses between 94 and 198 person-rem (see Figure 3.9-1). For 2005, no worker received doses greater than 3 rem. Only 17 workers (0.01 percent) received an occupational dose exceeding 2 rem during 2005. At BWRs, less than 0.03 percent of the workers received doses greater than 2 rem. At PWRs, no worker received a dose greater than 2 rem, and less than 0.3 percent of the workers received doses greater than 1 rem (Table 3.9-12).

Over the years, ALARA programs continue to limit occupational doses. Occupational doses have shown a declining trend over the past 10 years and have recently leveled off. As plants age, there may be slight increases in radioactive inventories, which would result in slight increases in occupational radiation doses, but that trend has not yet appeared.

Overall, data presented in Tables 3.9-1 to 3.9-13 provide evidence that doses to nearly all radiation workers are far below the worker dose limit established by 10 CFR Part 20 and that the continuing efforts to maintain doses at ALARA levels have been successful.

It is expected that occupational doses from refurbishment activities associated with license renewal and occupational doses for continued operations during the license renewal term would be similar to the doses during the current operations and bounded by the analysis conducted in the 1996 GEIS. It is estimated that the occupational doses would be much less than the regulatory dose limits, as described above. Expected occupational radiation exposures meet the standard for being of SMALL significance. No mitigation measures beyond those implemented during the current license term would be warranted, because the ALARA process continues to be effective in reducing radiation doses. The risks to an individual worker from radiological exposure would increase by 50 percent as a result of the plant operating for 20 more years, but it is unlikely that the same worker would be employed for all 60 years of plant operations.

In the 1996 GEIS, the NRC concluded that the occupational radiological exposure impact during license renewal and refurbishment would be SMALL for all plants; it was therefore designated as a Category 1 issue. No new information has been identified in the SEISs prepared to date or the literature that would alter that conclusion. On this basis, the NRC concludes that the impact of continued operations and refurbishment activities on occupational radiological exposure would be SMALL for all nuclear plants and remains a Category 1 issue.

Radiation Exposures to the Public

Radiological exposures to the public from current operations at nuclear power plants are discussed in Section 3.9.1.3. That section includes a discussion of the effluent pathways used in calculating dose and the radiological monitoring performed by each site to ensure that unanticipated buildup of radioactivity have not occurred in the environment. The risk estimates for the public from radiation exposure are discussed in Section 3.9.1.4.

Refurbishment Activities—To determine the relative significance of the estimated public dose from refurbishment, the public dose during the year refurbishment activities occurred was compared with the doses in consecutive years. Exposure from other ongoing support activities similar to those that occurred during the current license term (e.g., construction of new parking lots, access roads, and buildings) would be less than or equal to the impacts associated with refurbishment.

In the 1996 GEIS, the NRC identified the replacement of steam generators at PWRs and the replacement of recirculation piping at BWRs as the major anticipated refurbishment activities. Public radiation exposures from refurbishment activities during the license renewal term can be evaluated on the basis of information derived from past occurrences and projections for other repairs. Effluents anticipated during major refurbishment actions were estimated on the basis of historical information derived for steam generator replacements at PWRs and replacements of recirculation piping at BWRs. These refurbishment tasks have already taken place several times within the commercial nuclear power reactor industry. From these estimates, the maximum individual dose to the member of the public was compared with the design objective of Appendix I to 10 CFR Part 50 (Table 3.9-2) and with baseline effluents produced during normal reactor operations.

Public radiation exposures from gaseous and liquid effluents produced during refurbishment can be evaluated on the basis of effluent data from the replacement of steam generators and recirculation piping. During the replacement of steam generators and recirculation piping, releases of effluents have occurred under controlled conditions and in accordance with ALARA principles. Similar refurbishment efforts that may occur as part of the license renewal process would also take place under controlled conditions and in accordance with ALARA principles.

The first several plants to replace steam generators estimated the amounts of radioactivity expected to be released in liquid and gaseous effluents as a result of the repair (Parkhurst et al. 1983). Actual effluent measurements were performed in several cases. In the 1996 GEIS, the NRC listed the radioactive effluent releases for early steam generator replacements and compared them with typical 1986 effluent releases for PWRs and BWRs (see Table 3.10 in NRC 1996). It was found that the effluent releases were approximately the same or much less than those from normal operations for a year. For BWR recirculation piping replacement, the NRC compared the annual release and dose commitment information for five reactor sites (Cooper, Monticello, Nine Mile Point, Peach Bottom, and Vermont Yankee) during recirculation piping replacement with the data from normal operations of the same plants. It was found that the radiation doses to the public were similar to or less than those resulting from normal operations (see Table 3.11 in NRC 1996). On the basis of this finding, the NRC concluded in the 1996 GEIS that gaseous effluents and liquid discharges occurring during a 9-month refurbishment action would not be expected to result in maximum individual doses exceeding the design objectives of Appendix I to 10 CFR 50 or the allowable EPA standards of 40 CFR Part 190 (Table 3.9-2).

For estimating the impacts from refurbishment activities during the license renewal term in this GEIS revision, radioactive effluent releases and the dose to the public from the gaseous and liquid effluent releases were evaluated for the three sites that have gone through steam generator replacement in recent years. The effluent releases and the doses that occurred during the year refurbishment was done are compared with the values for prior and subsequent years.

Table 4.9-2 presents the radioactive effluent releases at three sites that have had their steam generators replaced in recent years. For Arkansas Unit 2, the steam generator was replaced in 2000, and the effluent releases are listed from 1999 to 2003. For Calvert Cliffs Unit 1, the steam generator was replaced in 2002, for Unit 2, it was replaced in 2003. The effluent releases are listed from 2000 to 2004. For Palo Verde Unit 2, the steam generator was replaced in 2003. The effluent releases are listed from 2001 to 2005. For this site, there are no liquid effluent releases beyond the site boundary. The data show that the effluent releases for the year that the steam generators were replaced are on the same order of magnitude or much less than the effluent releases for the following year. The effluent releases were also much less than or on the same order of magnitude as those shown in Table 3.10 of the 1996 GEIS.

Table 4.9-3 presents the dose to the public from the gaseous and liquid effluent releases for the same three sites. No significant difference in the dose from normal operations was observed when the steam generator was replaced. All doses are much less than the design objectives shown in Table 3.9-2. Tables 4.9-2 and 4.9-3 show that effluents and dose impacts during the year when a steam generator replacement is performed do not differ significantly from those in years of normal operations.

It is expected that doses during any future recirculation piping replacement would not be much different than the doses shown in Table 3.11 in the 1996 GEIS. The NRC is updating these tables for recent year data. The NRC will also assess dose contributions from the numerous plants that have replaced reactor vessel heads.

When a major refurbishment is performed, it is expected that more work will be performed and thus the amounts of some of the effluents, especially atmospheric particulates and possibly

some liquid effluents associated with decontamination, may be slightly greater than those found during the steam generator changeouts or recirculation piping replacements.

Continued Operations—During normal operations after license renewal, small quantities of radioactivity (fission, corrosion, and activation products) will continue to be released to the environment in a manner similar to that occurring during present operations (see Section 3.9.1).

The concentration of radioactive materials in soils and sediments increases in the environment at a rate that depends on the rate of release and the rate of removal. Removal can take place through radioactive decay or through chemical, biological, or physical processes. For a given rate of release, the concentrations of longer-lived radionuclides and, consequently, the dose rates attributable to them would continue to increase if license renewal was granted.

Regulatory Guide 1.109 (NRC 1977) provides guidance for calculating the dose for significant release pathways. To account for the buildup of radioactive materials, buildup factors are included in the calculations. Initially, most of the calculations for the construction and operating stage permits used 15 years as the approximate midpoint of a facility's operating life. This value is now more often taken to be 20 years. The potential license renewal term is an additional 20 years; thus, the effective midlife is 30 years.

The accumulation of radioactive materials in the environment is of concern not only with regard to license renewal but also with regard to operation under current licenses. NRC reporting rules require that pathways that may arise as a result of unique conditions at a specific site be considered in licensees' evaluations of radiation exposures. If an exposure pathway is likely to contribute significantly to total dose (10 percent or more to the total dose from all pathways), it must be routinely monitored and evaluated. Environmental monitoring programs are in place at all sites to provide a backup to the calculated doses based on effluent release measurements. Since these programs are ongoing for the duration of the license, locations where unique situations give rise to significant pathways that are not detailed in NRC Regulatory Guide 1.109 are to be identified if and when they become significant. If such pathways result in doses at a plant exceeding the design objectives of Appendix I to 10 CFR Part 50, action is required.

The radiation dose to the public from current operations results from gaseous effluent releases and from liquid effluent releases, as presented in Section 3.9.1.3. At present, for all operating nuclear plants, doses to the maximally exposed individual (MEI) are much less than the design objectives of Appendix I to 10 CFR Part 50 (Table 3.9-2). No aspect of future operation has been identified that would substantially alter this situation.

Maximum individual doses are reported in annual effluent release reports, and if these doses exceed Appendix I to 10 CFR Part 50 design objectives, the NRC would pursue remedial action. Thus these issues are handled on a case-by-case basis. Many plants have gone through license renewal, and no aging phenomenon that would increase public radiation doses has been identified. The operating reactors are not expected to reach regulatory dose limits more often in the period after license renewal than they do at present. For these reasons, dose impacts on MEIs in the public during future operation under license renewal are judged to be unchanged from those during present operations. The MEI dose ranges from 0.02 to 15.3 mrem/yr (see Table 3.9-16). At these dose levels, the increase in fatal cancer risk (using ICRP risk coefficients) to the MEI ranges from 1×10^{-8} to 7.7×10^{-6} for 1 year of reactor operations. Although dose rates (mrem/yr) are not expected to change during license renewal, the cumulative dose (total mrem) would increase as a result of 20 more years of operations. If the reactor operates for 60 years, it is estimated that the increase in fatal cancer risk to the MEI would range from 6×10^{-7} to 4.6×10^{-4} (a 50 percent increase over the baseline of 40 years of operation). However, it is unlikely that the same person would be exposed to these doses for 60 years of plant operations.

One of the pathways considered in calculating the MEI doses is direct radiation from operating plants. Radiation fields are produced around nuclear plants as a result of radioactivity within the reactor and its associated components, low-level storage containers, and components such as steam generators that have been removed from the reactor (as described in Section 3.9). Direct radiation from sources within a light water reactor (LWR) plant is due primarily to nitrogen-16, a radionuclide produced in the reactor core by neutron activation of oxygen-16 from the water. Because the primary coolant of an LWR is contained in a heavily shielded area, dose rates in the vicinity of LWRs are generally undetectable and less than 1 mrem/yr at the site boundary. Some plants (mostly BWRs) do not have completely shielded secondary systems and may contribute some measurable offsite dose. However, these sources of direct radiation will be unaffected by license renewal.

In addition to the regulations within 10 CFR 20.1101 that speak directly to required operation under ALARA principles, 10 CFR 50.36a imposes conditions on licensees in the form of technical specifications on effluents from nuclear power reactors. These specifications are intended to keep releases of radioactive materials to unrestricted areas during operations to ALARA levels. Appendix I to 10 CFR Part 50 provides numerical guidance on dose-design objectives and limiting conditions for the operation of LWRs to meet the ALARA requirements. These regulations will remain in effect during the period of license renewal (see Section 3.9.1.1).

To date, more than 70 operating reactors at over 40 nuclear power plant sites have gone through license renewal since 1996. In all cases, the radiation dose to members of the public from routine operations was within NRC regulations. This information was used to support the conclusion that the radiation dose to the public will continue at current levels associated with normal operations and are expected to remain much lower than the applicable standards.

Offsite doses to the public attributable to refurbishment activities were examined for the MEI. Because the focus of the analysis is on annual dose, only the results based on the most likely major refurbishment action were examined (i.e., replacing steam generators in PWRs and primary recirculation piping in BWRs). For this action, doses to the public were found to be SMALL. To date, effluents and doses during periods of major refurbishments have not been seen to differ significantly from those during normal operations. Consequently, gaseous effluents and liquid discharges occurring during major refurbishment actions are not expected to result in maximum individual doses exceeding the design objectives of Appendix I to 10 CFR Part 50 or the allowable EPA standards of 40 CFR Part 190 (Table 3.9-2).

Radiation doses to members of the public from the current operations of nuclear power plants have been examined from a variety of perspectives, and the impacts were found to be well within design objectives and regulations in each instance. No effect of aging that would significantly affect the radioactive effluents has been identified. Public doses are expected to remain well within design objectives and regulations. The cumulative cancer risk to the MEI would increase by 50 percent because the plant would operate for 20 more years, but the risk would still be small when compared with the cancer risk from background radiation.

Because there is no reason to expect effluents to increase in the period after license renewal, doses from continued operation are expected to be well within regulatory limits. No mitigation measures beyond those implemented during the current term license would be warranted, because current mitigation practices have kept public radiation doses well below regulatory standards and are expected to continue to do so.

Public radiological exposure impacts during license renewal and refurbishment were considered to be SMALL for all plants and were designated as Category 1 issues in the 1996 GEIS. No new information has been identified in the plant-specific SEISs prepared to date, the literature, or effluent and monitoring reports prepared by operating plants that would alter that conclusion. On the basis of these considerations, the NRC concludes that the impact of continued operations and refurbishment activities on public radiological exposure would be SMALL for all nuclear plants and remains a Category 1 issue.

4.9.1.1.2 Chemical Hazards

In nuclear power plants, chemical effects could result from discharges of chlorine or other biocides, small-volume discharges of sanitary and other liquid wastes, chemical spills, or heavy metals leached from cooling system piping and condenser tubing. Impacts of chemical discharges to human health are considered to be SMALL if the discharges of chemicals to water bodies are within effluent limitations designed to ensure protection of water quality, and if ongoing discharges have not resulted in adverse effects on aquatic biota. During the license renewal term, human health impacts from chemicals are expected to be the same as those experienced during operations in the original license term (see Section 3.9.2 for more details).

One environmental issue related to chemical hazards is reviewed here: human health impact from chemicals. This issue was not evaluated in the 1996 GEIS.

Human Health Impact from Chemicals

The types of chemical hazards that exist at a nuclear power plant are discussed in Section 3.9.2. Plant workers may encounter hazardous chemicals when the chemistries of the primary and secondary coolant systems are being adjusted, biocides are being applied to address the fouling of cooling system components, equipment containing hazardous oils or other chemicals is being repaired or replaced, solvents are being used for cleaning, or other equipment is being repaired. Exposures to hazardous chemicals are minimized when plant workers follow good industrial hygiene practices.

Reviews of the literature and operational monitoring reports and consultations with utilities and regulatory agencies that were done for the 1996 GEIS indicated that the effects of the discharge of chlorine and other biocides on water quality would be of SMALL significance for all plants. Small quantities of biocides are readily dissipated and/or chemically altered in the body of water receiving them, so significant cumulative impacts to water quality would not be expected. Major changes in the operation of the cooling system are not expected during the license renewal term, so no change in the effects of biocide discharges on the quality of the receiving water is anticipated. Major proposed changes in cooling system operations (e.g., those affecting the plant's licensing basis and possibly triggering a license amendment) would require a separate NEPA review including an examination of human health effects. In addition, proposed changes in the use of cooling water treatment chemicals would require review by the plant's NPDES permit-issuing authority and possible modification of the existing NPDES permit, including examination of the human health effects of the change. Effects of biocide discharges could be reduced by increasing the degree to which discharge water is treated, reducing the concentration of biocides, or treating only a portion of the plant cooling and service water systems at one time. Discharges of sanitary wastes are regulated by NPDES permit, and discharges that do not violate the permit limits are considered to be of SMALL significance.

The effects of minor chemical discharges and spills at nuclear plants on water quality have been of SMALL significance and mitigated as needed. Significant cumulative impacts on water quality would not be expected because the small amounts of chemicals released by these minor discharges or spills are readily dissipated in the receiving water body. Spills and off-specification discharges occur so seldom that regulatory agencies have not expressed any concern about them with regard to operating nuclear power plants. While there may be additional management practices or discharge-control devices that could further reduce the frequency of accidental spills and off-specification discharges, they are not warranted because impacts are already SMALL and occur at a low frequency.

Heavy metals (e.g., copper, zinc, and chromium) may be leached from condenser tubing and other heat exchangers and discharged by power plants as small-volume waste streams or corrosion products. Although all are found in small quantities in natural waters (and many are essential micronutrients), concentrations in the power plant discharge are controlled in the NPDES permit because excessive concentrations of heavy metals can be toxic to aquatic organisms.

Nuclear power plants may be required in some instances to submit annual reports on the environmental releases of listed toxic chemicals manufactured, processed, or otherwise used that are above identified threshold quantities depending on State regulations or other specific circumstances. The disposal of essentially all of the hazardous chemicals used at nuclear power plants is regulated by Resource Conservation and Recovery Act (RCRA) or NPDES permits. The NRC requires nuclear power plants to operate in compliance with all of its permits, thereby minimizing adverse impacts to the environment and on workers and the public. It is anticipated that all plants will continue to operate in compliance with all applicable permits, and no mitigation measures beyond those implemented during the current term license would be warranted as a result of license renewal.

On the basis of these considerations, the health impact from chemicals to workers and the public is considered SMALL for all nuclear plants. This is a Category 1 issue.

4.9.1.1.3 Microbiological Hazards

Some microorganisms associated with nuclear power plant cooling towers and thermal discharges can have deleterious impacts on the health of plant workers and the public. Certain microorganisms can benefit from thermal effluents. The potential for adverse health effects from microorganisms on nuclear power plant workers is an issue for plants that use cooling towers. Potential adverse health effects on the public from microorganisms in thermal effluents is an issue for nuclear plants that use cooling ponds, lakes, or canals, and that discharge to rivers. During the license renewal term, plant workers and members of the public would be exposed to microbiological hazards in the same way that they are exposed during operations in the original license term (see Section 3.9.3 for details).

Two environmental issues related to microbiological hazards are reviewed here:
(1) microbiological hazards to plant workers (issue was renamed from the 1996 GEIS) and
(2) microbiological hazards to the public (plants with cooling ponds or canals or cooling towers that discharge to a river) (issue was renamed and modified from the 1996 GEIS to include all rivers).

Microbiological Hazards to Plant Workers

The types of microbiological hazards that exist for nuclear power plant workers are discussed in Section 3.9.3. Pathogens of concern include *Salmonella* spp., *Shigella* spp., *Pseudomonas aeruginosa,* thermophilic fungi, *Legionella* spp., and *N. fowleri*. These species are all associated with nuclear plants that use cooling towers as part of their cooling water system. Because of the presence of these microorganisms, workers at nuclear power plants are typically required to use respiratory protection when cleaning cooling towers and condensers. Prairie Island Nuclear Generating Plant, which had high concentrations of *N. fowleri* in the circulating water, successfully controlled the pathogen and protected workers through chlorination before its yearly downtime operation (NRC 1980). The NRC has concluded that microorganisms that live in high-radiation and extreme heat conditions typical of the spent fuel pool do not pose a risk to plant workers (NRC 1999a).

No change in existing microbiological hazards is expected over the license renewal term. It is considered unlikely that any plants that have not already experienced occupational microbiological hazards would do so during the license renewal term or that hazards would increase over that period. It is anticipated that all plants will continue to employ proven industrial hygiene principles so that adverse occupational health effects associated with microorganisms will be of SMALL significance at all sites, and no mitigation measures beyond those implemented during the current term license would be warranted. Aside from continued application of accepted industrial hygiene procedures, no additional mitigation measures are expected to be warranted as a result of license renewal. This remains a Category 1 issue.

Microbiological Hazards to the Public (Plants with Cooling Ponds or Canals or Cooling Towers That Discharge to a River)

N. fowleri, which is the pathogenic strain of the free-living amoebae *Naegleria* spp., appears to be the most likely microorganism that may pose a public health hazard resulting from nuclear power plant operations. Increased populations of *N. fowleri* may have significant adverse impacts. On entry into the nasal passage of a susceptible individual, *N. fowleri* will penetrate the nasal mucosa. The ensuing infection results in a rapidly fatal form of encephalitis. Fortunately, humans in general are resistant to infection with *N. fowleri*. Hallenbeck and Brenniman (1989) have estimated individual annual risks for primary amebic meningoencephalitis caused by the free-living *N. fowleri* to swimmers in freshwater to be approximately 4×10^{-6}. Exposure to *Legionella* spp. from power plant operations would not generally impact the public because concentrated aerosols of the bacteria would not traverse plant boundaries. The information available on microorganisms that may inhabit high-radiation, high-temperature environments (such as the spent fuel pool) indicates that they are very unlikely to significantly increase in number in the environment and that they would not have a deleterious effect on public health (NRC 1999a).

From the studies presented in Section 3.9.3, it is clear that heavily used bodies of freshwater merit special attention and also possibly routine monitoring for pathogenic *Naegleria*. Since *Naegleria* concentrations in freshwater can be enhanced by thermal effluents, nuclear power plants that use cooling lakes, canals, ponds, or rivers experiencing low-flow conditions may enhance the populations of naturally-occurring thermophilic organisms. There are currently 23 reactor sites that fit this category. Data for 14 sites from this category that have gone through license renewal were reviewed to predict the level of thermophilic microbiological organism enhancement at any given site with current knowledge. For all 14 sites, no actual hazards to public health from enhancement of thermophilic microbiological organisms were identified, documented, or substantiated. However, without site-specific data, the same conclusion cannot be drawn for all reactor sites that would go through license renewal.

Changes in microbial populations and in the public use of water bodies might occur after the operating license is issued and the application for license renewal is filed. Other factors could also change, including the average temperature of the water, which could result from climate change that affected water levels and air temperature. Finally, the long-term presence of a power plant might change the natural dynamics of harmful microorganisms within a body of water. Therefore, the magnitude of the potential public health impacts associated with thermal enhancement of thermophilic organisms could be SMALL, MODERATE, or LARGE, depending on plant-specific conditions. This is considered a Category 2 issue.

4.9.1.1.4 Electromagnetic Fields

Nuclear power plants use power-transmission systems that consist of switching stations or substations located on the plant site and transmission lines located primarily offsite that connect the power plant to the regional electric grid. Electric fields and magnetic fields, collectively referred to as EMF, are produced by operating transmission lines. During the license renewal term, plant workers and members of the public who live, work, or pass near an associated operating transmission line may be exposed to the EMF in the same way that they are exposed during the current license term (see Section 3.9.4 for more detail). One environmental issue related to EMFs is reviewed in this section: chronic effects of electromagnetic fields (EMFs) (issue was renamed from the 1996 GEIS). The issue is further evaluated below by reviewing the relevant literature.

It should be noted that the scope of the evaluation of transmission lines in this revised GEIS is reduced from that of the 1996 GEIS. For this revision, only those transmission lines currently needed to connect the nuclear power plants to the regional electric distribution grid are considered within scope (see Sections 3.1.1 and 3.1.6.5 in this GEIS). Thus, the number and length of the transmission lines within the scope of license renewal environmental review are greatly reduced.

Ongoing Research on the Effect of Electromagnetic Fields

In 1990, the EPA's Office of Health and Environmental Assessment reviewed epidemiology studies, chronic lifetime animal tests, and laboratory studies of biological phenomena related to carcinogenesis. The review indicated that some epidemiological studies found an association between EMF and certain types of cancers, but others did not find any association. It was concluded that the scientific issues concerning the relationship between EMF and adverse health effects are very complex and difficult to interpret (EPA 1990). Without an understanding of how these EMF fields are interacting with biological functions, the knowledge gained from scientific studies was of limited value both in evaluating the importance of the study results and in devising protection strategies for the public and for utility workers.

A substantial body of evidence has been accumulated indicating that EMFs may influence biological function at exposure levels capable of producing relatively high current densities (10 to 100 mA/m^2) (IRPA/INIRC 1990). Such exposures have been suggested to induce chromosome aberrations, alter the distribution in molecular weights during protein synthesis, inhibit production of melatonin, alter calcium binding in brain tissue, influence ribonucleic acid (RNA) transcription, and produce a variety of other effects (OTA 1989). Questions concerning the potential carcinogenic effects of EMF field exposure have been raised as a result of suggestive epidemiological findings and some laboratory experiments. One accepted model on the development of cancer is the initiation-promotion paradigm (Easterly 1981). Most investigators conclude that EMFs are not likely to act as initiators because they have not been shown to cause genetic damage (Aldrich and Easterly 1987). EMF effects on RNA transcription, however, could imply increased reduction of oncogene products, and some investigators consider such data to be indicative of genetic effects (Goodman et al. 1987; Goodman and Henderson 1986, 1988). It has not been shown that EMF fields are cancer promoters, but the presence of some reported EMF biological effects reveals the need for further study of this issue (Byus et al. 1987).

Section 2118 of the Energy Policy Act of 1992 (Public Law 102-486, codified at 42 U.S.C. 13478) authorized the Electric and Magnetic Fields Research and Public Information Dissemination Program. The National Institute of Environmental Health Sciences (NIEHS), National Institutes of Health (NIH), and DOE were designated to direct and manage a program of research and analysis aimed at providing scientific evidence to clarify the potential for health risks from exposure to EMF (NIEHS 1999).

Over the course of this program, DOE and NIEHS managed more than 100 cellular and animal studies, exposure assessment studies, and engineering studies. No additional epidemiology studies were conducted; however, analyses of the studies that had already been conducted were an important part of the assessments (NIEHS 2002). In 1998, NIEHS completed the review of a comprehensive body of scientific research on the potential health effects of EMF.

NIEHS organized several technical symposia and a working group meeting to review EMF research. The working group was made up of scientists representing a wide range of disciplines (including engineering, epidemiology, cellular biology, medicine, toxicology, statistics, and pathology) brought together to review and evaluate the RAPID research and other research.

In June 1999, the NIEHS submitted the report, *NIEHS Report on Health Effects from Exposure to Power-Line Frequency Electric and Magnetic Fields* (i.e., extremely low frequency electromagnetic fields [ELF-EMFs]) to Congress. In part, the report (NIEHS 1999) concluded the following:

> The scientific evidence suggesting that ELF-EMF exposures pose any health risk is weak. The strongest evidence for health effects comes from associations observed in human populations with two forms of cancer: childhood leukemia and chronic lymphocytic leukemia in occupationally exposed adults…. In contrast, the mechanistic studies and the animal toxicology literature fail to demonstrate any consistent pattern across studies and the animal toxicology literature fail to demonstrate any consistent pattern across studies although some sporadic findings of biological effects have been reported. No indication of increased leukemia in animals has been observed…. Virtually all of the laboratory evidence in animals and humans and most of the mechanistic work done in cells fail to support a causal relationship between ELF-EMF at environmental levels and changes in biological function or disease status. The lack of consistent, positive findings in animal or mechanistic studies weakens the belief that this association is actually due to ELF-EMF, but it cannot completely discount the epidemiological findings.

The NIEHS concluded that ELF-EMF exposure cannot be recognized as entirely safe because of weak scientific evidence that exposure may pose a leukemia hazard. In the NIEHS opinion, this finding is insufficient to warrant aggressive regulatory concern. However, because virtually everyone in the United States uses electricity and is therefore routinely exposed to ELF-EMF, passive regulatory action is warranted, such as a continued emphasis on educating both the public and the regulatory community on ways in which to reduce exposure. NIEHS suggested that the power industry continue its current practice of siting power lines to reduce exposure and continue to explore ways to reduce the creation of magnetic fields around transmission and distribution lines without creating new hazards. NIEHS also encourages the use of technologies that lower exposures from neighborhood distribution lines, provided they do not increase other risks, such as those from accidental electrocution or fire. NIEHS does not believe that other cancers or noncancer outcomes provide sufficient evidence of a risk to warrant concern (NIEHS 1999).

In the United Kingdom, the National Radiological Protection Board (NRPB) established an independent Expert Advisory Group on Non-Ionizing Radiation (AGNIR) that reviewed scientific evidence relating possible adverse health effects to low-frequency EMFs (NRPB 2001, 2004). The earlier review (NRPB 2001) provided no firm evidence of a carcinogenic hazard to children or adults from exposure to normal levels of low-frequency EMFs, but made a number of recommendations for epidemiological studies and experimental work. The NRPB review in 2004 (NRPB 2004) concluded that currently, the results of these studies on EMF and health do not warrant quantitative restrictions on exposure to EMF. However, such studies, together with people's concerns, provide a basis for precautionary measures (NRPB 2004).

The World Health Organization (WHO) published an environmental health criteria monograph (WHO 2007) that addresses the possible health effects of ELF-EMF exposure. It reviewed the scientific literature on biological effects to assess the health risk from ELF-EMF exposure. It concluded the following about childhood leukemia:

> Scientific evidence suggesting that everyday, chronic low-intensity (above 0.3 to 0.4 μT) low-frequency magnetic field exposure poses a health risk is based on epidemiological studies demonstrating a consistent pattern of increased risk for childhood leukemia. Uncertainties in the hazard assessment include the role that control selection bias and exposure misclassification might have on the observed relationship between magnetic fields and childhood leukemia. In addition, virtually all of the laboratory evidence and the mechanistic evidence fail to support a relationship between low-level ELF magnetic fields and changes in biological function or disease status. Thus, on balance, the evidence is not strong enough to be considered causal, but sufficiently strong to remain a concern.

The potential for transmission line EMF to cause adverse health impacts in humans has been reviewed by many scientific groups. The hazard is assessed by a standard scientific approach that considers data from epidemiologic, laboratory, and biophysical studies. A number of epidemiologic studies have reported a small degree of association between measures of EMF and several diseases such as childhood leukemia. Other studies have failed to find an association. A causal basis for the EMF associations is not supported by laboratory and biophysical evidence, and the actual basis remains unexplained. Nonetheless, in 2002, the International Agency for Research on Cancer (IARC 2002) designated EMF as a class 2B carcinogen ("possibly carcinogenic"), on the basis of "consistent statistical associations of high-level residential magnetic fields with a doubling of the risk of childhood leukemia." The WHO (2007) monograph did not change the EMF classification on the basis of new human, animal, and in vitro studies published since the IARC (2002). In 2002, the California Department of Health Services issued a report (CADHS 2002) concluding that "EMFs can cause some degree of increased risk of childhood leukemia, adult brain cancer, Lou Gehrig's disease, and miscarriage." Kheifets et al. (2005) assessed the potential susceptibility of children to EMFs and recommended additional research and the development of precautionary policies.

The WHO (2007) monograph also reviewed literature that looked at a number of other diseases such as cancers in children and adults, depression, suicide, reproductive dysfunction, developmental disorders, immunological modifications, and neurological disease. On the basis of this review, it concluded the following:

> The scientific evidence supporting a linkage between ELF magnetic fields and any of these diseases is much weaker than for childhood leukemia and in some cases (for example, for cardiovascular disease or breast cancer) the evidence is sufficient to give confidence that magnetic fields do not cause the disease.

Extensive investigations of animals exposed at much higher levels of magnetic fields (up to 5 mT) have not demonstrated adverse health effects (Boorman et al. 2000). The elevated levels of EMF exposure in occupational settings likewise do not show a consistent pattern of increased risk for acute myocardial infarction or chronic coronary heart disease (Sahl et al. 2002). Laboratory studies of cells and tissues do not support the hypothesis that EMF exposure at ambient levels is a significant risk factor for human disease (NIEHS 1999). The failure to observe biological effects from EMF exposure may be due to the fact that, mechanistically, effects of EMF on biology are very weak (Valberg et al. 1997) or the association between the epidemiological results on childhood leukemia and EMF be the result of chance or a confounding factor (Draper et al. 2005).

Chronic Effects of Electromagnetic Fields (EMFs)

An important question regarding regulations is whether transmission line exposures contribute significantly to total EMF exposures. In most cases, fields produced inside the home by appliances and electrical wiring are greater than the contributions from transmission line fields. Exceptions to this rule are individuals living next to a high-voltage transmission line ROW. Also relevant is the fact that exposures to transmission line fields are considered more continuous than those to appliance fields because transmission line fields permeate large areas (e.g., an entire home). Fields generated by appliances are generally more localized, resulting in intermittent exposures as individuals move around and as the appliances are turned on and off.

The earth's atmosphere produces slowly varying electric fields that average less than a few hundred V/m, and the earth's core produces a steady magnetic field in a range from about 0.3 to 0.6 G. Near appliances, the magnetic fields can be high, but they diminish sharply with distance. Table 4.9-4 shows the magnetic fields at different distances from household appliances (HCCP 2007). Typical house wiring and appliances contribute a 60-Hz magnetic field that can be up to about 3 mG (not in the vicinity of appliances). Some comparisons

Table 4.9-4. Magnetic Fields at Different Distances from Household Appliances

Household Appliance	Magnetic Fields (mG) at Different Distances		
	3 cm	30 cm	100 cm
Microwave oven	750–2,000	40–80	3–8
Fluorescent lamp	400–4,000	5–20	0.1–3
Electric cooking stove	60–2,000	4–40	0.1–1
Television	25–500	0.4–20	0.1–2
Clothes washer	8–400	2–30	0.1–2

Source: HCCP 2007

(of induced currents) among transmission line exposures, domestic exposures, and exposures used in biological effects experiments can be made by using induced current density as an exposure metric. According to data provided in OTA (1989), field strengths on the ROW of a 500-kV line induce body currents that are higher than those induced by domestic exposures produced by typical electrical appliances. A comparison with the results of biological effects experiments (OTA 1989) shows that while current densities in many biological effects experiments are higher than those typically induced by household exposures, some current densities are significantly lower. These comparisons are based, however, on average current densities predicted in humans, because EMF dosimetry has not advanced to the point of determining specific current densities in various tissues and organs. Moreover, researchers have not identified what field characteristics are important biologically.

Conclusion on Electromagnetic Fields

A review of the biological and physical studies of 60-Hz EMFs did not find any consistent evidence that would link harmful effects with field exposures. EMFs are unlike other agents that have a toxic effect (e.g., toxic chemicals and ionizing radiation) in that dramatic acute effects cannot be forced, and longer-term effects, if real, are subtle. Nonetheless, a wide range of biological responses have been reported to be affected by EMFs.

Even if clear adverse effects were apparent in the epidemiology literature or with some biological assay, considerable additional work would be required to determine how and what to mitigate, because evidence suggests that some EMF biological effects do not follow the typical “more intensity is worse” relationship. Furthermore, there may be a subtle relationship between the intensity of the local geomagnetic field and the appearance of effects for some intensities of 60-Hz fields. This complicating evidence points to the fact that, while much experimental and epidemiological evidence has been accrued, the pieces still do not fit together very well.

Because of inconclusive scientific evidence, the chronic health effects of EMF are considered uncertain, and currently, no generic impact level can be assigned. The NRC will continue to monitor the research initiatives—both those within the national EMF program and others internationally—to evaluate the potential carcinogenicity of EMFs as well as other progress in the EMF study disciplines. If the NRC finds that the appropriate Federal health agencies have reached a consensus on the potential human health effects from exposure to EMF, the NRC will revise the GEIS to include the new information and determine what to require of all future license renewal applicants.

4.9.1.1.5 Other Hazards

Two additional human health issues are addressed in this section: (1) physical occupational hazards (new issue not considered in the 1996 GEIS) and (2) electric shock hazards (issue was renamed from the 1996 GEIS).

Nuclear power plants are industrial facilities that have many of the typical occupational hazards found at any other electric power generation utility. Workers at or around nuclear power plants would be involved in some electrical work, electric power line maintenance, repair work, and maintenance activities and exposed to some potentially hazardous physical conditions (e.g., excessive heat, cold, and pressure). The issue of physical occupational hazards is generic to all nuclear power plants.

Transmission lines are needed to transfer energy from the nuclear power plant to consumers. The workers and general public at or around the nuclear power plants and along the transmission lines are exposed to the potential for acute electrical shock from these lines. The issue of electrical shock is generic to all nuclear power plants. As described in Sections 3.1.1 and 3.1.6.5, in-scope transmission lines include only those lines that would not continue to operate if a plant's license was not renewed. Using this criterion, in-scope transmission lines are those lines that connect the plant to the first substation of the regional electric grid. This substation is frequently, but not always, located on the plant property.

During the license renewal term, human health impacts from physical occupational hazards and acute shock hazards would be the same as those from operations during the original license term (see Section 3.9.5 for more detail).

<u>Physical Occupational Hazards</u>

The types of occupational hazards that exist at a nuclear power plant are discussed in Section 3.9.5. The issue of occupational hazards is evaluated by comparing the rate of fatal injuries and nonfatal occupational injuries and illnesses in the utility sector with the rate in all industries combined. Occupational hazards can be minimized when workers adhere to safety standards and use appropriate personal protective equipment; however, fatalities and injuries from accidents can still occur. Data for occupational injuries from the U.S. Bureau of Labor Statistics (BLS) for 2005 (BLS 2005a,b,c) indicate that the rate of fatal injuries in the utility sector is less than the rate for many sectors (construction; transportation and warehousing; agriculture, forestry, fishing, and hunting; wholesale trade; and mining) and that the incidence rate for nonfatal occupational injuries and illnesses is the least for electric power generation, followed by electric power transmission control and distribution (see Section 3.9.5). The fatality rate for electric power line installers and repairers can be estimated at 0.032 percent (BLS 2005a). It is expected that over the license renewal term, workers would continue to adhere to safety standards and use protective equipment, so adverse occupational impacts would be of SMALL significance at all sites, and no mitigation measures beyond those implemented during the current license term would be warranted. The impact of these hazards is a Category 1 issue.

Electric Shock Hazards

The greatest hazard from a transmission line is direct contact with the conductors. Tower designs preclude direct public access to the conductors. However, electrical contact can be made without physical contact between a grounded object and the conductor. Secondary shock currents are produced when humans make contact with (1) capacitively charged bodies, such as a vehicle parked near a transmission line, or (2) magnetically linked metallic structures, such as fences near transmission lines. A person who contacts such an object could receive a shock and experience a painful sensation at the point of contact. The intensity of the shock would depend on the EMF strength, size of the object, and how well the object and person were insulated from ground.

Design criteria for nuclear power plants that limit hazards from steady-state currents are based on the National Electrical Safety Code (NESC), adherence to which requires that utility companies design transmission lines so that the short-circuit current to ground produced from the largest anticipated vehicle or object is limited to less than 5 mA (IEEE 2007). With respect to shock safety issues and license renewal, three points must be made. First, in the licensing process for the earlier licensed nuclear plants, the issue of electrical shock safety was not addressed. Second, some plants that received operating licenses with a stated transmission line voltage may have chosen to upgrade the line voltage for reasons of efficiency, possibly without reanalysis of induction effects. Third, since the initial NEPA review for those utilities that evaluated potential shock situations under the provision of the NESC, land use may have changed, resulting in the need for a reevaluation of this issue. The electrical shock issue, which is generic to all types of electrical generating stations, including nuclear plants, is of SMALL significance for transmission lines that are operated in adherence with the NESC. Without a review of the conformance of each nuclear plant's transmission lines, within this scope of review, with NESC criteria, it is not possible to determine the significance of the electrical shock potential generically; it could be SMALL, MODERATE, or LARGE. The impact of this hazard remains a Category 2 issue.

4.9.1.2 Environmental Consequences of Postulated Accidents

Design-Basis Accidents and Severe Accidents

Chapter 5 of the 1996 GEIS assessed the impacts of postulated accidents at nuclear power plants (NPPs) on the environment. The postulated accidents included design-basis accidents and severe accidents (e.g., those with core damage). The impacts considered included:

- Dose and health effects of accidents (5.3.3.2 through 5.3.3.4);
- Economic impacts of accidents (5.3.3.5); and
- Impact of uncertainties on results (5.3.4).

The estimated impacts were based upon the analysis of severe accidents at 28 NPPs,[c] as reported in the environmental impact statements (EISs) and/or final environmental statements (FESs) prepared for each of the 28 plants in support of their operating licenses. With few exceptions, the severe accident analyses were limited to consideration of reactor accidents caused by internal events. The 1996 GEIS addressed the impacts from external events qualitatively. The severe accident analysis for the 28 plants was extended to the remainder of plants whose EISs did not consider severe accidents (since such analysis was not required at the time the other plants' EISs were prepared). The estimates of environmental impact contained in the 1996 GEIS used 95th percentile upper confidence bound (UCB) estimates whenever available. This provides conservatism to cover uncertainties, as described in Section 5.3.3.2.2 of the 1996 GEIS. The 1996 GEIS concluded that the probability-weighted consequences and impacts were SMALL compared to other risks to which the populations surrounding NPPs are routinely exposed.

Appendix E of this document provides an update on postulated accident risk. Since the NRC's understanding of accident risk has evolved since the issuance of the 1996 GEIS, Appendix E assesses more recent information on postulated accidents that might have had the potential to alter the conclusions in Chapter 5 of the 1996 GEIS. This update considers how these

(c) The 28 sites are listed in Table 5.1 of the 1996 GEIS. There are a total of 44 units included in this list, but 4 of these units never operated (Grand Gulf 2, Harris 2, Perry 2, and Seabrook 2). For the purpose of this document, this list will be referred to as containing 28 NPPs, but when mean values are calculated for this subset of NPPs, the 40 units that operated are considered.

developments would affect the conclusions in the original GEIS and provides comparative data where appropriate.

The different sources of new information can be generally categorized by their effect of either decreasing, not affecting, or increasing the best-estimate environmental impacts associated with postulated severe accidents. Those areas where a decrease in best-estimate impacts would be expected are:

- New internal events information (decreases by an order of magnitude), and
- New source term information (significant decreases).

Areas likely leading to either a small change or no change include:

- Use of BEIR-VII risk coefficients.

Lastly, those areas leading to an increase in best-estimate impacts would consist of:

- Consideration of external events (comparable to internal event impacts),
- Power uprates (small to moderate increase),
- Higher fuel burnup (small to moderate increases),
- Low power and reactor shutdown events (could be comparable to full-power event impacts), and
- Spent fuel pool accidents (could be comparable to full-power event impacts).

Given the difficulty in conducting a rigorous aggregation of these results with the differences in the information sources utilized, a fairly simple approach is taken. The latter group contains three areas where the increase could be comparable to the current risk and two areas where the increase could approach 30–40 percent. The net increase from these five areas would therefore be (in a simplistic sense) approximately 470 percent[d] (increase by a factor of 4.7). The reduction in risk due to newer internal event information would account for a decrease by a factor of 5 to 100. The net effect of an increase on the order of 500 percent and a decrease on the order of 500 percent to 10,000 percent would be lower estimated impacts (as compared to the 1996 GEIS assessment).

(d) This approximation simply assumes that each comparable area results in an increase of 100 percent and the other two areas (uprates and burnup) each result in an increase of 35 percent.

Furthermore, even if one assumed that the net effect of the new information was no change in risk, the information provided throughout Appendix E demonstrates that the level of conservatism in the upper bound estimates utilized in the 1996 GEIS is much larger than the individual (or cumulative) deltas from the updated information. In particular, Section E.3.1 of Appendix E demonstrates that the 1996 GEIS values were a factor of 2 to 4 higher than the underlying EIS values.

With respect to uncertainties, the 1996 GEIS contained an assessment of uncertainties in the information used to estimate the environmental impacts. Section 5.3.5 of the 1996 GEIS discusses the uncertainties and concludes that they could cause the impacts to vary anywhere from a factor of 10 to a factor of 1,000. This range of uncertainties bounds the uncertainties discussed in Section E.3.9 of Appendix E of this document, which ranged from a factor of 3 to 10, as well as the uncertainties brought in by the other sources of new information.

Given the discussion in Appendix E of this document, the staff concludes that the reduction in environmental impacts from the use of new information (since the 1996 GEIS analysis) outweighs any increases resulting from this same information. As a result, the findings in the 1996 GEIS remain valid. Therefore, design-basis accidents remain a Category 1 issue, and although the probability-weighted consequences of severe accidents are SMALL for all plants, severe accidents remain a Category 2 issue to the extent that only alternatives to mitigate severe accidents must be considered for all plants that have not previously considered such alternatives.

In addition, it is reasonable based on the discussion in Appendix E that, in license renewal applications, the impacts from reactor accidents at full power (including internal and external events) should continue to be considered in assessing severe accident mitigation alternatives (SAMAs). The impacts of all other new information do not contribute sufficiently to the environmental impacts to warrant their inclusion in the SAMA analysis since the likelihood of finding cost-effective plant improvements is small. Alternatives to mitigate severe accidents still must be considered for all plants that have not considered such alternatives; however, as discussed further in Appendix E, those plants that have already had a SAMA analysis considered by the NRC as part of an EIS, supplement to an EIS, or EA, need not perform an additional SAMA analysis for license renewal. Table 4.9-5 provides a summary of the conclusions discussed above.

Table 4.9-5. Summary of Issues Covered in Appendix E

Topic (Section)	Conclusions
New Internal Events Information (Section E.3.1)	New information on the risk and environmental impacts of severe accidents caused by internal events indicates that PWR and BWR core damage frequencies (CDFs) are generally comparable to or less than those forming the basis of the 1996 GEIS. In some cases, these differences are significant (approaching 1 order of magnitude). Comparison of population dose from newer assessments illustrates a reduction in impact by a factor of 5 to 100 when compared to older assessments, and an additional factor of 2 to 4 due to the conservatism built into the 1996 GEIS values. This would also mean that contamination of open bodies of water and economic impacts would, in most cases, be significantly less. Additionally, the likelihood of basemat melt-through accidents is less than that used in the analysis supporting the 1996 GEIS.
Consideration of External Events (Section E.3.2)	The 1996 GEIS did not quantitatively consider severe accidents initiated by external events in assessing environmental impacts. When the environmental impacts of external events are considered, they can be comparable to those from internal events; however, they are generally lower than the estimates used in the 1996 GEIS for internal events. This conclusion would also apply to the contamination of open bodies of water, groundwater and economic impacts.
New Source Term Information (Section E.3.3)	More recent source term information indicates that the timing from dominant severe accident sequences, as quantified in NUREG/CR-6295, is comparable to the analysis forming the basis of the 1996 GEIS. In most cases, the release frequencies and release fractions are significantly lower for the more recent estimate. Thus, the environmental impacts used as the basis for the 1996 GEIS are higher than the impacts that would be estimated using the more recent source term information.
Power Uprates (Section E.3.4)	Based on a comparison of the change in large early release frequency (LERF) for extended power uprates, a small to moderate increase in environmental impacts results from the increase in operating power level.
Higher Fuel Burnup (Section E.3.5)	Increased peak fuel burn-up from 42 to 75 GWd/MT for PWRs and 60 to 75 GWd/MT for BWRs is estimated to result in small to moderate increases in the environmental impacts in the event of a severe accident.
Consideration of Low Power and Reactor Shutdown Events (Section E.3.6)	The environmental impacts from accidents at low power and reactor shutdown conditions are generally comparable to those from accidents at full power when comparing the values in NUREG/CR-6143 and NUREG/CR-6144 to those in NUREG-1150. Even so, the 1996 GEIS estimates of the environmental impact of severe accidents bound the potential impacts from accidents at low power and reactor shutdown. Finally, as cited above and discussed in SECY-97-168, industry initiatives taken during the early 1990s have also contributed to the improved safety of low power and reactor shutdown operation.
Consideration of Spent Fuel Pool Accidents (Section E.3.7)	The environmental impacts from accidents at spent fuel pools (SFPs) (as quantified in NUREG-1738) can be comparable to those from reactor accidents at full power (as estimated in NUREG-1150). Subsequent analyses performed and mitigative measures employed since 2001 have further lowered the risk of this class of accidents. In addition, the conservative estimates from NUREG-1738 are much less than the impacts from full-power reactor accidents that are estimated in the 1996 GEIS.

Table 4.9-5. (cont.)

Topic (Section)	Conclusions
Use of BEIR-VII Risk Coefficient (Section E.3.8)	Use of newer risk coefficients such as in BEIR VII is expected to have a small impact on the results presented in the 1996 GEIS.
Uncertainties (Section E.3.9)	The impact and magnitude of uncertainties, as estimated in the 1996 GEIS, bound the uncertainties introduced by the new information and considerations.
SAMAs (Section E.4)	The current process and scope of SAMA analysis is sufficient for determining the need for additional mitigative measures.
Summary/Conclusion (Section E.5)	Given the new and updated information, the reduction in estimated environmental impacts from the use of new internal event and source term information outweighs any increases from the consideration of external events, power uprates, higher fuel burnup, low power and reactor shutdown risk, and SFP risk.

4.9.2 Environmental Consequences of Alternatives to the Proposed Action

Construction—Impacts on workers are expected to be similar to those experienced during construction of any major industrial facility. Impacts from construction of combustion-based renewable energy facilities are expected to be the same as those for construction of fossil fuel facilities. Construction would increase traffic on local roads, which could affect the health of the general public. Human health impacts would be the same for all facilities whether located on greenfield sites, brownfield sites, or at an existing nuclear plant. Personal protective equipment, training, and engineered barriers would protect the workforce.

Summaries of statistics maintained by the U.S. Department of Labor, Bureau of Labor Statistics (Meyer and Pegula 2006) indicate that construction activities are responsible for a significant share of workplace accidents. In 2004, the construction industry accounted for 1 in 5 fatal workplace injuries and 1 in 10 nonfatal workplace injuries. With a workforce of 10,272,000 workers in 2004, the private construction industry registered 1,234 total fatalities in the following categories: falls, 445 (36 percent); transportation incidents, 287 (23 percent) (highway 148, non-highway 45, worker struck by vehicle/mobile equipment, 78); contact with objects and equipment, 267 (18 percent) (struck by object, 150; caught in or crushed in collapsing materials 71); exposure to harmful substances and environments, 170 (14 percent); and contact with electric current, 122 (10 percent). Over that same period, of a total of 401,000 nonfatal injuries and illnesses in the construction industry (nonfatal injuries that resulted in at least one day away from work) totaled 153,200 in the following categories: overexertion, 30,460 (20 percent); struck by object, 27,950 (18 percent); fall to lower level, 20,950 (14 percent); fall to same level, 12,700 (8 percent); and struck against object, 12,720 (8 percent).

4.9.2.1 Fossil Energy Alternatives

Environmental Consequences of Normal Operating Conditions

Operations—In 2006, the U.S. Department of Labor's (DOL's) Bureau of Labor Statistics revealed 134,400 individuals employed in the fossil fuel electric power generation industrial sector (North American Industry Classification System (NAICS) Code 221112) (DOL 2007a). For 2006 (DOL 2007b), DOL documented 17 total fatalities for all of the electric power generating industrial sector (NAICS Code 22111) and 5 fatalities for fossil fuel electric power generation. In 2006, the nonfatal injury and illness incident rate was 3.9 cases per 100 fulltime workers, slightly higher than the incident rate of 3.1 cases per 100 full-time workers for the entire electric power generation sector. Total reportable incidents occurred at a rate of 2.2 per 100 full-time workers. Those incidents that resulted from lost time at work occurred at a rate of 1.2 cases per 100 full-time workers.

Human health risks are associated with the management and disposal of coal combustion waste. Human health risks may extend beyond the facility workforce to the public and are proximate to the coal combustion waste disposal facility. The character and the constituents of coal combustion waste depend on both the chemical composition of the source coal and the technology used to combust it. Generally, the primary sources of adverse consequences from coal combustion waste are the presence of leachable, toxic (and, in some cases, carcinogenic) heavy metals primarily contained in fly ash and bottom ash, especially arsenic, selenium, and mercury. With future implementation of regulations limiting mercury emissions, the amount of mercury present in coal combustion waste is expected to rise, and, depending on the particular chemical speciation, the amount of leachable mercury in coal combustion waste may also increase. Depending on the coal source, radionuclides may also be present in coal combustion waste.

The EPA is considering regulations specific to disposal of coal combustion waste under the authority of Subtitle D of RCRA (EPA 2007). Preliminary (draft) risk assessments of historical disposal practices for coal combustion waste in landfills and surface water impoundments identified both direct and indirect (food chain contamination) pathways for human exposure. Overall, when all types of landfills and surface impoundments are evaluated in aggregate, the cancer risk criterion for arsenic (1×10^{-6}) can be exceeded for both unlined units (5×10^{-4}) and clay-lined units (2×10^{-4}). Arsenic cancer risks are higher for unlined surface impoundments (9×10^{-3}) and for clay-lined units (3×10^{-3}). Composite (synthetic) liners, which have been used in the majority of the most recently constructed landfills and surface impoundments, greatly reduce infiltration of leachable constituents, so much so that risks at all percentiles fall below both the cancer and noncancer risk criteria for both landfills and surface impoundments.

Although future alternative power generating facilities are most likely to use offsite disposal of coal combustion waste, some short-term storage of coal combustion waste (either in open piles or in surface impoundments) is likely to take place onsite, thus establishing the potential for leaching of toxic constituents into the local environment. Mobility studies indicate that toxic constituents take hundreds to thousands of years to leach through the bottoms of landfills and less than 100 years to leach through the bottom surface impoundments. However, because each batch of coal combustion waste would likely remain in interim onsite storage for only a short period, the potential for release of toxic constituents into the environment is greatly reduced. Offsite disposal facilities would be designed and operated in a manner that minimizes impacts from leached constituents.

Environmental Consequences of Accidents

Operations—Accidents involving fossil fuel energy sources that affect the functionality of the boiler or the steam cycle would have the most significant impacts. Steam explosions and other mechanical failures have the potential for adverse consequences on the workforce, but are not likely to directly affect the surrounding public or natural resources. Failures of pollution control devices would have an immediate but short-term impact on the environment because of the resulting release of pollutants. However, operating permits would require immediate shutdown of combustion sources whose pollution control devices became inoperative and prohibit continued operation that bypasses the failed control device. However, pollution control device failures, as well as other accidents that are sufficiently severe so as to require the shutdown of operations, would result in indirect impacts on the public in the form of reduced available power and possible short-term brownouts or blackouts. Although power might be restored relatively quickly, longer-term impacts may include a temporary rise in the levelized cost of electricity.

Overall, impacts on the environment from accidents at a fossil-fuel fired plant are expected to be short-lived and small. Longer-term impacts on socioeconomics could be anticipated both as a result of job loss and (temporary) higher costs of energy, but overall would be expected to be SMALL.

4.9.2.2 New Nuclear Alternatives

Environmental Consequences of Normal Operating Conditions

Operations—Operational human health impacts for a new nuclear plant would include radiation exposure to the public (at very low levels) and to the operational workforce; impacts from exposure to microbiological organisms; occupational safety risks; impacts from electromagnetic fields; and exposure to chemicals used onsite by the workers. Impacts on human health, in most cases, were determined to be SMALL in 10 CFR Part 51, Appendix B, Table B-1, and although the table is specific to license renewal, similar human health impacts would be expected from the operation of a new nuclear facility. Human health impacts would be the same for all facilities, whether located on greenfield sites, brownfield sites, or sites located at a previously existing nuclear plant, and are expected to be SMALL.

Environmental Consequences of Accidents

A detailed analysis of postulated accidents in currently operating reactors (affected by license renewal) is provided in Section 4.9.1.2. Although the analysis is specific to license renewal, the impacts are representative of the impacts expected for new reactors. New reactor designs incorporate additional safety features not found in currently operating reactors. As a result, it is expected that the risks associated with the new reactors would be comparable to or less than the risks associated with currently operating reactors. Before a license is granted, the application for a new reactor would undergo a detailed safety and environmental review to ensure that the plant, if constructed, would operate in accordance with all applicable NRC rules and regulations.

4.9.2.3 Renewable Alternatives

Operations—The operational impacts of alternative energy technologies on human health are presented in the following subsections.

Hydroelectric Energy Sources

Impacts on workers include working near energized systems and high pressure water.

Geothermal

Operating workers could be affected by exposure to toxic gases and other constituents present in geothermal fluids, energized systems, including high pressure and high temperature gases and fluids, and electromagnetic fields associated with the generation, conditioning, and transmission of electricity. Workers could be affected by exposure to toxic constituents, including boron, arsenic, radon, and mercury.

Wind

Operational hazards for the workforce include working at heights, near rotating mechanical or energized equipment, and working in extreme weather. Additional hazards unique to offshore wind farms include navigating and working in heavy seas. Potential impacts to workers and the public include ice thrown from rotor blades and blades thrown from mechanical failure and disintegration. Potential impacts also include EMF exposure, aviation safety, electromagnetic interference, and exposure to low-frequency sound.

Biomass

Human health risks to workers are expected to be similar to workers in a coal combustion facility. Work hazards include exposure to heat, gases, chemicals, high temperature liquids, and energized mechanical and electrical equipment. The potential exists for exposure to inhalable particulates and polycyclic aromatic hydrocarbons (PAHs) resulting from incomplete combustion of complex organic molecules. The public could be affected by fugitive dust and contaminated water.

Municipal Solid Waste, Refuse-Derived Fuel, and Landfill Gas

Combustion of municipal solid waste and/or refuse-derived fuel may result in the release of constituents that are persistent, bioaccumulative, and toxic, PAHs, and chlorinated hydrocarbons. The workforce as well as nearby residents could be affected by the release of toxic constituents to the air. The workforce could also be affected by exposure to toxic wastes.

Solar Thermal

Potential hazards to workforce include exposure to extremely hot heat transfer fluids or burned from misaligned mirrors and contact with energized system components.

Solar Photovoltaic

Workers could be exposed to airborne toxic heavy metals (e.g., cadmium) and silicon if the photovoltaic cell loses integrity from a fire. Workers could also inhale silicon dust if the integrity of photovoltaic cells was compromised by an accident.

Ocean Wave and Current

Operation of wave- and current-energy capturing systems would not be expected to affect human health. Workers could be affected by possible exposure to energized systems, inclement weather conditions, and high sea states. Workers could be affected by work underwater inspecting and repairing cables and tethers.

4.10 Environmental Justice

4.10.1 Environmental Consequences of the Proposed Action—Continued Operations and Refurbishment Activities

Impacts of nuclear plant operations and refurbishment on minority and low-income populations living in the vicinity of nuclear power plants were not addressed in the 1996 GEIS because guidance for implementing Executive Order 12898 was not available at the time. Environmental justice was listed in Table B-1 in Appendix B, Subpart A, of 10 CFR Part 51, but was not assigned an issue category or impact significance. The finding in Table B-1 stated that “the need for and the content of an analysis of environmental justice will be addressed in plant-specific reviews.” Therefore, impacts to “minority and low-income populations,” was evaluated as a new issue for this GEIS revision.

The NRC addresses environmental justice matters for license renewal through (1) identifying the location of minority and low-income populations that the continued operation of the nuclear power plant may affect during the license renewal term, (2) determining whether there would be any potential human health or environmental effects to these populations and special pathway receptors, and (3) determining if any of the effects may be disproportionately high and adverse.

Minority and Low-Income Populations

The environmental justice impact analysis considers the potential for disproportionately high and adverse human health and environmental effects on minority and low-income populations that could result from continued nuclear plant operations and refurbishment activities at a nuclear power plant. Adverse health effects are measured in terms of the risk and rate of fatal or nonfatal adverse impacts on human health. Disproportionately high and adverse human health effects occur when the risk or rate of exposure to an environmental hazard for a minority or low-income population is significant and exceeds the risk or exposure rate for the general population or for another appropriate comparison group. Disproportionately high environmental effects refer to impacts or risk of impact on the natural or physical environment in a minority or low-income community that are significant and appreciably exceed the environmental impact on the larger community. Such effects may include biological, cultural, economic, or social impacts. Some of these potential effects have been identified in resource areas discussed in this section. For example, increased demand for rental housing during replacement power plant construction could disproportionately affect low-income populations. Minority and low-income populations are subsets of the general public residing around the site, and all are exposed to the same risks and hazards generated from operating a nuclear power plant.

Continued reactor operations and other activities associated with license renewal could have an impact on air, land, water, and ecological resources in the region around each nuclear power plant site, which might, create human health and environmental effects on the general population. Depending on the proximity of minority and low-income populations in relation to each nuclear plant, the environmental impacts of license renewal could have a disproportionate effect on these populations.

There is considerable variation in the representation of minority and low-income populations within 50 mi (80 km) of each nuclear power plant site. Sites located in the southern and southwestern United States have large minority populations (e.g., Browns Ferry, Brunswick, Catawba, Farley, North Anna, Robinson, Summer, and Surry plants). Sites located close to metropolitan areas also have larger minority populations as well as larger low-income populations (e.g., Dresden, Ginna, Indian Point, and Pilgrim plants).

The location and significance of environmental impacts may affect population groups that are particularly sensitive because of their resource dependencies or practices (e.g., subsistence agriculture, hunting, or fishing) that reflect the traditional or cultural practices of minority and low-income populations. The analysis of special pathway receptors can be an important part of the identification of resource dependencies or practices. Special pathways take into account the levels of contaminants in native vegetation, crops, soils and sediments, surface water, fish, and game animals on or near the power plant sites in order to assess the risk of radiological exposure through subsistence consumption of fish, native vegetation, surface water, sediment, and local produce; the absorption of contaminants in sediments through the skin; and the inhalation of airborne particulates. All licensed nuclear plants have a comprehensive radiological environmental monitoring program to assess the impact of site operations on the environment. Samples are collected from the aquatic and terrestrial pathways applicable to these sites. Aquatic pathways include fish, surface water, and sediment; terrestrial pathways include airborne particulates, radioiodine, milk, food products, crops, and direct radiation. Concentrations of contaminants in native vegetation, crops, soil, sediment, surface water, fish, and game animals in areas surrounding nuclear power plants have generally been found to be quite low (at or near the threshold of detection) and seldom above background levels.

Pathways associated with continued operations and other activities at nuclear plants associated with the license renewal might affect human populations were considered. Also considered was the extent to which minority and low-income populations in the area around these plants could be disproportionately affected, through resource dependencies and practices (e.g., subsistence agriculture, hunting, or fishing). In addition, plant-specific impacts that could affect minority and low-income populations were also identified at nuclear power plants. Although the overall impact of nuclear plants on the general population has usually been found to be small, because of these unique considerations, the additional examination of the nature and geographic extent of impacts and population demographics should be considered on a plant-specific basis.

While not binding upon independent regulatory agencies such as the NRC, Executive Order 12898 requires certain specified Federal agencies to identify and address, as appropriate, “disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority populations and low-income populations.” The NRC’s “Policy Statement on the Treatment of Environmental Justice Matters in NRC Regulatory and Licensing Actions” (69 FR 52040, August 24, 2004) requires a determination of whether human health and environmental effects of continued operations during the license renewal term and refurbishment associated with license renewal on minority populations and low-income populations would be disproportionately high and adverse. This determination will be made by the NRC in each plant-specific SEIS. On the basis of these considerations, the impact of continued operations and other activities on minority populations and low-income populations would depend on site-specific conditions and is therefore a Category 2 issue.

4.10.2 Environmental Consequences of Alternatives to the Proposed Action

Construction—Minority and low-income populations could be directly or indirectly affected by the construction of a new replacement power plant. The extent of effect experienced by these populations is difficult to determine since it would depend on the location of the power plant. For example, increased demand for rental housing during construction could disproportionately affect low-income populations. However, demand for rental housing could be mitigated if the plant is constructed near a metropolitan area. Replacement power plants would likely be sited at existing power plant or industrial brownfield sites, which are often located in or near low-income and minority communities. Construction would also create employment opportunities for minority and low-income individuals. However, construction at a brownfield site could disproportionately affect minority and low-income populations residing in the vicinity of the proposed plant site. Minority and low-income populations may be disproportionately affected by air emissions and noise from construction and by increased truck and commuter traffic.

Increased fossil fuel consumption may affect employment opportunities and environmental conditions in low-income regions that supply the fossil fuel. Power plants that rely on fossil fuels would likely be sited at brownfield sites situated near low-income and minority populations.

Operation—Low-income populations that rely on subsistence consumption of fish and wildlife, living near power plants could be disproportionately affected. Minority and low-income populations may be disproportionately affected by air emissions and noise from facility operation and by increased truck and commuter traffic.

4.11 Waste Management and Pollution Prevention

4.11.1 Environmental Consequences of the Proposed Action—Continued Operations and Refurbishment Activities

The effects of license renewal (including operations and refurbishment that would occur during the license renewal term) on waste management is presented in this section. Baseline conditions at operating reactors are discussed in Section 3.11. License renewal is expected to result in a continuation of these conditions for an extended period commensurate with the license renewal term, usually 20 years. The annual quantities of waste generated during the license renewal term are not expected to change from the amount generated during the current licensed term. However, the accumulated quantity of waste material needing long-term storage or disposal is expected to be approximately 50 percent larger.

The impacts associated with onsite waste management activities at nuclear plants are addressed in other parts of Chapter 4 under various resource discussions. These activities include waste collection, treatment, packaging, and loading onto conveyance vehicles for shipment offsite. These activities are considered to be part of the normal operations at the site. For example, the annual radioactive effluent release reports issued by the sites include a summary of radioactive effluent releases from all the facilities on the site, including the waste management and storage facilities. The same reports also provide data on volume and radioactivity content of solid radioactive waste shipped offsite for processing and disposal. Similarly, the radiological environmental monitoring program conducted at each site measures the direct radiation as well as environmental concentrations of all radionuclides originating at the site as well as background radiation. The impact from the transportation of wastes from the reactor to a third-party waste treatment center or directly to a disposal site is addressed generically in Table S-4 in 10 CFR 51.52 (see Section 4.12.1.1).

The issues that are addressed in this section are

- Low-level radioactive waste (LLW) storage and disposal (issue from the 1996 GEIS);
- Onsite storage of spent nuclear fuel (issue was renamed from the 1996 GEIS);
- Offsite radiological impacts of spent nuclear fuel and high-level waste disposal (issue was renamed from the 1996 GEIS);
- Mixed waste storage and disposal (issue from the 1996 GEIS); and
- Nonradiological waste storage and disposal (issue was renamed from the 1996 GEIS).

These are five of the nine issues evaluated in the 1996 GEIS (NRC 1996) in the chapter on the uranium fuel cycle and waste management. They relate to waste management at all nuclear fuel cycle facilities, including nuclear power plants. The other four issues, which pertain specifically to aspects of the uranium fuel cycle other than the nuclear power plants themselves, are addressed in Section 4.12.1.1. As discussed in Section 4.12.1.1, the other nuclear fuel cycle facilities include uranium mining and milling, uranium hexafluoride (UF_6) production, isotopic enrichment, fuel fabrication, fuel reprocessing, and disposal facilities.

4.11.1.1 Low-Level Waste Storage and Disposal

Section 3.11.1.1 provides the quantities and characteristics of LLW that are normally generated at nuclear plants under routine operating conditions. As stated in the introduction to Section 4.11.1, these baseline conditions are expected to continue during the license renewal term.

Prior to July 1, 2008, most of the LLW generated at reactor sites is shipped offsite for disposal either immediately after generation or after a brief storage period onsite (see Section 3.11.1.1). This trend is expected to continue. However, the Barnwell disposal facility in South Carolina ceased accepting waste from States that are not a part of the Atlantic compact as of July 2008. As a result, the only remaining disposal facility that is available to the nuclear power plant operators in those States is the EnergySolutions facility in Clive, Utah, which is licensed to accept only Class A LLW. Under these circumstances, the options available to the nuclear power plants in those States are to store their Class B and C (and Class A as appropriate) wastes onsite or offsite until a disposal facility becomes available. Such activities are conducted in accordance with NRC regulations and any applicable State or local requirements. One new facility is being developed by the Waste Control Specialists in Texas for the Texas compact, comprised of Texas and Vermont. That facility has been licensed by the State of Texas (an NRC agreement State) and is authorized to dispose of Class A, B, and C LLW (WCS 2009). The owners of the facility are in the process of developing rules governing the disposal of commercial LLW and other types of waste from waste generators in States other than Texas and Vermont. When this process is finalized, the facility could provide an outlet for disposal of LLW generated on those States that used to ship their waste to Barnwell prior to July 2008.

The NRC believes that the comprehensive regulatory controls that are in place and the low public doses being achieved at reactors ensure that the radiological impacts on the environment will remain SMALL during the term of a renewed license. The maximum additional onsite land that may be required for LLW storage during the term of a renewed license and associated impacts would be SMALL. Nonradiological impacts on air and water would be negligible. The radiological and nonradiological environmental impacts of long-term disposal of LLW from any individual plant at licensed sites are SMALL. In addition, the NRC concludes that there is reasonable assurance that sufficient LLW disposal capacity will be made available when needed for facilities to be decommissioned consistent with NRC decommissioning requirements.

On the basis of the above considerations, the impact of LW storage and disposal during the renewal term is considered SMALL for all sites. As in the 1996 GEIS, this issue is considered to be and remains Category 1.

In addition to being generated at the reactor sites, LLW is also generated from the rest of the uranium fuel cycle as part of the front-end operations during the mining and milling of uranium ores and during the steps leading up to the manufacture of new fuel. If the recycling option is made available and the decision is made to reprocess the spent fuel in the United States, the reprocessing operations would also generate LLW. The impacts associated with management of LLW from these other fuel cycle operations are addressed in Table S-3 in 10 CFR 51.51 (see Section 4.12.1.1).

4.11.1.2 Onsite Storage of Spent Nuclear Fuel

The NRC first adopted the Waste Confidence Decision and Rule in 1984. The NRC amended the decision and rule in 1990, reviewed them in 1999, and amended them again in 2010 (49 FR 34694 (August 31, 1984); 55 FR 38474 (September 18, 1990); 64 FR 68005 (December 6, 1999); and 75 FR 81032 and 81037 (December 23, 2010)). The Waste Confidence Decision and Rule are codified in the NRC regulation 10 CFR 51.23. Under the Waste Confidence Rule and Decision, the NRC had determined that spent fuel can be stored onsite safely and with minimal environmental impact for at least 30 years beyond the current licensed operating life (which may include the term of a revised or renewed license) of nuclear power plants. The Commission determined, in the 1996 GEIS, that onsite storage of spent fuel during the term of a renewed operating license is a Category 1 issue. Further, the Commission also concluded in the 1996 GEIS that continued storage of existing spent fuel and storage of spent fuel generated during the license renewal term can be accomplished safely and without significant environmental impacts, as radiation doses will be well within regulatory limits. Thus, the environmental impacts were classified as SMALL for this Category 1 issue. The following new discussion provides information regarding the potential impacts of onsite storage of spent nuclear fuel during the license renewal term.

As discussed in Section 3.11.1.2, spent nuclear fuel is currently stored at reactor sites either in spent fuel pools or in ISFSIs. The storage of spent fuel in spent fuel pools was considered for each plant in the safety and environmental reviews at the construction permit and operating license stage. This onsite storage of spent fuel and high-level waste (HLW) is expected to continue into the foreseeable future.

Interim storage needs vary among plants, with older units likely to lose pool storage capacity sooner than newer ones. Given the uncertainties regarding the final disposition of spent fuel and high-level waste, it is expected that expanded spent fuel storage capacity will be needed at all nuclear power plants.

As discussed above, current and potential environmental impacts from spent fuel storage onsite at the current reactor sites have been studied extensively, are well understood, and the environmental impacts during the license renewal term were found to be SMALL. No new information was found during the development of this GEIS revision that would alter that conclusion.

For the time period after permanent reactor shutdown, the Waste Confidence Decision and Rule represented the Commission's generic determination that spent nuclear fuel can continue to be stored safely and without significant environmental impacts for a period of time after the end of the licensed life for operation of a nuclear power plant (after the permanent shutdown of the power reactor and expiration of the plant's operating license). This generic determination meant that the NRC did not need to consider the storage of spent nuclear fuel after the end of a reactor's licensed life for operation in the NEPA documents that support its reactor and spent-fuel storage license application reviews.

On December 23, 2010, the Commission published a revision of the Waste Confidence Decision and Rule to reflect information gained from experience in the storage of spent nuclear fuel and the increased uncertainty in the siting and construction of a permanent geologic repository for the disposal of spent nuclear fuel and high-level waste. In response to the 2010 Waste Confidence Decision and Rule, the states of New York, New Jersey, Connecticut, and Vermont, along with several other parties, challenged the Commission's NEPA analysis in the decision, which provided the regulatory basis for the rule. On June 8, 2012, the United States Court of Appeals, in *New York v. NRC*, 681 F.3d 471 (D.C. Cir. 2012), vacated the NRC's Waste Confidence Decision and Rule, after finding that it did not comply with NEPA.

The court concluded that the Waste Confidence Decision and Rule is a major federal action necessitating either an EIS or an environmental assessment that results in a "finding of no significant impact." In vacating the 2010 decision and rule, the court identified three specific deficiencies in the analysis:

1. As to the Commission's conclusion that permanent disposal will be available "when necessary," the court held that the Commission did not evaluate the environmental effects of failing to secure permanent disposal;

2. As to the storage of spent fuel on-site at nuclear plants after the expiration of a plant's operating license, the court concluded that the Commission failed to properly examine the risk of spent fuel pool leaks in a forward-looking fashion; and

3. Also related to the post-license storage of spent fuel, the court concluded that the Commission failed to properly examine the consequences of spent fuel pool fires.

In response to the court's ruling, the Commission issued CLI-12-16 on August 7, 2012, in which the Commission determined that it would not issue licenses that rely upon the Waste Confidence Decision and Rule until the issues identified in the court's decision are appropriately addressed by the Commission (NRC 2012). CLI-12-16 provided, however, that the decision not to issue licenses only applied to final license issuance; all licensing reviews and proceedings should continue to move forward. In SRM-COMSECY-12-0016, dated September 6, 2012, the Commission directed the NRC staff to proceed with a rulemaking that includes the development of a generic EIS to support a revised Waste Confidence Decision and Rule and to publish both the EIS and the revised decision and rule in the *Federal Register* within 24 months (by September 6, 2014). The Commission indicated that both the EIS and the revised Waste Confidence Decision and Rule should build on the information already documented in various NRC studies and reports, including the existing environmental assessment that the NRC developed as part of the 2010 Waste Confidence Decision and Rule. The Commission directed that any additional analyses should focus on the three deficiencies identified in the D.C. Circuit's decision. The Commission also directed that the NRC staff provide ample opportunity for public comment on both the draft EIS and the proposed Waste Confidence Decision and Rule.

In accordance with CLI-12-16, the NRC will not approve any site-specific license renewal applications until the deficiencies identified in the D.C. Circuit's decision have been resolved. Two Table B-1 license renewal issues that rely, wholly or in part, upon the Waste Confidence Decision and Rule are the "onsite storage of spent nuclear fuel" and "offsite radiological impacts of spent nuclear fuel and high-level waste disposal." Both of these issues were classified as Category 1 in the 1996 GEIS; the draft revised GEIS that was published for comment in 2009 continued the Category 1 classification for both of these issues. As part of the NRC's response to the *New York v. NRC* decision, the NRC has revised these two issues accordingly.

Specifically, the NRC has revised the Category 1 "Onsite storage of spent nuclear fuel" issue to narrow the period of onsite storage to the license renewal term. In the 1996 GEIS and in the 2009 draft revised GEIS, the NRC relied upon the Waste Confidence Decision and Rule to make a generic finding that spent nuclear fuel could be stored safely onsite with no more than a small environmental impact for the term of the extended license (from approval of the license renewal application to the expiration of the operating license) plus a 30 year period following the permanent shutdown of the power reactor and expiration of the operating license.

The Waste Confidence Decision and Rule provided the basis for the 30 year period following the permanent shutdown of the reactor and expiration of the operating license. The 2010 Waste Confidence Decision and Rule extended this post-reactor shutdown onsite storage period from 30 years to 60 years. Given the *New York v. NRC* decision, and pending the issuance of a generic EIS and revised Waste Confidence Decision and Rule (as directed by SRM-COMSECY-12-0016), the period of onsite storage of spent nuclear fuel following the permanent shutdown of the power reactor and expiration of the operating license is now excluded from this GEIS issue. This issue now only covers the onsite storage of spent fuel during the license renewal term.

4.11.1.3 Offsite Radiological Impacts of Spent Nuclear Fuel and High-Level Waste Disposal

As a result of the *New York v. NRC* decision, and pending the issuance of a generic EIS and revised Waste Confidence Decision and Rule (see the discussion in section 4.11.1.2 above), the NRC has revised the Category 1 issue, “Offsite radiological impacts of spent nuclear fuel and high-level waste disposal.” This issue pertained to the long-term disposal of spent nuclear fuel and high-level waste, including possible disposal in a deep geologic repository. Although the Waste Confidence Decision and Rule did not assess the impacts associated with disposal of spent nuclear fuel and high-level waste in a repository, it did reflect the Commission’s confidence, at the time, in the technical feasibility of a repository and when that repository could have been expected to become available. Without the analysis in the Waste Confidence Decision, the NRC cannot assess how long the spent fuel will need to be stored onsite. Therefore, the NRC reclassifies this GEIS issue from a Category 1 issue with no assigned impact level to an uncategorized issue with an impact level of uncertain.

Moreover, the ultimate disposal of spent nuclear fuel in a potential future geologic repository is a separate and independent licensing action that is outside the regulatory scope of license renewal. However, because of questions and concerns that have been raised regarding this issue during scoping for the revised GEIS, the following discussion provides relevant information with respect to developments pertaining to the consideration of an ultimate repository site for the disposal of spent nuclear fuel.

At the time the 1996 GEIS was issued, there were no established regulatory limits for offsite releases of radionuclides from the ultimate disposal of spent nuclear fuel and HLW, since a candidate repository site had not been established. It was assumed that for such a site, limits would eventually be developed along the lines of those given in the 1995 National Academy of Sciences (NAS) report, *Technical Bases for Yucca Mountain Standards*.

On February 15, 2002, on the basis of a recommendation by the Secretary of Energy, the President recommended the Yucca Mountain site for the development of a repository for the geologic disposal of spent nuclear fuel and HLW. Congress approved this recommendation on July 9, 2002, in Joint Resolution 87, which designated Yucca Mountain as the repository for spent nuclear waste. On July 23, 2002, the President signed Joint Resolution 87 into law. Public Law 107-200, 116 *Statutes at Large* (Stat.) 735, 42 U.S.C. 10135 (note), designates Yucca Mountain as the site for the development of the repository for spent nuclear waste.

Subsequently, the EPA developed Yucca-Mountain-specific repository release standards, which were also adopted by the NRC in 10 CFR Part 63. These standards:

- Establish a dose limit of 15 millirem (0.15 mSv) per year for the first 10,000 years after disposal;
- Establish a dose limit of 100 millirem (1.0 mSv) exposure per year between 10,000 years and 1 million years;
- Require the Department of Energy (DOE) to consider the effects of climate change, earthquakes, volcanoes, and corrosion of the waste packages to safely contain the waste during the 1 million-year period; and
- Consistent with the recommendations of the NAS by establishing a radiological protection standard for this facility at the time of peak dose up to 1 million years after disposal.

On June 3, 2008, the DOE submitted a license application to the NRC, seeking authorization to construct a geologic repository for the disposal of spent nuclear fuel and high-level waste at Yucca Mountain, Nevada. As part of the site characterization and recommendation process for the proposed geologic repository at Yucca Mountain, Nevada, the DOE was required by the Nuclear Waste Policy Act of 1982, 42 U.S.C. 10101 *et seq*. (NWPA), to prepare an EIS. In accordance with the NWPA (42 U.S.C. 10134(f)(4)), the NRC was required to adopt DOE's EIS, to "the extent practicable," as part of any possible NRC construction authorization decision. DOE submitted the following NEPA documents along with its application, which include analyses that address radiological impacts to workers and the public.

- *Final Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada* (FEIS) (February 2002) (DOE/EIS-0250F) (ML032690321)
- *Final Supplemental Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain,*

Nye County, Nevada (Repository SEIS) (June 2008) (DOE/EIS-0250F-S1) (ML081750191)

The NRC formally accepted for docketing DOE's license application for Yucca Mountain, Nevada on September 8, 2008. In its acceptance, NRC staff also recommended that the Commission adopt, with further supplementation, the EIS and supplements prepared by DOE (73 FR 53284). With respect to radiological impacts, DOE's FEIS and Repository SEIS indicate that the disposal of spent nuclear fuel and high-level waste would be SMALL with exposures well below regulatory limits. However, on March 3, 2010, the U.S. Department of Energy (DOE) filed a motion with the Atomic Safety and Licensing Board (Board) seeking permission to withdraw its application for authorization to construct a high-level waste geological repository at Yucca Mountain, Nevada. The Board denied that request on June 29, 2010, in LBP-10-11 (ADAMS Accession No. ML101800299), whereuponthe parties involved in the preceding filed petitions asking the Commission to uphold or reverse this decision.

On September 9, 2011, the Commission issued a Memorandum and Order, CLI-11-07, stating that it found itself evenly divided on whether to take the affirmative action of overturning or upholding the Board's June 29, 2010, decision. Exercising its inherent supervisory authority, the Commission directed the Board to complete all necessary and appropriate case management activities by September 30, 2011. On September 30, 2011, the Board issued a Memorandum and Order suspending the proceeding.

On October 1, 2010, the NRC staff initiated an orderly closure of its Yucca Mountain activities. As part of the orderly closure, the NRC staff prepared three technical evaluation reports documenting its work.

The NRC's non-sensitive Yucca Mountain-related documents are being preserved and made available to the public as part of the NRC staff's activities to retain the accumulated knowledge and experience gained as a result of its Yucca Mountain-related activities. These documents can be viewed on the NRC's public Web site, http://www.NRC.gov/waste/hlw-disposal.html.

NRC decisions and recommendations concerning the ultimate disposition of spent nuclear fuel are ongoing and outside the scope of license renewal, and as such, of this GEIS.

Separate from the regulatory actions taken by the NRC, in 2009 and early 2010, the president and his administration decided not to proceed with the Yucca Mountain nuclear waste repository. Instead, on January 29, 2010, the Secretary of Energy announced the formation of a Blue Ribbon Commission to conduct a comprehensive review of policies for managing the back end of the nuclear fuel cycle (DOE 2010). The Blue Ribbon Commission will provide advice and make recommendations on issues including alternatives for the storage, processing, and disposal of civilian and defense spent nuclear fuel and HLW. The Blue Ribbon Commission issued its recommendations to the Secretary of Energy on January 26, 2012 (www.brc.gov). The report contained eight key elements:

1. A new, consent-based approach to siting future nuclear waste management facilities.
2. A new organization dedicated solely to implementing the waste management program and empowered with the authority and resources to succeed.
3. Access to the funds nuclear utility ratepayers are providing for the purpose of nuclear waste management.
4. Prompt efforts to develop one or more geologic disposal facilities.
5. Prompt efforts to develop one or more consolidated storage facilities.
6. Prompt efforts to prepare for the eventual large-scale transport of spent nuclear fuel and high-level waste to consolidated storage and disposal facilities when such facilities become available.
7. Support for continued U. S. innovation in nuclear energy technology and for workforce development.
8. Active U. S. leadership in international efforts to address safety, waste management, non-proliferation, and security concerns.

DOE will be the lead Federal agency responsible for developing a new national strategy for nuclear waste management; the NRC will play a supporting role in those areas associated with its regulatory review.

4.11.1.4 Mixed Waste Storage and Disposal

This issue addresses the storage and disposal of mixed waste generated at nuclear power plants and other uranium fuel-cycle facilities during the license renewal term. As discussed in Section 3.11.3, nuclear power plants generate small quantities of mixed waste. Other uranium fuel-cycle facilities are also expected to generate small quantities of mixed waste. Mixed waste is regulated both by the EPA or the authorized State agency under RCRA and by the NRC or the Agreement State agency under the Atomic Energy Act (AEA; Public Law 83-703). The waste is either treated onsite or sent offsite for treatment followed by disposal at a permitted landfill. The comprehensive regulatory controls and the facilities and procedures that are in place at nuclear power plants ensure that the mixed waste is properly handled and stored and that doses to and exposure to toxic materials by the public and the environment are negligible at all plants. License renewal will not increase the small but continuing risk to human health and the environment posed by mixed waste at all plants. The radiological and nonradiological environmental impacts from the long-term disposal of mixed waste at any individual plant at licensed sites are considered SMALL for all sites. The issue was considered a Category 1 issue in the 1996 GEIS, and no new information that would alter this conclusion has been identified.

4.11.1.5 Nonradioactive Waste Storage and Disposal

This issue addresses the storage and disposal of nonradioactive waste generated at commercial nuclear power plants and during the rest of the uranium fuel cycle during the license renewal term. Nonradioactive waste consists of hazardous and nonhazardous waste. Storage and disposal of hazardous waste generated at nuclear plants is discussed in Section 3.11.2. As indicated in that section, nuclear plants generate small quantities of hazardous waste during operation and refurbishment. A special class of hazardous waste, known as universal waste, consisting of commonly used yet hazardous materials (batteries, pesticides, mercury-containing equipment, and lamps), is also generated. Similar types of hazardous wastes are also generated at other uranium fuel-cycle facilities. The management of hazardous wastes generated at all of these facilities, both onsite and offsite, is strictly regulated by the EPA or the responsible State agencies per the requirements of RCRA.

As does any industrial facility, nuclear power plants and the rest of the uranium fuel-cycle facilities also generate nonradioactive nonhazardous waste (see Section 3.11.4). These wastes are managed by following good housekeeping practices and are generally disposed of in local landfills permitted under RCRA Subtitle D regulations.

In the 1996 GEIS, the impacts associated with managing nonradioactive wastes at uranium fuel cycle facilities, including nuclear power plants, were found to be SMALL. It was indicated that no changes to nonradioactive waste generation would be anticipated for license renewal, and that systems and procedures are in place to ensure continued proper handling and disposal of the wastes at all plants. The issue was considered a Category 1 issue in the 1996 GEIS, and no new information that would alter this conclusion has been identified.

4.11.2 Environmental Consequences of Alternatives to the Proposed Action

Construction—Construction-related wastes include various fluids from the onsite maintenance of construction vehicles and equipment (e.g., used lubricating oils, hydraulic fluids, glycol-based coolants, spent lead-acid storage batteries) and incidental chemical wastes from the maintenance of equipment and the application of corrosion-control protective coatings (e.g., solvents, paints, coatings), construction-related debris (e.g., lumber, stone, and brick), and packaging materials (primarily wood and paper). All materials and wastes would be accumulated onsite and disposed of or recycled through licensed offsite disposal and treatment facilities. Life-cycle management of chemicals and wastes generated during construction and pollution prevention initiatives (such as spill prevention plans) will serve to mitigate the impact of wastes. The impacts of waste management are expected to be the same for greenfield, brownfield, and existing nuclear power plant sites.

Operations—Solid wastes would be generated throughout the period of plant operations. The character of wastes would depend on chemical constituents of the fuel, efficiency of combustion, and operational efficiencies of the various air pollution control devices. Wastes routinely associated with the maintenance of mechanical and electrical equipment include: used lubricating oils and hydraulic fluids, cleaning solvents, corrosion control paints and coatings, and dielectric fluids.

4.11.2.1 Fossil Fuel Alternatives

Operations—Solid wastes in the form of coal combustion waste (and, in some instances, flue gas desulfurization sludge and spent catalysts) would be generated during plant operations. The exact character of the coal combustion waste would depend on the chemical constituents of the coal, efficiency of the combustion device, and operational efficiencies of the various air pollution control devices.

4.11.2.2 New Nuclear Alternatives

Operations—Liquid, gaseous, and solid radioactive waste management systems would be used to collect and treat radioactive materials during operations. Waste processing systems would be designed so that radioactive effluents released to the environment would meet the objectives of Appendix I to 10 CFR Part 50. The primary source of radioactive waste from a new nuclear facility is fission products that escape from the fuel rods into the reactor coolant. Coolant could also become contaminated from neutron activation of the primary cooling system. LLW disposal is assumed to occur at an offsite location, while spent fuel would be stored onsite either in spent fuel pool storage or dry cask storage.

Nonradioactive effluent and wastes include cooling water and steam condensate blowdowns that contain various water-treatment chemicals or biocides, wastes from the onsite treatment of cooling water and steam cycle water, floor and equipment drain effluent, stormwater runoff, laboratory waste, trash, hazardous waste, effluent from the sanitary sewer system, miscellaneous gaseous emissions, and liquid and solid effluent. Wastes discharged to waters of the United States would be regulated by NPDES permits. All other wastes would be properly disposed of in accordance with Federal, State, and local regulations. Waste impacts for a nuclear plant are described in Section 4.11.1 and in 10 CFR Part 51, Appendix B, Table B-1. Impacts are expected to be SMALL for all facilities, whether located on greenfield sites, brownfield sites, or at existing nuclear plant sites.

4.11.2.3 Renewable Alternatives

Operations—The operational impacts of alternative energy technologies on waste management are presented in the following subsections.

Geothermal

Small amounts of industrial solid wastes associated with onsite maintenance of equipment and infrastructure would be generated, including: used oils, used glycol-based antifreeze, waste lead-acid storage batteries, spent cleaning solvents, and excess corrosion control coatings. Operational solid wastes could include precipitates (scale) resulting from cooling and depressurized hydrothermal fluids that must be periodically removed from equipment; some precipitates may include naturally occurring radioactive material (NORM).

Wind

Minimal amounts of wastes are generated from the maintenance of wind turbines; wastes consist mainly of spent lubricating and gear oils removed from equipment during routine preventive maintenance, small amounts of battery electrolyte from onsite back-up power systems, and minor amounts of solvents and coatings from ongoing corrosion control activities. Modern turbine designs allow for the easy removal of malfunctioning equipment for replacement and repair; consequently, wastes generated onsite would be limited to preventive maintenance-related wastes.

Biomass

Major operating wastes would include fly ash and bottom ash that results from the combustion of the carbonaceous fuels. Scrubbers for control of sulfur oxide emissions would not be expected to be needed for units combusting wood and energy crops that have little to no sulfur content. Temporary storage of operational solid wastes onsite could affect local ecological systems, especially surface waters.

Municipal Solid Waste, Refuse-Derived Fuel, and Landfill Gas

Small amounts of industrial solid wastes typically associated with maintenance of equipment and infrastructure would be generated, including used oils and lubricants, used glycol-based coolants, waste lead-acid batteries, spent cleaning solvents, and excess corrosion control wastes. Operating wastes also would include small amounts of sanitary wastewaters and sanitary solid wastes from support of the workforces. Toxic constituents in municipal solid waste or refuse-derived fuel could cause solid wastes from air pollution devices to become hazardous due to leachability of toxic constituents. Sanitary wastewater and well as wastewaters from industrial operations would be containerized and removed to offsite treatment; cooling water blowdown and steam cycle blowdown may be discharged to the land surface or to surface impoundments. Temporary storage of operational solid wastes on site could impact local ecological systems, especially surface waters.

Solar Thermal

Spills and leaks of the heat transfer fluids could occur; affected soil would need to be removed and disposed of properly. Routine maintenance-related wastes would be expected. Spills or leaks from electrical components could create waste dielectric fluids (all assumed to be free of PCBs).

Solar Photovoltaic

Proper precautions would have to be made for the disposal of solar cells, although recycling of materials would reduce impacts.

Ocean Wave and Current

Wastes associated with facility operation would include small amounts of wastes related to facility maintenance, including waste lubricating oils, hydraulic fluids, cleaning solvents, and protective corrosion-control paints and coatings. Wastes also include those associated with the application of antifouling agents to the underwater portions of components to control interference by marine organisms. Major repairs of electrical components could result in waste dielectric fluids (mineral oil).

4.12 Impacts Common to All Alternatives

This section describes impacts that are considered common to all alternatives discussed in the GEIS including the proposed action (license renewal) and replacement power alternatives. The continued operation of a nuclear power plant and replacement fossil fueled power plants both involve the mining, processing, and the consumption of fuel, which results in comparative environmental impacts. Environmental impacts associated with power plant fuel cycles are presented in Section 4.12.1. The termination of operations and the decommissioning of a nuclear power plant and replacement fossil fueled power plants as well as renewable energy systems are presented in Section 4.12.2. In addition, greenhouse gas emissions from the nuclear lifecycle as well as replacement fossil fueled power plants and climate change impacts are presented in Section 4.12.3.

4.12.1 Environmental Consequences of Fuel Cycles

This section describes the environmental impacts associated with fuel cycles associated with the proposed action (license renewal) and replacement power alternatives. Most, if not all, replacement power alternatives, including the continued operation of the nuclear power plant during the license renewal term, employ a set of steps in the utilization of its fuel source. These steps can include, but are not limited to, extraction, transformation, transportation, and, combustion. Emissions generally occur at each stage of a fuel cycle. Also, some aspects of the fuel cycle (e.g., storage and disposal) described here are common to each alternative.

4.12.1.1 Uranium Fuel Cycle

In the United States, all currently operating commercial plants are light water reactors and use uranium for fuel. Therefore, in this section and in the rest of this GEIS, the term "uranium fuel cycle" is used interchangeably with "nuclear fuel cycle."

Uranium Fuel Cycle Facilities

The NRC evaluated the environmental impacts that would be associated with operating uranium fuel cycle facilities other than the reactors themselves in two NRC documents: WASH-1248 (NRC 1974) and NUREG-0116 (NRC 1976). The types of facilities considered in these two documents include:

- Uranium mining—facilities where the uranium ore is mined.
- Uranium milling—facilities where the uranium ore is refined to produce uranium concentrates in the form of triuranium octaoxide (U_3O_8).
- Uranium hexafluoride (UF_6) production—facilities where the uranium concentrates are converted to UF_6.
- Isotopic enrichment—facilities where the isotopic ratio of the uranium-235 isotope in natural uranium is increased to meet the requirements of light water reactors.
- Fuel fabrication—facilities where the enriched UF_6 is converted to uranium dioxide (UO_2) and made into sintered UO_2 pellets. The pellets are subsequently encapsulated in fuel rods, and the rods are assembled into fuel assemblies ready to be inserted into the reactors. Two options were considered: (1) carrying out all steps involved in manufacturing the fuel assemblies at the same location and (2) carrying the steps out at two separate facilities (at one facility, UO_2 is produced in powder form from the enriched UF_6, and at the other facility, the fuel assemblies are manufactured).

- Reprocessing—facilities that disassemble the spent fuel assemblies, chop up the fuel rods into small sections, chemically dissolve the spent fuel out of sectioned fuel rod pieces, and chemically separate the spent fuel into reusable uranium, plutonium, and other radionuclides (primarily fission products and actinides).

- Disposal—facilities where the radioactive wastes generated at all fuel cycle facilities including the reactors, are buried. Spent nuclear fuel that is removed from the reactors and not reprocessed was also assumed to be disposed of at a geologic repository.

Environmental Impacts

In addition to impacts occurring at the above facilities, the impacts associated with the transportation of radioactive materials among these facilities, including the transportation of wastes to disposal facilities, were evaluated. The results were summarized in a table and promulgated as Table S-3 in 10 CFR 51.51(b). Table S-3 is provided as Table 4.12-1 for ease of reference. 10 CFR 51.51(a) states:
