Attachment 4

Columbia Generating Station
Final Safety Analysis Report
Amendment 67, Publicly Available

GENERAL TABLE OF CONTENTS

Chapter 1

INTRODUCTION AND GENERAL DESCRIPTION OF PLANT

1.1 Introduction
1.2 General Plant Description
1.3 Comparison Tables
1.4 Identification of Agents and Contractors
1.5 Requirements for Further Technical Information
1.6 Material Incorporated by Reference
1.7 Acronyms
1.8 Conformance to NRC Regulatory Guides

Chapter 2

SITE CHARACTERISTICS

2.1 Geography and Demography
2.2 Nearby Industrial, Transportation, and Military Facilities
2.3 Meteorology
2.4 Hydrology Engineering
2.5 Geology, Seismology, and Geotechnical Engineering

Chapter 3

DESIGN CRITERIA - STRUCTURES, COMPONENTS, EQUIPMENT, AND SYSTEMS

3.1 Conformance with NRC General Design Criteria
3.2 Classification of Structures, Components, and Systems
3.3 Wind and Tornado Loadings
3.4 Water Level (Flood) Design
3.5 Missile Protection
3.6 Protection Against Dynamic Effects Associated with the Postulated Rupture of Piping
3.7 Seismic Design
3.8 Design of Seismic Category I Structures
3.9 Mechanical Systems and Components
3.10 Seismic and Dynamic Qualification of Safety-Related Instrumentation and Electrical Equipment
3.11 Environmental Design of Mechanical and Electrical Equipment
3.12 Computer Programs for Structural Analysis and Design
3A Plant Design Assessment Report (DAR) for SRV and LOCA Loads

GENERAL TABLE OF CONTENTS

Chapter 4

REACTOR

4.1 Summary Description
4.2 Fuel System Design
4.3 Nuclear Design
4.4 Thermal-Hydraulic Design
4.5 Reactor Materials
4.6 Functional Design of Reactivity Control Systems

Chapter 5

REACTOR COOLANT SYSTEMS AND CONNECTED SYSTEMS

5.1 Summary Description
5.2 Integrity of Reactor Coolant Pressure Boundary
5.3 Reactor Vessel
5.4 Component and Subsystem Design

Chapter 6

ENGINEERED SAFETY FEATURES

6.1 Engineered Safety Feature Materials
6.2 Containment Systems
6.3 Emergency Core Cooling System
6.4 Habitability Systems
6.5 Fission Product Removal and Control Systems
6.6 Inservice Inspection of ASME Code Class 2 and Class 3 Components
6.7 Main Steam Isolation Valve Leakage Control System

GENERAL TABLE OF CONTENTS (Continued)

Chapter 7

INSTRUMENTATION AND CONTROL SYSTEMS

7.1 Introduction
7.2 Reactor Protection (Trip) System
7.3 Engineered Safety Feature Systems
7.4 Systems Required for Safe Shutdown
7.5 Safety-Related Display Instrumentation
7.6 All Other Instrumentation Systems Required for Safety
7.7 Control Systems Not Required for Safety

Chapter 8

ELECTRIC POWER

8.1 Introduction
8.2 Offsite Power System
8.3 Onsite Power Systems
8A Station Blackout

Chapter 9

AUXILIARY SYSTEMS

9.1 Fuel Storage and Handling
9.2 Water Systems
9.3 Process Auxiliaries
9.4 Heating, Ventilating, and Air Conditioning Systems
9.5 Other Auxiliary Systems

Chapter 10

STEAM AND POWER CONVERSION SYSTEM

10.1 Summary Description
10.2 Turbine Generator
10.3 Main Steam Supply System
10.4 Other Features of Steam and Power Conversion System

GENERAL TABLE OF CONTENTS (Continued)

Chapter 11

RADIOACTIVE WASTE MANAGEMENT

11.1 Source Terms
11.2 Liquid Waste Management System
11.3 Gaseous Waste Management Systems
11.4 Solid Waste Management System
11.5 Process and Effluent Radiological Monitoring and Sampling Systems
11.6 Postaccident Sampling System

Chapter 12

RADIATION PROTECTION

12.1 Ensuring that Occupational Radiation Exposures and Radiation Exposures to Members of the Public are As Low As Is Reasonably Achievable
12.2 Radiation Sources
12.3 Radiation Protection Design Features
12.4 Dose Assessment
12.5 Radiation Protection Program

Chapter 13

CONDUCT OF OPERATIONS

13.1 Organization Structure
13.2 Training
13.3 Emergency Planning
13.4 Review and Audit
13.5 Plant Procedures
13.6 Industrial Security

Chapter 14

INITIAL TEST PROGRAM

14.1 Specific Information Included in Preliminary Safety Analysis Reports
14.2 System Lineup, Preoperational, and Initial Startup Test Program

GENERAL TABLE OF CONTENTS (Continued)

Chapter 15

ACCIDENT ANALYSES

15.0 General
15.1 Decrease in Reactor Coolant Temperature
15.2 Increase in Reactor Pressure
15.3 Decrease in Reactor Coolant System Flow Rate
15.4 Reactivity and Power Distribution Anomalies
15.5 Increase in Reactor Coolant Inventory
15.6 Decrease in Reactor Coolant Inventory
15.7 Radioactive Release from Subsystems and Components
15.8 Anticipated Transients without Scram

Chapter 16

TECHNICAL SPECIFICATIONS

(Separate Volume)

Chapter 17

QUALITY ASSURANCE

17.1 Quality Assurance During the Design and Construction Phases
17.2 Quality Assurance During the Operations Phase

APPENDIXES

A Supplement Aging Management Programs and Activities Credited for Columbia License Renewal
B Response to Regulatory Issues Resulting from TMI-2
F Fire Protection Evaluation
I Licensing Review Group Issues
J Shielding Evaluation Report

Chapter 1

INTRODUCTION AND GENERAL DESCRIPTION OF PLANT

1.1 INTRODUCTION

This Final Safety Analysis Report (FSAR) was submitted in support of an application by Energy Northwest for a Class 103 operating license for a single unit nuclear power plant. The facility is known as the Columbia Generating Station (CGS) and was formerly known as WNP-2.

Energy Northwest was the applicant for the operating license for CGS. The plant was designed, constructed, and is being operated under the responsibility of Energy Northwest.

CGS is located within the Hanford Site of the Department of Energy (DOE), Benton County, Washington, approximately 12 miles north of the City of Richland. The site is approximately 3 miles west of the Columbia River at River Mile 352.

This plant has a boiling water reactor (BWR) nuclear steam supply system (NSSS) designed and supplied by the General Electric Company (GE). The plant utilizes a single-cycle, forced-circulation system and is designated as a BWR/5.

The containment was designed by Burns and Roe, Inc., and consists of primary and secondary containment systems. The primary containment structure is a free-standing steel pressure vessel of a specific design by Pittsburgh Des Moines Steel Co. The vessel contains both a drywell and a suppression chamber, which is consistent with the features of a BWR/Mark II containment.

The secondary containment structure is composed of the reactor building, which completely encloses primary containment.

The authorized maximum rated power level limit of the reactor is 3544 MWt. The design power level limit is 3629 MWt. The net electrical power output is approximately 1190 MWe and the gross electrical output is 1230 MWe.

Energy Northwest was granted an operating license for CGS on December 20, 1983, and the plant began commercial operation on December 13, 1984.

1.2 GENERAL PLANT DESCRIPTION

1.2.1 PRINCIPAL DESIGN CRITERIA

The principal design criteria are presented in two ways. First, they are classified as either a power generation function or a safety function. Second, they are grouped according to system. Although the distinctions between power generation or safety functions are not always clear-cut and are sometimes overlapping, the functional classification facilitates safety analyses, while the grouping by system facilitates the understanding of both the system function and design.

1.2.1.1 General Design Criteria

1.2.1.1.1 Power Generation Design Criteria

a. The plant was designed so that it can be fabricated, erected, and operated to produce electric power in a safe and reliable manner. Plant design conforms to applicable codes and regulations as stipulated in Table 1.2-1;

b. The plant is designed to produce steam for direct use in a turbine-generator unit;

c. Heat removal systems are provided with sufficient capacity and operational adequacy to remove heat generated in the reactor core for the full range of normal operational conditions and abnormal operational transients;

d. Backup heat removal systems are provided to remove decay heat generated in the core under circumstances wherein the normal operational heat removal systems become inoperative. The capacity of such systems is adequate to prevent fuel cladding damage;

e. The fuel cladding, in conjunction with other plant systems is designed to retain integrity throughout the range of normal operational conditions and abnormal operational transients;

f. The fuel cladding can accommodate, without loss of integrity, the pressures generated by fission gases released from fuel material throughout the design life of fuel;

g. Control equipment has been provided to allow the reactor to respond automatically to minor load changes, major load changes, and abnormal operational transients;

h. Reactor power level can be manually controlled;

i. Control of the reactor is possible from a single location;

j. Reactor controls, including alarms, are arranged to allow the operator to rapidly assess the condition of the reactor system and locate system malfunctions; and

k. Interlocks or other automatic equipment are provided as backup to procedural controls to avoid conditions requiring the functioning of nuclear safety systems or engineered safety features (ESF).

1.2.1.1.2 Safety Design Criteria

a. The plant design conforms to applicable codes and regulations;

b. The plant is designed, fabricated, erected, and will be operated in such a way that the release of radioactive materials to the environment is limited to the limits and guideline values of applicable federal regulations pertaining to the release of radioactive materials for normal operations and abnormal transients and accidents;

c. The reactor core is designed so its nuclear characteristics do not contribute to a divergent power transient;

d. The reactor is designed so there is no tendency for divergent oscillation of any operating characteristic, considering the interaction of the reactor with other appropriate plant systems;

e. Gaseous, liquid, and solid waste disposal facilities are designed so the discharge and offsite shipment of radioactive effluents can be made in accordance with applicable regulations;

f. The design provides means by which plant operators can be informed when limits on the release of radioactive material are approached;

g. Sufficient indications are provided to allow determination that the reactor is operating within the envelope of conditions considered by plant safety analysis;

h. Radiation shielding is provided and access control patterns have been established to allow a properly trained operating staff to control radiation doses within the limits of applicable regulations in any mode of normal plant operations;

i. Those portions of the nuclear system that form part of the reactor coolant pressure boundary (RCPB) are designed to retain integrity as a radioactive material barrier following abnormal operational transients and accidents;

j. Nuclear safety systems and ESF act to ensure that no damage to the RCPB results from internal pressures caused by abnormal operational transients and accidents;

k. Where positive, precise action is immediately required in response to abnormal operational transients and accidents, such action is automatic and requires no decision or manipulation of controls by plant operations personnel;

l. Essential safety actions can be carried out by equipment of sufficient redundance and independence such that no single failure of active components can prevent the required actions. For systems or components to which IEEE-279 (Criteria for Protection Systems for Nuclear Power Generating Stations) and/or IEEE-308 (Criteria for Class 1E Electrical systems for Nuclear Power Generating Stations) applies, single failures of both active and passive electrical components were considered in recognition of the higher anticipated failure rates of passive electrical components relative to passive mechanical components;

m. Provisions have been made for control of active components of nuclear safety systems and ESF from the control room;

n. Nuclear safety systems and ESF are designed to permit demonstration of their functional performance requirements;

o. The design of nuclear safety systems and ESF includes allowances for natural environmental disturbances such as earthquakes, tornadoes, floods, and storms at the site;

p. Standby electrical power sources have sufficient capacity to power all nuclear safety systems and ESF requiring electrical power;

q. Standby electrical power sources are provided to allow prompt reactor shutdown and removal of decay heat under circumstances where offsite power sources are not available;

r. Features of the plant that are essential to the mitigation of accident consequences are designed, fabricated, and erected to quality standards that reflect the importance of the safety action to be performed;

s. A primary containment has been provided that completely encloses the reactor system, drywell, and suppression pool. The primary containment employs the pressure suppression concept;

t. The primary containment is designed to retain integrity as a radioactive material barrier during and following accidents that release radioactive material into the primary containment volume;

u. It is possible to test primary containment integrity and leaktightness at periodic intervals;

v. A secondary containment has been provided that completely encloses both the primary containment and fuel storage areas. The secondary containment includes the standby gas treatment (SGT) system for controlling release of radioactive materials leaking from the primary containment in the event of an accident and also has the capability for filtering radioactive materials directly from the primary containment atmosphere during shutdown conditions;

w. The secondary containment has been designed to act as a radioactive material barrier, if required, when the primary containment is open for expected operational purposes;

x. The primary containment and secondary containment, in conjunction with other ESF, limit radiological effects of accidents resulting in the release of radioactive material to the containment vessel to significantly less than 10 CFR 50.67 limits;

y. Provisions have been made for removing energy from within the containment vessel as necessary to maintain the integrity of the containment system following accidents that release energy to the primary containment;

z. Piping that penetrates the primary containment structure and could serve as a path for the uncontrolled release of radioactive material to the environs is automatically isolated whenever such uncontrolled radioactive material release is threatened. Such isolation shall be effected in time to limit radiological effects to less than specified acceptable limits;

aa. Emergency core cooling systems (ECCS) are provided to limit fuel cladding temperature to temperatures below the onset of fragmentation in the event of a loss-of-coolant accident (LOCA);

bb. The ECCS provide for continuity of core cooling over the complete range of postulated break sizes in the RCPB and are redundant;

cc. Operation of the ECCS is initiated automatically when required, regardless of the availability of offsite power supplies and the normal generating system of the plant;

dd. The control room has been shielded against radiation and provided with a high efficiency filtration system so that continued occupancy under accident conditions is possible;

ee. In the event that the control room becomes inaccessible, it is possible to bring the reactor from power range operation to cold shutdown conditions by utilizing the local controls and equipment that are available outside the control room on the remote shutdown control panels;

ff. Backup reactor shutdown capability has been provided independent of normal reactivity control provisions. This backup system has the capability to shut down the reactor from any normal operating condition and subsequently to maintain the shutdown condition; and

gg. Fuel handling and storage facilities are designed to prevent inadvertent criticality and to maintain adequate shielding and cooling of spent fuel. Provision is made for maintaining the cleanliness of spent fuel cooling and shielding water.

1.2.1.2 System Criteria

The principal design criteria for particular systems are listed in the following subsections.

1.2.1.2.1 Nuclear System Criteria

a. The fuel cladding is designed to retain integrity as a radioactive material barrier throughout the design power range. The fuel cladding is designed to accommodate, without loss of integrity, the pressures generated by the fission gases released from the fuel material throughout the design life of the fuel;

b. The fuel cladding, in conjunction with other plant systems, is designed to retain integrity throughout any abnormal operational transient;

c. Those portions of the nuclear system that form part of the RCPB are designed to retain integrity as a radioactive material barrier following abnormal operational transients and accidents;

d. Heat removal systems are provided in sufficient capacity and operational adequacy to remove heat generated in the reactor for the full range of normal operational conditions from plant shutdown to design power and for any abnormal operational transient. The capacity of such systems is adequate to prevent fuel cladding damage;

e. Heat removal systems are provided to remove decay heat generated in the core under circumstances wherein the normal operational heat removal systems become inoperative. The capacity of such systems is adequate to prevent fuel cladding damage. The reactor is capable of being automatically shut down in sufficient time to permit decay heat removal systems to become effective following loss of operation of normal heat removal systems;

f. The reactor core and reactivity control system is designed so that control rod action is capable of bringing the core subcritical and maintaining it so, even with the rod of highest reactivity worth fully withdrawn and unavailable for insertion;

g. The reactor core is designed so that its nuclear characteristics do not contribute to a divergent power transient; and

h. The nuclear system is designed so there is no tendency for divergent oscillation of any operating characteristic, considering the interaction of the nuclear system with other appropriate plant systems.

1.2.1.2.2 Power Conversion System Criteria

Components of the power conversion system have been designed to perform the following basic objectives.

a. Produce electrical power from the steam exiting from the reactor, condense the steam into water, and return the water to the reactor as heated feedwater, with a major portion of its gaseous and particulate impurities removed; and

b. Ensure that any fission products or radioactivity associated with the steam and condensate during normal operation are safely contained inside the system or are released under controlled conditions in accordance with waste disposal procedures.

1.2.1.2.3 Electrical Power Systems Criteria

Sufficient offsite and onsite standby sources of electrical power are provided to attain prompt shutdown and continued maintenance of the plant in a safe condition under all credible

circumstances. The power sources are adequate to accomplish all required engineered safety feature functions under postulated design basis accident conditions.

1.2.1.2.4 Radwaste System Criteria

a. The gaseous and liquid radwaste systems are designed to limit the release of radioactive effluents from the plant during normal operation within those limits specified in 10 CFR 20 and 10 CFR 50, Appendix I;

b. The solid radwaste disposal system is designed so that during normal operation offsite shipments will be in accordance with applicable regulations, including 10 CFR 20, 10 CFR 71, and 49 CFR 171 through 10 CFR 179, as appropriate; and

c. The design of the systems provide means by which plant operations personnel are alerted whenever operational limits on the release of radioactive material are approached.

1.2.1.2.5 Auxiliary Systems Criteria

a. Fuel handling and storage facilities are designed to prevent criticality and to maintain adequate shielding and cooling for spent fuel. Provision is made for maintaining the cleanliness of spent fuel cooling and shielding water;

b. Other auxiliary systems, such as standby service water (SW), high pressure core spray (HPCS) SW, fire protection (FP), heating and ventilating, communications, and lighting systems, are designed to function during normal, abnormal, and/or accident conditions; and

c. Auxiliary systems that are not required to effect safe shutdown of the reactor or maintain it in a safe shutdown condition are designed such that failure of these systems shall not prevent the essential auxiliary systems from performing their design functions.

1.2.1.2.6 Shielding and Access Control Criteria

a. Radiation shielding is provided and access control patterns are established to allow a properly trained operating staff to control radiation doses within the limits of published regulations in any normal mode of plant operation; and

b. The control room is shielded against radiation and has a high efficiency filtration system, so that occupancy is possible under accident conditions and

TEDE doses are less than those set by Criterion 19 of 10 CFR Part 50, Appendix A and 10 CFR 50.67.

1.2.1.2.7 Nuclear Safety Systems and ESF Criteria

Principal design criteria for nuclear safety systems and ESF correspond to criteria j through q, aa through cc, and ee through ff in Section 1.2.1.1.2.

1.2.1.2.8 Process Control Systems Criteria

The principal design criteria for the process control systems are listed for the nuclear system, the power conversion system, and the electrical power system:

a. Nuclear System Process Control Criteria

1. Control equipment is provided to allow the reactor to respond automatically to load changes within design limits.

2. It is possible to manually control the reactor power level.

3. Control of the reactor is possible from a central location.

4. Nuclear systems process controls and alarms are arranged to allow the operator to rapidly assess the condition of the nuclear system and to locate process system malfunctions.

5. Interlocks or other automatic equipment are provided as a backup to procedural controls to avoid conditions requiring the actuation of nuclear safety systems or ESF.

b. Power Conversion System Process Control Criteria

1. Control equipment is provided to control the reactor pressure throughout its operating range.

2. The turbine is able to respond automatically to minor changes in load.

3. Control equipment in the feedwater system maintains the water level in the reactor vessel at the optimum level required by steam separators.

4. Control of the power conversion equipment is possible from a central location.

5. Interlocks or other automatic equipment are provided in addition to procedural controls to avoid conditions requiring the actuation of ESF.

c. Electrical Power System Process Control Criteria

1. The redundant portions of the Class 1E power systems are designed with either division of the system being adequate to safely shut down the unit.

2. Protective relaying is used to detect and isolate faulted equipment from the system with a minimum of disturbance in the event of equipment failure.

3. Primary and secondary undervoltage relays are located on the 4.16-kV Class 1E equipment buses to isolate these buses from the normal auxiliary power system in the event of Class 1E bus under voltage and to initiate starting of the standby power system diesel generators.

4. Standby power diesel generators' start is initiated by control relays. The generators are also loaded by a sequenced control system to meet the existing emergency condition.

5. All electrically operated breakers can be operated from the main control room.

6. Metering for essential generators, transformers, and circuits is monitored in the main control room.

1.2.1.3 Plant Design Criteria

The plant design criteria are based on general design criteria given in Appendix A of 10 CFR Part 50. Conformance to these criteria is discussed in Section 3.1. The classification of structures, components, and systems is discussed in Section 3.2.

The principal regulations are codes that are used extensively in plant design are highlighted in Table 1.2-1. Note that the codes listed may not be applicable in their entirety. The many codes and regulations applicable to individual systems or structures are discussed throughout the FSAR.

The plant shielding and radiation zone classification can be found in Table 1.2-2. Chapter 12 provides further details.

1.2.2 PLANT DESCRIPTION

1.2.2.1 Site Characteristics

1.2.2.1.1 Site Location and Size

Columbia Generating Station (CGS) is located in the southeast area of the Department of Energy (DOE) Hanford Reservation in Benton County, Washington. The site is approximately 3 miles west of the Columbia River at River Mile 352, approximately 12 miles north of the City of Richland, 18 miles northwest of Pasco, and 21 miles northwest of Kennewick. The site is approximately square shaped with a corridor extending to the makeup water pump house located on the Columbia River as shown in Figure 1.2-1. The CGS site encompasses an area of approximately 1089 acres.

1.2.2.1.2 Description of Site Environs

1.2.2.1.2.1 Site Land. See Section 2.1 for site land description.

1.2.2.1.2.2 Population. See Section 2.1 for population description.

1.2.2.1.2.3 Land Use. Natural physical characteristics of the site which make it well-suited for operation of the plant include: favorable geographical, geological, and seismological characteristics; adequate water supply; ideal climatological characteristics; and remoteness from population centers or areas of special ecological concern. The site area had served as a nuclear industrial center since 1943 when it was selected by the federal government as the location for construction of one of the world's first nuclear production reactors. Since 1943, nine plutonium production reactors and a number of test reactors have been constructed and operated at the Hanford Site.

1.2.2.1.2.4 Meteorology. The climate around CGS is basically continental with a wide range of annual temperatures. See Section 2.3 for additional information.

1.2.2.1.2.5 Hydrology. The Columbia River is the major surface water resource of the region. The river also forms a potential discharge boundary for the aquifer. The surface soils at Hanford are sufficiently permeable to take in water from precipitation and industrial discharges. See Section 2.4 for additional information.

1.2.2.1.2.6 Geology. The Hanford site lies in the east central part of the Pasco Basin, a structural and topographic depression in the Columbia Plateau. The region is underlain by three major geologic units: (a) Tertiary basaltic lavas and intercalated sediments of the Columbia River Group at the base, (b) Plio-Pleistocene sediments of the Ringold Formation, and (c) the Pasco (glaciofluvial) gravels and associated sediments of late Pleistocene age at the surface. See Section 2.5 for additional information.

1.2.2.1.2.7 Seismology. The CGS site is situated in an area characterized by low seismicity and widely scattered epicenters. See Section 2.5 for additional information.

1.2.2.1.3 Design Basis Depending on Site Environs

a. Offgas System

An offgas (OG) system consisting of hold-up piping, charcoal adsorbers, and an elevated release is provided for the controlled release of gaseous effluent to the atmosphere. Gaseous releases will be as low as reasonably achievable (ALARA) in accordance with 10 CFR Part 50, Appendix I, and less than 10 CFR Part 20 limits;

b. Liquid Waste Effluents

Liquid waste will be processed and recycled, and releases of excess inventory will be such that concentrations at the point of discharge will be as low as reasonably achievable in accordance with 10 CFR Part 50, Appendix I, and less than 10 CFR Part 20 limits;

c. Wind Loading and Seismic Design

The structures and components whose failure might cause a design basis accident or result in an uncontrolled release of radioactive fission products will be designed to resist wind loads of tornado velocity and earthquake ground motions which are significantly higher than those expected to occur at the site during the service life of the plant; and

d. Flooding

The maximum assumed flood elevation for design purposes is the sum total of the elevations of water due to the following effects:

1. Breach of any of the upstream dams due to seismic forces,
2. High flow in the Columbia River, and
3. Wind and wave action.

1.2.2.2 General Arrangement of Structures and Equipment

The principal structures located on the plant site are the following:

a. Reactor building - the building that houses the major portion of the nuclear steam supply system (NSSS), the drywell, suppression pool, primary containment, new and spent fuel pools, refueling equipment, and ECCS;

b. Radwaste and control building - the building that houses the liquid and solids radwaste systems, components of the OG system, and the main control room;

c. Turbine building - the building that houses the power conversion equipment;

d. Diesel generator building - the building that houses the standby diesel generators, diesel fuel oil (DO) storage tanks, and associated controls and instrumentation;

e. Circulating water pump house (Wind River Building) - a structure housing the main circulating water (CW) pumps, plant service water (TSW) pumps, and FP pumps;

f. Standby service water pump houses - structures that house the redundant standby SW pumps and the HPCS SW pump;

g. Spray ponds - cooling ponds provided as the ultimate heat sink (UHS);

h. Makeup water pump house - a structure that houses the cooling tower makeup (TMU) water pumps;

i. General service building (Yakima Building) - a structure that houses the potable water (PWC) storage tank, demineralized water (DW) storage tank, offices for plant administration, lunch room, and machine shop;

j. Transformer yard;

k. Condensate storage tanks (CSTs);

l. Cooling towers; and

m. Plant Engineering Center (Deschutes Building).

The arrangement of these structures on the plant site is shown in Figure 1.2-1. The arrangement of the equipment inside the main buildings is shown in Figures 1.2-2 through 1.2-24.

1.2.2.3 Symbols Used on Engineering Drawings

Figure 1.2-25 defines General Electric's (GE) piping and instrumentation symbols, and Figure 1.2-26 through 1.2-28 shows Burns and Roe piping and instrumentation symbols. Figure 1.2-29 defines the logic symbols used on NSSS functional control diagrams.

1.2.2.4 Nuclear System

The nuclear system includes a direct-cycle, forced-circulation, GE boiling water reactor (BWR) that produces steam for direct use in the steam turbine. A heat balance showing the major parameters of the nuclear system for the rated power conditions is shown in Figure 10.1-1.

1.2.2.4.1 Reactor Core and Control Rods

Fuel for the reactor core consists of slightly enriched uranium dioxide pellets sealed in Zircaloy-2 tubes. These tubes (or fuel rods) are assembled into individual fuel assemblies. Gross control of the core is achieved by movable, bottom-entry control rods. The control rods are cruciform in shape and are dispersed throughout the lattice of fuel assemblies. The control rods are positioned by individual control rod drives (CRDs).

Each fuel assembly has several fuel rods with gadolinia (Gd_2O_3) mixed in solid solution with UO_2. The Gd_2O_3 is a burnable poison which diminishes the reactivity of the fresh fuel. It is depleted as the fuel reaches the end of its first cycle.

A fuel design specific limit on cladding strain is the design criterion used for fuel rod cladding failure. The peak linear heat generation for steady-state operation is well below the fuel damage limit even late in life. Experience has shown that the control rods are not susceptible to distortion and have an average life expectancy many times the residence time of the fuel loading.

1.2.2.4.2 Reactor Vessel and Internals

The reactor vessel contains the core and supporting structures; the steam separators and dryers; the jet pumps; the control rod guide tubes; the distribution lines for reactor feedwater (RFW), HPCS, low-pressure core spray (LPCS), and standby liquid control (SLC); the in-core instrumentation; and other components. The main connections to the vessel include main steam (MS) lines, reactor recirculation (RRC) lines, RFW lines, CRD and in-core nuclear instrument housings, HPCS and LPCS lines, residual heat removal (RHR) lines, SLC line,

core differential pressure line, jet pump pressure-sensing lines, and water level instrumentation.

The reactor vessel is designed and fabricated in accordance with applicable codes for a pressure of 1250 psig. The nominal operating pressure in the steam space above the separators is 1035 psia. The vessel is fabricated of low-alloy steel and is clad internally with stainless steel (except for the top head, and certain nozzles and nozzle weld zones which are unclad).

The reactor core is cooled by demineralized water that enters the lower portion of the core and boils as it flows upward around the fuel rods. The steam leaving the core is dried by steam separators and dryers located in the upper portion of the reactor vessel. The steam is then directed to the turbine through the MS lines. Each MS line is provided with two MS isolation valves (MSIVs) in series, one on each side of the primary containment barrier.

1.2.2.4.3 Reactor Recirculation System

The RRC system pumps reactor coolant through the core. This is accomplished by two recirculation loops external to the reactor vessel but inside the primary containment. Each external loop contains a mechanical pump, two motor-operated maintenance valves, and one flow control valve which is mechanically blocked full open. The two motor-operated valves are used as pump suction and pump discharge shutoff valves. The flow control valves are no longer used to control reactor power level and therefore are kept in a mechanically blocked full open position.

The internal portion of the loop consists of the jet pumps, which contain no moving parts. The jet pumps provide a continuous internal circulation path for the major portion of the core coolant flow. The jet pumps are located in the annular region between the core shroud and the vessel's inner wall. Any recirculation line break would still allow core flooding to approximately two-thirds of the core height, the level of the inlet of the jet pumps.

1.2.2.4.4 Residual Heat Removal System

The RHR system is a system of pumps, heat exchangers, and piping that fulfills the following functions:

a. Removes decay and sensible heat during and after plant shutdown;

b. Injects water into the reactor vessel, following a LOCA, rapidly enough to reflood the core and maintain fuel cladding below the fragmentation temperature independent of other core cooling systems. This is further discussed in Section 1.2.2.5.8;

c. Removes heat from the primary containment, following a LOCA, to limit the increase in primary containment pressure. This is accomplished by cooling and recirculating the suppression pool water (containment cooling) and by spraying the drywell and suppression pool air spaces (containment spray) with suppression pool water; and

d. Removes some of the airborne radioactivity from the primary containment atmosphere following a LOCA by spraying the drywell.

1.2.2.4.5 Reactor Water Cleanup System

The reactor water cleanup (RWCU) system recirculates a portion of reactor coolant through a filter-demineralizer to remove particulate and dissolved impurities from the reactor system under controlled conditions. It also removes excess coolant from the reactor system under controlled conditions.

1.2.2.4.6 Nuclear Leak Detection System

The nuclear leak detection (LD) system consists of temperature, pressure, flow, and fission-product sensors with associated instrumentation and alarms. This system detects and annunciates leakage in the following systems:

a. Main steam system,
b. Reactor water cleanup system,
c. Residual heat removal system,
d. Reactor core isolation cooling (RCIC) system,
e. Reactor feedwater system,
f. High-pressure core spray system,
g. Low-pressure core spray system,
h. Reactor recirculation system, and
i. Reactor pressure vessel (RPV) flange.

Small leaks generally are detected by temperature and pressure changes, fill-up rate of drain sumps, and fission-product concentration inside the primary containment. Large leaks are also detected by changes in reactor water level and changes in flow rates in process lines.

1.2.2.5 Nuclear Safety Systems and Engineered Safety Features

1.2.2.5.1 Reactor Protection System

The reactor protection system (RPS) initiates a rapid, automatic shutdown (scram) of the reactor, if required, to prevent fuel cladding damage or nuclear system process barrier damage following abnormal operational transients. The RPS overrides all operator actions and process

controls and is based on a fail-safe design philosophy that allows appropriate protective action even if a single component failure occurs.

1.2.2.5.2 Neutron Monitoring System

Although not all portions of the neutron monitoring system qualify as a nuclear safety system, those that provide high neutron flux signals to the RPS do. The intermediate range monitors (IRMs) and average power range monitors (APRMs), which monitor neutron flux via in-core detectors, signal the RPS to scram in time to prevent excessive fuel cladding damage as a result of overpower transients. The APRM modules also provide inputs to the thermal power monitors (TPMs) which approximate fuel thermal conditions and also provide scram signals to the RPS.

1.2.2.5.3 Control Rod Drive System

When a scram is initiated by the RPS, the CRD system inserts the negative reactivity necessary to shut down the reactor. Each control rod is controlled individually by a hydraulic control unit. When a scram signal is received, high-pressure water stored in an accumulator in the hydraulic control unit forces its control rod into the core.

1.2.2.5.4 Control Rod Drive Housing Supports

Control rod drive housing supports are located underneath the reactor vessel near the control rod housings. The supports limit the travel of a control rod in the event that a control rod housing is ruptured. The supports prevent a nuclear excursion as a result of a housing failure and thus protect the fuel barrier.

1.2.2.5.5 Control Rod Velocity Limiter

A control rod velocity limiter is attached to each control rod to limit the velocity at which a control rod can fall out of the core should it become detached from its CRD. This action limits the rate of reactivity insertion resulting from a rod drop accident. The limiters contain no moving parts.

1.2.2.5.6 Pressure Relief System (Nuclear System)

A pressure relief system consisting of safety/relief valves (SRVs) mounted on the MS lines is provided to prevent excessive pressure inside the nuclear system following either abnormal operational transients or accidents.

1.2.2.5.7 Reactor Core Isolation Cooling System

The RCIC system provides makeup water to the reactor vessel when the vessel is isolated. The RCIC system uses a steam-driven turbine-pump unit and operates automatically in time and with sufficient coolant flow to maintain adequate water level in the reactor vessel. RCIC is not an engineered safety feature. It is included here, however, because of its similar functions.

1.2.2.5.8 Emergency Core Cooling System

Four ECCS are provided to maintain fuel cladding below fragmentation temperature in the event of a breach in the RCPB that results in a loss of reactor coolant. The systems are

a. High-pressure core spray system,
b. Automatic depressurization system (ADS),
c. Low-pressure core spray system, and
d. Low-pressure coolant injection (LPCI), an operating mode of the RHR system.

1.2.2.5.8.1 High-Pressure Core Spray System. The HPCS system provides and maintains an adequate coolant inventory inside the reactor vessel to maintain fuel cladding temperatures below the fragmentation temperature in the event of breaks in the RCPB. The system is initiated by either high pressure in the drywell or low water level in the vessel. It operates independently of all other systems over the entire range of pressure differences from greater than normal operating pressure to zero. The HPCS cooling decreases vessel pressure to enable the low pressure cooling systems to function. The HPCS system is powered by its own diesel generator if auxiliary power is not available, and the system may also be used as a backup for the RCIC system.

1.2.2.5.8.2 Automatic Depressurization System. The ADS rapidly reduces reactor vessel pressure during a LOCA situation in which the HPCS system fails to maintain the reactor vessel water level. The depressurization provided by the system enables the low pressure ECCS to deliver cooling water to the reactor vessel. The ADS uses some of the relief valves that are part of the nuclear system pressure relief system. The automatic relief valves are arranged to open when conditions indicate that the HPCS system is not delivering sufficient cooling water to the reactor vessel to maintain the water level above a preselected value. The ADS will not be activated unless either the LPCS or LPCI pumps are operating. This is to ensure that adequate coolant will be available to maintain reactor water level after the depressurization.

1.2.2.5.8.3 Low-Pressure Core Spray System. The LPCS system consists of one independent pump and the valves and piping to deliver cooling water to a spray sparger over the core. The system is actuated by conditions indicating that a breach exists in the RCPB but water is delivered to the core only after reactor vessel pressure is reduced. This system provides the capability to cool the fuel by spraying water into each fuel channel. The LPCS loop

functioning in conjunction with either the ADS or HPCS can maintain the fuel cladding below the prescribed temperature following a LOCA.

1.2.2.5.8.4 Low-Pressure Coolant Injection. The LPCI is an operating mode of the RHR system, but is discussed here because the LPCI mode acts as an engineered safety feature in conjunction with other ECCS. The LPCI uses the pump loops of the RHR to inject cooling water directly into the pressure vessel. The LPCI is actuated by conditions indicating a breach in the RCPB, but water is delivered to the core only after reactor vessel pressure is reduced. The LPCI operation provides the capability of core reflooding, following a LOCA, in time to maintain the fuel cladding below the prescribed temperature limit.

1.2.2.5.9 Primary Containment

1.2.2.5.9.1 Functional Design. The primary containment is part of the overall containment system which provides the capability to reliably limit the release of radioactive materials to the environs subsequent to the occurrence of the postulated LOCA so that offsite doses will be below the limits stated in 10 CFR Part 50.67. Its design employs an over-and-under, steel pressure vessel which houses the reactor vessel, the RRC loops, and other branch connections of the reactor primary system. The pressure suppression system consists of a drywell, a pressure suppression chamber which stores a large volume of water, a connecting submerged vent system between the drywell and water pool, isolation valves, containment cooling system, and other service equipment. In the event of a RCPB piping failure within the drywell, reactor water and steam would be released into the drywell air space. The resulting increase of drywell pressure would then force a mixture of air, steam, and water through the vents into the pool of water which is stored in the suppression pool, resulting in a rapid pressure reduction in the drywell. Air which is transferred to the suppression chamber, pressurizes the suppression chamber, and is subsequently vented back to the drywell.

1.2.2.5.9.2 Drywell Cooling System. The drywell cooling system is based on recirculating cooling water through the drywell air-handling units to maintain the required ambient temperature. Air is distributed through ductwork and/or up through the annular space between the reactor vessel insulation and the sacrificial shield wall. Air is distributed to areas requiring cooling, such as the RRC motors, the CRD area, and the bellows area. Return air is ducted back to the operating units. The arrangement simplifies the design, operation, and air distribution balance of the system.

Reactor building closed cooling water (RCC) is supplied to the air handling units to dissipate absorbed heat only under normal and loss of power conditions.

The drywell cooling system is not required for safe shutdown, but it is designed with redundant equipment and powered from essential buses to ensure continuous operation to satisfy the power-generation design objective.

The drywell cooling system is designed to operate during offsite power loss. Control switches for operating the equipment are located in the main control room.

1.2.2.5.9.3 Suppression Pool Cooling. The containment cooling subsystem of the RHR system is placed in operation to limit the temperature of the water in the suppression pool following a design basis LOCA, to control the pool temperature during normal operation of the SRVs and the RCIC system, and to reduce the pool temperature following an isolation transient. In the containment cooling mode of operation, the RHR main system pumps take suction from the suppression pool and pump the water through the RHR heat exchangers where cooling takes place by transferring heat to SW. The fluid is then discharged back to the suppression pool or the RPV.

1.2.2.5.9.4 Containment Spray. The redundant containment spray cooling subsystems of the RHR system provide containment cooling for postaccident conditions. Water pumped through the RHR heat exchangers can be diverted to spray headers in the drywell and above the suppression pool. The spray removes energy from the drywell atmosphere by condensing the water vapor. The drywell spray also removes particulate fission product from the drywell atmosphere. Approximately 5% of this flow can be directed to the suppression chamber to cool the gas above the water surface.

1.2.2.5.9.5 Containment Atmosphere Control. In the event of a LOCA, hydrogen and oxygen will be generated in the reactor. Containment atmosphere control is provided by inerted containment, containment atmosphere mixing, and hydrogen and oxygen monitoring in a post-LOCA event.

1.2.2.5.10 Primary Containment and Reactor Vessel Isolation System

The primary containment and reactor vessel isolation system includes sensors, trip channels, control switches and remotely activated valve closing mechanisms associated with the valves, which, when closed, effect isolation of the primary containment or reactor vessel or both.

The purpose of the system is to provide timely protection against the onset and consequences of accidents involving the gross release of radioactive materials from the fuel and the nuclear system process barrier. The primary containment and reactor vessel isolation control system initiates automatic isolation of the RCPB and the primary containment vessel whenever monitored variables exceed preselected operation limits.

All pipelines that both penetrate the primary containment and offer a potential release path for radioactive material are provided with redundant isolation capabilities.

1.2.2.5.11 Main Steam Line Isolation Valves

Although all pipelines that both penetrate the containment and offer a potential release path for radioactive material are provided with redundant isolation capabilities, the main steam lines, because of their large size and large mass flow rates, are given special isolation consideration. Automatic MSIVs are provided in each MS line. Each is powered by both air pressure and spring force. These valves fulfill the following objectives:

a. Prevent excessive damage to the fuel barrier by limiting the loss of reactor coolant from the reactor vessel resulting from either a major leak from the steam piping outside the primary containment or from a malfunction of the pressure control system resulting in excessive steam flow from the reactor vessel,

b. Limit the release of radioactive materials (i.e., iodine spiking) by isolating the RCPB in case of a rapid depressurization of RPV and resulting release of radioactive materials from the fuel to the reactor cooling water and steam, and

c. Limit the release of radioactive materials by closing the primary containment barrier in case of a major leak from the nuclear system inside the primary containment.

1.2.2.5.12 Main Steam Line Flow Restrictors

A venturi-type flow restrictor is installed in each MS line. These devices limit the loss-of-coolant from the reactor vessel before the MSIVs are closed in case of an MS line break outside the primary containment.

1.2.2.5.13 Main Steam Line Radiation Monitoring System

The main steam line radiation monitoring system consists of four gamma radiation monitors located externally to the main steam lines just outside the containment. The monitors are designed to detect a gross release of fission products from the fuel. On detection of high radiation, the trip signals generated by the monitors are used to initiate a closure to the reactor water sample valves, mechanical vacuum pump trip, the mechanical vacuum pump lines isolation, and alarms.

1.2.2.5.14 Standby Service Water and High-Pressure Core Spray Service Water Systems

The SW system consists of two completely redundant systems. Each system consists of a pump and piping supplying the associated RHR system heat exchanger, standby diesel generator, essential heating, ventilating, and air conditioning (HVAC) coolers, RHR pump seal coolers, SW motor bearing coolers, and sample coolers with safety grade cooling water from

the UHS spray ponds. The Division I SW system also provides cooling water to the LPCS motor bearing cooler.

Cooling water is supplied during a postulated LOCA to the RHR heat exchangers to remove heat when the containment cooling mode of the RHR system is placed in operation. During normal operation, SW is also supplied to the RHR heat exchangers for the shutdown function of the RHR system.

The SW is available to the shell side of the fuel pool cooling and clean up (FPC) system heat exchangers in the event that the normal cooling water supply from the RCC system becomes unavailable.

The HPCS SW system shares spray pond A with the SW system. The pump supplies cooling water to the HPCS diesel generator and the essential HVAC coolers for the HPCS diesel generator and HPCS pump areas.

Cooling water is supplied to all diesel generator cooling systems whenever the diesel generators are started.

1.2.2.5.15 Reactor Building - Secondary Containment

The reactor building completely surrounds the primary containment. The building provides secondary containment when the primary containment is closed and in service. The reactor building also houses refueling and reactor servicing equipment, new and spent fuel storage facilities, and other reactor safety and auxiliary systems. Secondary containment is not required during movement of irradiated fuel assemblies or core alterations.

The design of the reactor building includes provisions for seismic load resistance and low infiltration and exfiltration rates. The building consists of poured-in-place, reinforced-concrete exterior walls up to the refueling floor. Above this level, the building structure is steel frame with insulated metal siding with sealed joints. Access to the building is through interlocked double doors.

1.2.2.5.16 Reactor Building Ventilation Exhaust Radiation Monitoring System

The reactor building ventilation exhaust radiation monitoring system consists of a number of radiation monitors arranged to monitor the activity level of the ventilation exhaust from the reactor building and primary containment. Upon detection of high radiation, the reactor building is automatically isolated and the SGT system is started.

1.2.2.5.17 Standby Gas Treatment System

The SGT system consists of two identical filter trains. Each filter train consists of a filter unit, two fans, ductwork, and associated valves.

Either filter train may be considered as an installed spare with the other train capable of passing the required amount of air. Either train alone is capable of exchanging the total reactor building volume once in a 24 hr period.

Each filter unit contains electric heaters, a prefilter, high-efficiency particulate filters (water and fire resistant), an iodine filter (high ignition temperature), and instrumentation to measure temperature and flow.

The system maintains a slightly negative internal building pressure and can process all gaseous effluent prior to its discharge from the reactor building.

All equipment is connected to the essential buses and is started either automatically or manually from the main control room.

1.2.2.5.18 Standby Alternating Current Power Supply System

The standby ac power supply system consists of two diesel generator sets, switchgear, and associated distribution system equipment and auxiliaries.

These diesel generator sets are associated with redundant (Divisions 1 and 2) separation divisions; each diesel generator set serves a particular division. The capacity of each diesel generator set is sufficient to attain shutdown under both normal and LOCA conditions, in the event that both the offsite and the normal auxiliary power sources are unavailable to supply plant loads. Since load distribution is such that redundant auxiliary systems are separated by division, safe shutdown can be achieved with only one of the two diesel generators operating.

The standby ac power supply system diesel generators and associated equipment are designed to Class 1E standards and are located within Seismic Category I structures. Equipment of each division is separated so that failure of any component of one division will not jeopardize proper functioning of the other division.

Although it is not a part of the standby ac power supply system, another independent diesel generator unit supplies ac power exclusively to the HPCS system (see Section 1.2.2.5.8.1) in the event that both the offsite and the normal auxiliary power sources are unavailable to supply plant loads.

The HPCS diesel generator may also be cross connected to either Division 1 or to Division 2 as described in Section 8.3.1.1.7.2.1.

1.2.2.5.19 Direct Current Power Supply System

The dc power supply system consists of station batteries, battery chargers, distribution equipment, and related auxiliaries.

The dc system furnishes power at three voltage levels: 250 V, 125 V, and +24 V. The 250-V and 125-V subsystems supply power to both Class 1E and non-Class 1E loads; the 24-V subsystem supplies power for the startup range and power range neutron monitoring systems.

The primary power sources for the system are the dc output station battery chargers. Station batteries associated with each charger operate in a "float-charge" configuration to ensure maintaining the batteries in a fully charged condition. In the event of loss of charger dc output, the station batteries furnish a secondary source of dc supply.

The 125-V and +24-V dc power supply subsystems are each divided into electrically and physically independent divisions. Each battery, together with its independent battery charger, is associated with one of the segregated divisions. The batteries and their associated chargers are located in separate rooms.

The ampere-hour capacity of each battery is capable of supplying all essential loads for a minimum of 2 hr in the event that dc output from the battery chargers is lost.

1.2.2.5.20 Standby Liquid Control System

Although not intended to provide prompt reactor shutdown, as the control rods are, the Standby Liquid Control (SLC) system provides a redundant, independent, and alternate method to bring the nuclear fission reaction to subcriticality and to maintain a subcritical condition as the reactor cools. The system makes possible an orderly and safe shutdown in the event that not enough control rods can be inserted into the reactor core to accomplish shutdown in the normal manner. The system is sized to counteract the positive reactivity effect from rated power to the cold, clean shutdown condition.

The SLC system is also used to maintain the suppression pool pH greater than 7.0 following a LOCA to minimize re-evolving gaseous iodine fission products to the containment atmosphere.

1.2.2.5.21 Safe Shutdown from Outside the Main Control Room

In the event that the control room becomes inaccessible, the reactor can be brought from power range operation to cold shutdown conditions by the use of local controls and equipment that are available outside the control room.

1.2.2.5.22 Main Steam Line Isolation Valve Leakage Control System (Deactivated)

The main steam line isolation valve leakage control (MSLC) system was designed to minimize the fission products which could bypass the SGT system after a LOCA. The MSLC system is not credited for accident mitigation and is no longer needed; MSLC is administratively de-activated. Connections between MSLC and other systems are physically isolated, MSLC components are de-energized, closed, or otherwise taken out of service.

1.2.2.5.23 Fuel Pool Cooling and Cleanup System

The FPC system provides for the removal of decay heat from stored spent fuel and maintains specified water temperature, purity, clarity, and level. This prevents boiling of the pool water and controls the buildup of excessive radioactive materials in the cooling water, thereby minimizing potential radiation exposure to plant personnel. The cooling portion of the system is designed to Seismic Category I requirements and may be isolated from the Seismic Category II cleanup portion of the system by automatic Seismic Category I isolation valves which actuate on low-fuel pool water level. Normally the RCC system furnishes non-safety grade cooling water to the FPC system. If required, safety grade cooling and makeup water is available to the FPC system from the SW system.

1.2.2.5.24 Hardened Containment Vent (HCV) System

The HCV system is designed to meet the requirements of NRC Order EA-13-109. The primary design objective of the HCV system is to provide sufficient venting capacity from the wetwell to prevent an overpressure failure of the containment by maintaining containment pressure below the primary containment design pressure and the primary containment pressure limit (PCPL). The HCV system is designed to operate during severe accident conditions which include the elevated temperatures, pressures, radiation levels, and concentrations of combustible gases such as hydrogen and carbon monoxide associated with accidents involving extensive core damage, including accidents involving a breach of the reactor vessel by molten core debris.

The HCV system is designed as a stand-alone system that can function without the support of other plant systems. Other than the two containment isolation valves, the remaining components such as the dedicated nitrogen and battery systems and control room and remote operating stations or instrumentation are not discussed or assumed in mitigating any Chapter 15 accidents.

1.2.2.6 Power Conversion System

1.2.2.6.1 Turbine Generator

The turbine is an 1800 rpm, tandem-compound (one double-flow high-pressure turbine and three double-flow low-pressure turbines), reheat unit with an electrohydraulic governor for

normal operation. The turbine generator is provided with an emergency trip system for turbine overspeed. The rating of the turbine generator is 1,173,046 kW.

The generator is a direct-driven, three-phase, 60 Hz, 25,000 V, 1800 rpm, hydrogen inner-cooled, synchronous generator rated at 1,230 MVA at 0.975 power factor, 0.58 short circuit ratio at a maximum hydrogen pressure of 78 psig.

1.2.2.6.2 Main Steam System

The MS system consists of four 26-in. diameter lines (which expand to 30-in. diameter lines inside the turbine building) extending from the outermost MSIVs to the main turbine stop valves. The use of four main steam lines permits testing of the turbine stop valves and MSIVs during station operation with only a minimum of load reduction. The design pressure and temperature of the MS system from the outermost MSIV to the turbine stop valve is 1250 psig at 575°F. Other features include drains and parts of the turbine bypass system.

1.2.2.6.3 Main Condenser

The main condenser is a triple-pressure, single-pass, deaerating-type condenser with a divided water box. The condenser includes provisions for accepting up to 25% of the MS flow at design conditions from the turbine bypass system and serves as a heat sink for several other flows, such as exhaust steam from the RFW pump turbines, cascading heater drains, feedwater heater shell operating vents, and condensate pump suction vents.

1.2.2.6.4 Main Condenser Evacuation System

The main condenser evacuation system is designed to remove noncondensable gases from the condenser, including air inleakage and dissociation products originating in the reactor, and to continuously exhaust them to the gaseous radwaste system during operation. The system consists of two 100%-capacity, twin-element first stage and single-element second stage steam jet air ejector units complete with intercondensers for normal plant operation and a mechanical vacuum pump for use during startup. Discharge from the vacuum pumps during startup is routed to the elevated release point.

1.2.2.6.5 Turbine Gland Seal System

The turbine gland seal system is designed to provide a means of preventing air leakage into or radioactive steam leakage out of the turbine. The system consists of two 100% steam evaporators, steam seal pressure regulators, steam seal header, gland seal steam condenser and blowers, and the associated piping, valves, and instrumentation.

1.2.2.6.6 Steam Bypass System and Pressure Control System

A turbine bypass system is provided which passes steam directly to the main condenser under the control of the pressure regulator. Steam is bypassed to the condenser whenever the reactor steaming rate exceeds the load permitted to pass to the turbine generator. The capacity of the turbine bypass system is 25% of the turbine design steam flow. The Digital Electro-Hydraulic (DEH) control system provides main turbine control (governor) valve and bypass valve position demands so as to maintain a nearly constant reactor pressure during normal plant operation.

1.2.2.6.7 Circulating Water System

The CW system provides the condenser with a continuous supply of cooling water. It is a closed system utilizing forced draft cooling towers. Makeup water to the system is provided from TMU pumps located in an intake structure on the Columbia River. The makeup water replaces the water lost by evaporation, drift, and blowdown.

1.2.2.6.8 Condensate and Feedwater System

The condensate and feedwater system pumps condensate from the condenser hotwell to the RPV. Condensate is pumped by three main condensate (COND) pumps through the gland seal steam condenser, the steam jet air ejector condensers, and the offgas condenser. After leaving the offgas condenser, the condensate is pumped through a full-flow condensate filter-demineralizer system. The filter-demineralizer effluent is then pumped by three condensate booster pumps through the five low-pressure heaters. The last low-pressure heater discharges to the suction of the RFW pumps. The discharge from the two turbine-driven RFW pumps passes through the sixth stage of feedwater heating and then flows to the RPV. Feedwater flow is controlled by varying the speed of the steam-driven turbine.

1.2.2.6.9 Condensate Filter-Demineralizer System

The full-flow condensate filter-demineralizer system with instrumentation and semiautomatic controls is designed to ensure a constant supply of high-quality water to the reactor.

1.2.2.7 Electrical Systems, Instrumentation, and Control

1.2.2.7.1 Electrical Power Systems

The plant consists of a single main generator directly connected to a main power transformer through an isolated phase electrical bus duct. The main power transformer steps up the output of the 25-kV generator to a nominal 500-kV transmission system voltage.

The output of the main power transformer is connected to a 500-kV switchyard consisting of circuit breakers, disconnect switches, buses, and associated equipment arranged in a ring bus configuration.

A 230-kV offsite supply is provided to a separate startup auxiliary transformer to supply maximum startup, operating and shutdown load requirements for a normal plant auxiliary loads and for safety loads. In addition, a separate 115-kV offsite supply serves a backup auxiliary transformer with sufficient capacity to provide the power requirements of plant safe shutdown loads.

1.2.2.7.2 Electrical Power Systems Process Control and Instrumentation

Main generator electrical controls are located in the main control room. These include main generator circuit breaker controls, synchronizing equipment, and generator excitation and voltage control equipment. Instrumentation is also provided in the main control room for the main generator connections and equipment. This includes indicating instruments for voltage, current, kW, MVAR, and frequency. Recording instruments are provided for generator MW output and main bus voltage. Kilowatt-hour meters are provided for main generator outputs and for auxiliary power system loads. Instrumentation is provided for monitoring generator and transformer temperatures. Other types of monitoring instrumentation are provided as required to ensure proper operation of equipment. Circuit breaker controls, metering, and indication for the auxiliary power system are also located in the main control room.

High-speed protective relaying equipment is provided for the main generator, main and auxiliary transformers, main buses, transmission lines, and interconnecting cables and bus ducts to provide proper isolation of this equipment in the event of electrical faults. The protective relay system includes breaker failure protection and backup relaying to ensure proper isolation of electrical faults in the event of a failure of the primary protective relaying.

1.2.2.7.3 Nuclear System Process Control and Instrumentation

1.2.2.7.3.1 Reactor Manual Control System. The reactor manual control system (RMCS) provides the means by which control rods are positioned from the control room for power control. The system operates valves in each CRD hydraulic control unit to change control rod position. Only one control rod can be manipulated at a time. The RMCS includes the logic that restricts control rod movement (rod block) under certain conditions as a backup to procedural controls.

1.2.2.7.3.2 Recirculation Flow Control System. During normal power operation, a variable frequency power supply is used to control flow by varying the RRC pump motor speed. Adjusting the frequency changes motor speed and the coolant flow-rate through the core, thereby changing the core power level.

1.2.2.7.3.3 Neutron Monitoring System. The neutron monitoring system is a system of in-core neutron detectors and out-of-core electronic monitoring equipment. The system provides indication of neutron flux, which can be correlated to thermal power level for the entire range of flux conditions that can exist in the core. The source range monitors (SRM) and the intermediate range monitors (IRM) provide flux level indications during reactor startup and low power operation. The local power range monitors (LPRM) and average power range monitors (APRM) allow assessment of local and overall flux conditions during power range operation. The traversing in-core probe system (TIP) provides a means to calibrate the individual LPRM sensors. The neutron monitoring system provides inputs to the reactor manual control system to initiate rod blocks if preset flux limits are exceeded, and inputs to the RPS to initiate a scram if other limits are exceeded.

1.2.2.7.3.4 Refueling Interlocks. A system of interlocks that restricts movement of refueling equipment and control rods when the reactor is in the refueling and start-up modes is provided to prevent an inadvertent criticality during refueling operations. The interlocks back up procedural controls that have the same objective. The interlocks affect the refueling platform, refueling platform hoists, fuel grapple, and control rods.

1.2.2.7.3.5 Reactor Vessel Instrumentation. In addition to instrumentation for the nuclear safety systems and ESF, instrumentation is provided to monitor and transmit information that can be used to assess conditions existing inside the reactor vessel and the physical condition of the vessel itself. This instrumentation monitors reactor vessel pressure, water level, coolant temperature, reactor core differential pressure, coolant flow rates, and RPV head inner seal ring leakage.

1.2.2.7.3.6 Process Computer System. An on-line process computer is provided to monitor and log process variables and to make certain analytical computations. The rod worth minimizer function of the computer prevents rod withdrawal under low power conditions if the rod to be withdrawn is not in accordance with a preplanned pattern. The effect of the rod block is to limit the reactivity worth of the control rods by enforcing adherence to the preplanned rod pattern.

1.2.2.7.4 Power Conversion Systems Process Control and Instrumentation

1.2.2.7.4.1 Digital Electro-Hydraulic Control System. The DEH control system maintains control of the turbine governor valves and turbine bypass valves to allow proper generator and reactor response to system load demand changes while maintaining the nuclear system pressure essentially constant. When the generator is not connected to the grid, the DEH control system maintains turbine-generator speed (frequency) in response to reactor pressure changes by adjusting steam flow to the turbine valves and bypass valves.

The turbine generator speed/load controls can initiate rapid closure of the turbine control (governor) valves and rapid opening of the turbine bypass valves to prevent turbine overspeed on a generator electric load loss.

1.2.2.7.4.2 Feedwater System Control. A three-element controller is used to regulate the feedwater system so that proper water level is maintained in the reactor vessel. The controller uses main steam flow rate, reactor vessel water level, and feedwater flow rate signals. The feedwater control signal is used to control the speed of the steam turbine-driven feedwater pumps. During startup, shutdown, and low plant load conditions, the steam turbine-driven feedwater pumps are run at constant speed, and the feedwater control signal is used to modulate a startup feedwater control valve to maintain proper reactor water level.

1.2.2.8 Radioactive Waste Systems

1.2.2.8.1 Liquid Radwaste System

This system collects, treats, stores, and disposes of all radioactive liquid wastes. These wastes are accumulated directly in radwaste tanks or in sumps at various locations throughout the plant for subsequent transfer to collection tanks in the radwaste facility. Wastes are processed on a batch basis with each batch being processed by such method or methods appropriate for the quality and quantity of materials determined to be present. Processed liquid wastes may be returned to the condensate system or discharged to the circulating water blowdown line to the river. The liquid wastes in the discharge piping are diluted with circulating water blowdown to achieve a concentration at the site boundary which is below the limits of 10 CFR Part 20.

Equipment is selected, arranged, and shielded to permit operation, inspection, and maintenance with minimum personnel exposure. For example, tanks and processing equipment which contain significant radiation sources are located behind shielding, and sumps, pumps, instruments, and valves are located in controlled access rooms or spaces. Processing equipment is selected and designed to require a minimum of maintenance.

Protection against accidental discharge of liquid radioactive waste is provided by design redundancy, instrumentation for detection and alarm of abnormal conditions, and procedural controls.

1.2.2.8.2 Solid Radwaste System

Solid radioactive wastes are collected, processed, and packaged for storage and ultimate burial. These wastes are generally stored on the site until the short half-lived isotopes have decayed. Wet solid wastes are collected, dewatered, and solidified in steel containers. Examples of these wastes are filter residue, concentrated wastes, and spent resins. Dry solid wastes such as paper, air filters, rags, and used clothing are compressed and packaged in steel containers.

1.2.2.8.3 Gaseous Radwaste System

The purpose of the gaseous radwaste system is to process and control the release of gaseous radioactive wastes to the site environs so that the total radiation exposure to persons outside the controlled area does not exceed the limits of the applicable regulations, 10 CFR 20 and 10 CFR 50, Appendix I, even with some defective fuel rods.

The offgases from the main condenser are the major source of gaseous radioactive waste. The treatment of these gases includes volume reduction through a catalytic hydrogen-oxygen recombiner, water vapor removal through a condenser, decay of short-lived radioisotopes through a holdup line, further condensation, filtration, adsorption of isotopes on activated charcoal beds, further filtration through high efficiency filters, and final release.

Continuous radiation monitors are provided which indicate radioactive release from the reactor and from the charcoal absorbers. The radiation monitors are used to isolate the OG system on high radioactivity to prevent gas of unacceptably high activity from release.

Since clean gland seal steam is used, the offgases from the gland seal steam condenser are not treated prior to release.

The design of the OG system is such that the annual exposure to any offsite person during normal operation from gaseous sources will be ALARA and less than 10 CFR 20.

1.2.2.9 Radiation Monitoring and Control

1.2.2.9.1 Process Radiation Monitoring

Radiation monitors are provided on various lines to monitor either for radioactive materials released to the environs via process liquids and gases or for process system malfunctions. All effluents from the plant which are potentially radioactive are monitored. Several of the effluent monitoring systems record the results prior to discharge as noted on the following list of the major monitoring systems provided.

a. Main steam line radiation monitoring system,

b. Air ejector and offgas radiation monitoring systems (results recorded except for the charcoal bed vault),

c. Liquid radwaste effluent radiation monitoring system,

d. Plant service water and circulating water blowdown radiation monitoring systems,

e. Standby service water radiation monitoring system,

f. Reactor building ventilation exhaust plenum radiation monitoring system (results recorded),

g. Reactor building elevated release point radiation monitoring system (results recorded except for particulate/iodine sample),

h. Turbine building ventilation exhaust radiation monitoring system, (results recorded),

i. Radwaste building ventilation exhaust radiation monitoring system (results recorded), and

j. Reactor building closed cooling water monitoring system.

1.2.2.9.2 Area Radiation Monitors

Radiation monitoring devices are provided in key areas throughout the plant buildings to ensure that plant personnel will not be inadvertently exposed to high radiation doses.

1.2.2.9.3 Site Radiological Environmental Monitoring

A comprehensive radiation surveillance program was initiated in the spring of 1978 to measure radiation levels in the environs surrounding the plant. The program is designed to measure radiation exposure or radioisotope levels in the environment.

The details of this monitoring program are given in the Offsite Dose Calculation Manual (ODCM).

1.2.2.9.4 Liquid Radwaste System Control

Liquid wastes to be discharged are handled on a batch basis with protection against accidental discharge provided by procedural controls. Instrumentation with alarms to detect abnormal concentration of the radwaste is provided, including automatic closure of discharge valves isolating the system from the environment.

1.2.2.9.5 Solid Radwaste System Control

The solid radwaste system collects, treats, and stores solid radioactive wastes for offsite shipment. Wastes are handled on a batch basis. Radiation levels of the various batches are monitored by the operator.

1.2.2.9.6 Gaseous Radwaste System Control

Gaseous radwastes are discharged through a reactor building elevated release point. Radiation levels of the release are continuously monitored and recorded. Isolation of the main condenser

offgas is automatically initiated prior to release should the activity of the offgas exceed discharge limits.

1.2.2.10 Shielding

The shielding in the plant is designed to minimize exposure of plant personnel to radiation. The radiation levels during operation or shutdown conditions have been considered in determining the shielding requirements.

1.2.2.11 Fuel Handling and Storage Systems

1.2.2.11.1 New and Spent Fuel Storage

New and spent fuel storage racks are designed to prevent inadvertent criticality and load buckling. Sufficient coolant and shielding are maintained to prevent overheating and excessive personnel exposure, respectively. The design of the fuel pool provides for corrosion resistance, adherence to Seismic Category I requirements, and prevention of K_{eff} from exceeding 0.95 under dry or flooded conditions.

1.2.2.11.2 Fuel Handling System

The fuel handling equipment includes a fuel inspection stand, fuel preparation machine, a 125-ton crane, a refueling platform, a new fuel transfer basket, jib cranes, and other related tools for fuel and reactor servicing.

1.2.2.11.3 Fuel Pool Cooling and Cleanup System

The FPC system removes decay heat from stored spent fuel and maintains specified water temperature, purity, clarity, and level. This prevents fuel pool boiling and buildup of excessive radioactive materials in the cooling water, thereby minimizing possible exposures to plant personnel.

Cooling of spent fuel is accomplished by the Seismic Category I cooling system as described in Section 9.1.3. It can be isolated from the Seismic Category II cleanup portion of the system by automatic, redundant, Seismic Category I isolation valves which actuate on low fuel pool water level. If required, safety grade cooling and makeup water from the SW system is available to the system by remote-manual operation of redundant Seismic Category I valves to provide long-term cooling and prevent fuel pool boiloff which might result in unacceptable building environmental conditions.

1.2.2.12 Cooling Water and Auxiliary Systems

1.2.2.12.1 Reactor Building Closed Cooling Water System

The RCC system consists of pumps, heat exchangers, controls, and instrumentation to provide adequate cooling for the reactor auxiliary systems. The system is designed to provide a closed cooling water loop between nonessential systems which are potentially radioactive and the TSW system.

1.2.2.12.2 Plant Service Water System

Normal TSW is supplied from service water pumps located in the circulating water pump house. Two service water pumps are provided. The TSW system is designed to remove heat from various auxiliary equipment located within the plant.

1.2.2.12.3 Ultimate Heat Sink

Two spray ponds that serve as the UHS conservatively have a combined equivalent storage of 30 days, assuming no makeup and maximum evaporation and drift losses. Provisions are made to replenish the sink to allow continued cooling capability beyond the initial 30-day period.

1.2.2.12.4 Demineralized Water Makeup System

The DW makeup system is comprised of the trailer-mounted demineralizers and the DW system.

The DW system is designed to provide demineralized water to the CSTs for plant makeup and demineralized water for other plant operating requirements.

1.2.2.12.5 Potable Water and Sanitary Drain Systems

The plant potable water (PW) system provides water for drinking and sanitary purposes. Potable water is normally supplied from the tower makeup system (see Section 9.2.3).

The sanitary drain system effluent is directed to a central sanitary waste treatment facility which uses aerated lagoons in series with lined facultative stabilization ponds. The treatment plant, about 2500 ft SE of the CGS reactor, also receives waste from the WNP-1/4, the Plant Support Facility, and the DOE's 400 Area.

1.2.2.12.6 Process Sampling Systems

The process sampling system provides process information that is required to monitor plant and equipment performance and changes to operating parameters. Representative liquid and

gas samples are taken automatically and/or manually during normal plant operation for laboratory or on-line analyses.

1.2.2.12.7 Condensate Supply System

The condensate storage facility provides a source of water for testing and makeup during operation. Two 400,000 gal CSTs are interconnected to simultaneously supply condensate to the main condenser via one header, to the CRD pumps via a second header, and to the RHR, RCIC, and HPCS systems and condensate supply and condensate filter/demineralizer backwash pumps via a third header. The condensate supply pumps deliver condensate to miscellaneous services in the reactor and radwaste buildings.

Condensate is returned to the CSTs from the RCIC, and radwaste systems, from CRD, condensate supply, and condensate filter/demineralizer backwash pump mini-flows, and from the main condensate system (equivalent to excess CRD injection water). Initial fill and makeup is from the DW system.

1.2.2.12.8 Equipment and Floor Drainage Systems

Plant equipment and floor drainage systems handle both radioactive and nonradioactive drains. Drainage systems which carry radioactive waste are isolated from drainage systems which do not carry radioactive waste.

All drains in the reactor building and radwaste building are considered radioactive. Turbine building drains are divided into radioactive and nonradioactive but all are directed to the radwaste system for processing. Floor and equipment drains in the diesel generator building and service building are routed to the storm water drainage system. The storm water drainage system is normally nonradioactive, however some accumulation of radioactive material (notably tritium) can occur.

1.2.2.12.9 Compressed Air Systems

The compressed air system consists of the control and service air system and the containment instrument air (CIA) system.

The control air system (CAS) is designed to supply clean, dry, oil-free air to station instrumentation and controls and to the accumulators of the MSIVs located outside the primary containment.

The service air (SA) system is designed to supply clean, oil-free air for station services, such as backwashing demineralizers and filters, hose connections for maintenance throughout the station and breathing air at selected locations.

The CIA system is designed to deliver nitrogen or clean, dry, oil-free air for MSIVs, SRV accumulators, and pneumatic operators located inside the primary containment.

1.2.2.12.10 Heating, Ventilating, and Air Conditioning Systems

The HVAC systems are designed to maintain proper air quality for personnel comfort and safety. In addition, the main control room, the critical switchgear area, the cable spreading room HVAC systems, the SW pump room heat removal systems, the reactor building emergency pump and critical electric equipment area cooling systems, and the ventilation system for the standby diesel generators are designed to operate under all station conditions. The primary containment drywell cooling and ventilation system is designed to operate during normal operation and under most upset conditions except a LOCA. All air distribution systems are designed so that airflow is directed from areas of lesser potential contamination to areas of progressively greater potential contamination.

Three separate and redundant HVAC systems service the main control room, cable spreading room, and critical switchgear areas. SW is used as the cooling medium for each system when the normal cooling water supply is unavailable.

Heating and ventilation for the standby diesel generator rooms is provided continuously for each diesel generator unit. Water cooled air handling units provide additional cooling when the diesel generators operate.

The turbine building is provided with a once-through ventilation system based on the use of evaporative coolers.

Ventilation for the radwaste building is provided by means of a once-through ventilation system with particulates filtered before release to the atmosphere.

The SW pump room heat removal systems consist of two independent and separate fan coil units.

The reactor building emergency pump and critical electric equipment area cooling system consists of 13 air handling units which operate to supply cool air to each of the critical equipment rooms when pumps are started and during abnormal conditions.

The primary containment drywell cooling and ventilation system consists of five fan coil units and nine recirculation fans. During normal operation, a minimum three out of five fan coil units are operating.

Ventilation for the reactor building is provided by a once-through ventilation system based on the use of evaporative coolers. The system incorporates the necessary isolation valves to

ensure the necessary secondary containment integrity. A drywell and suppression chamber purge capability is provided as part of this system.

Other HVAC systems provide ventilation to the service building and other miscellaneous areas.

1.2.2.12.11 Fire Protection System

The FP system is designed to provide for the detection and extinguishing of fires.

Manual pull stations and automatic fire detectors are located appropriately throughout the plant and fire alarms are annunciated in the main control room.

The FP system provides a reliable water distribution system for extinguishing fires. Two motor-driven fire pumps are used for normal service, with a diesel-engine-driven fire pump as a backup. A second diesel-driven fire pump with a separate water supply provides an additional backup. Motor-driven jockey pump is provided to maintain system pressure and to prevent cycling of the main fire pumps.

Automatic suppression systems provide protection to higher hazard areas of the plant including:

- Deluge systems protect the transformers and most other areas containing oil piping and oil storage equipment.
- A low-pressure carbon dioxide (CO_2) system is provided for the generator exciter housing.
- A total flooding Halon system is provided for the main control room power generation control complex (PGCC) subfloor.
- Wet pipe sprinklers protect the turbine/generator bearings and other miscellaneous areas.
- Preaction sprinkler systems protect diesel generators, day tank/transfer pump rooms, and areas with high concentrations of electrical cables.

Manual suppression includes:

- Fire hydrants spaced around the yard fire main loop.
- Fire hose stations located throughout the plant.

- Portable fire extinguishers of appropriate types are strategically and conspicuously placed throughout the plant.

1.2.2.12.12 Communications Systems

The plant communication systems are designed to provide reliable communication inside and outside the plant and from the plant to local fire protection and law enforcement authorities. The system utilizes a public address and building wide alarm system, a public telephone system, a private digital telephone system, a sound powered telephone system, a radio communication system, and an automatic transmission telephone link to the Dittmer Control Center of the Bonneville Power Administration (BPA).

1.2.2.12.13 Lighting Systems

The plant lighting systems are normal ac lighting, normal-emergency ac lighting, dc lighting, and battery-pack emergency lighting. Lighting intensities are designed to provide indoor and outdoor illumination consistent with the July 1974 Illumination Engineering Society recommendations, and meet or exceed Occupational Safety and Health Act (OSHA) requirements.

1.2.2.12.14 Normal Auxiliary Alternating Current Power System

The plant normal auxiliary ac power system consists of two normal auxiliary transformers, the 4.16-kV and 6.9-kV normal auxiliary (non-Class 1E) distribution system, the 480-V auxiliary power distribution system and the 120/208-V non-Class 1E distribution system.

The normal ac auxiliary transformers provide power to all plant auxiliaries and comprise the normal plant ac power source when the main generator is operating. One of the normal auxiliary transformers is a dual secondary type with both secondary windings stepping down the generator voltage to 4.16 kV for supply to 4.16-kV non-Class 1E switchgear buses. The other normal auxiliary transformer steps down the generator voltage to 6.9 kV for supply of 6.9-kV non-Class 1E switchgear buses.

The plant 480-V ac auxiliary power system distributes ac power necessary for normal auxiliary and ESF 480-V plant loads. All non-ESF elements of this distribution system are capable of being supplied from the normal auxiliary power source or from the startup power source via the 4.16 kV-non-Class 1E switchgear. The ESF portions of the 480-V distribution system are supplied via the 4.16-kV Class 1E switchgear, and therefore are capable of being supplied by either the normal, startup, backup, or standby sources.

The 120/208-V non-Class 1E ac power system provides power for non-ESF loads.

1.2.2.12.15 Diesel Generator Fuel-Oil Storage and Transfer System

The diesel fuel oil storage and transfer system consists of separate, independent diesel oil supply subsystems serving each of two emergency diesel generators and the HPCS diesel generator. Each full capacity subsystem consists of a fuel oil storage tank, a transfer pump, a day tank, interconnecting piping, strainers and valves, and associated instrumentation and controls.

1.2.2.12.16 Auxiliary Steam System

The auxiliary steam (AS) system normally operates only when the heating steam evaporators are inoperative during plant shutdown. The system then supplies steam to HVAC systems for air and water space heating and for humidification and also to the radwaste system. The system consists of fuel oil storage tank and transfer pumps, auxiliary boiler, blowdown tank, chemical feed tank and metering pump, deaerator and boiler feed pumps, condensate return tank pumps, steam supply and condensate return piping and valves, and associated instruments and controls.

1.2.3 COMPLIANCE WITH NRC REGULATORY GUIDES

The CGS conformance to the NRC regulatory guides is documented in Section 1.8 and in appropriate sections of this FSAR.

Table 1.2-1

Principal Regulations and Codes Followed in Plant Design

Number	Title
10 CFR series	Code of Federal Regulations, principally:
10 CFR 20	Standards for Protection Against Radiation
10 CFR 50	Licensing of Production and Utilization Facilities
10 CFR 50, Appendix A	General Design Criteria for Nuclear Power Plant Construction Permits
10 CFR 50, Appendix B	Quality Assurance Criteria
10 CFR 50, Appendix I	Numerical Guides for Design Objectives and Limiting Conditions for Operation to Meet the Criterion "As Low As Is Reasonably Achievable"
10 CFR 100	Reactor Site Criteria
IEEE-279	IEEE Criteria for Nuclear Power Generating Station Protection Systems
IEEE-308	IEEE Criteria for Class IE Electrical Systems for Nuclear Power Generating Stations
ASME B&PV	ASME Boiler and Pressure Vessel Code:
Section III	Nuclear Components
Section VIII	Pressure Vessels
Section XI	Inservice Inspection
AEC Press Release IN-817	Tentative Regulatory Supplementary Criteria for ASME Code-Constructed Pressure Vessels
ANSI-B31.1.0	ANSI Standard Code for Pressure Piping, Power Piping

NOTE: Additional codes and regulations applying to specific areas of system design are referenced in discussions of individual systems.

Table 1.2-2

Plant Shielding and Zone Classification

Zone	Description	Design Dose Rate (mrem/hr)
I	Uncontrolled, unlimited access	≤1.0
II	Controlled, limited access	≤2.5
III	Controlled, occupancy for short periods, normally inaccessible	≤100
IV	For very short periods. Secured and controlled entrance.	>100

NOTES:

1. Radiation Zone I areas can be occupied by plant personnel or visitors for unlimited periods.
2. Radiation Zone II areas are areas where whole body dose is not expected to exceed 1.25 rem per calendar quarter.
3. Areas having dose rates in excess of 100 mrem/hr are posted as high radiation areas and access is secured and controlled.
4. Radiation Zone III and IV areas can be entered only after the radiation level is determined and the working time limit is established.
5. Accessible areas have dose rates of less than 100 mrem/hr.
6. Access to all controlled areas is through controlled check points.
7. Controlled and limited access areas are identified by warning signs.

BASIC CONTROLLER
CONTAINS 1 OR 3-MODE CONTROL, SET POINT, MANUAL-AUTOMATIC SELECTION, REVERSE OR DIRECT ACTING, CASCADE SWITCH, AND VALVE POSITION INDICATOR.

BASIC M/A CONTROLLER
CONTAINS 1 OR 3-MODE CONTROL, MANUAL AUTOMATIC SELECTION, REVERSE OR DIRECT ACTING, AND INDICATORS FOR PROCESS VALUE AND VALVE POSITION. THE CONTROLLER SET POINT MUST COME FROM SOME EXTERNAL DEVICE. SYMBOL WILL ALSO BE USED TO INDICATE ONLY A MANUAL TO AUTOMATIC TRANSFER STATION.

RATIO SET STATION
CONTAINS A RATIO ADJUSTMENT KNOB (.1 TO 3.0), INPUT AND OUTPUT INDICATORS, AND THE RATIO AMPLIFIER.

BIAS-MANUAL-AUTOMATIC STATION
CONTAINS A BIAS ADJUSTMENT KNOB -20 TO +20%, INPUT AND OUTPUT INDICATORS, BIAS AMPLIFIER, AND MANUAL-AUTOMATIC SELECTION.

BASIC CASCADE COMBINATION
UTILIZES THE STANDARD CONTROLLER AS THE PRIMARY AND A CONTROLLER WITHOUT INTEGRAL SET POINT ON THE SECONDARY. MUST BE OPERATED IN CASCADE OR IN MANUAL.

CASCADE (2 STANDARD CONTROLLERS)
ANY TWO STANDARD CONTROLLERS MAY BE OPERATED IN CASCADE. THIS COMBINATION MAY BE OPERATED OUT OF CASCADE WITH THE "SECONDARY" CONTROLLER ON AUTOMATIC.

MANUAL LOADING STATION
CONTAINS A DIGITAL HOLD, POWER SUPPLY, AND VALVE POSITION INDICATOR. SIMPLY PROVIDES 1-5 MA INTO A 600 OHM LOAD FOR REMOTE POSITIONING OF VALVES AND DAMPERS. MAY BE USED FOR A SET POINT STATION WHEN PRECISION IS NOT CRITICAL.

SET POINT STATION
CONTAINS THE PRECISE SET POINT UNIT ONLY. TO BE USED WHEN SET POINT MUST BE REMOTE FROM THE CONTROLLER.

HIGH-LOW LIMIT STATION
CONTAINS ELECTRONIC CIRCUITRY TO LIMIT CONTROL SIGNALS TO A PRESET VALUE.

INTEGRATOR
PANEL MOUNTED INTEGRATOR FOR TOTALIZING FLOW SIGNALS. 6 DIGIT COUNTER.

RACK-MOUNTED 3-MODE CONTROLLER
PROPORTIONAL PLUS RESET PLUS RATE.

RACK-MOUNTED 2-MODE CONTROLLER
PROPORTIONAL PLUS RESET.

RACK-MOUNTED RATE ACTION DEVICE
CONTAINS ADJUSTABLE RATE ACTION UNIT.

MANUALLY OPERATED ROTARY SWITCH
WITH ROUND KNOB OPERATOR

2-INPUT PROPORTIONAL AMPLIFIER (RACK-MOUNTED)
CONTAINS TWO INPUT CIRCUITS, INPUT BIAS ADJUSTMENT, OUTPUT BIAS ADJUSTMENT AND GAIN ADJUSTMENT.

3-INPUT SUMMATION AMPLIFIER (RACK-MOUNTED)
SAME AS 2 INPUT SUMMATION AMPLIFIER BUT CONTAINS 3 INPUT CIRCUITS.

8-INPUT SUMMATION AMPLIFIER (RACK-MOUNTED)
SAME AS 2 INPUT SUMMATION AMPLIFIER BUT CONTAINS 8 INPUT CIRCUITS.

SQUARE-ROOT EXTRACTOR (PANEL OR RACK MOUNTED)
CONTAINS CIRCUITRY TO EXTRACT THE SQUARE-ROOT OF THE INPUT SIGNAL AND TRANSMIT A LINEAR SIGNAL.

FUNCTION GENERATOR (RACK-MOUNTED)
CONTAINS CIRCUITRY TO PROVIDE AN OUTPUT AS A VARIABLE FUNCTION OF THE INPUT SIGNAL.

SIGNAL SELECTOR (RACK MOUNTED)
CONTAINS CIRCUITRY TO SELECT THE HIGHER OR LOWER OF A GROUP OF INPUT SIGNALS.

MULTIPLIER-DIVIDER (RACK-MOUNTED)
GENERALLY USED FOR COMPENSATION OF FLOW SIGNALS.

MILLIVOLT CONVERTER
CONVERTS MILLIVOLT INPUT SIGNALS TO ELECTRONIC OUTPUT SIGNALS 10-50 MA.

3-UNIT POWER SUPPLY

DIFFERENTIAL PRESSURE TRANSMITTER
CONVERTS DIFFERENTIAL PRESSURE TO AN ELECTRONIC SIGNAL, 10-50 MA.

PROCESS PRESSURE TRANSMITTER
CONVERTS PROCESS PRESSURE TO AN ELECTRONIC SIGNAL, 10-50 MA.

SINGLE UNIT POWER SUPPLY

ADJUSTABLE HIGH OR LOW ALARM UNIT

ELECTRO-PNEUMATIC CONVERTER

RACK-MOUNTED SET POINT
THIS IS A PRECISE SET POINT UNIT FOR RACK MOUNTING ONLY.

LARGE CASE ROUND CHART RECORDER
DIRECTLY OPERATED.

INDICATING CONTROLLING PYROMETER
MILLIVOLT OR 0-10 V DC INPUT, CURRENT OUTPUT, POSITION MODULATION OR TIME DURATION CONTROL MODELS.

ELECTRO-MECHANICAL CONTROLLER
CONTAINS 1 3-MODE CONTROLLER EITHER TIME, POSITION, OR CURRENT MODULATION. SET POINT COMES FROM A CONTROL SLIDE-WIRE MOUNTED IN A SERVO RECORDER.

RECORDER & CONTROLLER IN COMMON CASE
TWO OR THREE WIRE CONTROLLER, SINGLE-PEN RECORDER.

MINIATURE STRIP-CHART RECORDER
SINGLE-PEN POTENTIOMETRIC TYPE, 4" CHART, 1/2% ACCURACY.

MINIATURE STRIP-CHART RECORDER
TWO-PEN POTENTIOMETRIC TYPE, 4" CHART, 1/2% ACCURACY.

EDGEWISE INDICATORS, GANG MOUNTED

LARGE-CASE STRIP-CHART RECORDER
POTENTIOMETRIC, 12" CHART, 1/4% OF FULL SCALE ACCURACY

LARGE-CASE ROUND-CHART RECORDER
POTENTIOMETRIC, 12" CHART, 1/4% ACCURACY.

INDICATING GAGE, DIRECTLY OPERATED
PANEL MOUNTING

PNEUMATIC OPERATOR
WITH COVER AND CURRENT-TO-PNEUMATIC TRANSDUCER.

PNEUMATIC OPERATOR
WITHOUT COVER BUT WITH CURRENT-TO-PNEUMATIC TRANSDUCER.

HEAVY-DUTY PNEUMATIC OPERATOR

PNEUMATIC POSITIONER AND VALVE
PIPE MOUNTED.

PNEUMATICALLY OPERATED CONTROL VALVE
MAY OR MAY NOT HAVE INTEGRAL I/P TRANSDUCER-WITH ACTUATOR.

PNEUMATICALLY OPERATED CONTROL VALVE
MAY OR MAY NOT HAVE INTEGRAL I/P TRANSDUCER - WITHOUT ACTUATOR.

3-WAY SOLENOID-OPERATED VALVE

EDGEWISE INDICATOR

TEMPERATURE SENSOR
THERMOCOUPLE OR RESISTANCE TEMPERATURE DETECTOR

LIQUID-LEVEL TRANSMITTER
DIFFERENTIAL PRESSURE TYPE

2-2A42-04	1	0	/
CVI NO.	CVI SHT.	ABOVE	DWG. SHT.

DEVICE PLATE INSTALLATION
PLATE AND FLANGES

INDUSTRIAL MASS FLOWMETER
WITH SELF-CONTAINED INTEGRATOR, DIGITAL READOUT.

INDICATOR ELECTRICALLY OPERATED
250° SCALE, PANEL MOUNTING.

MANUALLY OPERATED ROTARY SWITCH
WITH PISTOL GRIP HANDLE.

P	-	PROPORTIONAL CONTROLLER
P + R	-	PROPORTIONAL PLUS RESET CONTROLLER
P + R + R	-	PROPORTIONAL PLUS RESET PLUS RATE CONTROLLER
M/A	-	MANUAL-AUTOMATIC SELECTION
S.P.	-	SET POINT

Columbia Generating Station Final Safety Analysis Report	General Electric Piping and Instrumentation Drawing Symbols		
	Draw. No. 02A42-04,1	Rev. 0	Figure 1.2-25

VALVES

- GATE (NORMALLY OPEN) (SEE NOTE 6)
- GATE (NORMALLY CLOSED) (SEE NOTE 6)
- GLOBE (NORMALLY OPEN)
- GLOBE (NORMALLY CLOSED)
- GLOBE, STOP CHECK
- CHECK
- EXCESS FLOW CHECK
- BLEEDER CHECK
- COMBINED BLEEDER CHECK AND STOP (ISOLATION CHECK)
- REVERSE CURRENT CHECK (SHOWN WITH PILOT LIGHTS)
- PLUG OR BALL (NORMALLY OPEN)
- PLUG OR BALL (NORMALLY CLOSED)
- NEEDLE (NORMALLY OPEN)
- NEEDLE (NORMALLY CLOSED)
- SQUIB ACTUATED SHEAR PLUG
- GLAND LEAK OFF
- GLAND SEAL WATER
- BUTTERFLY (POSITION SHOULD BE IDENTIFIED) — NC OR NO
- SAUNDER'S TYPE (WEIR) (NORMALLY OPEN)
- SAUNDER'S TYPE (WEIR) (NORMALLY CLOSED)
- ANGLE (NORMALLY OPEN)
- ANGLE (NORMALLY CLOSED)
- ANGLE STOP CHECK
- HOSE
- RELIEF OR SAFETY
- RELIEF WITH REMOTE ELECTRICAL SETTING
- SOLENOID VALVE WITH BUILT-IN FLOW CONTROL
- THREE WAY (FIG. A) (SEE NOTE 5) SHOWN TO INDICATE EITHER 1-PORT STATUS (OPEN OR CLOSED) NOT DETERMINED OR 2-MODULATING 3 WAY CONTROL VALVE
- THREE WAY (FIG. B) (SEE NOTE 5) — NEXT PORT OF CLOSURE NORMALLY CLOSED PORT NORMALLY OPEN PORT
- FOUR WAY
- FOUR WAY (PLUG)
- PRESSURE REGULATING
- AIR VENT
- MANUAL EMERGENCY PULL BOX
- FIRE HYDRANT (FIRE PROTECTION)
- ALARM (FIRE PROTECTION)
- DELUGE (FIRE PROTECTION)
- FLOODING (FIRE PROTECTION)
- DIAPHRAM OPERATED CONTROL OPENS ON AIR FAILURE
- DIAPHRAM OPERATED CONTROL CLOSES ON AIR FAILURE

  APPLIES TO ALL TYPES OF VALVES. USED TO DESIGNATE DIAPHRAM ACTION.
- SHUTTLE VALVE DOUBLE CHECK
- SPRING CHECK

OPERATORS

- AO — (LIMIT SWITCH AS REQ'D) — AIR OPERATOR (TYP FOR VALVE OR DAMPER)
- EHO — ELECTRO HYDRAULIC OPERATOR (TYP FOR VALVE OR DAMPER)
- HO — (LIMIT SWITCH AS REQ'D) — HYDRAULIC PISTON OPERATOR (TYP FOR VALVE OR DAMPER)
- MO — (LIMIT SWITCH) — MOTOR OPERATOR
- NE (SEE NOTE 1) — SOLENOID
- RM — MANUAL REMOTE
- DIAPHRAGM
- DIAPHRAGM WITH POSITIONER
- FLOAT
- MANUAL TRIP AND RESET
- WITH MANUAL OVERRIDE
- QUICK OPENING
- SELF ACTUATED PRESSURE CONTROL
- TCV — SELF ACTUATED TEMPERATURE CONTROL
- TH — THERMOSTATICALLY ACTUATED CONTROL

MISC. SYMBOLS

- DRIP PAN ELBOW
- PITOT TUBE (ANNUBAR) FLOW ELEMENT
- METERING ORIFICE PLATE FLOW ELEMENT
- PIPING SPOOL PIECE (SHOWN FOR FLOW TEST SECTION)
- FLOW NOZZLE
- FLOW CONTROLLER (FLOW REGULATOR)
- FLOW METER (POSITIVE DISPLACEMENT)
- IN LINE FLOW INDICATOR, ELEMENT, ETC. (SEE MEL COMPONENT LISTING)
- SIGHT FLOW GLASS
- SNUBBER
- INDICATION THAT ITEM IS FURNISHED WITH ASSOCIATED EQUIPMENT (UON)
- EJECTOR
- FLOW DIRECTION ARROW
- REDUCER (OR INCREASER)
- THREADED CAP (SEE NOTE 12)
- WELDED CAP
- THREADED PLUG (SEE NOTE 12)
- QUICK DISCONNECT (SEE NOTE 12)
- HOSE CONNECTION (SEE NOTE 12)
- FLEXIBLE CONNECTION
- FLANGE
- BLIND FLANGE
- SPECTACLE FLANGE
- INSULATING FLANGE
- THREADED COUPLING
- CLAMP COUPLING (VICTAULIC)
- RUPTURE DISC
- EXPANSION JOINT
- TRAP
- SEAL WATER TRAP
- "Y" TYPE STRAINER
- IN LINE CONICAL STRAINER
- BASKET STRAINER (SIMPLEX)
- BASKET STRAINER (DUPLEX)
- TEMPORARY STRAINER
- FILTER
- RESTRICTING ORIFICE
- VARIABLE RESTRICTING ORIFICE
- MULTIPLE ORIFICE

MISC. SYMBOLS

- INSTRUMENT AIR SUPPLY (70-100 PSIG)
- INSTRUMENT AIR SUPPLY (REDUCED)
- EQUIPMENT DRAIN FUNNEL
- FLOOR (AREA) DRAIN
- SAMPLE POINT (SAMPLE CONNECTION)
- BOLTED HOT-TAP TEE
- SPRAY HEADER OR RING
- MOISTURE SEPARATOR (IN LINE TYPE)
- PRIMARY CONTAINMENT PENETRATION
- SECONDARY CONTAINMENT PENETRATION
- MUFFLER (EXHAUST SILENCER)
- PUMP
- SET PRESSURE VERIFICATION DEVICE (SPVD)
- AUTOMATED TEST SYSTEM

LOGIC DIAGRAM SYMBOLS

REF M620-501-1

MISC. ABBREVIATIONS

A/S	AIR SUPPLY
E/S	ELECTRONIC POWER SUPPLY
FAI	FAIL AS IS
FC	FAIL CLOSED (CLOSES ON AIR OR ELECTRICAL FAILURE)
FO	FAIL OPEN (OPENS ON AIR OR ELECTRICAL FAILURE)
NC	NORMALLY CLOSED
ND	NORMALLY DE-ENERGIZED
NE	NORMALLY ENERGIZED
NO	NORMALLY OPEN
TH	THROTTLED

MISC. EQUIPMENT LEGEND

ACV	AIR CONTROL VALVE
GLA	GAS AND LIQUID ANALYZER
H/A	HAND/AUTO STATION
HS	HAND SWITCH
HSE	HOSE
LE	LABORATORY EQUIPMENT
MA	MANIFOLD
MS	MANUAL SWITCH
S/S	SELECTOR SWITCH
TFC	TANK FILL CONNECTION
VPI-LVDT	VALVE POSITION INDICATION-LINEAR VARIABLE DIFFERENTIAL TRANSFORMER
FX	FLOW TEST POINT (SEE NOTES 9 & 13)
PX	PRESSURE TEST POINT (SEE NOTES 9 & 13)
TX	TEMPERATURE TEST POINT (SEE NOTES 9 & 13)

HVAC EQUIPMENT LEGEND

ATD	AIR TURNING DEVICE
BD	BACKDRAFT DAMPER
BG	BOTTOM GRILLE (VERTICAL BELOW 6'-0")
BR	BOTTOM REGISTER (VERTICAL BELOW 6'-0")
CD	CEILING DIFFUSER (HORIZONTAL WITH OR WITHOUT CEILING)
CG	CEILING GRILLE (HORIZONTAL WITH OR WITHOUT CEILING)
CR	CEILING REGISTER (HORIZONTAL WITH OR WITHOUT CEILING)
DC	DUST COLLECTOR
FC	FAN COIL UNIT
FRP	FIBERGLASS REINFORCED POLYESTER DUCT
PF	PORTABLE FILTER
PRD	PRESSURE REDUCING DAMPER
RHC	REHEAT COIL
SD	SPLITTER DAMPER
TG	TOP GRILLE (VERTICAL ABOVE 6'-0")
TR	TOP REGISTER (VERTICAL ABOVE 6'-0")
VD	VOLUME DAMPER
WHA	WATER HAMMER ARRESTOR

ELECTRICAL SYMBOLS

- LOCAL
- REMOTE PANEL OR RACK MOUNTED
- MAIN CONTROL ROOM (PANEL OR RACK MOUNTED)
- TRANSMITTER (SHOWN AS LOCAL)
- COMPUTER INPUT
- TDAS INPUT (TRANSIENT DATA ACQUISITION SYSTEM)
- TEMPERATURE SCANNER INPUT
- ALARM ANNUNCIATOR ON LOCAL PANEL (AL, ALL, AH, AHH AND ALH USED WHEN SERVICE IS DEFINED)
- ALARM ANNUNCIATOR ON REMOTE PANEL (AL, ALL, AH, AHH AND ALH USED WHEN SERVICE IS DEFINED) — (ALARM LOW)
- ALARM ANNUNCIATOR SHOWING ALARM ON IMPROPER VALVE POSITION (ONE OR BOTH DESIGNATORS MAY BE USED) — (NOT FULLY OPEN) O, (NOT FULLY CLOSED) ■
- ALARM ANNUNCIATOR (USED WHEN SERVICE IS NOT DEFINED)
- O (OPEN) C (CLOSED) PILOT LIGHTS
- PROPELLER TYPE AGITATOR
- ELECTRIC WATER HEATER
- 2HP ELECTRIC MOTOR (SHOWN AS 2 HORSEPOWER)
- DEH — DIGITAL ELECTRO HYDRAULIC PROGRAMMABLE LOGIC CONTROLLER

HVAC SYMBOLS

- OUTSIDE AIR INTAKE LOUVER
- PARALLEL DAMPER
- OPPOSED BLADE DAMPER
- BACKDRAFT DAMPER
- FIRE DAMPER
- MANUALLY OPERATED DAMPER (PARALLEL)
- AUTO. DIAPHRAM OPERATED DAMPER (PARALLEL)
- AUTO. DIAPHRAM OPERATED DAMPER WITH POSITIONER (PARALLEL)
- MOTOR OPERATED DAMPER (PARALLEL)
- ROUGHING FILTER OR PREFILTER
- HIGH EFFICIENCY FILTER
- CHARCOAL FILTER
- UNIT HEATER (ELECTRIC STEAM OR HOT WATER)
- HUMIDIFIER
- FAN (SHOWN WITH INLET VANE CONTROL DAMPER)
- PROPELLOR TYPE FAN
- VANEAXIAL OR TUBEAXIAL FAN (NOT USED ON FLOW DIAGRAMS)
- AO — VANEAXIAL FAN WITH AUTOMATIC VARIABLE PITCH BLADES OR INLET VANES (NOT USED ON FLOW DIAGRAMS)
- D — INCLINED DROP IN RESPECT TO AIR FLOW (NOT USED ON FLOW DIAGRAMS)
- R — INCLINED RISE IN RESPECT TO AIR FLOW (NOT USED ON FLOW DIAGRAMS)
- 12 X 20 — DUCT SIZE (FIRST NO. IS SIDE SHOWN) (NOT USED ON FLOW DIAGRAMS)
- SQUARE ELBOW WITH TURNING VANE (NOT USED ON FLOW DIAGRAMS)
- SUPPLY DUCT (NOT USED ON FLOW DIAGRAMS)
- EXHAUST OR RETURN DUCT (NOT USED ON FLOW DIAGRAMS)

NOTES

1. ALL SOLENOID VALVES SHOWN IN DE-ENERGIZED POSITION. "NE" DENOTES SOLENOID NORMALLY ENERGIZED DURING PLANT OPERATION, "ND" DENOTES NORMALLY DE-ENERGIZED.
2. TYPICAL INSTRUMENT DESIGNATION (EPN): INSTRUMENT (SEE NOTE 9) — INSTRUMENT NUMBER — SYSTEM (SEE NOTE 9) — PS 18A RRC (EPN = RRC-PS-18A)
3. TYPICAL EQUIPMENT DESIGNATION (EPN): SYSTEM (SEE NOTE 9) — EQUIPMENT (SEE NOTE 9) — EQUIPMENT NUMBER (SDA-HV-1)
4. TYPICAL PIPING DESIGNATION: A" MS(1)-1-4 — PIPE SIZE — SYSTEM AND (SUBSYSTEM) (SEE NOTE 9) — UNIQUE LINE NUMBER IDENTIFIER (AS REQ'D) FOR ASME SECTION III LINES (SEE NOTE 10) — SERVICE RATING: 1 = 150# CLASS, 2 = 300# CLASS, 3 = 600# CLASS, 4 = 900# CLASS, 5 = 1500# CLASS, 6 = 2500# CLASS
5. WHERE THREE WAY VALVE OPERATIONS ARE NOT FINAL, "FIG. A" IS USED (SEE VALVE SYMBOLS). WHERE VALVE OPERATION IS FINAL, "FIG. B" IS USED.
6. "NORMALLY OPEN" SYMBOL (UNSHADED) AND "NORMALLY CLOSED" SYMBOL (SHADED) VALVE POSITIONS OR ORIENTATIONS ARE DRAWN TO DEPICT THE SYSTEMS IN NORMAL POWER OPERATION OF THE PLANT, WITH STANDBY, SUPPORTING, OR EMERGENCY SYSTEMS SHOWN IN STANDBY CONDITION. TO DETERMINE ACTUAL VALVE POSITIONS THE USER MUST CONSULT THE SYSTEM OPERATION PROCEDURES AND THE OPERATIONS CREW.
7. FOR OPERATING CONDITIONS, DESIGN CONDITIONS AND COMPLETE PIPING DESIGNATION SEE THE WNP-2 SPECIFICATION TABLES 1 & 2; SECTION 15B.1 FOR B31.1 PIPING; SECTION 1 FOR ASME SECTION III PIPING AND SECTION 2 FOR ASME SECTION III TUBING.
8. CODE GROUP DESIGNATION APPLIES ONLY THROUGH PRIMARY ROOT VALVES UNLESS SPECIFICALLY NOTED OTHERWISE. M619 DRAWING SERIES GIVES CODE GROUP FOR INSTRUMENTATION.
9. SYSTEM AND COMPONENT ABBREVIATIONS CAN BE FOUND IN THE MASTER EQUIPMENT LIST (MEL) OR IN SECTION 1.2 OF THE FSAR.
10. THE SUBSYSTEM (NOTE 4) DESIGNATES A PROCESS FUNCTION.
11. FOR "ISOLATION SIGNAL CODES" FOR PRIMARY CONTAINMENT ISOLATION VALVES SEE FSAR TABLE 6.2-16.
12. WHERE A THREADED CAP IS USED, QUICK DISCONNECT STYLE FITTINGS (CAMLOCK, CHICAGO QUICK DISCONNECT, ETC) MAY BE USED ON A ONE FOR ONE BASIS.
13. TEST POINTS SHOWN ON ALL FLOW DIAGRAMS DO NOT EXIST IN THE MASTER EQUIPMENT LIST (MEL). THESE ARE LOCAL TEST POINTS ONLY.
14. SEE PPM 1.3.29 AND/OR PPM 15.1.18 FOR THE VALVE LOCKED POSITION.

PIPING AND SYSTEM CODE GROUPS

CODE GROUP	APPLICABLE CODE
A	ASME BOILER AND PRESSURE VESSEL CODE SECTION III CLASS 1.
B	ASME BOILER AND PRESSURE VESSEL CODE SECTION III CLASS 2.
C	ASME BOILER AND PRESSURE VESSEL CODE SECTION III CLASS 3.
D	ANSI B31.1 CODE FOR PRESSURE PIPING.
E	NSSS ENGINEERED INSTRUMENTS.

QUALITY ASSURANCE CLASSES

REQUIREMENTS FOR QUALITY ASSURANCE CLASSES ARE SPECIFIED IN THE WNP-2 SPECIFICATIONS.

SEISMIC REQUIRMENTS

REQUIREMENTS FOR SEISMIC CLASSES ARE SPECIFIED IN THE WNP-2 SPECIFICATIONS.

BUILDING LOCATION LEGEND

A	AUXILIARY BUILDINGS
C	PART OF OR WITHIN PRIMARY CONTAINMENT
D	DIESEL GENERATOR BUILDING
L	OFFSITE LOCALE
M	MAKEUP WATER PUMP HOUSE
O	OUTDOORS ON SITE
P	PUMP HOUSE
R	REACTOR BUILDING
S	SERVICE BUILDING
T	TURBINE GENERATOR BUILDING
W	RADWASTE/CONTROL BUILDING

LINES

- MAIN PROCESS LINE
- AUXILIARY PROCESS OR INSTRUMENT LINE
- INSTRUMENT OR SERVICE AIR
- INSTRUMENT CAPILLARY TUBING
- INSTRUMENT AND CONTROL ELECTRICAL LEADS
- HEAT TRACED LINE
- LINES DESIGNATED ON OTHER FLOW DIAGRAMS

LINES (HVAC)

- SUPPLY OR RETURN AIR
- EXHAUST AIR
- LEAKAGE AIR
- U — UNDERCUT DOOR
- L — LOUVERED DOOR
- R — REFRIGERANT LINE

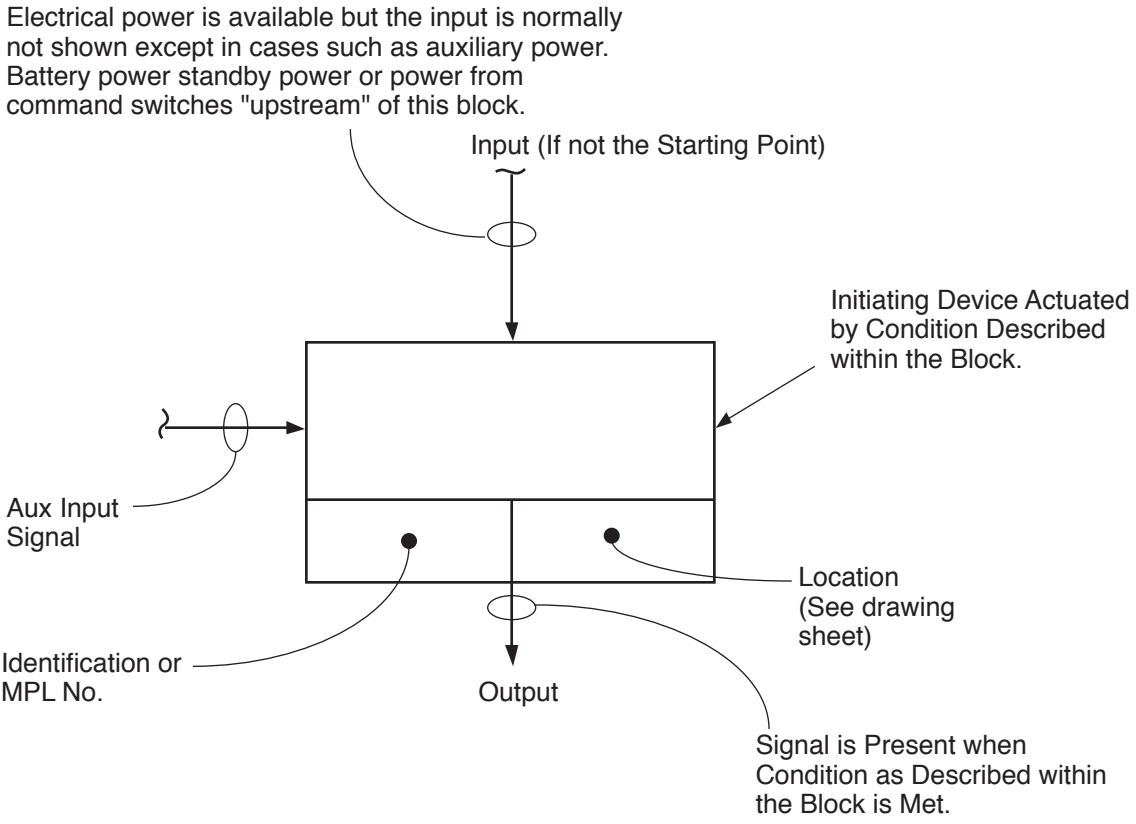
Flow Diagram Legend, Symbols and Abbreviations

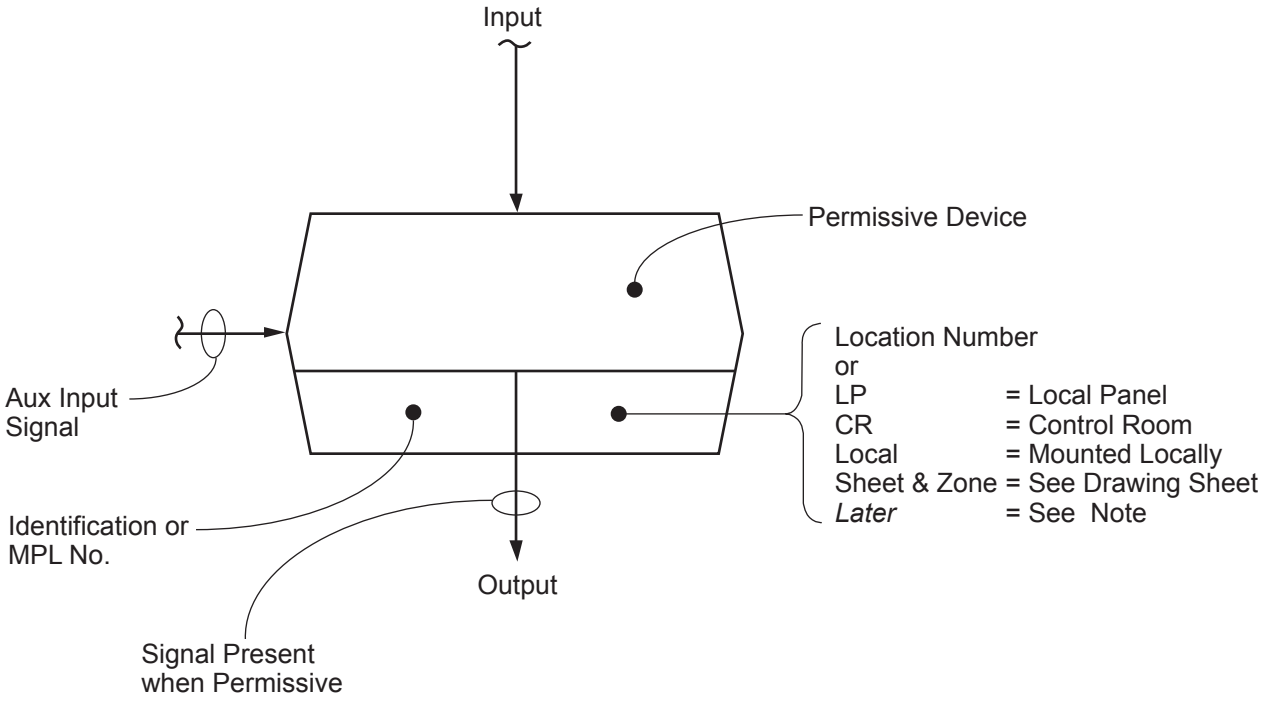
Draw. No. M501	Rev. 59	Figure 1.2–26

System Acronyms

AAP	Alternate Access Point Bldg. and Appurtenances
AEA	Tech. Support Cntr. Exhaust Air
AMA	Tech. Support Cntr. Mixed Air
ANN	Annunciators
AOA	Tech. Support Cntr. Outside Air
APRM	Average Power Range Monitors
APWH	Tech. Support Cntr. Potable Hot Water
AR	Air Removal
ARA	Tech. Support Cntr. Return Air
ARE	Tech. Support Cntr. Refrig. Equipment
ARI	Alternate Rod Insertion
ARM	Area Radiation Monitoring
AS	Auxiliary Steam
BA	Backwash Air
BAS	Breathing Air Supply
BCF	Boiler Chemical Feed
BD	Cond. Blowdown or Rad. Boards
BS	Bleed (Extraction) Steam
CAC	Containment Atmosphere Control (Deactivated)
CAS	Control Air System
CBD	Circ. Water Blowdown
CCH	Control Room Chilled Water
CEP	Containment Exhaust Purge
CF	Chemical Feed
CHEM	Chemistry Equipment
CIA	Containment Instrument Air
CJW	Cooling Jacket Water
CL	Chlorine
CMS	Containment Monitoring System
CN	Containment Nitrogen
CND	Condenser Drains & Vents
CO	Condensate (Auxiliary)
CO_2	Carbon Dioxide
COMM	Communications
COND	Condensate (Nuclear)
CP	Cathodic Protection
CPR	Condensate Demineralizer
CRA	Containment Recirculating Air
CRD	Control Rod Drive
CSP	Containment Supply Purge
CTMA	Cooling Tower Electrical Bldg. Mixed Air
CVB	Containment Vacuum Breakers
CW	Circulating Water
DCN	CRD Decontamination
DCW	Diesel Cooling Water
DE	Diesel Exhaust (Engine)
DEA	Diesel Building Exhaust Air
DEH	Digital Electro-hydraulic Control
DG	Diesel Generator
DLO	Diesel Lube Oil
DMA	Diesel Building Mixed Air
DO	Diesel Oil
DOA	Diesel Building Outside Air
DRA	Diesel Building Return Air
DSA	Diesel (Engine) Starting Air
DW	Demineralized Water
EDR	Equipment Drains Radioactive
ELEC	Electrical Maintenance Equipment
EOF	Emergency Offsite Facility
ERM	Environmental Rad. Monitoring
ES	Exhaust Steam (Turbine)
FAC	Facilities Generic Equipment
FD	Floor Drain
FDR	Floor Drain Radioactive
FO	Fuel Oil
FP	Fire Protection
FPC	Fuel Pool Cooling
FW	Filtered Water
GEA	Guard House Exhaust Air
GFP	Guard House Fire Protection
GH	Main Guard House
GMA	Guard House Mixed Air
GOA	Guard House Outside Air
GPWH	Guard House Water Hot Potable
GRA	Guard House Return Air
GY	Glycol
H_2	Hydrogen (Turbine Generator)
HCO	Heating Steam Condensate
HD	Heater Drain
HHW	Heating Hot Water
HP	Health Physics
HPCS	High Pressure Core Spray
HS	Heating Steam
HSSF	Hydrogen Storage and Supply Facility
HSV	Heating Steam Vent
HT	Heat Tracing
HV	Heater Vent
HWC	Hydrogen Water Chemistry
HY	RRC Hydraulic Control
IBD	ISO Phase Bus Duct Cooling
IR	Instrument Rack
IRM	Intermediate Range Monitor
IRON	Chemical Feed
LD	Leak Detection
LE	Laboratory Equipment (Permanent Plant)
LF	Laundry Facility
LPCS	Low Pressure Core Spray
LPDS	Loose Parts Detection System
LPRM	Local Power Range Monitor
MD	Miscellaneous Drain
MECH	Mechanical Maintenance Equipment
MEL	Master Equipment List
MET	Meteorological
MLF	Mobile Laundry Facility
MS	Main Steam (Nuclear)
MSH	Machine Shop Equipment
MSLC	Main Steam Leakage Control (Deactivated)
MT	Material Transport
MW	Miscellaneous Waste
MWR	Miscellaneous Waste Radioactive
NSSE	Nuclear System Servicing Equipment
NSSS	Nuclear Steam Supply System
OFEA	Offsite Facility Exhaust Air
OFMA	Offsite Facility Mixed Air
OFOA	Offsite Facility Outside Air
OFRA	Offsite Facility Recirculation Air
OG	Off Gas
OL	Obstruction Lighting
PDIS	Plant Data Information System
PEA	Pumphouse Exhaust Air
PI	Process Instrumentation
PL	Plant Equipment
PMA	Pumphouse Mixed Air
POA	Pumphouse Outside Air
PPC	Plant Process Computer
PRA	Pumphouse Return Air
PRM	Process Radiation Monitoring
PS	Process Sampling
PSD	Plant Sanitary Drain
PSR	Process Sampling Radioactive
PVMS	Plant Vibration Monitoring System
PVR	Process Vents Radioactive
PWC	Potable Cold Water
PWH	Potable Hot Water
PWR	Process Waste Radioactive
RBM	Rod Block Monitor
RCC	Reactor Closed Cooling Water
RCIC	Reactor Core Isolation Cooling
RD	Roof Drain
REA	Reactor Building Exhaust Air
RFT	Reactor Feedwater Turbine
RFW	Reactor Feedwater
RHR	Residual Heat Removal
ROA	Reactor Building Outside Air
RPIS	Rod Position Indicator System
RPS	Reactor Protection System
RPWH	Reactor Building Potable Hot Water
RRA	Reactor Building Return Air
RRC	Reactor Recirculation
RSE	Reactor Service Equipment
RWCU	Reactor Water Cleanup
RWM	Rod Worth Minimizer
S	Sampling
SA	Service Air
SAT	Sulfuric Acid Treatment
SCH	Service Building Chilled Water
SCI	Supervisory Control
SCW	Stator Cooling Water
SEA	Service Building Exhaust Air
SEC	Plant Security
SEIS	Seismic Monitoring System
SFS	Spent Fuel Storage
SGT	Standby Gas Treatment
SHCO	Service Building Heating Condensate
SHHW	Service Building Heating Hot Water
SLC	Standby Liquid Control
SM	Salinity Monitoring
SMA	Service Building Mixed Air
SO	Seal Oil
SPTM	Suppression Pool Temp Monitoring
SPWH	Service Building Potable Hot Water
SRA	Service Building Return Air
SRM	Source Range Monitoring
SS	Sealing Steam
SW	Standby Service Water
SWA	Solid Waste
SWCF	Service Water Chemical Feed
TDAS	Transient Data Acquisition System
TEA	Turbine Building Exhaust Air
TG	Turbine Generator
TIP	Traversing Incore Probe
TMU	Tower Makeup Water
TO	Turbine (Lube) Oil
TOA	Turbine Building Outside Air
TPWH	Turbine Bldg. Potable Hot Water
TRA	Turbine Building Return Air
TSC	Technical Support Center
TSW	Plant Service Water
VES	Vessel (Sect. 8, Non Power Block)
VRMA	Variable Speed Drive Bldg. Mixed Air
WCH	Radwaste Building Chilled Water
WEA	Radwaste Building Exhaust Air
WHCO	Radwaste Heating Condensate
WMA	Radwaste Building Mixed Air
WNP2	Washington Nuclear Plant 2 (Columbia Generating Station)
WOA	Radwaste Building Outside Air
WPWH	Radwaste Bldg. Potable Hot Water
WRA	Radwaste Building Return Air
WRE	Radwaste Building Refrigeration
WRM	Wide Range Monitoring
ZINC	Chemical Feed System



Equipment Acronyms

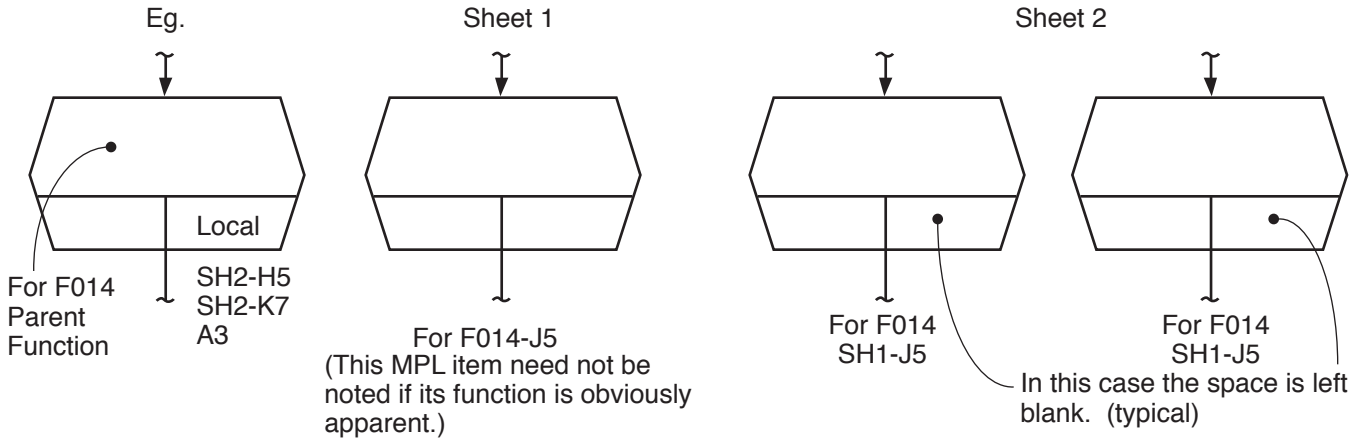


AA	Audio Alarm
AC	Air Conditioning Unit
ACC	Accumulator
ACM	Acoustic Monitor/Sensor
AD	Air Damper
AH	Air Handling Unit
AI	Air Indicator
ALM	Alarm Annunciator-Do Not Use
ALT	Alternating Relay
AM	Ammeter
AMP	Amplifier
ANN	Annunciator
AO	Air Operator
AR	Air Receiver
AR/FR	Analyzer and Flow Recorder
ASM	Assembly
ASW	Air Switch (4-way Valve)
AT	Air Transmitter
ATD	Amp Transducer
ATS	Automatic Transfer Switch
AUD	Audio Monitor
AUX	Auxiliary Unit
AV	Air Valve
AW	Air Washer
AY	Analyzer
B0	24 Volt Battery
B1	125 Volt Battery
B2	250 Volt Battery
B3	12 Volt Battery
B4	48 Volt Battery
BDET	Badge (Keycard) Detector
BELL	Bell (Fire Protection)
BFI	Blown Fuse Indicator
BL	Baler
BLDG	Bldg (For PSD System Only)
BLR	Boiler
BT	Bolted Tee (For SA System)
BU	Emerg Lighting Battery Unit
BUOY	Buoy
C	Compressor
C0	24 Volt Battery Charger
C1	125 Volt Battery Charger
C2	250 Volt Battery Charger
C3	12 Volt Battery Charger
CAB	Cabinet
CAP	Capacitor
CB	Circuit Breaker
CC	Cooling Coil
CCTV	Closed Circuit Television
CCU	Central Control Unit
CE	Conductivity Element
CERA	Cond Element Retractor Assembly
CF	Charcoal Filter
CFG	Centrifuge
CH	Channel
CHL	Chlorinators
CHM	Chamber
CHR	Chiller
CHS	Chassis
CI	Conductivity Indicator
CIC	Conductivity Ind Controller
CIS	Conductivity Ind Switch
CIT	Conductivity Ind Transmitter
CITS	Conductivity Ind Transmitter Switch
CJW	Cooling Jacket Water
CM	Communications Monitor
CNTR	Contractor
COE	Corrosivity Element
COIC	Corrosivity Indic Cont
COMP	Computer
CONN	Connector
COR	Corrosivity Recorder
COS	Carbon Monoxide Sensor
COT	Corrosivity Transmitter
CP	Control Panel
CPL	Data Coupler
CPTR	Compactor
CPU	Central Processing Unit
CR	Conductivity Recorder; Control Room Chiller
CRA	Crane
CRB	Control Rod Blade
CRM	Control Module
CRS	Conductivity Recorder Switch
CRT	Terminal Display Screen
CS	Conductivity Switch
CSK	Shield Transfer Cask
CT	Current Transformer/Cooling Tower
CU	Condensing Unit
D	Damper (Backdraft Or Motor)
DC	Decoder
DCM	Dry Cleaning Machine
DCN	CRD Decontamination System
DDR	Disk Drive Recorder
DE	Density Element
DET	Detector
DFS	Differential Flow Switch
DG	Digital Display Generator
DH	Drywell Head
DIF	Diffuser
DIO	Diode, Control Rectifier
DISC	Disconnect Switch
DLR	Differential Level Recorder
DLS	Differential Level Switch
DLT	Differential Level Transmitter
DM	Demineralizer
DMM	Display Memory Module
DMS	Demister
DMTR	Demand Meter
DOE	Dissolved Oxygen Element
DOIT	Dissolved Oxygen Indic Trans
DOOR	Door
DOR	Dissolved Oxygen Recorder
DP	Distribution Panel
DPC	Diff Press Controller
DPE	Drip Pan Elbow
DPI	Diff Press Ind
DPIC	Diff Press Ind Controller
DPIR	Diff Press Ind Recorder
DPIS	Diff Press Ind Switch
DPIT	Diff Press Ind Transmitter
DPR	Diff Press Recorder
DPS	Diff Press Switch
DPT	Diff Press Transmitter
DR	Demand Recorder
DRVE	Drive Mechanism For CRD
DS	Density Switch
DT	Dens Trans Or Drive Turbine
DTIS	Diff Temp Indicating Switch
DTRS	Diff Temp Recording Switch
DTS	Diff Temp Switch
DTT	Diff Temp Transmitter
DU	Deaerator
DV	Deluge Valve
DVSP	Dump Valve Solenoid Pilot
DVSPV	Dump Valve Solenoid Pilot Valve
DWS	Demineralized Water Shower
DY	Dryer
E/I	Volt To Current Converter
E/P	Electro Pneumatic Converter
E/S	Electronic Power Supply
EAMP	Preamplifier
EC	Electronic Controller
ECG	Electrochemical Generator
ED	Eductor
EF	Electronic Filter
EFC	Excess Flow Check Valve
EHC	Electric Heating Coil
EHO	Electrohydraulic Operator
EI	Power Supply Monitor
EIS	Power Supply Monitor Switch
EJ	Expansion Joint
EJC	Ejector
ELEV	Elevator
ELP	Emergency Lighting Panel
EMSQ	Mean Square Voltage Device
ENG	Engine
EPA	Electrical Protection Assem
EPP	Emergency Power Panel
EQ	Speciality Equip and Tools
ERB	Emerg Rmt Ballast (Lighting)
ES	Exhaust Silencer
ESH	Electric Strip Heater
EUH	Electric Unit Heater
EV	Evaporator
EX	Exhauster
EXC	Exciter
F	Filter
F/U	Flow Unit
FA	Flame Arrestor
FC	Flow Controller
FCN	Fuel Oil Tk Fill Connector
FCV	Flow Control Valve
FD	Fire Damper
FDg	Freon Degreaser
FE	Flow Element
FG	Flow Glass
FGEN	Function Generator
FH	Fume Hood
FHB	Fuel Handling Box
FI	Flow Indicator
FIC	Flow Indicating Controller
FICS	Flow Indicating Controller Switch
FIS	Flow Indicating Switch
FIT	Flow Indicating Transmitter
FL	Filter
FLP	Fillport Assem
FLT	Filter
FLX	Flexible Connection
FN	Fan
FO	Freon Actuated Operator
FP	Filter Polisher
FQ	Flow Integrator
FQI	Flow Integrating Indicator
FQS	Flow Integrating Switch
FR	Flow Recorder
FR/DL	Flow and Diff. Level Recorder
FRC	Flow Recording Controller
FRDLR	Flow and Diff Level Recorder
FRS	Flow Recording Switch
FS	Flow Switch
FSPV	Flow Solenoid Pilot Valve
FT	Flow Transmitter
FTD	Frequency Transducer
FU	Filter Unit
FUSE	Fuse
FX	Flow Test Connection
FY	Flow Sig. Cond.
GATE	Gate
GCAL	AGS Calibrator
GEN	Generator
GOV	Governor
GVT	Gravity Ventilator
H	Heater
H_2E	Hydrogen Element
H_2I	Hydrogen Indicator
H_2IS	H_2 Indicating Switch/Monitor
H_2IT	Hydrogen Ind Transmitter
H_2R	Hydrogen Recorder
H_2T	Hydrogen Transmitter
HAS	High Amplitude Selector
HC	Heating Coil
HCU	Hydraulic Control Unit
HF	HEPA Filter
HM	Hour Meter
HMI	Human Machine Interface
HO	Hydraulic Operator
HOI	Hoist
HP	Valve Act. Hyd. Power Unit
HPU	Hydraulic Power Unit
HR	Hydrogen Recombiner
HS	Hose Station
HSS	High Selector Switch
HT	Hydrant
HTC	Heat Trace Cable
HTP	Heat Trace Panel
HU	Humidifier
HUM	Humidifier (Obsolete. Use HU)
HV	Heating and Ventilation Unit
HVRB	High Voltage Rubber Blanket
HX	Heat Exchanger
HZM	Hertz Meter
I/P	Current Pneumatic Converter
ID	Ionization Detector
IL	Indicating Light
IMD	Inductive Motor Drive
IN	Inverter
IND	Inductor
INDX	Indexer
IOS	Current Operated Switch
IR	Instrument Rack
IS	Intake Silencer
ISOL	Isolator, Isolation Device
ITD	Current Transducer
IX	Ion Exchanger
JB	Junction Box
JP	Jet Pump
KBD	Computer Keyboard (Security)
L	Lubricator
LA	Lightning Arrestor
LAG	Dynamic Compensator
LAS	Low Amplitude Selector
LC	Level Controller
LCRM	Log Count Rate Meter
LCV	Level Control Valve
LE	Level Element
LF	Lighting Fixture
LG	Level Glass
LI	Level Indicator
LIC	Level Indicating Controller
LIS	Level Indicating Switch
LITS	Level Indic Trans Switch
LMS	Limit Switch
LMTR	V/I Signal Limiter
LNR	Linear Reactor
LOC	Lube Oil Conditioner
LP	Lighting Panel
LPW	24 Volt Lambda Power Supply
LR	Level Recorder
LR/PR	Level/Pressure Recorder
LRS	Level Recording Switch
LS	Level Switch
LSC	Lightning Strike Counter
LSPV	Sol. Pilot Valve TMU-level
LSS	Low Selector Switch
LT	Level Transmitter
LTD	Level Transmitter Detector
LVDT	Linear Var. Dif. Transformer
LVS	Low Volume Selector
LWS	Low Differential Pressure
M	Motor
M/A	Manual/Auto Station
MA	Manifold
MACH	Machine
MBS	Maint. Bypass Switchgear
MC	Moisture Controller
MDET	Metal Detector
MDS	Manual Discharge Station
MDU	Motion Detection Unit
ME	Moisture Element
MG	Motor-Generator Set
MHDD	Moving Head Disc Drive
MI	Moisture Indicator
MIC	Moisture Indicating Controller
MIS	Moisture Indicating Switch
MM	Motor Module (TIP System)
MO	Motor Operator
MODEM	Modem
MON	Monitor
MPDS	Microprocessor Data System
MPS	Manual Pull Station
MR	Moisture Recorder
MS	Moisture Separator
MT	Mositure Transmitter
MTA	Dew Point Transmitter Amplif
MTS	Manual Transfer Switch
MUX	Multiplexer
MV	Manifold Valve
MV/I	M/Volt To Current Converter
MW	Microwave Receiver
MX	Mixer

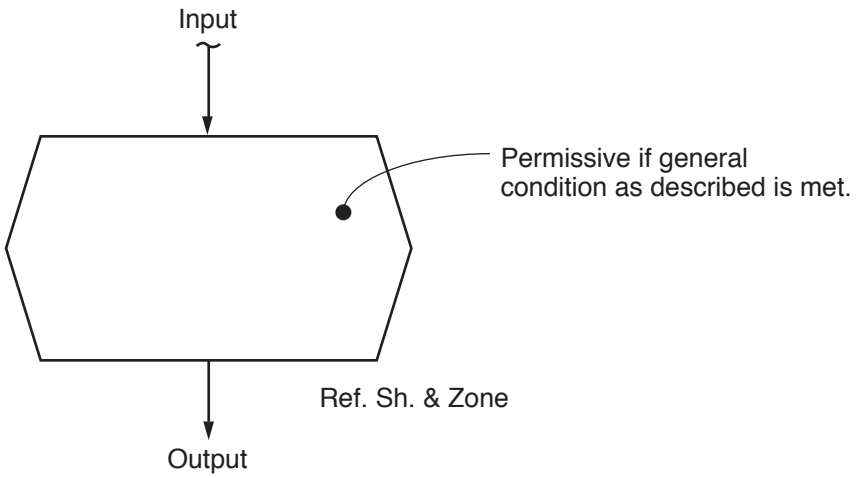
Equipment Acronyms (con't)

MZ	Multizone Air Conditioner
NR	Neutral Grounding Resistor
O/M	Input/Out Module
O_2/H_2	Oxygen /Hydrogen$_2$
O_2E	Oxygen Element$_2$
O_2H_2R	Oxygen/Hydrogen Recorder$_2$
O_2I	Oxygen Indicator$_2$
O_2R	Oxygen Recorder$_2$
OS	Oil Separator
OSC	Oscillograph
OZG	Ozone Generator
P	Pump
P/B	Push Button
P/E	Pneumatic/Electric Converter
P/I	Pressure/Current Converter
P/P	Pressure Inverter
PA	Pre-Amps
PBU	Seismic Playback Unit
PC	Pressure Controller
PCV	Pressure Control Valve
PDM	Power Distribution Module
PDP	Power Distribution Panel
PE	Pressure Element
PH	Ph Ind Transmitter Recorder
PHB	Pneumatic Hydraulic Booster
PHC	Ph Controller
PHE	Ph Element
PHEC	Photoelectric Controller
PHED	Photoelectric Detector
PHIC	Ph Indicating Controller
PHIT	Ph Indicating Transmitter
PHITS	Ph Indicating Transmitter Switch
PHR	Ph Recorder
PHT	Ph Transmitter
PI	Pressure Indicator
PIC	Press Indicating Controller
PICS	Press Indicating Controller and Switch
PIS	Pressure Indicating Switch
PL	Programmable Logic Card
PLC	Programmable Logic Controller
PNL	Panel
POC	Disc Position Signal Conv
POE	Position Indication Element
POI	Position Indicator
POIC	Position Indicating Controller
POS	Position Switch
POT	Position Transmitter
POTR	Potentiometer "CL.1E Only"
POV	Pilot Operated Pop Off Valve
PP	Power Panel
PR	Pressure Recorder
PRN	Line Printer
PROG	Programmer
PRTM	Programmable Timer
PRV	Pressure Reg. Valve
PS	Pressure Switch
PT	Poten. Xmfer Or Press. Transm.
PTA	Barometric Pressure Amplifier
PTD	Pressure Transducer
PTZM	Pan Tilt Zoom Monitor
PUI	Purity Indicator
PUIT	Purity Indicator Transmitter
PUS	Purity Switch
QCC	Quick Couple Connection
QDC	Quick Disconnect
QHM	Run Time Meter
QSV	Quick Acting Solenoid Valve
R	Reservoir
R/I	Resistance/Current Converter
RA	Radiation Amplifier
RAD	Radiation Mon. Control Board
RC	Radiation Controller
RCM	Respirator Cleaning Module
RD	Rupture Disc
RDCC	Rod Drive Control Cabinet
RDD	Rod Detector Display
RE	Radiation Element
RECT	Rectifier
REL	Relay
RES	Resistor
RF	Refrigeration Machine(OG)
RFM	Radio Frequency Monitor
RG	Regulator
RI	Radiation Indicator
RIS	Radiation Indicating Switch
RLY	Relay
RM	Radiation Monitor
RMC	Remote Manual Controller
RMS	Remote Manual Switch
RO	Restricting Orifice
ROD	Control Rod
RPIS	Rod Position and Info Sys.
RPV	Reactor Pressure Vessel
RR	Radiation Recorder
RRM	Refrigerant Recovery Machine
RSA	Response Spectrum Annunciator
RSCC	Rod Sequence and Control Cab
RSDP	Rod Sequence Display Panel
RSM	Radiation Sampler
RSMD	Rod Select Module
RSR	Response Spectrum Recorder
RSRT	RSR Transducer for RSA
RST	Resin Trap
RT	Radiation Transmitter
RTM	Run Time Meter
RV	Relief Valve
RVT	Roof Ventilator
S	Electronic Trip Unit
SC	Speed or Seismic Controller
SCAN	Scanner
SCL	Scaler
SCR	Screen
SE	Speed Element
SEW	Safety Eye Wash/Shower
SF	Spectacle Flange
SH	6.9 Kv Switch Gear
SHRED	Shredder
SI	Speed Indicator
SIOA	Silicon and Oxygen Analyzer
SL	480 Volt Switch Gear
SM	4.16 Kv Switch Gear
SMA	Smoke Alarm, Surface Mt. Acceler.
SMD	Smoke Detector
SNB	Snubber
SOL	Solenoid (Mech. Linkage)
SP	Sample Probe
SPC	Spacer
SPS	Speed Switch (Temp. Entry)
SPV	Solenoid Pilot Valve
SPVD	Set Press Verification Device
SQRT	Square Root Extractor
SR	Sample Rack
SRU	Signal Resistor Unit
SS	Speed or Seismic Switch
SSW	Step Switch
ST	Strainer
SUH	Steam Unit Heater
SUM	Summer
SUMP	Sump
SV	Solenoid Valve
SYNC	Synchroscope Meter
T	Trap
T/SS	Temp Selector Switch
TA	Trip Auxiliary Unit
TAPE	Magnetic Tape Unit
TAS	Tamper Alarm Switch
TB	Terminal Box
TBE	Turbidity Element
TBIT	Turbidity Indicating Trans
TBR	Turbidity Recorder
TBS	Turbidity Switch
TBT	Turbidity Transmitter
TC	Temperature Controller
TCV	Temperature Control Valve
TD	Time Delay
TDS	Time Delay Relays
TE	Temperature Element
TE/ME	Temperature/Moisture Element
TEST	Test (MEL Diagnostics)
THD	Thermal Detector
TI	Temperature Indicator
TIC	Temperature Indicating Controller
TIS	Temperature Indicating Switch
TJR	Temperature Scanning Recorder
TK	Tank
TM	Timer
TN	Turn Style
TNG	Turning Gear
TPA	Triaxial Peak Accelerograph
TPSA	Testable Pipe Spool Assembly
TQ	Time Totalizer
TQR	Torque Recorder
TQS	Torque Switch
TQT	Torque Transmitter
TR	Temp./ Triax. Record./Transform.
TRB	Terminal Block
TRC	Temperature Recorder Controller
TRL	Translator
TRS	Temperature Recording Switch
TS	Temperature Switch
TSC	Temperature Scanner
TT	Temperature Transmitter
TT/MT	Temperature/Moisture Transmitter
TUBE	LPRM Guide Tube Assembly
TV	Test Valve
TW	Thermal Well
TY	SMA HVAC, Special Func. Relay
UFM	Uniplex Field Module
USG	Ultra-Sonic Generator
UTD	Ultra-Sonic Transducer
UV/OR	UV Oxidation Reactor
UVD	Ultra-Violet Detector
V	Valve
V/F	Voltage/Freq. Converter
VARM	Var. Meter
VATD	Var. Transducer
VBAM	Vibration Differential Amp
VBE	Vibration Element
VBEC	Vibration/Eccentricity Indicator
VBI	Vibration Indicator
VBIS	Vibration Indicating Switch
VBR	Vibration Recorder
VBS	Vibration Switch
VCR	Video Cassette Recorder
VD	Viewing Device
VE	Vibration Element
VIR	Vibration Instrument Rack
VM	Voltmeter
VMP	Vibration Monitoring Panel
VPI	Valve Pos. Indication System
VSC	Variable Speed Controller
VT	Velocity Transmitter
VTD	Voltage Transducer
VX	Process Instrument Valve
VZ	Vaporizer
W	Watt
WDA	Wind Direction Amplifier
WDR	Wind Direction Recorder
WDT	Wind Direction Transmitter
WELL	Well (For PSD System Only)
WHM	Watt Hour Meter
WM	Watt Meter
WR	Water Reprocessing Unit
WSA	Wind Speed Amplifier
WSR	Wind Speed Recorder
WST	Wind Speed Transmitter
WTD	Watt Transducer
WUH	Water Unit Heater
X	Primary Containment Penetration
XAR	Resid. Chlorine Analyzer Recorder
XAY	Analyzer, Special Types
XD	Explosives Detector
XE	Element, Special Types
XI	Indicator, Special Types
XR	Recorder, Special Types
XS	Sensor, Special Types
XT	Transmitter, Special Types
ZONE	Fire Protection Zone Desig.
ZS	Tamper Switch

This block is the command switching or primary actuating function. This block can represent a switch, valve probe timer, or trip circuit. This block is normally the starting point of a functional sequence with an output only, but can have input and aux. input depending on the type of device. The same device may have a number of outputs, but each functional sequence initiated shall be shown by an individual block showing the same identification number and cross-reference. (See drawing sheet.)



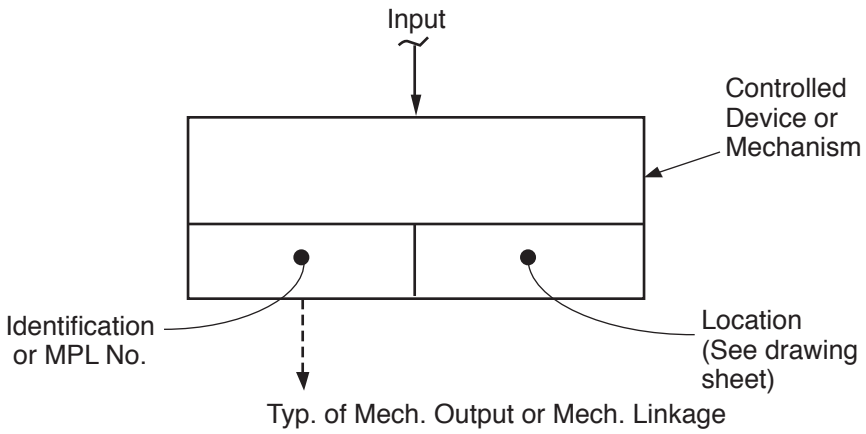
This block defines a permissive function which must be satisfied to permit the signal flow to pass to the next block. This block has incoming, outgoing, and may have auxiliary signals. The output from this permissive may be sealed in.



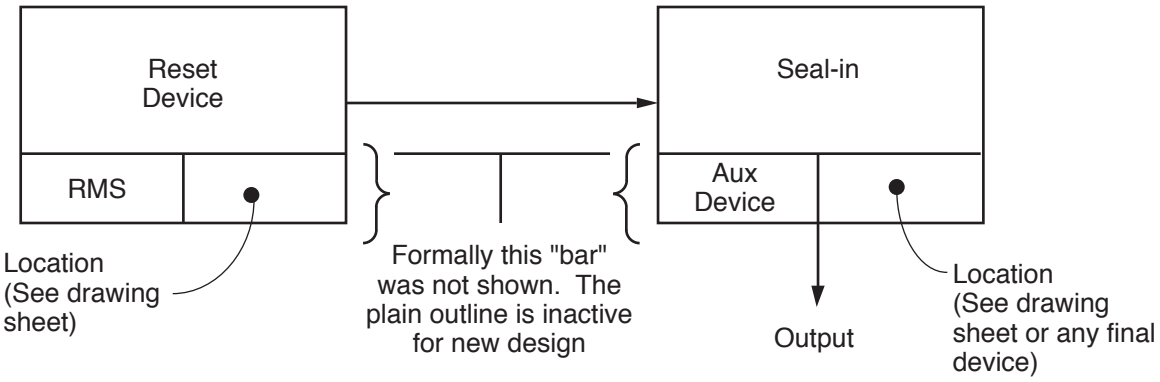
Note:

The word *later* may be used if the location is unknown but the correct location shall be noted on a future revision.

If a permissive or a primary function is shown in more than one place on drawings, provide a cross-reference to the parent function. (Formally an "X" was shown in the location of other switch handle positions, indicating that their blocks were an intricate part of the numbered switch assembly, but a different position of the switch handle. The "X" in location is inactive for new design.)

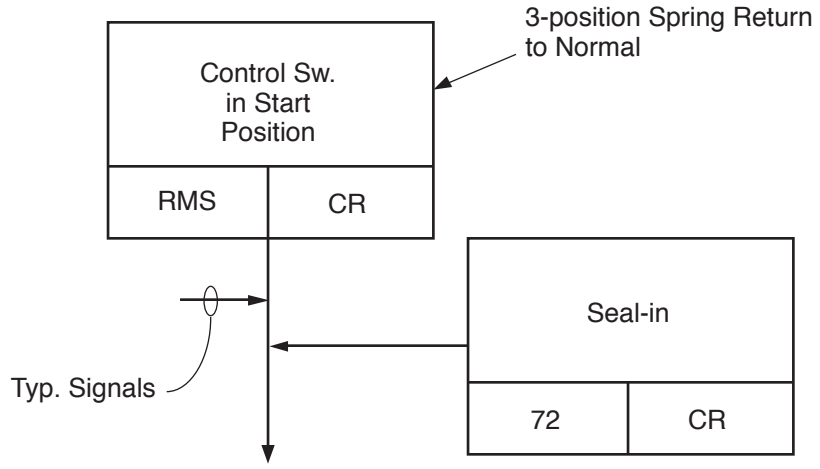


Show MPL item number of the valve or equipment served adjacent to the permissive or primary function. (See example)



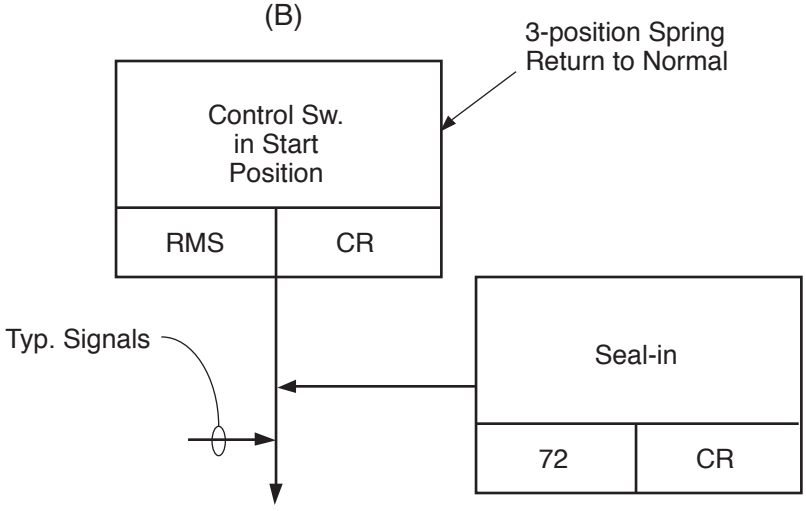
This block is a permissive condition.

Where the permissive is a general condition and not identified with a single device, the outer enclosure only is shown. It only has an input and output.



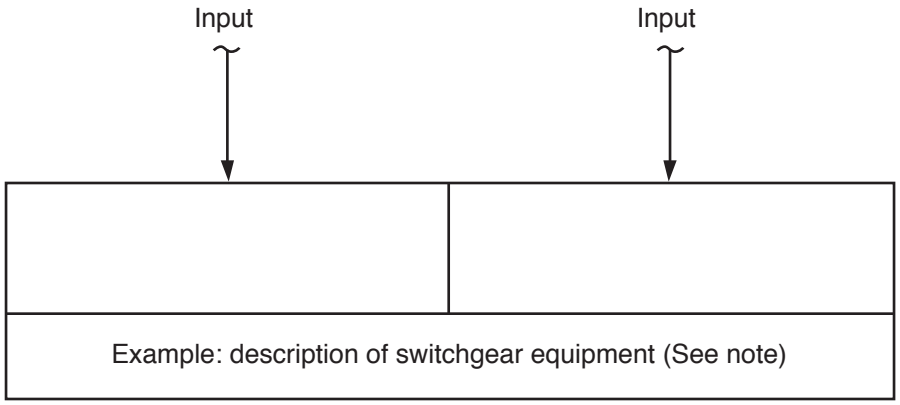
This block is a final device. It can be a relay, valve, electro-mech. sw., etc. Normally it has only inputs, but can have mech. outputs or position switch outputs.

This is a seal-in with a manual reset device. The function of the seal-in is to latch in a signal and to continue that signal until manually reset. A seal-in shown without a reset device implies that the reset device is part of, and located on the nearest valve or contactor and is automatically reset by breaking the signal downstream of the seal-in signal. In all other cases the reset device shall be shown in conjunction with the seal-in.



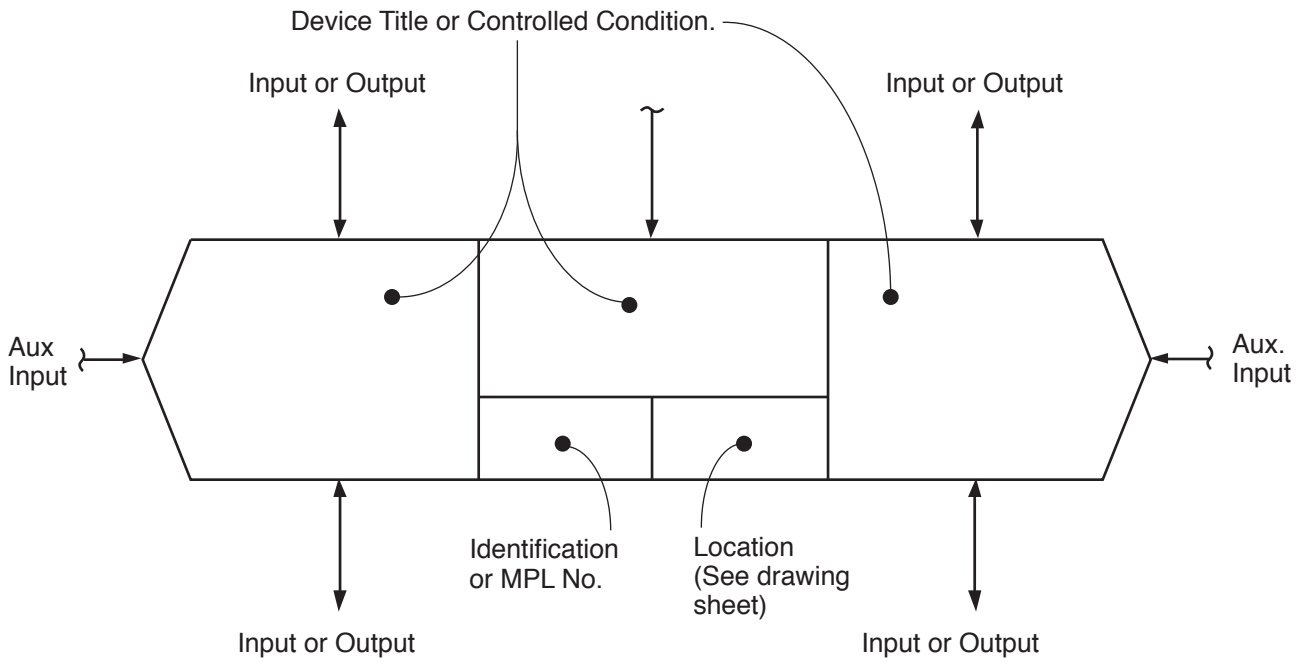
Examples of Typical Seal-in Blocks.

(A)

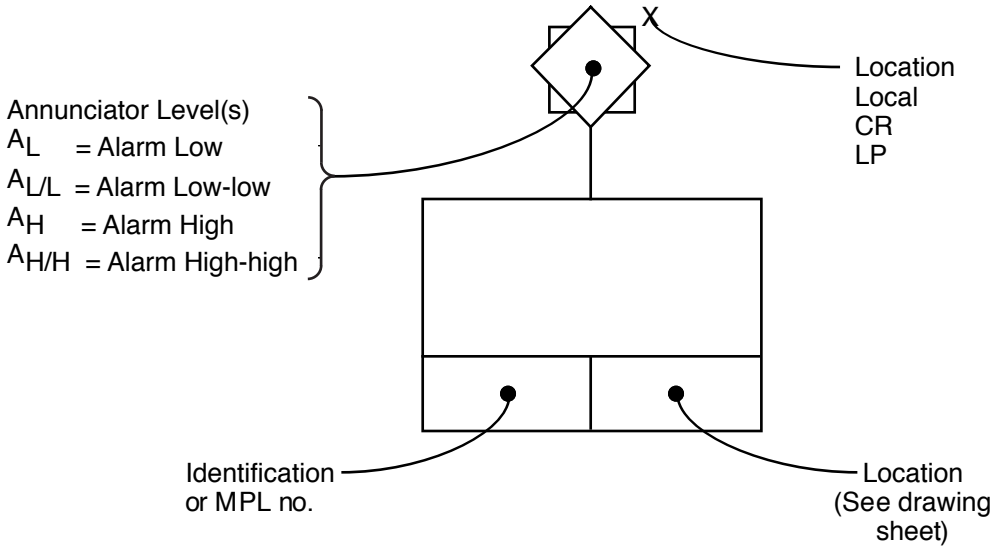


In this case, all signals at this point would be sealed-in.

(B)

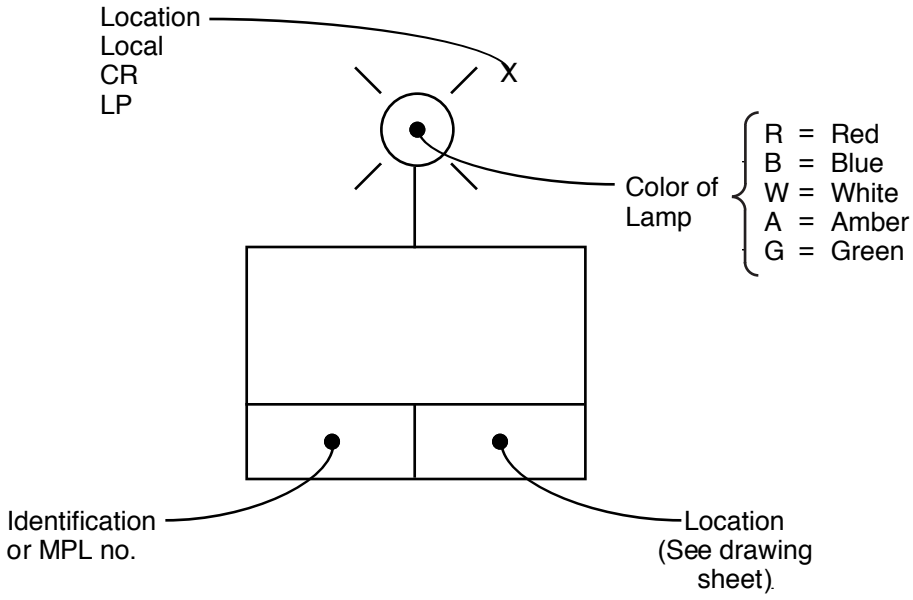


In this case, only the control sw. signal would be sealed-in.



This block is a final device used to represent motor starters, circuit breakers, etc. It has only input signals. The input to the right causes an opposed action to the input on the left, such as left-open: right-close.

Note:



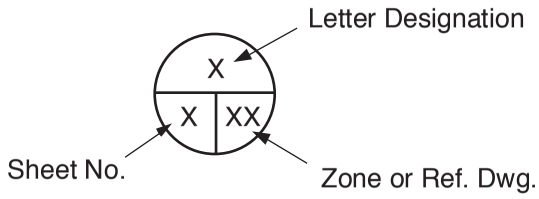
A final device may have more than one input. Each of these inputs can initiate the block. The block can have electrical inputs to indicating devices. Switchgear descriptions are found in ANSI spec. C37.2.

This block is a permissive operated by devices such as valve or pump switchgear designated in the inner block. This condition or device effects the operation of the final device. It has elect. inputs, mech. inputs, aux. inputs (mech. or elec.), and mech. or elect. outputs. This device is normally a valve. This is also used for other input/output power sources such as air or hydraulic. A solenoid pilot valve for an air operated valve is an example of this type of device (see Figure 1.2-26). When the two side blocks are the controlling blocks they have aux. input signals.

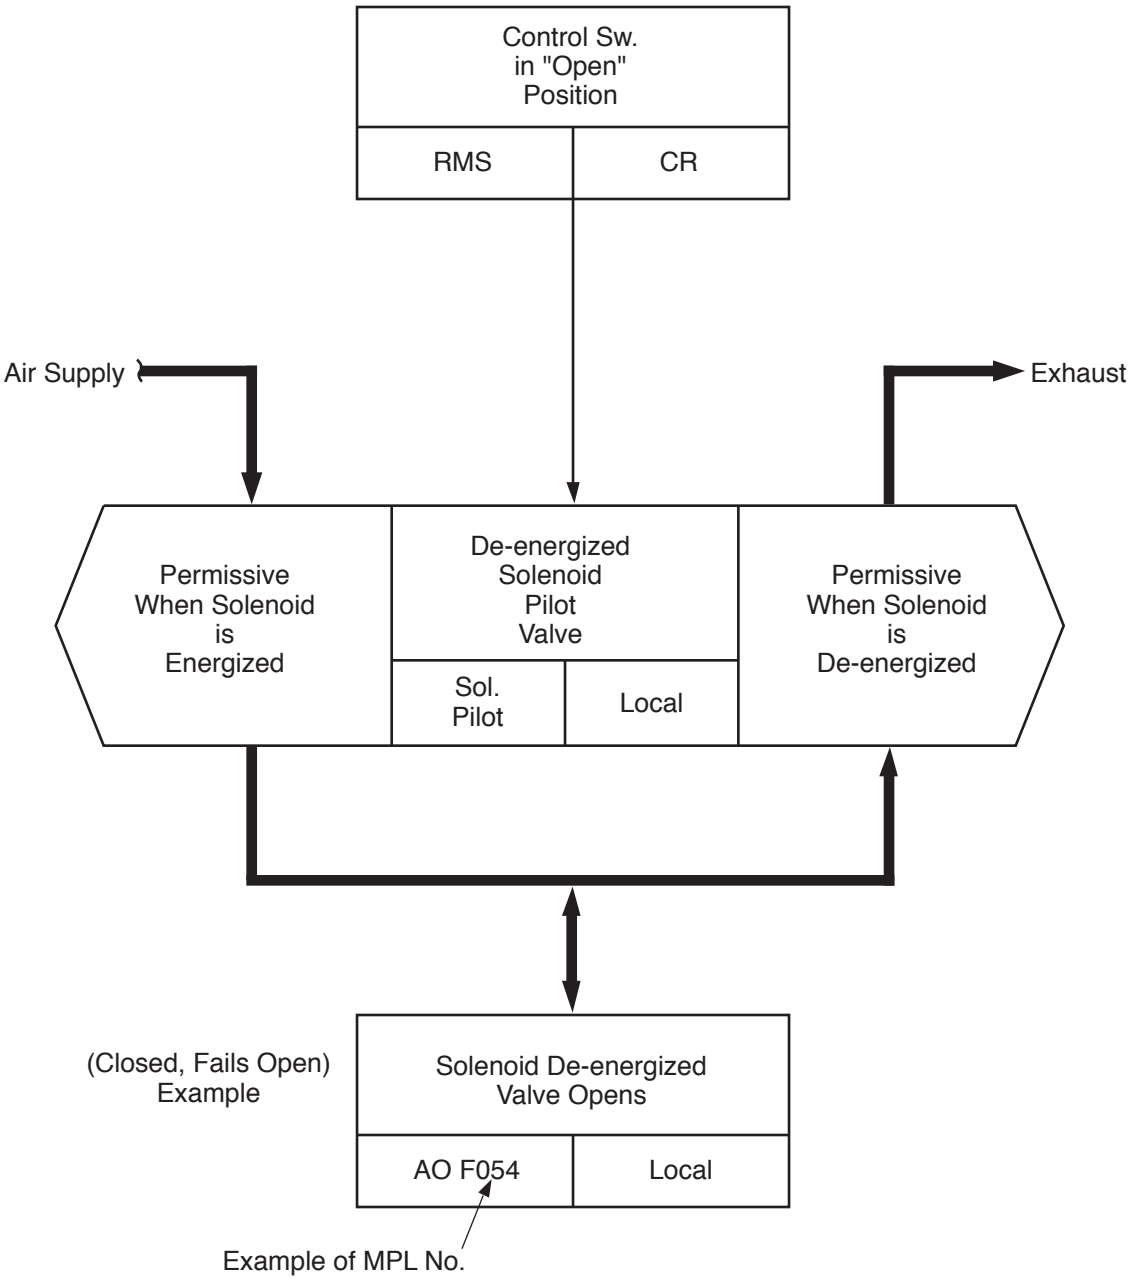
This block is a primary function for annunciators.

This block is a primary function for ind. lights.

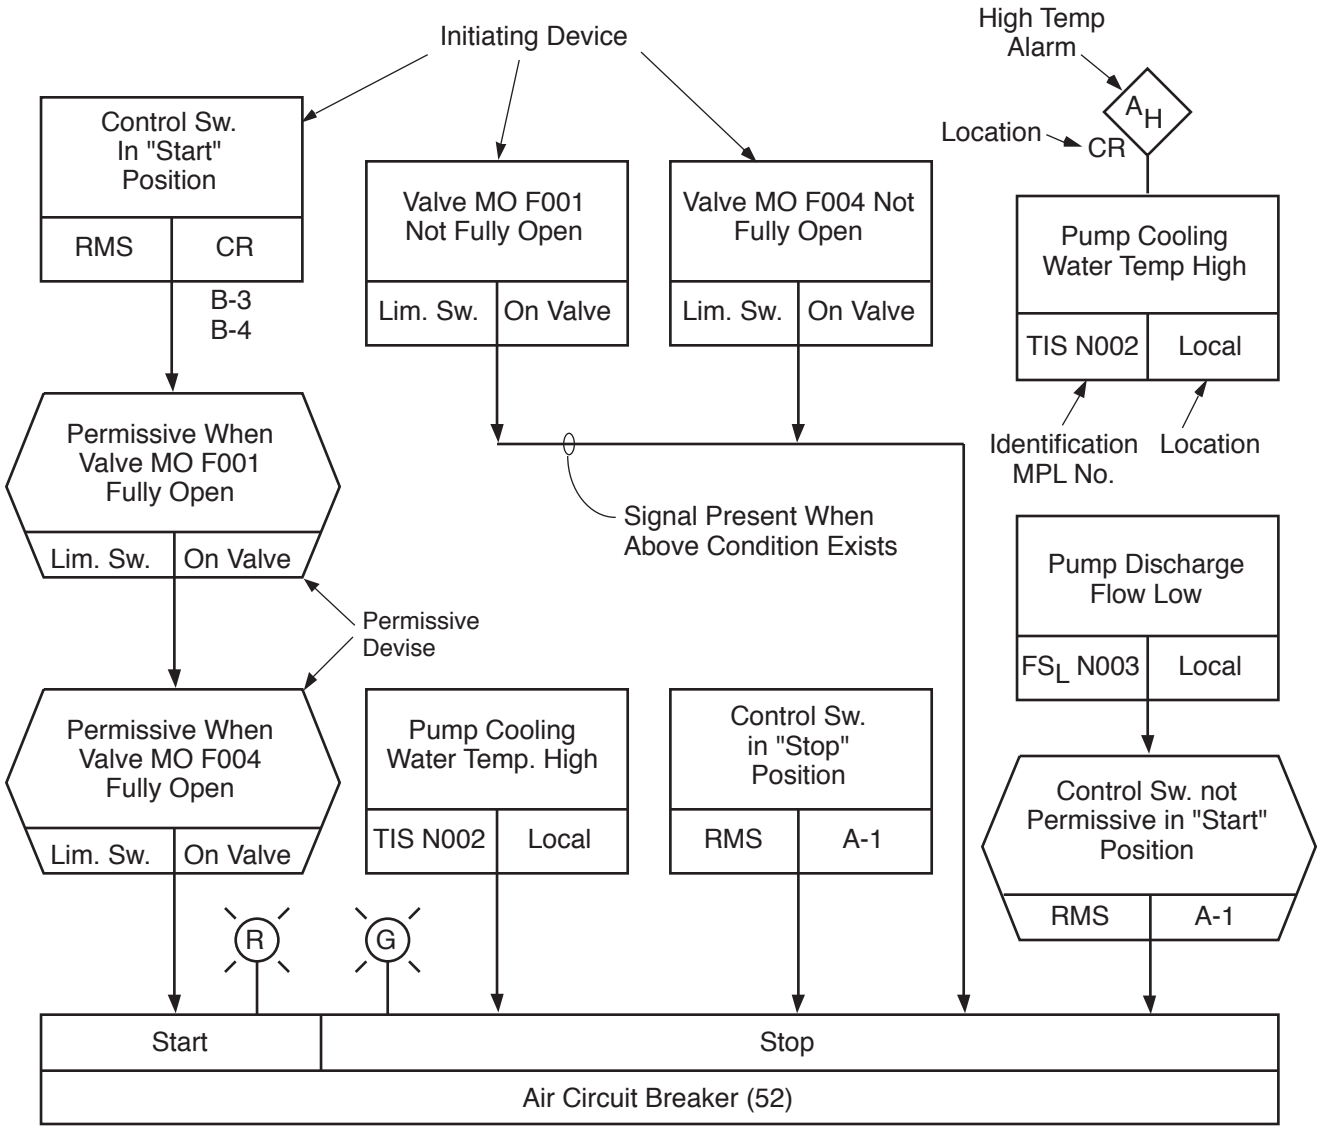
This line represents an elec. flow signal. This line may actuate a final device and may be used to represent actuation of a permissive block.



This line represents an auxiliary signal source such as air or hydraulic, and is not electrical.

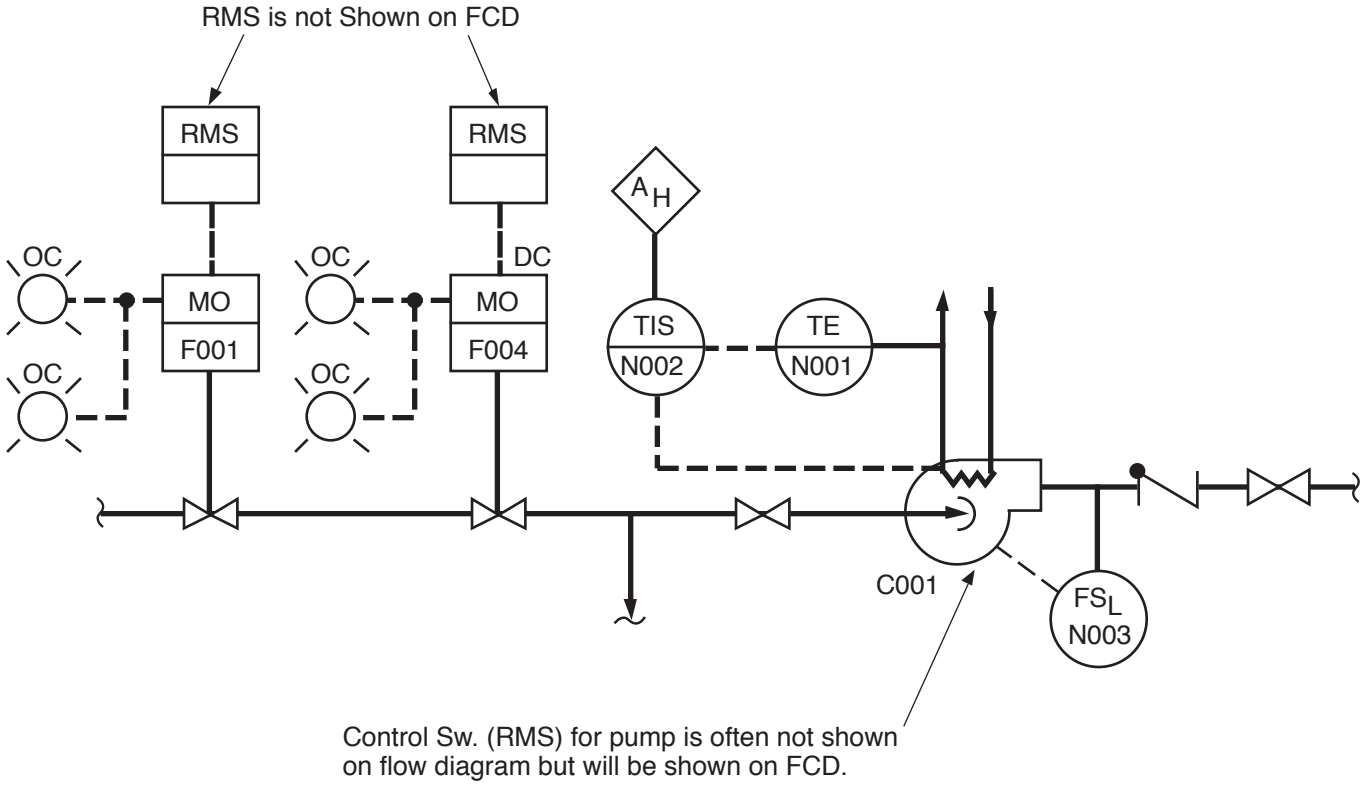


This line represents mechanical outputs and /or mechanical linkage.

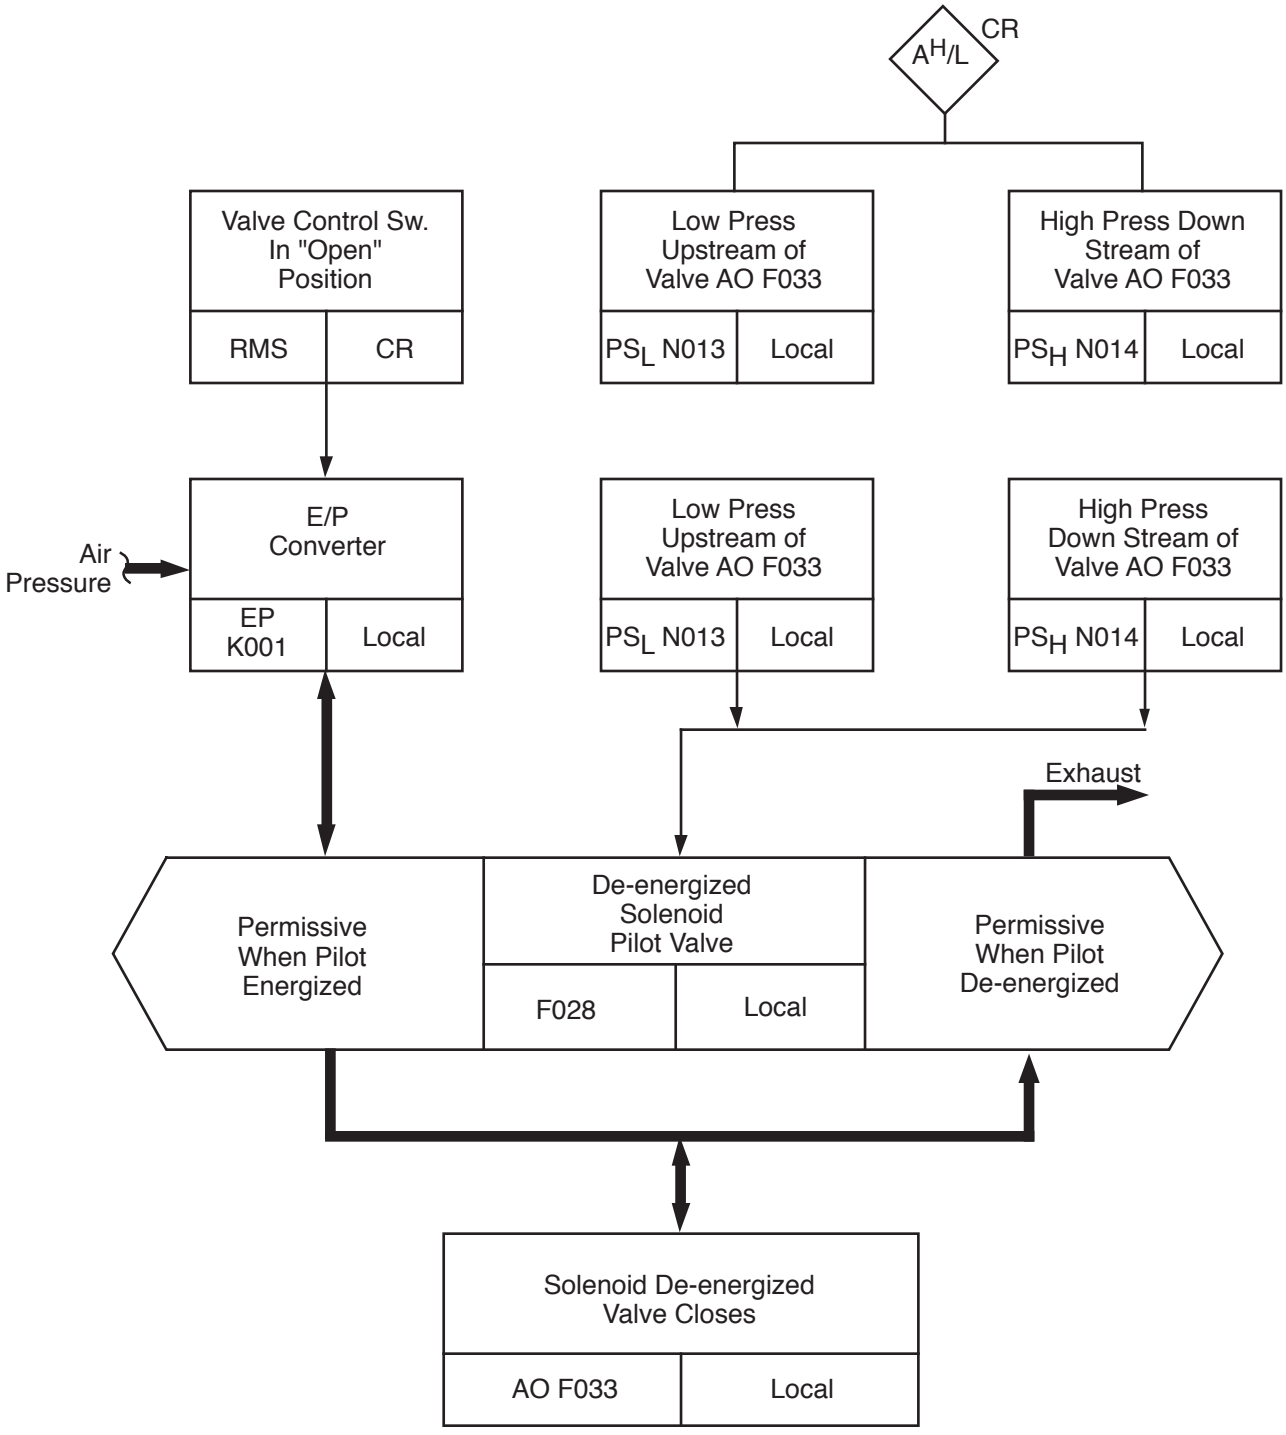


This symbol represents the start of the primary initiating signal.

This symbol represents a match circle. The letter designation on one dwg. must match the letter on the interfacing dwg.

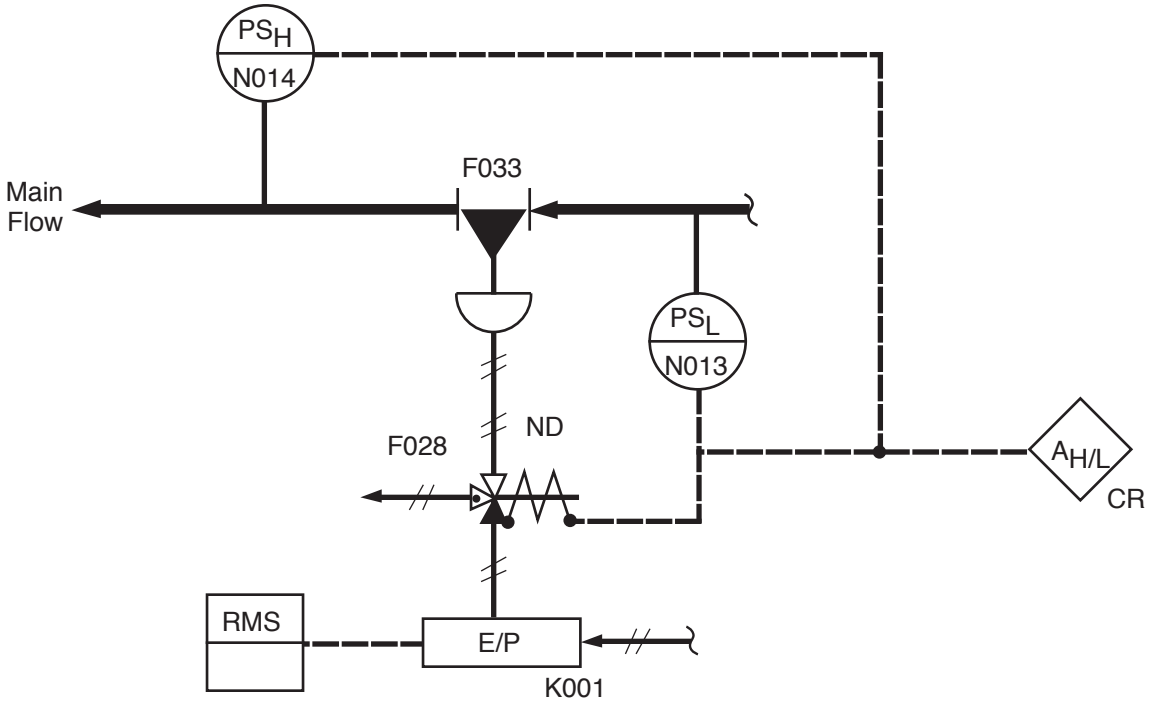


Typical A.O. Valve Example

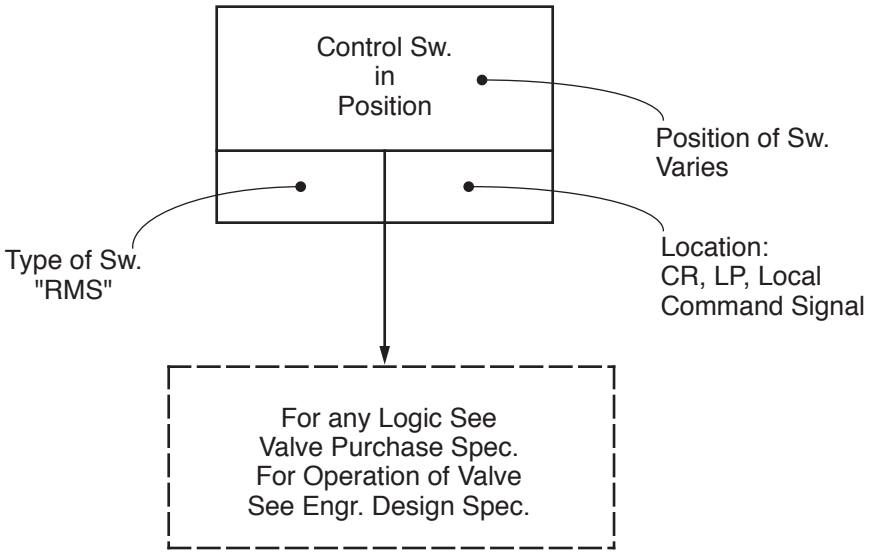


Columbia Generating Station Final Safety Analysis Report	**Logic Symbols for NSSS Functional Control Diagrams**		
	Draw. No. **950021.55**	Rev.	Figure **1.2-29.11**

Form No. 960690



Typical Flow Diagram Example



Bleed-off Flow Control Valve AO F033
Functional Control Diagram

Typical Flow Diagram Example

Notes: 1. Aux relays and devices are not shown on FCD.

This Figure is for a Typical Check Valve.

Testable Check Valve AO _ _ _ _

Reason for the above change is to have one standard logic for all testable check valve AO regardless of manufacturer.

1.3 COMPARISON TABLES

The italicized information is historical and was provided to support the application for an operating license.

1.3.1 COMPARISONS WITH SIMILAR FACILITY DESIGNS

This section highlights the principal design features of CGS and compares its major features with other boiling water reactor (BWR) facilities. The design of this facility is based on proven technology obtained during the development, design, construction, and operation of BWRs of similar types. The data, performance, characteristics, and other information presented here represent the design of the facilities at the time of the CGS operating license review.

1.3.1.1 Nuclear Steam Supply System Design Characteristics

Table 1.3-1 summarizes the design and operating characteristics for the nuclear steam supply systems. Parameters are related to rated power output for a single plant unless otherwise noted. The fuel thermal, hydraulic, and nuclear design data are that for the initial core load. Cycle specific data are provided in Chapter 4, Section 5.2, and Appendix 15F.

1.3.1.2 Power Conversion System Design Characteristics

Table 1.3-2 compares the power conversion system design characteristics.

1.3.1.3 Engineered Safety Features Design Characteristics

Table 1.3-3 compares the engineered safety features design characteristics.

1.3.1.4 Containment Design Characteristics

Table 1.3-4 compares the containment design characteristics.

1.3.1.5 Radioactive Waste Management Systems Design Characteristics

Table 1.3-5 compares the radioactive waste management design characteristics.

1.3.1.6 Structural Design Characteristics

Table 1.3-6 compares the structural design characteristics.

1.3.1.7 Electrical Power Systems Design Characteristics

Table 1.3-7 compares the electrical power systems design characteristics.

1.3.2 COMPARISON OF FINAL AND PRELIMINARY INFORMATION

Significant changes that have been made in the facility design since submission of the PSAR are listed in Table 1.3-8. Items in Table 1.3-8 are cross referenced to the appropriate portion of the FSAR that describes the changes and the bases for them.

Table 1.3-1

Comparison of Nuclear Steam Supply System Design Characteristics[a]

	CGS[b] *BWR 5 251-764*	*HATCH 1*[c] *BWR 4 218-560*	*ZIMMER*[c] *BWR 5 218-560*
Thermal and Hydraulic Design (see Section 4.4)

Number of 250-V buses	*1*	*2*	*1*

[a] *Does not include 450-V dc security system.*
[b] *HPCS system included.*
[c] *Total of five for two units.*
[d] *HPCS battery and bus included.*

Table 1.3-8

Significant Design Changes from PSAR to FSAR

Item	*Change*	*Reason for Change*	*FSAR Portion in Which Change is Discussed*
Offgas system class change	*The offgas system components are Quality Group C, whereas the system components were described in the PSAR as being Quality Group D.*	*Improve assurance of system integrity.*	*11.3.1*
Control rod drive position indication	*Changed to 11 wire probe and solid state.*	*Improved reliability and increased frequency of checking actual rod position.*	*7.7.1*
Control rod drive system	*Deleted CRD return line and pump test bypass, revised cooling and exhaust water headers, added relief valves interconnecting cooling water and exhaust headers, redirected system exhaust flow through the multiple solenoid valves in each HCU.*	*GE recommendation.*	*4.6.1.1.2.4*
Recirculation pump and motor	*The flow rate and horsepower required has been reduced; voltage has changed from 4160 V to 6600 V. A low-frequency motor generator set was added to provide 25% speed.*	*Detailed system.*	*5.4.1*
Jet pumps	*The jet pump design was changed to improve five-hole type.*	*Design improvement, increased efficiency.*	-
Recirculation flow measurement	*The recirculation flow measurement design was changed from a flow element to an elbow-tap type.*	*To improve flow measurement accuracy.*	*7.3.1*
Recirculation system	*The pressure interlock for RHR injection was changed.*	*IEEE-279 requirements.*	*7.3.1, 7.6.1*
Recirculation system	*Bypass line around reactor recirculation system flow control valve was eliminated.*	*Reduce the possibility of cavitation and cracking of piping in the recirculation system. Need eliminated by addition of low frequency motor generator set.*	

Table 1.3-8

Significant Design Changes from PSAR to FSAR (Continued)

Item	*Change*	*Reason for Change*	*FSAR Portion in Which Change is Discussed*
Nuclear fuel	*The number of fuel pins in each fuel bundle has been changed from 7 x 7 to 8 x 8 (including two water rods).*	*Improved fuel performance by increasing safety margins.*	*4.2*
Nuclear boiler	*A turbine building high temperature trip for MSIVs was added.*	*Improve leak detection capability.*	*7.3.1*
Nuclear boiler	*An additional test mode was added for closing MSIVs one at a time to 90% of full open in the fast mode (close in slow mode already existed).*	*Verifies that the spring force on the valves will cause them to close under loss-of-air conditions.*	*5.4.5*
Main steam line isolation	*A main condenser low vacuum initiation of the main steam line isolation was added.*	*NRC requirement.*	*7.3.1*
Main steam line isolation	*Reactor isolation was deleted for reactor high water level.*	*To provide improved plant availability.*	*5.4.5*
Main steam line drain system	*A main steam line drain system was improved.*	*Prevent accumulation of condensate in an idle line outboard of MSIV.*	*5.1.1*
RPV code	*The RPV code was updated to ASME 1971 and Summer 1971 addenda.*	*Update to applicable code as much as possible.*	*5.2.1*
Level instrumentation	*The RPV level instrumentation was revised to eliminate Yarway columns and replace them with a conventional condensing chamber type; also, separation and redundancy features were added.*	*Improve ECCS separation per IEEE-279 and improve reliability.*	*7.3.1*
Turbine seal setpoint pressure	*The turbine seal setpoint pressure was changed from 50 psia to 125 psia.*	*Ensures that main turbine condenser can extract reactor steam at temperature above cooling capability of RWCU system.*	-
Leak detection system	*The leak detection system was revised to upgrade the capability and incorporate the requirements of IEEE-279.*	*To meet IEEE-279 requirements.*	*7.6.1*

Table 1.3-8

Significant Design Changes from PSAR to FSAR (Continued)

Item	*Change*	*Reason for Change*	*FSAR Portion in Which Change is Discussed*
Reactor vibration monitoring	*A confirmatory vibration monitoring test was added.*	*NRC requirement.*	*14.2.12.3.34*
RWCU system sample station	*The P&IDs were changed to provide continuous monitoring.*	*Technical Specifications requirements.*	-
LPCS system	*Valve F011 was changed from air-operated to motor-operated control.*	*To provide Seismic Category I rated control power to this essential active component.*	*7.3.1.1.1.3*
LPCS system	*Direct connection to condensate storage replaced by removable spool piece connection to RHR.*	*Condensate used only for system commissioning tests.*	*Figure 6.3-5*
PRT replaced by RPT	*Prompt relief trip (PRT) was replaced by recirculation pump trip (RPT) for quick insertion of negative reactivity.*	*Increased reliability.*[a]	*7.6.1.5*
Main steam system	*Relief valve augmented bypass (REVAB) was deleted.*	*Licensing requirement.*[a]	-
Feedwater sparger	*The thermal sleeve was changed to provide welded design of sparger to nozzle.*	*To eliminate vibration, failure, and leakage.*	*5.3*
Standby liquid control (SLC) system	*Interlocks on the SLC system were revised.*	*To prevent inadvertent boron injection during system testing.*	*7.4.1, 9.3.5*
Standby liquid control (SLC) system	*RCPB extended to explosive valves*	*To meet isolation criteria.*	-
RCIC steam supply	*A warmup bypass line and valve was added.*	*Permits pressurizing and prewarming of the steam supply line downstream to the turbine during reactor vessel heatup.*	*5.4.6*
RCIC vacuum breaker system	*A vacuum breaker system was added to the RCIC turbine exhaust line into the suppression pool.*	*To prevent backup of water in the pipe and consequential high dynamic pipe loads and reactions.*	*5.4.6*

Table 1.3-8

Significant Design Changes from PSAR to FSAR (Continued)

Item	*Change*	*Reason for Change*	*FSAR Portion in Which Change is Discussed*
RCIC system	*Each component has been made capable of functional testing during normal plant operation.*	*Improved testability.*	*5.4.6*
Automatic depressurization system (ADS)	*The interlocks on the automatic depressurization system were revised.*	*To meet lEEE-279 requirements.*	*7.3.1*
RPV support	*The support for the RPV was changed from a ring girder to a bearing plate.*	*Provides a better seismic and alignment capability.*	*5.3.3.1.4.1*
Plant service water pumps	*Upon loss of offsite power without a LOCA, the normal 4160 V service buses (SM-75, SM-85), are connected to SM-7 and SM-8 to provide automatic starting of a plant service water pump for drywell cooling.*	*Provides service water for drywell cooling automatically after loss of offsite power without a LOCA.*	*Figure 8.1-2, Tables 8.3-1 and 8.3-2*
Reactor building cooling system	*ESF cooling units have been added to critical electric equipment areas in the reactor building.*	*To provide suitable ambient temperature conditions for essential electrical and control equipment located in the reactor building in the event of a LOCA.*	*9.4.9*
Standby gas treatment system	*Added second fan (powered from alternate power bus) to each standby gas treatment system.*	*To remove need for crosstie between the two systems.*	*6.5.1.2*
Standby gas treatment system	*Added facility to recirculate air from SGTS back into reactor building.*	*So that potential decay heat in filter can be removed without discharge to atmosphere in event of divisional power failure.*	*6.5.1.2*
Standby gas treatment system	*Added second electric preheater (powered from alternate power bus) to each SGTS unit.*	*To provide means of controlling relative humidity of air entering charcoal filter in event of primary heater or divisional power failure.*	*6.5.1.2*

Table 1.3-8

Significant Design Changes from PSAR to FSAR (Continued)

Item	*Change*	*Reason for Change*	*FSAR Portion in Which Change is Discussed*
Control room HVAC system	*Added two remote air intakes for pressurizing control room in event of a LOCA.*	*To limit doses to operating personnel to limits of 10 CFR 50.*	*9.4.1.2*
Ventilation system for areas in which essential cable is routed	*Added to ESF ventilation system to ventilate corridors and cable chases through which essential cable is routed (diesel generators to control room).*	*To provide suitable ambient temperatures for essential cable in the event of a LOCA*	*9.4.8*
Offgas system charcoal vault	*Added a refrigeration system to the vault in which the offgas system charcoal adsorber filters are housed.*	*To maintain charcoal adsorbers at a temperature of 0°F.*	*9.4.5, 11.3.2.1*
Makeup water pumps transformer vault ventilation	*Added a ventilation system to makeup water pump transformer rooms powered from the emergency buses.*	*To ensure suitable ambient temperatures for transformers in the event of a loss of offsite power caused by a tornado.*	*9.4.6*
Radioactive waste solidification process	*Cement-sodium silicate solidification process to be used in lieu of urea-formaldehyde process.*	*To eliminate the generation of free water in solidified containers, a problem inherent to the urea-formaldehyde process.*	*11.4*
Air ejector	*Three-stage air ejector to two-stage air ejector.*	*Manufacturer offered a two-stage unit that meets the same operating conditions.*	*10.4.2*
Sealing steam supply	*The gland steam evaporator will produce sealing steam using main steam on its tube side during startup and shutdown modes. PSAR stated auxiliary boiler would be used.*	*Adequate sealing steam can be produced with main steam pressure down to 125 psig.*	*10.4.3*
Containment instrument air	*The CIA air compressors were removed and the system is now supplied with nitrogen during reactor operation. Redundant bottled gas supply utilized for supplying ADS valve accumulators for accident conditions.*	*The purpose of the safety related bottled gas supplies is to back up the non-safety-related cryogenic nitrogen supply.*	*9.3.1.1.2*

Table 1.3-8

Significant Design Changes from PSAR to FSAR (Continued)

Item	*Change*	*Reason for Change*	*FSAR Portion in Which Change is Discussed*
Offgas holdup line	*Radiography of circumferential welds was not done.*	*A partial section of the line was buried before radiography was done. Welds were magnetic particle tested and line was hydro-tested at 1200 psig and then helium pressure decay leak tested with a sensitivity of 10^{-2} cm^3/sec.*	-
Wet solid radwastes	*Packaged in 50 ft^3 containers rather than 50-gal drums.*	*Reduce handling time and operator exposure.*	*11.4.2.10*
Turbine bypass valve system	*Four bypass valves are used rather than three.*	*Solution to operating problems with bypass valves on Cooper Nuclear station.*	*10.4.4*
Main steam isolation valve leakage control system	*Added to plant.*	*NRC requirement.*	*6.7*
Main steam line from outermost isolation valve to turbine stop valve	*Piping has been upgraded from Code Group D to Code Group B.*	*NRC requirement.*	*10.3.2*
Radwaste tank sizes			
1. Waste sludge phase separator	*From 12,500 to 13,000 gal.*	*To increase capacity.*	*Table 11.4-4*
2. Chemical waste tank	*From 13,000 to 15,000 gal.*	*To increase capacity.*	*Table 11.2-13*
3. Decontamination solution concentrated waste tank	*From single 700-gal to two 700-gal tanks.*	*To provide spare tank.*	*Table 11.4-4*

Table 1.3-8

Significant Design Changes from PSAR to FSAR (Continued)

Item	*Change*	*Reason for Change*	*FSAR Portion in Which Change is Discussed*
4. Concentrated waste measuring tank	*From 100 to 400 gal.*	*Due to increase in shipment container size from 50 gal to 50 ft^3.*	*Table 11.4-4*
5. Condensate phase separators	*From 12,500 to 23,500 gal.*	*To increase capacity in event of higher than normal backwash requirements.*	*Table 11.4-4*
6. Chemical addition tank	*From single 1000-gal tank to two 200-gal tanks.*	*To provide capability for both acid and caustic addition from separate tanks. Original tank oversized.*	*Table 11.2-13*
Floor drain system	*Influent waste radionuclide concentration changed from range of10^{-4} to 10^{-2} µCi/ml to on order of 10^{-1} µCi/ml.*	*Reevaluation of source terms.*	*11.2.2.2.2*
Liquid radwaste system	*GALE code was used to calculate radioactive discharges with 2500-gpm blowdown. Blowdown of 4000 gpm was used in the PSAR.*	*NRC requirement to use GALE Code. Change in blowdown results in more conservative (higher) radionuclide concentrations.*	*11.2.3.2*
Cleaning of filters	*Changed from steam cleaning connections to chemical cleaning system.*	*Design improvement.*	*Figure 10.4-5*
Missiles from tornadoes	*Selection of credible missiles.*	*For FSAR, followed specific missiles identified in NRC Standard Review Plan.*	*3.5.1.4*
Cleaning of filters	*Changed from steam cleaning connections to chemical cleaning system.*	*Design improvement.*	*Figure 10.4-5*
Missiles from tornadoes	*Selection of credible missiles.*	*For FSAR, followed specific missiles identified in NRC Standard Review Plan.*	*3.5.1.4*
Primary containment vessel	*New loads due to hydro-dynamic effects of safety/relief valve actuation and LOCA (neither in PSAR or FSAR; see Dynamic Analysis Report).*	*To accommodate new GE load requirements.*	*3.8.2*

Table 1.3-8

Significant Design Changes from PSAR to FSAR (Continued)

Item	*Change*	*Reason for Change*	*FSAR Portion in Which Change is Discussed*
Diesel generator building fire protection system	*Changed from CO_2 system to dry pipe preaction system. after a fire.*	*To provide accessibility to the diesel immediately. Also availability of unlimited water supply*	*Appendix F*
Cable chase fire protection system	*Added dry pipe preaction system for cable chase and diesel generator building corridor.*	*To protect divisional cable concentrations in these areas.*	*Appendix F*
500-kV line	*Hookstick changed to motor-operated switch.*	*Available standard switches are supplied with motor operators.*	*Fig. 8.1-2*
500-kV line	*Line terminates at H. J. Ashe Swtichyard rather than Hanford Switching Station.*	*BPA revisions to 500 kV grid.*	*8.1.2*
230-kV line	*Deleted hookstick and 230-kV OCB at plant switchyard.*	*OCB relocated to H. J. Ashe Switchyard.*	*Fig. 8.1-2*
115-kV line	*Replace circuit interrupter with 115-kV circuit breaker at plant switchyard.*	*Equipment availability.*	*Fig. 8.1-2.1*
Backup source	*Utilized to supply essential loads during diesel generator testing.*	*PSAR did not consider particulars of diesel generator testing.*	*8.3.1.1.7.1.7*
Diesel generator starting	*Deleted automatic starting due to startup or backup transformer undervoltage.*	*Class 1E bus undervoltage is the only undervoltage condition requiring diesel generator start*	*8.3.1.1.7.1.7* *8.3.1.1.7.2.7*
Diesel generator trips during emergency operation	*Added incomplete sequence trip to Division 1 and 2 diesel generators.*	*Incomplete sequence indicates a diesel generator malfunction having an imminent possibility of unit damage.*	*8.3.1.1.7.1.8*
125-V, 250-V-dc battery capability	*Revised supply capability from 4 hr to 2 hr.*	*Increased dc load*	*8.3.2*
125-V, 250-V-dc charger capability	*Revised recharge capability from 8 hr to 24 hr.*	*Increased dc load*	*8.3.2*

Table 1.3-8

Significant Design Changes from PSAR to FSAR (Continued)

Item	*Change*	*Reason for Change*	*FSAR Portion in Which Change is Discussed*
Spare 125-V-dc charger	*Spare charger serves as a backup for Divisions 1 and 2 only.*	*Spare charger is too large to provide backup to Division 3.*	*8.3.2*
Communication systems	*The commercial telephone exchange system is not redundant.*	*Redundancy not required.*	*8.2.1.5*
Fuel pool cooling and cleanup system	*Upgraded cooling portion of system to Seismic Category I to provide long-term cooling and safety grade makeup water capability for coolant of spent fuel following refueling.*	*To prevent fuel pool boiling and resultant adverse environmental conditions which could affect safety-related electrical equipment in the reactor building.*	*9.1.3*

[a] *PRT and REVAB were proposed at the CP stage as non-safety-related power generation type systems to reduce the thermal-hydraulic effects of transient events in the core. However, during experiments in the MK-11 suppression pool dynamics test program, it was decided that less frequent relief valve cycling during plant operation was desirable. Consequently, the recirculation pump trip (RPT) system was developed to perform functions previously assigned to PRT and REVAB.*

1.4 IDENTIFICATION OF AGENTS AND CONTRACTORS

The italicized information is historical and was provided to support the application for an operating license.

1.4.1 APPLICANT/OPERATOR

Energy Northwest is a municipal corporation and a joint operating agency of the State of Washington, organized in January 1957, pursuant to Chapter 43.52 of the Revised Code of Washington, as amended. Energy Northwest assumes the responsibility for safe operation and maintenance of the plant and for providing related services as described in Chapter 13.

1.4.2 ENGINEER AND CONSTRUCTION MANAGEMENT - BURNS & ROE, INC.

Burns and Roe, Inc. (B&R) provides engineering and initial construction management and quality assurance services for the design and construction of the plant, integrating the major plant items furnished by the General Electric Company (GE) and Westinghouse Electric Corporation.

Burns & Roe was founded in 1932 and incorporated in 1935 as Burns and Roe, Inc. Burns & Roe has been active in the fields of power generation and distribution, sea water and brackish water desalination, waste water renovation, and engineering, design, and/or construction management services for over 50 thermal power generating units representing more than 11,400,000 kW of new generating capacity, of which more than 4,800,000 kW is nuclear. Burns & Roe, Inc., has been continuously engaged in construction of engineering activities since 1935.

1.4.3 NUCLEAR STEAM SYSTEM SUPPLIER - GENERAL ELECTRIC COMPANY

General Electric designed, fabricated, and delivered the direct-cycle boiling water nuclear steam supply system (NSSS) for Columbia Generating Station (CGS). General Electric also fabricated the first core of nuclear fuel and provided technical direction of installation and startup of this equipment.

General Electric has engaged in the development, design, construction, and operation of boiling water reactors (BWRs) since 1955. Table 1.4-1 lists GE reactors completed, under construction, or ordered (several later canceled). Thus, GE has substantial experience, knowledge, and capability to design, manufacture, and furnish technical assistance for the installation and startup of reactors.

General Electric continues to provide technical support for the operation of CGS as requested by Energy Northwest. This includes providing support for the CGS Megawatt Improvement Program (see Section 1.1).

1.4.4 TURBINE GENERATOR SUPPLIER - WESTINGHOUSE ELECTRIC CORP.

Westinghouse Electric Corporation designed, fabricated, delivered, and installed the turbine generator for CGS. They also provided technical assistance for the startup of this equipment.

Westinghouse Electric Corporation has a long history in the application of turbine generators in nuclear power stations going back to the inception of commercial electrical power production using nuclear facilities. Westinghouse furnished the turbine generator unit for Shippingport No. 1. This unit was shipped in 1956. Westinghouse also furnished the turbine generator unit for Yankee Atomic Power Company Rowe No. 1. This unit was shipped in 1959. San Onofre No. 1 and Connecticut Yankee, Haddam Neck No. 1 unit went into commercial operation in 1968. Westinghouse nuclear turbine generators produced over 300 billion kW hr of electricity through May 1976, when 25 nuclear turbine generators totaling over 16,500 MW were in service. By 1984, 75 Westinghouse nuclear turbine generators should be in service producing over 61,319 MW. Inlet steam pressures of these units vary between 750 psig and 1000 psig and electrical outputs vary from 500,000 kW to 1,090,000 kW.

Westinghouse continues to provide technical and maintenance support for the turbine generator on an as-requested basis. They also provided replacement for the three low-pressure turbine rotors installed in the Spring 1992 refueling outage.

1.4.5 SYSTEM COMPLETION CONTRACTOR - BECHTEL

As System Completion Contractor, Bechtel provides field and home office services in project planning and control, engineering, construction completion, startup support, and quality verification for CGS. The Bechtel organization was founded in 1898, in the midwest, by Warren A. Bechtel. In 1940, Bechtel went international, working on a pipeline system in Venezuela; and then vastly diversified its activities during World War II, becoming involved in naval bases, shipyards, pipelines, refineries, and aircraft modification. Next, Bechtel pioneered in the nuclear power field, constructing the first reactor to produce useful electricity in 1949, and building Dresden I, the first commercial nuclear power station. Today, Bechtel is recognized as one of the world's leading engineering and construction firms.

1.4.6 MAJOR CONTRACTORS

1.4.6.1 <u>Fischbach/Lord</u>

Fischbach/Lord is responsible for the major electrical installation at CGS, consisting of raceways, conduit, cable, terminators, and electrical equipment. They were formed as a joint venture, solely for this project, in 1974.

1.4.6.2 Pittsburgh-Des Moines Steel Company

Pittsburgh-Des Moines Steel Company is responsible for engineering, fabrication, and installation of materials in the Primary Containment Vessel.

1.4.6.3 Wright-Schuchart- Harbor/Boecon (Boeing Construction)/General Energy Resources, Inc.

Wright-Schuchart-Harbor/Boecon/General Energy Resources, Inc. (WBG) was formed as a joint venture October 1, 1977, to be responsible for installation of major mechanical equipment, power, and process piping for CGS.

1.4.6.4 Bechtel

During plant construction, Bechtel served as the Construction Manager. During the operating phase Bechtel, as the Site Support Services contractor, is providing field engineering and installation support for plant modifications. Also, as Technical Services contractor, they are providing engineering support under Energy Northwest direction and under the Energy Northwest quality assurance program as requested by Energy Northwest. Under these contracts Bechtel is providing support to the Megawatt Improvement Program (see Section 1.1).

1.4.6.5 Deleted

1.4.6.6 Westinghouse Electric

Westinghouse provided the turbine generator. They provided replacement of the three low-pressure rotors which were installed in 1992. Westinghouse also provided a new plant simulator which was installed in 1995.

1.4.7 CONSULTING ENGINEER - R. W. BECK AND ASSOCIATES

The independent consulting firm of R. W. Beck and Associates is the consulting engineer for Energy Northwest's Columbia Generating Station. This firm was also a consulting engineer for WNP-1. Having extensive experience in preparing engineering feasibility and financing studies and reports necessary for the success of utility and civic improvement projects, the firm is well qualified for employment as a consulting engineer and was chosen as a result of its experience.

The duties of the consulting engineer are briefly summarized as follows: prepare estimates of plant capability, energy potential, usability within area loads and resources, the cost of power and energy output of the project, and generally determine the feasibility of the project. These duties will include assisting in preparation of a Bond Resolution, preparation of an engineering report, schedules for investment of funds, schedules for debt service payments, and other engineering services necessary to facilitate the financing of the project.

1.5 REQUIREMENTS FOR FURTHER TECHNICAL INFORMATION

The italicized information is historical and was provided to support the application for an operating license.

1.5.1 GENERIC ISSUES

NUREG-0933, "A Prioritization of Generic Safety Issues" presents the generic issues as follows:

a. TMI action plan items

In NUREG-0933, these follow the content and format of NUREG-0660 and NUREG-0737.

b. Task action plans

These include both the unresolved safety issues (USIs) previously included in NUREG-0606 and the Category A Generic Activities previously included in NUREG-0371 and the Category B, C and D Generic Activities previously included in NUREG-0471.

c. Human factors

These are the human factors considerations of NUREG-0660 and NUREG-0737.

d. Chernobyl Issues

This part addresses the recommendations of NUREG-1251.

In the sections below, these issues are addressed as unresolved safety issues (USIs), generic safety issues (GSIs), and TMI Task Action Plans. Human Factors considerations are included as part of the TMI Task Action Plans. Chernobyl is not addressed below or on the CGS docket as NUREG-1251 lead to the conclusion that no immediate changes in NRC regulations regarding the design or operation of U.S. commercial reactors were required. However, NUREG-1251 and INPO SER 34-86, "Chernobyl Unit 4 Accident," and INPO SOER 87-1, "Core Damaging Accident Following an Improperly Conducted Test," were reviewed by Energy Northwest to identify the need for any changes to hardware, procedures, or training at CGS.

1.5.1.1 Unresolved Safety Issues

1.5.1.1.1 Unresolved Safety Issues Introduction

Unresolved safety issues are issues identified by the NRC that affect a number of plants, question the adequacy of existing requirements, have no current resolution and are judged to be unacceptable if left unresolved for the life of the plant.

A December 20, 1977, amendment to the Energy Reorganization Act required that the NRC develop a plan providing for specification and analysis of USIs and take action as necessary to implement corrective measures with respect to such issues. In a joint Explanatory Statement of the House - Senate Conference Committee for the FY 1978 Appropriations Bill this was explained to mean that a plan was to be developed to resolve the USIs. In September 1989, the NRC achieved resolutions of all of the identified USIs.

On October 19, 1989, the NRC issued Generic Letter 89-21, "Request for Information Concerning Status of Implementation of Unresolved Safety Issue (USI) Requirements." This generic letter requested that licensees and construction permit holders review and report on the status of the implementation of USIs for which final technical resolution had been achieved.

Energy Northwest responded to this request in Reference 1.5-1. The NRC responded to this submittal by Reference 1.5-2 and identified anticipated transient without scram (ATWS), Station Blackout and Safety Implications of Control Systems (A-9, A-44, and A-47, respectively) as not being implemented. (Subsequently, these have been resolved as discussed below.)

1.5.1.1.2 Implementation of Specific Unresolved Safety Issues

A-8 Mark II Containment Pool Dynamic Loads

Resolution of A-8 for CGS is documented in NUREG-0892 (the SER for CGS) and Supplements 4 and 5 in Sections 6.2.1.8 and 3.9.3.1, respectively.

A-9 Anticipated Transients Without Scram

In the safety evaluation transmitted with Reference 1.5-7, the NRC stated that the standby liquid control (SLC) flow and sodium pentaborate decahydrate concentration for CGS were in compliance with the ATWS rule.

The design requirements for resolution of ATWS for CGS were to install an alternate rod injection (ARI) system (see Section 7.4.1.6), a standby liquid control (SLC) system (see Sections 7.4.1.2 and 9.3.5), and to trip the reactor recirculation pumps automatically by a recirculation pump trip (RPT) system under conditions indicative of an ATWS (Section

7.4.1.5). In addition, ATWS equipment needed to be qualified for the environmental conditions associated with anticipated operational occurrences and to ATWS conditions up to the time the required function is completed (Reference 1.5-10). The FSAR Section 15.8 ATWS analysis also needed to be revised.

In Reference 1.5-3, the NRC stated that the CGS alternate rod injection system was in compliance with the ATWS rule. The reference also stated that the RPT system required two modifications to be in compliance with the rule. Reference 1.5-4 documents the implementation of the changes required to resolve these two issues.

In Reference 1.5-5, Energy Northwest informed the NRC that confirmation of the environmental qualifications of ATWS equipment remained to be confirmed. Reference 1.5-6 documented that the confirmation had been completed.

In FSAR Amendment 42, Section 15.8 was revised to include new ATWS analyses. Technical Specification Amendment 93 was issued on August 9, 1991 which addressed modifications to the ATWS-RPT system. With this amendment, all activities required for ATWS resolution for CGS were completed.

A-10 BWR Feedwater Nozzle Cracking

NRC review of CGS relative to A-10 and NUREG-0619, which Generic Letter 89-21 states resolves this USI, is documented in NUREG-0892, Sections 3.9.3.1, 5.2.3.1, and 5.2.4. While these sections address A-10, they do not specifically state that the total issue is resolved for CGS. However, as no concerns were raised in the subsequent five supplements to NUREG-0892 and as Energy Northwest was not aware of a concern of the NRC's regarding A-10 subsequent to the issuance of the operating license, in Reference 1.5-1 Energy Northwest stated that it believed A-10 to be resolved for CGS. This position was apparently accepted by the NRC by the issuance of Reference 1.5-2.

A-11 Reactor Vessel Material Toughness

NRC acceptance of the CGS commitment to 10 CFR 50, Appendix G, is discussed in NUREG-0892, Section 5.3.2. In NUREG-0744 and Generic Letter 82-26 issued subsequent to the publication of the original issue of NUREG-0892, a response by licensees was not required; they only provided guidance to licensees who may have been required to submit a fracture analysis to justify continued operation. This was not the case for CGS.

A-17 Systems Interactions

Generic Letter 89-18 issued September 6, 1989 transmitted NRC final resolution of this USI. No formal reply was required. Energy Northwest incorporated information contained and referenced in this Generic Letter into the CGS IPE program, the results of which were

submitted to the NRC by Reference 1.5-22. However, as no formal action to Generic Letter 89-18 was required, Energy Northwest considered this USI closed for CGS prior to the completion of the IPE. This was so stated in Reference 1.5-1.

A-24 Qualification of Class 1E Safety Related Equipment

In NUREG-0892 Supplement 4, Section 3.11.5, the NRC states that CGS has demonstrated conformance to NUREG-0588. Generic Letter 89-21 states that Revision 1 to NUREG-0588 resolved A-24. By NRC memorandum, J. Knight to T. Novak, dated November 1983 (8312120370), Mr. Knight states that the CGS review was to Revision 1 of the NUREG.

A-31 Residual Heat Removal Shutdown Requirements

NUREG-0892 states in Section 5.4.2.1 that the CGS RHR system conforms to the Commission's regulations and applicable Regulatory Guides. Generic Letter 89-21 states that A-31 was resolved in May 1978 by publication of SRP 5.4.7. As NUREG-0892 was written in May 1982, Energy Northwest stated in Reference 1.5-1 that this established closure of A-31 for CGS.

A-36 Control of Heavy Loads

NUREG-0892 Supplement 4, Section 9.1.5, states that the guidelines of NUREG-0612 have been satisfied for CGS. Generic Letter 89-21 states that NUREG-0612 resolves A-36.

A-39 Determination of Safety Relief Valve Pool Dynamic Load and Temperature Limits

Section 6.2.1.8 of NUREG-0892 Supplements 1 and 4, provides NRC acceptance of the resolution of this issue for CGS.

A-40 Seismic Design Criteria

NUREG-1233 issued September 1989 states that the proposed changes that constitute the resolution of USI-40 are to apply to new applicants only. CGS is not one of the plants identified in Generic Letter 89-21 that needed to be reviewed to the new criteria.

A-42 Pipe Cracks in Boiling Water Reactors

NUREG-0892 states in Section 5.2.3.1 that CGS conforms to the requirements of NUREG-0313, Revision 1, which Generic Letter 89-21 states resolves A-42. NUREG-0892 Supplement 5, Section 5.2.3.2, provides additional information on this issue. Also see Section 5.2.3.2.3. Additional consideration for BWR pipe cracks beyond the scope of A-42 were raised by the NRC in Generic Letter 88-01. The resolution of Generic Letter 88-01 for CGS

is provided in References 1.5-21, 1.5-35, and 1.5-36, and in the Bases for CGS Technical Specifications.

A-43 Containment Emergency Sump Performance

Generic Letter 89-21 states that resolution of A-43 only applies to new plants (i.e., those reviewed after October 1985) and, as such, does not apply to CGS.

A-44 Station Blackout

See Appendix 8A.

A-45 Shutdown Decay Heat Removal

According to guidance provided in Generic Letter 89-21 and Supplement 9 to NUREG-0933, Energy Northwest incorporated closure of A-45 into the CGS IPE program the results of which were submitted to the NRC by Reference 1.5-22.

A-46 Seismic Qualification of Equipment in Operating Plants

Generic Letter 87-03 issued February 27, 1987 which addresses A-46 resolution for CGS did not require any action or plant review. NUREG-1211, Enclosure 1, established Generic Letter 87-03 as applicable to CGS rather than Generic Letter 87-02. As such, Energy Northwest considers this USI closed for CGS. Also, NUREG-0892, Supplement 5 in Appendix C states that A-46 only applies to plants that were operating at the time.

A-47 Safety Implication of Control System

Generic Letter 89-19 provides requirements to close A-47. The overfill protection system required of BWRs is provided for in CGS. Closure of this issue was provided by Reference 1.5-9.

A-48 Hydrogen Control Measures and Effects of Hydrogen Burn on Safety Equipment

As stated in Generic Letter 89-21, A-48 is closed and implemented for Mark II BWRs such as CGS.

1.5.1.1.3 Unresolved Safety Issues Implementation Summary

The resolution of all USIs for CGS has been achieved with the NRC. Regarding Station Blackout (A-44), 10 CFR 50.63(c)(4) provides for a 2 year implementation schedule for closure of identified modifications.

1.5.1.2 Generic Safety Issues

1.5.1.2.1 Generic Safety Issues Introduction

In Generic Letter 90-04, Reference 1.5-12, the NRC requested that licensees and construction permit holders address a list of specific generic safety issues (GSIs) listed in the generic letter. Energy Northwest's response to this request for CGS was provided in Reference 1.5-13.

1.5.1.2.2 Implementation of Specific Generic Safety Issues

The following summarizes the CGS implementation of applicable GSIs listed in Generic Letter 90-04 and other GSIs that have been resolved for CGS subsequent to the issuance of the Generic Letter. The following is a summary of information provided in Reference 1.5-13 with updated information provided as appropriate.

GSI/Subject	*Status*
40/BWR Scram System Pipe Breaks	*Closed as documented in NUREG-0892 (p. 4-4) and documents listed in Reference 1.5-13*
41/BWR Scram Discharge Volume	*Closed as documented in NUREG-0892 (p. 7-6)*
43/Reliability of Air Systems	*Closed as discussed in References 1.5-13 and 1.5-15*
48/LCOs for Class 1E vital Instrumentation Buses - Generic Letter 91-11 (added subsequent to Generic Letter 90-04 response)	*Closed as documented in Reference 1.5-19*
49/Interlocks and LCOs for Class 1E Tie Breakers - Generic Letter 91-11 (added subsequent to Generic Letter 90-04 response).	*Closed as documented in Reference 1.5-19*
51/Improved Reliability of Open-Cycle Service Water Systems	*Closed subsequent to Generic Letter 90-04 as addressed by References 1.5-11, 1.5-37, and 1.5-38*

67/Improved Accident Safety Report Monitoring	*Closed as summarized in NRC Evaluation for CGS Regulatory Guide 1.97 implementation (Reference 1.5-14)*
75/Salem ATWS Events	*Closed subsequent to the Generic Letter 90-04 response by letters listed in Reference 1.5-13, Reference 1.5-17, and issuance of Technical Specification Amendment 90. Generic Letter 83-28, Supplement 1, issued October 7, 1992, did not change this status as CGS does not use reactor trip breakers.*
79/RPV Thermal Stress During Natural Convection Cooldown	*Closed subsequent to Generic Letter 90-04 by Generic Letter 92-02 as not impacting BWRs*
86/Long Range Plan for Stress Corrosion Cracking in BWR Piping	*Closed based upon documents listed in Reference 1.5-13.*
A-13/Snubber Operability Assurance	*NUREG-0933 states that this issue was resolved in 1980 by revision to the Standard Technical Specifications (STS). As the original CGS Technical Specifications were based upon Revision 3 to the BWR STS issued in 1980, this concern is resolved for CGS. In particular, for the five issues mentioned for GSI A-13 resolution in Generic Letter 90-04:* *1. The arbitrary capacity limit of 50,000 lbs that previously existed in Technical Specifications does not appear in the CGS Technical Specifications.* *2. The requirement for NRC approval of seal material does not appear in the CGS Technical Specifications.* *3, 4. Monitoring and IST programs to ensure snubber reliability do exist in the CGS Licensee Controlled Specifications. They are significantly expanded from that included in earlier programs.*

	5. The CGS Licensee Controlled Specifications allow for an in-place snubber IST program. *Thus, the five requirements of A-13 resolution as discussed in Generic Letter 90-04 have been implemented for CGS*
A/30 Adequacy of Safety Related DC Power Supplies - Generic Letter 91-06 (added subsequent to Generic Letter 90-04 response)	*Closed as documented in Reference 1.5-18*
A-35/Adequacy of Offsite Power Systems	*Closed as documented in NUREG-0892 (p. 8-16) and discussed in Reference 1.5-13)*
B-63/Installation of Low Pressure Systems Connected to the RCPB	*Closed as discussed in Question 040.079 (FSAR Volume 22) and Reference 1.5-13*

1.5.1.2.3 Generic Safety Issues Implementation Summary

Implementation of the applicable GSIs of Generic Letter 90-04 is complete.

1.5.1.3 TMI Task Action Plans

The CGS responses to the TMI-2 action plans as they were included in NUREG-0737 are provided in Appendix B. This Appendix agrees with Reference 1.5-16 in documenting that all TMI Task Action Plans have been implemented for CGS.

1.5-7 *Letter, R. B. Samworth (NRC) to G. C. Sorensen (SS), "Issuance of Amendment No. 43," dated May 29, 1987.*

1.5-8 *Letter, GO2-89-062, G. C. Sorensen (SS) to NRC, "Response to Station Blackout Rule using HPCS Diversion III as Alternate AC Power," dated April 17, 1989.*

1.5-9 *PL Eng (NRC) to G. C. Sorensen (SS), Response to "Request for Action Related to Resolution of Unresolved Safety Issue A-47 - Safety Implications of Control System in LWR Nuclear Power Plants, pursuant to 10 CFR 50.54(f) - Generic Letter 89-19 (TAC NO. 75019)," dated November 13, 1991.*

1.5-10 *BWROG Topical Report NEDE-31096-P, "Anticipated Transients Without Scram; Response to NRC ATWS Rule 10 CFR 50.62," dated December 1985.*

1.5-11 *Letter, PL Eng (NRC) to G. C. Sorensen (SS), Evaluation of Response to NRC Generic Letter 89-13, "Service Water System Problems Affecting Safety-Related Equipment (TAC No. 74086)," dated April 26, 1992.*

1.5-12 *Generic Letter 90-04, "Request for Information on the Status of Licensee Implementation of Generic Safety Issues Resolved With Imposition of Requirements or Corrective Actions," dated April 25, 1990.*

1.5-13 *Letter, GO2-90-113, G. C. Sorensen to NRC, "Response to Generic Letter 90-04 Regarding Status of Implementation of Generic Safety Issues, (TAC No. 75993)," dated June 28, 1990.*

1.5-14 *Letter, G. W. Knighton (NRC) to G. C. Sorensen (SS), "Emergency Response Capability - Conformance to Regulatory Guide 1.97, Revision 2, (TAC No. 59516)," dated March 23, 1988.*

1.5-15 *Letter, GO2-89-128, G. C. Sorensen to NRC, "Final Response to Generic Letter 88-14, 'Instrument Air Supply Problems Affecting Safety-Related Equipment," dated July 28, 1989.*

1.5-16 NUREG-1435 Supplement 2, "Status of Safety Issues at Licensed Power Plants," dated December 1992.

1.5-17 Letter, P. L. Eng (NRC) to G. C. Sorensen (SS), "Response to Generic Letter 90-03 for Washington Nuclear Plant 2 (TAC No. 76314)," dated November 8, 1990.

1.5-18 Letter, W. M. Dean (NRC) to G. C. Sorensen (SS), "Response to Generic Letter 91-06, MPA L106, Resolution of Generic Issue A-30, Adequacy of Safety Related DC Power Supplies, Pursuant to 10 CFR 50.54(f) for Washington Public Power Supply System Unit 2 (TAC NO. M81515)," dated March 27, 1992.

1.5-19 Letter, P. L. Eng (NRC) to G. C. Sorensen (SS), "Response to Generic Letter 91-11, 'Resolution of Generic Issues 48-LCOs for Class 1E Vital Instruments Buses and 49 - Interlocks and LCOs for Class 1E Tie Breakers' pursuant to 10 CFR 50.54(f) for Washington Public Power Supply System Nuclear Plant No. 2 (TAC No. M82484)," dated March 2, 1992.

1.5-20 Letter, P. L. Eng (NRC) to G. C. Sorensen (SS), "Status of TMI Item I.D.1.2, 'Detailed Control Room Design Review (DCRDR) at Washington Public Power Supply System Nuclear Project No. 2 (WNP-2) (TAC No. 56181)," dated November 13, 1991.

1.5-21 Letter, P. L. Eng (NRC) to G. C. Sorensen (SS), "Response to GL 88-01, Intergranular Stress Corrosion in Piping (TAC No. 69161)," dated December 28, 1990.

1.5-22 Letter, GO2-92-206, G. C. Sorensen (SS), "Response to Generic Letter 88-20," Individual Plant Examinations for Severe Accident Vulnerabilities 10 CFR 50.54(f)," dated August 28, 1992.

1.5-23 through 1.5-34 Deleted

1.5-35 Letter, GO2-92-004, G. C. Sorensen to NRC, "Response to NRC SER on Generic Letter 88-01 (TAC No. 69161)," dated January 8, 1992.

1.5-36 Letter, GO2-92-086, G. C. Sorensen to NRC, "Additional Response to Generic Letter 88-01 Safety Evaluation Report (TAC Nos. M80358 and M69161)," dated April 10, 1992.

1.5-37 *Letter, GO2-90-017, G. C. Sorensen to NRC, "Response to Generic Letter 89-13, Service Water System Problem Affecting Safety-Related Equipment," dated February 5, 1990.*

1.5-38 *Letter, GO2-91-041, G. C. Sorensen to NRC, "Response to Generic Letter 89-13, Service Water System Problems Affecting Safety-Related Equipment," dated February 28, 1991.*

1.6 MATERIAL INCORPORATED BY REFERENCE

Table 1.6-1 is a list of General Electric topical reports and other reports and documents which are incorporated in whole or in part by reference. These documents were filed with the NRC.

Table 1.6-1

Topical Reports

Report	Title	FSAR Section
General Electric Company		
APED-4824	Maximum Two-Phase Vessel Blowdown from Pipes (April 1965)	6.2
APED-5458	Effectiveness of Core Standby Cooling Systems for General Electric Boiling Water Reactors (March 1968)	5.4
APED-5460	Design and Performance of General Electric BWR Jet Pumps (July 1968)	3.9
APED-5555	Impact Testing on Collet Assembly for Control Rod Drive Mechanism 7RDB144A (November 1967)	4.6
APED-5640	Xenon Considerations in Design of Large Boiling Water Reactors (June 1968)	4.1
APED-5652	Stability and Dynamic Performance of the General Electric Boiling Water Reactor (April 1969)	4.1
APED-5696	Tornado Protection for the Spent Fuel Storage Pool (November 1968)	3.3, 3.5, 9.1
APED-5706	Incore Neutron Monitoring System for General Electric Boiling Water Reactors (November 1968; revised April 1969)	7.6
APED-5750	Design and Performance of General Electric Boiling Water Reactor Main Steam Line Isolation Valves (March 1969)	3.9, 5.4
GEAP-5620	Failure Behavior in ASTM A106B Pipes Containing Axial Through-Wall Flaws (April 1968)	5.2

Table 1.6-1

Topical Reports (Continued)

Report	Title	FSAR Section
GEAP-10546	Theory Report for Creep-Plast Computer Program (January 1972)	4.1
GEAP-13197	Emergency Cooling in BWRs Under Simulated Loss-of-Coolant (BWR PLECMP) Final Report (June 1971)	6.2
GE-NE-778-028-0790	GE Duralife 215 Control Rod Safety Evaluation, Revision 2 (July 1992)	4.2
GE-NE-187-24-0992	Washington Public Power Supply System Nuclear Project 2, SRV Setpoint Tolerance and Out-of-Service Analysis, Revision 2 (July 1993)	6.3
NEDC-31984-P	Generic Evaluations of General Electric Boiling Water Reactor Power Uprate - (July 1991)	5.4, 15.8
NEDC-32115-P	Washington Public Power Supply System Nuclear Project 2, SAFER/GESTR-LOCA Loss-of-Coolant Accident Analysis (September 1992)	6.3
NEDC-32141-P	Power Uprate With Extended Load Line Limit Safety Analysis for WNP-2 (June 1993)	5.4, 15.8
NEDC-32232-P	WNP-2 Reactor Recirculation Adjustable Speed Drive (ASD) System Reliability Analysis (August 1993)	7.7
NEDC-32983-P-A	General Electric Methodology for Reactor Pressure Vessel Fast Neutron Flux Evaluations (January 2006)	4.3.2.8, 4.3.4
NEDC-33507-P	Energy Northwest Columbia Generating Station APRM/RBM/Technical Specifications/Maximum Extended Load Line Limit Analysis (ARTS/MELLLA), Revision 1 (January 2012)	15.4

Table 1.6-1

Topical Reports (Continued)

Report	Title	FSAR Section
NEDE-10169	Safe-System Analysis for Standby Core Cooling Equipment (September 1970)	3A
NEDE-10313-P	PDA - Pipe Dynamic Analysis Program for Pipe Rupture Movement	3.6
NEDE-11146-P	Design Basis for New Gas System (July 1971)	11.3
NEDE-13442-P-01	Mark II - Pressure Suppression Test Program (May 1976)	3A
NEDE-20944-P	BWR/4 and BWR/5 Fuel Design (October 1976)	Table 1.3-1
NEDE-21175-3-P	Fuel Assembly Evaluation of Combined Safe Shutdown Earthquake (SSE) and Loss-of-Coolant Accident (LOCA) Loadings (July 1982)	3.9
NEDE-21354-P	BWR Fuel Channel Mechanical Design and Deflection (September 1976)	3.9
NEDE-21471-P	Analytical Model for Estimating Drag Forces on Rigid Submerged Structures Caused by LOCA and Safety/Relief Valve Ramshead Air Discharges (September 1977)	3A
NEDE-21544-P	Mark II Pressure Suppression Containment System, an Analytical Model of the Pool Swell Phenomenon (December 1976)	3A, 6.2
NEDE-21821	BWR Feedwater Nozzle/Sparger Final Report (March 1978)	5.2, 5.3
NEDE-23604	Brunswick Unit 1 Reactor Internals Vibration and Temperature Measurements (June 1977)	5.3

Table 1.6-1

Topical Reports (Continued)

Report	Title	FSAR Section
NEDE-23749-P	Analytical Model for Computing Transient Pressure and Forces in the S/RVDL (February 1978)	3.9
NEDE-23806-P	MK II Main Vent Lateral Loads Summary Report (October 1978)	3A
NEDE-24010-P	Technical Bases for the Use of the SRSS Method for Combining Dynamic Loads for Mark II Plants (July 1977) with Supplement 1 (October 1978), Supplement 2 (December 1978), and Supplement 3 (August 1979)	3.9
NEDE-24011-P-A	General Electric Standard Application for Reactor Fuel (most recent approved version referenced in COLR)	1.8, 3.9, 4.1, 4.2, 4.3, 4.4, 15.1, 15.4
NEDE-24057-P	Assessment of Reactor Internals Vibration in BWR/4 and BWR/5 Plants (November 1977)	3.9
NEDE-24106-P	Dynamic Lateral Loads on a Main Vent Downcomer - Mark II Containment (March 1978)	3A
NEDE-24222	Assessment of Boiling Water Reactor Mitigation of Anticipated Transient Without Scram, Volume II (December 1979)	15.8
NEDE-24285-P	Chugging Loads - Revised. Definition and Application Methodology for Mark II Containments (July 1981)	3A
NEDE-24288-P	Generic Condensation Oscillation Load Definition Report (November 1980)	3A
NEDE-24302-P	Generic Chugging Load Definition Report (April 1981)	3A

Table 1.6-1

Topical Reports (Continued)

Report	Title	FSAR Section
NEDE-24695	RVF0R04 User's Manual, S/RVDL Clearing Transient Pressures and Forces in the S/RDL (December 1979)	3.9
NEDE-24794-P	Dynamic Lateral Loads on Mark II Main Vent Downcomer - Correlation of Independent Reference Data (March 1980)	3A
NEDE-24811-P	4T Condensation Oscillation Test Program Final Test Report (May 1980)	3A
NEDE-24822-P	Mark II Improved Chugging Methodology (May 1980)	3A
NEDE-24834	Hanford 2 Crimped Control Rod Drive Line (June 1980)	3.6
NEDE-24988-P	Analysis of Generic BWR Safety/Relief Valve Operability Test Results (October 1981)	5.2, 5.4, Table F.4-1
NEDE-25100-P	CAORSO SRV Discharge Tests Phase I Test Report (May 1979)	3A
NEDE-25118	CAORSO SRV Discharge Tests Phase II ATR Report (August 1979)	3A
NEDE-31096-P	Licensing Topical Report, Anticipated Transient Without Scram (February 1987)	4.6, 7.4, 9.3
NEDM-10320	The General Electric Pressure Suppression Containment Analytical Model (March 1971)	3A, 6.2
NEDO-10029	An Analytical Study on Brittle Fracture of GE BWR Vessel Subject to the Design Basis Accident (July 1969)	1.8
NEDO-10320	The General Electric Pressure Suppression Containment Analytical Model (April 1971)	3A 6.2

1.7 ACRONYMS

The acronyms used in this FSAR follow

ACI	American Concrete Institute
ACRS	Advisory Committee on Reactor Safeguards
ADS	automatic depressurization system
AEC	Atomic Energy Commission
AISC	American Institute of Steel Construction
ALARA	as low as is reasonably achievable
ALI	annual limit on intake
AMP	Aging Management Programs
ANSI	American National Standards Institute
APRM	average power range monitor
ARM	area radiation monitor
ART	adjusted reference temperature
AS	auxiliary steam
ASCE	American Society of Civil Engineers
ASD	adjustable speed drive
ASME	American Society of Mechanical Engineers
ASTM	American Society for Testing and Materials
ATWS	anticipated transient without scram
AWS	American Welding Society
B&R	Burns and Roe, Inc.

BISI	bypass & inoperable status indication
BOC	beginning of cycle
BPA	Bonneville Power Administration
BPC	Bechtel Power Corporation
BWR	boiling water reactor
BWROG	Boiling Water Reactor Owners Group
BWRVIP	BWR Vessel and Internals Project
CAS	central alarm station, control air system
CASS	Cast Austenitic Stainless Steel
CEP	containment exhaust purge
CGS	Columbia Generating Station
CHF	critical heat flux
CIA	containment instrument air
CLB	current licensing basis
CMFA	common mode failure analysis
COLR	Core Operating Limits Report
COND	main condensate system
CPR	critical power ratio
CRA	primary containment cooling system
CRD	control rod drive
CRDA	control rod drop accident
CRDRL	control rod drive return line

CREF	control room emergency filtration
CRPI	control rod position indication
CSP	containment purge supply
CST	condensate storage and transfer, condensate storage tank
CUF	Cumulative Usage Factor
CW	circulating water
DAC	derived air concentrations
DAW	dry active radioactive waste
DB	design basis
DBA	design basis accident
DBE	design basis earthquake
DG	diesel generator
DEH	digital electrohydraulic
DLR	dosimeter of legal record
DOE	Department of Energy
DOP	dioctylphthalate
DSA	Diesel Starting Air
DZO	depleted zinc oxide
ECA	engineering change authorization
ECCS	emergency core cooling system
ECN	engineering change notice
EDR	equipment drain (radioactive) processing

EFCV	excess flow check valve
EFPY	Effective Full Power Years
EHC	electrohydraulic control
EMA	Equivalent Margin Analysis
EOC	end of cycle
EOF	emergency operations facility
EPA	electrical protection assembly
EPN	equipment piece number
EPRI	Electric Power Research Institute
EPZ	emergency planning zone
EQ	Environmental Qualification, Environmentally Qualified
ESF	engineered safety feature
EWD	electrical wiring diagram
FA	full arc (mode of TGV operation)
FAC	Flow Accelerated Corrosion
FANP	Framatome ANP
F-B/V	front to back/vertical
FCD	functional control diagram
FCV	flow control valve
FDDR	Field Deviation Disposition Request
FDR	floor drain (radioactive) processing system
FLECHT	full-length emergency cooling heat transfer

FMEA	failure modes effects analysis
FPC	fuel pool cooling and cleanup
FSAR	Final Safety Analysis Report
GE	General Electric Company
HAD	heat actuated device
HCA	horizontal control accelerometer
HCU	hydraulic control unit
HCV	Hardened Containment Vent
HELB	high energy line break
HEPA	high-efficiency particulate air/absolute
HID	high-intensity discharge (lighting--vapor lamp)
HPCS	high-pressure core spray
H&V	heating and ventilating
HVAC	heating, ventilating, and air conditioning
HX	heat exchanger
IASCC	Irradiation Assisted Stress Corrosion Cracking
IBA	intermediate break accident
IDC	incident detection circuitry
IDS	instrument data sheet
IED	instrument engineering diagram
IEEE	Institute of Electrical and Electronics Engineers
IGA	Intergranular Attack

IGSCC	intergranular stress corrosion cracking
IHSI	Induction Heat Stress Improvement
IRM	intermediate range monitor
ISA	Instrument Society of America
ISI	In-Service Inspection
ISP	Integrated Surveillance Program
LCO	Limiting Condition of Operation
LCS	leak control system
LDS	leak detection system
LHGR	linear heat generation rate
LLRT	local leak rate test
LOCA	loss-of-coolant accident
LPCI	low-pressure coolant injection
LPCS	low-pressure core spray
LPRM	local power range monitor
LPZ	low population zone
LRA	License Renewal Application
LSSS	limiting safety system setting
MAPLHGR	maximum average planar linear heat generation rate
MCC	motor control center
MCPR	minimum critical power ratio
MEL	Master Equipment List

MG	motor-generator
MLD	mean low water datum
MLHGR	maximum linear heat generation rate
MOV	motor-operated valve
MS	main steam
MSIV	main steam isolation valve
MSIV-LCS	main steam isolation valve leakage control system
msl	mean sea level
MSL	main steam line
MSLC	main steam isolation valve leakage control
MWR	mixed waste (radioactive)
MWt	Megawatt thermal
NB	nuclear boiler
NBR	nuclear boiler rated (power)
NDE	nondestructive examination
NDT	nil-ductility transition
NDTT	nil-ductility transition temperature
NEC	National Electrical Code
NED	Nuclear Energy Division (GE)
NFPA	National Fire Protection Association
NEPIA	Nuclear Energy Property Insurance Association
NMS	neutron monitoring system

NPDES	National Pollutant Discharge Elimination System
NPHS	net positive suction head
NRC	Nuclear Regulatory Commission
NSAS	non-safety affecting safety
NSOA	nuclear safety operational analysis
NSSS	nuclear steam supply system
NSSSS	nuclear steam supply shutoff system
OBE	operating basis earthquake
OQAPD	Operational Quality Assurance Program Description
ODCM	Offsite Dose Calculation Manual
OPRM	Oscillation Power Range Monitor
OSHA	Occupational Safety and Health Act
OT	operating transient
OS&Y	outside screw and yoke
OT	operating transient
PA	Public Address (System)
PABX	Private Automatic Branch Exchange
PATP	Power Ascension Test Program
PCIOMR	preconditioning cladding interim operating management recommendation
PCRVICS	primary containment and reactor vessel isolation control system
PCS	process computer system

PCT	peak cladding temperature
PDIS	plant display information system
PEC	Plant Engineering Center
PGCC	power generation control complex
P&ID	piping and instrumentation diagram
PMF	probable maximum flood
PPM	Plant Procedure Manual
PRM	power range monitor
PSAR	Preliminary Safety Analysis Report
PSF	Plant Support Facility
PVS	plant vent stack
RBM	rod block monitor
RCC	reactor building closed cooling water
RCIC	reactor core isolation cooling
RCPB	reactor coolant pressure boundary

1.8 CONFORMANCE TO NRC REGULATORY GUIDES

1.8.1 INTRODUCTION

This section of the FSAR contains information on Energy Northwest's conformance assessment of CGS to Regulatory Guides, Division 1, Power Reactor Guides and revisions thereof as noted.

Since the scope of equipment responsibility is project unique and the time of equipment design, procurement, manufacture, installation, and operation varies with the supplier, a unique assessment for the nuclear steam supply system (NSSS) scope of supply and balance of plant (BOP) scope of supply is necessary and is presented.

1.8.2 NUCLEAR STEAM SUPPLY SYSTEM SCOPE OF SUPPLY EVALUATION

The following paragraphs define the nomenclature and the manner in which the NSSS scope of supply assessment is to be interpreted.

Regulatory Guides - Incorporated in the Design

This section serves to identify specific safety or regulatory guides which were included in the plant as a design commitment during the construction permit review. It also identifies those incorporated by commitment after the construction permit issuance. All of these are specifically noted as "Incorporated in the Design."

Regulatory Guides - Assessed Capability in the Design

For those other regulatory guides which have been issued before, during, or after the construction permit issuance, Energy Northwest (through his agents and/or suppliers) has performed an assessment evaluation to determine the capability of the previously approved design to accommodate and meet these new requirements. These are noted as "Assessed Capability in the Design."

Conformance to the regulatory guide falls under either one of two categories - "Full Compliance" or "Meeting Intent Through an Alternate Approach."

Regulatory Guide - Full Compliance

Any regulatory guide so noted, whether by direct conformance or by assessed capability, complies with subject requirements as described in the FSAR.

Regulatory Guide - Meeting Intent by Alternate Approach

This designation is based on NRC rules which state that "Regulatory Guides are not substitutes for regulations, and compliance with them is not required. Methods and solutions different from those set out in the guides will be acceptable if they provide a basis for the findings requisite to the issuance or continuance of a permit or license by the Commission." The description and justification of an alternate approach is provided where this method is employed.

The following evaluation represents the NSSS scope of supply regulatory guide assessment.

Regulatory Guide 1.1, Revision 0, November 1970

Net Positive Suction Head for Emergency Core Cooling and Containment Heat Removal Pumps.

Regulatory Guide Intent:

This guide prohibits design reliance on pressure and/or temperature transients expected during a loss-of-coolant accident (LOCA) for ensuring adequate net positive suction head (NPSH). The requirements of this regulatory guide are applicable to the high-pressure core spray (HPCS), low-pressure core spray (LPCS), and residual heat removal (RHR) pumps.

Applicable Assessment:

Incorporated in design.

Compliance or Alternate Approach Statement:

Identified NSSS scope of supply analysis, design, and/or equipment used in CGS is in full compliance with this regulatory guide.

General Compliance or Alternate Approach Assessment:

The boiling water reactor (BWR) design conservatively assumes 0 psig containment pressure and maximum expected temperature of the pumped fluids; thus no reliance is placed on pressure and/or temperature transients to assure adequate NPSH.

Requirements for NPSH are available at the centerline of the pump suction nozzles for each pump.

Specific Evaluation Reference:

See Sections 6.2 and 6.3.

Similar Application Reference:

Similar application was used for LaSalle and GESSAR.

Regulatory Guide 1.2, Revision 0, November 1970

Thermal Shock to Reactor Pressure Vessels

Regulatory Guide Intent:

This regulatory guide states that potential reactor pressure vessel brittle fracture which may result from emergency core cooling systems (ECCS) operation need not be reviewed in individual cases if no significant changes in presently approved core and pressure vessel designs are proposed. Should it be concluded that the margin of safety against reactor pressure vessel brittle failure due to ECCS operation is unacceptable, and engineering solution, such as annealing, could be applied to ensure adequate recovery of the fracture toughness properties of the vessel material. This regulatory guide requires that available engineering solutions be outlined and requires that it be demonstrated that the design does not preclude their use.

Application Assessment:

Incorporated in design.

Compliance or Alternate Approach Statement:

Identified NSSS scope of supply analysis, design, and/or equipment used in CGS is in compliance with the intent of this regulatory guide through the incorporation of the alternate approach cited.

General Compliance or Alternate Approach Assessment:

The reactor pressure vessel used for CGS employs no significant core or vessel design changes from previously approved BWR pressure vessels such as Browns Ferry, all units.

An investigation of the structural integrity of BWR pressure vessels during a design-basis accident (DBA) has been conducted (see NEDO-10029, "An Analytical Study on Brittle Fracture of GE-BWR Vessel Subject to the Design Basis Accident"). It has been determined, based on methods of fracture mechanics, that no failure of the vessel by brittle fracture as a result of a DBA will occur.

The investigation included

a. A comprehensive thermal analysis considering the effect of blowdown and the LPCI system reflooding,

b. A stress analysis considering the effects of pressure, temperature, seismic load, jet load, dead weight, and residual stresses,

c. The radiation effect on material toughness [nil ductility transition temperature (NDTT) shift and critical stress intensity], and

d. Methods for calculating crack tip stress intensity associated with a nonuniform stress field following DBA.

This analysis incorporated very conservative assumptions in all areas (particularly in the areas of heat transfer, stress analysis effects of radiation on material toughness, and crack tip stress intensity). Therefore, the results reported in NEDO-10029 provide an upper bound limit on brittle fracture failure mode studies. Because of the upper bound approach, it is concluded that catastrophic failure of the pressure vessel due to the DBA is shown to be impossible from a fracture mechanics point of view. In the case studies, even if an acute flaw does form on the vessel inner wall, it will not propagate as the result of the DBA.

The criteria of 10 CFR 50, Appendix G, are interpreted as establishing the requirement for annealing. Paragraph IV C of Appendix G requires vessels to be designed for annealing of the beltline only where the predicted value of adjusted RT_{NDT} exceeds 200°F as defined in paragraph NB2331 of the ASME Section III Code. This predicted value is not exceeded; therefore design for annealing is not required.

Specific Evaluation Reference:

See Section 5.3.1.5.

Similar Application Reference:

Similar application was used for Browns Ferry 1, 2, and 3.

Regulatory Guide 1.6, Revision 0, March 1971

Independence Between Redundant Standby (Onsite) Power Source and Between Their Distribution Systems

Regulatory Guide Intent:

The guide states the extent and nature of independence of the two onsite power divisions required by General Design Criterion (GDC) 17. Key features that ensure operation and prevent cascading single failures from disrupting both power systems are delineated.

Application Assessment:

Incorporated in design.

Compliance or Alternate Approach Statement:

Identified NSSS scope of supply analysis, design, and/or equipment used in this facility is in compliance with the intent of this regulatory guide through the incorporation of the alternate approach cited.

General Compliance or Alternate Approach Assessment:

This regulatory guide is applicable to redundant standby (onsite) power sources and their distribution systems.

HPCS Onsite Power System (NSSS Scope of Supply)

Division 3 (HPCS) is provided with one offsite power source. Only one offsite supply is connected because no credit is given to offsite power sources in accident analysis. The diesel generator breaker can be closed automatically only if the other source breakers to the (HPCS) load group are open.

When the HPCS diesel generator breaker is closed, no other source breaker can be closed automatically. No other means exist for automatically connecting redundant load groups with each other. The HPCS diesel generator may be manually connected to either Division 1 or to Division 2 in the extended station blackout (SBO) or non-DBA loss of offsite power (LOOP) scenario described in Section 8.3.1.1.7.2.1. The source breakers are administratively controlled in the open position to prevent paralleling of standby sources.

Sufficient interlocks are provided to prevent paralleling the diesel generators manually by operator error during loss of offsite power. Division 3 diesel generator is provided with only one prime mover.

The HPCS division dc load group is fed from one battery charger and one battery.

The HPCS standby power source and distribution system is independent from the other two standby power sources and associated distribution system in the plant.

Specific Evaluation Reference:

See Section 8.3.1.2.

Similar Application Reference:

Similar application was used for LaSalle.

Regulatory Guide 1.9, Revision 0, March 1971

Selection of Diesel Generator Set Capacity for Standby Power Supplies

Regulatory Guide Intent:

This guide provides an approach for ensuring sufficient onsite power capability and for determining load requirements of diesel generator set power sources.

Application Assessment:

Incorporated in design.

Compliance or Alternate Approach Statement:

Identified NSSS scope of supply analysis, design, and/or equipment used in this facility is in compliance with the intent of this regulatory guide through the incorporation of the alternate approach cited.

General Compliance or Alternate Approach Assessment:

This regulatory guide is applicable to the standby ac power supply for the HPCS diesel. The specific guidelines are unduly restrictive when applied to the selection of the diesel generator set dedicated to the HPCS system. This is mainly due to the unique application of the special HPCS equipment relative to normal diesel generator units.

Specific conformance and alternate positions to and with Regulatory Guide 1.9 are described in the following statements:

Regulatory Guide 1.9, Position 2 Conformance

Chapter 8 illustrates that the 2000-hr rating of the HPCS diesel generator, the 90% of 30-minute rating, and the maximum coincidental load, are in conformance with this position. Intermittent loads such as motor-operated valves are considered for long-term loads.

Regulatory Guide 1.9, Position 3 Conformance

CGS load requirements were verified as test data was completed and analyzed, following the preoperational tests.

Regulatory Guide 1.9, Position 4 Conformance

The HPCS diesel generator unit is considered as a unique application with justifiable departure from the strict conformance to Regulatory Guide 1.9, Revision 0, regarding voltage and frequency limits during the initial loading transient. The HPCS system consists of one large pump and motor combination which represents more than 90% of the total load; consequently, limiting the momentary voltage drop to 25% and the momentary frequency drop to 5% would not significantly enhance the reliability of HPCS operation. To meet the specific regulatory guide requirements, a diesel generator unit approximately two to three times as large as that required to carry the continuous rated load would be necessary. The specific diesel engine-electric generator-pump assembly was designed specifically for this integral operation. The frequency and voltage over-shoot requirements of Regulatory Guide 1.9, Revision 0, are met. A factory testing program on a prototype unit has verified the following functions:

a. System fast-start capabilities,

b. Load-carrying capability,

c. Load shedding capability,

d. Ability of the system to accept and carry the required loads, and

e. The mechanical integrity of the diesel-engine generator unit and all of the major system auxiliaries.

GE Licensing Topical Report, HPCS Power Supply, NEDO-10905, describes the theoretical analytical aspects of the unique application including prototype and reliability test considerations.

The design of the HPCS diesel generator conforms with the applicable sections of IEEE criteria for Class 1E "Electrical Systems for Nuclear Power Generation Stations," IEEE 308-1971.

The generator has the capability of providing power for starting the required loads with operationally acceptable voltage and frequency recovery characteristics. A partial or complete load rejection will not cause the diesel engine to trip on overspeed.

A special prototypic test conducted at the LaSalle facility verified the hardware and load aspects of the HPCS power supply concept. This test is described in topical report NEDO-10905, Revision 3.

The scope of Regulatory Guide 1.9, Revision 0 does not include recommendations for surveillance testing. The surveillance requirements for demonstrating the operability of the diesel generators are consistent with the recommendations of Regulatory Guide 1.9 Revision 3 as described in the Bases for Technical Specification B 3.8.1. Additionally, periodic testing of all diesel generators is accomplished at intervals specified in the Technical Specifications (TS) which are controlled under the Surveillance Frequency Control Program (SFCP). Compliance with Regulatory Guide 1.9 Rev. 0, as an acceptable basis for the selection of diesel generator sets of sufficient margin to implement General Design Criterion 17, remains as described herein.

Specific Evaluation Reference:

See Section 8.3.1.2.1.4.

Similar Application Reference:

Similar application was used for LaSalle; for comparison see Table 8.3-6.

Regulatory Guide 1.13, Revision 0, March 1971

Fuel Storage Facility Design Basis

Regulatory Guide Intent:

This guide delineates design criteria that are appropriately applied to the fuel storage facility of the CGS plant.

Application Assessment:

Incorporated in design.

Compliance or Alternate Approach Statement:

Identified NSSS scope of supply analysis, design, and/or equipment used in this facility is in compliance with the intent of this regulatory guide through the incorporation of the alternate approach cited.

General compliance or Alternate Approach Assessment:

This regulatory guide is applicable to the refueling platform within NSSS scope of supply.

The refueling platform is designed to prevent it from toppling into the pools during a safe shutdown earthquake (SSE). Redundant safety interlocks are provided as well as limit switches to prevent accidentally running the grapple into the pool walls.

Specific Evaluation Reference:

See Section 9.1.4.3.

Similar Application References:

Similar application was used for Nine Mile Point 2.

Regulatory Guide 1.20, Revision 2, May 1976

Comprehensive Vibration Assessment Program for Reactor Internals During Preoperational and Initial Startup Testing

Regulatory Guide Intent:

Regulatory Guide 1.20 describes a comprehensive vibration assessment program for reactor internals during preoperational and initial startup testing. The vibration assessment program meets the requirements of Criterion 1, "Quality Standards and Records," of Appendix A to 10 CFR Part 50 and Section 50.34, "Contents of Applications; Technical Information," of 10 CFR Part 50.

Application Assessment:

Incorporated in design.

Compliance or Alternate Approach Statement:

Identified NSSS scope of supply analysis, design, and/or equipment used in this facility is in compliance with the intent of this regulatory guide through the incorporation of the alternate approach cited.

General or Alternate Approach Statement:

This regulatory guide is applicable to the core support structures and other reactor internals.

A vibration measurement program has been defined for the confirmatory testing of this plant during initial startup tests.

CGS *reactor internals were tested in accordance with provisions of Regulatory Guide 1.20, Revision 2, Category IV, using Tokai-2 as the limited valid prototype.*

Specific Evaluation Reference:

See Sections 3.9.2.1, 3.9.2.3, and 3.9.2.4.

Similar Application Reference:

Similar application was used for Browns Ferry 1.

Regulatory Guide 1.21, Revision 1, June 1974

Measuring, Evaluating, and Reporting Radioactivity in Solid Wastes and Releases of Radioactive Materials in Liquid and Gaseous Effluents from Light-Water-Cooled Nuclear Power Plants

Regulatory Guide Intent:

Regulatory Guide 1.21 describes programs for measuring, reporting, and evaluating releases of radioactive materials in liquid and gaseous effluents and guidelines for classifying and reporting the categories and curie content of solid wastes.

Application Assessment:

Assessed capability in design.

Compliance or Alternate Approach Statement:

Identified NSSS scope of supply analysis, design, and/or equipment used in this facility is in compliance with the intent of this regulatory guide through the incorporation of the alternate approach cited.

General Compliance or Alternate Approach Assessment:

The process and effluent radiological monitoring and sampling system is designed to provide the monitoring and sampling capability required to make the measurements, evaluations, and reports recommended by this guide.

The Reactor Building elevated release duct radioactivity monitoring and sampling portion of the process radiation monitoring (PRM) system complies with ANSI N13.1-1999 (see Figure 11.5-11). All other portions of the PRM system, including the portion that monitors the effluent flow inside the Reactor Building elevated release duct, comply with ANSI N13.1-1969. All other systems comply with ANSI N13.1-1969.

The radiation monitoring systems (RMS) provided to meet these objectives are

a. For gaseous effluent streams

   Reactor building ventilation exhaust plenum RMS

b. For liquid effluent streams

   1. Radwaste effluent RMS, and

   2. Service water RMS

c. For gaseous process streams

1. Offgas pretreatment RMS,
2. Offgas posttreatment RMS, and
3. Carbon bed vault RMS

d. For liquid process streams

1. RHR service water RMS, and
2. Reactor building closed cooling water RMS

These systems have the capability for alarm and initiation of automatic closure of waste treatment discharge valves in the affected systems prior to exceeding the normal operation limits specified in Technical Specifications thereby satisfying the intent of the regulatory guide.

Specific Evaluation Reference:

See Sections 7.6.1.1 and 11.5.1 and 11.5.2.2.1.5.

Similar Application Reference:

Similar application has not been used for other projects.

Regulatory Guide 1.22, Revision 0, February 1972

Periodic Testing of Protection System Actuation Function

Regulatory Guide Intent:

This guide describes acceptable design approaches that facilitate the periodic testing, during reactor operation, of actuation devices/equipment incorporated into the reactor protection system design. This regulatory guide is applicable to the systems within NSSS scope of supply listed in this regulatory guide.

Application Assessment:

Incorporated in design.

Compliance or Alternate Approach Statement:

Identified NSSS scope of supply analysis, design, and/or equipment used for this facility is in full compliance with this regulatory guide.

General Compliance or Alternate Approach Assessment:

Compliance for each system is discussed for this plant in the listed references.

	Section
Reactor protection system	7.2.2.3
Emergency core cooling system	
HPCS	7.3.2.1.3
Automatic depressurization system (ADS)	7.3.2.1.3

Primary containment and reactor vessel isolation control system (PCRVICS)	7.3.2.1.3
Reactor core isolation cooling (RCIC)	7.4.2.3
Leak detection system	7.6.2.4
HPCS standby power supply	8.1.3
RHR system containment spray cooling system	7.3.2.1.3
Suppression pool cooling system	7.3.2.1.3
Reactor shutdown cooling system	7.4.2.3
Standby liquid control system	7.4.2.3
Process radiation monitoring system	7.6.2.4

Specific Evaluation Reference:

See above.

Similar Application Reference:

Similar application has not been used for other projects.

Regulatory Guide 1.26, Revision 3, February 1976

Quality Group Classifications and Standards for Water-, Steam-, and Radioactive-Waste-Containing Components of Nuclear Power Plants

Regulatory Guide Intent:

Regulatory Guide 1.26 describes a quality classification system for determining acceptable quality standards for important to safety components containing water, steam, or radioactive material other than those components addressed in 10 CFR 50.55a.

Application Assessment:

Assessed capability in design.

Compliance or Alternate Approach Statement:

Identified NSSS scope of supply analysis, design, and/or equipment used in this facility complies with the guidance set forth in this regulatory guide.

General Compliance or Alternate Approach Assessment:

The definition of quality group classifications for this plant was made initially and recorded in the Preliminary Safety Analysis Report (PSAR) in accordance with ASME Boiler and Pressure Vessel Code (B&PV), Sections III and VIII. Quality group classifications were maintained during design and construction and are actively maintained during plant operations and modifications commensurate with the safety functions performed by the safety-related components.

This regulatory guide is applicable to Quality Groups B through D pressure parts including piping, pumps, valves, and vessels. Section 3.2 shows the quality groups classifications of these parts.

Note: Classification of the RWCU system in the Radwaste Building takes exception to Reg. Guide 1.26. Piping, pumps, valves, and supports of the RWCU system in the Radwaste Building have been reclassified as Quality Group D, taking exception to the Reg. Guide 1.26 recommended classification of Quality Group C. Quality Group classification does meet the intent of Reg. Guide 1.26 footnote 6. Valves RWCU-V-40, RWCU-V-5A, RWCU-V-5B, RWCU-V-768, and RWCU-V-769 provide additional leak tight isolation of the reclassified from the Reactor Coolant Pressure Boundary.

Specific Evaluation Reference:

See Section 3.2.

Similar Application Reference:

Similar application was used for LaSalle.

The italicized information is historical and was provided to support the application for an operating license.

Regulatory Guide 1.28, Revision 0, June 1972

Quality Assurance Program Requirements (Design and Construction).

Regulatory Guide Intent:

This guide describes an acceptable method of complying with the NRC's regulations with regard to overall quality assurance program requirements.

Application Assessment:

Assessed capability in design.

Compliance or Alternate Approach Statement:

The identified BWR Quality Assurance Program used in this facility reflects compliance with provisions of NRC regulations and regulatory guides or NRC-approved alternate positions.

General Compliance or Alternate Approach Assessment:

The General Electric BWR Quality Assurance Program has been developed over the years such that at any point in time it has been in compliance with mandatory regulatory requirements such as 10 CFR 50, Appendix B, and the ASME Code. Implementation of the applicable ANSI-N45.2 series standards and the associated NRC regulatory guides (or NRC-approved GE alternate positions) has been an evolutionary process and although partial implementation has always been effected before the date of issue of the regulatory guide or "AEC Guidance on Quality Assurance," which recognized applicable ANSI standards, full implementation was not necessarily in place until the GE commitment date (see Attachment A for complete listing of GE commitment dates and extent of commitment).

Since GE operates under a single quality assurance (QA) program, quality system improvements, such as more formalized audits or certification programs, are generally implemented across the board on all active projects with no opportunity for retrofit of completed work; therefore, work performed later in a project is typically subject to more quality assurance effort as a result of additional requirements. Attachment B gives a graphic representation of the time relation of some of the major project activities with the date of issue of regulatory guides and the GE commitment dates. Because of the long generation cycle of the related ANSI Standard, GE had already

upgraded its QA program to at least partially implement each of the related ANSI Standards, where applicable, prior to the date of issue of the regulatory guide.

Attachment B also shows approximate dates of NRC and utility customer/architect-engineer QA audits. These audits have been performed frequently enough and over a long enough time period to establish confidence that GE has been following a QA program which has kept current with customer and regulatory requirements. Obviously, where most equipment is ordered years in advance of shipment, the QA program at the time of shipment will necessarily be somewhat different from that which was in effect at the time of ordering; however, at any point in time the GE QA program has been equal or better than the requirements in effect at that time.

Specific Evaluation Reference:

Information was provided at the PSAR stage.

Similar Application Reference:

Similar application has not been used for other projects.

Regulatory Guide 1.29, Revision 3, September 1978

Seismic Design Classification

Regulatory Guide Intent:

Regulatory Guide 1.29 describes an acceptable method of identifying and classifying those features of light-water-cooled nuclear power plants that should be designed to withstand the effects of the SSE.

Application Assessment:

Assessed capability in design.

Compliance or Alternate Approach Statement:

Identified NSSS scope of supply analysis, design, and/or equipment used in this facility is in compliance with the intent of this regulatory guide through the incorporation of the alternate approach cited.

General Compliance or Alternate Approach Assessment:

This regulatory guide is used as a basis for defining the systems and components which must meet Seismic Category I requirements.

For the purpose of defining equipment that should be described to withstand the SSE, NSSS equipment conforms to the guide. The regulatory guide needs to be more specifically integrated in the following areas:

C.1(b)

Application of this guide is limited to those reactor vessel internals which use engineered safety features, such as core spray piping, core spargers, and hardware, etc.

C.1(h)

The component cooling water portions of the reactor recirculation pumps are not required to be Seismic Category I since the pumps do not perform a safety function.

Specific Evaluation Reference:

See Section 3.2, Table 3.2-1, and the OQAPD.

Similar Application Reference:

Similar application was used for LaSalle.

Regulatory Guide 1.30, Revision 0, August 1972

Quality Assurance Requirements for the Installation, Inspection, and Testing of Instrumentation and Electric Equipment.

Regulatory Guide Intent:

This guide describes an acceptable method of complying with the NRC's regulations with regard to overall QA program requirements.

Application Assessment:

Assessed capability in design.

Compliance or Alternate Approach Statement:

The identified BWR Quality Assurance Program used in this facility reflects compliance with the provisions of NRC regulatory guide or NRC regulations and NRC-approved alternate positions.

General Compliance or Alternate Approach Assessment:

Reference compliance assessment for Regulatory Guide 1.28.

Specific Evaluation Reference:

Information was provided at the PSAR stage. Compliance is discussed in the OQAPD.

Similar Application Reference:

Similar application has not been used for other projects.

Regulatory Guide 1.31, Revision 1, June 1973

Control of Stainless Steel Welding

Regulatory Guide Intent:

Regulatory Guide 1.31 describes an acceptable method of implementing requirements with regard to the control of welding when fabricating and joining austenitic stainless steel components and systems.

Application Assessment:

Assessed capability in design.

Compliance or Alternate Approach Statement:

Identified NSSS scope of supply analysis, design, and/or equipment used in this facility is in compliance with the intent of this regulatory guide through the incorporation of the alternate approach cited.

General Compliance or Alternate Approach Assessment:

All austenitic stainless steel weld filler materials were supplied with a minimum of 5% delta ferrite. This amount of ferrite is considered adequate to prevent microfissuring in austenitic stainless steel welds.

An extensive test program performed by GE, with the concurrence of the NRC, has demonstrated that controlling weld filler metal ferrite at 5% minimum produces production welds which meet the requirements of this regulatory guide.

A total of approximately 400 production welds in five BWR plants were measured and all welds met the requirements of the Interim Regulatory Position.

Specific Evaluation Reference:

See Section 5.2.3.

Similar Application Reference:

Similar application was used for LaSalle.

Regulatory Guide 1.32, Revision 1, March 1976

Use of IEEE 308-1974, "Criteria for Class 1E Electric Systems for Nuclear Power Generating Stations"

Regulatory Guide Intent:

This guide describes a method for implementation of electrical safety related equipment design relative to GDC 17 and 18. This guide does contain some conflicts between GDC 17 and IEEE 308-1974 that of course will require resolution by plant design implementation. This regulatory guide is applicable to the battery and battery charger of the HPCS standby power system.

Applicable Assessment:

Assessed capability in design.

Compliance or Alternate Approach Statement:

Identified NSSS scope of supply analysis, design, and/or equipment used in this facility is in compliance with the intent of this regulatory guide through incorporation of the alternate approach cited.

General Compliance or Alternate Approach Assessment:

The HPCS battery charger has sufficient capacity to restore its battery to full charge under the maximum steady-state load within a 24-hr period. A period of 24 hr is considered to be adequate to restore the battery from the design minimum charge state to the fully charged state irrespective of the status of the plant.

Specific Evaluation Reference:

See Section 8.3.1.2.

Similar Application Reference:

Similar application was used for LaSalle.

Regulatory Guide 1.34, Revision 0, December 1972

Control of Electroslag Weld Properties.

Regulatory Guide Intent:

Regulatory Guide 1.34 describes an acceptable method of implementing requirements regarding control of weld properties when fabricating electroslag welds for nuclear components made of ferritic or austenitic materials.

Application Assessment:

Not applicable.

Compliance or Alternative Approach Statement:

Not applicable.

General Compliance or Alternate Approach Assessment:

The electroslag welding process is not used on components within the NSSS scope of supply. Therefore this regulatory guide is not applicable.

Specific Evaluation Reference:

Not applicable.

Similar Application Reference:

Not applicable.

Regulatory Guide 1.37, Revision 0, March 1973

Quality Assurance Requirements for Cleaning of Fluid Systems and Associated Components of Water-Cooled Nuclear Power Plants.

Regulatory Guide Intent:

This guide describes an acceptable method of complying with the NRC's regulations with regard to overall QA program requirements.

Application Assessment:

Assessed capability in design.

Compliance or Alternate Approach Statement:

The identified BWR Quality Assurance Program used in this facility reflects compliance with the provisions of NRC regulations and NRC regulatory guide or NRC-approved alternate position.

General Compliance or Alternate Approach Assessment:

Reference compliance assessment for Regulatory Guide 1.28.

Specific Evaluation Reference:

Information was provided at the PSAR stage. Compliance is discussed in the OQAPD.

Similar Application Reference:

Similar application has not been used for other projects.

Regulatory Guide 1.38, Revision 2, May 1977

Quality Assurance Requirements for Packaging, Shipping, Receiving, Storage and Handling of Items for Water-Cooled Nuclear Power Plants.

Regulatory Guide Intent:

This guide describes an acceptable method of complying with the NRC's requirements for handling of nuclear materials.

Application Assessment:

Assessed capability in design.

Compliance or Alternate Approach Statement:

The identified BWR Quality Assurance Program used in this facility reflects compliance with the provisions of NRC regulations and the NRC regulatory guide or NRC-approved alternate position.

General Compliance or Alternate Approach Assessment:

Reference compliance assessment for Regulatory Guide 1.28.

Specific Evaluation Reference:

Information was provided at the PSAR stage.

Similar Application Reference:

Similar application has not been used for other projects.

Regulatory Guide 1.41, Revision 0, March 1973

Preoperational Testing of Redundant On-Site Electric Power Systems to Verify Proper Load Group Assignments.

Regulatory Guide Intent:

The requirements of this regulatory guide are applicable to the total onsite electric power systems within Energy Northwest's responsibility.

Application Assessment:

Assessed capability in design.

Compliance or Alternate Approach Statement:

Identified NSSS scope of supply analysis, design, and/or equipment used in this facility is in full compliance with this regulatory guide.

General Compliance or Alternate Approach Assessment:

The HPCS power system is designed to be tested independently of any other redundant load group.

Specific Evaluation Reference:

See Sections 8.3 and 14.2.

Similar Application Reference:

Similar application was used for LaSalle.

Regulatory Guide 1.43, Revision 0, May 1973

Control of Stainless Steel Weld Cladding of Low-Alloy Steel Components

Compliance or Alternate Approach Statement:

This regulatory guide is not applicable since stainless steel cladding on coarse grain low-alloy steel for safety class components is not used.

General Compliance or Alternate Approach Assessment:

Not applicable.

Specific Evaluation Reference:

Not applicable.

Regulatory Guide 1.44, Revision 0, May 1973

Control of the Use of Sensitized Steel

Regulatory Guide Intent:

The purpose of Regulatory Guide 1.44 is to address GDC 1 and 4 and 10 CFR 50 Appendix B requirements to control "the application and processing of stainless steel to avoid severe sensitization could lead to stress corrosion cracking." The guide proposes that this should be done by limiting sensitization due to welding as measured by ASTM A 262 Practice A or E, or another method that can be demonstrated to show nonsensitization in austenitic stainless steels.

Application Assessment:

Assessed capability in design.

Compliance or Alternate Approach Statement:

Identified NSSS scope of supply analysis, design, and/or equipment used in this facility is in compliance with the intent of this regulatory guide through the incorporation of the alternate approach cited.

General Compliance or Alternate Approach Assessment:

Tests by GE indicate that the test specified by A262 A or E (Detecting Susceptibility to Intergranular Attack in Stainless Steel) detects sensitization in a gross way, and the tests do not provide a precise method of predicting susceptibility to stress corrosion cracking in the BWR environment.

All austenitic stainless steel for CGS was purchased in the solution heat treated condition in accordance with applicable ASME and ASTM specifications. Carbon content was limited to 0.08% maximum, and cooling rates from solution heat treating temperatures were required to be rapid enough to prevent sensitization.

Welding heat input was restricted to 110,000 joules per inch maximum, and interpass temperature was restricted to 305°F. High heat welding processes such as block welding and electroslag welding were not permitted. All weld filler metal and castings were required by specification to have a minimum of 5% ferrite.

Whenever any wrought austenitic stainless steel was heated to temperatures over 800°F, by means other than welding or thermal cutting, the material was re-solution heat treated.

These controls were used to avoid severe sensitization and to comply with the intent of Regulatory Guide 1.44.

Similar application was used for LaSalle.

Regulatory Guide 1.45, Revision 0, May 1973

Reactor Coolant Pressure Boundary Leak Detection System.

Regulatory Guide Intent:

The guidelines are prescribed to ensure that leakage detection and collection systems provide maximum practical identification of leaks from within the reactor coolant pressure boundary (RCPB).

Application Assessment:

Assessed capability in design.

Compliance or Alternate Approach Statement:

Identified NSSS scope of supply analysis, design, and/or equipment used in this facility is in compliance with the intent of this regulatory guide through the incorporation of the alternate approach cited.

General Compliance or Alternate Approach Assessment:

The leak detection system consists of temperature, pressure, fission product monitoring and flow sensors with associated instrumentation and alarms. This system detects, annunciates, and isolates (in certain cases) leakages in the following systems:

a. Main steam lines,
b. Coolant systems within the drywell,
c. Reactor water cleanup (RWCU) system,
d. RHR system,
e. RCIC system,
f. Feedwater system, and
g. HPCS system.

Leakage is separated into identified and unidentified categories thus meeting position C.1 of Regulatory Guide 1.45. The affected systems and the leakage detection methods are discussed in Section 5.2.5.1.

Small unidentified leaks (5 gpm and less) inside the drywell are detected by temperature changes, pressure changes, drain sump pump activities, fission product monitoring, and floor drain flow monitoring; floor drain flow includes drywell cooler condensate flow.

Large leaks are also detected by changes in reactor water level and changes in flow rates in process lines.

The 5 gpm leakage rate is the limit on unidentified leakage inside the drywell. The leak detection system is capable of monitoring the flow rates with an accuracy of 1 gpm and is thus in compliance with paragraph C.2 of Regulatory Guide 1.45.

By monitoring drywell equipment and floor drain sump flow rates, which includes drywell coolers' condensate flow rates and fission products (airborne particulate and gaseous radioactivity), position C.3 is satisfied.

Isolation and/or alarm of affected systems and the detection methods used are summarized in Table 5.2-12.

Monitoring of coolant for radiation in the Residual Heat Removal (RHR) and Reactor Water Cleanup (RWCU) heat exchangers satisfies position C.4 of the Regulatory Guide. (For system details see Sections 7.6.1.2 and 11.5.)

The three methods differ in sensitivity and response time. Position C.5 requires the leak detection system be able to detect a leakage rate of 1 gpm in less than 1 hour. See Section 7.6.2.4 for further discussion.

The leakage detection system instruments listed in Table 7.6-2 have been evaluated and are capable of performing their functions following an operating basis seismic event. The drywell airborne particulate monitoring channel will remain functional following a safe shutdown earthquake. This satisfies position C.6 of Regulatory Guide 1.45.

Leakage detection indicators and alarms are provided in the main control room. This satisfies C.7 for the NSSS scope of supply. Procedures are developed for converting the various indications to a common leakage equivalent for the operators to satisfy remainder of C.7.

The leakage detection systems are equipped with provisions to permit testing for operability and calibration during operation by the following methods:

a. Continuous monitoring of sump level compared to flow rates into sump,
b. Operability checked by comparing one method to another,
c. Simulation of signals into trip monitors, and
d. Channel "A" against Channel "B" of the same method.

Thus position C.8 is satisfied.

Limiting conditions for identified and unidentified leakage are established as 20 gpm and 5 gpm respectively, thus satisfying position C.9.

Specific Evaluation Reference:

See Sections 5.2.5 and 7.6.2.4.

Regulatory Guide 1.46, Revision 0, May 1973

Protection Against Pipe Whip Inside Containment

Regulatory Guide Intent:

Regulatory Guide 1.46 describes an acceptable basis for selecting the design locations and orientations of postulated breaks in fluid system piping within the reactor containment and for determining the measures that should be taken for restraint against pipe whipping that may result from such breaks.

Application Assessment:

Assessed capability in design.

Compliance or Alternate Approach Statement:

Identified NSSS scope of supply analysis, design, and/or equipment used in this facility is in compliance with the intent of this regulatory guide through the incorporation of the alternate approach cited.

General Compliance or Alternate Approach Assessment:

This regulatory guide is applicable to the recirculation pipe lines.

The design of the containment structure, component arrangement, Class 1 pipe runs, pipe whip restraints and compartmentalization was done in consonance with the acknowledgment of protection against dynamic effects associated with postulated rupture of piping. Analytically sized and positioned pipe whip restraints were engineered to preclude damage based on the pipe break evaluation.

Pipe whip requirements for fluid system piping within the primary containment that, under normal operation, has service temperature greater than 200°F or pressures greater than 275 psig, complied with ANS N176, "Design Basis for Protection Against Pipe Whip," and Regulatory Guide 1.46 except as delineated in the following criteria for no breaks in Class 1 piping:

a. If Equation 10 of NB-365301, ASME Code Section III results in $S < 2.4\ S_m$ for ferritic or austenitic steels, no other requirements need be met. Stress range should be calculated between any two load sets (including zero load set) according to NB-3600 for upset and on operating basis earthquake (OBE) event transient;

b. If Equation 10 results in $2.4 < S < 3.0\ S_m$ for ferritic or austenitic steels, the cumulative usage factor, U, calculated on the bases of Equation 14 of NB-3653.6, must be less than 0.1; and

c. If Equation 10 results in $S > 3.0\ S_m$ for ferritic or austenitic steels, then the stress value in Equations 12 and 13 of NB-3653.6 must not be greater than $2.4\ S_m$.

Similar application was used in GESSAR.

Regulatory Guide 1.47, Revision 0, May 1973

Bypassed and Inoperable Status Indication for Nuclear Power Plant Safety Systems.

Regulatory Guide Intent:

This guide describes an acceptable method of complying with the requirements of IEEE 279-1971 and Appendix B to 10 CFR 50.

Application Assessment:

Assessed capability in design.

Compliance or Alternate Approach Statement:

Identified NSSS scope of supply analysis, design, and/or equipment used in this facility is in compliance with the intent of the regulatory guide through the incorporation of the alternate approach cited.

General Compliance or Alternate Approach Assessment:

The alternate approach is provided in Section 7.1.2.4.

Specific Evaluation Reference:

See Section 7.1.2.4.

Similar Application Reference:

Similar application was used for LaSalle.

Regulatory Guide 1.48, Revision 0, May 1973

Design Limits and Loading Combinations for Seismic Category I Fluid System Components.

Regulatory Guide Intent:

Regulatory Guide 1.48 provides acceptable design limits and appropriate combinations of loadings associated with normal operation, postulated accidents, and specified seismic events for the design of the Seismic Category I fluid system components.

Application Assessment:

Assessed capability in design.

Compliance or Alternate Approach Statement:

Identified NSSS scope of supply analysis, design, and/or equipment used in this facility is in compliance with the intent of this regulatory guide through the incorporation of the alternate approach cited.

General Compliance or Alternate Approach Assessment:

For a comparison of NSSS with Regulatory Guide 1.48, see the attached tabulation.

The design basis was representative of good industry practices at the time of design, procurement, and manufacture and is shown to be in general agreement with requirements of Regulatory Guide 1.48, with the following clarifications:

a. The probability of an OBE of the magnitude postulated for CGS is consistent with its classification as an emergency event. However, for design conservatism, loads due to the OBE vibration motion have been included under upset conditions; loads due to the OBE vibratory motion plus associated transients, such as a turbine trip, have been considered in the equipment design under emergency conditions consistent with the probability of the OBE occurrence; and

b. The use of increased stress levels for Class 2 components is consistent with industry practice as specified in ASME Code Section III.

Specific Evaluation Reference:

See Section 3.9.3.

COMPARISON WITH REGULATORY GUIDE 1.48 (Continued)

NOTES

Numerical indicators (e.g., 1/) in the regulatory guide portion of the table correspond to the footnotes of Regulatory Guide 1.48. Alphabetical indicators in CGS portion of table (or comparative column) correspond to the following:

[a]In addition to compliance with the design limits specified, assurance of operability under all design loading combinations shall be in accordance with Section 3.9.3.2.

[b]Referenced paragraphs of code currently in course of preparation.

[c]The design limit for local membrane stress intensity or primary membrane plus primary bending stress intensity is 150% of that allowed for general membrane (except as limited to 2.4S for inactive components under faulted condition). See Section 3.9.5.2.

[d]Not used.

[e]Inactive limits may be used since operability will be demonstrated in accordance with Section 3.9.3.2.

[f]When selecting plant events for evaluation, the choice of the events to be included in each plant condition is selected based on the probability of occurrence of the particular load combination. The combination of loads are those identified in Table 3.9-2.

LEGEND:

UPC = upset plant conditions
NPC = normal plant conditions
EPC = emergency plant conditions
DSL = dynamic system loading
SSE = safe shutdown earthquake

Regulatory Guide 1.50, Revision 0, May 1973

Control of Preheat Temperature for Welding of Low-Alloy Steel

Regulatory Guide Intent:

This guide delineates preheat temperature control requirements and welding procedure qualifications supplementing those in ASME Sections III and IX.

Application Assessment:

Assessed capability in design.

Compliance or Alternate Approach Statement:

Identified NSSS scope of supply analysis, design, and/or equipment used in this facility is in compliance with the intent of this regulatory guide through the incorporation of the alternate approach cited.

General Compliance or Alternate Approach Assessment:

The use of low-alloy steel is restricted to the reactor pressure vessel. Other ferritic components in the RCPB are fabricated from carbon steel materials.

Preheat temperatures employed for welding of low-alloy steel meet or exceed the requirements of ASME Section III. Components were either held for an extended time at preheat temperature to ensure removal of hydrogen, or preheat was maintained until postweld heat treatment. The minimum preheat and maximum interpass temperature were specified and monitored.

All welds were nondestructively examined by radiographic methods. In addition, a supplemental ultrasonic examination was performed.

By meeting and/or exceeding the recommendation of the ASME Code, the intent of the regulatory guide is satisfied even though the design was significantly developed prior to issuance of the specific guide wording.

Specific Evaluation Reference:

See Section 5.2.3.

Similar Application Reference:

Similar application was used for LaSalle.

Regulatory Guide 1.53, Revision 0, June 1973

Application of the Single-Failure Criterion to Nuclear Power Plant Protection Systems

Regulatory Guide Intent:

Regulatory Guide 1.53 requires that protection systems meet the requirements of Section 4.2 of IEEE 279-1971, which is also required by ANSI-N 42.7-1972 in that any single failure within the protection systems shall not prevent proper protective action at the system level when required. This guide provides guidance on an acceptable method of complying with this requirement.

Application Assessment:

Assessed capability in design.

Compliance or Alternate Approach Statement:

Identified NSSS scope of supply analysis, design, and/or equipment used in this facility is in full compliance with this regulatory guide.

General Compliance or Alternate Approach Assessment:

Compliance is achieved by specifying, designing, and constructing the engineered safeguards systems to meet the single failure criterion, Section 4.2 of IEEE 279-1971, "Criteria for Protection Systems for Nuclear Power Generating Stations," and IEEE 379-1972, "IEEE Trial-Use Guide for the Application of the Single-Failure Criterion to Nuclear Power Generating Station Protection Systems."

This regulatory guide applies to the following NSSS supplied protection systems: reactor protection system (RPS), ECCS, and PCRVICS.

The reactor protection system has separate and redundant instrument channels, logic, and actuation circuits to ensure that the single failure criterion is met. The PCRVICS is similarly designed.

The ECCS is divided into the ADS, HPCS, LPCS and RHR (LPCI) which meets the single failure criterion on a network basis.

Regulatory Guide 1.56, Revision 0, June 1973

Maintenance of Water Purity in Boiling Water Reactors

Regulatory Guide Intent:

This guide describes an acceptable method of implementing GDC 13, 14, 15, and 31 with regard to minimizing the probability of corrosion-induced failure of the RCPB in BWRs by maintaining acceptable purity levels in the reactor coolant and acceptable instrumentation to determine the condition of the reactor coolant.

Application Assessment:

Assessed capability in design.

Compliance or Alternate Approach Statement:

Identified NSSS scope of supply analysis, design, and/or equipment used in this facility is in compliance with the intent of this regulatory guide through the incorporation of the alternate approach cited.

General Compliance or Alternate Approach Assessment:

Materials in the primary system are primarily Type 304 stainless steel and Zircaloy cladding. The reactor water chemistry limits have been established to provide an environment favorable to these materials. Design and Licensee Controlled Specifications (LCS) limits are placed on conductivity and chloride concentrations. Operationally, the conductivity is limited because it can be continuously and reliably measured and gives an indication of abnormal conditions and the presence of unusual materials in the coolant. Chloride limits are specified to prevent stress corrosion cracking of stainless steel.

The water quality requirements are further supported by GE topical report NEDO-10899.

Specific Evaluation Reference:

See Section 5.2.3.

Information was provided at the PSAR stage. Compliance is discussed in the OQAPD.

Similar Application Reference:

Similar application has not been used in other plants.

Regulatory Guide 1.60, Revision 1, December 1973

Design Response Spectra for Seismic Design of Nuclear Power Plants.

Regulatory Guide Intents:

This guide delineates procedures for defining response spectra for designing Seismic Category I structures, systems, and components.

Application Assessment:

Assessed capability in design.

Compliance or Alternate Approach Statement:

Identified NSSS scope of supply analysis, design, and/or equipment used in this facility is in compliance with the intent of this regulatory guide through the incorporation of the alternate approach cited.

General Compliance or Alternate Approach Assessment:

The input loadings for the seismic analysis of the CGS plant structures were given in terms of response spectra based on data available on earthquake acceleration time history records which was accepted industry practice at the time of the CGS design. This method was acceptable to the NRC prior to the issuance of this regulatory guide because no other guidance was available.

Specific Evaluation Reference:

See Section 3.7.1.1.

Similar Application Reference:

Similar application was used for LaSalle.

Regulatory Guide 1.61, Revision 0, October 1973

Damping Values for Seismic Design of Nuclear Power Plants

Regulatory Guide Intent:

This guide delineates damping values that should be applied to modal dynamic analysis of Seismic Category I elements.

Application Assessment:

Assessed capability in design.

Compliance or Alternate Approach Statement:

Identified NSSS scope of supply analysis, design, and/or equipment used in this facility is in compliance with the intent of this regulatory guide through the incorporation of the alternate approach cited.

General Compliance or Alternate Approach Assessment:

The damping values used in the seismic analysis conform to the data available on this at the time the analysis was performed which was the practice accepted by industry and the NRC at the time of the CGS design.

The values used in Table 3.7-1 are less than those given by the regulatory guide. The calculated responses are therefore conservative.

Specific Evaluation Reference:

See Section 3.7.1.3.

Similar Application Reference:

Similar application was used for LaSalle.

Regulatory Guide 1.62, Revision 0, October 1973

Manual Initiation of Protective Actions.

Regulatory Guide Intent:

Regulatory Guide 1.62 requires that manual initiation of each protective action at the system level be provided, that such initiation accomplishes all actions performed by automatic initiation, and that protective action at the system level go to completion once manually initiated. In addition, manual initiation should be by switches readily accessible in the control room, and a minimum of equipment should be used in common with automatically initiated protective action.

Application Assessment:

Assessed capability in design.

Compliance or Alternate Approach Statement:

Identified NSSS scope of supply analysis, design, and/or equipment used in this facility is in full compliance with this regulatory guide.

General Compliance or Alternate Approach Assessment:

Means are provided for manual initiation of primary containment and reactor vessel isolation control system (NSSS only), ECCS, and reactor protection system scram at the system level through the use of armed push buttons, as described below:

Action Initiated	Number of Switches
Primary containment and reactor vessel isolation (NSSS Only)	Four, two in Division 1 and two in Division 2
ADS	Four, two in Division 1 and two in Division 2
HPCS	One switch in Division 3
RHR (loop A)/LPCS	One switch in Division 1
RHR (loop B)/RHR (loop C)	One switch in Division 2
Reactor protection system (SCRAM)	Four, two in Division 1 and two in Division 2

Operation of these switches accomplishes the initiation of all actions performed by the automatic initiation circuitry.

The amount of equipment common to both manual and automatic initiation of the above function is kept to a minimum through implementation of manual activation as close as possible to the final devices actuators (relays, scram contractor) of the protection system. No failure in the manual, automatic or common portions of the protection system will prevent initiation of a given function by manual or automatic means.

Manual initiation of any of the above functions, once initiated, goes to completion as required by IEEE 279-1971, Section 4.16.

Specific Evaluation Reference:

Similar application has not been used for other projects.

Regulatory Guide 1.65, Revision 0, October 1973

Materials and Inspection for Reactor Vessel Closure Studs.

Regulatory Guide Intent:

Regulatory Guide 1.65 defines acceptable materials and testing procedures with regard to reactor vessel closure stud bolting for light-water-cooled reactors.

Application Assessment:

Assessed capability in design.

Compliance or Alternate Approach Statement:

Identified NSSS scope of supply analysis, design, and/or equipment used in this facility is in compliance with the intent of this regulatory guide through the incorporation of the alternate approach cited.

General Compliance or Alternate Approach Assessment:

The reactor pressure vessel closure studs are SA-540 Grade B23 or 24 (AISI4340) and have a maximum ultimate tensile strength of 170 ksi. Additionally, specified bolting material must have Charpy V notch impact properties of 45 ft-lb minimum with 25 mils lateral expansion. Nondestructive examination before and after threading is specified to be in accordance with subarticle NB-2580 ASME Section III, which complies with regulatory position C.2. Subsequent to fabrication, the studs are manganese phosphate coated and are lubricated with a graphite/alcohol or a nickel powder base lubricant.

In relationship to regulatory position C.2.b, the bolting materials were ultrasonically examined after final heat treatment and prior to threading, as specified. The specified requirement for examination according to ASME Section II Recommended Practice SA-388 was complied with. The specific procedures approved for use in practice are judged to ensure comparable material quality and, moreover, are considered adequate on the basis of compliance with the applicable requirements of ASME Section III paragraph NB-2585.

Additionally, straight beam examination was performed on 100% of cylindrical surfaces, and from both ends of each stud using a 3/4 maximum diameter transducer. In addition to the code required notch, the reference standard for the radial scan contained a 0.5-in. diameter flat bottom hole with a depth of 10% of the thickness, and the end scan standard contained a 0.25-in. diameter flat bottom hole 0.5-in. deep. Also, angle beam examination was performed on the outer cylindrical surface of nuts

and washers per ASME SA-388 in both an axial and circumferential direction. Any indication greater than the indication from the applicable calibration feature is unacceptable. A distance-amplitude correction curve per NB-2585 is used for the longitudinal wave examination. Surface examinations were performed on the studs and nuts after final heat treatment and threading, as specified in the Regulatory Guide, in accordance with NB-2583 of ASME Code Section III, 1971 Edition through November 1971 Addenda.

In relationship to regulatory position C.3, GE practice allows exposure of stud bolting surfaces to high purity fill water; nuts and washers are stored dry during refueling.

In relationship to regulatory position C.4, ASME Section XI and Appendix VIII guidance is followed, as implemented in the In-Service Inspection Program, to monitor the structural integrity of the stud bolting and ability to perform their function.

Specific Evaluation Reference:

See Section 5.3.1.7.

Similar Application Reference:

Similar application was used for LaSalle.

Regulatory Guide 1.66, Revision 0, October 1973

Nondestructive Examination of Tubular Products.

Regulatory Guide Intent:

This guide describes a method of implementing requirements acceptable to NRC regarding nondestructive examination requirements of tubular products used in the RCPB.

Applicable Assessment:

Assessed capability in design.

Compliance or Alternate Approach Statement:

Identified NSSS scope of supply analysis, design, and/or equipment used in this facility is in compliance with the intent of this regulatory guide through the incorporation of the alternate approach cited.

General Compliance or Alternate Approach Assessment:

Wrought tubular products were supplied in accordance with applicable ASTM/ASME material specifications. These specifications require a hydrostatic test on each length of tubing. Additionally, the specification for the tubular product used for CRD housings specified ultrasonic examination to paragraph NB-2550 of ASME Code Section III.

These RCPB components met the requirements of ASME Codes existing at time of placement of order which predated Regulatory Guide 1.66. At the time of the placement of the orders, 10 CFR 50, Appendix B requirements and ASME code requirements assured adequate control of quality for the products.

This regulatory guide was withdrawn on September 28, 1977, by the NRC because the additional requirements imposed by the guide were satisfied by the ASME Code Section III.

Specific Evaluation Reference:

See Sections 4.5.2.3 and 5.2.3.3.

Similar Application Reference:

Similar application was used for LaSalle.

Regulatory Guide 1.67, Revision 0, October 1973

Installation of Overpressure Protection Devices

Regulatory Guide Intent:

This regulatory guide describes a method acceptable to the NRC staff for implementing GDC 1 with regard to the design of piping for safety valve and relief valve stations which have open discharge systems with limited discharge pipes and which have inlet piping that neither contains a water seal nor is subject to slug flow of water on discharge of the valves.

Application Assessment:

Assessed capability in design.

Compliance or Alternate Approach Statement:

Identified RHR shutdown suction line thermal relief piping is located between the containment isolation valves. However, the intent of the regulatory guide does not apply due to the very short duration and small discharge of the thermal relief function.

General Compliance or Alternate Approach Assessment:

This regulatory guide is not considered to be applicable to this piping due to the small size and very short operation time of the valve (0.75 in. x 1 in.). The only purpose of the valve is to relieve the excess pressure caused by the difference of thermal expansion between the pipe and the water contained between the containment isolation valves.

Specific Evaluation Reference:

See Section 3.9.3.1.14.

Similar Application Reference:

Not applicable.

Regulatory Guide 1.68, Revision 0, November 1973

Preoperational and Initial Startup Test Programs for Water-Cooled Power Reactors

Regulatory Guide Intent:

Regulatory Guide 1.68 describes the requirements for the initial startup test programs. This regulatory guide is applicable to such activities as precritical tests and low-power tests.

Application Assessment:

Assessed capability in design.

Compliance or Alternate Approach Statement:

Identified NSSS scope of supply analysis, design, and/or equipment used in this facility is in compliance with the intent of this regulatory guide through the incorporation of the alternate approach cited.

General Compliance or Alternate Approach Assessment:

The following discussion describes the alternate acceptable approaches for specific conformance to this regulatory guide.

The format of the CGS test procedures is different from that of the guide, but since the content specifies the required elements, the procedures are in compliance.

The reference sections refer to those of the regulatory guide. Those sections not listed are in compliance.

Section C.2.b: Operational limitations for the protection of public health and safety are included in the Technical Specifications for the plant. The General Electric startup instructions contain notes of caution which supplement the Technical Specifications. The Technical Specifications should be the instrument for describing operational (including testing) limitations. Therefore, the identification of "safety precautions" in test procedures should be limited to those items which, if not observed, could lead to reduction of system safety performance below expected levels and not the minor procedural and test details which would not cause such a reduction.

Section C.2.c: The generic simulation test appearing in Chapter 14 should appear by reference in preoperational and initial startup test programs where onsite full

simulation tests are not possible. The guide wording would change to "… less than full simulation should be provided or referenced for test where full…"

Appendix A, Section C.2.h: The comparison of critical control rod pattern with predicted patterns (Appendix A, Section C.2.d) provides required knowledge of effective overall rod worth. Individual control rod calibrations cannot be performed in a meaningful manner in a large multirodded BWR. Therefore, this part of the guide is not applicable to BWRs.

Appendix A, Section C.2.i: The functional requirement of the reactor head cooling system design is required at operating pressures less than or equal to 135 psig. Therefore, for this paragraph to be applicable "(135 psig)" should be part of last sentence.

Appendix A, Section D.2.a: The high-pressure coolant injection (HPCI) has been replaced by an HPCS system. Due to the configuration of the sprays directly on the core, this system cannot be operated at power. The HPCS injection/core spray is demonstrated during the preoperational test program.

Appendix A, Section D.2.b: Friction tests are performed on four drives at rates pressure.

Appendix A, Section D.2.f: It is necessary to make more than two calibrations and, therefore, it is not appropriate to limit the test to 50% and 100% power levels.

Appendix A, Section D.2.g: At least six chemical analyses of fluid system are necessary; therefore, the limitations of 25%, 50%, 75%, and 100% are not appropriate.

Appendix A, Section D.2.1: Since this plant design does not include an emergency condenser, this section is not appropriate.

Appendix A, Section D.2.n: Control rod calibration in a large multirodded BWR has not been found to provide meaningful data. Any safety-related problems associated with control rods would be discovered during safety related testing, and therefore, this section is not appropriate.

Appendix A, Section D.2.p: Since the main steam valve function tests are conducted at a minimum of six power and flow conditions, the limitations of 25%, 50%, and 75% are not appropriate.

Appendix A, Section D.2.s and t: Turbine trip and generator trip have essentially the same effect on the reactor and safety related system actuation. Sections D.2.s and D.2.t should be combined into one test.

Appendix A, Section D.2.y: Minimum critical heat flux ratio (MCHFR) is an obsolete limit that has been replaced with minimum critical power ratio (MCPR). Core performance evaluation tests must be performed at every test condition.

Appendix A, Section D.2.aa: Comparison tests are made throughout the test program, and therefore, limitations of 25%, 50% and 100% are not appropriate.

Appendix C, Section B.2.d: Functionally testing the associated control rod immediately following installation of each fuel cell is not appropriate. Functional testing of all control rods after fuel loading and prior to startup to critical procedures is applicable.

Appendix A, Section A.5.a: The "demonstration of water injection for a LOCA" is an ECCS test. Therefore, "demonstration of water injection for a loss-of-coolant accident" is not within the scope of the reactor coolant makeup system test.

Appendix A, Section C.2.c: The "calibration of intermediate range monitor with power" is not meaningful due to local control rod effects.

Appendix A, Section D.2.w: Feedwater pump trip should be performed to check recirculation pump runback.

Appendix C, Section B.1.b: Poison curtains are not applicable since they are not used in this plant.

Appendix C, Section B.2.a: Poison curtains are not applicable.

Appendix C, Section B.3.c: The insertion of locked control rods is excluded in any withdrawal sequence.

Appendix D, Section D.2.0: The rod pattern exchange is not a part of the Startup Power Ascension Program since it does not involve the approach of any safety margin or operating limit. The rod pattern exchange procedure at power is part of the Nuclear Performance Evaluation Procedure and will be performed during the fuel cycle as necessary. The simultaneous trip of both recirculation pumps is not performed at 100% of rated power. The analysis of this event (see Section 15.3.1) indicates there is no decrease in the MCPR and therefore, it does not involve the approach of any safety margin or operating limit.

Specific Evaluation Reference:

See Section 14.2.

Similar Application Reference:

Similar application was used for Brunswick 1 and Browns Ferry 3.

Regulatory Guide 1.70, Revision 2, September 1975

Standard Format and Content of Safety Analysis Reports for Nuclear Power Plants

Regulatory Guide Intent:

This guide describes the minimum acceptable requirements for format and content of Safety Analysis Reports.

Application Assessment:

Assessed capability in design.

Compliance or Alternate Approach Statement:

Identified NSSS scope of supply analysis, design, and/or equipment used in this facility is in full compliance with this regulatory guide or through the incorporation of the NRC approved alternate approach cited.

General Compliance or Alternate Approach Assessment:

The NSSS scope of supply inputs include all the appropriate scope responsibilities and information required in Regulatory Guide 1.70, Revision 2, in both format and content, except as described below. Appendix A of NEDE-24011-P-A, General Electric Standard Application for Reactor Fuel (GESTAR II) (most recent approved revision referenced in the COLR), provides a road map for incorporating nuclear fuel design and analysis characteristics described in GESTAR II into the FSAR. GESTAR II is consistent with Regulatory Guide 1.70, Revision 3.

Specific Evaluation Reference:

For Regulatory Guide 1.70, Revision 2, see NSSS scope of supply portions of this FSAR.

For Regulatory Guide 1.70, Revision 3, see Sections 4.1, 4.2, 4.3 and 4.4.

Similar Application Reference:

Similar application was used for Grand Gulf 1 and 2 and Susquehanna 1 and 2.

Regulatory Guide 1.71, Revision 0, December 1973

Welder Qualification for Areas of Limited Accessibility

Regulatory Guide Intent:

Regulatory Guide 1.71 requires that weld fabrication and repair for wrought low-alloy and high-alloy steels or other materials such as static and centrifugal castings and bimetallic joints should comply with fabrication requirements of Section III and Section IX of the ASME B&PV Code. It also requires additional performance qualifications for welding in areas of limited access.

Application Assessment:

Assessed capability in design.

Compliance or Alternate Approach Statement:

Identified NSSS scope of supply analysis, design, and/or equipment used in this facility is in compliance with the intent of this regulatory guide through the incorporation of the alternate approach cited.

General Compliance or Alternate Approach Assessment:

All ASME Section III welds were fabricated in accordance with the requirements of Section III and IX of the ASME B&PV Code. There are few restrictive welds involved in the fabrication of BWR components. Welder qualification for welds with the most restrictive access was accomplished by mock-up welding. Mock-ups were examined with radiography or sectioning.

All reactor pressure boundary welding was performed in accordance with ASME Section IX. Reactor internal component welding was performed in accordance with ASME Section IX or appropriate AWS requirements.

Specific Evaluation Reference:

See Section 5.2.3.

Similar Application Reference:

Similar application was used for Zimmer and LaSalle.

Regulatory Guide 1.73, Revision 0, January 1974

Qualification Tests of Electric Valve Operators Installed Inside the Containment of Nuclear Power Plants.

Regulatory Guide Intent:

Regulatory Guide 1.73 endorses the requirements of IEEE 382-1972, "Trial-Use Guide for Type Test of Class 1 Electric Valve Operators for Nuclear Power Generating Station." Regulatory position stipulations are also included.

Application Assessment:

Assessed capability in design.

Compliance or Alternate Approach Statement:

Identified NSSS scope of supply analysis, design, and/or equipment used in this facility is in full compliance with this regulatory guide.

General Compliance or Alternate Approach Assessment:

This regulatory guide is applicable to the recirculation system gate valve and the HPCS injection valve motor operators.

These valve operators have been tested in accordance with the test sequence outlined in Section 4.5.2 of the IEEE 382-1972. The qualifying tests have been made under environmental conditions (temperature, pressure, humidity, radiation) that are at least as severe as those that the valve operator will be exposed to during and following a DBA (LOCA).

Specific Evaluation Reference:

See Section 3.11.

Similar Application Reference:

Similar application was used for LaSalle.

Regulatory Guide 1.74, Revision 0, February 1974

Quality Assurance Terms and Definitions

Regulatory Guide Intent:

This guide identifies quality assurance terms and acceptable definitions.

Application Assessment;

Assessed capability in design.

Compliance or Alternate Approach Statement:

The identified BWR Quality Assurance Program used in this facility reflects compliance with the provisions of NRC regulations and the NRC regulatory guide or NRC-approved alternate position.

General Compliance or Alternate Approach Assessment:

Reference compliance assessment for Regulatory Guide 1.28.

Specific Evaluation Reference:

Information was provided at the PSAR stage. Compliance is discussed in the OQAPD.

Similar Application Reference:

Similar application has not been used for other projects.

Regulatory Guide 1.75, Revision 0, February 1974

Physical Independence of Electrical Systems

Regulatory Guide Intent:

This guide presents a detailed method of ensuring physical independence of electric systems, including requirements of preparation, identification, and isolation.

Application Assessment:

Assessed capability in design

Compliance or Alternate Approach Statement:

Identified NSSS scope of supply analysis, design, and/or equipment used in this facility is in compliance with the intent of this regulatory guide through the incorporation of the alternate approach cited.

General Compliance or Alternate Approach Assessment:

When evaluating the applicability of Regulatory Guide 1.75 and its attendant IEEE Standard (IEEE-384-1971), consideration should be given to the fact that design was significantly developed prior to their issuance.

The following is a point-by-point definition of the implementation of IEEE-384 as modified by Regulatory Guide 1.75 for the CGS plant. The numbers and titles in the following see those of IEEE-384.

1. Scope

   Compliance with scope.

2. Purpose

   Compliance with purpose.

3. Definitions

   All definitions apply including Regulatory Guide 1.75 except for small nomenclature aspects in C.1 and C.2 associated within floor sections.

4. General Separation Criteria

4.1 Required Separation

4.2 Equipment and Circuits Requiring Separation

The equipment and circuits requiring separation are determined and delineated early in the plant design. Distinctive identification of those equipment and circuits were not provided on specifically noted documents and drawings but the documents and drawings are identified as applying to the "protection systems."

4.3 Methods of Separation

Barriers are used to separate divisional devices and wiring. Safety system logic is implemented with relay coil to relay contact separation of multidivisional and nondivisional signals. Distance separation was provided to the extent feasible at manufacturing time. These served the purpose or intent of requirements at that time.

4.4 Compatibility with Mechanical Systems

The Class 1E equipment and circuits are specified to be located so that a failure in the mechanical systems served by the Class 1E systems does not disable redundant portions of the Class 1E systems.*

4.5 Associated Circuits

Associated circuits are treated as non-Class 1E circuits and are separated to the extent that good electrical isolation is assured. This assurance was provided without Class 1E isolators. Some physical separation is provided.

4.6 Non-Class 1E Circuits

4.6.1 Separation from Class 1E Circuits

Same as 4.5 response above.

* Information on compliance of actual installation is provided in Section 1.8.3.

4.6.2 Separation from Associated Circuits

Same as 4.5 response above.

5. Specific Separation Criteria

5.1 Cables and Raceways

To the extent that the 5.1 series of subparagraphs might be used to critique the power generation control complex (PGCC) equipment, the physical reality of the floor sections is obviously not recognized in the IEEE-384 test. However, the floor sections are inherently in accordance with the design concepts stated in these subparagraphs and therefore comply on that basis.

5.2 Standby Power Supply

Comply as applied to the Division 3 HPCS Diesel Generator.*

5.3 DC System

Comply as applied to the Division 3 HPCS Diesel Generator.*

5.4 Distribution System

Comply as applied to the Division 3 HPCS Diesel Generator.*

5.5 Containment Electrical Penetrations

Not in NSSS scope of supply.

5.6 Control Switch Boards

5.6.1 Location and Arrangement†

Class 1E equipment and circuits are located on separate control switchboards or where operationally necessary on a single control switchboard.

* Division 1 and 2 power compliance is provided in Section 1.8.3.
† The control room structure and location as well as local control switchboard location is discussed in Section 1.8.3.

5.6.2 Internal Separation

Most of the devices requiring separation are separated by barriers. With several divisions in one panel, and for relays which must accept multidivisional signals, 6-inch separation is impossible. Therefore, separation is done on a best effort approach. Design has used the relay coil to relay contact separation to comply with the regulatory guide.

5.6.3 Internal Wiring Identification

Panel internals wiring is not color-coded, but wires are marked with their respective Connection Diagram identify at each point of termination.

5.6.4 Common Terminations

Relay coil to relay contact separation has been used.

5.6.5 Non-Class 1E Wiring

Electrical isolation is provided, though not necessarily with Class 1E isolators. Some physical separation is provided.

5.6.6 Cable Entrance

Not in NSSS scope of supply.

5.7 Instrumentation Cabinets

Compliance

5.8 Sensors and Sensor to Process Connections

Compliance

5.9 Actuated Equipment

Not in NSSS scope of supply.

Specific Evaluation Reference:

See Section 8.3.1.4.2.7

Similar Application Reference:

Application of this regulatory guide is plant unique due to NRC agreements during the various stages of licensing and scope of responsibility of design and engineering necessary to comply with the NRC interpretation. Therefore reference plants cannot be cited.

Regulatory Guide 1.84

Design, Fabrication, and Materials Code Case Acceptability, ASME Section III

Regulatory Guide Intent:

This guide lists all Section III Code Cases that the NRC has approved for use. It is updated on a regular basis to reflect the changes to the ASME Code Cases and the current position of the NRC on acceptability for use. The guide contains tables that detail the NRC acceptance requirements for current, annulled, and superseded Code Cases. Code Cases that the NRC determined to be unacceptable are listed in Regulatory Guide 1.193, "ASME Code Cases Not Approved for Use".

Application Assessment:

Assessed capability in design.

Compliance or Alternate Approach Statement:

The current version of the Regulatory Guide is utilized to determine acceptable Code Cases for all new and existing plant applications. The FSAR does not track individual Code Cases and revision numbers. Not all acceptable Code Cases listed in the regulatory guide are used. The Code Cases that are utilized for Columbia are referred to in the plant design/installation documentation.

General Compliance or Alternate Approach Assessment:

Code Cases are utilized in accordance with the requirements of the regulatory guide provisions for acceptance. Section III Code Cases that are not yet endorsed may be utilized via submittal to the NRC for approval in accordance with the regulatory guide. The plant scope of supply is in full compliance with this regulatory guide.

Specific Evaluation Reference:

See Section 3.2.

Similar Application Reference:

None.

Regulatory Guide 1.85, Revision 31, 1998*

Code Case Acceptability ASME Section III Materials

Regulatory Guide Intent:

This guide provides a list of ASME materials code cases that have been generically approved by the NRC.

Code cases on this list may be used until annulled. Annulled cases are considered "active" for equipment that has been contractually committed to fabrication prior to the annulment.

This guide and later revisions require NRC approval of code cases for Class 1, 2, and 3 components.

Application Assessment:

Assessed capability in design.

Compliance or Alternate Approach Statement:

Identified NSSS scope of supply analysis, design, and/or equipment used in this facility is in compliance with the intent of this regulatory guide through the incorporation of the alternate approach cited.

General Compliance or Alternate Approach Assessment:

The GE procedure is to obtain NRC approval of code cases on Class 1 components only. NRC approval of Class 2 and 3 code cases was not required by 10 CFR 50.55(a).

All Class 2 and 3 equipment has been designed to ASME Code or ASME approved Code Cases. This provision together with quality control requirements provide adequate safety equipment functional assurances.

Specific Evaluation Reference:

See Section 5.2.1.

* Regulatory Guide 1.85 was withdrawn in 2004. See Regulatory Guide 1.84 for NRC acceptance of current Materials Code Cases.

Similar Application Reference;

Similar application was used for LaSalle.

Regulatory Guide 1.88, Revision 2, October 1976

Collection, Storage, and Maintenance of Nuclear Power Plant Quality Assurance Records.

Regulatory Guide Intent:

This guide describes an acceptable method of complying with the NRC's regulations for collection, storage, and maintenance of quality assurance records.

Application Assessment:

Assessed capability in design.

Compliance or Alternate Approach Statement:

The identified BWR Quality Assurance Program used in this facility reflects compliance with the provisions of NRC regulations and the regulatory guide or NRC-approved alternate position.

General Compliance or Alternate Approach Assessment:

Reference compliance assessment for Regulatory Guide 1.28.

Specific Evaluation Reference:

Information was provided at the PSAR stage. Compliance is discussed in the OQAPD.

Similar Application Reference:

Similar application has not been used for other projects.

Regulatory Guide 1.89, Revision 1, June 1984

Qualification of Class 1E Equipment for Nuclear Power Plants

Regulatory Guide Intent:

Regulatory Guide 1.89 Rev. 1 endorses both the requirements and recommendations of IEEE 323-1974, "IEEE Standard for Qualifying Class 1E Equipment for Nuclear Power Generating Stations." Additional regulatory position stipulations are also included.

Compliance or Alternate Approach Statement:

CGS complies with this regulatory guide for equipment requiring environmental qualification procured after February 22, 1983.

General Compliance or Alternate Approach Assessment:

For equipment requiring environmental qualification installed prior to February 22, 1983, CGS follows the guidance in NUREG-0588 Cat II.

In view of the NRC Memorandum and Order (CLI-80-21), dated May 23, 1980, all environmental qualifications of Class 1E equipment within the NSSS scope of supply was reevaluated for compliance with NUREG-0588, Category II. Where significant deviation from those guidelines was found in specific equipment qualifications, additional testing and/or analysis was performed to demonstrate the adequacy of the equipment to perform its safety-related function.

Specific Evaluation Reference:

Delineation of the degree of compliance is contained in Section 3.11.

Regulatory Guide 1.92, Revision 1, February 1976

Combination of Modes and Spatial Components in Seismic Response Analysis.

Regulatory Guide Intent:

This guide describes methods acceptable to the NRC for combining the values of the response spectrum nodal dynamic analysis and in combining maximum values (in case of time history dynamic analysis) or the representative maximum values (in case of spectrum dynamic analysis).

Application Assessment:

Assessed capability in design.

Compliance or Alternate Approach Statement:

Identified NSSS scope of supply analysis, design, and/or equipment used in this facility is in compliance with the intent of this regulatory guide through the incorporation of the alternate approach cited.

General Compliance or Alternate Approach Assessment:

Three Components of Earthquake Motion

Response Spectrum Method

The use of three components of earthquake motion was not a design basis requirement of the construction permit for this plant. The total seismic response is predicted by combining the response calculated from analyses due to one horizontal and one vertical seismic input. For this case, where the response spectrum method of seismic analysis is used, the basis for combining the loads from the two analyses is given as follows:

a. The peak of the different modes for the same earthquake excitations do not occur at the same time,

b. The peak responses of a particular mode due to earthquake excitations from different directions do not occur at the same time, and

c. The peak stresses due to different modes and due to different excitations may not occur at the same location nor in the same direction.

To implement the above, the two translation components of earthquake excitations are combined by summing the absolute sum of all responses of interest (e.g., strain, displacement stress, moment, shear, etc.) from seismic motion, the one horizontal (x or z) and one vertical direction (y), i.e., $|x+y|$ or $|y+z|$. The design is made for the larger of the two sums $|x+y|$ or $|y+z|$.

Time History Method

The algebraic sum of contributions (to displacements, loads, stresses, etc.) due to the two earthquake components are calculated for each natural mode for each time interval of analysis. The time interval should be less than or equal to 0.2 of the smallest period of interest. The maximum values of all time intervals are the design displacements, accelerations, loads, or stresses.

It is concluded that the above method adequately demonstrates the integrity of the Seismic Category I subsystems and was found acceptable as a basis of current operating BWR plants.

Combination of Modal Responses

When the response spectra method of modal analysis is used, all modes are combined by the square root of the sum of the squares (SRSS) described as follows:

The SRSS combination of modal responses is defined mathematically as

$$R = \sqrt{\sum_{i=1}^{n} (R_i)^2}$$

where

R = Combined response

R_i = Response in the i^{th} mode

n = Number of modes considered in the analysis

Closely spaced modes are not accounted for as required by the guide because the design was significantly developed prior to issuance of the guide.

Specific Evaluation Reference:

See Sections 3.7.3.6 and 3.7.3.7.

Similar Application Reference:

Similar application was used for LaSalle.

Regulatory Guide 1.99, Revision 2, May 1988

Radiation Embrittlement of Reactor Vessel Materials

Regulatory Guide Intent:

This regulatory guide provides guidance for the prediction of irradiation damage of the reactor vessel belt line materials for the life of the vessel. This information is used to develop the pressure/temperature limit curves for the reactor pressure vessel based on material chemistry and end-of-life neutron exposure.

Application Assessment:

Assessed capability in design.

Compliance or Alternate Approach Statement:

The reactor pressure vessel pressure/temperature limit curves are in full compliance with the identified requirements in the regulatory guide.

General Compliance or Alternate Assessment:

Compliance is achieved by using a calculated end-of-life fluence for the CGS reactor vessel to evaluate the material damage due to this fluence. This information is used to predict the end-of-life NDT temperature for the limiting belt line material for the vessel. Using linear elastic fracture mechanics, the requirements of Welding Research Council Bulletin 175, the Standard Review Plan, and the requirements of Regulatory Guide 1.99, Revision 2, the pressure/temperature limit curves were developed for CGS. These curves will be used to evaluate the predictions determined by the regulatory guide until the submittal of new curves that incorporate the results of the surveillance capsule test data.

Specific Evaluation Reference:

See Sections 5.3.1.5.2.1 through 5.3.1.5.2.6 and the Technical Specifications.

Similar Application Reference:

Similar application is used on all reactor vessels.

Regulatory Guide 1.100, Revision 1, August 1977

Seismic Qualification of Electric Equipment for Nuclear Power Plants

Regulatory Guide Intent:

Regulatory Guide 1.100 endorses both the requirements and recommendations of IEEE 344-1975, "IEEE Recommended Practices for Seismic Qualification of Class 1E Equipment for Nuclear Power Generating Stations," when such qualification is performed in conjunction with Regulatory Guide 1.89, and subject to the regulatory position stipulations.

Compliance or Alternate Approach Statement:

General Compliance or Alternate Approach Assessment:

All Class 1E equipment seismic qualifications are evaluated against the requirements set forth within IEEE 344-1975 as clarified in Section 3.10.1.2. The evaluations are documented and demonstrated adequacy of the methods and results of the qualifications as equal or conservative to the requirements of IEEE 344-1975. This qualification documentation includes evaluation of seismic and hydrodynamic load combinations.

Specific Evaluation Reference:

See Section 3.10 and *"WNP-2 Dynamic Qualification Report for Safety-Related Equipment," dated September 1982*.

Regulatory Guide 1.145, Revision 1, November 1982/February 1983

Atmospheric Dispersion Models for Potential Accident Consequence Assessments at Nuclear Power Plants

Regulatory Guide Intent

This guide provides acceptable methodology to determining site-specific off-site air dispersion factors (χ/Q) for assessing the potential offsite radiological consequences of postulated accidental releases of radioactive material to the atmosphere.

Application Assessment

Assessed capability in design.

Compliance or Alternate Approach Statement:

Identified NSSS scope of supply analysis, design, and equipment used in this facility is in full compliance with the regulatory guide.

General Compliance or Alternate Approach Assessment

Two of the procedures contained in the PAVAN code were implemented. The procedures were run with the desert sigma and with the Pasquill-Gifford sigma enabled. The most conservative χ/Q values were used in the accident analysis.

Specific Evaluation Reference:

See Section 2.3 and Chapter 15.0.

Regulatory Guide 1.183, Revision 0, July 2000

Alternative Radiological Source Terms For Evaluating Design Basis Accidents At Nuclear Power Reactors

Regulatory Guide Intent:

This guide provides guidance to licensees of operating power reactors on acceptable applications of alternative source terms; the scope, nature, and documentation of associated analyses and evaluations; consideration of impacts on analyzed risk; and content of submittals. This guide establishes an acceptable alternative source term (AST) and identifies the significant attributes of other ASTs that may be found acceptable by the NRC staff. This guide also identifies acceptable radiological analysis assumptions for use in conjunction with the accepted AST.

Application Assessment:

Assessed capability in design.

Compliance or Alternate Approach Statement:

Identified NSSS scope of supply analysis, design, and equipment used in this facility is in compliance with this regulatory guide or through the incorporation of the NRC approved alternate approach cited.

General Compliance or Alternate Approach Assessment:

This regulatory guide is applicable to the analyses for the FSAR. The Columbia analysis methods and assumptions (see Energy Northwest, "Columbia Generating Station Alternative Source Term," CGS-FTS-0168, Revision 0, August 2007) conform to position of this Regulatory Guide with the following specific considerations.

[Guide Section 3.4] Table 5 of the regulatory guide lists the elements in each radionuclide group that should be considered in design basis analyses. The intent of the guidance is met by an alternate approach. The Columbia analyses consider 66 nuclides consisting of 60 identified as being potentially important contributors to TEDE in NUREG/CR-4691 plus seven additional noble gas isotopes and Ba-137m.

[Guide Section 4.3] Columbia conforms with guide section 4.3 with the exception that the TID-14844 source term continues to be used as the radiation dose basis for equipment qualification.

[Guide Section 3.3 of Appendix A] The intent of the guidance is met by the conservative approach used in the Columbia analysis. The SRP 6.5.2 model is used. Elemental iodine is assumed to be removed at the same rate as particulate. The approach of treating elemental iodine as particulate is a conservative representation of the situation in which some elemental iodine would be removed by diffusion to spray water droplets and some elemental iodine would adsorb onto particulate. A reduction of 10 in iodine removal lambda is taken when 98% of the particulate has been removed. The method results in a conservative dose.

Specific Evaluation Reference:

See Chapter 15.4.9, 15.6.4, 15.6.5, 15.7.4.

Similar Application Reference:

Similar application was used for Grand Gulf and Brunswick.

Regulatory Guide 1.190, Revision 0, March 2001

Calculational and Dosimetry Methods for Determining Pressure Vessel Neutron Fluence

Regulatory Guide Intent:

This Regulatory Guide has been developed to provide state-of-the-art calculations and measurement procedures that are acceptable to the NRC staff for determining pressure vessel fluence.

Application Assessment:

Assessed capability in design.

Compliance or Alternate Approach Statement:

The methodology for the neutron flux calculation for the CGS reactor vessel conforms to Licensing Topical Report (LTR) NEDC-32983-P-A. In general, the methodology described in the LTR adheres to the guidance in Regulatory Guide 1.190 for neutron flux evaluation and was approved by the U.S. NRC in the Safety Evaluation Report (SER) for referencing in Licensing submittals.

General Compliance or Alternate Assessment:

Reference compliance assessment for Regulatory Guide 1.99.

Specific Evaluation Reference:

See Section 4.3.2.8.

Similar Application Reference:

Similar application is used for Browns Ferry Nuclear Plant, Units 2 and 3, reactor vessels.

Regulatory Guide 1.194, Revision 0, June 2003

Atmospheric Relative Concentrations for Control Room Radiological Habitability Assessments at Nuclear Power Plants

Regulatory Guide Intent:

This guide provides guidance on determining atmospheric relative concentrations (χ/Q) values in support of design basis control room radiological habitability assessments at nuclear power plants. This guide describes methods acceptable to the NRC staff for determining χ/Q values that will be used in control room radiological habitability assessments performed in support of applications for licenses and license amendment requests.

Application Assessment:

Assessed capability in design.

Compliance or Alternate Approach Statement:

Identified NSSS scope of supply analysis, design, and equipment used in this facility is in compliance with this regulatory guide or through the incorporation of the NRC approved alternate approach cited.

General Compliance or Alternate Approach Assessment:

This regulatory guide is applicable to the analyses for the FSAR. The Instantaneous Puff Release alternative method provided by this guide is used to calculate χ/Q for the Main Steam Line Break accident.

Specific Evaluation Reference:

See Section 15.6.4.

Similar Application Reference:

1.8.3 BALANCE OF PLANT SCOPE OF SUPPLY EVALUATION

The following evaluations of implementation of regulatory guides are relative to BOP scope of supply. Thus, reference to CGS in the following evaluations is restricted to the BOP scope of supply portions of CGS. For NSSS scope of supply implementation of regulatory guides, see Section 1.8.2.

Conformance to the regulatory guides falls under either of the two following categories:

a. Compliance with the guidance set forth in this regulatory guide as described in this FSAR or

b. Compliance with the intent of the guidance set forth in this regulatory guide by an alternate approach.

The second category is based on NRC rules which state:

> Regulatory guides are not substitutes for regulations, and compliance with them is not required. Methods and solutions different from those set out in the guides will be acceptable if they provide a basis for the findings requisite to the assurance or continuance of a permit or license by the NRC.

Regulatory guides and their revisions are addressed in the following.

Regulatory Guide 1.6, Revision 0, March 1971

Independence Between Redundant Standby (Onsite) Power Sources and Between Their Distribution Systems

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in this regulatory guide.

General Compliance or Alternate Approach Assessment:

The compliance assessments given below correspond numerically to the Regulatory Positions as enumerated in Section C of Regulatory Guide 1.6, Revision 0.

1. The electrically powered safety loads, both ac and dc, are separated into redundant load groups such that loss of any one group will not prevent the minimum safety function from being performed.

2. Each ac load group has a connection to the preferred offsite power source and to a standby onsite power source. The standby power sources have no automatic connection to any other redundant load groups.

3. Each dc load group is energized by a battery and battery charger. The battery-charger combination has no automatic connection to any other redundant dc load group.

4. When operating from the standby sources, redundant load groups and the redundant standby sources are independent of each other.

5. A single generator driven by two prime movers in tandem is the standby power source for the Division 1 and 2 ac load groups. The Division 3 ac load group power is supplied by a single generator driven by a single prime mover.

Specific Evaluation Reference:

See Sections 8.1.5.2, 8.3.1.1.7, 8.3.1.2.1.3, 8.3.1.2.1.4, 8.3.1.3, 8.3.1.4, 8.3.2.1.1, 8.3.2.2.1.2, 8.3.2.3, and 8.3.2.4.

Regulatory Guide 1.8, Rev. 1-R (May 1977)

Personnel Selection and Training

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in this regulatory guide.

General Compliance or Alternate Approach Assessment:

The Regulatory Position of Regulatory Guide 1.8, Rev. 1-R (May 1977) will be implemented.

Specific Evaluation Reference:

See Sections 13.1.3, 13.2.1, and the OQAPD.

Regulatory Guide 1.9, Revision 0, March 1971

Selection of Diesel Generator Set Capacity for Standby Power Supplies.

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in this regulatory guide.

General Compliance or Alternate Approach Assessment:

The compliance assessments given below correspond numerically to the regulatory positions as enumerated in Section C of Regulatory Guide 1.9, Revision 0.

1. Both the Division 1 and Division 2 diesel generator sets were selected to have a continuous load rating equal to or greater than the sum of the conservative estimated loads needed to be powered at any one time.

2. The predicted loads on both the Division 1 and the Division 2 diesel generator sets do not exceed the 2000-hr rating of either set, respectively, or 90% of the 30-minute rating of either set, respectively.

3. Predicted loads on Division 1 and Division 2 were verified by tests during preoperational testing.

4. The Division 1 and Division 2 diesel generator sets are capable of starting and accelerating to rated speed, in the required sequence, all the needed engineered safety feature and emergency shutdown loads.

   The Division 1 and Division 2 diesel generator sets are within the limits of undervoltage, under-frequency, overspeed and voltage and frequency restoration time limits, set forth in the regulatory guide.

5. The suitability of each diesel generator set of the standby power supply was confirmed by prototype qualification test data and preoperational tests.

The scope of Regulatory Guide 1.9, Revision 0 does not include recommendations for surveillance testing. The surveillance requirements for demonstrating the operability of the diesel generators are consistent with the recommendations of Regulatory Guide 1.9 Revision 3 as described in the Bases for Technical Specification B 3.8.1. Additionally, periodic testing of all diesel generators is accomplished at intervals specified in the Technical Specifications (TS) which are controlled under the Surveillance Frequency Control Program (SFCP). Compliance with Regulatory Guide 1.9 Rev. 0, as an acceptable basis for the selection of diesel generator sets of sufficient margin to implement General Design Criterion 17, remains as described herein.

Specific Evaluation References:

See Sections 8.1.5.2, 8.3.1.1.7, and 8.3.1.2.1.3.

Regulatory Guide 1.10, Revision 1, January 1973

Mechanical (Cadweld) Splices in Reinforced Bars of Category I Concrete Structures.

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in this regulatory guide.

General Compliance or Alternate Approach Assessment:

The requirements of the guide have been included in the appropriate specifications for the project construction. Compliance with the guide is ensured by testing and control procedures and reporting program. The program includes splicing crew qualifications, visual inspection of each splice, tensile testing of splice samples, tensile test frequency program, and a procedure for evaluating substandard test results. The procedure for testing and sampling of mechanical splices have been implemented.

Specific Evaluation Reference:

See Sections 3.8.3.2 and 3.8.4.2 and Table 3.8-4.

Regulatory Guide 1.11, Revision 0, March 1971

Instrument Lines Penetrating Primary Reactor Containment.

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in this regulatory guide.

General Compliance or Alternate Approach Assessment:

CGS design includes flow restriction orifices and/or excess flow check valves with position indication in instrument lines which penetrate primary reactor containment. In the event of an instrument line rupture outside primary containment, the integrity and functional performance of the secondary containment system and its associated filtration systems are maintained.

Specific Evaluation Reference:

See Sections 7.1.2.4 and 6.2.4.

Regulatory Guide 1.12, Revision 2, March 1997

Instrumentation for Earthquakes

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in this regulatory guide.

General Compliance or Alternate Approach Assessment:

Triaxial strong-motion accelerographs are installed at appropriate locations to provide data on the seismic input to the free field area, containment; data on frequency, amplitude, and phase relationship of the seismic response of the containment structure; and data on the seismic input to other Category I structures, systems, and components.

Specific Evaluation Reference:

See Section 3.7.4.

Note: While RG 1.12, Rev 2 is designed to meet 10 CFR 50, Appendix S, CGS is using it as an alternative method of complying with seismic requirements applicable to CGS, namely 10 CFR 100, Appendix A.

Regulatory Guide 1.13, Revision 1, December 1975

Spent Fuel Storage Facility Design Basis

Compliance or Alternate Approach Statement:

CGS complies with the intent of the guidance set forth in this regulatory guide by an alternate approach.

General Compliance or Alternate Approach Assessment:

A controlled leakage building is provided enclosing the fuel pool. The building is not designed to withstand extremely high winds, but leakage is suitably controlled during refueling operations. The building is equipped with a ventilation and filtration system which is designed to limit the potential consequences of the release of radioactivity specified in Regulatory Guide 1.183 to those requirements set forth in 10 CFR 50.67.

The movement paths of heavy objects such as the reactor pressure vessel head, containment vessel head, and the spent fuel cask are designed not to pass over the spent fuel racks. Furthermore, the reactor building crane and its auxiliary hoist are prevented by means of interlocks from passing over any of the spent fuel pool except the spent fuel cask area. Bypassing of the interlocks is permitted only during fuel handling and storage operations and is administratively controlled.

The fuel pool is designed so that no pipe break will drain water from the fuel pool.

Specific Evaluation Reference:

See Section 9.1.

Regulatory Guide 1.15, Revision 1, December 1972

Testing of Reinforcing Bars for Category I Concrete Structures

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in this regulatory guide.

General Compliance or Alternate Approach Assessment:

The requirements of the guide have been included in the appropriate specifications for project construction. Compliance with the guide is assured by the implementation of qualified testing and control procedures and reporting. Included are qualified control procedures and reporting for the yield strength and tensile strength tests and deformation inspections recommended by the guide.

Specific Evaluation Reference:

See Sections 3.8.3.2, 3.8.4.2, and 3.8.5.2 and Table 3.8-4.

Regulatory Guide 1.16, Revision 4, August 1975

Reporting of Operating Information - Appendix A Technical Specifications

Compliance or Alternate Approach Statement:

This regulatory guide was withdrawn in August 2009 and is no longer applicable.

General Compliance or Alternate Approach Assessment:

Not applicable.

Specific Evaluation Reference:

Not applicable.

Regulatory Guide 1.17, Revision 1, June 1973

Protection of Nuclear Power Plants Against Industrial Sabotage

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in this regulatory guide.

General Compliance or Alternate Approach Assessment:

This information is considered proprietary and is subject to limited distribution. All specifics have been forwarded to the NRC as part of the Energy Northwest proprietary physical security plan for CGS.

Specific Evaluation Reference:

See proprietary physical security plan.

Regulatory Guide 1.18, Revision 1, December 1972.

Structural Acceptance Test for Concrete Primary Reactor Containments

Compliance or Alternate Approach Statement:

This regulatory guide is not applicable since CGS does not have a concrete primary containment.

General Compliance or Alternate Approach Assessment:

Not applicable.

Specific Evaluation Reference:

Not applicable.

Regulatory Guide 1.19, Revision 1, August 1972

Nondestructive Examination of Primary Containment Liner Welds

Compliance or Alternate Approach Statement:

This regulatory guide is not applicable since CGS does not have a concrete primary containment with a steel liner.

General Compliance or Alternate Approach Assessment:

Not applicable.

Specific Evaluation Reference:

Not applicable.

Regulatory Guide 1.21, Revision 1, June 1974

Measuring, Evaluating, and Reporting of Radioactivity in Solid Wastes and Releases of Radioactive Materials in Liquid and Gaseous Effluents from Light-Water-Cooled Nuclear Power Plants

Compliance or Alternate Approach Statement:

CGS complies with the intent of the guidance established in this regulatory guide by an alternate approach.

General Compliance or Alternate Approach Assessment:

The following categories of monitoring systems incorporated into the CGS design fulfill the requirements for monitoring in Regulatory Guide 1.21.

a. Gaseous effluents,
b. Liquid effluents, and
c. Solid Waste.

The above categories of monitoring systems adequately monitor effluent discharge paths for radioactivity that may be released from normal operations, including anticipated operational occurrences, and from postulated accidents.

Columbia Generating Station complies with Section C.11.b (Quality Controls) requirements for blind duplicate analysis by an alternate approach. An intralaboratory blind sample program is performed on selected samples. The blinds are prepared from samples sent from a cross check laboratory and split between several analysts as determined by the Chemistry Operations Supervisor or designee. This process allows evaluation of individual analysts' performance while at the same time satisfying the blind duplicate and cross check laboratory requirements.

Section C.11.c (Calibrations) suggests that appropriate standards be used to calibrate continuous radioactivity monitors and that the relationship be established between monitor readings and concentration over the full range of the readout device. In those cases where mixed fission gases or corrosion and activation products are not available, vendor instrument performance data or calculations will be used. Subsequent inservice calibrations will be performed using the specific radionuclide analytical results from grab samples taken from the effluent release path.

Appendix A, Section A.3.a (1) and Section A.3.a (3), analytical frequencies are not consistent with standard sampling and analytical techniques. Improved sensitivities and

more realistic quantity measurements can be made by performing ^{140}Ba-La, $^{89\text{-}90}$Sr, and gross alpha measurements on a monthly composite sample of weekly samples.

Exception is taken to the Appendix A, Section B.1.c, requirement for a special sample and analysis of one liquid waste batch per month for entrained fission and activation gases. The gamma spectrum analysis performed prior to the release of any waste liquid batch will identify such gases without performing a separate or special analysis.

The sensitivity slated in Appendix A, Section B.3, for gamma-emitting radionuclides (5×10^{-7} µCi/ml) will be applied in the case of principal gamma-emitting nuclides.

Specific Evaluation Reference:

See Section 11.5.

Regulatory Guide 1.22, Revision 0, February 1972

Periodic Testing of Protection System Actuation Functions

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in this regulatory guide.

General Compliance or Alternate Approach Assessment:

The CGS protection system and the systems whose operation it initiates are designed to permit periodic testing of the actuation devices during reactor operation. The periodic tests will duplicate, as closely as practical, the performance that is required of the actuation devices in the event of an accident. The tests will be performed in overlapping portions so that an actual reactor scram will not occur as a result of the testing.

Specific Evaluation Reference:

See Section 7.3.2.1.3.

Regulatory Guide 1.23, Revision 0, February 1972

Onsite Meteorological Program

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in this regulatory guide.

Where conflicts exist between the recommendations specified in Regulatory Guide 1.23, Revision 0 and those recommended in Regulatory Guide 1.97, Revision 2, the Columbia Generating Station will comply with the recommendations of Regulatory Guide 1.97, Revision 2 unless noted in the text discussions as meeting Regulatory Guide 1.97, Revision 3 requirements (see Section 7.5.2.2.3).

General Compliance or Alternate Approach Assessment:

The requirements of this regulatory guide for a meteorological program to provide the meteorological data required to estimate potential radiation doses to the public have been and are being implemented for CGS.

Specific Evaluation Reference:

See Sections 2.3.2, 2.3.3, 7.7.1, and the Emergency Plan.

Regulatory Guide 1.26, Revision 3, February 1976

Quality Group Classifications and Standards for Water-, Steam-, and Radioactive-Waste Containing Components of Nuclear Power Plants

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in this regulatory guide.

General Compliance or Alternate Approach Assessment:

The definition of quality group classifications for CGS was provided in the PSAR in accordance with ASME B&PV Code, Sections III and VIII. Quality group classifications have been maintained during design and construction. Quality group classifications are maintained during plant operations and modifications by plant administrative procedures and the plant modification control process. The quality group classifications are commensurate with the safety functions performed by the safety-related components.

The turbine stop valves and bypass valve, which are classified Quality Group D, are subject to an enhanced quality assurance program comparable to that of Quality Group B.

Specific Evaluation Reference:

See Section 3.2.

Regulatory Guide 1.27, Revision 2, January 1976

Ultimate Heat Sink for Nuclear Power Plants

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in this regulatory guide.

General Compliance or Alternate Approach Assessment:

Energy Northwest complies with Regulatory Guide 1.27, Revision 2, without any exceptions and with one clarification.

The clarification is that the tower makeup system (TMU) water supply is only an ultimate heat sink feature in the event of a design basis tornado. Since Regulatory Guide 1.27 states that we need not consider two or more most severe natural phenomena occurring simultaneously, the TMU was designed to be tornado proof but was not designed and constructed to withstand the effects of the operating basis earthquake (OBE) and water flow based on severe historical events in the region.

Specific Assessment Reference:

See Section 9.2.5.

Regulatory Guide 1.28, Revision 0, June 1972

Quality Assurance Program Requirements (Design and Construction)

Compliance or Alternate Approach Statement:

CGS *complies with the guidance set forth in this regulatory guide as described below.*

General Compliance or Alternate Approach Assessment:

Procurement documents issued after November 1973 required compliance with ANSI N45.2. Prior to that time, an "explanative version" of 10 CFR 50 Appendix B was used. The design and construction activities initially complied with 10 CFR 50 Appendix B. In November 1974, reference to ANSI N45.2 was added to the construction specifications.

ANSI N45.2 does not apply to the activities covered by Section III and Section XI of the ASME Code; however, the quality assurance program requirements may be extended to these activities based on project requirements.

Specific Evaluation Reference:

None

Regulatory Guide 1.29, Revision 3, September 1978

Seismic Design Classification

Compliance or Alternate Approach Statement:

CGS complies with the intent of the guidance set forth in this regulatory guide by an alternate approach.

General Compliance or Alternate Approach Assessment:

CGS classifications are consistent with Regulatory Guide 1.29 with the following clarification:

Cooling of the spent fuel storage pool is accomplished by the spent fuel cooling and cleanup system or by the seismic category RHR cross connection. The spent fuel pool cooling portion which is used normally to cool the spent fuel pool water was Seismic Category I by the first refueling outage. The cleanup portion of the system is not Seismic Category I. However, all structures, systems, and components required for maintaining water cover for the spent fuel are Seismic Category I. The spent fuel cooling system uses some common pump suction and discharge piping which is embedded in concrete. Prior to the first refueling outage, the Seismic Category I RHR system cross connection would have been used in case of core offload (see Section 9.1.3).

Specific Evaluation Reference:

See Sections 3.2.1, 3.7, 3.8, 3.9, 3.10, 9.1.3, and the OQAPD.

Regulatory Guide 1.30, Revision 0, August 1972

Quality Assurance Requirements for the Installation, Inspection, and Testing of Instrumentation and Electrical Equipment.

I Design and Construction Phase

Compliance or Alternate Approach Statement:

CGS generally complies with the guidance set forth in this regulatory guide. In a few cases, CGS complied with the intent of this guidance by an alternate approach.

General Compliance or Alternate Approach Assessment:

Procurement documents require compliance with ANSI N45.2.4 for the installation, inspection, and testing activities performed, except in those isolated instances where requirements were entered directly in the specification with limited or no reference to ANSI N45.2.4 or IEEE 336.

Specific Evaluation Reference:

None

II Operational Phase

Compliance is discussed in the OQAPD.

Regulatory Guide 1.31, Revision 3, April 1978

Control of Ferrite Content in Stainless Steel Weld Metal

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in this regulatory guide.

General Compliance or Alternate Approach Assessment:

CGS complies fully with Revision 3 of this guide on all contracts initiated after the date of its publication. Prior to issuance of Revision 3, CGS conformed to Revision 2 of this regulatory guide.

Specific Evaluation Reference:

See Sections 4.5.2.4, 5.2.3.3, and 5.3.1.4.

Regulatory Guide 1.32, Revision 2, February 1977

Criteria for Safety Related Electric Power Systems for Nuclear Power Plants

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in Revision 0 of this regulatory guide.

(Revisions 1 and 2 are not applicable to CGS since they are for use in evaluations of construction permits docketed after November 1, 1976, and April 15, 1977, respectively.)

General Compliance or Alternate Approach Assessment:

The CGS design is in full compliance with both Revision 0 of this regulatory guide and with Revision 2 of this regulatory guide, with the exception of those sections of the regulatory guide which require compliance with Regulatory Guides 1.93, Revision 0, and 1.75, Revision 0. See Section 8.3.1.2.1.1 for analysis of the CGS design relative to Regulatory Guide 1.75, Revision 0.

Specific Evaluation References:

See Sections 8.1.5.1, 8.1.5.2, 8.2.2.4, 8.3.1.1.7.1, 8.3.1.2.1.3, 8.3.1.3, 8.3.1.4, 8.3.2.1.1, 8.3.2.2.1, 8.3.2.3 and 8.3.2.4.

Regulatory Guide 1.33, Revision 2, February 1978

Quality Assurance Program Requirements (Operation)

Compliance or Alternate Approach Statement:

CGS complies with the intent of the guidance set forth in this regulatory guide by an alternate approach.

Compliance or Alternate Approach Assessment:

Compliance is discussed in the OQAPD.

Specific Evaluation Reference:

See Section 13.5.1.1 and the OQAPD.

Regulatory Guide 1.34, Revision 0, December 1972

Control of Electroslag Weld Properties

Compliance or Alternate Approach Statement:

This regulatory guide is not applicable to CGS since electroslag welding has not been used for welding of Class 1 or 2 vessels or components fabricated of low alloy or austenitic steel.

General Compliance or Alternate Approach Assessment:

Not applicable.

Specific Evaluation Reference:

Not applicable.

Regulatory Guide 1.35, Revision 2, January 1976

Inservice Inspection of Ungrouted Tendons in Prestressed Concrete Containment Structures

Compliance or Alternate Approach Statement:

This regulatory guide is not applicable to CGS since CGS does not have a prestressed concrete containment structure with ungrouted tendons.

General Compliance or Alternate Approach Assessment:

Not applicable.

Specific Evaluation Reference:

Not applicable.

Regulatory Guide 1.36, Revision 0, February 1973

Nonmetallic Thermal Insulation for Austenitic Stainless Steel

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in this regulatory guide.

General Compliance or Alternate Approach Assessment:

Thermal insulation on stainless steel piping conforms to requirements of this regulatory guide.

Specific Evaluation Reference:

Not applicable.

Regulatory Guide 1.37, Revision 0, March 1973

Quality Assurance Requirements for Cleaning of Fluid Systems and Associated Components of Water-Cooled Nuclear Power Plants

I Design and Construction Phase

Compliance or Alternate Statement:

CGS generally complies with the guidance set forth in this regulatory guide. In a few cases, CGS complied with the intent of this guidance by an alternate approach.

General Compliance or Alternate Approach Assessment:

Procurement documents generally required compliance with ANSI N45.2.1. Whether or not reference to ANSI N45.2.1 was provided, a detailed specification section supplied comprehensive instructions on cleaning and cleanliness.

Specific Evaluation Reference:

None

II Operational Phase

Compliance is discussed in the OQAPD.

Regulatory Guide 1.38, Revision 2, May 1977

Quality Assurance Requirement for Packaging, Shipping, Receiving, Storage, and Handling of Items for Water-Cooled Nuclear Power Plants

I Design and Construction Phase

Compliance or Alternate Approach Statement:

CGS generally complies with the guidance set forth in Revision 0 of this regulatory guide. In a few cases, CGS complied with the intent of this guidance by an alternate approach.

The changes to the regulatory positions of Revision 1 and 2 of this regulatory guide, which specify additional detailed requirements and make certain nonmandatory sections of ANSI N45.2.2 mandatory, are not implemented.

General Compliance or Alternate Approach Assessment:

Procurement documents required compliance with ANSI N45.2.2, Revision 0, and/or contained a generic specification packaging section and/or specified directly requirements for these functions.

The regulatory positions contained in Revision 1 and 2 of this regulatory guide changed significantly from the original issue. Revision 1 and 2 contain additional detailed requirements and make nonmandatory sections of ANSI N45.2.2 mandatory. Some, but not all, of the changes to the regulatory positions are included in procurement documents. Since these changes were made after award of the applicable procurement documents, Revision 1 and 2 are not fully implemented.

Specific Evaluation Reference:

None

II Operational Phase

Compliance is discussed in the OQAPD.

Regulatory Guide 1.39, Revision 1, October 1976

Housekeeping Requirements for Water-Cooled Nuclear Power Plants

I Design and Construction Phase

Compliance or Alternate Approach Statement:

CGS generally complies with the guidance set forth in this regulatory guide. In some cases, CGS complied with the intent of this guidance by an alternate approach.

General Compliance or Alternate Approach Assessment:

Procurement documents required compliance with ANSI N45.2.3 or with selected portions of ANSI N45.2.3 or specified directly applicable housekeeping requirements.

Specific Evaluation Reference:

None

II Operational Phase

Compliance is discussed in the OQAPD.

Regulatory Guide 1.40, Revision 0, March 1973

Qualification Tests of Continuous Duty Motors Installed Inside the Containment of Water-Cooled Nuclear Power Plants

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in the regulatory guide.

General Compliance or Alternate Approach Assessment:

Containment fans have been qualified for in containment use in accordance with IEEE 334-1974.

Specific Evaluation Reference:

See Section 9.4.11.3.

Regulatory Guide 1.41, Revision 0, March 1973

Preoperational Testing of Redundant On-Site Electrical Power Systems to Verify Proper Load Group Assignments

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in the regulatory guide.

General Compliance or Alternate Approach Assessment:

As part of the preoperational test program, the onsite electric power systems will be tested in order to verify the existence of independence among redundant onsite power sources and their respective load groups.

Specific Evaluation Reference:

See Sections 8.1.5.2, 8.3.1.2.2 and 14.2.

Regulatory Guide 1.43, Revision 0, May 1973

Control of Stainless Steel Weld Cladding of Low-Alloy Steel Components

Compliance or Alternate Approach Statement:

This regulatory guide is not applicable to CGS since CGS does not use stainless steel cladding on coarse grain low-alloy steel for safety class components.

General Compliance or Alternate Approach Assessment:

Not applicable.

Specific Evaluation Reference:

Not applicable.

Regulatory Guide 1.44, Revision 0, May 1973

Control of the Use of Sensitized Stainless Steel

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in this regulatory guide.

General Compliance or Alternate Approach Assessment:

CGS conforms fully to the recommended welding controls for stainless steel welding. All materials are purchased to the latest ASME and ASTM specifications at time of order, and the cleaning requirements set forth in the guide are implemented during document review of vendor cleaning procedures.

Specific Evaluation Reference:

See Sections 4.5.2.4 and 5.3.1.4.

Regulatory Guide 1.46, Revision 0, May 1973

Protection Against Pipe Whip Inside Containment

Compliance or Alternate Approach Statement:

CGS complies with the intent of the guidance set forth in this regulatory guide by an alternate approach.

Pipe break location criteria is based on guidelines provided in this regulatory guide, as well as the NRC Branch Technical Positions ASB 3-1, Appendix B, and MEB 3-1. The criteria is applicable to all piping systems inside as well as outside containment. Pipe whip protection for the recirculation system is provided by the NSSS supplier. Pipe whip protection for all other piping systems, including the NSSS-furnished main steam piping, is provided by the architect-engineer.

Specific Evaluation Reference:

See Section 3.6.2.1.

Regulatory Guide 1.47, Revision 0, May 1973

Bypassed and Inoperable Status Indication for Nuclear Power Plant Safety Systems

Compliance or Alternate Approach Statement:

CGS complies with the intent of the guidance set forth in this regulatory guide by an alternate approach.

General Compliance or Alternate Approach Assessment:

The alternate approach is provided in Section 7.1.2.4.

Specific Evaluation Reference:

Not applicable.

This page left intentionally blank.

Regulatory Guide 1.48, Revision 0, May 1973

Design Limits and Loading Combinations for Seismic Category I Fluid System Components

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in this regulatory guide.

General Compliance or Alternate Approach Assessment:

Implementation of this regulatory guide is discussed in Section 3.9.3.1.1.7.

Specific Evaluation Reference:

See Section 3.9.3.1.1.7.

Regulatory Guide 1.50, Revision 0, May 1973

Control of Preheat Temperature for Welding Low-Alloy Steel

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in this regulatory guide.

General Compliance or Alternate Approach Assessment:

CGS complies with the guidance set forth in the regulatory guide by maintaining the preheat temperature of low alloy steel welds until the post-weld heat treatment has been performed. For welds which were made without this "keep hot" requirement, Regulatory Position C4 for determining the soundness of the weld by acceptable examination procedures, has been enforced.

Specific Evaluation Reference:

See Section 5.3.1.4.

Regulatory Guide 1.51, Revision 0, May 1973

In-Service Inspection of ASME Code Class 2 and 3 Nuclear Power Plant Components

Compliance or Alternate Approach Statement:

This regulatory guide has been withdrawn and is no longer applicable.

General Compliance or Alternate Approach Assessment:

Inservice inspection of CGS is based on ASME Section XI for Classes 1, 2, and 3.

Specific Evaluation Reference:

See Section 3.9.6.

Regulatory Guide 1.52, Revision 2, March 1978

Design, Testing, and Maintenance Criteria for Atmosphere Cleanup System Air Filtration and Adsorption Units of Light-Water-Cooled Nuclear Power Plants

Compliance or Alternate Approach Statement:

CGS complies with the intent of the guidance given in Revision 2 of this regulatory guide with the exception that the operation identified in C-4.d, Revision 2 is modified by Technical Specification Amendment 239 which adopts the testing criteria identified in Regulatory Position 6.1 of Revision 3.

General Compliance or Alternate Approach Assessment:

Standby gas treatment filter units and the control room emergency filter units are required to perform safety-related functions. A comparison of the engineered safety feature air filtration systems with respect to the regulatory position of Regulatory Guide 1.52, Revision 2, Article C, is as follows:

Paragraph Number	SGTS	Control Room System
C-1. "Environmental Design Criteria"		
1.a	In compliance	In compliance
1.b	In compliance	In compliance
1.c	In compliance	In compliance
1.d	In compliance	In compliance
1.e	In compliance	In compliance

C-2. "System Design Criteria"

2.a	In compliance	See Note 1
2.b	In compliance	In compliance
2.c	In compliance	In compliance
2.d	See Note 2	See Note 2
2.e	In compliance	In compliance
2.f	In compliance	In compliance
2.g	See Note 3	See Note 3
2.h	In compliance	In compliance
2.i	In compliance	In compliance
2.j	See Note 4	See Note 4
2.k	In compliance	In compliance
2.1	In compliance	In compliance

C-3. "Component Design Criteria and Qualification Testing"

3.a	See Note 5	See Note 5
3.b	In compliance	In compliance
3.c	In compliance	In compliance
3.d	See Note 6	See Note 6
3.e	In compliance	In compliance
3.f	In compliance	In compliance
3.g	See Note 7	See Note 7
3.h	In compliance	In compliance
3.i	See Note 8	See Note 8
3.j	In compliance	In compliance
3.k	In compliance	In compliance
3.l	In compliance	In compliance
3.m	In compliance	In compliance
3.n	In compliance	In compliance

3.p	In compliance	In compliance

C-4. "Maintenance"

4.a	See Note 9	See Note 9
4.b	See Note 10	See Note 10
4.c	In compliance	In compliance
4.d	See Note 11	In compliance
4.e	In compliance	In compliance

C-5. "In-Place Testing Criteria"

5.a	In compliance	In compliance
5.b	See Note 13	In compliance
5.c	See Note 14	See Note 14
5.d	See Note 14	See Note 14

C-6. "Laboratory Testing Criteria For Activated Carbon"

6.a	See Note 12	See Note 12
6.b	See Note 12	See Note 12

Note 1 (C-2.a) Demisters are not provided in the control room filter units due to the absence of entrained moisture during normal and abnormal conditions. High-efficiency particulate air (HEPA) filters are not provided after the charcoal filter because filter unit discharges into control room air conditioning unit on intake side of medium efficiency filters.

Note 2 (C-2.d) Both units of the standby gas treatment system are located in secondary containment and are not subject to containment pressure surges during accidents. Redundant Seismic Category I valves in series isolate and protect these units from containment DBA pressures. Both units of the control room emergency filter system are not subject to containment pressure surges during accidents.

Note 3 (C-2.g) Abnormal pressure drops across critical components of the SGTS and control room filter units cause an alarm in the main control room, however, no facilities to record the pressure drops are provided. A record of pressure drop across individual components and the total SGTS system would be of no value because the SGTS is a variable flow system, with flow modulated to maintain the reactor building at a fixed negative pressure. Flow through the system, which is the pertinent parameter, is recorded in the main control room, and computer input is provided to record high pressure alarms across critical components.

Note 4 (C-2.j) SGTS filter units are not designed to be removable from the building as an intact unit. The size of the units precludes removal in one section. In the event the units become radioactively contaminated they will be permitted to decay in place until radiation levels are sufficiently low to permit the removal of all internals for disposal.

Note 5 (C-3.a) SGTS system demisters furnished by FARR Company, are not in complete conformance with ANSI N509-1976 because they were not qualified by testing in accordance with AEC report MSAR-71-45. A moisture eliminator study performed by FARR Company in 1970, which did not conform to the MSAR-71-45 test setup, indicated that the installed demisters will protect the HEPA filters in the system from blinding under conditions far more severe than those hypothesized for the SGTS system. Since, under the accident mode, entrained water droplets will not be in the inlet air stream, the FARR tests and qualification are considered adequate.

Note 6 (C-3.d) HEPA filters are not subjected to iodine removal sprays, therefore, aluminum separators are used.

An alternate approach to determine acceptable design and qualification testing of HEPA filters is the use of Regulatory Guide 1.52, Revision 3, Section 4.4.

Note 7 (C-3.g) Access doors into SGTS units are 50 x 20 in. Vacuum breakers are not provided on doors of SGTS and control room units. Unit fans are normally off.

Note 8 (C-3.i) Test 4, Activity (Ref. Table 5-1, ANSI N509-1976)

Base carbon (unimpregnated) activity test was not previously required. Because all available carbon was of the impregnated type this was not run.

Test 5, Radioiodine Removal Efficiency (Ref. Table 5-1, ANSI N509-1976)

New carbon will be tested in accordance with ASTM D3803-1989.

Average atmosphere resident time in each SGTS unit is greater than 0.5 sec.

Note 9 (C-4.a) Doors provided on SGTS Units are 50 x 20 in. Access panels are provided on control room units. Vacuum breakers are not provided on any of the units since they are normally not operational.

Note 10 (C-4.b) Control room filter units have approximately 18 in. between prefilter and HEPA filter frames, and approximately 4 ft are provided between HEPA and charcoal filter frames. SGTS filter units have a minimum of three feet provided between demister, heater, prefilter, HEPA and charcoal filter frames.

Note 11 (C-4.d) Strip heaters are provided in the charcoal filter plenum of the SGTS units to maintain charcoal beds moisture free, therefore, operation of the fans is not required for that purpose. Testing of the blast coil heaters is performed in accordance with the requirements of Regulatory Position 6.1 of Revision 3 of the Regulatory Guide 1.52

Note 12 (C-6.a C-6.b)	The laboratory testing criteria for the carbon adsorber section of the SGTS and CREF System meets the objectives of this section of the guide. Twelve representative test samples of four-inch length are provided across each of the two 4 in. deep beds in each SGTS filter unit. At least once per 30 months one sample from across each SGT and CREF adsorber bed is removed and sent to a laboratory for testing. For the SGTS, samples are tested in series to represent the 8-inch total bed depth. Laboratory tests are performed in accordance with ASTM D3803-1989 with methyl iodide at 30°C and 70% relative humidity with a penetration of less than 0.5% for the SGTS and less than 2.5% for the CREF System as an acceptance level. The SGTS will also be tested at a face velocity of 75 ft per minute. In the event that a sample fails this test, the carbon adsorber in its bed will be replaced.
Note 13 (C-5.b)	The flow distribution tests developed by the designer combined with the series filter design at CGS adequately meet the intent of this test. The results of the flow distribution tests as set forth in ANSI N51 are difficult to interpret with the 'U' shaped charcoal beds installed due to air flow disturbance caused by the measuring apparatus. This is particularly true on the parallel legs of the 'U' shaped beds, where the flow measuring device must be placed in the rather narrow air passage. Flow distribution criteria was developed by the designers based on the ±20% variation criteria established in Regulatory Guide 1.52 and has been met in field tests. In addition, each of the filter trains has two separate charcoal beds in series. This allows mixing of the filtered gas between the beds and further reduces the effects of variations in charcoal packing distribution.
Note 14 (C-5.c C-5.d)	The inplace leak testing of the SGT and CREF HEPA and carbon filters meets the objectives of this section of the guide with the exception that testing is performed in accordance with ASME N510-1989, Sections 10 and 11, respectively.

Specific Evaluation Reference:

See Section 6.5.1.

Regulatory Guide 1.53, Revision 0, June 1973

Application of the Single-Failure Criterion to Nuclear Power Plant Protective Systems

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in the regulatory guide.

General Compliance or Alternate Approach Assessment:

Regulatory Guide 1.53 provides guidance for the application of the single-failure criterion as discussed in IEEE 379-1972. The regulatory guide recommends the application of IEEE 379-1972 with four supplemental conditions. The design of the CGS electrical system is in conformance with IEEE 379-1972 and the four supplemental conditions noted in Regulatory Position C.

Specific Evaluation Reference:

See Section 8.1.5.2.

Regulatory Guide 1.54, Revision 0, June 1973

Quality Assurance Requirements for Protective Coatings Applied to Water-Cooled Nuclear Power Plants

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in this regulatory guide as described below.

General Compliance or Alternate Approach Assessment:

Special decontaminable coatings in primary containment areas are manufactured and applied in accordance with quality assurance requirements of ANSI N101.4.

Specific Evaluation Reference:

See Section 6.1.2.

Regulatory Guide 1.55, Revision 0, June 1973

Concrete Placement in Category I Structures

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in this regulatory guide.

General Compliance or Alternate Approach Assessment:

The requirements of the guide have been included in the appropriate construction contract specifications. Compliance with the guide is assured by the application of appropriate concrete specifications, construction practices, codes and standards, including the documents recommended by the guide, for the placement of concrete; by the implementation of approved communications procedures between qualified design and construction forces; and by implementation of an approved QA program which ensures design control and coordinated quality control of concrete material, placement, inspection and testing between applicant, designer and constructor.

Specific Evaluation Reference:

See Sections 3.8.3.2, 3.8.3.6, 3.8.4.2, 3.8.4.6, and 3.8.5.2 and Table 3.8-4.

Regulatory Guide 1.56, Revision 0, June 1973

Maintenance of Water Purity in Boiling Water Reactors

I. Design and Construction Phase

Compliance or Alternate Approach Statement:

The design of CGS complies with the guidance set forth in this regulatory guide.

General Compliance or Alternate Approach Assessment:

CGS design complies with the guidance of this regulatory guide by providing for the following:

a. Conductivity measurement and recording of the condenser hotwell and condensate flow discharge to the condensate demineralizer system,

b. Flow measurement and recording of flow through each condensate demineralizer unit,

c. Conductivity measurement, recording, and alarming of the condensate effluent discharge from each condensate demineralizer unit and from the combined system effluent,

d. Conductivity measurement, recording, and alarming of the inlet and outlet coolant to and from the RWCU system,

e. Extensive sampling of reactor coolant and auxiliary systems,

f. Full flow condensate demineralizer system, and

g. Excess condensate demineralizer capacity to permit recharging of resin beds during normal plant operation.

Specific Evaluation Reference:

See Section 5.2.3.2.2.

II. Operations Phase

Compliance or Alternate Approach Statement:

Operation of CGS RWCU and condensate demineralizer system complies with the general guidance set forth in Revision 1, July 1978, of this regulatory guide.

General Approach or Alternate Approach Assessment:

Operation of CGS complies with the guidance of the regulatory guide by providing the following:

a. Operating limits are prescribed for condensate filter demineralizers. Plant operating conductivity limits are defined for the RWCU demineralizers. Effluent conductivity for the individual demineralizers is recorded and a main control room alarm is triggered when conductivity limits are reached or exceeded;

b. Condensate filter demineralizer conductivity and flow instrumentation are used in the general assessment of individual demineralizer unit performance and capacity;

c. An operational limit is set for hotwell conductivity which triggers a main control room alarm. Hotwell conductivity, in conjunction with precalculated assessment of condenser inleakage rates and demineralizer performance permits appropriate action to be taken on exceeding the operating limit setpoint;

d. Laboratory analyses are performed for chloride, pH, and conductivity at intervals appropriate to the plant operating status. Sampling and analysis frequency is described in the LCS and plant procedures; and

e. Not applicable exception is taken to item C.4.d which applies to bead-type, deep-bed demineralizer systems, which are not incorporated into the CGS design. The general guidance of this item will, however, be applied to the pressure precoat filter demineralizer systems. Each lot of precoat resins will be analyzed for capacity and impurity levels. Frequency of precoat changeout will be staggered and is initially dictated by pressure drop associated with suspended solids. Subsequent to pressure drop limitations, frequency of sequential precoat changeout is established based on dissolved chemical constituents and flow throughput parameters.

Regulatory Guide 1.57, Revision 0, June 1973

Design Limits and Loading Combinations for Metal Primary Reactor Containment System Components

Compliance or Alternate Approach Statement:

CGS complies with the intent of the guidance set forth in this regulatory guide by an alternate approach.

General Compliance or Alternate Approach Assessment:

The structural design criteria for the primary containment vessel is consistent with the provisions of this regulatory guide, except with respect to the stress limits specified in Section C-1-b(2) of the guide, for the load combination of accident recovery flooding plus OBE. For this load combination, the stress limits used for CGS are within the limits set forth in the NRC Standard Review Plan Section 3.8.2, Table 3.8.2-1.

This exception has precedent as stated in GESSAR, paragraph 3.8.2.3.12, "Accident Recovery Evaluation," Page 3.8-9b, and has been accepted by the NRC, as documented in paragraph 3.8.2, page 3-14, of the NRC Safety Evaluation Report for the GESSAR-328 Nuclear Island Standard Design dated December 1975.

Specific Evaluation Reference:

See Section 3.8.2.3.10.

Regulatory Guide 1.58, Revision 1, August 1980

Qualification of Nuclear Power Plant Inspection, Examination, and Testing Personnel

I Design and Construction Phase

Compliance or Alternate Approach Statement:

As of November 1980, CGS complies with the guidance set forth in this regulatory guide via an alternate approach described below.

General Compliance or Alternate Approach Assessment:

Prior to issuance of Revision 1 of this Regulatory Guide, personnel performing quality-related activities were provided indoctrination and training in the requirements of the applicable quality assurance program, procedures, instructions and drawings affecting their work. Documented evidence of the above training was maintained. The indoctrination and training complied with the requirements of Appendix B, 10 CFR Part 50, and ANSI N45.2.

As of November 1980, in addition to the indoctrination and training requirements noted above, requirements which meet this regulatory guide were imposed on site contractors for personnel performing inspections, examinations, and tests. These requirements specify that initial evaluations of education, experience, and qualifications are to be performed and documented; however, formal certificates are not required to be issued because specific inspections, examinations, and tests are performed in accordance with approved procedures. Therefore, specific capability identification and levels of certification are not required.

Specific Evaluation Reference:

None

II Operational Phase

Compliance is discussed in the OQAPD. Also see Section 14.2.

Regulatory Guide 1.59, Revision 1, April 1976

Design Basis Floods for Nuclear Power Plants

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in this regulatory guide.

General Compliance or Alternate Approach Assessment:

All the requirements that are specified in Regulatory Guide 1.59 are followed in the design of CGS.

Based on Regulatory Guide 1.102, the plant site is classified as "Dry Site." Therefore, CGS is considered to be in compliance with Regulatory Guide 1.59 and its Appendix A.

Specific Evaluation Reference:

See Section 2.4.

Regulatory Guide 1.60, Revision 1, December 1973

Design Response Spectra for Seismic Design of Nuclear Power Plants

Compliance or Alternate Approach Statements:

CGS complies with the intent of the guidance set forth in this regulatory guide by an alternate approach.

General Compliance or Alternate Approach Assessment:

CGS meets the seismic requirements previously acceptable to the NRC as discussed in Section 3.7.1.1.

Specific Evaluation Reference:

See Section 3.7.1.1.

Regulatory Guide 1.61, Revision 0, October 1973

Damping Values for Seismic Design of Nuclear Power Plants

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in this regulatory guide.

General Compliance or Alternate Approach Assessment:

The damping values recommended by Regulatory Guide 1.61 are greater, and therefore less conservative, than the values used for CGS. The more conservative CGS design satisfies the requirements of Regulatory Guide 1.61.

Specific Evaluation Reference:

See Section 3.7.1.3.

Regulatory Guide 1.62, Revision 0, October 1973

Manual Initiation of Protective Actions

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in this regulatory guide.

General Compliance or Alternate Approach Assessment:

Means are provided in the main control room for the manual initiation of BOP engineered safety feature systems or supporting systems at the division level by the operation of a minimum of equipment.

Specific Evaluation Reference:

See Section 7.3.2.1.3.

Regulatory Guide 1.63, Revision 2, July 1978, and Revision 3, February 1987

Electric Penetration Assemblies in Containment Structures for Light-Water-Cooled Nuclear Power Plants

Compliance or Alternate Approach Statement:

Revisions 2 and 3 are not applicable to CGS since they apply to the evaluation of construction permit applications docketed after August 31, 1978 and February 28, 1987, respectively. CGS complies with the guidance set forth in IEEE 317-1972 as modified by Revision 0 of Regulatory Guide 1.63.

General Compliance or Alternate Approach Assessment:

The compliance assessment given below correspond numerically to the regulatory positions as indicated in Section C of Regulatory Guide 1.63, Revision 0, October 1973.

1. Capability of withstanding maximum fault I^2T heating in the case that overload protective devices fail:

   CGS is in compliance with this requirement. In all cases, the overcurrent protective devices in circuits subject to short circuit are backed up by other overcurrent protective devices which are also designed to limit the fault current I^2T heating experienced by the penetration conductors to levels below the conductor ratings.

2. The maximum containment pressure specified for CGS complies with the safety margins required by the ASME B&PV Code, Article N3000, footnote 1.

3. The position refers to specific applicability or acceptability of other codes, standards, and guides covered separately in other regulatory guides.

4. CGS complies with the requirement of IEEE 336 and ANSI N45.2 concerning the QA.

Specific Evaluation Reference:

See Sections 3.8.6, 7.1.2.3, and 8.1.5.2.

Regulatory Guide 1.64, Revision 2, June 1976

Quality Assurance Requirements for the Design of Nuclear Power Plants

I. Design and Construction Phase

Compliance or Alternate Approach Assessment:

Regulatory Guide 1.64, Revision 0, Revision 1, and Revision 2 do not apply to CGS since they apply to construction permits docketed after September 1973.

General Compliance or Alternate Approach Assessment:

Not applicable.

Specific Evaluation Reference:

Not applicable.

II. Operational Phase

Compliance is discussed in the OQAPD.

Regulatory Guide 1.67, Revision 0, October 1973

Installation of Overpressure Protection Devices

Compliance or Alternate Approach Statement:

This regulatory guide is not applicable to CGS since the reactor coolant system pressure boundary safety/relief valve relieves to a closed discharge system.

General Compliance or Alternate Approach Assessment:

Not applicable.

Specific Evaluation Reference:

Not applicable.

Regulatory Guide 1.68, Revision 1, January 1977

Initial Test Programs for Water-Cooled Reactor Power Plants

Compliance or Alternate Approach Statement:

This regulatory guide is not applicable to the CGS initial test program since Revision 0 of this regulatory guide is committed to in Section 14.2.7. However, CGS complies with the intent of the guidance set forth in this regulatory guide by an alternate approach.

General Compliance or Alternate Approach Assessment:

See Section 14.2 for description of initial testing program and to Sections 14.2.7 and 1.8.2 for statements concerning compliance with Regulatory Guide 1.68, Revision 0. Revision 1 of this guide in general clarifies Revision 0 and therefore there are no exceptions to the intent of this procedure.

Specific Evaluation Reference:

See Sections 14.2.7 and 1.8.2 for a discussion of Regulatory Guide 1.68, Revision 0.

Regulatory Guide 1.68.1, Revision 1, January 1977

Preoperational and Initial Startup of Feedwater and Condensate Systems for Boiling Water Reactor Power Plants.

Compliance or Alternate Approach Statements:

CGS complies with the intent of the guidance set forth in this regulatory guide by an alternate approach.

General Compliance or Alternate Approach Assessments:

The preoperational testing and the initial Startup testing as described in Section 14.2 complies with the intent of this regulatory guide. However, due to the limitations of the auxiliary steam supply system, the confirmation that the feedwater pumps satisfy required head, flow rate and suction head will not occur until the startup phase of the initial test program when the normal steam supply is available to the feedwater pump turbines.

Specific Evaluation Reference:

See Section 14.2.12.1.1.

Regulatory Guide 1.68.2, Revision 0, January 1977

Initial Startup Test Program To Demonstrate Remote Shutdown Capability For Water-Cooled Nuclear Power Plants

Compliance or Alternate Approach Statement:

CGS complies with the intent of the guidance set forth in this regulatory guide by an alternate approach.

General Compliance or Alternate approach assessment:

The startup test described in Section 14.2.12.3.28 complies with the regulatory guide with the following exceptions:

a. The test will be initiated by scramming plant from the control room versus a location outside the control room as described in Section C.3 of the regulatory guide. This exception is made to better simulate the actual procedure which would be followed if a control evacuation were to occur. The capability to scram the reactor outside the control room exists; for example, tripping the RPS motor generator (MG) sets.

b. The cold shutdown demonstration procedure as described in Section C.4 of the Regulatory Guide may not be performed immediately following the demonstration of achieving and maintaining safe hot standby from outside the control room. Rather this cooldown portion may be performed when cooldown is required during the course of the normal power ascension test program. Although this is an exception to Regulatory Guide 1.68.2, Revision 0, Revision 1 of this Guide contains provisions for a delay in the demonstration of cooldown.

Specific Evaluation Reference:

See Sections 14.2.12.3.28 and 7.4.1.4.

Regulatory Guide 1.69, Revision 0, December 1973

Concrete Radiation Shields for Nuclear Power Plants

Compliance or Alternate Approach Statement:

CGS complies with the intent of the guidance set forth in this regulatory guide by an alternate approach.

General Compliance or Alternate Approach Assessment:

Although the regulatory guide was promulgated after design and specification implementation of the engineering criteria, the recommended design and construction practices specified in the regulatory guide are documented in codes and specifications which were used in the development of the engineering criteria and contract specifications.

Specific Evaluation Reference:

See Section 12.3.2.

Regulatory Guide 1.70, Revision 2, September 1975

Standard Format and Content of Safety Analysis Reports for Nuclear Power Plants - LWR Edition

Compliance or Alternate Approach Statement:

This FSAR complies with the guidance set forth in this regulatory guide.

General Compliance or Alternate Approach Assessment:

The FSAR has generally been prepared to satisfy the requirements of Regulatory Guide 1.70, Revision 2. This includes both format and content.

Specific Evaluation Reference:

The balance-of-plant (BOP) portions of this FSAR.

Regulatory Guide 1.71, Revision 0, December 1973

Welder Qualifications for Areas of Limited Accessibility

Compliance or Alternate Approach Statement:

CGS complies with the intent of the guidance set forth in this regulatory guide by an alternate approach.

General Compliance or Alternate Approach Assessment:

There are few incidents where welding accessibility is limited during fabrication. Where accessibility to any weld joint was restricted to a degree which prevented the welder from direct visual observation of the arc and the puddle in any area of the weld, or which required the use of mirrors or extensions to the torch handle or electrode holder, the contractor notifies the welding engineer. All limited access welds are determined by a welding engineer. For ASME Section III, Class 1, 2, and 3 components and Subsection NF and NE, a performance qualification test that simulates the limited access condition is required by the welding engineer. For welds in the pressure retaining components the welder's test weld is radiographed in accordance with and shall conform to the acceptance standards of ASME Section VIII, Division 1, U.W.-51. Alternately, the weld may be examined ultrasonically in accordance with ASME Section VIII, Division 1, Appendix U.

Specific Evaluation Reference:

See Sections 4.5.2.4, 5.2.3.3, and 5.3.1.4.

Regulatory Guide 1.72, Revision 0, December 1973

Spray Pond Plastic Piping

Compliance or Alternate Approach Statement:

This regulatory guide is not applicable to CGS because CGS does not use plastic piping in its spray ponds.

General Compliance or Alternate Approach Assessment:

Not applicable.

Specific Evaluation Reference:

Not applicable.

Regulatory Guide 1.73, Revision 0, January 1974

Qualification Tests of Electric Valve Operators Installed Inside the Containment of Nuclear Power Plants

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in this regulatory guide.

General Compliance or Alternate Approach Assessment:

Auxiliary equipment associated with valve operators are tested in accordance with the subject standards. Designed service conditions are implemented in the tests. Conservative values of the environmental variables during and after a design basis accident are used in the tests to assure that the testing is carried out under more severe environmental conditions than those expected.

Specific Evaluation Reference:

See Sections 3.11 and 8.1.5.2.

Regulatory Guide 1.74, Revision 0, February 1974

Quality Assurance Terms and Definitions

I Design and Construction Phase

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in this regulatory guide.

General Compliance or Alternate Approach Assessment:

The terms used in describing and implementing quality assurance programs for CGS have complied with ANSI N45.2.10-1973 or were clarified at the point of application.

Specific Evaluation Reference:

None

II Operational Phase

Compliance is discussed in the OQAPD.

Regulatory Guide 1.75, Revision 1, January 1975

Physical Independence of Electric Systems

Compliance or Alternate Approach Statement:

This regulatory guide is not applicable to CGS since it applies to the evaluation of construction permit applications docketed after February 1974. However, CGS complies with the intent of the guidance set forth in this regulatory guide by an alternate approach.

General Compliance or Alternate Approach Assessment:

See Section 8.3.1.4.2.7 for an assessment of CGS relative to this regulatory guide.

Specific Evaluation Reference:

See Section 8.3.1.4.2.7.

Regulatory Guide 1.76, Revision 0, April 1974

Design Basis Tornado for Nuclear Power Plants

Compliance or Alternate Approach Statement:

CGS complies with the intent of the guidance set forth in this regulatory guide by an alternate approach.

General Compliance or Alternate Approach Assessment:

The tornado design criteria for Columbia Generating Station were revised based on design basis tornado characteristics in NUREG-1503. The design basis tornado characteristics used are less severe than those specified in Regulatory Guide 1.76 for Region III. In January 1996, the revised criteria were found acceptable by the NRC.

Specific Evaluation Reference:

See Section 3.3.2.

Regulatory Guide 1.78, Revision 0, June 1974

Assumptions for Evaluating the Habitability of a Nuclear Power Plant Control Room During a Postulated Hazardous Chemical Release

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in this regulatory guide.

General Compliance or Alternate Approach Assessment:

The main control room habitability during a postulated hazardous chemical release evaluation complies with assumptions and toxicity limits in Revision 0 of this regulatory guide. The evaluation uses toxicity limits presented in Revision 1 for those chemicals not discussed in Revision 0. The results are presented in Chapter 6.

Specific Evaluation Reference:

See Sections 2.2.3 and 6.4.

Regulatory Guide 1.80, Revision 0, June 1974

Preoperational Testing of Instrument Air Systems

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in this regulatory guide.

General Compliance or Alternate Approach Assessment:

The primary containment instrument air system preoperational test procedure incorporated the requirements of this regulatory guide.

Specific Evaluation Reference:

See Sections 14.2.7.3 and 14.2.12.1.34.

Regulatory Guide 1.82, Revision 0, June 1974

Sumps for Emergency Core Cooling and Containment Spray Systems

Compliance or Alternate Approach Statement:

This regulatory guide is not applicable to CGS since no sumps are used for ECCS and containment spray.

General Compliance or Alternate Approach Assessment:

Not applicable.

Specific Evaluation Reference:

Not applicable.

Regulatory Guide 1.84

Design, Fabrication, and Materials Code Case Acceptability, ASME Section III

Regulatory Guide Intent:

This guide lists all Section III Code Cases that the NRC has approved for use. It is updated on a regular basis to reflect the changes to the ASME Code Cases and the current position of the NRC on acceptability for use. The guide contains tables that detail the NRC acceptance requirements for current, annulled, and superseded Code Cases. Code Cases that the NRC determined to be unacceptable are listed in Regulatory Guide 1.193, "ASME Code Cases Not Approved for Use".

Application Assessment:

Assessed capability in design.

Compliance or Alternate Approach Statement:

The current version of the Regulatory Guide is utilized to determine acceptable Code Cases for all new and existing plant applications. The FSAR does not track individual Code Cases and revision numbers. Not all acceptable Code Cases listed in the regulatory guide are used. The Code Cases that are utilized for Columbia are referred to in the plant design/installation documentation.

General Compliance or Alternate Approach Assessment:

Code Cases are utilized in accordance with the requirements of the regulatory guide provisions for acceptance. Section III Code Cases that are not yet endorsed may be utilized via submittal to the NRC for approval in accordance with the regulatory guide. The plant scope of supply is in full compliance with this regulatory guide.

Specific Evaluation Reference:

See Section 3.8.2.2.

Similar Application Reference:

None.

Regulatory Guide 1.85, Revision 31, 1998*

Materials Code Case Acceptability - ASME Section III, Division 1

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in this regulatory guide as described below.

General Compliance or Alternate Approach Assessment:

The use of an ASME Section III, Division 1, code case applicable to materials use on CGS is approved by Energy Northwest only after evaluating its technical acceptability and confirming that its use is acceptable to the NRC. This confirmation is by ascertaining that the code case is listed in this regulatory guide (or applicable earlier revision) or by specific written acceptance by the NRC.

Specific Evaluation Reference:

See Section 3.8.2.2.

* Regulatory Guide 1.85 was withdrawn in 2004. See Regulatory Guide 1.84 for NRC acceptance of current Materials Code Cases.

Regulatory Guide 1.88, Revision 2 October 1976

Collection, Storage and Maintenance of Nuclear Power Plant Quality Assurance Records

I Design and Construction Phase

Compliance or Alternate Approach Statement:

I Design and Construction Phase

Prior to the original issue of this regulatory guide and construction of the CGS records facility, Project Quality Assurance complied with the intent of 10 CFR Part 50, Appendix B, by duplicate storage of records. Project Quality Assurance also complied with the original issue and revisions of this regulatory guide by duplicate storage. Since March 1977, Project Quality Assurance has complied with Revision 2 of this regulatory guide as described below.

General Compliance or Alternate Approach Assessment:

Since March 1977, the collection, storage, and maintenance of quality assurance records by Project Quality Assurance has been in compliance with ANSI N45.2.9 and NFPA No. 232-1975 for fire protection as imposed by this regulatory guide. The record facility has a minimum of a 2-hr rating.

Procurement documents directly specify requirements for collection, storage, and maintenance of records. The requirements generally meet the intent of ANSI N45.2.9 except that storage facilities or cabinets are only required to meet a 1-hr rating.

II Operational Phase

Compliance is discussed in the OQAPD.

Regulatory Guide 1.89, Revision 1, June 1984

Qualification of Class 1E Equipment for Nuclear Power Plants

Regulatory Guide Intent:

Regulatory Guide 1.89 endorses both the requirements and recommendations of IEEE 323-1974, "IEEE Standard for Qualifying Class 1E Equipment for Nuclear Power Generating Stations." Additional regulatory position stipulations are also included.

Compliance or Alternate Approach Statement:

CGS complies with this regulatory guide for equipment requiring environmental qualification procured after February 22, 1983.

General Compliance or Alternate Approach Statement:

For equipment requiring environmental qualification installed prior to February 22, 1983, CGS follows the guidance in NUREG-0588 Cat II.

In view of the NRC Memorandum and Order (CLI-80-21), dated May 23, 1980, all environmental qualifications of Class 1E equipment located in harsh environments are reevaluated for compliance with NUREG-0588, Category II. Where significant deviation from those guidelines is found in specific equipment qualifications, additional testing and/or analysis is performed to demonstrate the adequacy of the equipment to perform its safety-related function. *For equipment whose qualification program has not been completed, a justification for interim operation in accordance with 10 CFR 50.49 is performed as described in the "WNP-2 Environmental Qualification Report for Safety-Related Equipment," Reference 3.11-1.*

Specific Evaluation Reference:

See Section 3.11.

Regulatory Guide 1.90, Revision 0, November 1974

In-Service Inspection of Prestressed Concrete Containment Structures with Grouted Tendons

Compliance or Alternate Approach Statement:

This regulatory guide is not applicable because CGS does not have a prestressed concrete containment structure with grouted tendons.

General Compliance or Alternate Approach Assessment:

Not applicable.

Specific Evaluation Reference:

Not applicable.

Regulatory Guide 1.91, Revision 0, January 1975

Evaluation of Explosions Postulated to Occur on Transportation Routes Near Nuclear Power Plant Sites

Compliance or Alternate Approach Statement:

This regulatory guide is not applicable to CGS since it applies to the evaluation of construction permit applications docketed on or after March 14, 1975. However, CGS complies with the guidance set forth in this regulatory guide.

General Compliance or Alternate Approach Assessment:

It has been determined that the peak overpressures produced by postulated explosions occurring on transportation routes near the plant are no greater than the wind pressures caused by the design basis tornado. Therefore, postulated explosions will not cause an accident or prevent the safe shutdown of the plant.

Specific Evaluation Reference:

See Sections 2.2.1, 2.2.2.2, and 2.2.2.4.

Regulatory Guide 1.92, Revision 1, February 1976

Combining Modal Responses and Spatial Components in Seismic Response Analysis

Compliance or Alternate Approach Statement:

This regulatory guide is not a requirement for CGS since it applies to the evaluation of construction permit applications docketed after February 1976. CGS complies with the intent of the guidance set forth in this regulatory guide by implementing the regulatory guide criteria or by an alternate approach.

General Compliance or Alternate Approach Assessment:

The method of combining modal responses has been implemented in accordance with the guide's recommendations.

The combining of spatial components was performed prior to the issuance of the guide and follows the method presented in the PSAR. The method used is an industry-accepted alternate method. The method considers the combination of the maximum structural responses to the more critical one of the two horizontal components and the vertical component of earthquake motion, using the absolute sum method. Alternatively, when the regulatory guide is followed, two horizontal components and one vertical component of earthquake motion are combined by the square root sum of the squares method.

Specific Evaluation Reference:

See Sections 3.7.2.6 and 3.7.2.7.

Regulatory Guide 1.93, Revision 0, December 1974

Availability of Electric Power Sources

Compliance or Alternative Approach Statement:

CGS complies with the regulatory position for operating the plant whenever the available electric power sources are less than the limiting conditions for operation (LCO) as defined in the regulatory guide.

General Compliance or Alternate Approach Assessment:

Operating procedures incorporate the requirements of this guide.

Specific Evaluation Reference:

See the Technical Specifications.

Regulatory Guide 1.94, Revision 1, April 1976

Quality Assurance Requirements for Installation, Inspection, and Testing of Structural Concrete and Structural Steel During the Construction Phase of Nuclear Power Plants.

I Design and Construction Phase

Compliance or Alternate Approach Statement:

This regulatory guide is not applicable to CGS since it applies to the evaluation of construction permits docketed after October 15, 1976. However, CGS complies with the intent of the guidance set forth in the guide.

General Compliance or Alternate Approach Assessment:

The guidelines included in ANSI 45.2.5-1974 for installation, inspection and testing of structural concrete and structural steel, including nonpressure vessel elements of the primary containment vessel during the construction phase of CGS are reflected in the structural concrete and structural steel contract specifications for project construction. The QA requirements of ANSI 45.2 were incorporated in these specifications.

Specific Evaluation Reference:

See Sections 3.8.3.2, 3.8.4.2, 3.8.5.2, and Table 3.8-4.

II Operational Phase

Compliance is discussed in the Topical Report referenced in the OQAPD.

Regulatory Guide 1.95, Revision 1, January 1977

Protection of Nuclear Power Plant Control Room Operators Against an Accidental Chlorine Release

Compliance or Alternate Approach Statement:

This regulatory guide is not applicable to CGS since chlorine gas is not stored at CGS or nearby facilities and the expected quantities of chlorine shipped within five miles is less than the threshold volumes specified in Regulatory Guide 1.78.

Specific Evaluation Reference:

See Section 6.4.4.2.

Regulatory Guide 1.97, Revision 2, December 1980

Instrumentation for Light Water Cooled Nuclear Power Plants to Assess Plant Conditions During and Following an Accident

Compliance or Alternate Approach Statement:

The CGS safety-related display instrumentation meets the intent of Regulatory Guide 1.97.

General Compliance or Alternate Approach Assessment:

Instrumentation is provided in the main control room to monitor plant variables and systems during and following an accident. The instrumentation is qualified to remain functional as required by the regulatory guide.

Portable multichannel gamma-ray spectrometer instrumentation provided for use by field teams during emergencies is not used at CGS, contrary to the recommendation contained in Regulatory Guide 1.97, Revision 2, Table 2, Plant and Environs Radioactivity (portable instrumentation). Regulatory Guide 1.97, recommends the use of these instruments for release assessment and analysis. Alternative methods that produce more reliable indication of fuel failure during a radioactive release are used instead, such as air sample analysis and validation of dose projections using field team sample results.

Deviations relative to RG 1.97 category for O2 and H2 as discussed in Section 7.5.2.2.3.

Specific Evaluation Reference:

See Section 7.5.

Regulatory Guide 1.100, Revision 1, August 1977

Seismic Qualification of Electric Equipment for Nuclear Power Plants

Regulatory Guide Intent:

Regulatory Guide 1.100 endorses both the requirements and recommendations of IEEE 344-1975, "IEEE Recommended Practices for Seismic Qualification of Class 1E Equipment for Nuclear Power Generating Stations," when such qualification is performed in conjunction with Regulatory Guide 1.89, and subject to the regulatory position stipulations.

Compliance or Alternate Approach Statement:

This regulatory guide is applicable to CGS as clarified in Section 1.8.3 for Regulatory Guide 1.89, Revision 1 and Section 3.10.1.2.

General Compliance or Alternate Approach Assessment:

All Class 1E equipment seismic qualifications are evaluated against the requirements set forth within IEEE 344-1975 as clarified in Section 3.10.1.2. The evaluations are documented and demonstrate adequacy of the methods and results of the qualifications as equal or conservative to the requirements of IEEE 344-1975. These include evaluations of seismic and hydrodynamic load combinations.

Specific Evaluation Reference:

See Section 3.10.

Regulatory Guide 1.101, Revision 1, March 1977

Emergency Planning for Nuclear Power Plants

Compliance or Alternate Approach Statement:

CGS complies with the intent set forth in this regulatory guide.

General Compliance or Alternate Approach Statement:

See NUREG-0654.

Specific Evaluation Reference:

See the CGS Emergency Plan.

Regulatory Guide 1.102, Revision 1, September 1976

Flood Protection for Nuclear Power Plants

Compliance or Alternate Approach Statement

CGS complies with the guidance set forth in this regulatory guide.

General Compliance or Alternate Approach Assessment:

The safety-related buildings and spray ponds are located far above the water level estimated for the largest historical flood. Based on the criteria stipulated in Regulatory Guide 1.102, the CGS plant site is classified as a "Dry Site."

Specific Evaluation Reference:

See Section 2.4.

Regulatory Guide 1.103, Revision 1, October 1976

Post-Tensioned Prestressed Systems for Concrete Reactor Vessels and Containments

Compliance or Alternate Approach Statement:

This regulatory guide is not applicable since CGS does not have a concrete reactor vessel or containment.

General Compliance or Alternate Approach Assessment:

Not applicable.

Specific Evaluation Reference:

Not applicable.

Regulatory Guide 1.104, Revision 0, February 1976

Overhead Crane Handling Systems for Nuclear Power Plants

Compliance or Alternate Approach Statement:

CGS complies with the intent of the guidance set forth in this regulatory guide by an alternate approach.

General Compliance or Alternate Approach

The following safeguards are included in the design of the overhead crane:

a. Redundant low limit, main hoist,

b. Redundant equalizer bar limit switch,

c. "Critical Control Path" series of limit switches for the spent fuel cask handling mode, and

d. Main hoist "paddle" type upper limit switch to prevent the inadvertent "two-blocking" condition.

Specific Evaluation Reference:

See Sections 3.8.4.1.1.5 and 9.1.4.2.2.

Regulatory Guide 1.105, Revision 1, November 1976

Instrument Setpoints

Compliance or Alternate Approach Statement:

This regulatory guide is not applicable to CGS since it applies to the evaluation of construction permit applications docketed after December 15, 1976.

General Compliance or Alternate Approach Assessment:

Instrumentation is provided in a main control room to monitor plant variables and systems. The range of instrumentation is selected to cover the anticipated ranges of variables for the following plant conditions:

a. Normal operation,
b. Anticipated operational occurrences, and
c. Accident conditions.

To ensure adequate safety, the following plant parameters and systems are monitored and provided with appropriate controls to maintain them within prescribed operating ranges:

1. Variables and systems that affect the fission process,
2. Variables and systems that affect the reactor core,
3. Reactor coolant pressure boundary, and
4. Containment and associated systems.

Specific Evaluation References:

See Section 7.1.2.5.

Regulatory Guide 1.106, Revision 1, March 1977

Thermal Overload Protection for Electric Motors on Motor Operated Valves

Compliance or Alternate Approach Statement:

This regulatory guide is not applicable to CGS since it applies to the evaluation of construction permit applications docketed after July 15, 1976. However, CGS design complies with the intent of the guidance set forth in Section C.2 of the regulatory guide.

General Compliance or Alternate Approach Assessment:

Class 1E motor-operated valve (MOV) overloads are chosen two sizes above those which would be required based on normal full load running current. The resultant overload protection (approximately 140%) permits MOV motors to operate for extended periods at moderate overloads; tripping occurs just prior to motor damages.

Specific Evaluation Reference:

See Section 8.3.1.1.9.

Regulatory Guide 1.107, Revision 1, February 1977

Qualifications for Cement Grouting for Prestressing Tendons in Containment Structures

Compliance or Alternate Approach Statement

This regulatory guide is not applicable to CGS because CGS does not have a prestressed concrete containment structure with grouted tendons.

General Compliance or Alternate Approach Assessment:

Not applicable.

Specific Evaluation Reference:

Not applicable.

DELETED.

Regulatory Guide 1.109, Revision 0, March 1976

Calculation of Annual Doses to Man From Routine Releases of Reactor Effluents.

Compliance or Alternate Approach Statement:

CGS complies with the intent of the guidance set forth in this regulatory guide using an alternate approach.

General Compliance or Alternate Approach Statement:

CGS is meeting the guidance of this regulatory guide by using Battelle Northwest models which are acceptable to the NRC.

Specific Evaluation Reference:

See Sections 11.2.3.3, 11.3.3.3, and 5.2 of the Environmental Report.

Regulatory Guide 1.110, Revision 0, March 1976

Cost-Benefit Analysis for Radwaste Systems for Light-Water-Cooled Nuclear Power Reactors

Compliance or Alternate Approach Statement:

This regulatory guide is not applicable to CGS since a cost-benefit analysis, as described in Appendix I of 10 CFR 50 Section II-D is not required for CGS.

General Compliance or Alternate Approach Assessment:

Not applicable.

Specific Evaluation Reference:

See Section 11.2.3.4.

Regulatory Guide 1.111, Revision 1, July 1977

Method for Estimating Atmospheric Transport and Dispersion of Gaseous Effluents in Routine Releases from Light-Water Cooled Reactors

Compliance or Alternate Approach Statement:

CGS complies with the intent of the guidance set forth in this regulatory guide by an alternate approach.

General Compliance or Alternate Approach Assessment:

Analyses of atmospheric transport and dispersion of gaseous effluents at CGS are performed using the standard NRC diffusion models in NUREG/CR-2919, XOQ/DOQ: Computer Program for the Meteorological, Evaluation of Routine Effluent Releases at Nuclear Power Stations, September 1982.

Specific Evaluation References:

See Section 2.3.5.

Regulatory Guide 1.112, Revision 0-R, May 1977

Calculation of Releases of Radioactive Materials in Gaseous and Liquid Effluents from Light-Water Cooled Power Reactors.

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in this regulatory guide.

General Compliance or Alternate Approach Assessment:

The methods for calculating annual average releases of radioactive material in liquid and gaseous effluents from the plant were originally based on the GALE Code as suggested in this regulatory guide. See the sections referenced below for discussions of the methods currently used.

Specific Evaluation Reference:

See Sections 11.2.3.2 and 11.3.3.3.

Regulatory Guide 1.113, Revision 1, April 1977

Estimating Aquatic Dispersion of Effluents From Accidental and Routine Reactor Releases For the Purpose of Implementing Appendix I.

Compliance or Alternate Approach Statement:

CGS complies with the intent of the guidance set forth in this regulatory guide using an alternate approach.

General Compliance or Alternate Approach Assessment:

Routine and accidental releases of radioactive liquid, heat, and chemical discharges to the Columbia River via the CGS cooling tower blowdown line are discussed in Section 2.4.12. CGS final Environmental Report (ER) 6.1.1.1 describes in detail the advection/diffusion equations used in the near-field thermal analysis. This analysis provides dispersion characteristics, presented in ER 5.1, to 500 ft below the point of discharge. A simplified and conservative approach to estimating the far-field concentrations of routine releases is presented in ER 5.2.2. The affects of an accidental release of radioactive liquid to the ground within the CGS site area were investigated and are discussed in Section 2.4.13.3.

Specific Evaluation Reference:

See Sections 2.4.12 and 2.4.13.3 and Environmental Report Sections 5.1, 5.2.2, and 6.1.1.1.

Regulatory Guide 1.114, Revision 1, November 1976

Guidance to Operator at the Controls of a Nuclear Power Plant.

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in this regulatory guide.

General Compliance or Alternate Approach Assessment:

Plant administrative procedures implement the requirements of this regulatory guide.

Specific Evaluation Reference:

Not applicable.

Regulatory Guide 1.115, Revision 0, March 1976

Protection Against Low-Trajectory Turbine Missiles

Compliance or Alternate Approach Statement:

This regulatory guide is not applicable to CGS since it applies to the evaluation of construction permit applications docketed after November 15, 1976.

General Compliance or Alternate Approach Assessment:

Extensive amounts of concrete used in the construction of CGS serve as radiation shielding and formidable barriers protecting essential systems from low trajectory missiles.

Specific Evaluation Reference:

See Section 3.5.1.3.

Regulatory Guide 1.116, Revision 0, June 1976

Quality Assurance Requirements for Installation, Inspection, and Testing of Mechanical Equipment and Systems

I Design and Construction Phase

Compliance or Alternate Approach Statement:

CGS complied with the intent of the guidance set forth in this regulatory guide by an alternate approach.

General Compliance or Alternate Approach Assessment:

The requirements for installation, inspection, and testing are specified in procurement documents which require a quality assurance program in compliance with ANSI N45.2.

Specific Evaluation Reference:

None

II Operational Phase

Compliance is discussed in the OQAPD.

Regulatory Guide 1.117, Revision 0, June 1976

Tornado Design Classification

Compliance or Alternate Approach Statement:

This regulatory guide is not applicable to CGS since it applies to the evaluation of construction permit applications docketed after February 15, 1977.

General Compliance or Alternate Approach Assessment:

Essential systems are protected from tornadoes by structures designed for design basis tornadoes (DBT). See Regulatory Guides 1.27 and 1.76.

Specific Evaluation Reference:

See Sections 3.3.2.4 and 9.2.5.

Regulatory Guide 1.118, Revision 0, June 1976

Periodic Testing of Electric Power and Protection Systems.

Compliance or Alternate Approach Statement:

This regulatory guide is not applicable to CGS since the construction permit for CGS was issued prior to February 15, 1977.

General Compliance or Alternate Approach Assessment:

Electric power and protection systems are tested periodically as specified in the Technical Specifications. As described in Section 13.5.2, surveillance procedures have been prepared for periodic testing of these systems.

Specific Evaluation Reference:

See the Technical Specifications.

Regulatory Guide 1.120, Revision 0, June 1976

Fire Protection Guidelines for Nuclear Power Plants

Compliance or Alternate Approach Statement:

This regulatory guide is not applicable to CGS since it applies to the evaluation of construction permit applications docketed after February 28, 1977. However, the NRC requested a reevaluation of the fire protection program of CGS and a comparison with the guidelines in Appendix A to Branch Technical Position APCSB 9.5-1, "Guidelines for Fire Protection For Nuclear Power Plants, Docketed Prior to July 1, 1976." CGS complies with the intent of the guidance set forth in Appendix A to Branch Technical Position APCSB 9.5-1.

General Compliance or Alternate Approach Assessment:

Appendix F includes the fire hazard analysis and compares in detail the fire protection provisions for CGS with the guidelines in Appendix A to Branch Technical Position APCSB 9.5-1.

Regulatory Guide 1.122, Revision 0, September 1976

Development of Floor Design Response Spectra for Seismic Design of Floor Supported Equipment or Components

Compliance or Alternate Approach Statement:

CGS complies with the intent of the guidance set forth in this regulatory guide by an alternate approach.

General Compliance or Alternate Approach Assessment:

CGS complies with some of the regulatory positions and where not in compliance, alternate methods are used as discussed in Sections 3.7.2.5 and 3.7.2.6.

Specific Evaluation Reference:

See Sections 3.7.2.5 and 3.7.2.6.

Regulatory Guide 1.123, Revision 0, October 1976

Quality Assurance Requirements for Control of Procurement of Items and Services for Nuclear Power Plants

I Design and Construction Phase

Compliance or Alternate Approach Statement:

CGS complied with the intent of the guidance set forth in this regulatory guide by an alternate approach.

General Compliance or Alternate Approach Assessment:

ANSI N45.2.13-1976, the subject of this regulatory guide, requires certain supplier selection, evaluation, and pre- and post-award activities.

Prequalification of suppliers was generally not performed. The procurement documents required prospective suppliers to submit information pertaining to experience, facilities, personnel, and quality program with their bids for evaluation prior to award of a contract.

Pre-award evaluations were restricted to the information submitted with bid and selected clarifications when an adequate evaluation could not be accomplished with the information supplied. Post-award evaluations were performed in conjunction with the quality assurance program evaluation and approval after award of a contract.

Inspection and hold points were not established through agreement with the bidder but through contract requirements to notify Energy Northwest of all inspections and tests which were selectively witnessed by Energy Northwest.

Specific Evaluation Reference:

None

II Operational Phase

Compliance is discussed in the OQAPD.

Regulatory Guide 1.124, Revision 0, November 1976

Design Limits and Loading Combinations for Class 1 Linear Type Component Supports

Compliance or Alternate Approach Statement:

This regulatory guide is not applicable to CGS since it applies to the evaluation of construction permit applications docketed after July 1, 1977. However, CGS complies with the intent of the guidance set forth in this regulatory guide by an alternate approach.

General Compliance or Alternate Approach Assessment:

Design and fabrication requirements for CGS, including those requirements for linear type components supports, are in accordance with the ASME Code Section III Subsection NF, Winter 1973 Addenda. The actual design criteria were established prior to Winter 1973 Addenda and are conservative with respect to the Winter 1973 Code. Regulatory Guide 1.124 provides design limits and appropriate combinations of loadings which reflect the requirements set forth in the 1974 Edition of the ASME Code Section III, Subsection NF, along with additional requirements. Although the detailed requirements of the regulatory guide have not been incorporated as project criteria, review of the design criteria used for CGS indicates that the intent of this regulatory guide is met.

Specific Evaluation Reference:

See Sections 3.9.3.4 and 5.4.14.

Regulatory Guide 1.125, Revision 0, March 1977

Physical Models for Design and Operation of Hydraulic Structures and Systems for Nuclear Power Plants

Compliance or Alternate Approach Statement:

The guide is not applicable to CGS since it applies to the evaluation of construction permit application docketed on or after November 1, 1977. Furthermore, the guide is not applicable to CGS for reasons stated below.

General Compliance or Alternate Approach Assessment:

Physical hydraulic model testing is not used for CGS for predicting the performance of hydraulic structures, systems, and components located outside the primary containment vessel or provided for the prevention of accidents and the mitigation of the consequences of accidents. Therefore, the details and documentation of data and studies required by the guide to support such testing is not applicable.

Specific Evaluation Reference:

Not applicable.

Regulatory Guide 1.127, Revision 0, April 1977

Inspection of Water-Control Structures Associated With Nuclear Power Plants

Compliance or Alternate Approach Statement:

This regulatory guide is not applicable to CGS since water-control structures as defined in this regulatory guide do not exist.

General Compliance or Alternate Approach Assessment:

Not applicable.

Specific Evaluation Reference:

Not applicable.

Regulatory Guide 1.128, Revision 0, April 1977

Installation Design and Installation of Large Lead Storage Batteries for Nuclear Power Plants.

Compliance or Alternate Approach Statement:

This regulatory guide is not applicable to CGS since it applies to the evaluation of construction permit applications docketed after December 1, 1977. However, CGS complies with the intent of the guidance set forth in this regulatory guide by an alternate approach.

General Compliance or Alternate Approach Assessment:

Safety-related battery installation design criteria conforms to IEEE 484-1975. A Class 1E ventilation system is also provided which is capable of limiting hydrogen concentrations to 1%.

Storage prior to installation was not in strict compliance with Section 5.1.3 of this regulatory guide. However, preoperational tests established whether or not any damage or loss of capacity resulted from storage.

Specific Evaluation Reference:

See Sections 8.3.2.1.5, 8.3.2.1.6, 8.3.2.2.1.1, and 8.3.2.2.1.2.

Regulatory Guide 1.129, Revision 0, April 1977

Maintenance, Testing, and Replacement of Large Lead Storage Batteries for Nuclear Power Plants

Compliance or Alternate Approach Statement:

Although Regulatory Guide 1.129 is not directly applicable to CGS, Energy Northwest's maintenance procedures conform to IEEE 450- 2002, "IEEE Recommended Practice for Maintenance, Testing, and Replacement of Large Lead Storage Batteries for Generating Stations and Substations." The frequency for "service" testing is in accordance with Technical Specifications or Licensee Controlled Specifications.

General Compliance or Alternate Approach Assessment:

See Section 8.3.2.1.7.

Specific Evaluation Reference:

See Section 8.3.2.1.7.

Regulatory Guide 1.137, Revision 1, October 1979

Fuel Oil Systems for Standby Diesel Generators

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in this guide with the exception of the following:

Piping on the engine skid is ANSI B 31.1, Seismic Category I, Quality Class I, as noted in Section 9.5.4.1.

Item 11, cathodic protection surveillance. The standby diesel fuel oil storage tanks are protected with cathodic protection by anodes which are located in the near vicinity, but there are no pigtails connected to the fuel oil system piping, thus no leads to maintain. CGS does not perform the 90% distillation test before putting the fuel in the tanks as noted in Section 9.5.4.4 and the Technical Specifications.

The diesel fuel oil supply is gravity feed down to the low fuel oil alarm level. The pump suction, however, is 2.3 ft higher than the bottom of the tank. Therefore, if the transfer pump fails, the last few hours of running before the day tank is empty would be at a pump suction lift of up to 2.3 ft.

The auxiliary boiler storage tank is considered part of the diesel fuel oil system in that it is an additional diesel fuel oil storage tank. This deviates from the ANSI N195-1976 standard because of the permanent interconnection between the standby power system and the auxiliary boiler system. The auxiliary boiler storage tank and its connective piping are not Safety Class 3. The auxiliary boiler storage tank and its connecting auxiliary boiler system are not in a vital area, although ANSI N195-1976 specifies that the fuel oil system is a vital system and shall be located in a vital area. However, loss of the stored fuel oil in the auxiliary boiler storage tank or its connective piping will not affect the safety function of the diesel fuel oil system.

The diesel storage minimum required volume does not include volume for testing, as specified by ANSI N195-1976. Instead, Energy Northwest procedurally provides for makeup, as needed, during testing activities to ensure that the minimum required volume is maintained.

Specific Evaluation Reference:

See Section 9.5.4.4.

Regulatory Guide 1.143, Revision 1, October 1979

Design Guidance for Radioactive Waste Management Systems, Structures, and Components Installed in Light-Water-Cooled Nuclear Power Plants

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in this regulatory guide.

General Compliance or Alternate Approach Assessment:

CGS began implementing the guidance set forth in this regulatory guide in July 1982. Prior to this time the solid, liquid, and gaseous radioactive waste systems were being designed and fabricated as ASME Section III, Class 3, systems. Therefore, although the guidance in the regulatory guide does not call for N-stamped components, in many cases N-stamped components are found in the radwaste systems. To avoid the confusion which may result from the implementation of this regulatory guide these systems, and components which follow the guidance found in the regulatory guide are indicated as Quality Class II+ and Code Group D+.

Specific Evaluation Reference:

See Sections 3.2.4 and 3.2.6.

Regulatory Guide 1.144, Revision 1, September 1980

Auditing of Quality Assurance Programs for Nuclear Power Plants

I Design and Construction Phase

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in this regulatory guide as described below.

General Compliance or Alternate Approach Assessment:

Contractors and suppliers complied with the requirements imposed by procurement documents.

Energy Northwest, the architect-engineer (Burns and Roe), and the construction manager (Bechtel) complied with the guidance set forth in this regulatory guide except for the following.

The requirements of ANSI N45.2.12-1977 as modified and interpreted by the regulatory position were applied to the Bechtel quality program for safety-related items except as modified or interpreted below:

a. Reference: Standard Sections 4.3.2.4 and 4.5.1 (Investigation). As an equivalent alternative to the requirement for the audited organization to investigate any adverse audit finding to determine and schedule appropriate corrective action, Bechtel's auditing organization may determine the investigatory action and corrective action including action to prevent recurrence pertinent to adverse audit finding. These actions are agreed to by the audited organization. Further, in Section 4.5.1, as equivalent alternative to the 30-day response time, a response time appropriate to the finding is agreed to by the audited and auditing organizations.

b. Reference: Regulatory Section C.7, Standard Section 5.2 (Audit Records). Audit records shall include documents as defined in the standard and other documents if necessary to support audit findings.

Early project procurements specified audit program requirements in terms of Appendix B to 10 CFR 50 and ANSI N45.2. As appropriate, future procurements required that audit programs comply with ANSI Standard N45.2.12.

II Operational Phase

Compliance is discussed in the OQAPD.

Regulatory Guide 1.145, Revision 1, November 1982/February 1983

Atmospheric Dispersion Models for Potential Accident Consequence Assessments at Nuclear Power Plants

Regulatory Guide Intent

This guide provides acceptable methodology to determining site-specific relative concentrations for assessing the potential offsite radiological consequences of postulated accidental releases of radioactive material to the atmosphere.

Application Assessment

Assessed capability in design.

Compliance or Alternate Approach Statement:

Identified BOP scope of supply analysis, design, and/or equipment used in this facility is in full compliance with the regulatory guide.

General Compliance or Alternate Approach Assessment

Two of the procedures contained in the PAVAN code were implemented. The procedures were run with the desert sigma and with the Pasquill-Gifford sigma enabled. The most conservative χ/Q values were used in the accident analysis.

Specific Evaluation Reference:

See Section 2.3 and Chapter 15.0.

Regulatory Guide 1.146, Revision 0, August 1980

Qualification of Quality Assurance Program Audit Personnel for Nuclear Power Plants

I Design and Construction Phase

Compliance or Alternate Approach Statement:

CGS complied with the guidance set forth in this regulatory guide as described below.

General Compliance or Alternate Approach Assessment:

Energy Northwest, the architect-engineer (Burns and Roe), and the construction manager (Bechtel) complied with the guidance set forth in this regulatory guide.

Contractors and suppliers comply with the requirements imposed by procurement documents.

Early project procurements specified audit program requirements in terms of Appendix B 10 CFR 50 and ANSI N45.2. Where appropriate, future procurements required that auditor qualification comply with ANSI Standard N45.2.23.

II Operational Phase

Compliance is discussed in the OQAPD.

Regulatory Guide 1.147

Inservice Inspection of Code Case Acceptability ASME Section XI Division I.

By the reference below, the NRC approved application of Code Case N416 for CGS which at that time was not addressed in Regulatory Guide 1.147. The approval letter required that Energy Northwest document application of the code case in the FSAR.

The code case was first used for CGS in 1988 for deferral of hydrostatic testing of main steam drip line modifications.

As the code case has now been accepted by Regulatory Guide 1.147, Energy Northwest does not plan to document future use of the code case.

Reference:

Letter from T. M. Novak (NRC) to G. C. Sorensen (SS), "Use of ASME Code Case N-416 for the WNP-2, WPPSS Nuclear Project No. 2 (WNP-2)," dated August 8, 1985.

Regulatory Guide 1.155, Reissued August 1988

Station Blackout

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in this regulatory guide.

Compliance or Alternate Approach Assessment:

Regulatory Guide 1.155 was issued to describe a method acceptable to the NRC staff for complying with the NRC regulation that requires nuclear power plants to be capable of coping with a station blackout for a specified duration. The NRC acceptance of the CGS proposed plan for providing this capability is provided in the reference.

Specific Evaluation Reference:

See Appendix 8A.

Reference:

Letter from R. R. Assa to G. C. Sorensen, "Supplemental Safety Evaluation (SSE) of the Washington Public Power Supply System Nuclear Project No. 2 (WNP-2) Station Blackout Analysis (TAC M68626)," dated June 26, 1992.

Regulatory Guide 1.160, Revision 3, May 2012

Monitoring the Effectiveness of Maintenance at Nuclear Power Plants

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in this regulatory guide.

General Compliance or Alternate Approach Assessment:

Compliance with the guidance provided is ensured by the implementation of a maintenance program and implementing procedures at CGS.

Specific Evaluation References:

Not applicable.

Regulatory Guide 1.166, Revision 0, March 1997

Pre-Earthquake Planning and Immediate Nuclear Power Plant Operator Post-Earthquake Actions.

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in this regulatory guide.

General Compliance or Alternate Approach Assessment:

This regulatory guide provides guidance on planning and shutdown of a nuclear power plant.

Specific Evaluation References:

See Section 3.7.4.2

Regulatory Guide 1.167, Revision 0, March 1997

Restart of a Nuclear Power Plant Shut Down by a Seismic Event.

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in this regulatory guide.

General Compliance or Alternate Approach Assessment:

This regulatory guide provides guidance on a restart of a nuclear power plant after it has been shut down by an earthquake.

Specific Evaluation References:

See Section 3.7.4.2

Regulatory Guide 1.196, May 2003

Control Room Habitability at Light-Water Nuclear Power Reactors

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in this regulatory guide.

General Compliance or Alternate Approach Assessment:

Compliance with the guidance provided is ensured by the implementation of a Control Room Envelope Habitability (CREH) Program and implementing procedures at CGS.

Specific Evaluation References:

Not applicable.

Regulatory Guide 1.197, May 2003

Demonstrating Control Room Envelope Integrity at Nuclear Power Reactors

Compliance or Alternate Approach Statement:

CGS complies with the guidance set forth in this regulatory guide.

General Compliance or Alternate Approach Assessment:

Compliance with the guidance provided is ensured by the implementation of a Control Room Envelope Habitability (CREH) Program and implementing procedures at CGS.

Specific Evaluation References:

Not applicable.

Chapter 2

SITE CHARACTERISTICS

2.1 GEOGRAPHY AND DEMOGRAPHY

2.1.1 SITE LOCATION AND DESCRIPTION

2.1.1.1 Specification of Location

Columbia Generating Station (CGS) is located in the southeast area of the U.S. Department of Energy's (DOE) Hanford Site in Benton County, Washington. The site is approximately 3 miles west of the Columbia River at River Mile 352, approximately 10 miles north of north Richland, 18 miles northwest of Pasco, and 21 miles northwest of Kennewick (Figures 2.1-1 and 2.1-2).

The reactor is located at 46° 28' 18" north latitude and 119° 19' 58" west longitude. The approximate Universal Transverse Mercator coordinates are 5,148,840 meters north and 320,930 meters east.

2.1.1.2 Site Area Map

The CGS site area is that real estate over which Energy Northwest has the legal right to control access. It is the area enclosed by the exclusion area boundary plus the plant property lines as shown in Figure 3-1 of the Offsite Dose Calculation Manual (ODCM). The property line and nearby industrial facilities are shown in Figure 2.1-3. Industrial facilities located in the site area are the H. J. Ashe Substation and Energy Northwest's Nuclear Projects 1 and 4 (WNP-4 was terminated in January 1982, and WNP-1 was terminated in May 1994). Highway and railway facilities located within the site area are shown in Figure 2.1-3. The relative locations of the plant structures are shown in Figure 1.2-1.

The boundary of the exclusion area is a circle with its center at the reactor and a radius of 1950 m. Ownership and control of the land outside the CGS property line but within the site exclusion area are discussed in Section 2.1.2.

The site is situated near the middle of the relatively flat, essentially featureless plain, which is best described as a shrub steppe with sagebrush interspersed with perennial native and introduced annual grasses extending in a northerly, westerly, and southerly direction for several miles. The plain is characterized by slight topographic relief of approximately 20 ft across the plant site.

The dominant topographic features in the area are the Rattlesnake Hills, 13 to 15 miles west southwest, 3200 ft above the elevation of the plant site; Gable Mountain, approximately

10 miles northwest of the site and about 670 ft above the site grade; and the steep river cut bluffs forming the east bank of the Columbia River, approximately 3.5 miles east of the site (Figure 2.1-1).

2.1.1.3 Boundaries for Establishing Effluent Release Limits

The boundary for establishing effluent release limits (unrestricted area boundary as defined in 10 CFR Part 20) is the site area boundary as shown in the ODCM, Figure 3-1. The site area is the area enclosed by the exclusion area boundary and the plant property lines that fall outside the exclusion area. All area within the site area boundary is considered a controlled area as defined by 10 CFR 20.1003.

A number of restricted areas (as defined in 10 CFR 20.1003) are associated with CGS. The primary CGS restricted area is located within the plant security fence which also is the boundary of the protected area (as defined in 10 CFR 73.2). This is shown as the double fence line in Figure 1.2-1. Unescorted access to the protected area is controlled by CGS security staff. Other restricted areas include the Independent Spent Fuel Storage Installation, stormwater ponds, Plant Support Facility calibration laboratory, Warehouse No. 5, the cooling tower sediment disposal area, and Building 167 on the WNP-4 site. Access to these secondary restricted areas is controlled by locks and fences. Temporary restricted areas may be established and removed as dictated by activities at CGS.

2.1.2 EXCLUSION AREA AUTHORITY AND CONTROL

2.1.2.1 Authority

Energy Northwest leased 1089 acres from the DOE, within the DOE Hanford Site, to be used for CGS. A letter from the DOE Richland Operations office to the Managing Director of Energy Northwest (Reference 2.1-1) advises that the DOE has the authority to sell or lease land on the Hanford Site and the letter further states

> This Authority is contained in Section 120 of the Atomic Energy Community Act of 1955, as amended, and Section 161g of the Atomic Energy Act of 1954, as amended. There is also general federal disposal authority available under the Federal Property Administrative Services Act of 1949, as amended.

The 1950-m radius exclusion area extends beyond the CGS property lines and overlaps DOE lands as well as the additional land leased by Energy Northwest for the construction of the WNP-1 and WNP-4 projects (see Figure 2.1-3 and ODCM Figure 3-1). All land outside the Energy Northwest leased property but within the exclusion area is managed by the DOE.

In recognition of the requirement specified in 10 CFR 100.3(a) [Now 100.3] that a licensee have control over access to the exclusion area, the following terms have been incorporated as Article 7 of the site property lease agreement between Energy Northwest and the DOE (as modified in 1975):

Notwithstanding any provisions of this lease to the contrary, the Administration [Energy Research and Development Administration -- now DOE] agrees that the Supply System [now Energy Northwest] has the authority to determine all activities within the exclusion area within the meaning of 10 CFR Section 100.3(a) [Now 100.3], including the authority to remove a personnel and property from the area. The Supply System agrees that it will exercise such authority in a manner so as not to preclude the Administration from undertaking any action or activity within the exclusion area that is permissible under the provisions of 10 CFR Section 100.3(a) [Now 100.3]. As used herein, the term "exclusion area" includes both the leased and nonleased portions of the exclusion area.

Therefore, any actions such as public access and actions concerning mineral rights and easements taken within the exclusion area but outside the leased property are under the control of the DOE with the provision that Energy Northwest has the legal right to control access of individuals to the exclusion area if necessary. All rail shipments on the track which traverses the property (Figure 2.1-3) are also under control of the DOE and are also subject to the above provision and controls imposed by Energy Northwest Security.

The only paved roads that traverse the exclusion area of CGS are the CGS, WNP-1, and WNP-4 facility access roads shown in Figure 2.1-3. Access by land from outside of the Hanford Site to the plant site is over DOE roads. Travel within the exclusion area on the access roads will be under the authority of Energy Northwest.

In the event that evacuation or other control of the exclusion area should become necessary, appropriate notice will be given to the DOE-Richland Operations Office for control of non-Energy Northwest originated activities.

The above provisions provide the necessary assurance that the exclusion area is properly controlled. If Energy Northwest should decide that an easement would be useful in ensuring continued control, there is a provision in Article 5(b) of the lease as follows:

> Subject to the provisions of Section 161g of the Atomic Energy Act of 1954, as amended, the Commission has authority to grant easements for rights-of-way for roads, transmission lines and for any other purpose, and agrees to negotiate with Energy Northwest for such rights-of-way over the Hanford Operations Area as are necessary to service the Leased Premises.

Pursuant to this provision Energy Northwest could obtain an easement over the exclusion area in question from the DOE, which would ensure that no permanent structures or other activities inconsistent with the exclusion area would be carried on therein.

2.1.2.2 Control of Activities Unrelated to Plant Operation

In accordance with, and as defined by 10 CFR 100.3, Energy Northwest has the authority to determine all activities within the exclusion area, including the authority to remove all personnel and property from the area. The following activities unrelated to plant operation are permitted within the exclusion area:

2.1.2.2.1 Industrial Development Complex

Energy-Northwest is conducting site restoration and economic development (such as leasing of excess facilities for office space and manufacturing) activities at the WNP-1 and WNP-4 sites (the WNP-1 and WNP-4 sites are also leased from the DOE and controlled by Energy Northwest). The number of personnel at the WNP-1 and WNP-4 sites varies. However, coordination of activities within the exclusion area is under the control of Energy Northwest and the CGS emergency plan. This includes notification and evacuation considerations in the event of an emergency at CGS.

2.1.2.2.2 618-11 (Wye) Waste Burial Ground

The 618-11 site is a DOE waste burial ground, encompassing an eight-acre parcel directly adjacent to Energy Northwest leased land (see Figure 2.1-3) and located wholly within the CGS exclusion area. All 618-11 site activities are controlled by DOE in accordance with 10 CFR Chapter III. DOE has responsibility for the 618-11 site in accordance with 10 CFR 830.204. The soil overburden covering the caissons and vertical pipe units at the 618-11 site is identified as a passive design feature that serves a mitigative function. Existing soil overburden shall not be removed.

Following non-intrusive surveillance and characterization activities, the site was returned to inactive status.

2.1.2.3 Arrangements for Traffic Control

The only roads within the exclusion area are the Energy Northwest access roads. These roads are normally used only by employees and visitors associated with the CGS, WNP-1, and WNP-4 facilities, DOE, and DOE contractors. The security force, with offsite assistance as required, controls traffic during emergencies.

2.1.2.4 Abandonment or Relocation of Roads

There were no public roads transversing the exclusion area that had to be abandoned or relocated as a result of the construction of CGS.

2.1.3 POPULATION DISTRIBUTION

Table 2.1-1 presents the compass sector population estimates for 1980 and the forecasts for the same compass sectors by decade from 1990 to 2030.* Cumulative totals are also shown in Table 2.1-1. This table may be keyed to Figures 2.1-4 and 2.1-5, which show the sectors and major population centers within 10 and 50 miles of the site. As can be seen in Figure 2.1-6, population centers, within 50 miles of the site include the Tri-Cities area of Richland, Pasco, and Kennewick; Moses Lake; Hermiston; and the communities lying along the Yakima River from Prosser to Toppenish. Figure 2.1-4 shows that there are no towns located within 10 miles of the site, with the exception of a small part of Richland.

The 1990 to 2030 forecasts presented here (Reference 2.1-2) are based on

a. 1979 population figures provided by the Washington State Office of Financial Management,

b. Benton and Franklin County Traffic Analysis Zone population distributions,

c. Computed annual average area growth rates from 1975 through 1979 which were utilized to obtain the total 1980 population estimated for each area, and

d. County forecasts prepared by the Bonneville Power Administration. (References 2.1-3 and 2.1-4).

Table 2.1-2 presents the compass sector population estimates for 2010 based on U.S. Census Bureau data (Reference 2.1-5). See also Figures 2.1-4 and 2.1-5.

2.1.3.1 Population Within Ten Miles

An estimated 3000 people live within 10 miles of the site. The nearest inhabitants occupy farms which are located east of Columbia River and are thinly spread over five compass sectors. There are no permanent inhabitants located within 3 miles of the site.

No significant changes in land use within five miles are anticipated. The Hanford Site is expected to remain dedicated primarily to industrial use without private residences. No change in the use of the land east of the Columbia River is expected since it currently is irrigated to

---

* Population estimates out to 50 miles were derived to serve the licensing requirements of WNP-1, CGS, and WNP-4. Therefore, estimates were made relative to the centroid of the triangle formed by the three reactors. This point is located 2800 ft east of CGS and has coordinates longitude 119° 19' 18" west, latitude 46° 28' 19" north. This shift does not affect the overall accuracy or applicability of the population distribution projections.

about the maximum amount practicable. The primary increase in population within the 10-mile radius is expected to be in the area south and south-southeast of the plant (see Figure 2.1-4).

2.1.3.2 Population Between Ten and Fifty Miles

As indicated in Table 2.1-2, about 450,000 people were estimated to be living within a 50-mile radius of CGS in 2010. Projections for the 10-50 mile region are shown in Table 2.1-1 which is based on earlier (1979-1980) population counts.

2.1.3.3 Transient Population

The transient population consists of agricultural workers needed for harvesting crops produced in the region, industrial and construction workers, and sportsmen engaged in hunting, fishing, and boating. A description of the transient population is discussed in Section 5.6 of the CGS Emergency Plan.

2.1.3.4 Low Population Zone

The low population zone (LPZ) [see 10 CFR 100.3(b)] for CGS is defined as all land within a 3-mile radius of the reactor. This LPZ was selected on the basis that it is not expected to have a large population in the future and that effective protective measures could be established. As shown in Table 2.1-2, no permanent residents are located within a 3-mile radius of the reactor, and none are anticipated in the future.

There are no public facilities or institutions such as schools and hospitals within a 3-mile radius of the plant. The transportation facilities and topographic features of the LPZ are shown in Figure 2.1-7.

2.1.3.5 Population Center

The nearest population center is the City of Richland, 12 miles to the south.

2.1.3.6 Population Density

In 2000, the population densities within the 10, 20, and 30-mile radii were 9, 96, and 73 people per square miles, respectively. In 2030, the densities out to the same distances are estimated to be 13, 123, and 84, respectively, based on the projections in Table 2.1-1.

2.2 NEARBY INDUSTRIAL, TRANSPORTATION, AND MILITARY FACILITIES

This section describes the industrial, transportation, and military installations and operations in the vicinity of the site which may have a potential effect on the safe operation of Columbia Generating Station (CGS).

2.2.1 LOCATION AND ROUTES

There are no military bases, missile sites, manufacturing plants, chemical plants, commercial chemical storage facilities, or airports within a 5-mile radius of the site. A security barrier completely surrounds the station and its major supporting facilities to keep unauthorized vehicles a safe distance from critical structures.

According to the Richland Operations Office of the Department of Energy (DOE) (Reference 2.2-1), there are no plans for petrochemical storage facilities, airports, oil and gas pipelines, or petrochemical tank farms on the Hanford Site. Plans for modifications to or new radiological material treatment or storage facilities are discussed in Section 2.2.2.

As shown in Figure 2.1-3, the following facilities are located at or near the CGS site:

- Energy Northwest Plant Engineering Center,
- H. J. Ashe Substation,
- DOE Fast Flux Test Facility (FFTF),
- WNP-1 and WNP-4 sites,
- DOE 618-11 (Wye) radioactive waste burial ground,
- Permanent meteorological tower,
- Independent Spent Fuel Storage Installation (ISFSI), and
- Hydrogen Storage and Supply Facility.

Other facilities that are located within a 5-mile radius of the site include:

- The Plant Support Facility/Emergency Operation Facility which is located 0.75 miles southwest of CGS on Energy Northwest property,

- The Benton Substation which is located 3 miles east-southeast of CGS on DOE property,

- The Laser Interferometer Gravitational-Wave Observatory (LIGO) which is located approximately 3.3 miles west-southwest of CGS on DOE property, and

- The DOE 618-10 (300 North) radioactive waste burial ground which is located approximately 3.5 miles south of CGS on DOE property.

Transportation needs of CGS can be met by existing barge, rail, and highway facilities. Barges of up to 3000 tons capacity can be accommodated on the Columbia River within the Hanford Site. A barge unloading facility 9 miles south of the plant was used for delivery of large construction items for the DOE FFTF and Energy Northwest nuclear projects. These materials were transported by truck or rail to the construction sites from the Port of Benton landing.

The CGS site is serviced by a two-lane paved access road connected to Hanford Site Route 4, which is a paved four-lane major artery located 1.6 miles west of the station. Route 4 is part of the DOE road system. The DOE-owned road system connects the areas of the Hanford Site with paved two-lane and four-lane primary roads, secondary gravel roads, and unimproved roads. State Highway 240 traverses the Hanford Site from the southeast to the northwest. The highway passes within about 7 miles of CGS in the southwest quadrant. The highway connects into State Highway 24, which goes west to Yakima, Washington, and across the Vernita Bridge on the Columbia River 22 miles to the northwest (see Figure 2.2-1).

The Hanford Site (DOE) railroad system (see Figure 2.2-2) connects with commercial rail systems in Richland and Kennewick, Washington. Railroad operations that pass through CGS property are restricted to only those trains that have been authorized by Energy Northwest Security. The rail line is physically blocked at the two points where the plant vehicle barrier crosses the tracks.

Heavy barge traffic north of the Port of Benton dock is not feasible because the river channel is too shallow and the current is too swift. The environmental impact and economic cost of constructing a new barge slip at some upstream location and channeling the river cannot presently be justified with the availability of land transportation between the Port of Benton facility and the Hanford Site.

Making the Columbia River navigable for barges from north of Richland to Wenatchee would result in barge traffic past the CGS site at River Mile 352. However, this situation would not likely occur. Locks or other lift facilities would have to be constructed at the Priest Rapids, Wanapum, and Rock Island Dams. Furthermore, in 2000, a presidential executive order created the Hanford Reach National Monument, protecting the 51-mile Hanford Reach of the Columbia River (Reference 2.2-2). The protected area includes a ¼-mile-wide corridor on the west side of the river in the vicinity of CGS.

Airports, military facilities, low-level Federal airways, and airport instrument approaches in the vicinity of CGS are discussed in Section 3.5.1.6 and shown in Figure 2.2-3.

An explosives and ordinance test site operated by Pacific Northwest National Laboratory approximately 13 miles northwest of the site was abandoned in mid-1975 (Reference 2.2-3). Explosives for operations such as quarrying or seismic studies on the Hanford Site are brought to the blasting site as needed and unused quantities are removed. Normally the only explosives

stored on the Hanford Site are small arms ammunition for use by the security patrols. A small arms firing range used for training by the DOE security patrol is located 8 miles due south of the plant (Reference 2.2-3). Another range, used by Energy Northwest security personnel, is located on Energy Northwest lease property.

2.2.2 DESCRIPTIONS

2.2.2.1 Description of Facilities

Energy Northwest's Plant Engineering Center is located west of the CGS turbine generator building as shown in Figure 1.2-1. It is a two-story, 100,000 ft^2 facility designed to house approximately 470 CGS plant staff personnel.

The H. J. Ashe Substation is located approximately 0.5 mile north of CGS and is operated by the Bonneville Power Administration as part of its transmission system.

The Energy Northwest permanent meteorological tower is located less than 0.5 mile west of the plant site. The tower is automated so that the only personnel at the tower are those required to make adjustments to the instruments or to perform repairs to the system. There are no permanent personnel at the facility.

The ISFSI is located immediately north-northwest of the plant. Confinement of all radioactive materials at the ISFSI is provided by the required use of NRC certified spent fuel storage casks listed in 10 CFR 72.214. The ISFSI storage cask system consists of an inner stainless steel multi-purpose canister (MPC) and an outer storage overpack. The MPC contains the spent fuel. It is a welded pressure vessel with no bolted closure or mechanical seals. Primary closure welds are examined and leakage tested to ensure their integrity. The MPC redundant closures are designed to maintain confinement integrity during normal conditions of storage, and off-normal and postulated accident conditions. The outer storage overpack is fabricated from concrete and structural steel components that are classified as important to safety. A fully loaded spent fuel storage cask weighs approximately 185 tons. The spent fuel loaded storage casks are located within the Energy Northwest ISFSI protected area which is surrounded by a fence and topped with barbed wire. The ISFSI access gates are locked except when in use.

The Hydrogen Storage and Supply Facility is located 0.6 miles south-southeast of the plant site. The facility is part of a hydrogen water chemistry system to prevent and mitigate intergranular stress corrosion cracking in reactor internal structures and piping welds. The facility consists of a fenced gravel yard with concrete pads constructed to accommodate a liquid hydrogen tank, nitrogen tank, gaseous hydrogen tubes, and all supporting piping and equipment necessary to supply CGS with gaseous hydrogen. The liquid and compressed gases are delivered to the facility by truck.

Within the exclusion area radius of 1950 m is Energy Northwest's 1250-MWe WNP-1 project. Construction of the PWR plant, located 1500 m (4925 ft) east-southeast of CGS, was suspended in April 1982. In May 1994 the Energy Northwest Board of Directors voted to terminate WNP-1. The construction of twin unit WNP-4, located 1250 m (4100 ft) east-northeast of CGS, was terminated in January 1982. These projects have a separate access road that ties into the Hanford Site Route 4, 1.6 miles south of the CGS access road. Support activities at either the WNP-1 or WNP-4 sites do not interfere with operation of CGS. These may include activities associated with site restoration and economic development (such as leasing of excess facilities for office space and manufacturing). Within the exclusion area, Energy Northwest has the authority to determine all activities within the meaning of 10 CFR 100.3(a), including the authority to remove all personnel and property from the area.

The Laser Interferometer Gravitational-Wave Observatory (LIGO) is located approximately 3.3 miles west-southwest from the plant site. The mission of this research facility is to observe gravitational waves of cosmic origin. The facility houses laser interferometers, consisting of mirrors suspended at each of the corners of an L-shaped vacuum system measuring 2.5 miles on a side. The materials and activities at this facility do not impact the operation of CGS.

As discussed in Section 2.1.1 and shown in Figure 2.1-1, CGS is located on the DOE Hanford Site. In reviewing the plant site and the vicinity for potential external hazards or hazardous material, the Hanford facilities currently operating, recently operating, or with the potential for operating were screened. The facilities discussed below are those believed to pose the most risk to the safe operations of CGS. The safety analysis reports and accident analysis prepared for those facilities were reviewed to determine possible hazards. No accidents evaluated present a physical challenge to the CGS buildings. Releases with the potential to impact the operation of CGS were radioactive particulate that would be effectively mitigated within General Design Criterion (GDC) 19 limits by the control room high-efficiency particulate air (HEPA) filters. Considered but not included were the 200 East Burial Grounds, the Critical Mass Laboratory, the Liquid Effluent Retention Facility, and the Effluent Treatment Facility in the 200 East Area. In the 200 West Area, the T Plant, U Plant, Reduction-Oxidation Plant, and the 222-S Laboratory were considered but not included. These facilities have insufficient radiological or toxicological inventories in a dispersible form to represent a risk to CGS operation. The specific facilities included are discussed in Table 2.2-1.

Three DOE facilities are located within a 5-mile radius of the plant site. These are the Fast Flux Test Facility (FFTF) and two radioactive waste burial grounds. The specific hazards associated with these facilities are summarized in Table 2.2-1 and the specific activities are listed below:

- The FFTF is a deactivated sodium cooled breeder reactor located approximately 3 miles southwest of CGS. All fuel has been removed and shipped to the Idaho National Laboratory. All sodium has been removed, solidified, and is stored on-site. The facility has been placed in a long-term, low-cost surveillance and maintenance condition.

- The 618-10 (300 North) Waste Burial Ground is approximately 3.5 miles south of CGS. DOE has initiated remediation activities at the site.

- The 618-11 (Wye) Waste Burial Ground is directly west of CGS, outside of Energy Northwest leased land, but within its 1950-meter exclusion area radius and security perimeter. The site received low- to high-activity waste, fission products, some plutonium-contaminated waste, and non-radiological hazardous waste from March 1962 to December 1967 from the Hanford 300 Area. The waste is buried in 3 trenches, 50 Vertical Pipe Units (VPUs), and four caissons. The site was covered with an overburden of soil when it was closed. The surface was stabilized in 1982 with an additional 2 ft of soil. Since surface stabilization, activities at the site have been limited to monitoring and surveillance. DOE completed non-intrusive surveillance and characterization activities at the site in 2011 to obtain data information and information for planning remediation activities.

The DOE 300, 200 East, and 200 West Areas are located within a 10-mile radius of the site. The current waste management activities (storage, disposal, and treatment) conducted in these areas are discussed in Table 2.2-1. The 300 Area is approximately 7 miles southeast of CGS. The only hazard presented to CGS from this site is from the spent nuclear fuel and other radioactive material stored there. There is an unknown quantity of miscellaneous reactor fuel material in the 300 Area. This quantity is not publicly available information.

The DOE 200 East and 200 West Areas are approximately 10 miles northwest of CGS. Originally these facilities were constructed to support the extraction of weapons grade plutonium for the defense program. However, as the Hanford mission has changed from production to environmental cleanup, so has the purpose of the facilities discussed. This change in mission has, in some cases, resulted in a change in the hazards presented to CGS plant site and personnel.

A private (non-DOE) low-level radioactive waste disposal area is adjacent to 200 East Area. There are also plans to build private waste vitrification facilities adjacent to 200 East. These facilities are also discussed in Table 2.2-1.

Several plutonium production reactor facilities are located approximately 20 miles north-northwest of CGS. All of the reactors were water cooled, graphite moderated. The last operating reactor, the N Reactor, was permanently shut down in 1991. The N Reactor also provided steam for the Energy Northwest Hanford Generating Station until 1987. The fuel has been removed from the reactors for storage or treatment. The current activities at these reactor sites are also discussed in Table 2.2-1.

The nearest petroleum product storage tanks are located 22 miles southeast of the site: approximately 23 million gal capacity at the Chevron Pipeline Company and approximately 20 million gal capacity at the Tidewater Barge Lines.

2.2.2.2 Description of Products and Materials

The existing Hanford Site railroad track (owned by the DOE and operated by a private contractor in support of the Hanford Operations), and the CGS, the WNP-1, WNP-4, and the FFTF railroad spurs all run within the exclusion area of the plant site. Shipments of large quantities of hazardous materials on this track that existed during initial licensing of CGS are no longer made (Reference 2.2-4).

The DOE has no plans for railroad shipments of explosives in the foreseeable future. However the DOE's Richland Operations Office has agreed to notify Energy Northwest prior to transporting any explosive shipments of more than 1800 lb past CGS (Reference 2.2-5). Energy Northwest will provide an analysis to the NRC of the potential consequences prior to the start of such shipping (Reference 2.2-6).

Hazardous material is also transported on Hanford Route 4 by DOE. Chlorine is the only material of concern transported on Route 4 with the potential for impacting CGS operation. Section 6.4.4.2.1 provides additional information on control room habitability assessments for CGS.

The Yakima Training Center, a sub-installation of Fort Lewis, is 30 miles northwest of the site. The center consists of 327,000 acres. The center provides training facilities and logistical support and it is used for firing of all types of ordnance, both in a direct mode and by indirect artillery and mortars. Weapons to 155mm are fired. This type firing occurs frequently. Other types of live ordnance use at the center include aerial delivery by high performance aircraft of ordnance to include 2,000-lb bombs, helicopter weapons which include automatic weapons and

2.75-in. folding fin rockets, and anti-aircraft missiles. These latter activities are significant as to occurrence. The majority of the ordnance impacts a 20,000-acre area which is generally located in the central portion of the center. All activities are confined to the geographical limits of the center and/or its restricted air space unless special arrangements are made with affected agencies. Mechanized units (i.e., tanks and armored personnel carriers) from Fort Lewis and reserve components conduct extensive maneuvers on all accessible areas of the Training Center and use specially designed ranges to practice firing their weapons. Infantry and engineer units that support the mechanized units also train at the center. Training activity is greatest from March to November. War games sometimes involve troop and equipment deployment at the Richland Airport and along Highway 243 west of Vernita Bridge. Helicopters may fly near the Hanford Site, or military vehicles may travel over Highway 240 (Reference 2.2-7).

2.2.2.3 Pipelines

There are no commercial oil or gas pipelines in the vicinity of CGS. The nearest major natural gas transmission pipeline to the site is about 12 miles. A 20-in. gas transmission line of the Northwest Pipeline Corporation is located east and essentially parallel to U.S. Highway 395 between Pasco and Ritzville, Washington. A second pipeline system consisting of parallel 36-in. and 42-in. lines, owned by Pacific Gas Transmission Company, passes through Wallula, approximately 24 miles from the site (Reference 2.2-8). These distances eliminate any potential hazard to plant operations due to a natural gas fire or explosion. The Energy Northwest Hydrogen Storage and Supply Facility is located 0.6 miles south-southeast of the plant and is connected to the plant with a 2-in NPS gas pipeline. The pipeline runs north from the facility approximately 400 ft east of the plant and then turns and runs west approximately 400 feet north of the plant then south approximately 200 ft west of the plant to its connection point on the west side of the Turbine Building. Fire and explosion risks to the plant involving this pipeline are discussed in Appendix F and Section 3.5.1.5.

2.2.2.4 Waterways

Makeup water inlet structures are located in the Columbia River 315 ft from the shoreline at low river flow (36,000 cfs; el. 341.73 ft) at river mile 351.75.

A significant amount of Columbia River barge traffic moves as far upstream as the Ports of Pasco and Kennewick. Also, a docking facility established by the Port of Benton in North Richland (approximately 9 miles downstream of the CGS site) is accessible by barges with a maximum 16 ft of draft (normally 2500 to 3000 tons). The first use of this facility was in April 1973 when the FFTF reactor vessel was off-loaded. Traffic to the North Richland dock is very infrequent in comparison to that in Pasco and Kennewick due to the lack of large industrial concerns in the region between Richland and Priest Rapids Dam. This facility is most often used to off-load dismantled nuclear components. On several occasions in the past,

lightly loaded barges have transported material to the vicinity of the Hanford Site. This required maintenance of an adequate flow from Priest Rapids Dam during the transit period.

2.2.2.5 Airports

Two commercial airports are within 20 miles of CGS. The closest is Richland Airport 11 miles south of the plant. This general aviation airport has two 4000-ft runways, one with a 010°/190° orientation and the other with a 070°/250° orientation. Visual flight rule landings are standard for Federal Aviation Administration (FAA) non-control-tower airports.

The Tri-Cities Airport 17 miles southeast near Pasco is the largest airport within 40 miles. The FAA operates the air traffic tower and airport radar approval control facility. The airport has two 7700-ft crossing runways with 120°/300° and 030°/210° orientations. The latter has a 4430-ft parallel runway. Runway 30 has a very high frequency omnirange (VOR) instrument approach and Runway 21R has an instrument landing system and is an instrument approach runway.

Information relative to the flight paths and activity at these two commercial airports, the Yakima Training Center, and the nearby private airstrips is discussed in Section 3.5.1.6.

2.2.2.6 Projection of Industrial Growth

There is no projected growth of waterway traffic nor plans for oil and gas pipelines within 10 miles of CGS.

2.2.3 EVALUATION OF POTENTIAL ACCIDENTS

2.2.3.1 Determination of Design Basis Events

Energy Northwest has investigated the resistance of plant structures to explosions. The reactor building is a reinforced-concrete structure up to the refueling floor and is designed to withstand the worst probable combination of wind velocity and associated pressure drop due to a design basis tornado. A differential pressure of 3 psi between the exterior and interior of the building is also considered in the design. At its nearest point, the railroad is 510 ft from the reactor building.

From the above criteria, it has been determined that the reactor building can resist an explosion of 20,000 lb of dynamite on a railway car 510 ft from the reactor building. The performance of the reactor building structure for this blast loading condition will be similar to that for the

original design basis tornado loading condition based on the 3 psi differential pressure used in the original tornado analysis.

In the unlikely event of an explosion or fire on the railroad affecting the 115-kV shutdown power supply, the 230-kV power supply or the diesel generators would fulfill that function.

It is extremely unlikely that an explosion or fire on the mainline railroad would compromise the safe shutdown of the facility. As noted in Section 2.2.2.2, DOE has no plans to ship explosives on the railroad, and the agency will notify Energy Northwest prior to the shipment of explosives in a quantity greater than 1800 lb. Energy Northwest Security controls access to the rails that pass near the plant. The only explosives on the Hanford Site are small arms munitions. As described in Section 2.2.2.2, this represents no hazard to the operation of CGS. The Yakima Training Center does not endanger the site. Hydrogen gas stored in the gas bottle storage building and in a trailer parked adjacent to the gas bottle storage building will not pose any fire or explosion problem because of the light weight properties and dispersal qualities of the gas and the distances (approximately 400 ft) between the storage areas and any safety-related equipment. Hydrogen gas stored at the Hydrogen Storage and Supply Facility (HSSF) and transported to the plant by pipeline does not pose a significant fire or explosion risk to the plant as discussed in Appendix F and Section 3.5.1.5. Habitability considerations for the control room and quantities of hydrogen gas stored in/adjacent to the gas bottle storage building and at the HSSF are discussed in Section 6.4.4.2.3.

Table 2.2-1 summarizes the potential events at the Hanford Site facilities that could present a radiological or chemical hazard or hazardous situation to the continued safe operation of CGS. The cesium and strontium capsules stored at the Waste Encapsulation and Storage Facility (WESF), the fuel stored at the K Basins, and the high level waste stored in the tank farms present contributions to risk at CGS due to presence of ^{137}Cs, ^{90}Sr, and ^{241}Am. However, based on consideration of the radionuclide inventory at risk, the ability to transport this inventory, and the proximity of the storage facility, the risk is dominated by the inventory stored at WESF. The probability of the loss of cooling in the capsule storage pool is extremely low, but the potential dose to unprotected CGS personnel due to the release is significant. Any required evacuations would be performed as discussed in the Emergency Plan. The design basis accident at WESF would not result in a condition at CGS which would challenge the criteria established in 10 CFR 100.

In each event evaluated, the radiological dose resulting from particulate releases would be adequately filtered by the control room HEPA filters, mitigating any challenge to the habitability of the control room. None of the facilities present a chemical exposure risk to CGS. Radiological exposures for postulated events on the Hanford Site are characterized by the contribution from gaseous radionuclides because of the short half-life of ^{131}I and because the other noble gases were released during the spent fuel processing.

The Yakima Training Center, discussed in Section 2.2.2.2, is used for military maneuvers and weapons training and is the only significant military activity in the vicinity of the Hanford Site. The only weapon currently in use at the Yakima Training Center known to present a hazard to the Hanford Site is the multiple launch rocket system (MLRS). With a range in excess of 25 miles, the MLRS could potentially impact the CGS site. However, the MLRS is only fired from the perimeter of the Yakima Training Center into a centrally located impact zone and is only fired with dummy warheads. Given this information, additional safety features, and the administrative controls in place at the Yakima Training Center, a weapons accident having an impact on CGS is very improbable.

As stated in Section 2.2.2.1, confinement of all radioactive materials at the ISFSI is provided by the required use of NRC certified spent fuel storage casks listed in 10 CFR 72.214. Pursuant to the 10 CFR 72.212 report, evaluations performed in support of the ISFSI have demonstrated the reactor site-specific parameters are bounded by the safety analysis for the generically approved cask. Accordingly, activities associated with the facility do not adversely impact operation of CGS (Reference 2.2-10).

Brush fires have occurred on the Hanford Site and have presented no potential hazard to existing facilities. Areas adjacent to CGS major buildings and auxiliary facilities are maintained to prevent weed growth by landscaping, gravel, ground cover, and weed control spraying. The Hydrogen Storage and Supply Facility (HSSF) is landscaped with gravel beyond the perimeter of the site, exceeding the code required clearance distance, to keep the area free from dry vegetation and combustible materials. These or similar methods of weed control minimize brush fire hazards to CGS facilities.

The potential effects of fires that involve materials used in the operation of the plant are discussed in Appendix F.

The formation of unconfined vapor clouds caused by the accidental release of flammable or toxic liquids or vapors stored at the plant site is discussed in Section 6.4 and addressed by the Emergency Plan.

The non-safety-related makeup water intake consists of two sets of paired perforated pipe sections. One set is capable of supplying the full makeup water requirements of the plant. Extreme low river flow (36,000 cfs) will provide about 0.5 ft of water over the top of the intake pipes. The probability of damage to both sets of intakes as a result of a pleasure boat or barge accident is extremely remote given the infrequency of both extreme low flows and large boat and barge traffic. In the unlikely event that such an accident might occur, destruction of the makeup water intake structure would be comparable in effect to loss of offsite power to the makeup water pumps. The Seismic Category I spray ponds provide for 30-day cooling without makeup. This is ample time to restore makeup from either the river or wells.

There are no upstream industrial facilities for which waterborne deliveries of significant quantities of petroleum products, corrosive chemicals, or other hazardous materials are expected. Fuel oil, diesel oil, acids, and caustics are stored at the N-Reactor site. The oil storage facilities are protected by dikes, and the chemical storage facilities are far enough from the river to avoid direct discharge. Thus, there is no possible hazard to the plant due to spillage of such materials into the river. There are no upstream releases which may be corrosive, cryogenic, or coagulant.

2.2.3.2 Effects of Design Basis Events

As discussed in Section 2.2.3.1, the activities of nearby industrial, transportation, and military facilities will have no adverse effect on the plant.

2.3 METEOROLOGY

The italicized information, including associated tables and figures, is historical and was provided to support the application for an operating license.

2.3.1 REGIONAL CLIMATOLOGY[*]

2.3.1.1 General Climate

The site is located in a mid-latitude semi-arid (steppe) climatic region in the Lower Columbia Basin which is the lowest elevation of any part of central Washington. A major factor influencing this climatological region is its location in the continent, well away from the windward coast and protected to the west by the 4,000 to 7,000-ft average elevation Cascade Mountains. Dominant air masses affecting the region are of maritime polar origin as modified by the presence of these mountains. Modified continental tropical and polar air masses also periodically affect the climate. In winter, there is a succession of cyclones as the westerlies and the polar front prevail in these latitudes. The mountain barriers commonly induce these storms to occlude by delaying air mass movement. Fewer frontal passages occur during the summer months since subtropical oceanic high cells reach their highest latitudes thereby diverting cyclonic storms poleward. Along the eastern margin of the Pacific anticyclone, an out-flow of stable subsiding air brings distinctly drier conditions to the North American Pacific coast.

The regional temperatures, precipitation, and winds are greatly affected by the presence of the mountain barriers. The Rocky Mountains and ranges in Southern British Columbia are effective in protecting the inland basin from the more severe winter storms and associated cold polar air masses moving southward across Canada. Occasionally, an outbreak of cold air will pass through the Basin and result in low temperatures or a damaging spring or fall frost. Maritime polar air traveling eastward from the coastal zone cools as it rises along the western slope of the Cascade Range. These orographic effects cause heavy precipitation on the windward and light precipitation on the leeward slopes. The prevailing westerly. winds are normally strongest during winter and spring due to the presence of cyclonic scale disturbances and associated frontal activity. During those months, foehn or chinook winds (a warm dry

---

[*] *This section is based on records kept at the Hanford Meteorology Station (14 miles northwest of the site, elevation 733 ft MSL) from 1945 to 1980 (2) and 100-N area sites (1) (supplemented with precipitation and temperature data taken by U.S. Weather Bureau cooperative observers at a site about 25 miles north of the present station location during the period from 1912 to 1944 (2,3) and regional climatological data gathered during the period from 1931 to 1960). (4) Other references are as indicated.*

wind on the lee side of a mountain range; the warmth and dryness of the air is due to adiabatic compression upon descending the mountain slopes) occur whenever cyclonic circulation is sufficiently strong and deep to force air completely across the cascades in a short period of time. At other times during the winter, warm front occlusions can force moist air over the Cascade Range. The mixing of this moist air with relatively cooler air in the Basin results in considerable cloudiness and fog. The percent of possible sunshine ranges from 20 to 30 percent in winter, 50 to 60 percent in spring and fall, and 80 to 85 percent in mid-summer.

Because the site is in the rain shadow of these mountains, annual average precipitation decreases from about 100 inches near the summit of the Cascades to about 6 or 7 inches in the Basin. Approximately 70 percent of the annual total precipitation occurs from November through April and about 10 percent occurs during July through September. Rainfall amounts are normally light in the summer and gradually increase in late fall, reaching a peak of about one inch each month in midwinter due to cyclonic storm and frontal activity. Rainfall amounts decrease in Spring, increase somewhat in June, and again sharply decrease in July. During mid-summer, it is not uncommon to have 3- to 6-week periods with trace rainfall. There are only two occurrences per year of 24-hour amounts of 0.50 inch or more, while occurrences of 24-hour amounts of 1.00 inch or more number only four in the entire 25 years of record (1946 to 1970). One of these was the record storm of October 1 through 2, 1957, in which rainfall totaled 1.08 inches in three hours, 1.68 inches in six hours, and 1.88 inches in twelve hours. At the other extreme, there have been 81 consecutive days without measurable rain (June 22 through September 10, 1967), 139 days with only 0.18 inch (June 22 through November 7, 1967), and 172 days with only 0.32 inch (February 24 through August 13, 1968).

About 45 percent of all precipitation during the months of December, January, and February is in the form of snow. Regional annual total snowfall amounts have ranged from less than 1/2 inch in 1957 to 1958 to 56.1 inches for the winter of 1992-1993; the annual average total is about 14 inches.

Snow rarely remains on the ground longer than two to four weeks or reaches a depth at any time in excess of four to six inches, as rapid melting, which often contributes to local stream flooding, can occur from rain or Chinook winds. The record greatest depth of 24.5 inches occurred in February 1916.

Thunderstorms have been observed in the area in every month except November. Although severe ones are rare, lightning strikes have occasionally ignited grass fires which burned thousands of acres of the Hanford Reservation and resulted subsequently in considerable wind erosion of soil. The most notable of these occurrences were in August 1961, July 1963, and July 1970, and August 1984.

The continental-type climate not only affects precipitation in the Basin but also results in wide ranges and variations in annual temperature conditions. While the regional annual average temperature is about 53°F, the coldest month, January, has a mean of about 29°F; the

warmest month, July, has a mean of about 76°F. Although the presence of the cascades contributes to the wide differences in monthly average temperatures, other mountain ranges shield the area from many of the arctic surges, and half of all winters are free of temperatures as low as 0°F. However, six winters in 58 of record have contributed a total of 16 days with temperatures of -20°F or below; and in January to February 1950, there were four consecutive such days. There are ten days of record when even the maximum temperature failed to rise above zero. At the other extreme, in the winter of 1925 to 1926, the lowest temperature all season was +22°F.

Although winter minima have varied from -27°F to +22°F, summer maxima have varied only from 100°F to 115°F. However, there is considerable variation in the frequency of such maxima. In 1954, for example, there was only one day with a maximum as high as 100°F. On the other hand, there have been two summers (1938 and 1967) when the temperature went to 100°F or above for 11 consecutive days.

Although temperatures reach 90°F or above on about 56 days a year, there are only about seven annual occurrences of overnight minima 70°F or above. The usual cool nights are a result of gravity winds.

The channeling of air by the Cascade Mountains and surrounding terrain produces a prevailing WNW and NW regional flow. Local topographic features can cause other channeling effects and formation of local diurnal wind circulation systems which produce a greater degree of variability in winds at locations within the Basin. For example, the Columbia Generating Station (CGS) site experiences a bimodal wind direction distribution from approximately south and also northwest; at the Hanford Meteorological Station (HMS) about 14 miles northwest, the direction distribution displays a single peak at approximately WNW to NW (refer to 2.3.2).

Drainage (gravity) winds channeled by topographic features produce a marked effect on diurnal range of wind speed and cause the highest monthly average speeds of about 9 mph to occur during the summer months. In July, for example, hourly average speeds range from a low of 5.2 mph from 9 to 10 a.m. to a high of 13.0 mph from 9 to 10 p.m. In contrast, the corresponding speeds in January are 5.5 and 6.3 mph. These warm season diurnal winds, resulting from relatively cold air draining from the Cascade Mountains, occur in response to pressure gradients created between surface-heated warm, dry basin air and cooler air situated over the mountains and coastal region. This favors an outbreak of stronger winds during the afternoon and evening hours. Although the gravity wind occurs with regularity in summer, it is never strong unless reinforced by frontal activity. In June, the month of highest average speed, there are fewer instances of hourly averages exceeding 31 mph than in December, the month of lowest average speed. A complete summary of the monthly averages and extremes of climatic elements at the Hanford Reservation appears in Table 2.3-1.

2.3.1.2 Regional Meteorological Conditions for Design and Operating Bases

2.3.1.2.1 Severe Weather Phenomena

2.3.1.2.1.1 Heavy Rain, Snow, and Ice. Glaze is a coating of ice, generally clear and smooth, but with some air pockets. It is formed on exposed objects by the freezing of super-cooled drizzle or rain drops. Glaze is denser, harder, and more transparent than either rime or hoar frost. Although the record shows an average of seven glaze days per year, many of these cause little or no inconvenience to the public. Two outstanding exceptions occurred on February 11 to 12, 1954, and on November 23 to 24, 1970. There was serious disruption to Hanford traffic in each instance although there was no known damage to transmission lines. In each instance, rising temperatures soon melted the ice.

Precipitation frequency (rain and snow), intensity, and quantity statistics are presented in Figures 2.3-1 and 2.3-2 and Tables 2.3-2 and 2.3-3. For the winter of 1992-93, the following snowfall records were set: greatest winter snowfall (56.1 inches); most days with greater than 1, 6, and 12 inches on the ground (71, 41, and 9, respectively); and greatest 24-hour snowfall (10.2 inches) on February 18 and 19. Probable maximum precipitation is given in 2.4.3.1.

2.3.1.2.1.2 Thunderstorms and Hail. Thunderstorms may occur during any month of the year at Hanford. A thunderstorm day is one in which thunder is heard. If a thunderstorm should begin in late evening and last past midnight, it is counted as two thunderstorm days even though only one storm event occurred. Similarly, should there be two or more distinct thunderstorms in a day - and this sometimes happens - it is counted as a single thunderstorm day. The table below shows the monthly frequency of thunderstorms.

HMS THUNDERSTORM DAYS: 1945-1970

	J	F	M	A	M	J	J	A	S	O	N	D	SUM
Total	0	1	7	18	53	64	46	54	24	5	0	0	272
Average	0	#	#	1	2	3	2	2	1	#	0	0	11
% of Total	0	#	3	7	19	23	17	20	9	2	0	0	100

 # = Less than 0.5

Although the table above shows 0 for the months of November through January, a thunderstorm occurred at HMS on December 22, 1971. In Richland, one occurred on January 18, 1953. However, the thunderstorm season essentially includes only the months of April through September. Although the average is eleven days per year, the number has varied from three to twenty-three. In June 1948, there were eight thunderstorm days during the month; and this record was repeated in August 1953. The records show that cold fronts probably constitute the greatest single cause of thunderstorms at HMS. During the years of 1947 to 1955, 43 percent of all thunderstorm days during the months of May through August

were directly associated with cold frontal passages. On several occasions (notably on August 7, 1953), lightning has struck the HMS tower.

Peak gust data are not available for the 50-, 200-, and 400- ft levels prior to 1952. Of the 185 thunderstorm days occurring during the period of 1952 to 1970, the speed classification of peak gusts on these days is as follows:

	Number of Cases			% of Total		
mph	50 ft	200 ft	400 ft	50 ft	200 ft	400 ft
< 21	18	9	5	10	5	3
21 -30	75	45	42	40	24	23
31 -40	63	80	73	34	43	39
41 -50	23	34	46	12	19	25
51 -60	4	11	12	2	6	8
61 -70	1	4	5	1	2	3
> 70	1	2	2	1	1	1
	185	185	185	100	100	100

Precipitation was not measured during 1945 and 1946 in which 26 thunderstorm days occurred. During the period of 1947 to 1970, 246 thunderstorm days were recorded. The daily precipitation distribution during these days was as follows:

Amount - Inches	Number of Cases	% of Total
None or trace	110	45
0.01 - 0.10	87	35
0.11 - 0.25	29	12
0.26 - 0.50	15	6
> 0.50	5	2
	246	100

Precipitation intensities are defined in Reference 2.3-5.

The record for rainfall intensity during a thunderstorm is 0.55 inch in 20 minutes (1.65 inches per hour) on June 12, 1969. This storm included hailstones of 1/4-inch diameter.

Hail was reported on fourteen, or 5 percent, of the total thunderstorm days. Blowing dust or dust was reported on sixteen thunderstorm days and both hail and blowing dust or dust on six days.

Hail is a rare phenomenon at Hanford. For all years of record, hail has not occurred more than twice in any year. Of the 272 thunderstorm days from 1945 to 1970, hail was reported on fourteen or 5 percent of these days. Hail was also reported on two days without occurrence

of either a cold frontal passage or a thunderstorm on the same day. The distribution by months of days on which hail occurred is as follows:

	J	F	M	A	M	J	J	A	S	O	N	D	Total
Number	0	1	1	4	2	1	2	2	1	0	0	0	14
% of Total	0	7	7	30	14	7	14	14	7	0	0	0	100

Where size was reported, all except two reports indicated sizes in the 0.2- to 0.3-inch range. The exceptions were May 26, 1954, and July 1, 1955, when the size reported was 0.4 inch.

There is no known case of local damage from hail.

2.3.1.2.1.3 Tornadoes

The State of Washington experiences, on the average, less than one tornado each year. Within a one hundred mile radius of the site, only fourteen tornadoes have been reported since 1916. These tornadoes are listed in Table 2.3-4. Of these fourteen recorded tornadoes, only five had any damage associated with them. A more extensive survey of tornadoes in the three northwestern states (Washington, Oregon, and Idaho) was performed by Fujita (6). His results indicate that tornadoes and hailstorms in this area occur primarily in "alleys". The locations of these "alleys" are shown in Figure 2.3-3 along with locations of tornadoes which have been recorded in the tri-state area during the twenty-year period from 1950 to 1969.

Jaech (7) has analyzed the data of Fujita (6) to determine the probability of a tornado striking the Jersey Nuclear Company Fuel Facility (now Siemens Power Corporation), which is located about eight miles from the site. His analysis estimates the probability of occurrence of a tornado in the vicinity of the Exxon site as six chances in a million during any given year or about one chance in four thousand during a forty-year plant life.

The peak tornado wind velocity estimated for the site is 214 mph (Reference 2.3-7). This includes an estimated maximum rotational and translational wind velocities (at a 95-percent confidence level). Daubek (Reference 2.3-8) estimates the maximum translational velocity to be 30 mph. The maximum pressure drop in the center of the tornado relative to the environment is estimated to be up to 1.5 psi (Reference 2.3-6).

These values are equal to or less than those tornado parameters listed for a Class III region (which includes the site location) in Regulatory Guide 1.76, issued April 1974. Prior to the issuance of this guide, CGS was designed to withstand some of the most stringent NRC tornado criteria presented for a site located within a Class I region.

A comparison between criteria used for CGS and those applicable to Class I and III regions are given below:

Design Basis Tornado Characteristics

	Maximum Wind Speed (mph)	*Rotational Speed (mph)*	*Translational Speed (mph)*	
			Maximum	*Minimum*
Class I Region	*360*	*290*	*70*	*5*
Class III Region	*240*	*190*	*50*	*5*
CGS	*360*	*300*	*60*	-

	Radius of Maximum Rotational Speed (ft)	*Pressure Drop (psi)*	*Rate of Pressure Drop (psi/sec)*
Class I Region	*150*	*3.0*	*2.0*
Class III Region	*150*	*1.5*	*0.6*
CGS	*264 - 880*	*3.0*	*1.0*

Wind and tornado loading criteria used in the CGS structural design are discussed in Section 3.3.

2.3.1.2.1.4 Strong Winds. *The Hanford region experiences high wind speeds due to squall lines, frontal passages, strong pressure gradients and thunderstorms.* The Hanford Reservation has experienced only one recorded tornado (June 1948) and has not been known to be affected by typhoons. No complete statistics are readily available which present frequency of occurrence of high winds produced or accompanied by a particular meteorological event. However, the highest winds produced by any cause are tabulated for HMS in Tables 2.3-5 and 2.3-6. Figure 2.3-4 indicates the return probability of any peak wind gust, again due to any cause.*

The speed-direction summary (Table 2.3-6) shows that daily peak gusts of at least 40 mph have occurred from all but four of the sixteen compass points indicated. The SW octant, however, accounts for 65 percent of such cases. The SSW octant accounts for 83 percent of daily peak gusts of 50 mph or over and 100 percent of those 60 mph or over. Since WNW and NW are the most frequently observed directions at HMS, they account for almost half of all daily peak gusts. However, less than 3 percent of these are at speeds of 40 mph or more. By contrast, 23 percent of daily peak gusts from the SSW and SW attain this speed. Although the winter season has a lower average wind speed than any other, it also has the greatest frequency of days with peak gusts 40 mph or over (10 percent). This compares with 8 percent for spring, 7 percent for fall, and 5 percent for summer. However, reflecting the frequent periods of stagnation in winter, this season also has the highest frequency of days with peak gusts under

**Peak wind gust data associated with thunderstorm activity are given in 2.3.1.2.1.2.*

10 mph (16 percent). This compares with 10 percent for fall and 1 percent for spring. In summer, such days are virtually non-existent with only one being tabulated in 1,102 days of record. About 60 percent of the days from May through August experience drainage winds of at least 13 mph from the west direction for at least two hours daily during the period of 1600 to 2400 PST.

The annual extreme fastest mile of wind speed* for a given region has been commonly used as the best available measure of wind for design purposes (Reference 2.3-9). The standard reference speed level is normally chosen at the 30-ft elevation, and wind speed is assumed to vary with the one-seventh power of height.

All CGS structures have been designed to withstand a basic wind (fastest mile) velocity, including gusts of 100 mph at an elevation of 30 ft above the site grade. *This design speed value is conservative for the CGS site since the 100 year return period peak gust as shown in Figure 2.3-4 at HMS is 86 mph at an elevation of 50 ft (as given in Tables 2.3-5 and 2.3-6 at that level peak gusts have not exceeded 80 mph during the period 1945 to present). The 100 year return period fastest mile of wind would be less than 86 mph since by definition gust velocity divided by an appropriate gust factor provides the velocity of the fastest mile of wind.* Although not recorded in historical records the 100 year fastest mile of wind can be expected to be in the range of 66 to 78 mph. These values are based on the application of gust factors of 1.3 and 1.1 (Reference 2.3-10) for gusts of one and 10 sec durations** respectively to the estimated historical value of 86 mph.

2.3.1.2.1.5 <u>High Air Pollution Potential (APP) and Dust Storm Potential</u>. Larson (11) has concluded that "consideration of the general weather parameters indicates a significantly high average annual APP over southeastern Washington." Holzworth (12) has estimated that the mean maximum January mixing depth in the Hanford area is about 250 meters, which is nearly the lowest in the contiguous United States, and for July about 2,000 meters. Hosler (13) has indicated a significantly high frequency of low-level inversion in winter over this area - on the order of 43 percent with bases below 150 meters. The occurrence of very stable and moderately stable conditions between the surface and 60 meters in winter at the Hanford Meteorology Tower is 66.5 percent.

Stagnation is defined by Huschke (14) as "the persistence of a given volume of air over a region, permitting an abnormal buildup of pollutants from sources within the region". Defining the establishment of stagnation as an uninterrupted period of daily average wind speed of 5.0 miles per hour or less and/or a peak gust of 15 miles per hour or less, Jenne (15)

---

* Fastest mile of wind is generally defined as either the fastest speed associated with 1 mile of passing wind or fastest observed 1 minute wind speed.

** According to Huschke (Glossary of Meteorology, 1959), the duration of a gust is usually less than 20 seconds.

compiled a 15-year summary of Hanford stagnation periods covering the months of November through February (1947-48 through 1961-62).

Both of the two most notable Hanford stagnation periods experienced during this time occurred in November and December 1952. The first period was from November 15 to December 3 (19 days). Then, after five days of ventilation, stagnation set in again December 9 and lasted through December 28 (20 days). Average wind speeds during the two periods were respectively, 2.6 and 2.9 miles per hour. Eleven days during the first period and eight during the second had peak gusts under 10 miles per hour. One day during the first period and two during the second had average speeds less than 1.0 miles per hour with peak "gusts" of 4 miles per hour. There were 13 days of fog in each period.

Although stagnation lasting for 20 days can be expected only one season in twenty, a 10-day stagnation period can be expected every other season. Only one season in three will fail to produce a stagnation period of at least eight days.

Air quality in the Hanford area, in terms of sulfur dioxide, nitrogen dioxide, and suspended particulates, is routinely measured by the Hanford Environmental Health Foundation. (18,29)

For the year 1971, SO2 measurement in Richland averaged less than 0.02 ppm. At other sampling stations, the concentrations were below the detection limit of 0.01 ppm. In 1974, all 24 hour sequential samples of SO2 measured in the vicinity of Richland, North Richland, and Hanford 300 Area had concentrations below the detection limit of 0.005 ppm which is 25% of the annual average ambient air standard of 0.02 ppm. The 1971 and 1974 measurements for NO2 and suspended particulates are shown below:

Air Quality Measurements-Annual Averages for 1971 and 1974 (18, 29[*])

The major cause of air pollution in the Hanford area is dust occurring during windy periods. The most significant sources are cultivated fields in the surrounding area. A limited amount of information is available regarding atmospheric dust loading in the Hanford area. Hilst and Nickola (16) conducted limited dust investigations over a range of wind speeds and to heights of 400 feet in the Hanford area. A portion of their findings is presented in Figure 2.3-5. Other investigations which have been made in the Hanford area and reported by Sehmel and Lloyd (17) demonstrate the dependence of airborne concentrations on wind speed as shown in Figure 2.3-6.

Measurements of the particulate burden in air at a specific observation point in the 200 Areas at Hanford showed values of around 100 micrograms per cubic meter of air when the wind was less than 8 mph. The particulate content increased when higher winds were present, averaging 1,000 micrograms per cubic meter with winds of 12 mph, and 3,000 micrograms per cubic meter with winds of 16 mph.

Additional considerations regarding the August 11, 1955 and January 11, 1972 dust storms shown in Figures 2.3-5 and 2.3-6 and other climatological dust storm characteristics at Hanford are contained in the following paragraphs.

2.3.1.2.1.5.1 Evaluation of August 11, 1955 and January 11, 1972 Dust Storms at Hanford. The wind speeds at 1.25 ft., 50 ft. and 400 ft. heights for the August 11, 1955 observation period were 14, 24, 31 mph respectively. Figure 2.3-5 represents atypical conditions for the site region. The case was originally selected for study as a situation with considerable airborne dust conditions compared to average conditions.

A Hanford climatological summary of dust storms is given in Table 2.3-40 for 1953-1970 (30). Dust dependence on wind speed and direction (50 ft.) at the Hanford Meteorological Station is given in Table 2.3-41 for the same period (30). Approximate values of dust concentrations are computed based on an empirical relationship using visibility observations (31). The relationship is

$$C6 = \frac{56}{v1.25}\ mg/m^3$$

where V is horizontal visibility in km. This is based on data from the Great Plains with visibilities 7 to 9 miles and wind speeds greater than 12 mph. Hourly weather observations at the Hanford Meteorological Station were used as input criteria to define a wind resuspension or dust storm period. Hours satisfying dust storm criteria at Hanford (1953-1970) had either visibilities less than 7 miles and dust reported, or visibilities between 7-14 miles, wind speeds greater than 5.8 m/s, and relative humidities less than 70%. Since the above empirical concentration - visibility relationship was based on observed dust concentrations at approximately 5-6 feet above the surface, any measured dust data should be interpolated to that height when comparing the measurements to the calculated 1953-1970 results of Table 2.3-41. (30)

The frequency of the hourly data satisfying the dust storm criteria at Hanford is given in Table 2.3-42. (30)

The August 11, 1955 dust storm has an interpolated 5-ft value of 17 mg/m^3 compared with the climatological average of about 7 mg/m^3. Further inspection of the climatological values in Table 2.3-41, supports a conclusion that the storm is an example of the more severe type of dust storm that occurs in this region.

Care must be taken in interpretation of Tables 2.3-40 to 2.3-42 to allow for certain limitations. Estimates based on visibilities and/or wind speeds outside the range used in formulation of Equation 1 are of unknown reliability. The average visibilities within each wind speed class were within the range of empirical validity except for the high wind cases. Another source of errors is the fact that the visibility observations are taken at specific times and are not hourly averages. Considering these limitations Tables 2.3-40 to 2.3-42 may be taken to represent overall aspects of the Hanford dust storm climatology. Individual values must be considered approximate estimates - particularly those based on only a few data points.

The extreme value in Table 2.3-41 in the 53 to 66 mph class (988 mg/m^3) represents a single observation of 0-1/16 miles visibility for a few minutes. Typically at the onset of a dust storm very low visibilities with high winds occur for a few minutes. The very limited visibility and high winds for such a period were coded for the data for that hour. The station log reveals that five minutes after the onset of this dust storm, the winds had dropped to 37 mph and visibility was 3/8 mile. The phenomenon was generated by a thunderstorm passing close to the station. Hence, the extreme value in Table 2.3-41 represents an occurrence of very short duration which was the onset of a dust storm that had a duration of about one hour. Qualitative observation indicates that this is not an atypical scenario. Over the 40 minute duration of the storm, the average calculated average dust concentration was 60 mg/m^3. It should be noted, however, that the onset concentration (988 mg/m^3) is of unknown validity because it is calculated from a visibility value for which the empirical model has not been validated.

The visibility during the January 11, 1972 storm was initially less than one mile, changing to four miles during the last half hour of the reported episode. The January 11, 1972 dust storm had winds at 50' WSW in the range 31 to 43 mph. Wind storms with peak gusts recorded at 50' on the Hanford Tower during this period have a three to four year return period at Hanford.

Actual particulate loading depends on other factors such as surface conditions and atmospheric stability. Hence, the wind gust return period does not necessarily apply to particulate loading although it is reasonable to assume the return period is not less than that for wind.

Detailed estimates of the particulate size and total mass concentrations cannot be accurately made for the January 11, 1972 dust storm as a result of the lack of any particle size distribution data. In addition, only one height of mass concentration datum (189 mg/m^3 at 0.2m) was made in the steep gradient region of the vertical profile. An indication of size distribution and mass loading profiles can be obtained from other data collected at Hanford. Sehmel (32) reports an April 1972 storm which has mass loadings near the surface which are similar to the January 11, 1972 storm. Although adjacent meteorological observations are not available for this episode, the fact that the mass loadings at the lower levels are of the same order as the January 11, 1972 dust storm provides a basis for comparison of the storms. The April 1972 storm has well documented mass loading profiles as a function of particle size. The table shown below contains the profiles of airborne soil concentrations as a function of particle diameter for the dust storm. These are based on optical measurements for smaller particles (.16 to 5 μm) at 0.9m and, impacter-cowl measurements for larger particles (1 to 230 μm) at the indicated heights. The mass loading is dominated by the larger particle data.

Soil Mass Loading for the April 1972 Dust Storm (mg/m^3)

Particle Diameter Range (μm)	*Height (m)* 0.3	1.0	2.0	3.0	10.	32.
0.9 - 5.0	*0.21*	*0.11*	*	*	*0.058*	*.0038*
5 - 20	*0.83*	*0.28*	*0.26*	*.25*	*0.070*	*.0056*
20 - 60	*14.*	*4.4*	*2.9*	*1.5*	*.81*	*.29*
60 - 240	*220.*	*6.6*	*2.8*	*1.3*	*.19*	*.11*
Total	*235*	*11.4*	*~6.0*	*~3.1*	*1.13*	*0.41*

Comparison of the dust loading of 6.0 mg/m^3 at 2 meters with the climatological summaries in Tables 2.3-41 and 2.3-42 indicates that this is a typical dust storm for the region.

The particle size distribution for the August 11, 1955 storm is shown in the following table for comparison.

Airborne Dust Loadings of Particles Greater Than 0.9μ For August 11, 1955 Dust Storm (mg/m^3)

Particle Diameter Range (μm)	*Height (m)* 0.38	2.0	15.2	30.5
0.9 - 5.0	*0.015*	*0.012*	*0.012*	*0.0079*
5 - 20	*0.39*	*0.32*	*0.23*	*0.17*
20 - 60	*3.1*	*2.2*	*1.1*	*0.77*
60 - 240	*18.*	*12.0*	*2.3*	*0.78*
Total	*22.*	*14.5*	*3.7*	*1.7*

The April 1972 dust storm has higher mass loadings near the surface in all size ranges. The August 11, 1955 dust storm had higher dust loadings above 1 to 2 m heights in the ranges greater than 5μ diameter. One interpretation of these profiles is that the 1972 storm had a source nearby and the 1955 data represents advection of airborne dust from more remote sources (33).

2.3.1.2.1.5.2 Hanford Dust Storm Climatology for Design and Operating Bases. *The Hanford climatological study of dust storms for 1953-1970 (30) (discussed in the previous subsection) was re-examined for the purpose of establishing the "worst case" dust storm which may have occurred during that period (33).* The worst case dust storm, i.e., that storm which had the largest calculated time integrated dust loading ($mg\text{-}hr/m^3$), is considered to be

* *No value in reference.*

160 mg-hr/m^2, duration of 18 hr, and average dust loading of 8.9 mg/m^3 at a height of 5 to 6 ft. The design basis dust storm is bounded by a postulated volcanic ashfall event (see Section 2.5.1.2.6) in the evaluation of the design and performance of HVAC systems and diesel generators. *Results of this worst case dust storm investigation are listed below. As mentioned above, these loadings would apply for a height of 5 to 6 feet above the ground.*

Detailed Estimates of the Dust Loadings for the Six Worst Storms Based on Surface Observations of the Hanford Meteorology Station, 1953-1970

Storm Number	*Total Dust Loading (mg-hr/m^3)*	*Actual Duration (hr)*	*Average Dust Loading (mg/m^3)*
1	*40**	*0.67*	*60*
2	*100*	*1.0*	*100*
3	*160*	*18***	*8.9*
4	*44*	*2.6*	*17*
5	*90*	*3.1*	*29*
6	*80*	*7*	*11*

The worst storm of these was storm No. 3. While it was also shown in this study that once a given dust storm terminated, there existed a 5% probability that another one would occur within 10 hours and a 50% probability that another one would occur within 30 days, none of the above six worst case dust storms had occurred within 30 days of each other. Most had occurred in different years during the 1953-1970 study period.

The dust loading for storm No. 3 is conservative in terms of its being considered as the worst case storm for use in plant design evaluations. As a result of the shorter storm durations of the measured August 11, 1955, January 11, 1972, and April 1972 dust storms, their time integrated dust loadings at 5-6 feet above the ground are not worse than that computed for storm No. 3 (33).

2.3.1.2.2 Design Snow Load

The American National Standards Institute (ANSI) in "Building Code Requirements for minimum Design Loads in Buildings and other Structures" (19) provides weights of 100-year return period ground level snow packs for the site region. The ANSI (Reference 2.3-19) value

---

* *Value is less than actual dust loading as a result of less than 1 hour duration.*

** *The detailed investigation yielded 18 hours as opposed to a range of 1-16 hours given in Table 2.3-40 of 2.3.1.2.1.5.1 for the range in duration of dust storms using the same 1953-1970 data.*

of 20 lb/ft^2 was used as the design snow load for all CGS structures.* Assuming a specific gravity of 0.1 or snow density 6.24 lb/ft^3, this design value corresponds to a snow depth of 3.2 ft. *The above snow load is conservative for the site as snow depth seldom exceeds six inches, and the greatest depth of 24.5 inches was recorded in February 1916. (4) The weight of the 48-hour probable maximum winter precipitation can be determined from the data presented in Table 2.3-3. Since the greatest snowfall in 24 hours was 10.2 inches (February 1993) and a record depth of approximately 12 inches lasted four days (December 1964) these depths would correspond to snow loads of 5.3 and 6.24 lb/ft^2 respectively.*

2.3.1.2.3 Meteorological Data Used for Evaluation of Ultimate Heat Sink

The ultimate heat sink is evaluated in Section 9.2.5.

The meteorological data presented in Figure 2.3-7 and Tables 2.3-1, 2.3-5, and 2.3-7a-7h was used to evaluate the performance of the CGS spray ponds in 9.2.5 with respect to (1) maximum evaporation and drift loss and (2) minimum water cooling. In accordance with Regulatory Guide 1.27, Rev. 1 "Ultimate Heat Sink for Nuclear Power Plants", the worst one-day and 30-day periods of meteorological record which resulted in minimum heat transfer to the atmosphere were established. The worst recorded 30-day period (30-day average) of maximum difference between dry-bulb and dewpoint temperature and highest simultaneously recorded wind speeds which resulted in the maximum evaporation and drift loss were also established.

Climatological moisture and temperature data presented as a function of time of day for each month in Figure 2.3-7, and wind statistics given in Table 2.3-5 were used to establish the maximum initial pond temperature for the ultimate heat sink analyses in 9.2.5. It was determined in 9.2.5 using these meteorological data, solar radiation formulas contained in ASHRAE Handbook of Fundamentals, and techniques outlined in the John Hopkins University Report "Cooling Water Studies" (Edison Electric Institute Research Report No. 5, Project RP-49, November 1969) that the month of July contained the worst average meteorological data which resulted in the maximum initial pond temperature.

The worst day meteorological data was considered to be the given combination of meteorological parameters in a particular consecutive twenty-four hour period which resulted in the worst pond thermal performance. The following recorded episodes of extreme wet bulb temperatures experienced at the CGS and/or HMS sites were evaluated in 9.2.5 to establish the worst pond thermal performance:

1) August 7-9, 1972 at CGS and HMS, presented in Table 2.3-7a (20),

* Ice loading is included in this CGS estimate.

2) July 4-12, 1975 at CGS, presented in Tables 2.3-7b to 2.3-7e from the onsite FSAR meteorological monitoring program,

3) August 4, 1961 at HMS, presented in Table 2.3-7f (21).

The meteorological conditions which occurred on July 10, 1975 at CGS resulted in the worst pond thermal performance as determined in 9.2.5.

The following worst month meteorological data were used in 9.2.5 to establish the second through thirtieth day worst pond thermal performance and worst 30-day drift loss and evaporation (Reference 2.3-21):

a) July 9 - August 8, 1961 at HMS, presented in Table 2.3-7a (minimum heat transfer)

b) July 2 - August 1, 1960 at HMS, presented in Table 2.3-7h (maximum evaporation and drift loss)

Diurnal variations in dry bulb and wet bulb temperatures for both 30-day periods assumed that the hourly temperature variation approximated a sine wave of one cycle in 24 hours (Reference 2.3-21). The average wind speeds during both 30-day periods was approximately 5.5 mph. The root mean square average of the hourly wind speed data for the 30-day mass loss period is 6.91 mph.

For conservatism in the thermal analysis, the worst day data for thermal performance was assumed to repeat in the analysis until pond temperature peaked (three days repetition). For conservatism in the mass loss analysis, an upper bound curve was fit to the drift loss data taken during spray pond testing. The drift loss value was obtained from this curve. See 9.2.5 for details.

2.3.2 LOCAL METEOROLOGY

2.3.2.1 Data Comparisons

The local meteorology prior to CGS plant operation at the CGS site can be described from FSAR meteorological data procured during the period April 1, 1974 to March 31, 1976 from the permanent onsite 7-ft and 245-ft meteorological towers. Data collected from the 245-ft CGS tower had been used for the short-term (accident) and long-term (routine) diffusion estimates. Onsite meteorological data were also obtained from a temporary 23-ft tower which commenced operation in April 1972 for the purpose of determining optimum cooling tower geometric orientation for performance during high wet bulb periods. The 23-ft meteorological tower data were also used with other regional data to establish the potential impact of proposed mechanical draft cooling tower atmospheric releases in the vicinity of CGS

(Reference 2.3-22). The permanent tower data have been compared where appropriate and possible, with simultaneously recorded and historical data obtained from the Hanford Meteorological Station (HMS) for the purpose of documenting the representativeness of the two years of onsite meteorological measurements. For the months of April through August 1974, comparisons have also been made with data from the onsite temporary tower; this tower and instrumentation were dismantled in September 1974. Monthly and annual average comparisons between simultaneously recorded and historical data for all the aforementioned meteorological tower sites have indicated that agreement between the data sources is reasonably good.

When comparing sources of data, it should be recognized that at any given time, significant differences can exist between the reported meteorological conditions at the CGS and HMS sites (see, for example, Table 2.3-7a). Differences in the frequencies of occurrence of various meteorological conditions at a given site can also exist from year to year or from one elevation to another elevation at a site for coincident observation times. Any discrepancies between summarized data sources can also be attributed (in addition to site separation and instrument height above ground) to differences in types and accuracies of instrumentation used and procedures considered for acquiring, processing, and analyzing raw meteorological data. Details regarding the onsite meteorological measurement program are presented in 2.3.3.

For the following data comparisons, the following definitions are used:

CGS[*]	*Data obtained from the permanent 7' and 245' towers at the CGS site; summarized here for April 1, 1974 - March 31, 1976.*
CGS (temp).	*Data obtained from the temporary 23' tower at the CGS site; summarized here for April 1, 1974 - August 31, 1975.*
HMS:	*Data obtained from the Hanford Meteorological Station; used here for April 1, 1974 - March 31, 1976.*
HMS (hist):	*Data obtained from the Hanford meteorology tower at the Hanford Meteorological Station, used here for various periods identified in the data comparison listings. The source is AEC Research and Development Report "Climatography of the Hanford Area", June 1972, BNWL-1605.*
Wind Variable:	*At CGS an hour of data which contains less than 15 minutes of any one direction sector; at Hanford, the same but for 20 minutes.*

---

[*]*Data obtained at the 33 foot (10 meter) elevation is presented since these data have been subsequently used in the site diffusion studies for postulated ground-level release cases.*

Wind Calm: *At CGS, an hour of data for which the average speed is 0.22 miles per hour or less; at Hanford, average speed less than 1 mph (as decided by weather observer, corresponds to no motion of strip-chart recorded pen).*

Sense of Delta T: *Positive values imply relative stability, negative values imply relative instability.*

The first annual cycle of CGS onsite meteorological data which covered the period April 1, 1974 through March 31, 1975 has been presented in detail. Local meteorological data collected during the second annual cycle (April 1, 1975 through March 31, 1976) generally portrayed the same characteristics as indicated by comparison with the first annual cycle data. Except for the high wet bulb episode experienced at CGS during July 1975 (refer to 2.3.1.2.3 and 2.3.2.3), no monitored onsite data proved to be more severe in terms of the design and operation of CGS than those data presented in 2.3.1.2. Hence, only the second annual cycle monthly averages have been presented in Table 2.3-8a which summarizes the two years of monitored on-site data with concurrently measured and historical HMS data. Any significant differences noted between first and second annual cycle onsite data and concurrently measured CGS and HMS data are discussed in 2.3.2.1. Otherwise, conclusions stated herein for the first annual cycle of data similarly apply to the second annual cycle data. It is observed in Table 2.3-8a that any year to year differences in the summarized monthly mean meteorological data at tend to parallel the differences in the means summarized for the HMS site for corresponding months during the two year monitoring period.

Summaries of joint frequency distributions of wind direction and wind speed by atmospheric stability class and results from accident and routine diffusion estimates for both annual cycles of CGS onsite meteorological data are presented in subsequent sections.

Magnetic tape files of the two years of hourly onsite data have been transmitted to the NRC.

2.3.2.1.1 Winds

Table 2.3-8b presents monthly and annual CGS joint wind speed and direction data for the first annual cycle of monitoring. Similar data for the HMS site are given in Table 2.3-9. The CGS data presented in the above tables were collected at an elevation of 33 feet above local grade for the one year period of record whereas the HMS historical data were collected at an elevation of 50 feet above local grade during the period 1955 through 1970 (HMS is approximately 280 feet higher in elevation than the CGS site). Additional wind direction frequency statistics are presented in Table 2.3-10.

The CGS 33 ft and CGS (temp) 23 ft wind direction data given in Table 2.3-10 have similar distributions of direction frequency and show a bimodal wind direction distribution from approximately South and also Northwest. These distributions differ from that given for the HMS site where the direction distribution displays a single peak at approximately West

Northwest to Northwest. Further, the wind direction distribution at the CGS site is much more uniform around the compass than it is at the HMS site. The differences in these distributions may be attributed to the influence of terrain features, causing variability of air flow at the CGS site. This conclusion is strengthened by the observation that the CGS monthly wind frequency distributions are similar through-out the period of data acquisition.

Tables 2.3-11 and 2.3-12 provide the 20 longest occurrences of wind direction persistence at CGS for an elevation of 33 feet. Table 2.3-11 shows persistence in one (22.5 degree) sector while Table 2.3-12 shows persistence within two (45 degrees) adjoining sectors; the corresponding stability class distributions and average wind speed within each stability class are also provided.

It is noted that the majority of the periods of high direction persistence at CGS are associated with unstable, neutral, and moderately stable atmospheric conditions and moderate to strong wind speeds. These represent relatively good diffusion conditions. Table 2.3-12a summarizes the longest persistences of wind direction in one and two sectors at CGS measured during the first and second annual cycles. The annual frequency and duration of episodes of high wind direction persistence at CGS depend upon the frequency and intensity of weather systems which result in regional large scale gradient flow. For example, during the first annual cycle, the longest persistence in one and two sectors lasted 14 hours (NW) and 26 hours (NW, NNW) respectively. During the second annual cycle, the longest persistence in one and two sectors lasted 33 hours (NNE) and 35 hours (N, NNE) respectively. Whereas the longest persistence in one sector during the first annual cycle lasted 14 hours, the duration of the first three longest persistences in one sector during the second annual cycle (33 hours from NNE, 20 hours from SSW, and 16 hours from NW) exceeded that longest duration.

Table 2.3-13 presents monthly frequency distributions and averages of wind speed measured at the CGS and HMS sites. Considering site separation, elevation of sensors, and instrumentation and procedural differences, the CGS wind data appear meteorologically reasonable and demonstrate consistency among data sources.

2.3.2.1.2 Moisture and Temperature

Diurnal variation and averages of dry-bulb, wet-bulb, and dew-point temperatures for the first annual cycle of monitoring at the CGS and HMS sites are given in Tables 2.3-14 to 2.3-16. Tables 2.3-17 to 2.3-19 present frequency distributions of dry-bulb, wet-bulb, and dewpoint temperatures, summarized for the first year of CGS site observations. Table 2.3-20 contains additional climatological summaries of monthly normals and extreme values of temperature and humidity measured at HMS.

Considering the 280 ft difference between the CGS and HMS sites and assuming a dry adiabatic lapse rate of 5.48°F/1000 ft, one can expect a temperature difference of about 1.5°F between the dry-bulb temperature data measured at both sites.

Higher monthly average wet-bulb and dewpoint temperatures occurred at CGS since the CGS site experienced air of slightly higher moisture content than the HMS site. The higher moisture content may be attributed to Columbia River proximity and irrigation of the fields in the vicinity of CGS. This conclusion is strengthened by the fact that moisture enhancement at CGS was at a minimum for the months of January, February, and March during the first annual cycle of CGS site observations.

During the second annual cycle of monitoring, it was observed that the CGS site experienced air of essentially the same moisture content as did the HMS site. The absence of the moisture enhancement at CGS, which was noted during the first annual cycle, may be attributed to reduced evaporation from the proximate river and irrigated fields. The periodic occurrences (during the second annual cycle) of cooler dry-bulb temperatures and precipitation deficits when high dry-bulb temperatures prevailed may have resulted in reduced evaporation.

2.3.2.1.3 Monthly Precipitation

Diurnal variation of precipitation intensity at CGS and monthly total precipitation at CGS and HMS for the first annual cycle of monitoring are given in Table 2.3-21. Frequency of occurrence of precipitation intensity data from April 1974 through March 1975 at CGS are presented in Table 2.3-22. Frequency of occurrence of wind speed and direction versus precipitation intensity for the same year of data is given in Table 2.3-22a. The data show that the CGS site experienced less precipitation than did the HMS site. The difference can be attributed to site separation and the incidence of precipitation falling in the form of showers of quite limited spatial extent. The precipitation deficit at CGS may also result from a rain shadow effect from Rattlesnake Mountain. A precipitation gradient is known to exist along the slope of this terrain feature.

2.3.2.1.4 Fog

Fog data are unavailable for the site. Although fog has been observed in every month of the year at HMS, it is essentially a seasonal phenomenon with 95 percent of it observed during the months of November through February. Inclusion of March and October fog would increase this percentage to 99.7. Tables 2.3-23 and 24 summarize the duration and persistence statistics for fog occurrences at HMS. Because of the relative proximity of the site to the Columbia River, it is expected that the frequency of occurrence, intensity and duration of fog would be somewhat greater than these data indicate (refer also to 2.3.2.1.5).

Most fog in the Hanford region is of the radiation type and hence occurs mostly in conjunction with light wind, inversion or stable atmospheric conditions. The occurrence of fog at the site can therefore be considered as one visual indicator of poor atmospheric diffusion conditions. Advection and frontal fogs occur occasionally at both HMS and the Tri-City stations of Richland and Pasco. In addition, at Richland and Pasco, there are occasional occurrences of

steam fog from the Columbia River. These are not usually deep and many would be classified as ground fog.

Statistics on fog persistence are limited to those at HMS. Although most dense (visibility 1/4 mile or less) fogs do not last longer than 3 hours, a few run for much longer periods as shown in Table 2.3-23. After a period of fog, there frequently follows a period of atmospheric stagnation with a low stratus overcast and light winds. Such conditions may persist for many days.

2.3.2.1.5 Stability Summaries

For the purposes of comparison, the t Δ (temperature difference) and sigma theta (standard deviation of the horizontal wind direction fluctuations) stability classifications which are used in diffusion studies at Hanford are given below with the t Δ"Pasquill" and sigma theta classes identified in NRC Regulatory Guide 1.23:

REGULATORY GUIDE 1.23

Pasquill Class		*Δt/ΔZ (°F/200 FT)*	*Sigma* Theta*
Extremely unstable	*A*	*Less than -2.1*	*25.0*
Moderately unstable	*B*	*-2.1 to -1.9*	*20.0*
Slightly unstable	*C*	*-1.9 to -1.6*	*15.0*
Neutral	*D*	*-1.6 to -0.6*	*10.0*
Slightly stable	*E*	*-0.6 to 1.6*	*5.0*
Moderately stable	*F*	*1.6 to 4.4*	*2.5*
Extremely stable	*G*	*greater than 4.4*	*1.7*

HANFORD RESERVATION CLASSIFICATION

Pasquill Class	*Δt/ΔZ (°F/200 FT)*	*Sigma Theta Groupings** (Degrees)*
Very unstable	*Less than -2.5*	*greater than 22.5*
Unstable	*-2.5 to -1.5*	*25.5 to 17.5*
		17.5 to 12.5

* *Period of 15 minutes to 1 hour.*

** *Note that these sigma theta groupings do not necessarily correspond to any particular Hanford Stability Class on the left, i.e., there can be a maximum of 35 group combinations of Δt/ΔZ and sigma theta although some combinations are unlikely to occur.*

Neutral	*-1.5 to 0.5*	*12.5 to 7.5* *7.5 to 3.75*
Moderately Stable	*0.5 to 3.5*	*3.75 to 2.1*
Very Stable	*greater than 3.5*	*less than 2.1*

Joint frequency distributions of wind speed and direction by atmospheric stability class (temperature difference and sigma theta combinations) for the first and second annual cycles of monitoring are presented in Section 2.3.3. Percent frequency of occurrence of stability (Δt distribution) at CGS and HMS are given in Table 2.3-25. Although the heights over which Δt was measured are similar for both sites, it is observed in Table 2.3-25 that CGS experiences air of greater thermal stability than HMS. This discrepancy between site stabilities may be accounted for because of terrain differences. The CGS site serves as a drainage basin for relatively cool air (especially at night), resulting in strong thermal low-level stratification and the formation of persistent temperature inversions. This conclusion is strengthened by the observation that the difference between the sites is much more pronounced during July, August, September and October than during all other months. It is during these months that pooling of relatively cool air is at a maximum due, partly, to minimum cloudiness and therefore, enhanced nocturnal cooling occurs at the ground. It is noted in Table 2.3-25 that the percent frequencies of stability types for both annual cycles of monitoring at CGS are very similar.

Frequencies of occurrence of Δt and sigma theta versus time of day for the first year of onsite meteorological measurements are given in Table 2.3-26 and 2.3-27. Although frequency of occurrence and duration of inversion conditions were not analyzed for the site, stagnation and inversion information contained in 2.3.1.2.1.5 and 2.3.2.1.5 for HMS should be representative for the site (except for the fact that the above data indicates that CGS experiences a greater frequency of surface-based inversions than does HMS). Figure 2.3-8 shows probabilities of inversion persistence at HMS from 1952-1969 (2).

2.3.2.2 Potential Influence of the Plant and Its Facilities on Local Meteorology

The shapes and sizes of the buildings erected on the plant site will produce a disturbed air flow which alters the initial distribution pattern and diffusion rates of plant release airborne contaminants. In the diffusion calculations this effect is considered.

Electrical power generation by steam turbines requires dissipation of large quantities of low grade thermal energy. Waste heat produced from the operation of CGS is dissipated by means of six circular mechanical draft cooling towers. These evaporative cooling towers release waste heat directly to the atmosphere in the form of sensible and latent heat. An extended visible plume consisting of liquid water droplets can occur principally during the winter months when periods of cold weather and high relative humidity prevail. Fogging is defined as occurring if visible plumes intersect the ground, buildings, or other elevated structures.

Fog occurs naturally in this region, and any cooling tower fog is an extension of the naturally occurring phenomenon. When air temperatures of 0°C or lower prevail, the additional potential exists for icing on these surfaces. At times, small cumulus clouds could form above or remote from the plant, depending on the atmospheric temperature and moisture conditions in the first several thousand feet above the cooling towers. No significant environmental or atmospheric impacts arising from CGS cooling tower operation have been observed or are foreseen based on dispersion meteorological studies performed by Battelle Northwest Laboratories (Reference 2.3-22). Details covering potential environmental impacts arising from CGS cooling tower operation are given in the CGS Environmental Report.

2.3.2.3 Local Meteorological Conditions for Design and Operating Bases

The regional long term meteorological conditions provided in Section 2.3.1.2 are applicable for use in establishing the plant design and station operating bases. Except for the high wet bulb episode experienced at CGS during July 1975 (refer to 2.3.1.2.3), none of the local short term meteorological data presented in 2.3.2.1 proved to be more severe in terms of the design and operation of CGS than those presented in 2.3.1.2. Data collected since January 1, 1984 form the revised long-term design and operating basis for dispersion calculation.

2.3.2.4 Topographic Description

As shown in Figures 2.1-1 and 2.1-2, the plant is located at a grade elevation of 441 feet MSL in a basin area formed by the Saddle Mountains to the northwest, bluffs and hills rising to about 900 feet MSL to the north and east, the Horse Heaven Hills to the south and the Rattlesnake Hills and Yakima, Umtanum and Manastach ridges to the west. Topographic cross-sections plotted out to 10 kilometers by sector from the plant are given in Figure 2.3-9. Except for the cliffs toward the east across the Columbia River, the region within this circumference is basically flat and featureless and slopes gradually toward the Columbia River. Additional details regarding the regional topography and geology are given in 2.5. The effects of regional topography on local meteorology are discussed in 2.3.1.1, 2.3.2.1.1 and 2.3.2.1.5. The need to consider plume height relative to land elevations has been obviated by the assumption of a ground-level release for the accident and routine station release cases which are presented in 2.3.4 and 2.3.5.

2.3.3 ONSITE METEOROLOGICAL MEASUREMENT PROGRAM

The permanent onsite meteorological data collection system in use since January 23, 1974 consisted of a 240 ft main tower, an auxiliary seven ft instrument mast, sensors with associated

electronics and recording devices, and a meteorological shelter.[*] A 23 ft onsite temporary tower was also used during the period April 1, 1972 through August 31, 1974.

The Battelle Memorial Institute, Pacific Northwest Laboratories, had been conducting a continuing two year program of acquisition, processing, and analysis of meteorological data for Energy Northwest Columbia Generating Station in a contractual arrangement with Burns and Roe, Inc.

The first and second annual cycles of reliable meteorological data were collected during the periods April 1, 1974 through March 31, 1975 and April 1, 1975 through March 31, 1976, respectively. The accuracy of these data had been established primarily through calibrations conducted at quarterly intervals as required through a formal program of quality assurance. The data were examined for meteorological reasonableness, after corrections were applied per the calibration Reports, through computer edit programs. No data were found to be unreasonable. The annual summaries were compared with the monthly summaries and all were found to be consistent. The computer summarization programs (identical for monthly and annual purposes) were tested at quarterly intervals by application to dummy data per the quality assurance program. (23) The computer calculation programs for x/Q were similarly tested. Comparisons between CGS meteorological data and concurrently measured and historical HMS data have been presented in 2.3.2.1.

2.3.3.1 Permanent Onsite Meteorological Tower and Instrumentation Characteristics

The meteorological tower, which is located approximately 2,500 feet west of the CGS plant site with its base at 455' MSL, consists of a 240 ft high primary tower with a five ft mast extending above it. The primary tower is triangular in shape and of open lattice construction to minimize tower interference with meteorological measurements. Wind and temperature measurements were made at the top of the mast and at the 33 ft level. The dewpoint temperature was measured at the 33 ft level. At the lower level the instruments were mounted on an eight ft horizontal boom extending southwest of the tower. Wind and temperature measurements were also made at the top of a seven ft mast which was located approximately 80 feet southwest of the 245 ft tower.

Wind speed measurements were made using conventional cup anemometers (Climet Instruments, Model 011-1 Wind Speed Transmitter) which have a response threshold of about 0.6 mph and a distance constant of less than five feet. Over a calibrated range of 0.6 to 90 mph the accuracy of these instruments is ± 1% or 0.15 mph (whichever is greater).

---

[*]Data collection on the 240 foot and seven foot towers was terminated on June 1, 1976 subsequent to the collection of two years of reliable tower data ending March 31, 1976, required for the CGS FSAR. Data collection on the Primary and backup towers began on July 1, 1984.

Wind direction measurements were made using lightweight vanes (Climet Instruments, Model 012-10 Wind Direction Transmitter).

The response threshold of these vanes is about 0.75 mph, and their damping ratio and distance constant are approximately 0.4 and 3.3 feet, respectively. Dual potentiometers in the Wind Direction Transmitter produce an electrical signal covering 540° in azimuth with an accuracy of ±3°. In addition, electronics had been included to provide signals which were proportional to the standard deviation of the wind direction fluctuations at each level.

Temperature instrumentation had been installed to provide measurements of both the ambient air temperature at the 245, 33 and 7 ft levels, as well as the temperature differences between these levels. The ambient air temperature and the temperature difference measurement systems were independent of each other to provide for reliability. Atmospheric stability delta - T classes were determined solely on the basis of the data from the electronic differencing bridge and not by subtracting the ambient air temperature measurements. All temperature measurements for both systems were made in aspirated radiation shields (Climet Instruments Model 016-1 or -2) using platinum resistance temperature detectors (Rosemount Engineering Co., Model 104 MB6ABCA). These instruments provided an ambient temperature range from -30°F to ±130°F and a temperature difference range of ±15°F. The accuracy of the instruments is ±.09°F in the measurement of temperatures and ±0.18°F in the measurement of temperature differences.

The dewpoint temperature was measured at the 33 ft level of the tower using a lithium chloride dewpoint sensor (Climet Instruments, Model 015-12) housed in an aspirated radiation shield (Climet Instruments Model 016-2). Precipitation was measured at ground level using a tipping bucket rain gage (Meteorology Research Incorporated, Model 302) located about 40 feet west of the main tower. This instrument is accurate to within 1% at rainfall rates up to 3 in./hr and has a resolution of 0.01 in. The instrument building provided a semi-controlled environment near the tower to house the instrument electronics and record the data. Analog strip chart and digital magnetic tape recorders were used to provide redundant data recording capability. The primary data recording system was a seven-track digital magnetic tape recorder (Kennedy, Model 1600) which used 1/2 inch tape. Logarithmically time-averaged wind speed, wind direction, temperature, temperature difference and dewpoint temperature signals were recorded at five minute intervals. The time constant of the averaging process was five to ten minutes. The standard deviation of wind direction fluctuations during the preceding five minutes at each level and the total precipitation were recorded along with the wind and temperature information. All data, except the wind direction standard deviations, were also recorded on strip charts which provided a backup data record to enhance data retrievability. In addition, since the strip charts contained an essentially instantaneous record of the signal from each instrument, they provided a rapid means of identifying instrument malfunctions and were useful in system calibration. These strip charts and magnetic tapes were changed weekly.

In summary, the total system accuracies for the measured meteorological parameters meet or exceed the following specifications:

air temperature	*±0.5°C*
temperature difference	*±0.2°C*
humidity (dew point)	*±2.8°C*
wind speed	*±0.5 mph from 0.5 to 5 mph, ±10% of reading above 5 mph per RG 1.97, Rev. 3.*
wind direction	*±5°*

These are verified by the end-to-end calibrations. Data recovery was better than 90%.

2.3.3.2 Quality Assurance Program

To ensure the quality of the meteorological data collected by the monitoring system, an extensive quality assurance program had been instituted. This program covered all phases of meteorological monitoring from the initial instrument acquisition through the analysis of data. Periodic checks and calibration of the instrument systems and individual components had been instituted. These periodic checks ranged from daily inspection of the strip charts to semiannual calibration of the complete system. All checks, calibrations and maintenance were fully documented, including traceability of test and calibration equipment to the National Bureau of Standards where necessary. Once collected, the data were protected from loss to the maximum extent possible; the digital tapes were examined to identify possible instrumentation malfunctions; and the data were then copied onto two master tapes. The original weekly tape and one master tape were stored in vaults for safekeeping while the second master tape was used in the preparation of data summaries. Finally, to ensure proper operation of computer hardware and software, all computer programs used to summarize or analyze the data were checked quarterly using a standard data input. The computer output from these tests was then saved to document computer operation.

The various phases of the quality assurance program pertaining to the two years of permanent onsite meteorological monitoring and data processing are discussed in the following subsections.

2.3.3.2.1 Data Recovery During April 1, 1974 - March 31, 1976

The meteorological data acquisition system was put into operation during January 1974. Outages in the digital system precluded an initiation date for the acquisition of reliable data prior to April 1, 1974 because the processing of an inordinate amount of data from strip charts

would have been required. The data utilized in the production of the monthly and annual summaries have been obtained exclusively with the primary data recording equipment (magnetic tape digital system) since August 1, 1974.

Recourse to data recorded on strip charts was required at times prior to August 1974 to assure, as viewed at the time, a recovery rate of 90% representative data as required by Nuclear Regulatory Guide 1.23. The percentages of monthly data read from strip charts is listed below:

April 1974 - 23.3%

May 1974 - 8.3%

June 1974 - 49.5% (W/S 33' - 59.1%)

July 1974 - 1.6%

From routine and anticipated causes (system maintenance and calibration) modest data losses were experienced on the order of 2% and 1.2% for the first and second annual cycles of onsite data collection respectively. A comparable amount, for some of the meteorological quantities, was caused by circumstances beyond Battelle's control (power outages, delay in receipt of spare parts, etc.). The percentages of missing annual data for various meteorological quantities are listed below:

	April 1, 1974- March 31, 1975	*April 1, 1975 March 31, 1976*
Wind Speed 33'	*4.0%*	*2.7%*
Wind Direction 33'	*4.0%*	*1.5%*
Dry Bulb Temperature 33'	*2.5%*	*1.2%*
Wet Bulb, Dewpoint Temperature 33'	*2.7%*	*1.2%*
Differential Temperature 33' - 245'	*3.1%*	*1.5%*

These percentages are representative of missing data for all meteorological quantities except precipitation. During the first annual cycle of monitoring, data recovery for precipitation was 100%. Precipitation data recovery was complete during the second annual cycle of monitoring, except possibly during December 1975 when a sand plug was discovered in the rain gauge funnel. As a result, it was estimated that less than 0.1 inch of precipitation was not recorded during that month. For the first annual cycle of monitoring, the data recovery rate was 96% or better for all meteorological quantities; this rata was 97% or better during the second annual cycle of monitoring.

2.3.3.2.2 Maintenance and Calibration

Assurance of quality data rests primarily with the calibrations performed at quarterly intervals and reported for July and October 1974; January, April, July and October 1975; and January and April 1976.

All evidence to date obtained through formal calibrations and routine daily and weekly inspection had demonstrated that the meteorological system remained electronically stable in terms of obtaining data of sufficient quality to meet the requirements in Regulatory Guide 1.23. The calibration corrections required are tabulated in the response to NRC question 6.4 on the FER. The calibrations established any system inaccuracies by comparisons to standards. These inaccuracies were corrected by appropriately adjusting the data at the data processing stage as opposed to adjusting the system electronics. The calibrations before and after each calibration period were used to determine if corrections were required to account for drift or if offset had occurred. No drift corrections were required. The offsets were discussed in the FER response. For corrections that were not constant throughout the range of a given parameter, a calibration table or curve was used to correct the data. Calibration corrections were applied as part of the computer programs used to edit and translate the data from the original raw-data tapes to a master file of hourly values.

2.3.3.2.3 Data Processing and Analysis

For the two years (1974-1976) of onsite FSAR meteorological monitoring at CGS, all data (magnetic tape and strip chart where required) were run through computer edit programs. No data were found to be unreasonable except for known causes as documented in Nonconformance Reports. Data corrections, per the Calibration Reports, were applied in the computer programs. Summarization of data has been accomplished only at such times as calibration information was available to bracket in time the acquired data.

The data for each hour is represented by an average of the data for the last 30 minutes in the hour. The averaging period of 30 minutes was selected for consistency with 1) the data used to formulate the Hanford Diffusion Model used for routine and accident dose calculations, 2) the recommendations in Regulatory Guide 1.23, and 3) computational economy. The only exception was wind direction which was averaged over one-hour to facilitate the formulation of wind direction persistence summaries.

One thirty-minute period per hour is considered adequate for climatological summaries consisting of averages of many hours. In addition, x/Qs based on thirty-minute averages will be conservative for estimates of the one-hour averages. All data products were based on these "hourly" averages.

Wet bulb from the permanent tower was obtained from standard psychrometric formulas presented in the Smithsonian Meteorological Tables, 1971 issue.

The above descriptions relate to data collected and used in FSAR submittals through Amendment #36. Data collection and processing since July 1, 1983 is described in 2.3.3.2.4. The Kennedy Tape Recorder has been replaced with a floppy disk recorder for increased reliability.

In several of the monthly summary reports, the computer programs as applied to dummy data have been compiled as called for in the Quality Assurance Manual (Reference 2.3-23) for the purpose of documenting proper programming and proper computer performance.

These computer computations have been verified with hand calculations made with the dummy data. The computational programs for x/Q were similarly tested.

2.3.3.2.4 Meteorological Monitoring Program During Plant Operation

The meteorological tower, which is located approximately 2500 ft west of the CGS plant site with its base at 455 ft msl consists of a 240-ft high primary tower with a 5-ft mast extending above it. This tower is triangular in shape and of open lattice construction to minimize tower interference with meteorological measurements. Wind and temperature measurements are made at the top of the mast and at the 33-ft elevation by duplicate sets of instruments. One set of instruments is the primary measurement system and the other set constitutes the backup instrumentation. The lower elevation wind speed/direction instruments are mounted on a horizontal boom, extending southwest of the tower.

Wind speed and wind direction measurements are made with a single instrument package that combines a wind speed propeller on the leading (upwind) end of the instrument and a wind direction vane, or tail, on the opposite end. Wind speed measurement range is 0.5 to 90 mph with a threshold sensitivity of about 1 mph. The wind direction measurements are made by the wind passing over the wind vane portion of the instrument. In addition, electronic modules process the data from these instruments and provide output data which is proportional to the standard deviation of the wind direction fluctuations over 15 minutes.

Temperature instrumentation provides measurements of the ambient air temperature at the 245 and 33-ft elevations. Temperature measurements are made in aspirated radiation shields using platinum RTDs. These instruments provide an ambient temperature range from -50°F to +150°F. Each set of RTDs (one from 33 ft level and one from 245 ft level) are calibrated together in the same temperature bath and electronic modules process the data from these instruments to provide a temperature difference range of ±15°F.

The relative humidity is measured at the 33-ft elevation of the tower using an intercap sensor with a range of 0 to 100% RH housed in an aspirated radiation shield. Precipitation is measured at ground level using a tipping bucket rain gauge located about 40-ft west of the main tower. The barometric pressure is measured by a pressure transmitter located inside the

Met Tower building. The Met Tower building provides a semi-controlled environment near the tower to house the instrument electronics. Signal conditioning is provided in the Met Tower by two GE FANUC PLC controllers, one for the primary instrumentation and one for the backup instrumentation. The primary controller feeds data to the Supervisory System and the PDIS via the LAN. The backup controller feeds data only to the PDIS via the LAN. Information will be available to all locations for both the primary and backup instruments on the LAN. The backup system does not provide data for the barometric pressure or the rain gauge. Wind speed, wind direction, temperature, temperature difference and relative humidity signals are averaged by the controllers using a 15 minute time constant device before sending the information to the control room. In the control room are three recorders which record 245-ft and 33-ft wind speed, wind direction, delta temperature, and ambient temperature at 33-ft elevation. The system accuracies for the measured meteorological parameters are demonstrated to meet or exceed the following specifications by performance of instrument loop calibrations:

Air temperature	±0.5°C (±0.9°F)
Temperature difference	±0.2°C (±0.36°F)
Humidity (dew point)	±2.8°C (±5.0°F)
Wind speed	±0.50 mph from 0.5 to 5 mph, ±10% of reading above 5 mph per RG 1.97, Rev. 3.
Wind direction	±5.0°

This data is processed by the Supervisory System which forms the primary communication vehicle for the meteorological system. The supervisory system located at the meteorological tower building and the control room digitizes and multiplexes the data to the control room where it is restored to analog format and sent to recorders and the PPCRS, as required, on a real-time basis. The data input to the supervisory system is 15-minute average analog values. Longer period averages will also be computed for trend analysis and report generation. These data are routed to satisfy display and processing requirements of the onsite technical support centers (TSC) and the emergency operations facility (EOF). The primary meteorological tower data is stored by the plant data acquisition system. Instrument calibrations and maintenance procedures meet the data recovery and system accuracy requirements of Regulatory Guide 1.23 except as noted above.

The Emergency Dose Projection system provides redundant data communication paths with remote access and redundant power sources as required for routine or emergency preparedness support. The near real time access to both the primary and backup meteorology systems, via the supervisory system or the LAN, thus satisfies the emergency preparedness requirements of Regulatory Guide 1.23.

These two systems are designed to meet or exceed data unavailability statements of Regulatory Guide 1.23. If offsite meteorological data is needed, data can be obtained from a network of meteorological towers located on the Hanford Site using methods described in the Emergency

Preparedness Plan. The accuracy, calibration, and reliability of all data not directly controllable by Energy Northwest is determined by the private/governmental controlling agency.

2.3.3.3 Other Meteorological Measurement Programs Considered for the Data Comparisons

2.3.3.3.1 CGS Temporary Tower

A temporary 23-ft onsite tower was used during the period April 1, 1972, through August 31, 1974, to obtain data input for CGS environmental studies and to provide a comparative overlap with the initially measured permanent tower data.

The temporary tower was located in the vicinity of the permanent towers with its base at approximately 448 ft msl. Wind data from the temporary tower were obtained at the 23-ft level while temperature data were acquired at the 3-ft level. Wet bulb data from the temporary tower were established from techniques and data contained in the U.S. Department of Commerce, Weather Bureau Office Document, Relative Humidity and Dewpoint Table. As a special quality assurance program was not initiated for the temporary tower installation, it is not possible to assert that this tower's data complied with the requirements contained in Regulatory Guide 1.23.

2.3.3.3.2 Hanford Meteorological Station

The Hanford Site maintains a network of meteorological towers, which can be accessed for data by telephone or electronic form.

2.3.3.4 Joint Stability - Wind Frequency Summaries

Joint frequencies of wind direction and wind speed by atmospheric stability class (sigma theta by Δt classes), collected at the 33 ft level of the permanent tower during the period from January 1, 1984 to December 31, 1989 are presented in Table 2.3-28A.

The sigma theta/Δt stability classification approach (see 2.3.2.1.5) has been used by Battelle to maintain consistency with the longer term HMS data to which existing data is compared and to satisfy the data requirements of the Hanford Diffusion Model (HDM) the HDM requires joint measurements of sigma theta and Δt for the more restrictive stable diffusion cases and utilizes the Sutton method with locally derived parameters for neutral and unstable cases (21). The HDM differs from the standard NRC diffusion models as a result of the incorporation of empirically derived diffusion coefficients based on historical experiments performed at Hanford. As a result of the extensive experimental data that were used in deriving the HDM, itis appropriate to consider this model when performing diffusion analysis at the Hanford Reservation.

In 2.3.2.1, comparisons between measured CGS onsite data and simultaneously recorded and historical HMS data illustrated the following differences between sites:

a. The CGS site experienced a small air moisture enhancement during the first annual cycle of monitoring. During the second annual cycle, the CGS site experienced air of essentially the same moisture content as did the HMS site.

b. The CGS site experiences a biomodal wind direction distribution from approximately south and also northwest. At HMS, the direction distribution displays a single peak at approximately west northwest to northwest.

c. The CGS site experiences air of greater thermal stability than does HMS.

Reasons for these differences were given in 2.3.2.1.

2.3.4 SHORT TERM DIFFUSION ESTIMATES

2.3.4.1 Objective

In this section brief descriptions of the sources, the receptors, and the methodologies used to calculate the air dispersion factors, χ/Q, for the Exclusion Area Boundary (EAB), the Low Population Zone (LPZ), and the control room are presented.

2.3.4.2 Exclusion Area Boundary

The EAB is located at a distance of 1950 m (approximately 1.2 miles) from the site. The χ/Qs were calculated using site-specific meteorological data from 1996 to 1999, (Reference 2.3-38). The Joint Frequency Distributions (JFDs), Table 2.3-28, were used as an input to the computer code PAVAN, (Reference 2.3-25) and the χ/Q results are presented in Table 2.3-37.

The χ/Q values at the EAB are calculated for each hour of data. The cumulative probability distribution of these values are determined for each of the wind direction sectors. Two distributions are calculated, Pasquill-Gifford (P-G) with meander sigmas and desert sigmas (includes meander). The distributions represent the annual probabilities that the given χ/Q values will be exceeded in each wind direction sector at the exclusion area distance. Table 2.3-34 incorporates the P-G meander effect and Table 2.3-33 has desert sigmas. From each of the sixteen sector distributions, the χ/Q value which is exceeded 0.5 percent of the total time was selected. This value was selected based on the percentage of total observations rather than the percentage of observations that the wind direction is within the appropriate sector. These 16 sector χ/Q values are given in Tables 2.3-33 through 2.3-34. The highest of these sixteen values is defined as the maximum sector χ/Q value.

2.3.4.3 Low Population Zone

The LPZ is located at a distance of 4827 m (approximately 3 miles) from the site. The χ/Qs were calculated using site specific meteorological data from 1996 to 1999, (Reference 2.3-38), the JFDs, Table 2.3-28, were used as an input to the computer code PAVAN, (Reference 2.3-25) and the χ/Q results are presented in Table 2.3-37.

The sector χ/Q values at the LPZ have been estimated for various fixed time intervals of a 30-day period. These time intervals are 0 - 2 hours, 2 - 8 hours, 8 - 24 hours, and 1 - 30 days. The estimates for these time periods are made by interpolation on a log-log plot of the two-hour and annual average values as described by Regulatory Guide 1.145. These interpolations are carried out for the value which is exceeded 5 percent of the time, and 0.5 percent of the time. The interpolations are displayed in Tables 2.3-35 (Desert) through 2.3-36 (P-G, meander). For these interpolations the 2-hour values are assumed equivalent to the 1-hour values. These depictions and interpolation schemes are identical to those specified in Regulatory Guide 1.145.

2.3.4.4 Control Room

The control room air dispersion factors χ/Q were calculated using the 1996 to 1999 site-specific hourly meteorological data, (Reference 2.3-37). The meteorological data and the input parameters were used as input to the computer code ARCON96, (Reference 2.3-36), and the χ/Q results are presented in Table 2.3-37.

2.3.4.5 Description of Sources

There are 4 sources at CGS that could release radioactivity to the environment following an accident. These sources are described below:

a. The roofline source is a vent (short stack) on top of the reactor building at a height of 70 m (approximately 229 ft) above the ground through which routine releases take place. Following an accident, the exhaust air from the reactor building passes through the SGT filtration system before exiting through the roofline stack. This source is treated as a ground level point source in the χ/Q calculations.

b. The reactor building railroad bay doors are located at the ground level on the eastside wall of the reactor building. It is assumed that some leakage to the environment takes place through these doors.

c. The reactor building walls from the 606 ft level to the 670 ft level (top of reactor building) are made of metal sheets and therefore they are assumed to be

a diffuse source capable of leaking radioactive materials to the atmosphere, this source is also treated as a ground level release source.

d. The Turbine Building Exhaust System (TBES) is a set of four circular vents (short stacks) located on top of the radwaste building roof. Air from the turbine building is exhausted to the atmosphere through these 4 vents.

2.3.4.6 Control Room Intakes

There are three intakes at CGS which draw air into the control room during normal operation as well as post accident. A description of these intakes is given below:

a. Local intake point: The local intake point is a vent located on the west side of the radwaste building wall at an elevation of 527 ft (26.5 m above the ground).

b. Remote intakes: there are two ground level remote intake points which are approximately 180 degrees from each other. One remote intake is located to the north-west side of the turbine building and is labeled remote-1, the other is located to the south-east side of the reactor building and is labeled remote-2.

2.3.4.7 Calculations

Formulations for calculating short term χ/Q values have been developed for licensing of nuclear power plants and are described in Regulatory Guide 1.145, (Reference 2.3-26) "Atmospheric Dispersion Models for Potential Accident Consequence Assessments at Nuclear Power Plants." For the CGS configuration, it is assumed that accidental releases are made at ground level. This assumption provides a conservative estimate of downwind χ/Q values. NRC code PAVAN (Reference 2.3-25) is used to produce dispersion estimates with the desert sigma option enabled.

Based on the guidance given in Regulatory Guide 1.145 the χ/Q values are calculated using three separate equations. The particular equation which is used depends upon the existing meteorological conditions. The equations are:

(1) $$\chi / Q = \frac{1}{U_{10}(\pi\sigma y\sigma z + A/2)}$$

(2) $$\chi / Q = \frac{1}{U_{10}(3\pi\sigma y\sigma z)}$$

(3) $$\chi / Q = \frac{1}{U_{10}\pi\Sigma y\sigma z}$$

Where χ/Q is relative concentration (sec/m^3)

π is 3.14159

U_{10} is the wind speed at the 10 meter level (m/sec)

σy is the horizontal desert diffusion parameter (m) determined from downwind distance and stability category.

σz is the vertical desert diffusion parameter (m) determined from downwind distance and stability category.

ΣY represents plume meander and building wake effects (m) and is a function of stability category, wind speed, and downwind distance.

A is the smallest vertical plane cross-sectional area of the reactor building (m^2).

During neutral or stable atmospheric stability conditions, the results of all three equations are used to determine dosages. The values from Equations (1) and (2) are compared and the larger is selected. This value is compared with that computed in Equation 3 and the lower value is selected as the appropriate χ/Q value.

During all other meteorological conditions (unstable and/or wind speeds of 6 m/sec or more), only equations (1) and (2) are considered. The appropriate χ/Q value is the larger of the two.

Values of σY and σz, the horizontal and vertical diffusion parameters are taken from Regulatory Guide 1.145 for the applicable stability category and downwind distance. For extremely stable condition (Category G), the following equations are applied:

$$\sigma Y(G) = 2/3\ \sigma Y(F)$$

$$\sigma z(G) = 3/5\ \sigma z(F)$$

2.3.5 LONG-TERM (ROUTINE) DIFFUSION ESTIMATES

2.3.5.1 Objectives

The joint wind direction and wind speed by atmospheric stability class data presented in Subsection 2.3.3 was used to assess annual average normalized concentrations, X/Q, for 16 radial sectors extending from the site boundary to a distance of 50 miles from the source. Tables 2.3-38 provides X/Q and D/Q concentrations for a mix mode release assuming desert

sigmas no decay, no plume depletion, recirculation, and a building wake (building height - 70.4 m). D/Q is normalized deposition.

2.3.5.2 Calculations

The calculational techniques used are consistent with the guidance provided in Regulatory Guide 1.111 "Methods for Estimating Atmospheric Transport and Dispersions of Gaseous Effluents in Routine Releases from Light-Water-Cooled Reactors". The joint frequency data presented in Subsection 2.3.3 were used in conjunction with the following equation to obtain X/Q values at appropriate downwind distance in each of the 16 sectors.

$$\frac{X(x,\kappa)}{Q} = \frac{2.032\Sigma_{ij} f_{ij\kappa} \exp\left[-h_e^2 / 2\sigma_{zj}^2(x)\right] R_{fx}(x)}{x\overline{u}_i(x)\left[\sigma_{zj}^2(x) + \frac{0.5D^2}{\pi}\right]^{1/2}}$$

Where:

$\frac{X(x,\kappa)}{Q}$ = *average effluent concentration in Ci/m³ normalized by source release rate (Ci/sec) at distance x and direction k.*

x = *downwind distance from release point.*

$\overline{u_i}$ = *midpoint value of ith wind speed class.*

h_e = *effective plume height.*

$\sigma_{zj}(x)$ = *vertical standard desert deviation of effluent spread at distance x for the jth stability class.*

R_{fx} = *factor to account for air recirculation and stagnation.*

f_{ijk} = *joint probability of the ith wind speed class, jth stability, class, and kth wind direction.*

π = *3.1416*

D = *maximum building height of adjacent buildings (D = 70.4 m)*

The building wake correction Equation 1 must not reduce the X/Q estimate by more than a factor of 3 or

$$\left(\sigma^2 xj\ (x) \quad + \frac{0.5D^2}{\pi}\right) \quad 1/2 \quad \leq \quad \left(3\sigma^2 zj(x)\right)\ 1/2$$

Equation 1 assumes a long-term continuous release whose effluent is distributed evenly across a 22.5° sector. The release was assumed to be ground level (i.e., he = 0 in Equation 1). Computer code X0QD0Q, with the Desert sigma option enabled described in NUREG-0324, was used to make two sets of calculations.

The nearest residences where maximum individual doses with single sector contributions occur at distances of 4.0 miles ENE (Ringold) and 4.2 miles ESE (Taylor Flats) of CGS. The annual average χ/Q values for these locations are calculated in Table 2.3-38c, 38f and 39c, 39f. The Columbia bluffs rise to an elevation of 878 ft just south of Taylor Flat. If it is considered that the low level sigma Z is less than 100 m out to 6 km for the P-G stability classes D-G, which are prevalent most of the winters and that low-level winds deflect either north or south near the bluffs (Reference 2.3-2), it is estimated that the total doses for these locations may be once again as large due to contributions of favorably oriented wind sectors.

The total dose in the channeling area of the Columbia River should include contributions from four other sectors with deflected winds and other channeling effects. The individual doses in that location could be twice as large as for the single sector, constant wind computations. The drift from the cooling towers should remove some of the effluent and deposit it on the site with the salts and counteract the bluff effect. The mechanical draft cooling towers should entrain part of the effluent, lift it with the plume and thus also make the χ/Q values over-predictive. Reasons for these differences were given in Subsection 2.3.2.1.

The results reported by Start and Wendell ("Regional Effluent Dispersion Calculation Considering spatial and Temporal Meteorological Variation," Preprint volume, Symposium on Atmospheric Diffusion and Air Pollution of the American Meteorological Society, September 9-13, 1974) indicate an average value at these distances of about 0.65 and a minimum single point value of about 1.75. If these factors are multiplied by the fraction of plume remaining at the distances in question, about 0.75, to account for the conservatism of the nondepleting model used to arrive at the dose estimates provided in 5.2 of the CGS Environmental Report, it is found that the most critical dose of 9.2 mrem to a child's thyroid (at Taylor Flat) is still within the 10 CFR Part 50 Appendix I design objective limit of 15 mrem. For example, 1.75 x 0.75 x 9.2 = 12.1 mrem. This value would still be conservative because the above recirculation factors do not account for the existence of a bluff line immediately downwind of Taylor Flat which will under the more stable conditions turn the plume before it reaches Taylor Flat. This effect would further reduce the effective recirculation factor.

At the nearest point of the nearest population center, about 9 miles, the average recirculation factor value from Start and Wendell, 1974, appears to be about 0.3 with the maximum single point value about 0.8. In addition to this effect, the effect of topographic channeling has been evaluated by conservatively hypothesizing that under stable conditions that winds blowing anywhere from the east to west (through north) sector might end up in the four sectors containing the majority of the population, SE through WSW (Pasco through Benton City). Including the effects due to channeling results in an estimated maximum factor of approximately 1.6. Applying the factors for recirculation and fraction of plume remaining after deposition results in a maximum effective factor of (1.6 x 0.8 x 0.67 = 0.86) less than one.

It therefore appears reasonable to conclude that the methodology employed to estimate doses is sufficiently conservative for the subject site to ensure that the doses to individuals and the general population have not been substantially underestimated due to the inherent assumptions.

REFERENCE NOTES

* PRECIPITATION OBSERVATIONS NOT BEGUN UNTIL 1946

\# LESS THAN 1/2

\+ ALSO ON EARLIER YEARS

LOCATION AND HISTORY

PRESENT LOCATION 25 MILES NW OF RICHLAND, WASHINGTON

LATITUDE 46°34'N; LONGITUDE 119°36'W, ELEVATION 733 FEET

OBSERVATIONS FROM 1912 TO 1944 WERE BY UNITED STATES WEATHER BUREAU COOPERATIVE OBSERVERS AT A SITE ABOUT 10 MILES ENE OF PRESENT LOCATION. SINCE 1944, OBSERVATIONS HAVE BEEN MAINTAINED ON A 24 HOUR-A-DAY BASIS BY THREE DIFFERENT DOE CONTRACTORS.

* No records have been kept for time periods of less than 60 minutes. However, the rain gage chart for 6-12-69 shows that 0.55 inch occurred during a 20-minute period from 1835 to 1855 PST. An additional 0.01 inch occurred between 1855 and 1910 to account for the record 60-minute amount of 0.59 inch.

\# Less than 1/2

1. Greatest number of days in a season -- occurred in 1969-70
2. Least number of days in a season -- occurred in 1948-49
3. Greatest number of hours in a season -- occurred in 1964-65
4. Least number of hours in a season -- occurred in 1948-49
5. Greatest number of days in a season -- occurred in 1950-51
6. Least number of days in a season -- occurred in 1948-49
7. Greatest number of hours in a season -- occurred in 1962-63
8. Least number of hours in a season -- occurred in 1948-49
9. AF denotes all fog (viz 0-6 miles)
10. DF denotes dense fog (viz 1/4 mile or less). Records for persistence of dense fog did not begin until 1953.

*Summation for the year does not necessarily reflect the summation of individual months.

Table 2.3-24

Percent Frequency Distribution of Wind Speeds During Hourly Observations of Fog at Pasco (1966-1970) and at HMS (1960-1970)

	Speed Class*					
Station	Calm	1-3	4-7	8-12	12	Total
HMS[1]	29	44	25	2	0	100
Pasco[2]	61	8	24	6	1	100

* Speed classes are in units of mph for HMS, and in units of knots for Pasco.

[1] Statistics for HMS are only for hourly observations of fog restricting visibility to 1/2 mile or less.

[2] Statistics for Pasco are for all hourly observations of fog (visibility 0-6 miles).

To use this chart, select any desired rainfall intensity and duration and read from the diagonal lines the expected frequency of such intensity and duration. For example, rainfall intensity of 1.3 inches per hour for 10 minutes can be expected to occur, on average, once every five years (point A). However, such intensity can be expected for 30 minutes duration only about once in 100 years (point B). The return period for intensity for 60 minutes duration is greater than 1000 years (point C).

There are, of course, variations in use of the chart. Suppose, for example, it is desired to find the "100-year storm" for 60 minutes. This is 0.8 inch (point D).

2.4 HYDROLOGY ENGINEERING

The italicized information is historical and was provided to support the application for an operating license.

2.4.1 HYDROLOGIC DESCRIPTION

2.4.1.1 Site and Facilities

Columbia Generating Station (CGS) is located in the Hanford Site within Benton County, Washington, approximately 3 miles west of the Columbia River at river mile (RM) 352, 10 miles north of Richland and 45 miles downstream from Grant County PUD Priest Rapids Dam. The site coordinates are approximately 46° 28' North Latitude and 119° 20' West Longitude.

The Columbia River is the predominant hydrologic feature of the area and provides principal drainage for the surrounding area. The riverbed is clearly marked in the terrain and at the proximity of the site the river flows between high banks. The Columbia River approximate riverbed elevation is 328 ft above mean sea level (msl); the ground elevation at the site is approximately 440 ft. Another hydrologic feature of the area is the Yakima River, which at its closest approach flows within 8 miles of the plant site. The river system is shown in the hydrographic map, Figure 2.4-1. Figures 2.1-1 and 2.1-2 show the major hydrologic features of the area.

All Seismic Category I structures are located above maximum postulated flood elevations. For flood elevations refer to Sections 2.4.3 and 2.4.4.

Water for cooling tower makeup water and other plant requirements is withdrawn from the Columbia River. The intake system is designed for a maximum capacity of 25,000 gpm (55.7 cfs). The non-safety-related makeup water intake system is approximately 3 miles east of the plant and is made up of two offshore perforated pipe inlets, two lead-in pipes, and pump house structure.

A topographic map and contour map of the region surrounding the site are shown in Figures 2.4-2 and 2.4-3. The natural drainage features of the surrounding area have not been changed by the construction of CGS.

2.4.1.2 Hydrosphere

The Columbia River, the largest river flowing into the Pacific Ocean from North America, is one of this world's greatest sources of hydroelectric power. Its annual discharge of 18,000,000 acre ft (1 acre-ft = 43,560 ft^3) is exceeded in the North American continent only by the Mississippi, Mackenzie and St. Lawrence Rivers.

The Columbia River drains an area of approximately 258,000 square miles, lying to the west of the Continental Divide in the northwestern part of the U.S. (85%) and southwestern part of Canada (15%). Major tributaries are the Kootenay, Snake, Pend Oreille, Spokane, Okanogan, Yakima, and Willamette Rivers.

In determining the Standard Project Flood (SPF) the drainage area was divided into subbasins. These subbasins can be grouped into six general areas with similar hydrometeorological characteristics.

The six areas are: (1) upper Columbia, which includes the drainage of the area in Canada and the northern part of the United States above Chief Joseph Dam; (2) Middle Columbia, which includes the area between Pasco and Chief Joseph Dam; (3) Upper and Middle Snake River; (4) Lower Snake River, the area between Weiser and Ice Harbor Dam; (5) Lower Columbia, including the area between Bonneville Dam and Pasco; (6) the Columbia below Bonneville Dam, including the Willamette River.

The river basin has five outstanding physical features: the Rocky Mountain System, the Columbia Plateau, the Columbia River Gorge, the Cascade Range and Puget Trough.

The Rocky Mountain System is the major range with elevations from 2000 to over 12,000 ft. There are permanent glaciers and extensive snow fields at higher elevations and deep valleys that provide the principal drainage for the head-waters of the Columbia, Kootenay and other rivers.

The Columbia Plateau is a great, generally treeless, semiarid plateau covering over 100,000 square miles in the central portion of the basin. This plateau is in an area between the Cascade Range and the Rocky Mountains. The plateau was formed by successive flows of lava and filled to a general thickness of approximately 4000 ft. The Columbia River flows 1214 miles from its source in Columbia Lake (el. 2700 ft) in British Columbia, near the crest of the Rockies, to the Pacific Ocean at Astoria, Oregon. It sweeps around the north and northwesterly sides of the Columbia Plateau to central Washington to be joined by the Snake River. The Columbia River flows directly across the axis of the Cascades in a narrow gorge to the Pacific.

The Columbia Gorge is the gateway from the Pacific Ocean to the intermountain Columbia Plateau. Tide flows 140 miles up-river. For most of its length the river flows in deep valleys and canyons.

High flows occur in late spring and early summer with melting of snow on the mountainous watershed. Low flows occur in autumn and winter.

The Columbia River has been regulated by dams and reservoirs over the past 35 years. A large portion of the main stream and major tributaries is developed to meet various

functional requirements, such as flood control, hydroelectric power, irrigation, municipal and industrial supply, etc. The regulation of Columbia River floods is accomplished by use of reservoir storage space provided primarily for irrigation or for hydroelectric power utilization. The volume of usable reservoir storage space is on the order of 20% to 25%.

There are seven dams upstream and four dams downstream of the site on the main stream of the Columbia River within the U.S. These dams are listed in Table 2.4-1. The Columbia River flow in the reach of CGS is controlled by regulation of the upstream reservoir projects, which have a total usable storage capacity of approximately 35 million acre-ft. Some control of flow in the immediate vicinity of the site is by regulation of the nearest upstream hydroelectric projects, Priest Rapids Dam, at RM 397, containing about 45,000 acre-ft of active storage, and Wanapum Dam, at RM 415, containing about 161,000 acre-ft of active storage. Some minimal effect on the river flow in the vicinity of the site is caused by McNary Dam, at RM 292, approximately 60 RM downstream from the site area.

Flows in the Columbia River during the summer, fall, and winter vary from a low of 36,000 ft^3/sec to as much as 160,000 ft^3/sec. During spring runoff high flows ranging from 250,000 ft^3/sec to 450,000 ft^3/sec have been recorded. The average annual flow is 120,000 ft^3/sec; during low flow periods flows may average about 60,000 ft^3/sec (see Figure 2.4-4).

The Grand Coulee and Bonneville dams were put into operation prior to World War II and several dams were built after the war. The four downstream dams include large locks to permit the passage of river vessels. Several of the dams provide emergency floodwater storage. Grand Coulee, the largest and most complex of the dams, augments the low winter flows for the entire system from its 9,402,000 acre-ft of available storage (of which approximately 5,100,000 acre-ft is active storage) and also pumps water to the Columbia River Irrigation Project.

The river channel near the CGS site varies between 400 and 600 yards in width for low water and normal high water level, respectively. The depth varies from about 25 ft to 45 ft for normal high water and flood high water levels, respectively. Velocities vary from 3 ft/sec to over 11 ft/sec depending on section and flow. Average water temperature is 51°F. Temperatures may reach a low of 32°F and a high of 68°F. (See Table 2.4-2 and Figure 2.4-4.)

A list of water usage downstream of CGS, obtained from records of the Department of Ecology, State of Washington, for water rights as of February 1980, is presented in Table 2.4-3. The closest municipal surface water user is the City of Richland with an intake approximately 12 miles downstream. *The location of local groundwater users is discussed in Section 2.4.13.2.*

2.4.2 FLOODS

2.4.2.1 Flood History

Floods in the Columbia River Basin are grouped as:

a. The interior basin east of the Cascades, caused by melting snowpack and occurring from May through June;

b. The Willamette and other basins, west of the Cascades, caused by direct runoff from intense winter rain occasionally augmented by snowmelt.

There is some overlapping effect within these two groupings. At certain elevations, basins in the interior Columbia drainage area occasionally have significant flood flows resulting from winter rain or snowmelt. These are local floods and do not usually contribute sufficient flow to cause flooding of the main Columbia River. Major floods in the Columbia River Basin result from rapid spring melting of the snowpack over a wide area, generally augmented by rain or by above-normal precipitation in May, accompanied by a major chinook wind which causes rapid area temperature rise. The annual spring snowmelt flood of the main interior basin is characterized by relatively uniform distribution over the basin. The snowfall and individual snow storms may vary, but the integration of all storms over the winter period smoothes the irregularities, with the result that the distribution of the flood runoff is reasonably constant from year to year.

The maximum historical flood of record is that of June 7, 1894, which resulted from a combination of hydrometeorologic conditions, including heavy snowpack and rapid melt plus rainfall. The peak discharge at CGS was 740,000 ft^3/sec for the Columbia River, as estimated from high water marks at Wenatchee, Washington (Reference 2.4-1). *The largest recent flood, occurring in 1948, had an observed peak discharge of 690,000 ft^3/sec at Hanford. These floods were spring floods resulting from the melt of a large snowpack combined with the spring rains (Reference 2.4-2).* Water surface profiles for the Columbia River in the vicinity of the site as derived by the Corps of Engineers (Reference 2.4-2) are given in Figure 2.4-5.

The plant site is located approximately three miles west of the Columbia River at RM 352 with reactor floor elevation of 441 ft msl, which is 68 ft above the water level estimated for the largest historical flood (approximately 373 ft msl). There is no record of flooding in the immediate site area.

2.4.2.2 Flood Design Considerations

Flood protection of safety-related components is based on the highest calculated flood water level including wave effects, resulting from intense local precipitation. Several different probable maximum events were considered, including the Corps of Engineers design-project

flood considered to be "the most severe reasonably possible." Wave action caused by storm winds, the effects of failure of upstream dam surge flooding, and ice flooding were also considered.

The results of these analyses (described in Section 2.4.3) indicate that the CGS site is safe from floods and that no flood protection measures are required. The Hydrogen Storage and Supply Facility located 0.6 miles south-southeast of the plant is subject to flooding due to the PMP flood discussed in Section 2.4.3.1. Equipment storing liquid and gaseous hydrogen has been analyzed for the effects of this flood (Section 2.4.2.3). As discussed in sections that follow, plant safety-related structures are located above high water elevations associated with Columbia River flooding (Sections 2.4.2.1 and 2.4.3), intense local precipitation (Sections 2.4.3.5 and 2.4.3.6), and upriver dam failures (Section 2.4.4).

2.4.2.3 Effects of Local Intense Precipitation

Intense local summer thunder storms can produce short duration rains which have the potential for causing serious flood. Winter precipitation may occur as rain or snow and would be less intense than the worst summer thunderstorm. The probable maximum precipitation (PMP) event for the CGS site has been determined using the methodology developed by the U.S. Weather Bureau and reported in Hydrometeorological Report No. 43, "Probable Maximum Precipitation, Northwest States" (Reference 2.4-3).

The plant area slopes easterly to a broad channel which is adequate to store and drain the PMP. Construction contours of the site are shown in Figure 2.4-28. The reactor building and the spray ponds are located at elevations that are safe from the effect of any flood resulting from the maximum precipitation event.

Winter precipitation may occur as rain or snow. The winter season snowfall has ranged from less than 0.5 in. to a maximum of 12 in. in December 1964. There is no ice accumulation at the site.

To accommodate surface drainage during severe climatic conditions such as rainfall and rapid snow melts, a system of catch basins and dry wells is provided with inlet elevations a minimum of 6 in. lower than the nearest road and a minimum of 12 in. lower than the finished floor elevation of the nearest building(s).

Runoff from the PMP event is accommodated by designing the roadways such that the high point of the road is 6 in. to 1 ft below the finished floor elevation of the adjacent safety-related building(s). Runoff from this event is from the northwest to the southeast across the site plateau to the low area southeast of the plant site. The general plant site is nominally 9 ft above the maximum calculated water surface elevation resulting from the postulated PMP (Section 2.4.3.3). Therefore, the site grading precludes the potential flooding of safety-related structures. The Hydrogen Storage and Supply Facility is subject to the PMP event flooding.

The elevation of the facility is 420 ft msl and the PMP flood level is 431.1 ft msl (Section 2.4.3.5). See Section 10.4.10 for more discussion.

Roofs of buildings are designed to take, with adequate drainage, any instantaneous or local intense precipitation. Discharge from roof drains is carried by means of a storm sewer system to a manhole located southeast of the reactor building. From that point a pipeline with a northeast alignment transfers the discharge to lined evaporation ponds about 1500 ft away from the plant site.

The roofs of safety-related buildings (diesel generator building, radwaste/control building, standby service water pump house) are concrete beam and slab construction except the high roof of the reactor building, which is metal deck on steel framing. The minimum roof slope for all structures is 1/8 in. per ft for adequate drainage and the roof areas are encompassed by curbs or parapet walls up to 3 ft 6 in. high. Roof plans, including details of roof drains and overflow scuppers, are provided in Figure 2.4-6. Assuming that the roof drains are completely blocked during the PMP event, overflow scuppers limit the depth of water to within the design load carrying capability of the roofs. Those safety-related structures that do not have this relief capability structurally can carry the entire PMP accumulations.

2.4.3 PROBABLE MAXIMUM FLOOD ON STREAMS AND RIVERS

Analyses for probable maximum flood (PMF) and SPF on the Columbia River (Reference 2.4-2) are consistent with the requirements of Regulatory Guide 1.59, Revision 2. The SPF for the Mid-Columbia Reach of the highly developed and regulated Columbia River is defined as 570,000 ft^3/sec (Reference 2.4-4). The unregulated SPF for the same reach is 740,000 ft^3/sec. The unregulated PMF at the site is estimated to be 1,600,000 ft^3/sec (References 2.4-2, 2.4-4, and 2.4-5).

Adjustment of the flood profiles for the Hanford region reported in Reference 2.4-4, results in a regulated PMF of 1,440,000 ft^3/sec and a water level of 390 ft at the Seismic Category II makeup water structure. This structure is not designed to function throughout the PMF but is designed for the SPF (unregulated) of 740,000 ft^3/sec.

Although assumed to exist for the purpose of flood hydrograph calculations, Ben Franklin Dam is not a federally authorized project. As originally planned it would have been a low head dam with only a negligible effect on extreme flood flows (Reference 2.4-6).

The design basis flood for the CGS site area results from the PMP event on the adjacent drainage basin and not from flooding of the Columbia River.

2.4.3.1 Probable Maximum Precipitation

The PMP event which was presented in the CGS PSAR was subsequently reevaluated in the preparation of the PSAR for WPPSS Nuclear Project No. 1 (Docket 50-460). The analysis presented here is consistent with the latter document.

Precipitation in the vicinity of the site has been classified by the U.S. Weather Bureau, Reference 2.4-3, as convergence precipitation, orographic precipitation, and thunderstorm precipitation. The methodology for predicting the total amount of precipitation from each of these events, as given in Reference 2.4-3, requires the adding together of the convergence PMP and the orographic PMP to obtain a single precipitation for a general storm. A separate analysis is then required for thunderstorms. Thunderstorms in the vicinity of the site can be locally very intense for short periods of time and hence, have the potential for causing serious flooding. The PMP for both a general storm and a thunderstorm were analyzed as given in Chapters 6 and 5, respectively, of Reference 2.4-3 for a 38.5 mile^2 basin at the site. This basin is shown in Figure 2.4-8 and is described in Section 2.4.3.3. The calculated general storm PMP results in a 24-hr and 48-hr precipitation of 7.9 in. and 10.1 in., respectively. A thunderstorm PMP yields 9.2 in. in a 6-hr period. Therefore, the thunderstorm is considerably more severe. The thunderstorm PMP hydrograph is

Time (hr)	Rain (in.)
1	0.6
2	1.6
3	5.2
4	0.9
5	0.5
6	0.4
Total	9.2

2.4.3.2 Precipitation Losses

Infiltration losses have been estimated in the vicinity of the sites as 1.5 in./hr (Reference 2.4-7). However, for the analysis below, an average antecedent moisture condition (Condition II as defined in Reference 2.4-8) was assumed. As explained in the following section, the 60-minute retention loss rate is 0.15 in./hr.

2.4.3.3 Runoff and Stream Course Models

The drainage basin common to the reactor building and spray ponds is shown in Figure 2.4-8. The entire area drains to a broad channel that extends in a north-south direction for about 7 miles, and ranges from about 2000 ft to over a mile wide. All plant structures are located on

high ground to the west of the channel. At a point about 2.8 miles south of the reactor site, the four-lane Department of Energy (DOE) highway crosses the drainage basin. The area above this section is 33.2 miles^2.

To evaluate the effect of the PMP event on the plant area, the peak discharge at the highway crossing, 2.8 miles downstream of the plant, was calculated using the U.S. Bureau of Reclamation procedure for computing design floods on ungauged basins from thunderstorm rainfall in the western U.S. (Reference 2.4-8). Important assumptions used in the triangular hydrograph procedure of Reference 2.4-8 are

a. Hydrologic soil group B,

b. Land use and treatment class - poor pasture or range,

c. Thunderstorm cover-index is brush-sage-grass combination with 50% or less cover density, and

d. Thunderstorm minimum 15-minute retention loss rate of 0.06 in./15 minutes and 60-minute retention loss rate of 0.15 in./hr.

Additionally, no credit was taken in the hydrograph analysis for potential storage in the stream channel or upstream sub-basins.

The time of concentration, T_c, for the watershed above the highway crossing was computed to be 7.5 hr. The PMF hydrograph is shown in Figure 2.4-7 for the 33.2 mile^2 drainage basin. A peak discharge of 21,400 ft^3/sec was determined.

Based on this PMF, an upstream water surface profile was determined using the Corps of Engineers HEC Standard-Step Procedure (Reference 2.4-9). A total of eleven cross sections were used (seven downstream, one at the plant, and three upstream as shown in Figure 2.4-3). Details of the channel cross sections are shown in Figure 2.4-9. The Manning roughness coefficient was conservatively taken as n=0.035 in the main channel sections, and n=0.05 in the overbank areas.

Using the computational procedure of Reference 2.4-9, it was determined that the channel restrictions at cross sections 5 and 7 (Figure 2.4-3) do not control the flow. The stillwater elevation at the plant site (cross section 8) was determined to be 431.1 ft msl. The water surface profile is shown in Figure 2.4-10.

2.4.3.4 Probable Maximum Flood Flow

The PMF runoff hydrograph produced by the PMP at cross section 1 (Figure 2.4-3) is shown in Figure 2.4-7. The peak discharge at this location is 21,400 ft^3/sec.

2.4.3.5 Water Level Determinations

As discussed in Section 2.4.3.3, the water elevation of a flood at the plant site generated by the PMP event is 431.1 ft msl. This flood condition has a higher estimated elevation than any flood of the Columbia River.

2.4.3.6 Coincident Wind Wave Activity

Procedures published by the Corps of Engineers (References 2.4-10 and 2.4-11 were used to determine the wind wave activity. The effective fetch for the predominant July wind direction (north) is 3450 ft (0.65 miles). The effective fetch diagram is shown in Figure 2.4-11. The calculated extreme 2-year over water wind for the north-to-south direction, based on area data, is 63.5 mph. This wind results in a maximum wave height of 4.0 ft, with the assumption of a water depth of 12 ft (the average depth in cross sections 8, 9, and 10). The other potential wind directions ENE and ESE were evaluated but found to be less severe.

The wind setup has been computed to be 0.3 ft, and the maximum wave runup is 1.9 ft on a smooth, 1 on 8 slope of compacted naturally occurring sands and gravels. Therefore, the design water surface elevation is 433.3 ft msl. This is less than the east spray pond overflow weir at elevation of 434.5 ft msl.

2.4.4 POTENTIAL DAM FAILURES, SEISMICALLY INDUCED

Analyses of floods resulting from potential dam failures were investigated by the Corps of Engineers for the Columbia River. These studies are consistent with Regulatory Guide 1.59, Revision 2. The flood resulting from the breaching of Grand Coulee Dam is considered in lieu of a seismically induced flood.

In 1951, the Seattle District Corps of Engineers made a confidential study (now declassified) to determine artificial flood hydrographs and the flood profile in the Columbia River Valley resulting from breaching the Grand Coulee Dam by enemy attack. The studies covered a spectrum of conditions in terms of breach openings and hydrologic conditions that might prevail at the time of attack. A postulated seismic failure of Grand Coulee Dam could result in displacement of part of the structure, but it would still act as a restriction or weir and minimize the hydraulic failure. For this reason, the explosion-induced artificial flood represents an upper limit to seismically induced failures. The failure of Grand Coulee Dam would initiate a catastrophic flood, which would be augmented by the failure of the earth portions of downstream dams and subsequent release of the storage pools. Figure 2.4-5 shows water surface profiles for RM 323 to RM 358 for various river flows, including Artificial Flood No. 1. This flood provides a "limiting case" assessment of the conservatism of CGS elevation. This flood would have an outfall peak of 8,800,000 ft^3/sec at Grand Coulee Dam at the moment of breaching and a peak discharge at RM 338 (Richland) of 4,800,000 ft^3/sec.

A base flow of 50,000 ft^3/sec was assumed above the mouth of the Snake for this flood (Reference 2.4-12).

An arbitrarily assumed dramatic failure of Arrow and/or Mica Dams in Canada could result in greater releases of storage in terms of volume than that from the Grand Coulee Dam, but the effects of such postulated releases are mitigated by a combination of valley storage and critical (flow limiting) valley cross sections. The Corps of Engineers states (Reference 2.4-13) that the river channel restrictions at Trail, British Columbia, would restrict river flow to about 3.1 x 10^6 cfs, regardless of the postulated dam failure. A major failure upstream would result in this maximum flow for many days causing overtopping of Grand Coulee Dam. An analysis by the Bureau of Reclamation (Reference 2.4-14) concluded that overtopping which might result from the failure of upstream dams will not cause failure of either the Grand Coulee Dam or the Forebay Dam.

Various studies (References 2.4-12, 2.4-15, 2.4-16 and 2.4-17) made by the Corps of Engineers, and others, since 1951 have considered that breaching of Grand Coulee Dam would represent the worst catastrophic event for downstream Columbia River occupants. Although these studies bear no relationship to flooding from natural causes, they have been used as the basis for a very conservative, limiting case approach.

Figure 2.4-5 shows water surface profiles for RM 323 to RM 395 for artificial and real stage flows, one of which corresponds to Artificial Flood No. 1 noted earlier, which has been established (Reference 2.4-18) as conservative (limiting case) criteria for Columbia River flooding. Since the base flow used to develop these curves was 50,000 ft^3/sec, an additional 570,000 ft^3/sec is added to account for simultaneous occurrence of the regulated SPF.

2.4.4.1 Dam Failure Permutations

The effect of potential dam failure on the water levels at the site is determined using the following assumptions:

a. The Columbia River is at flood stage, with a SPF (570,000 ft^3/sec regulated);

b. The reservoirs in each storage pool are full;

c. A massive hydraulic failure occurs at Grand Coulee Dam, releasing 8,800,000 ft^3/sec;

d. Following the above assumed failure, all downstream dams between CGS site and Grand Coulee Dam suffer some degree of failure and release their storage reservoirs to the flood. [The result of a stability analysis (Reference 2.4-15) showed that all mass concrete portions of the dams will resist sliding and overturning with the possible exception of part of Rock Island Dam.];

e. The explosion-induced failure of Grand Coulee Dam represents a more severe failure than any seismic event because of the failure mechanism;

f. Failure of Arrow and/or Mica Dam could result in greater release of storage volume than Grand Coulee Dam; however, the peak flow is limited to 3,100,000 ft^3/sec due to channel restrictions at Trail, British Columbia; and

g. Overtopping of Grand Coulee Dam would occur with failure of Arrow and/or Mica Dams in Canada. The failure of Grand Coulee, as a result of overtopping, is not considered to be a credible event in view of its concrete construction and rock abutments.

2.4.4.2 Unsteady Flow Analysis of Potential Dam Failures

The flood hydrographs developed by the Corps of Engineers are based on the results of extensive studies of the physical characteristics of the flood route (References 2.4-12 and 2.4-15). Subsequent studies made by the Corps of Engineers verify these results (Reference 2.4-17). Water levels following such a flood would depend on the status of reservoir storage upstream from Grand Coulee Dam but, without regulation of some dams, would approximate the natural seasonal flow conditions.

2.4.4.3 Water Level at Plant Site

The water elevations associated with limiting case flood (LCF) levels are shown in Figure 2.4-5. RM 350 provides the control for backwater flow to the plant area which is sheltered by higher ground east of WNP-1 and WNP-4.

Elevation at RM 350 (dam breach flood 4,800,000 ft^3/sec plus SPF, 570,000 ft^3/sec)	=	422 ft msl
Allowance for simultaneous wind and wave action	+	2 ft
Elevation:		424 ft msl = LCF

An adequate margin exists between the resultant flood elevation and the plant elevation of 441 ft msl.

2.4.5 PROBABLE MAXIMUM SURGE AND SEICHE FLOODING

The location of the CGS site is not close to any water body which experiences seiche flooding. Thus the site is not vulnerable to such flooding.

2.4.6 PROBABLE MAXIMUM TSUNAMI FLOODING

The location of the CGS site is in south-central Washington and it is not adjacent to any coastal area. It is not, therefore, vulnerable to tsunami flooding.

2.4.7 ICE EFFECTS

Historically, the Columbia River has never experienced complete flow stoppage or significant flooding due to ice blockage. Periodic ice blocking has caused reduced flows and limited flooding for only relatively short periods of time. *The most significant icing in recent recorded history occurred during the winter of 1936-37 prior to the construction of the upstream regulating dams. A relatively thick sheet of ice formed across the river. The minimum flow recorded near the Priest Rapids Dam site during this winter was 20,000 cfs. However, the ice forming on the river was caused primarily by the low flow rather than the reverse. The deltaic mouths of many of the tributaries to the Columbia River are frequently blocked by ice causing backup of flood waters. No instance of complete stoppage is known to have occurred.*

Ice blockage is most likely to occur when water temperatures are already low, when flows are small, and when a significant cold spell occurs. With the completion of Grand Coulee and other dams on the Columbia River main stream, the seasonal temperature and flow cycles have drastically changed. These changes will further aid to reduce the intensity and timing of the conditions which may contribute to potential ice blockage and flooding situations. Also average river flow rates, during the winter months, have been increased significantly. The water temperatures have shown a shift in time such that the peak temperatures occur 30-45 days later than formerly. In addition, the low extreme temperatures measured have risen over the years.

The long term trends of temperatures in the Columbia River been studied (Reference 2.4-19) using a 37 year record of measured temperatures. The trends for the maximum, average and minimum temperatures are shown in Figure 2.4-12. The erection of dams on the upper Columbia River has caused the extreme high and low river temperatures measured at Rock Island Dam (Columbia RM 453, 101 miles above the CGS site) to converge toward the average. Winter water temperatures are considerably warmer and summer temperatures cooler with a slightly lowered average of less than 1°F occurring during the 37 years.

On the basis of these studies and the recorded observation of 25 years of operation of the Hanford plutonium production plants, it is concluded that the potential for ice blockage or the combination of blockage and flooding behind ice dams is so low as to be considered insignificant. The erection of Mica, Arrow, and Libby Dams in the Columbia River Basin headwaters is expected to further raise winter water flows and also to increase winter water temperatures somewhat.

In any event, ice flooding will not effect the capability to shut down the reactor in a safe and orderly manner. Also, the daily fluctuating stage of the river at the intake location will discourage formation of sheet ice as well as ice jams. Ice flows, should they occur, will normally pass over intake structure due to relatively high winter discharge in the river.

2.4.8 COOLING WATER CANALS AND RESERVOIRS

There are no cooling water canals. The two spray ponds located southeast of the reactor building designed as Seismic Category I structures, have reinforced concrete side walls, and reinforced concrete base mats at el. 420 ft msl. The finished grade at the spray ponds is approximately at el. 434 ft msl and have top of wall elevations of 435 ft msl. The spray ponds are the ultimate heat sink for normal reactor cooldown and for emergency cooling.

The spray ponds are a part of the standby service water system which is discussed in Section 9.2.7. See also Section 2.4.11.6.

During normal reactor operation, the cooling water necessary for the plant is supplied from the cooling tower basins.

2.4.9 CHANNEL DIVERSIONS

The Columbia River flow in the Hanford reach is controlled to a large extent by regulation of the upstream reservoir projects. The riverbed in the vicinity of the site is well defined and it is very unlikely that the riverbed would be diverted from its present location by natural causes. Any possible effect on water supply to the makeup water pump house from riverbed changes would come from extremely slow changes which can be corrected if and when they occur.

As discussed in Section 2.4.7, the river has not frozen over in Hanford reach during at least the past 25 years, and icing on the river has not been a problem at pump house or outfall structures associated with the plutonium production plants.

2.4.10 FLOODING PROTECTION REQUIREMENTS

The design considerations of safety-related facilities to withstand floods and flood waves are described in Section 2.4.2.2. The PMF is discussed in Section 2.4.3.

All safety-related facilities are housed in Seismic Category I structures protected from flooding and designed to withstand the static and dynamic forces of all postulated floods. Flood considerations are described in Section 3.4 and the design of Seismic Category I structures, for all conditions including flood, is described in Section 3.8.

In the event of a flood at the site, it will be possible to place the plant in a safe shutdown condition.

All non-safety-related facilities with the exception of the makeup water pump house, are above the LCF elevation. The flooding of the makeup water pump house would not affect safety-related equipment and would not affect the safe shutdown of the plant. The approximate finished grade at all Seismic Category I structures except the spray ponds is at elevation 440 ft msl. The finished grade of the spray ponds is 434 ft msl.

The PMF elevation of the Columbia River (described in Section 2.4.3), at the site, is estimated to be 390 ft msl.

Seismic Category I structures are designed to withstand the static and dynamic forces which could result from a flood due to a breach of Grand Coulee Dam. Since this represents the LCF, the structures are also considered secure against the forces due to the lower PMF.

The access openings to all seismic Category I structures are located well above all flood water elevations, including that due to wind and wave action.

2.4.11 LOW WATER CONSIDERATIONS

As described in Section 2.4.1.1, plant water needs are supplied through an intake structure in the Columbia River. The top of the makeup water intake screens (at RM 352) are set below the water surface elevation that would be associated with the minimum allowable flow (36,000 cfs) at the federally licensed Priest Rapids Dam (at RM 397). Water levels at the CGS intake are not influenced by backwater from the downstream McNary Dam (RM 292). The Columbia River Basin upstream of CGS has in excess of 35 million acre-ft of usable reservoir storage capacity. Because of this storage and highly regulated river flows, it is improbable that flows below the licensed minimum will occur. Based on data for 1961 through 1994, 7-day low flow with a recurrence interval of 100 years has been estimated at 44,500 cfs.

Even if some event (e.g., very severe drought) caused the makeup water system to be inoperable, the loss of water would not compromise the safe shutdown of the plant. As is discussed in Sections 9.2.5 and 9.2.7, shutdown cooling water is supplied by the ultimate heat sink which contains a 30-day supply of water in two spray ponds. The only scenario in which the makeup water pump house is called on to supply water in an emergency situation is when a tornado removes a significant quantity of spray pond water (see Section 9.2.5.3). Therefore, the low river water condition is not a situation requiring safety-related features and procedures.

2.4.11.1 Low Flow in Streams

Reservoir projects on the Columbia River Basin upstream of the proposed site have a total usable storage capacity in excess of 35 million acre-ft. This capacity is sufficient to maintain a flow in the Columbia River, at the proximity of CGS, of 36,000 ft^3/sec for over 1 year with absolutely no inflow from other sources. Because of this regulation, the anticipated minimum

and maximum monthly mean flow rates will be 60,000 and 260,000 ft^3/sec in the vicinity of the site. It is improbable that minimum flows below that administratively set for dam operation (36,000 ft^3/sec) will occur due to drought conditions. Columbia River storage measurements have been extrapolated down to 25,000 cfs and are shown in Figure 2.4-13. The river elevation at RM 352, site of the CGS makeup water pump house, is 341.73 ft msl and has a corresponding flow of 36,000 ft^3/sec.

2.4.11.2 Low Water Resulting From Surges, Seiches, or Tsunami

There exists no possibility of low water conditions resulting from meteorological or geoseismic generated surges, seiches, or tsunami unless such natural phenomena effected rapid closure of the Priest Rapids Dam, which is located 45 miles upstream from the proposed site. Rapid closure of the dam would cause a negative surge to be generated downstream.

A complete stoppage of flow is an unlikely event because of the redundant equipment and operational procedure in place at the dam. Provisions to guard against an accidental shut off of Priest Rapids Dam include:

a. A gate actuation button in the control room of the Dam which is used to maintain at least minimum licensed flow from the facility in the event of one or more turbine shutdowns.

b. Independent motors on each gate which have redundant wiring and power supplies.

c. Electrical heating on four of the gates to prevent ice buildup which might interfere with gate operation.

d. Multiple offsite power sources in addition to an on-site diesel generator power backup for gate operation.

In the event of a rapid and complete stoppage of flow over Priest Rapids Dam the effect of the negative surge would pass the site in a few hours. Since the Priest Rapids Dam is a run of the river dam with low storage capacity, it is unlikely that its closure can restrict the Columbia River flow for a significant period of time before being topped.

2.4.11.3 Historical Low Water

Historical records of the U.S. Geological Survey gauging station (RM 394.5) located 2.6 miles downstream from Priest Rapids Dam show low daily averaged flows of 20,000 ft^3/sec (January 31, 1937) and low monthly averaged flows of 20,900 ft^3/sec (February 1937). An instantaneous low flow of 4120 ft^3/sec occurred February 10, 1932, due to activities connected with dam regulation of the river near Wenatchee, Washington, before construction of Priest

Rapids Dam. After completion of the Dam in 1956, the minimum flow rate of the Columbia River at RM 352, approximate location of the CGS makeup water pump house site, is 36,000 ft^3/sec. The flow is maintained by the Grant County PUD as operator of the Priest Rapids Dam (RM 397) under FPC license which states:

> *"The licenses shall so regulate the flow from the Project 2114 that it will not result in flows of less than 36,000 cfs of water at the Hanford Works of the Atomic Energy Commission except when conditions are beyond the licensee's control."*

In eighteen years of operation the flow has not dropped below the specified minimum.

The annual average flow of the Columbia River below Priest Rapids Dam is in the range of 115,000 cfs. The effect of use of upstream water for irrigation development on the stream flow has been taken into account and the modified mean monthly discharge variations for the period 1928-58 are shown in Table 2.4-4 and Figure 2.4-14. The discharge for the base period of 1929-58 was adjusted to reflect 1970 levels of water utilization, including water consumption due to activities of flood control, power generation and irrigation. Figure 2.4-15 shows the exceedance frequency for annual low flows for the period 1929 through 1958 with 1970 conditions measured at the gauging station (RM 394.5) immediately below Priest Rapids Dam. Because of the flow regulation on the Columbia River, the anticipated minimum and maximum monthly mean flow rates will approximate 60,000 and 260,000 cfs in the vicinity of the CGS site. The variations of the river flow in this reach are due not only to seasonal fluctuations, but also to the daily regulation of the power producing Priest Rapids Dam. Flow rates during the late summer, fall and winter may vary from a low of 36,000 cfs to 160,000 cfs each day.

The dependable yield for flows in the Columbia River below Priest Rapids Dam for periods of one year through 10 years, as well as the 30-year period 1929-58 is illustrated in Table 2.4-5. The flow duration curve resulting from a plot of Table 2.4-4 is shown by Figure 2.4-14 (Reference 2.4-20). This figure illustrates the percentage of time equaled or exceeded for different amounts of flows below Priest Rapids Dam on a monthly and on an annual basis.

2.4.11.4 Future Controls

Flows in the Columbia River at Hanford are required to be maintained above 36,000 ft^3/sec. This is the licensed minimum flow of Priest Rapids Dam and, as such, is a parameter closely monitored and controlled by the Grant County PUD. The State of Washington has administratively set higher average daily minimum flows (greater than 40,000 ft^3/sec) and will attempt to have the FERC licenses for the dams modified to insure the minimums (Reference 2.4-21).

2.4.11.5 Plant Requirements

All cooling water is supplied to the plant cooling towers via the circulating water system, the plant service water system, or the standby service water system described in Sections 9.2.1.2 and 10.4.5. In the event of an incident rendering the cooling towers inoperative, cooling water is supplied from the spray ponds by the standby service water system, described in Section 9.2.7. These are closed loop systems and the only water loss is through evaporative cooling.

Makeup to the plant cooling towers and spray ponds comes from the Columbia River. Should this capability be lost, the cooling load is taken over by the spray ponds. These ponds have sufficient capacity to provide shutdown cooling water for 30 days without makeup. Other sources of water are available to provide makeup after the initial 30-day period (see Section 9.2.5). Therefore, variation in river flow will not have any adverse affect on the capability to shut down the reactor in a safe and orderly manner.

2.4.11.6 Heat Sink Dependability Requirements

At the minimum river flow of 36,000 ft^3/sec described in Section 2.4.11.3, there is still sufficient submergence at the makeup water pumps to provide full makeup water requirements at full power operation. Sump level indication and low level alarms are provided in the main control room. Should the sump water elevation fall below the minimum submergence level for the makeup pumps, due either to low river flow or blocked inlets, the plant would be shut down if the situation could not be readily corrected with the safety-related standby service water coming from the spray ponds.

Section 9.2.5 discusses the design bases used in designing the two spray ponds which serve as the ultimate heat sink for CGS. Design of the CGS ultimate heat sink is in compliance with the guidelines presented in Regulatory Guide 1.27 Rev. 1, "Ultimate Heat Sink for Nuclear Power Plants," dated March 1974. The CGS spray ponds serve as the suction source and discharge point for the standby service water system. This system is discussed in Section 9.2.7 and identifies the uses and quantities of water drawn from the ultimate heat sink.

2.4.12 DISPERSION, DILUTION, AND TRAVEL TIMES OF ACCIDENTAL RELEASES OF LIQUID EFFLUENTS IN SURFACE WATERS

Small amounts of liquid radioactive wastes, processed within the plant and containing traces of radioactive nuclides, are discharged ultimately to the Columbia River via the plant blowdown line as discussed in Section 11.2.2.2.6 (see Figure 2.4-16). *In the vicinity of CGS, the Columbia River is wide, relatively shallow, and fast flowing. Field measurements have shown river velocities near the CGS discharge to be about 3 ft/sec for minimum flows (Reference 2.4-22) and 4.5 ft/sec for average flows (Reference 2.4-23). At the point of discharge the river is about 5 ft deep at minimum flow. Based on a dye dispersion study (Reference 2.4-22), the local eddy diffusivity at low flow has been conservatively estimated to*

be 4 ft^2/sec (Reference 2.4-24). With a combination of minimum river flow and maximum blowdown, it is estimated that an effluent would be diluted by a factor of about 60 at a distance of 300 ft and a factor of 200 at 3000 ft. Dilution factors and travel times for calculating doses to downstream water users are discussed in the CGS Offsite Dose Calculation Manual (ODCM).

Downstream surface water users are listed in Section 2.4.1.2. The travel time to the nearest withdrawal which could be affected by an accidental release is approximately 1 hr. At that point a radioactive release would be essentially completely mixed with the river resulting in a dilution factor of 1:200,000. It is concluded that water users are sufficiently removed from the release point, and the Columbia River is sufficiently dispersive to preclude adverse impacts due to accidental releases. The dispersion characteristics of the river and the effects of routine releases are discussed in Sections 5.1 and 5.2 of the Environmental Report - Operating License Stage.

2.4.13 GROUNDWATER

2.4.13.1 Description and Onsite Use

Subsurface soil conditions, across the site, have been classified as follows:

a. Loose to medium dense, fine to coarse sand with scattered gravel (glaciofluvial sediments).

b. Very dense, sandy gravel with interbedded sandy and silty layers (Ringold Formation, Middle Member).

c. Very dense, interbedded layers of sandy gravel silt and soft sandstone (Ringold Formation, Lower Member).

d. Basalt bedrock which forms the bedrock beneath the area.

The lithologic character and water bearing properties of the geologic units occurring in the Hanford region are summarized in Table 2.4-6. In general, groundwater in the surficial sediments occurs unconfined, although locally confined zones exist. Water in the basalt bedrock occurs mainly under confined conditions. Occasionally, the lower zone of the Ringold Formation occurs as a confined aquifer, separated from the overlying unconfined aquifer by thick clay beds which possess a distinct hydraulic potential.

The unconfined aquifer consists of both glaciofluvial sand and gravel deposits and the Ringold silts, clays, and gravels. Since these materials are very heterogeneous, often greater lithologic differences occur within a given bed than between beds. In the vicinity of CGS the water table is below the top of the Ringold Formation (see Figures 2.5-64 and 2.5-65). The unconfined

aquifer bottom is the basalt bedrock in some areas and silt/clay zones of the Ringold Formation in other areas. Clearly the bottom of the unconfined aquifer is not a continuous lithologic surface.

The Hanford Reservation contains over 2200 wells constructed from pre-Hanford work days to the present). Approximately 600 of these wells are used for groundwater monitoring (Reference 2.4-25). Figure 2.4-17 identifies the well locations in the Hanford Reservation as of September 1975. Figure 2.4-18 shows the December 1975 groundwater contour map. In general, the groundwater gradient resulting from groundwater flowing under the Reservation is the highest in the southwestern area toward Rattlesnake Mountain, and slopes toward the Hanford 200 Areas near the center of the reservation. From the 200 Areas the general slope in the gradient is toward northeast and southeast.

A groundwater contour map based on the potential construction of the Ben Franklin Dam at approximately RM 348 is illustrated by Figure 2.4-19. The CGS design basis groundwater level is based on the possible construction of the Ben Franklin Dam and is taken to be 420 ft msl, whereas the most recent study indicates that the water table would be about 405 ft msl (Reference 2.4-26). The feasibility of constructing Ben Franklin Hydroelectric Dam has been extensively studied. Its proposal was strongly contested by local groups and individuals concerned with environmental protection and preservation. Additionally, the matter of the impact such a facility would have on the DOE Hanford Reservation was believed by some to preclude its construction. Finally, the cost/benefit ratio was believed by many to be too low to make the project viable. The combination of the unresolved impediments to the project has effectively, though not conclusively, relegated it to a very low priority status. Planning studies for the project by the Corps of Engineers were suspended in 1969 and reinitiated in October 1979 as part of the development of a management plan for the Hanford reach. The most recent studies were terminated in November 1981.

Impermeable groundwater boundaries are the Rattlesnake Hills, Yakima Ridge, and Umtanum Ridge on the west and southwest sides of the Hanford Reservation. Gable Mountain and Gable Butte also impede the groundwater flow, as well as other small areas of basalt outcrop above the water table. The Yakima River recharges the unconfined aquifer along its reach from horn Rapids to Richland. The Columbia River forms a hydraulic potential boundary which is a discharge boundary for the aquifer. The major source of natural recharge is precipitation on Rattlesnake Hills, Yakima Ridge, and Umtanum Ridge.

Minor changes would be expected in the groundwater elevations during the summer months because of the charging stage of the Columbia River, which historically reaches peak flood stage in June. Because CGS is located about three miles from the river and because of the permeability characteristics and enormous volume of the Ringold Formation, there is a substantial time lag in changing water levels. For the same reasons, the range in water table fluctuations is very small.

Natural recharge due to precipitation over the lowlands of the Hanford Reservation is not measurable as the evaporation potential during the summer months greatly exceeds total precipitation. Data on migration of moisture from natural precipitation in deep soils (below 30 ft) show movement rates less than 1/2-in./yr at one measurement site (References 2.4-27, 2.4-28 and 2.4-29). The major artificial recharge of ground water to the unconfined aquifer occurs near the Hanford 200 East and 200 West Areas. The large volume of process water (1.35 x 1011 gal) discharged to ground during 1944-1973 has caused the formation of significant groundwater mounds in the water table (Figures 2.4-20 and 2.4-26). Other local groundwater mounds formerly existed along the Columbia River. The present Hanford 100-N Area mound is the only one of these remaining. A minor recharge mound also exists at the Hanford 300 Area.

The unconfined aquifer is characterized by its hydraulic conductivity, the storage coefficient, and the effective porosity. The hydraulic conductivity relates the water flow quantity to the hydraulic potential gradient, while the effective porosity gives the fraction of porous media volume that is available to transmit ground water flow. The storage coefficient relates a change in the water table elevation to a change in the volume of water contained in the aquifer per unit horizontal area. In the limit of no delayed yield, the storage coefficient is equal to the effective porosity of the soil through which the water table moves. These parameters vary widely over the Hanford Reservation.

Qualitatively the hydraulic conductivity, storage coefficient, and effective porosity distributions are a function of the different geologic formations in the unconfined aquifer. Ancestral Columbia River channels which incised in the Ringold Formation are now filled with more permeable glaciofluvial sediments. These channels have been identified extending eastward along the northern and southern flanks of Gable Mountain and extending southeastward from the 200 East Area to the Columbia River (see Figure 2.4-21). These permeable channels are reflected in the groundwater flow pattern of the region.

Quantitative measurements of the hydraulic conductivity of the unconfined aquifer have been made on the Hanford Reservation using a variety of techniques: pumping tests, specific capacity tests, and tracer tests. The most common method has been the pumping tests. Values obtained for the Ringold Formation range between 10 to 650 ft/day with a median of about 130 ft/day. In sharp contrast are the very large hydraulic conductivities of glaciofluvial sediments, ranging from 1,200 to 12,000 ft/day (Reference 2.4-30).

The storage coefficient is much more difficult to measure in the field and estimates are, therefore, less common. For the unconfined aquifer, estimates of the storage coefficient have ranged from 0.01 to 0.1 (Reference 2.4-30). An areal estimate of 0.11 has been provided for the 200 West Area based on the growth of groundwater mounds (References 2.4-30 and 2.4-31). The median specific yield (effective porosity) has been estimated by various researchers at Hanford to range from 4.8% to 11%; most commonly it is assumed to be 10% (Reference 2.4-32).

The unconfined groundwater aquifer is characterized by the contour map of the hydraulic potential or water table. The map for December 1975 appears in Figure 2.4-18. The depth to the water table varies greatly from place to place, depending chiefly on local topography which ranges from less than 1 to more than 300 ft below the land surface. Beneath most of the Hanford 200 Area disposal sites the depth of the water table averages about 250 ft. The current estimate of the maximum saturated thickness of the unconfined aquifer is approximately 230 ft.

The chemical quality of the groundwater in the unconfined aquifer is measured at seven locations. Sodium, calcium, and sulfate ions are measured as well as pH. Chromium and fluoride ions associated with fuel manufacturing operations are analyzed from Hanford 300 Area wells. Nitrate ion, which is a waste product from the manufacturing and chemical separation operations, is monitored over the entire Hanford Reservation. Annual maps of the nitrate ion concentration near the surface of the unconfined aquifer are published (Reference 2.4-33). The map showing nitrate concentration for December 1975 appears in Figure 2.4-22.

The radiological status of the groundwater near the surface of the unconfined aquifer is monitored regularly (Reference 2.4-34) and reported annually. Plots of gross beta (ruthenium) plumes and the tritium plumes are shown in Figures 2.4-23 and 2.4-24 for December 1975 (Reference 2.4-33). Since the nitrate ion is not adsorbed in the soil it can be used as a tracer for groundwater movement. The extent of movement of waste water containing radionuclides can thus be plotted. Respective tritium and nitrate ion concentrations under the CGS site are currently ranging from 30 to 300 pci/ml and 4.5 to 45 mg/l depending on the sampling location. Concentration guide for drinking water is 3,000 pci/ml for tritium and the recommended drinking water standard is 10 mg/l for nitrate ions. Gross beta concentrations do not extend to the site.

From the research that has been done to date, it appears that there are a number of confined aquifers underlying the Hanford Reservation. Relatively impermeable confining beds commonly include the individual basalt flows and the silts and clays of the lower part of the Ringold Formation.

Within the basalt sequence, groundwater is transmitted primarily in the interflow zones, either in sedimentary beds or in the scoria and breccia zones forming the tops and bottoms of the flows (References 2.4-35 and 2.4-36). Basalt flows in the Pasco Basin have been eroded particularly in the anticlinal ridges. In some locations the basalts are highly jointed and contain breccia, pillow and plagonite complexes through which groundwater can move. Consequently, hydraulic potential differences between water bearing zones in the upper part of the basalt sequence are small over hundreds of feet of depth. The lowermost Ringold Formation silts and clays are of variable thickness. Distinct hydraulic potential differences have been observed between aquifers below the silts and clays and the unconfined aquifer.

Groundwater flow in the uppermost confined aquifer is also to the southeast with possible discharge into the Columbia River somewhere below Lake Wallula. However, the flow rates are regarded as quite small due to the low transmissivity range of this water bearing zone. Groundwater in the lower confined aquifers does not appear to cross the major anticlinal divides that define the Pasco Basin.

The piezometric or hydraulic potential map for the confined zones above the basalt (Figure 2.4-25) was based on measurements made in 1970. In general, the hydraulic potential observed in the confined aquifer zones above the basalt is greater than in the overlying unconfined aquifer. The main exception is in the vicinity of the Hanford 200 Area recharge mounds which have raised the potential in the unconfined aquifer.

One recharge area that has been identified is from the Yakima River at Horn Rapids. The piezometric map in Figure 2.4-25 also suggests recharge from the upper Cold Creek Valley with flow toward a potential trough under the Columbia River. The Columbia Basin Irrigation Project to the northeast and east, and the Columbia River behind Priest Rapids and Wanapum Dams to the northwest are other probable recharge sites in both these areas the basalt is exposed and is covered by perennially saturated unconsolidated deposits. A site of possible minor recharge exists adjacent to Gable Butte and Gable Mountain anticline near the center of the Reservation.

Only 90 wells on the Hanford Reservation have been drilled to basalt. Thus data on the confined aquifers in the basalt flows are limited and more would have to be gathered to fully characterize the confined aquifers.

The plant is located on glaciofluvial outwash sands and gravels which are about 50 ft thick. Below this layer occurs very dense gravel. Sandy gravel occurs in a sequence approximately 200 ft thick which is assumed to be the middle member of the Ringold Formation. The lower member of the Ringold Formation consists of a very compact, interbedded gravel, sand, silt, and clay and extends down to a depth of about 500-525 ft. Basaltic bedrock underlies the lower Ringold member, at approximately 550 ft depth.

The water table is about 60 ft below the ground surface level at CGS. The water table elevation is about 378 $\pm$4 ft msl and appears to be stable. The effective bottom of the unconfined aquifer is assumed to be at about 220-260 ft msl at the top of the lower Ringold Formation. Groundwater potentials from the lower Ringold and from the basalt water bearing zones are about 25 ft higher than that of the unconfined aquifer. Test borings down to 925 ft reveal there are water bearing zones in the lower basalt flows and sedimentary interbeds at CGS. Piezometric level in basalt is 10 ft above unconfined water table and hence artesian.

Under the CGS site the unconfined groundwater is moving easterly toward the Columbia River, the nearest discharge boundary. Studies of the uppermost confined aquifer indicate that the

potential gradients at the proposed site are oriented in the same general direct ion as those of the unconfined aquifer.

Three water supply wells are located on the site. Two shallow wells were constructed in the unconfined aquifer (at approximately 240 ft deep) and a third well penetrates a confined aquifer in the underlying basalt flows (at approximately 695 ft deep). Normal water supply is from the river, and the deep well is maintained in the standby mode to provide supplemental makeup water for the potable and demineralized water system as needed. Pumping capability is about 250 gpm. The two shallow wells were used during construction.

2.4.13.2 Sources

Regional use of the unconfined aquifer occurs at two nearby locations. The first is at the DOE's 400 Area located about 3 miles southwest of the CGS site as shown in Figure 2.1-3. *Groundwater to this construction site is supplied from two wells and is used for sanitary and operation purposes. Maximum expected usage rate is between 2 million and 2.5 million gal/month. No data is available on drawdown tests performed on the FFTF water supply wells 699-SO-7 and SO-8.* The second location of ground water use is the WNP-1/4 site about 1 mile east of CGS. Water is drawn from two wells for sanitary and potable water requirements. *Usage rate is approximately 250,000 gal/month.*

The two onsite wells which drew from the unconfined aquifer (699-13-1A and 1B) are 234 and 244 ft deep. Drawdown tests for each well showed 22 and 91 ft of drawdown respectively, at pumping rates of 250 gpm and test durations of about 25 hr. These wells are no longer used. The third well (695 ft deep) is sealed from the unconfined aquifer and draws from confined water in the basalt. Drawdown on this well was 163 ft at a pumping rate of 275 gpm with a test duration of 25 hr.

Water table contours in the vicinity of CGS can be seen in Figure 2.4-26. The aquifer is assumed to be isotropic, therefore, flow occurs along instantaneous streamlines perpendicular to the equipotential contours. The groundwater flow is toward the discharge boundary at the Columbia River to the east of the site. The hydraulic potential gradient in this area is about 8-10 ft/mile in the unconfined aquifer. As described in Section 2.4.13.1, recharge and discharge of riverbank storage occur along the Columbia River with daily fluctuations superimposed on the seasonal variations in river stage. Hydrographs of wells in the vicinity of the plant site (Figure 2.4-27) show that riverbank storage is not detectable even in years of extreme spring runoff at the two wells that are about one mile from the riverbank. Thus no seasonal reversability of the gradients driving the groundwater flow occurs. In other areas of the Hanford Reservation, the seasonal fluctuations of groundwater levels from riverbank recharge can be detected 3-4 miles inland from the riverbank.

During early studies of groundwater in the area (References 2.4-37 and 2.4-31) little information was obtained on specific features at the plant site. The water table for 1944

(pre-Hanford Work conditions) was interpolated using 1948-1952 observation well data (Figure 2.4-20) and showed a water table elevation of about 370 ft msl under the site. The potential gradient was interpolated (References 2.4-31 and 2.4-38) to be about 5-6 ft per mile toward the Columbia River.

The earliest wells in the vicinity (699-2-3 and 17-5) were drilled in 1950. Their hydrographs, presented in Figure 2.4-27, show the gradual rise of the water table to approximately 15 ft above pre-Hanford Operations elevations. The peak rise in 1972 for well 699-2-3 shown on Figure 2.4-27 is believed to be a measurement error. Other wells were drilled in 1958, 1961, 1962 and 1966. Their hydrographs appear in Figure 2.4-27. Wells 669-14-E6-T and -20-E5T also show the gradual rise of the water table at their respective locations. Smaller apparent water table changes at the site between 1944- 1974 (see 2.4.13.1 and Figure 2.4-27, well 699-14-E6-T and 699-20-E5-T) indicated a zone of relatively lower hydraulic conductivity in this area.

Well 699-9-E2 is a deep well perforated in both the unconfined and lower confined aquifer zones. Its historical hydrograph (Figure 2.4-27) reflects a composite of confined and unconfined potentials with discontinuities caused by sanding in an subsequent maintenance operations. The 1962 peak of the hydrograph of well 699-20-E12 (Figure 2.4-27) is due to the influence of the high confined aquifer potential before the installation of piezometer tubes in this deep well. The 1972 peak, could be bank recharge from the high river stage of that year but the lack of previous response to river stage makes the measurement suspicious. Well 699-10-E12, also located within one mile of the river, does not show seasonal bank recharge (Figure 2.4-27). Over the past two years, a decrease in the rate of rise is evident.

Soil test borings and water supply wells drilled in conjunction with the CGS construction site, confirmed the present contouring interpretation of the water table. Recent data from boring at WNP-1 and WNP-4 are not reflected in the water table maps shown in Figures 2.4-18, 2.4-19, 2.4-26, and 2.4-25.

The historical well hydrographs for the uppermost confined aquifer in the vicinity of the plant site are given in Figure 2.4-27. Well number 699-20-E12-P shows a rather rapid rise of the confined aquifer potential in 1962-65. It has been postulated that this rise reflects recharge to the confined zones from irrigation across the river in the Columbia Basin Irrigation Project. The hydraulic potential in the uppermost confined aquifer near the plant site is presently about 390 ft msl, which is about 25 ft higher than the potential of the overlying unconfined aquifer.

The effects of the groundwater withdrawal at the site have been estimated to be local. No drawdown has been detected in the nearest observation wells, numbers 699-17-5 and 699-9-E2. The latter well is perforated over multiple aquifers so it does not give a representative measurement of the water table elevation. The radius of influence (defined to be the radius at which a 0.1 ft drawdown exists) of the CGS wells has been estimated to be about 3500-4500 ft. This is based on the ten months of high rate of withdrawal during compaction

operations taking into account the ambient water table gradient. The subsequent reduction in withdrawal flow rate to 25% of the early value would shrink the radius of influence considerably.

There is no groundwater recharge area within the influence of the plant. The 60-ft depth from the land surface to the water table and the arid condition of sediments above the water table make it virtually impossible to detect any recharge from precipitation over this area.

2.4.13.3 Accidental Effects

An evaluation of a possible radioactive liquid release is postulated due to the rupture of a 700-gal decontamination solution concentrator waste tank within the radwaste building (see Figure 11.2-1). The released effluent was then assumed to reach the soil environment outside the building and to percolate to the water table unimpeded. On entering the groundwater, the postulated radwaste release is dispersed, sorbed, decayed, and diluted along the potential groundwater pathway from the plant towards the Columbia River.

In the unconfined (water table) aquifer, there are no down gradient groundwater users between CGS and the Columbia River. However, the construction water needs at WNP-1/4 are supplied by the two deep wells that withdraw groundwater from the uppermost confined aquifer downgradient from the CGS radwaste building. During operation of WNP-1/4, these wells will be maintained in a standby mode. The uppermost screens in these wells are about 240 ft below the ground surface in the lower Ringold Formation. The effective bottom of the unconfined aquifer is generally assumed to be at the top of the lower Ringold Formation or about 200 ft below the surface. Thus, in all likelihood, any liquid radioactive spill to the groundwater beneath the CGS radwaste building would travel through the unconfined aquifer towards the Columbia River. However, for conservatism, analyses of postulated radionuclide movement assume that the WNP-1/4 wells draw from the unconfined aquifer. The remainder of this subsection provides estimates of travel times of critical radionuclides to move from the postulated spill to receptors and the corresponding concentration reduction factors.

For an assumed one-dimensional groundwater movement, the groundwater travel time, t, is the path length, L, divided by the groundwater velocity (seepage velocity), u. The groundwater velocity is the Darcy (apparent) velocity divided by the effective porosity, $u = Ki/n_e$, where K is the lateral permeability (hydraulic conductivity) of the aquifer, i is the hydraulic gradient, and ne is the effective porosity of the aquifer material.

For computational purposes, a conservative value for lateral permeability of 500 ft/day was selected to represent the unconfined aquifer located in the Ringold Formation beneath CGS (see Figure 2.4-21). From 2.4.13.1, effective porosity is taken 0.10. From Figure 2.4-26, the gradient in the water table aquifer between the plant and the Columbia River is about 8 or 9 ft/mile, and is taken conservatively as 10 ft/mile.

Using the above parameter values, groundwater velocities were computed to be 10 ft/day. With path lengths of 3.4 miles to the river and 1.0 mile to the WNP-1/4 wells, the respective travel times are estimated to be 5.2 years and 1.5 years.

Generally, the critical radionuclides of concern for a postulated liquid radwaste spill are ^{3}H, ^{90}Sr, and ^{137}Cs. These three radionuclides are fairly representative in terms of sorption characteristics, of those found in liquid radwaste tanks, since tritium does not sorb onto soil particles at all, strontium is an intermediate sorber, and cesium strongly sorbs to soil particles. The half-life of tritium is 12.3 years, whereas those of ^{90}Sr and ^{137}Cs are 29.0 and 30.1 years, respectively.

The travel time, t_i, for a particular radionuclide moving through groundwater depends upon the velocity, u_i, of the radionuclide

$$t_i = l/u_i$$

where the radionuclide velocity is

$$u_i = r_f u$$

in which r_f is the velocity reduction factor attributable to sorption

$$r_f = 1/1+\frac{\rho b}{n} k_d$$

In this equation, ρb is the bulk density of the aquifer material, n is the total porosity, and K_d is the equilibrium distribution coefficient for a particular radionuclide. The bulk density and total porosity are further related physically as

$$b = R_s (1 - n)$$

where R_s is the real specific gravity or particle density of the solid particles in the aquifer media.

The particle density, R_s, for Hanford soils is usually taken to be constant at 2.65 gm/cm^3, (Reference 2.4-39). The bulk density ρb, of Hanford soils has been determined to range from about 1.5 gm/cm^3 to about 1.75 gm/cm^3, with a median value of about 1.65 gm/cm^3, (Reference 2.4-40). For the median value of bulk density, the corresponding total porosity is about 0.377.

Using the above value for bulk density and total porosity, radionuclide travel time, ti, through the groundwater beneath WNP-1/4 can be expressed as

$$t_i = (1 + 4.4\,K_d)\,t$$

The following summarizes radionuclide travel times (in years) to the WNP-1/4 wells (1.0 miles) and to the Columbia River (3.4 miles):

Nuclide	*Half-life, years*	K_d	t_i *@ 1.0 miles*	t_i *@ 3.4 miles*
^{3}H	12.3	0	1.5	5.2
^{90}Sr	29.0	10	67.0	230.0
^{137}Cs	30.1	100	660.0	2300.0

The radionuclide concentration at the point of water use will be determined by the amount of decay, dispersion, and sorption on the aquifer media. The minimum concentration reduction factor, CRF_{min}, along the centerline of the contaminant plume from an instantaneous point source is given by (Reference 2.4-41)

$$CRF_{min} = \frac{C_o}{C} = \frac{(4\pi t)^{3/2}\ (K_x K_y K_z)^{1/2}}{2V}$$

for an effluent volume, V, with a specific gravity of 1.0 and an initial concentration, C_o, released to soil with dispersion coefficients, K_x, K_y, K_z, in the x, y, and z directions, respectively. This expression neglects the phenomena of sorption and decay which will be considered later.

It is generally accepted that the dispersion coefficients are proportional to groundwater velocity for unidirectional flow, i.e.,

$$K_{x,y,z} = \alpha_{x,y,z} u$$

where $\propto_{x,y,z}$, are constants called dispersivities which are a function of the nonhomogeneity of the material. The range in dispersivities in homogeneous granular aquifers may approach 1000 cm (33 ft) (Reference 2.4-42). Substituting this relationship into the above expression for concentration reduction, and noting that travel time is determined by path length and velocity, results in

$$CRF_{min} = \frac{(4\pi L)^{3/2}\ (\propto_x \propto_y \propto_z)^{1/2}}{2V}$$

For the conservative condition of $\alpha_x = \alpha_y = \alpha_z = 1.0$, then

$$CRF_{min} = \frac{(4\pi L)^{3/2}}{2V}$$

The concentration reduction factors at the WNP-1/4 wells and at the bank of the Columbia River, due only to dispersion, are 9.1 x 10^4 and 5.7 x 10^5, respectively, for the 700-gal concentrated waste tank. When sorption and decay are included, the concentration reduction is given by (Reference 2.4-42)

$$CRF = \frac{(4\pi L)3 / 2 (\propto_x \propto_y \propto_z)^{1/2}}{2V} e^{\lambda t_i}$$

in which λ is the radionuclide decay constant defined in terms of the half-life, T1/2, of a particular radionuclide as

$$\lambda = \frac{1n\ 2}{T_{1/2}}$$

The concentration reduction factor can be expressed as

$$CRF = CRF_{min} (e\ \lambda\ t_i)$$

The exponential term accounts for the effects of sorption and decay. The only effect of sorption on concentration reduction is to increase the travel time, thus allowing more time for decay. Concentration reduction factors (CRF) for the radionuclides listed were calculated for path lengths of 1.0 mile (to WNP-1/4 wells) and 3.4 miles (to Columbia River):

Nuclide	CRF (1.0 mile)	CRF (3.4 mile)
^{3}H	1.0 x 10^5	7.7 x 10^5
^{90}Sr	4.5 x 10^5	1.8 x 10^8
^{137}Cs	3.7 x 10^{11}	5.8 x 19^{28}

The above factors, derived through the application of conservative parameters, are used in Section 15.7.3 to evaluate concentrations offsite. *The consideration of the WNP-1/4 wells is especially conservative. Groundwater contamination from the 200 Areas which reached CGS over six years ago (see Section 2.4.13.1) has not been detected at WNP-1/4. This substantiates that the WNP-1/4 wells do not draw from the unconfined aquifer or, alternatively, the hydraulic conductivities are much less than assumed.*

It should also be noted that if Ben Franklin Dam were ever constructed, the concentration reduction factors at the river bank would be even larger than those noted above. This would be true, because the groundwater gradient (thus, the groundwater velocity) would be decreased as shown in Figure 2.4-19.

2.4.13.4 Monitoring or Safeguard Requirements

Plant water systems result in releases to the ground at a number of locations. Sanitary wastewater is routed to a central treatment system comprised of lined aeration lagoons and stabilization ponds. This treatment plant also receives wastes from the Plant Support Facility, WNP-1 and WNP-4, and the DOE's 400 Area. Periodically the treated effluent is discharged to percolation beds.

As discussed in Section 2.4.2.3, the storm water drainage system discharges to lined ponds northeast of the plant (see additional description in Section 9.3.3.2.3.1). Such sources as water treatment filter backwashes, heating, ventilating, and air conditioning (HVAC) air wash units, and some building sumps and floor drains (see Section 9.3.3.2.3) also contribute to flow in the storm water system. Periodic testing and flushing of the fire protection system and cleaning of the cooling towers and standby service water ponds result in localized discharges of water to the ground.

Monitoring of groundwater and plant-related discharges to ground is performed as described in the ODCM.

2.4.13.5 Design Bases for Subsurface Hydrostatic Loadings

CGS does not employ permanent dewatering systems. Site groundwater conditions are presented in Section 2.5.4.6 and the design bases for subsurface hydrostatic loadings are given in Section 3.4.

The design-basis groundwater elevation used for subsurface hydrostatic loadings is 420 ft msl and was predicated on the possible future construction of Ben Franklin Dam at RM 348. As noted in Section 2.4.13.1, planning for the dam has been terminated. The same section notes that the water table beneath CGS would rise to less than 405 ft msl if the dam were to be completed. The actual water table beneath the project is about 385 ft msl (see Sections 2.4.13.1 and 2.5.4.6). The design-basis groundwater level is adequate to account for seepage from the ultimate heat sink spray ponds or the rupture of any Seismic Category I or nonseismic pipe. As discussed in Section 3.8.4.1.5, the two, 250-ft^2 reinforced-concrete spray ponds are designed to Seismic Category I requirements and are designed to mitigate any possible water leakage. The bottom of the spray ponds are at 417 ft msl and the ponds are designed for external hydrostatic loading to 420 ft msl. The maximum combined leakage from the two ponds during the initial filling sequences was 120 gpm. It may be inferred from previous studies (Reference 2.4-7) that continued leakage cannot affect the groundwater level

beneath the ponds or other safety-related structures, the closest of which (500+ ft away) is the diesel generator building with a foundation at 434 ft msl. These early CGS hydrologic studies evaluated the effect of cooling pond leakage and cooling tower blowdown at the project site. Equivalent leakage/discharge rates used in these studies were very much greater than leakage from the spray ponds. For example, the continuous discharge of 2700 gpm of cooling tower blowdown to the depression just east of CGS was estimated to raise the water table about 20 ft beneath the point of discharge (Reference 2.4-7). Based on these previous studies, it can be concluded that the minimal amount of spray pond leakage will have no influence on the design-basis groundwater elevation of 420 ft msl.

With respect to a pipe break, the 144-in. circulating water system pipe on the discharge side of the condenser would produce the maximum release of water. The maximum quantity of water released from such a rupture is 199,180 ft^3. This discharge would have a negligible (less than 1 in.) and temporary effect on the groundwater level. Failure of the pipe at its closest proximity to a safety-related building may result in temporary saturation of the backfill. This material has been recompacted to a minimum relative density of 75% and an average relative density of 85%. As discussed in Section 2.5.4.8, these densities are not susceptible to liquefaction for motions associated with the safe shutdown earthquake, and as discussed in Section 2.5.4.10, temporary saturation would not significantly reduce the bearing capacity of the densely compacted backfill. A continuous but undetected leak from any major pipe would not influence the groundwater level enough to affect plant structures. This may be deduced from the time factors and water table rises predicted from a number of scenarios in the above mentioned hydrologic studies (Reference 2.4-7).

2.4.14 TECHNICAL SPECIFICATIONS AND EMERGENCY OPERATION REQUIREMENTS

The worst hydrological condition, as discussed in this section, is a flood caused by a postulated PMP event. This flood does not create an adverse hydrological condition on safety-related equipment. Emergency flood protection procedures are therefore unnecessary.

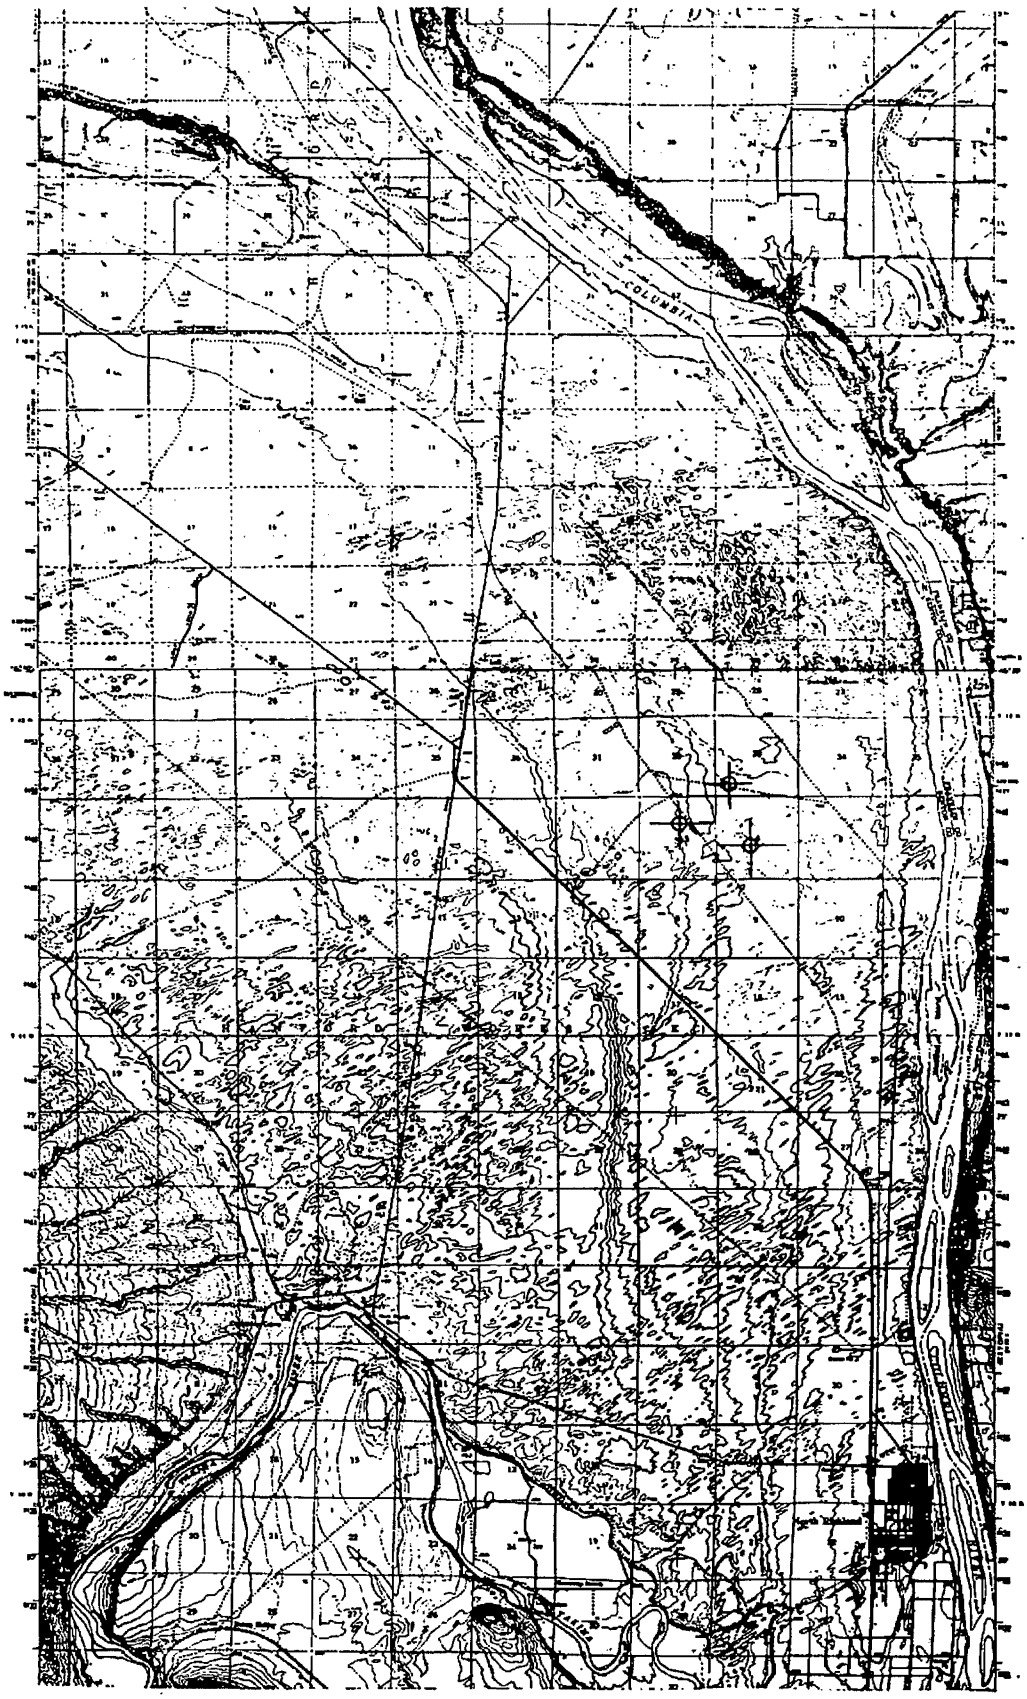
Table 2.4-6

Major Geologic Units in the Hanford Region
and Their Water-Bearing Properties



System	Series	Geologic Unit	Material	Water-Bearing Properties
		Fluviatile and glaciofluviatile sediments and the Touchet formation (0-200 ft thick)	Sands and gravels occurring chiefly as glacial outwash. Unconsolidated, tending toward coarseness and angularity of grains, essentially free of fines.	Where below the water table, such deposits have very high permeability and are capable of storing vast amounts of water. Highest permeability value determined was 12,000 ft/day.
	Pleistocene	Palouse soil	Wind deposited silt.	Occurs everywhere above the water table.
Quaternary		Ringold formation (200-1200 ft thick)	Well-bedded lacustrine silts and sands and local beds of clay and gravel. Poorly sorted, locally semi-consolidated or cemented. Generally divided into the lower "blue clay" portion which contains considerable sand and gravel, the middle conglomerate portion, and the upper silts and fine sand portion.	Has relatively low permeability; values range from 1 to 200 ft/day. Storage capacity correspondingly low. In very minor part, a few beds of gravel and sand are sufficiently clean that permeability is moderately large; on the other hand, some beds of silty clay or clay are essentially impermeable.
	Miocene and Pliocene	Columbia River basalt series (10,000 ft thick)	Basaltic lavas with interbedded sedimentary rocks, considerably deformed. Underlie the unconsolidated sediments.	Rocks are generally dense except for numerous shrink-age cracks, interflow scoria zones, and interbedded sediments. Permeability of rocks is small (e.g., 0.002 to 9 ft/day) but transmissivity of a thick section may be considerable (70 to 700 ft^2/day)

2.5 GEOLOGY, SEISMOLOGY, AND GEOTECHNICAL ENGINEERING

The information discussing the geology, seismology, and geotechnical engineering is contained in a technical memorandum, TM-2143, "Geology, Seismology, and Geotechnical Engineering Report." This report is incorporated by reference into the FSAR and as such is subject to the same controls as the FSAR.

DESIGN CRITERIA - STRUCTURES, COMPONENTS, EQUIPMENT, AND SYSTEMS

TABLE OF CONTENTS

Section — Page

3.1 CONFORMANCE WITH NRC GENERAL DESIGN CRITERIA 3.1-1
3.1.1 SUMMARY DESCRIPTION 3.1-1
3.1.2 CRITERION CONFORMANCE 3.1-1
3.1.2.1 Group I - Overall Requirements 3.1-1
3.1.2.1.1 Criterion 1 - Quality Standards and Records 3.1-1
3.1.2.1.2 Criterion 2 - Design Bases for Protection Against Natural Phenomena ... 3.1-3
3.1.2.1.3 Criterion 3 - Fire Protection 3.1-4
3.1.2.1.4 Criterion 4 - Environmental and Missile Design Bases 3.1-5
3.1.2.1.5 Criterion 5 - Sharing of Structures, Systems, and Components 3.1-6
3.1.2.2 Group II - Protection by Multiple Fission Product Barriers 3.1-7
3.1.2.2.1 Criterion 10 - Reactor Design 3.1-7
3.1.2.2.2 Criterion 11 - Reactor Inherent Protection 3.1-8
3.1.2.2.3 Criterion 12 - Suppression of Reactor Power Oscillations 3.1-9
3.1.2.2.4 Criterion 13 - Instrumentation and Control 3.1-10
3.1.2.2.5 Criterion 14 - Reactor Coolant Pressure Boundary 3.1-12
3.1.2.2.6 Criterion 15 - Reactor Coolant System Design 3.1-14
3.1.2.2.7 Criterion 16 - Containment Design 3.1-15
3.1.2.2.8 Criterion 17 - Electrical Power Systems 3.1-16
3.1.2.2.9 Criterion 18 - Inspection and Testing of Electric Power Systems 3.1-18
3.1.2.2.10 Criterion 19 - Control Room 3.1-19
3.1.2.3 Group III - Protection and Reactivity Control System 3.1-21
3.1.2.3.1 Criterion 20 - Protection System Functions 3.1-21
3.1.2.3.2 Criterion 21 - Protection System Reliability and Testability 3.1-22
3.1.2.3.3 Criterion 22 - Protection System Independence 3.1-23
3.1.2.3.4 Criterion 23 - Protection System Failure Modes 3.1-24
3.1.2.3.5 Criterion 24 - Separation of Protection and Control Systems 3.1-25
3.1.2.3.6 Criterion 25 - Protection System Requirements for Reactivity Control Malfunctions 3.1-26
3.1.2.3.7 Criterion 26 - Reactivity Control System Redundancy and Capability 3.1-27
3.1.2.3.8 Criterion 27 - Combined Reactivity Control Systems Capability 3.1-29
3.1.2.3.9 Criterion 28 - Reactivity Limits 3.1-30
3.1.2.3.10 Criterion 29 - Protection Against Anticipated Operational Occurrences 3.1-32
3.1.2.4 Group IV - Fluid Systems 3.1-33
3.1.2.4.1 Criterion 30 - Quality of Reactor Coolant Pressure Boundary 3.1-33

Chapter 3

DESIGN CRITERIA - STRUCTURES, COMPONENTS, EQUIPMENT, AND SYSTEMS

TABLE OF CONTENTS

Section — Page

3.1.2.4.2 Criterion 31 - Fracture Prevention of Reactor Coolant Pressure Boundary 3.1-34
3.1.2.4.3 Criterion 32 - Inspection of Reactor Coolant Pressure Boundary 3.1-35
3.1.2.4.4 Criterion 33 - Reactor Coolant Makeup 3.1-36
3.1.2.4.5 Criterion 34 - Residual Heat Removal 3.1-37
3.1.2.4.6 Criterion 35 - Emergency Core Cooling 3.1-39
3.1.2.4.7 Criterion 36 - Inspection of Emergency Core Cooling System 3.1-41
3.1.2.4.8 Criterion 37 - Testing of Emergency Core Cooling System 3.1-42
3.1.2.4.9 Criterion 38 - Containment Heat Removal 3.1-43
3.1.2.4.10 Criterion 39 - Inspection of Containment Heat Removal System 3.1-44
3.1.2.4.11 Criterion 40 - Testing of Containment Heat Removal System 3.1-45
3.1.2.4.12 Criterion 41 - Containment Atmosphere Cleanup 3.1-46
3.1.2.4.13 Criterion 42 - Inspection of Containment Atmosphere Cleanup Systems 3.1-47
3.1.2.4.14 Criterion 43 - Testing of Containment Atmosphere Cleanup Systems ... 3.1-47
3.1.2.4.15 Criterion 44 - Cooling Water 3.1-48
3.1.2.4.16 Criterion 45 - Inspection of Cooling Water System 3.1-49
3.1.2.4.17 Criterion 46 - Testing of Cooling Water System 3.1-50
3.1.2.5 Group V - Containment (Criteria 50-57) 3.1-50
3.1.2.5.1 Criterion 50 - Containment Design Basis 3.1-51
3.1.2.5.2 Criterion 51 - Fracture Prevention of Containment Pressure Boundary ... 3.1-52
3.1.2.5.3 Criterion 52 - Capability for Containment Leakage Rate Testing 3.1-53
3.1.2.5.4 Criterion 53 - Provisions for Containment Testing and Inspection 3.1-53
3.1.2.5.5 Criterion 54 - Piping Systems Penetrating Containment 3.1-54
3.1.2.5.6 Criterion 55 - Reactor Coolant Pressure Boundary Penetrating Containment 3.1-55
3.1.2.5.7 Criterion 56 - Primary Containment Isolation 3.1-56
3.1.2.5.8 Criterion 57 - Closed System Isolation Valves 3.1-57
3.1.2.6 Group VI - Fuel and Reactivity Control 3.1-58
3.1.2.6.1 Criterion 60 - Control of Releases of Radioactive Materials to the Environment 3.1-58
3.1.2.6.2 Criterion 61 - Fuel Storage and Handling and Radioactivity Control 3.1-59
3.1.2.6.2.1 New Fuel Storage 3.1-60
3.1.2.6.2.2 Spent Fuel Handling and Storage 3.1-60
3.1.2.6.2.3 Radioactive Waste Systems 3.1-61

3.6.1.18.3.7 Postulated Rupture of the Reactor Water Cleanup System Piping 3.6-26
3.6.1.19 Seismic and Quality Classifications of Piping Used in the Dynamic Analysis 3.6-26
3.6.1.20 Method Used to Predict Blowdown Rates and Subcompartment Pressure Transient After a Postulated Pipe Break 3.6-27
3.6.1.20.1 Blowdown Analysis for a Postulated Pipe Break Outside the Primary Containment 3.6-27
3.6.1.20.1.1 Method of Analysis for a Postulated Pipe Break in Larger Pipes 3.6-27
3.6.1.20.1.2 Method of Analysis for a Postulated Pipe Break in Smaller Pipes 3.6-27
3.6.1.20.1.3 Blowdown Mass and Energy Release Rates for a Postulated Pipe Break in the Main Steam Line and the Reactor Feedwater Line in the Main Steam Tunnel 3.6-27
3.6.1.20.2 Subcompartment Analysis for Postulated Pipe Break Outside the Primary Containment Excluding the Main Steam Tunnel, Ventway, and Tunnel Extension 3.6-27
3.6.1.20.2.1 Method of Analysis 3.6-27
3.6.1.20.2.2 Initial Atmospheric Conditions 3.6-28
3.6.1.20.2.3 Vent Flow 3.6-29
3.6.1.20.2.4 Results of Subcompartment Analyses 3.6-29
3.6.1.20.2.5 Verification of Structural Adequacy 3.6-29
3.6.1.20.3 Subcompartment Analysis for a Postulated Pipe Break in the Main Steam Tunnel 3.6-29
3.6.1.20.3.1 General Approaches 3.6-29
3.6.1.20.3.2 Description of the Main Steam Tunnel, Ventway, and Tunnel Extension 3.6-29
3.6.1.20.3.3 Analysis for a Postulated Pipe Break in the Main Steam Tunnel 3.6-30
3.6.1.20.3.4 Analysis for a Postulated Pipe Break in the Tunnel Extension 3.6-32
3.6.1.20.3.5 Verification of Structural Adequacy 3.6-33
3.6.1.20.3.6 Turbine Building Consequences of a Postulated Pipe Break in the Steam Tunnel Extension 3.6-33
3.6.1.21 Description of Methods of Analyses to Ensure That Primary or Secondary Containment Integrity Is Not Compromised by a Postulated Passive Component Failure 3.6-34

Chapter 3

DESIGN CRITERIA - STRUCTURES, COMPONENTS, EQUIPMENT, AND SYSTEMS

TABLE OF CONTENTS (Continued)

Section — Page

3.6.2 DETERMINATION OF BREAK LOCATIONS FOR DYNAMIC EFFECTS ASSOCIATED WITH THE POSTULATED RUPTURE OF PIPING 3.6-34
3.6.2.1 Criteria Used to Define Break and Crack Location and Configuration 3.6-34
3.6.2.1.1 Postulated Pipe Break Locations in High-Energy Fluid System Piping Not in the Containment Penetration Area 3.6-36
3.6.2.1.1.1 Postulated Pipe Break Locations in ASME Section III Class I Piping Runs 3.6-36
3.6.2.1.1.2 Postulated Pipe Break Locations in ASME Section III Class 2 and 3 Piping Runs 3.6-37
3.6.2.1.1.3 Break Locations in Other Piping Runs 3.6-37
3.6.2.1.2 Postulated Pipe Break Locations in High-Energy Fluid System Piping Between Primary Containment Isolation Valves 3.6-38
3.6.2.1.2.1 Postulated Pipe Break Locations in ASME Section III Class 1 Piping Between Primary Containment Isolation Valves 3.6-38
3.6.2.1.2.2 Postulated Pipe Break Locations in ASME Section III Class 2 and 3 Piping Between Primary Containment Isolation Valves 3.6-38
3.6.2.1.2.3 Primary Containment Penetration Piping 3.6-39
3.6.2.1.3 Postulated Through Wall Leakage Crack Locations in High- and Moderate-Energy Fluid Systems 3.6-39
3.6.2.1.4 Types of Breaks and Cracks Postulated in High-Energy and Moderate-Energy Fluid System Piping 3.6-40
3.6.2.1.4.1 Breaks in High-Energy Fluid System Piping 3.6-40
3.6.2.1.4.2 Cracks in High-Energy and Moderate-Energy Fluid System Piping 3.6-41
3.6.2.1.5 Protection Criteria for the Effects of Pipe Break 3.6-42
3.6.2.2 Analytic Methods to Define Blowdown Forcing Functions and Response Models 3.6-42
3.6.2.2.1 Analytical Methods to Define Blowdown Forcing Functions 3.6-42
3.6.2.2.2 Analytical Methods to Define Response Models 3.6-45
3.6.2.2.2.1 General Description of Analytical Methods 3.6-45
3.6.2.2.2.2 Dynamic Analysis of the Effects of Pipe Rupture 3.6-45
3.6.2.2.3 Material Properties Under Dynamic Loads 3.6-49
3.6.2.2.3.1 Dynamic Yield Strength 3.6-49
3.6.2.2.3.2 Maximum Strain of Tension Members 3.6-49
3.6.2.2.3.3 Maximum Deformation of Flexural Members 3.6-50

Section — Page

3.6.2.2.3.4 Materials and Proportions of Structural Shapes 3.6-50
3.6.2.3 Dynamic Analysis Methods to Verify Integrity and Operability 3.6-50
3.6.2.3.1 Dynamic Analysis Methods for Jet Impingement Effects 3.6-50
3.6.2.3.2 Jet Impingement Effect 3.6-54
3.6.2.3.2.1 Physical Separation 3.6-54
3.6.2.3.2.2 Jet Impingement Evaluation 3.6-54
3.6.2.3.2.3 Postulated Pipe Rupture Locations Inside Containment 3.6-54
3.6.2.3.2.4 Signals From Primary Containment 3.6-55
3.6.2.3.2.5 Signals to the Primary Containment 3.6-55
3.6.2.3.2.6 Power Requirement Inside Primary Containment 3.6-55
3.6.2.3.2.7 Mechanical Engineered Safety Systems 3.6-56
3.6.2.3.2.8 Jet Impingement on Major Structures Inside Primary Containment 3.6-56
3.6.2.3.3 Pipe Whip Restraints 3.6-56
3.6.2.3.3.1 Definition of Function 3.6-56
3.6.2.3.3.2 Pipe Whip Restraint Features 3.6-57
3.6.2.3.3.3 Pipe Whip Restraint Loading 3.6-58
3.6.2.3.4 Pipe Whip Effects on Safety-Related Components 3.6-59
3.6.2.3.4.1 Pipe Displacement Effects on Components in Same Piping Run 3.6-59
3.6.2.3.4.2 Pipe Displacement Effects on Structures, Other Systems, and Components 3.6-60
3.6.2.4 Guard Pipe Assembly Design Criteria for Dual Barrier Containment 3.6-60
3.6.2.5 Implementation of Criteria for Pipe Whip and Jet Impingement Protection 3.6-61
3.6.2.5.1 Piping Systems Outside Primary Containment 3.6-61
3.6.2.5.2 Piping Systems Inside Primary Containment 3.6-61
3.6.2.5.3 System Requirements Subsequent to Postulated Pipe Rupture 3.6-62
3.6.2.5.3.1 Control Rod Insertion Capability 3.6-62
3.6.2.5.3.2 Core Cooling Requirements 3.6-62
3.6.2.5.3.3 Maximum Allowable Break Areas 3.6-62
3.6.2.5.3.4 Break Combinations 3.6-62
3.6.2.5.3.5 Required Cooling Systems 3.6-62
3.6.2.5.3.6 Containment System Integrity 3.6-63
3.6.2.5.4 System by System Description of Pipe Whip Protection 3.6-63
3.6.2.5.4.1 Main Steam System 3.6-63
3.6.2.5.4.2 Reactor Feedwater System (Inside Primary Containment) 3.6-64

DESIGN CRITERIA - STRUCTURES, COMPONENTS, EQUIPMENT, AND SYSTEMS

LIST OF TABLES

Number	Title	Page
3.2-1	Equipment Classification	3.2-9
3.2-2	Code Group Designations - Industry Codes and Standards for Mechanical Components	3.2-63
3.2-3	Summary of Safety Class Design Requirements (Minimum)	3.2-65
3.5-1	Systems Description Outside Containment	3.5-33
3.5-2	Internally Generated Missiles Outside Containment	3.5-34
3.5-3	Plant Systems Protected by Missile Barriers	3.5-41
3.5-4	Systems Description Inside Containment	3.5-42
3.5-5	Tornado Missiles	3.5-43
3.5-6	Location of and Missile Protection Provided for Fresh Air Intakes (FAI) and Exhausts (EXH)	3.5-44
3.6-1	High Energy Fluid Systems Outside Primary Containment	3.6-77
3.6-2	Moderate Energy Fluid Systems Outside Primary Containment	3.6-78
3.6-3	Design Basis Break Locations Outside Primary Containment	3.6-79
3.6-4	Resistance-Yield Displacement Values for Beams	3.6-84
3.6-5	Resistance-Yield Displacement Values for Slabs and Plates	3.6-87
3.6-6	Design Load in Areas Where Piping Failures Occur	3.6-88
3.6-7	Maximum Ductility Ratios Steel Structural Components	3.6-90
3.6-8	Dynamic Strength of Materials	3.6-91

Chapter 3

DESIGN CRITERIA - STRUCTURES, COMPONENTS, EQUIPMENT, AND SYSTEMS

LIST OF TABLES (Continued)

Number	Title	Page
3.6-9	Summary of Subcompartment Pressure Analysis	3.6-92
3.6-10	Subcompartment Analysis - Nodal Volume Data for a Postulated Pipe Break in the Main Steam Tunnel	3.6-94
3.6-11	Subcompartment Analysis - Flow Junction Data for a Postulated Pipe Break in the Main Steam Tunnel	3.6-95
3.6-12	Main Steam Tunnel Subcompartment Analysis Information for Blowout Panels C and D	3.6-96
3.6-13	Subcompartment Analysis - Nodal Volume Data for a Postulated Pipe Break in the Main Steam Tunnel Extension	3.6-97
3.6-14	Subcompartment Analysis - Flow Junction Data for a Postulated Pipe Break in the Main Steam Tunnel Extension	3.6-98
3.6-15	Piping Systems Inside Containment for Which Design Basis Pipe Breaks are Postulated	3.6-99
3.6-16	Piping Systems Containing Break Exclusion Areas Between Primary Containment Isolation Valves	3.6-101
3.7-1	Damping Coefficients	3.7-39
3.7-2	Foundation/Supporting Media for Seismic Category I Structures	3.7-40
3.7-3	Reactor Building - Seismic Analysis Natural Frequency and Natural Period	3.7-41
3.7-4	Reactor Building - Seismic Analysis Horizontal N-S Direction - OBE Acceleration (units in g x 10^{-3})	3.7-42

Chapter 3

DESIGN CRITERIA - STRUCTURES, COMPONENTS, EQUIPMENT, AND SYSTEMS

LIST OF TABLES (Continued)

Number	Title	Page
3.7-5	Reactor Building - Seismic Analysis Horizontal N-S Direction - OBE Displacement (units in ft x 10^{-4})	3.7-43
3.7-6	Reactor Building - Seismic Analysis Horizontal N-S Direction - OBE Member Shears (units in kips)	3.7-44
3.7-7	Reactor Building - Seismic Analysis Horizontal N-S Direction - OBE Member Moments (units in ft-kips x 10^{3})	3.7-45
3.7-8	Reactor Building - Seismic Analysis Horizontal N-S Direction - SSE Acceleration (units in g x 10^{-3})	3.7-48
3.7-9	Reactor Building - Seismic Analysis Horizontal N-S Direction - SSE Displacement (units in ft x 10^{-4})	3.7-49
3.7-10	Reactor Building - Seismic Analysis Horizontal N-S Direction - SSE Member Shears (units in kips)	3.7-50
3.7-11	Reactor Building - Seismic Analysis Horizontal N-S Direction - OBE Member Moments (units in ft-kips x 10^{3})	3.7-51
3.7-12	Reactor Building - Seismic Analysis Vertical Direction - OBE Acceleration (units in g x 10^{-3})	3.7-54
3.7-13	Reactor Building - Seismic Analysis Vertical Direction - OBE Displacement (units in ft x 10^{-6})	3.7-55
3.7-14	Reactor Building - Seismic Analysis Vertical Direction - SSE Acceleration (units in g x 10^{-3})	3.7-56
3.7-15	Reactor Building - Seismic Analysis Vertical Direction - SSE Displacement (units in ft x 10^{-6})	3.7-57
3.7-16	Lumped Representation of Soil-Structure Interaction	3.7-58

Chapter 3

DESIGN CRITERIA - STRUCTURES, COMPONENTS, EQUIPMENT, AND SYSTEMS

LIST OF TABLES (Continued)

Number	Title	Page
3.7-17	Dynamic Response Cycles Expected During a Seismic Event for Nuclear Steam Supply Systems and Components	3.7-60
3.7-18	Fatigue Evaluation Due to Seismic Load	3.7-61
3.7-19	Comparison of the Maximum and Allowable Seismic Loads of Reactor Pressure Vessel and Internals	3.7-62
3.8-1	Primary Containment Drywell and Pressure Suppression Chamber Principal Design	3.8-143
3.8-2	Containment Environmental Design Conditions	3.8-145
3.8-3	Primary Containment Pressure Suppression System Maximum Accident Pressure Comparison	3.8-146
3.8-4	List of Applicable Codes, Standards, Specifications, and Regulatory Guides	3.8-147
3.8-5	Load Combinations and Load Factors Concrete Internal Structures of Steel Containment	3.8-153
3.8-6	Load Combinations and Load Factors Steel Internal Structures of Steel Containment	3.8-155
3.8-7	Section Strength Limits and Section Modulus for Structural Steel Internal Structures of Steel Containment	3.8-157
3.8-8	Radwaste and Control Building Quality Class and Design Bases Criteria	3.8-158
3.8-9	Load Combinations and Load Factors Seismic Category I and Nonseismic Category I Safety-Related Concrete Structures Outside Primary Metal Containment	3.8-159

Chapter 3

DESIGN CRITERIA - STRUCTURES, COMPONENTS, EQUIPMENT, AND SYSTEMS

LIST OF TABLES (Continued)

Number	Title	Page
3.8-10	Load Combinations and Load Factors Seismic Category I and Nonseismic Category I Safety-Related Steel Structures Outside Primary Metal Containment	3.8-161
3.8-11	Seismic Category I and Nonseismic Safety-Related Steel Structures Outside Primary Metal Containment	3.8-164
3.8-12	Maximum Permissible Stresses Seismic Category I and Nonseismic Category I Safety-Related Reinforced-Concrete Structures	3.8-166
3.8-13	Primary Containment Vessel Electrical Penetrations Principal Design Parameters	3.8-167
3.8-14	Primary Containment Vessel Piping Penetrations Principal Design	3.8-168
3.9-1	Plant Events (for Nuclear Steam Supply System and Balance-of-Plant)	3.9-77
3.9-2	Loading Combination and Acceptance Criteria for ASME Code Class 1, 2, and 3 Piping and Equipment	3.9-79
3.9-2a	Reactor Pressure Vessel and Shroud Support Assembly	3.9-85
3.9-2b	Reactor Internals and Associated Equipment	3.9-89
3.9-2c	Deleted	
3.9-2d	ASME Code Class 1 Main Steam Piping and Pipe Mounted Equipment - Highest Stress Summary	3.9-95
3.9-2e	ASME Code Class 1 Recirculation Piping and Pipe Mounted Equipment - Highest Stress Summary	3.9-99

DESIGN CRITERIA - STRUCTURES, COMPONENTS, EQUIPMENT, AND SYSTEMS

3.1 CONFORMANCE WITH NRC GENERAL DESIGN CRITERIA

3.1.1 SUMMARY DESCRIPTION

This section contains an evaluation of the design bases of the Energy Northwest Nuclear Project No. 2 (Columbia Generating Station (CGS)) nuclear generating station as compared to the NRC General Design Criteria (GDC) for Nuclear Power Plants, Appendix A of 10 CFR Part 50, effective May 21, 1971, and subsequently amended on July 7, 1971. The GDC, which are divided into six groups and total 55 in number, are intended to establish minimum requirements for the design of nuclear power plants.

The GDC were not written specifically for the boiling water reactor (BWR); rather, they were intended to guide the design of all water-cooled nuclear power plants. As a result, the criteria are generic in nature and subject to interpretation. For this reason, there are some cases where conformance to a particular criterion is not directly comparable. In these cases, the conformance of plant design to the interpretation of the criterion is discussed. For each of the 55 criteria, a specific assessment of the plant design is made, and a complete list of section references are included to identify where detailed design information pertinent to each criterion is discussed.

Based on the content herein, Energy Northwest concludes that CGS is in compliance with the GDC.

3.1.2 CRITERION CONFORMANCE

3.1.2.1 Group I - Overall Requirements

3.1.2.1.1 Criterion 1 - Quality Standards and Records

> Structures, systems, and components important to safety shall be designed, fabricated, erected, and tested to quality standards commensurate with the importance of the safety functions to be performed. Where generally recognized codes and standards are used, they shall be identified and evaluated to determine their applicability, adequacy, and sufficiency and shall be supplemented or modified as necessary to assure a quality product in keeping with the required safety function. A quality assurance program shall be established and implemented in order to provide adequate assurance that these structures, systems, and components will satisfactorily perform their safety

functions. Appropriate records of the design, fabrication, erection, and testing of structures, systems, and components important to safety shall be maintained by, or under the control of, the nuclear power unit licensee throughout the life of the unit (GDC 1).

Evaluation Against Criterion 1

Structures, systems, and components important to safety are identified in Section 3.2. The quality assurance program used during the operations phase is described in EN-QA-004, Energy Northwest Operational Quality Assurance Program Description. The quality assurance program used during the design and construction of the plant was provided at the Preliminary Safety Analysis Report (PSAR) stage and has been applied to the items contained in Table 3.2-1. The intent of the quality assurance program is to ensure sound engineering in all phases of design and construction through conformity to regulatory requirements and design bases described in the license application. In addition, the program ensures adherence to specified standards of workmanship and implementation of recognized codes and standards in fabrication and construction. It also includes the observance of proper preoperational and operational testing and maintenance procedures as well as keeping appropriate records. The total quality assurance program of Energy Northwest and its principal contractors is responsive to and satisfies the quality-related requirements of 10 CFR Part 50, including Appendix B.

Structures, systems, and components are first classified in Section 3.2 with respect to their location and service and their relationship to the safety function to be performed. Recognized codes and standards are applied to the equipment to ensure a quality product in keeping with the required safety function. In cases where codes are not available or the existing code must be modified, an explanation is provided.

Documents are maintained which demonstrate that the requirements of the quality assurance program are being satisfied. This documentation shows that appropriate codes, standards, and regulatory requirements are observed, specified materials are used, correct procedures are utilized, qualified personnel are provided, and that the finished parts and components meet the applicable specifications for safe and reliable operation. These records are available so that any desired item of information is retrievable for reference. These records will be maintained in accordance with the Operational Quality Assurance Program Description.

The detailed quality assurance program developed by the applicant and its contractors satisfies the requirements of Criterion 1.

For further discussion see the following sections:

a. Principal design criteria 1.2

b. Plant description 1.2

c. Classification of structures, components, and systems 3.2

d. Quality assurance 17

3.1.2.1.2 Criterion 2 - Design Bases for Protection Against Natural Phenomena

Structures, systems, and components important to safety shall be designed to withstand the effects of natural phenomena such as earthquakes, tornadoes, hurricanes, floods, tsunami, and seiches without loss of capability to perform their safety functions. The design bases for these structures, systems, and components shall reflect: (1) appropriate consideration of the most severe of natural phenomena that have been historically reported for the site and surrounding area, with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated, (2) appropriate combinations of the effects of normal and accident conditions with the effects of the natural phenomena, and (3) the importance of the safety functions to be performed (GDC 2).

Evaluation Against Criterion 2

The design criteria adopted for structures, systems, and components considers the magnitude and the probability of occurrence of natural phenomena at the specific site. The designs are based on the most severe natural phenomena recorded for the site with an appropriate margin to account for uncertainties in the historical data. Detailed discussion of the various phenomena considered and the design criteria developed are presented in the sections listed below.

The design criteria developed meet the requirements of Criterion 2.

For further discussion, see the following sections:

a. Meteorology 2.3

b. Hydrologic engineering 2.4

c. Geology and seismology 2.5

d. Classification of structures, components, and systems 3.2

e. Wind and tornado design loadings 3.3

f. Water level (flood) design 3.4

h.	Seismic design	3.7
i.	Design of Seismic Category I structures	3.8
j.	Mechanical systems and components	3.9
k.	Seismic qualification of Category I instrumentation and electrical equipment	3.10
l.	Environmental design of mechanical and electrical equipment	3.11

3.1.2.1.3 Criterion 3 - Fire Protection

Structures, systems, and components important to safety shall be designed and located to minimize, consistent with other safety requirements, the probability and effect of fires and explosions. Noncombustible and heat resistant materials shall be used wherever practical throughout the unit, particularly in locations such as the containment and control room. Fire detection and fighting systems of appropriate capacity and capability shall be provided and designed to minimize the adverse effect of fires on structures, systems, and components important to safety. Firefighting systems shall be designed to assure that their rupture or inadvertent operation does not significantly impair the safety capability of these structures, systems, and components (GDC 3).

Evaluation Against Criterion 3

Insurer and National Fire Protection Association guidelines were used for the design of the plant.

Noncombustible and fire resistant materials are used wherever practical throughout the facility, particularly in areas containing critical portions of the plant such as containment structure, control room, and components of systems important to safety. These systems are designed and located to minimize the effects of fires or explosions on their redundant components. Facilities for the storage of combustible materials such as fuel oil are located, designed, and protected to minimize both the probability and the effects of a fire.

Equipment and facilities for detecting, annunciating, and extinguishing fires are provided to protect both plant and personnel from fire or explosion.

Administrative controls are utilized where applicable throughout the facility to minimize the probability and consequences of fires and explosions.

The fire protection system is designed such that a failure of any component of the system will not

a. Generate an accident resulting in significant release of radioactivity to the environment, or

b. Impair the ability of redundant equipment to safely shut down and isolate the reactor or limit the release of radioactivity to the environment in the event of a loss-of-coolant accident (LOCA).

For further discussion, see the following sections:

a.	Design of Seismic Category I structures	3.8
b.	Fire protection system	9.5.1, Appendix F

3.1.2.1.4 Criterion 4 - Environmental and Missile Design Bases

> Structures, systems, and components important to safety shall be designed to accommodate the effects of and to be compatible with the environmental conditions associated with normal operation, maintenance, testing, and postulated accidents, including loss-of-coolant accidents. These structures, systems, and components shall be appropriately protected against dynamic effects, including the effects of missiles, pipe whipping, and discharging fluids, that may result from equipment failures and from events and conditions outside the nuclear power unit (GDC 4).

Evaluation Against Criterion 4

Structures, systems, and components important to safety are designed to accommodate the effects of and to be compatible with the environmental conditions associated with normal operation, maintenance, testing, and postulated accidents, including LOCAs. (See Section 3.11.)

These structures, systems, and components are appropriately protected against dynamic effects including the effects of missiles, pipe whipping, and discharging fluids that may result from equipment failures.

The electrical equipment, instrumentation, and associated cables of protection and engineered safety features (ESF) system which are located inside the containment are discussed in the

sections listed below. The design requirements in terms of the time that each must survive the extreme environmental conditions following a LOCA are indicated.

The design of these structures, systems, and components meets the requirements of Criterion 4.

For further discussion, see the following sections:

3.1.2.1.5 Criterion 5 - Sharing of Structures, Systems, and Components

Structures, systems, and components important to safety shall not be shared among nuclear power units unless it can be shown that such sharing will not significantly impair their ability to perform their safety functions, including, in the event of an accident in one unit, an orderly shutdown and cooldown of the remaining units (GDC 5).

Evaluation Against Criterion 5

CGS is a single unit plant, and therefore Criterion 5 does not apply.

3.1.2.2 Group II - Protection by Multiple Fission Product Barriers

3.1.2.2.1 Criterion 10 - Reactor Design

> The reactor core and associated coolant, control, and protection systems shall be designed with appropriate margin to assure that specified acceptable fuel design limits are not exceeded during any condition of normal operation, including the effects of anticipated operational occurrences (GDC 10).

Evaluation Against Criterion 10

The reactor core components consist of fuel assemblies, control rods, in-core ion chambers, neutron sources, and related items. The mechanical design is based on conservative application of stress limits, operating experience, and experimental test results. The fuel is designed to maintain integrity over a complete range of power levels including transient conditions. The core is sized with sufficient heat transfer area and coolant flow to ensure that fuel design limits are not exceeded under normal conditions or anticipated operational occurrences.

The reactor protection system (RPS) is designed to monitor certain reactor parameters, sense abnormalities, and to scram the reactor thereby preventing fuel design limits from being exceeded. Scram trip setpoints are selected on operating experience and by the safety design basis. There is no case in which the scram trip setpoints allow the core to exceed the thermal hydraulic safety limits. Power for the RPS is supplied by two independent ride-through ac power supplies. An alternate power source is available for each bus.

An analysis and evaluation has been made of the effects on core fuel following adverse plant operating conditions. The results of abnormal operational transients are presented in Chapter 15 and show that the minimum critical power ratio (MCPR) does not fall below the transient MCPR limit, thereby satisfying the transient design basis.

The reactor core and associated coolant, control, and protection systems are designed to ensure that the specified fuel design limits are not exceeded during the conditions of normal or abnormal operation and therefore meet the requirements of Criterion 10.

For further discussion, see the following sections:

g.	Functional design of reactivity control systems	4.6
h.	Reactor coolant system and connected systems	5
i.	Reactor trip system	7.2
j.	Accident analyses	15

3.1.2.2.2 Criterion 11 - Reactor Inherent Protection

The reactor core and associated coolant systems shall be designed so that in the power operating range the net effect of the prompt inherent nuclear feedback characteristics tends to compensate for a rapid increase in reactivity (GDC 11).

Evaluation Against Criterion 11

The reactor core is designed to have a reactivity response that regulates or damps changes in power level and spatial distributions of power production to a level consistent with safe and efficient operation.

The inherent dynamic behavior of the core is characterized in terms of the fuel temperature or doppler coefficient, the moderator void coefficient, and the moderator temperature coefficient. The combined effect of these coefficients in the power range is termed the power coefficient.

Doppler reactivity feedback occurs simultaneously with a change in fuel temperature and opposes the power change that caused it; this contributes to system stability. Since the doppler reactivity opposes load changes, it is desirable to maintain a large ratio of moderator void coefficient to doppler coefficient for optimum load-following capability. The BWR has an inherently large moderator-to-doppler coefficient ratio which permits the use of the coolant flow rate for load following.

In a BWR, the moderator void coefficient is of importance during operation at power. Nuclear design requires the void coefficient inside the fuel channel to be negative. The negative void reactivity coefficient provides an inherent negative feedback during power transients. Because of the large negative moderator coefficient of reactivity, the BWR has a number of inherent advantages, such as the use of coolant flow as opposed to control rods for

load following, inherent self-flattening of the radial power distribution, ease of control, and spatial xenon stability.

The reactor is designed so that the moderator temperature coefficient is small and positive in the cold condition; however, the overall power reactivity coefficient is negative. Typically, the power coefficient at full power is about -0.04 $\Delta k/k/\Delta P/P$ at the beginning of life and about -0.3 $\Delta k/k/\Delta P/P$ at 10,000 MWd/t. These values are well within the range required for adequate damping of power and spatial xenon disturbances.

The reactor core and associated coolant system are designed so that in the power operating range prompt inherent dynamic behavior tends to compensate for any rapid increase in reactivity in accordance with Criterion 11.

For further discussion, see the following sections:

a. Principal design criteria 1.2

b. Nuclear design 4.3

c. Thermal and hydraulic design 4.4

3.1.2.2.3 Criterion 12 - Suppression of Reactor Power Oscillations

The reactor core and associated coolant, control, and protection systems shall be designed to assure that power oscillations which can result in conditions exceeding specified acceptable fuel design limits are not possible or can be reliably and readily detected and suppressed (GDC 12).

Evaluation Against Criterion 12

The reactor core is designed to ensure that no power oscillation will cause fuel design limits to be exceeded. The power reactivity coefficient is the composite simultaneous effect of the fuel temperature or doppler coefficient, moderator void coefficient, and moderator temperature coefficient to a change in power level. It is negative and well within the range required for adequate damping of power and spatial xenon disturbances. Analytical studies indicate that for large BWRs, under-damped, unacceptable power disturbance behavior could only be expected to occur with power coefficients more positive than about -0.01 $\Delta k/k/\Delta P/P$. Operating experience has shown large BWRs to be inherently stable against xenon-induced power instability. The large negative operating coefficients provide

a. Good load following with well-damped behavior and little undershoot or overshoot in the heat transfer response,

b. Load following with recirculation flow control, and

c. Strong damping of spatial power disturbances.

The RPS design provides protection from excessive fuel cladding temperatures and protects the RCPB from excessive pressures that threaten the integrity of the system. Local abnormalities are sensed, and if protection system limits are reached, corrective action is initiated through an automatic scram. Integrity of the protection system is achieved through the combination of logic arrangement, trip channel redundancy, power supply redundancy, and physical separation.

The reactor core and associated coolant, control, and protection systems are designed to suppress any power oscillations which could result in exceeding fuel design limits. These systems ensure that Criterion 12 is met.

g.	Reactor trip system	7.2
h.	Reactor manual control system instrumentation and control	7.7
i.	Accident analyses	15

3.1.2.2.4 Criterion 13 - Instrumentation and Control

Instrumentation shall be provided to monitor variables and systems over their anticipated ranges for normal operation, for anticipated operational occurrences, and for accident conditions as appropriate to assure adequate safety, including those variables and systems that can affect the fission process, the integrity of the reactor core, the reactor coolant pressure boundary, and the containment and

its associated systems. Appropriate controls shall be provided to maintain these variables and systems within prescribed operating ranges (GDC 13).

Evaluation Against Criterion 13

The fission process is monitored and controlled for all conditions from source range through power operating range. The intermediate and power ranges of the neutron monitoring system detect core conditions that threaten the overall integrity of the fuel barrier due to excess power generation and provide a signal to the RPS. Fission detectors, located in the core, are used for neutron detection. The detectors are located to provide optimum monitoring in the intermediate and power ranges.

The intermediate range monitors (IRM) measure neutron flux from the upper portion of the source range monitors (SRM) to the lower portion of the local power range monitor (LPRM) subsystem. The IRM is capable of generating a trip signal to scram the reactor.

The LPRM subsystem consists of fission chambers located throughout the core, signal conditioning equipment, and trip functions. Local power range monitor signals are also used to block rod withdrawal and to generate the necessary trip signal for reactor scram [average power range monitor (APRM)].

The RPS protects the fuel barriers and the nuclear process barrier by monitoring plant parameters and causing a reactor scram when predetermined setpoints are exceeded. Separation of the scram and normal rod control function prevents failures in the reactor manual control circuitry from affecting the scram circuitry.

To provide protection against the consequences of accidents involving the release of radioactive materials from the fuel and RCPB, the containment and reactor vessel isolation control system initiates automatic isolation of appropriate pipelines whenever monitored variables exceed preselected operational limits.

Nuclear system leakage limits are established so that appropriate action can be taken to ensure the integrity of the RCPB. Nuclear system leakage rates are classified as identified and unidentified, which corresponds respectively to the flow to the equipment drain and floor drain sumps. The permissible total leakage rate limit to these sumps is based on the makeup capabilities of various reactor component systems. Flow integrator and recorders are used to determine the leakage flow pumped from the drain sumps. The unidentified leakage rate as established in Section 5.2.5 is less than the value that has been conservatively calculated to be a minimum leakage from a crack large enough to propagate rapidly, but which still allows time for identification and corrective action before the integrity of the process barrier is threatened.

The process radiation monitoring system monitors radiation levels of various processes and provides trip signals to the containment and reactor vessel isolation control system whenever preestablished limits are exceeded.

As noted above, adequate instrumentation is provided to monitor system variables in the reactor core, RCPB, and reactor containment. Appropriate controls are provided to maintain the variables in the operating range and to initiate the necessary corrective action in the event of abnormal operational occurrence or accident. These instrumentation and controls meet the requirements of Criterion 13.

For further discussion, see the following sections:

k.	All other instrumentation systems required for safety	7.6
l.	Control systems not required for safety	7.7

3.1.2.2.5 Criterion 14 - Reactor Coolant Pressure Boundary

The reactor coolant pressure boundary shall be designed, fabricated, erected, and tested so as to have an extremely low probability of abnormal leakage, of rapidly propagating failure, and of gross rupture (GDC 14).

Evaluation Against Criterion 14

The piping and equipment pressure parts within the RCPB through the outer isolation valves are designed, fabricated, erected, and tested to provide a high degree of integrity throughout the plant lifetime. Section 3.2 classifies systems and components within the RCPB to Quality Group A Requirements. The design requirements and codes and standards applied to this quality group ensure a quality product in keeping with the safety functions to be performed.

To minimize the possibility of brittle fracture within the RCPB, the fracture toughness properties and the operating temperature of ferritic materials are controlled to ensure adequate toughness. Section 5.2.3 describes the methods used to control toughness properties. Materials are impact tested in accordance with ASME Code Section III, where applicable. Where RCPB piping penetrates the containment, the fracture toughness temperature requirements of the RCPB materials apply.

Piping and equipment pressure parts of the RCPB are assembled and erected by welding unless applicable codes permit flanged or screwed joints. Welding procedures are employed which produce welds of complete fusion and free of unacceptable defects. All welding procedures, welders, and welding machine operators used in producing pressure-containing welds are qualified in accordance with the requirements of ASME Code Section IX, for the materials to be welded. Qualification records including the results of procedure and performance qualification tests and identification symbols assigned to each welder are maintained.

Section 5.2 contains the detailed materials and examination requirements for the piping and equipment of the RCPB prior to and after its assembly and erection. Leakage testing and surveillance is accomplished as described in the evaluation against Criterion 30 of the GDC.

The design, fabrication, erection, and testing of the RCPB ensure an extremely low probability of failure or abnormal leakage, thus satisfying the requirements of Criterion 14.

For further discussion, see the following sections:

f. Reactor coolant piping 5.4.3

g. Reactor trip system 7.2

h. Accident analyses 15

3.1.2.2.6 Criterion 15 - Reactor Coolant System Design

The reactor coolant system and associated auxiliary, control, and protection systems shall be designed with sufficient margin to assure that the design conditions of the reactor coolant pressure boundary are not exceeded during any condition of normal operation, including anticipated operational occurrences (GDC 15).

Evaluation Against Criterion 15

The reactor coolant system consists of the reactor vessel and appurtenances, the reactor recirculation system, the nuclear system pressure relief system, the main steam lines, the reactor core isolation cooling (RCIC) system, and the residual heat removal (RHR) system.

These systems are designed, fabricated, erected, and tested to stringent quality requirements and appropriate codes and standards that ensure the integrity of the RCPB throughout the plant lifetime. The reactor coolant system was designed and fabricated to meet the requirements of the ASME Code Section III, as indicated in Section 5.2.1.

The auxiliary, control, and protection systems associated with the reactor coolant system act to provide sufficient margin to ensure that the design conditions of the RCPB are not exceeded during any condition of normal operation, including anticipated operational occurrences. As described in the evaluation of Criterion 13, instrumentation is provided to monitor essential variables to ensure that they are within prescribed operating limits. If the monitored variables exceed their predetermined settings, the auxiliary, control, and protection systems automatically respond to maintain the variables and systems within allowable design limits.

An example of the integrated protective action scheme, which provides sufficient margin to ensure that the design conditions of the RCPB are not exceeded, is the automatic initiation of the nuclear system pressure relief system on receipt of an overpressure signal. To accomplish overpressure protection, a number of pressure-operated relief valves are provided that can discharge steam from the nuclear system to the suppression pool. The nuclear system pressure relief system also provides for automatic depressurization of the nuclear system in the event of a LOCA in which the vessel is not depressurized by the accident. The depressurization of the nuclear system in this situation allows operation of the low-pressure emergency core cooling system (ECCS) to supply enough cooling water to adequately cool the core. In a similar manner, other auxiliary, control, and protection systems provide assurance that the design

conditions of the RCPB are not exceeded during any conditions of normal operation, including anticipated operational occurrences.

The application of appropriate codes and standards and high quality requirements to the reactor coolant system and the design features of its associated auxiliary, control, and protection systems ensure that the requirements of Criterion 15 are satisfied.

f.	Reactor vessel	5.3
g.	Reactor coolant piping	5.4
h.	Reactor trip system	7.2
i.	Accident analyses	15

3.1.2.2.7 Criterion 16 - Containment Design

> Reactor containment and associated systems shall be provided to establish an essentially leak-tight barrier against the uncontrolled release of radioactivity to the environment and to assure that the containment design conditions important to safety are not exceeded for as long as postulated accident conditions require (GDC 16).

Evaluation Against Criterion 16

An essentially leaktight barrier is provided by a steel primary containment consisting of a drywell and suppression chamber and a containment isolation system. Release of radioactivity from the primary containment to the environment is further controlled by the reactor building, which provides secondary containment, and the standby gas treatment system (SGTS). These

systems are designed to protect the public from the consequences of a LOCA, based on a postulated break of the reactor coolant piping up to and including a double-ended break of the largest reactor coolant pipe.

The primary containment, reactor building, and the associated ESF systems are designed to safely sustain all internal and external environmental conditions that may be postulated to occur during the life of the plant, including both short- and long-term effects following a LOCA.

Containment temperature and pressure following an accident are limited by the suppression pool and the RHR system.

For further discussion, see the following sections:

a.	General plant description	1.2
b.	Steel containment	3.8
c.	Containment systems	6.2
d.	Accident analyses	15

3.1.2.2.8 Criterion 17 - Electric Power Systems

An onsite electric power system and an offsite electric power system shall be provided to permit functioning of structures, systems, and components important to safety. The safety function for each system (assuming the other system is not functioning) shall be to provide sufficient capacity and capability to assure that (1) specified acceptable fuel design limits and design conditions of the reactor coolant pressure boundary are not exceeded as a result of anticipated operational occurrences and (2) the core is cooled and containment integrity and other vital functions are maintained in the event of postulated accidents.

The onsite electric power supplies, including the batteries, and the onsite electric distribution system, shall have sufficient independence, redundancy, and testability to perform their safety functions assuming a single failure.

Electric power from the transmission network to the onsite electric distribution system shall be supplied by two physically independent circuits (not necessarily on separate rights of way) designed and located so as to minimize to the extent practical the likelihood of their simultaneous failure under operating and postulated accident and environmental conditions. A switchyard common to both circuits is acceptable. Each of these circuits shall be designed to be

available in sufficient time following a loss of all onsite alternating current power supplies and the other offsite electric power circuit, to assure that specified acceptable fuel design limits and design conditions of the reactor coolant pressure boundary are not exceeded. One of these circuits shall be designed to be available to assure that core coolant, primary containment integrity, and other vital safety functions are maintained.

Provisions shall be included to minimize the probability of losing electric power from any of the remaining supplies as a result of, or coincident with, the loss of power generated by the nuclear power unit, the loss of power from the transmission network, or the loss of power from the onsite electric power supplies (GDC 17).

Evaluation Against Criterion 17

Offsite power is transmitted to the plant transformer yard by two physically independent transmission lines which approach the plant along separate rights-of-way. Offsite power is available for plant startup or shutdown utilizing the 230-kV startup transformer. This transformer has sufficient capacity to carry all plant normal loads, in addition to those ESF loads required for plant shutdown or mitigation of the consequences of an accident.

A 115-kV transmission line, located on a separate right-of-way, provides power to a backup transformer which is capable of providing power for the plant safety-related systems to mitigate the effects of an accident. This power source is automatically transferred to the plant safety-related system on loss of all other offsite power sources.

The three independent onsite ac load groups provide independence and redundancy of equipment function. They meet the safety requirements assuming a single failure since the load groups are connected to offsite power by circuits having independent routes from the Class 1E switchgear.

For each of the three ac load groups there are independent batteries that furnish dc load and control power for the corresponding divisions.

The reactor protection instrumentation is powered from two independent ride-through ac power sources.

During normal plant operation, the station auxiliary power is supplied from the main generator through the plant auxiliary transformers. On loss of power from the normal auxiliary transformers, there will be an automatic transfer to a source of offsite power from the 230-kV startup or 115-kV backup transformers. In the event of a loss of the 230-kV and 115-kV offsite power sources, three onsite diesel generator sets and redundant sets of station batteries provide the necessary ac and dc power for safe shutdown or, in the event of an accident, to

restrict the consequences to within acceptable limits. The onsite emergency ac and dc power systems contain sufficient redundancy and independence such that a single failure does not prevent the systems from performing their safety function.

The power systems as designed meet the requirements of Criterion 17.

For further discussion, see the following sections:

a.	General plant description	1.2
b.	Seismic qualification of Seismic Category I instrumentation and electrical equipment	3.10
c.	Environmental design of mechanical and electrical equipment	3.11
d.	Electric power	8

3.1.2.2.9 Criterion 18 - Inspection and Testing of Electric Power Systems

> Electric power systems important to safety shall be designed to permit appropriate periodic inspection and testing of important areas and features, such as wiring, insulation, connections, and switchboards, to assess the continuity of the systems and the condition of their components. The systems shall be designed with a capability to test periodically (1) the operability and functional performance of the components of the systems, such as onsite power sources, relays, switches, and buses, and (2) the operability of the systems as a whole and, under conditions as close to design as practical, the full operation sequence that brings the systems into operation, including operation of applicable portions of the protection system, and the transfer of power among the nuclear power unit, the offsite power system, and the onsite power system (GDC 18).

Evaluation Against Criterion 18

The engineered safety systems power supply buses and associated diesel generators are arranged for periodic inspection and testing of each diesel generator independently.

At periodic intervals when the reactor is not at power operation, tests simulating loss of power and accident signals will be initiated to demonstrate the capability of the power systems to meet the starting and loading requirements.

Periodically during plant operation each diesel generator will be manually started and loaded. The redundant (Division 1 and 2) units will be synchronized to the startup power source and

loaded. The high-pressure core spray (HPCS) (Division 3) unit will be loaded by synchronizing to the startup power source.

These tests are designed to prove the operability of the onsite power system under conditions as close to design as possible, to assess the continuity of the systems and condition of the components.

The electrical power systems are configured to provide access for appropriate periodic inspection. For further discussion, see the following sections:

a. Onsite power systems 8.3

b. Initial test program 14

3.1.2.2.10 Criterion 19 - Control Room

A control room shall be provided from which actions can be taken to operate the nuclear power unit safely under normal conditions and to maintain it in a safe condition under accident conditions, including loss-of-coolant accidents. Adequate radiation protection shall be provided to permit access and occupancy of the control room under accident conditions without personnel receiving radiation exposures in excess of 5 rem whole body, or its equivalent to any part of the body, for the duration of the accident.

Equipment at appropriate locations outside the control room shall be provided (1) with a design capability for prompt hot shutdown of the reactor, including necessary instrumentation and controls to maintain the unit in a safe condition during hot shutdown, and (2) with a potential capability for subsequent cold shutdown of the reactor through the use of suitable procedures (GDC 19).

Evaluation Against Criterion 19

A control room is provided from which the nuclear power plant can be safely operated under normal conditions and can be maintained in a safe condition following postulated accidents.

The control room contains the following equipment: controls and necessary surveillance equipment for operation of the plant functions, such as the reactor and its auxiliary systems, ESF, turbine generator, steam and power conversion systems, and station electrical distribution boards.

The control room is located in a Safety Class 3, Seismic Category I structure. Safe occupancy of the control room during abnormal conditions is ensured by the design. Adequate shielding

is provided to maintain tolerable radiation levels in the control room in the event of a design basis accident for the duration of the accident.

The control room ventilation system has redundant and spatially separated fresh air intakes and redundant equipment, radiation detectors, and smoke detectors with appropriate alarms and interlocks. Redundant systems are provided for the control room air to be recirculated through high-efficiency particulate air (HEPA) and charcoal filters during isolation of the control room from outside air.

The control room can be continuously occupied under all operating and accident conditions. In the unlikely event that the control room must be vacated and access is restricted, instrumentation and controls are provided outside the control room from which safe shutdown of the reactor can be effected.

The above demonstrates that the control room design meets the requirements of Criterion 19.

For further discussion, see the following sections:

j.	Ventilation	12.3

3.1.2.3 Group III - Protection and Reactivity Control System

3.1.2.3.1 Criterion 20 - Protection System Functions

> The protection system shall be designed (1) to initiate automatically the operation of appropriate systems including the reactivity control systems, to assure that specified acceptable fuel design limits are not exceeded as a result of anticipated operational occurrences, and (2) to sense accident conditions and to initiate the operation of systems and components important to safety (GDC 20).

Evaluation Against Criterion 20

The RPS is designed to provide timely protection against the onset and consequences of conditions that threaten the integrity of the fuel barrier and the RCPB barrier. Fuel damage is prevented by the initiation of an automatic reactor shutdown if monitored system variables exceed limits of anticipated operational occurrences. Scram trip settings are selected and verified to be far enough above or below operating levels to provide proper protection but not be subject to spurious scrams. The RPS includes the high-inertia motor generator power system, sensors, relays, bypass circuitry, and switches that signal the control rod system to scram and shut down the reactor. The scrams initiated by neutron monitoring system variables, nuclear system high pressure, turbine stop valve closure, turbine control valve fast closure, MSIV closure, and reactor vessel low water level will prevent fuel damage following abnormal operational transients. Specifically, the process parameters initiate a scram in time to prevent the core from exceeding thermal hydraulic safety limits during abnormal operational transients. In addition, protection systems are provided to sense accident conditions and initiate automatically the operation of other systems and components important to safety.

The design of the protection system satisfies the functional requirements as specified in Criterion 20.

For further discussion, see the following sections:

a.	Principal design criteria	1.2
b.	Fuel system design	4.2
c.	Functional design of reactivity control systems	4.6
d.	Main steam line isolation system	5.4.5
e.	Reactor trip system	7.2
f.	Accident analyses	15

3.1.2.3.2 Criterion 21 - Protection System Reliability and Testability

> The protection system shall be designed for high functional reliability and inservice testability commensurate with the safety functions to be performed. Redundancy and independence designed into the protection system shall be sufficient to assure that (1) no single failure results in loss of the protection function, and (2) removal from service of any component or channel does not result in loss of the required minimum redundancy unless the acceptable reliability of operation of the protection system can be otherwise demonstrated. The protection system shall be designed to permit periodic testing of its functioning when the reactor is in operation, including a capability to test channels independently to determine failures and losses of redundancy that may have occurred (GDC 21).

Evaluation Against Criterion 21

The RPS design provides assurance that, through redundancy, each channel has sufficient reliability to fulfill the single-failure criterion. No single component failure, intentional bypass maintenance operation, calibration operation, or test to verify operational availability will impair the ability of the system to perform its intended safety function. Additionally, the system design ensures that when a scram trip point is exceeded there is a high scram probability. However, should a scram not occur, other monitored components will scram the reactor if their trip points are exceeded. There is sufficient electrical and physical separation between channels and between trip logics monitoring the same variable to prevent environmental factors, electrical transients, and physical events from impairing the ability of the system to respond correctly.

The RPS includes design features that permit inservice testing. This ensures the functional reliability of the system should the monitored reactor parameter exceed the corrective action setpoint.

The RPS initiates an automatic reactor shutdown if the monitored plant variables exceed preestablished limits. This system is arranged as two separately powered trip systems. Each trip system has two trip channels. An automatic or manual trip in either or both trip channels constitutes a trip system trip. A scram results when both trip systems have tripped. The logic scheme is a one-out-of-two twice arrangement. The RPS can be tested during reactor operation. Manual scram testing is performed by operating one of the four manual scram controls. Two manual scram controls are associated with each trip system, one in each trip channel. Operating one manual scram control tests one trip channel and one trip system. The total test verifies the ability to deenergize the scram pilot valve solenoids. Indicating lights verify that the actuator contacts have opened. This capability for a thorough testing program significantly increases reliability.

Control rod drive (CRD) operability can be tested during normal reactor operation. Drive position indicator and in-core neutron detectors are used to verify control rod movement. Each control rod can be inserted one notch and then withdrawn to the original position without significantly perturbing the nuclear system. One control rod is tested at a time. Control rod drive mechanism over-travel tests demonstrate rod-to-drive coupling integrity. Hydraulic supply subsystem pressures can be observed on control room instrumentation. More importantly, the hydraulic control unit scram accumulator and the scram discharge volume level are continuously monitored.

The MSIVs may be tested during full reactor operation. Individually, they can be closed to 90% of full open position without affecting the reactor operation. If reactor power is reduced sufficiently, the isolation valves on a single main steam supply line may be fully closed. Provisions are provided to evaluate valve stem leakage during reactor shutdown. During refueling operation, valve leakage rates can be determined.

The high functional reliability, redundancy, and inservice testability of the protection system satisfy the requirements specified in Criterion 21.

For further discussion, see the following sections:

a.	Principal design criteria	1.2
b.	Functional design of reactivity control systems	4.6
c.	Main steam line isolation system	5.4.5
d.	Reactor trip system	7.2

3.1.2.3.3 Criterion 22 - Protection System Independence

> The protection system shall be designed to assure that the effects of natural phenomena, and of normal operating, maintenance, testing, and postulated accident conditions on redundant channels do not result in loss of the protection function, or shall be demonstrated to be acceptable on some other defined basis. Design techniques, such as functional diversity or diversity in component design and principles of operation, shall be used to the extent practical to prevent loss of the protection function (GDC 22).

Evaluation Against Criterion 22

The components of protection systems are designed so that the mechanical and thermal environmental conditions resulting from any emergency situation in which the components are

required to function will not interfere with the operation of that function. The safety-related wiring and cabling necessary to support the operation of the RPS, outside of enclosures, are routed within totally enclosed and grounded raceway systems. The RPS has four independent initiation channels providing input to two trip systems for redundancy. Cabling for the four channels is routed in separate raceway systems to preserve channel independence. The wires from duplicate sensors on a common process tap are run in separate wireways. The system sensors are electrically and physically separated. Only one trip actuator logic circuit from each trip system may be run in the same wireway.

The RPS is designed to permit maintenance, calibration, and testing activities while the reactor is operating without restricting plant operation or affecting system safety function completion. This is accomplished by limiting these activities to only one of the independent initiation sensors or associated logic channels at a time leaving at least two channels per monitored parameter available to respond to an accident or transient. Only a single channel per trip system is required to initiate a scram. The protection system meets the design requirements for functional and physical independence as specified in Criterion 22.

For further discussion, see the following sections:

a.	Principal design criteria	1.2
b.	Functional design of reactivity control systems	4.6
c.	Main steam line isolation system	5.4
d.	Reactor trip system	7.2

3.1.2.3.4 Criterion 23 - Protection System Failure Modes

> The protection system shall be designed to fail into a safe state or into a state demonstrated to be acceptable on some other defined basis if conditions such as disconnection of the system, loss of energy (e.g., electric power, instrument air), or postulated adverse environments (e.g., extreme heat or cold, fire, pressure, steam, water, and radiation) are experienced (GDC 23).

Evaluation Against Criterion 23

The RPS components/logic are designed to fail into a safe state (system actuation) when conditions such as loss of electrical power source or fire occur. This is accomplished by maintaining the input/output logic components and final actuated devices in a normally energized state with deenergization resulting in the completion of their intended safety functions. Additionally, RPS cables that are located outside of panels are enclosed within totally enclosed and grounded raceways providing additional fail safe design.

Reactor protection system components that perform safety-related functions to mitigate a design basis event are designed to complete their intended safety functions even when exposed to adverse environmental conditions (e.g., temperature, pressure, steam, water, and radiation) postulated to occur during those events.

The failure modes of the protection system are such that it will fall into a safe state as required by Criterion 23.

For further discussion, see the following sections:

a.	Principal design criteria	1.2
b.	Environmental design of mechanical and electrical equipment	3.11
c.	Functional design of reactivity control systems	4.6
d.	Reactor trip system	7.2
e.	Electric power	8.3

3.1.2.3.5 Criterion 24 - Separation of Protection and Control Systems

> The protection system shall be separated from control systems to the extent that failure of any single control system component or channel, or failure or removal from service of any single protection system component or channel which is common to the control and protection systems leaves intact a system satisfying all reliability redundancy, and independence requirements of the protection system. Interconnection of the protection and control systems shall be limited so as to assure that safety is not significantly impaired (GDC 24).

Evaluation Against Criterion 24

There is separation between the RPS and the process control systems. Sensors, trip channels, and trip logics of the RPS are not used directly for automatic control of process systems. Therefore, failure in the controls and instrumentation of process systems cannot induce failure of any portion of the protection system. High scram reliability is designed into the RPS and hydraulic control unit for the CRD. The scram signal and mode of operation overrides all other signals.

The protection system is separated from control systems as required in Criterion 24.

For further discussion, see the following sections:

a.	Principal design criteria	1.2
b.	Functional design of reactivity control systems	4.6
c.	Reactor trip system	7.2
d.	Reactor manual control system instrumentation and controls	7.7

3.1.2.3.6 Criterion 25 - Protection System Requirements for Reactivity Control Malfunctions

The protection system shall be designed to assure that specified acceptable fuel design limits are not exceeded for any single malfunction of the reactivity control systems, such as accidental withdrawal (not ejection or dropout) of control rods (GDC 25).

Evaluation Against Criterion 25

The RPS provides protection against the onset and consequences of conditions that threaten the integrity of the fuel barrier and the RCPB. Any monitored variable exceeding the scram setpoint will initiate an automatic scram and not impair the remaining variables from being monitored. If one channel fails, the remaining portions of the RPS shall function.

The reactor manual control system is designed so that no single failure can negate the effectiveness of a reactor scram. The circuitry for the reactor manual control system is completely independent of the circuitry controlling the scram valves. This separation of the scram and normal rod control functions prevents failures in the reactor manual control circuitry from affecting the scram circuitry. Because each control rod is controlled as an individual unit, a failure that results in energizing any of the insert or withdraw solenoid valves can affect only one control rod. The effectiveness of a reactor scram is not impaired by the malfunctioning of any one control rod.

The most serious rod withdrawal errors are considered to be when the reactor is just subcritical and an out-of-sequence rod is continuously withdrawn. The rod worth minimizer would normally prevent the withdrawal of out-of-sequence rods. If such a continuous rod withdrawal were to occur, the increase in fuel temperature subsequent to scram would not be sufficient to exceed acceptable fuel design limits.

The design of the protection system ensures that specified acceptable fuel limits are not exceeded for any single malfunction of the reactivity control systems as specified in Criterion 25.

For further discussion, see the following sections:

a.	Principal design criteria	1.2
b.	Nuclear design	4.3
c.	Thermal and hydraulic design	4.4
d.	Functional design of reactivity control systems	4.6
e.	Reactor trip system	7.2
f.	Reactor manual control system instrumentation and controls	7.7
g.	Accident analyses	15

3.1.2.3.7 Criterion 26 - Reactivity Control System Redundancy and Capability

> Two independent reactivity control systems of different design principles shall be provided. One of the systems shall use control rods, preferably including a positive means for inserting the rods, and shall be capable of reliably controlling reactivity changes to assure that under conditions of normal operation, including anticipated operational occurrences, and with appropriate margin for malfunctions such as stuck rods, specified acceptable fuel design limits are not exceeded. The second reactivity control system shall be capable of reliably controlling the rate of reactivity changes resulting from planned, normal power changes (including xenon burnout) to assure acceptable fuel design limits are not exceeded. One of the systems shall be capable of holding the reactor core subcritical under cold conditions (GDC 26).

Evaluation Against Criterion 26

Two independent reactivity control systems using different design principles are provided. The normal method of reactivity control employs control rod assemblies. Positive insertion of these control rods is provided by means of the CRD hydraulic system. The control rods are capable of reliably controlling reactivity changes during normal operation (e.g., power changes, power shaping, xenon burnout, normal startup and shutdown) via operator-controlled insertions and withdrawals. The control rods are also capable of maintaining the core within acceptable fuel design limits during anticipated operational occurrences via the automatic

scram function. The unlikely occurrence of a limited number of stuck rods during a scram will not adversely affect the capability to maintain the core within fuel design limits.

The circuitry for manual insertion or withdrawal of control rods is completely independent of the circuitry for reactor scram. This separation of the scram and normal rod control functions prevents failures in the reactor manual control circuitry from affecting the scram circuitry. Two sources of scram energy (accumulator pressure and reactor vessel pressure) provide needed scram performance over the entire range of reactor pressure, i.e., from operating conditions to cold shutdown. The design of the control rod system includes appropriate margin for malfunctions such as stuck rods. Control rod withdrawal sequences and patterns are selected prior to operation to achieve optimum core performance, and simultaneously, low individual rod worths. The operating procedures to accomplish such patterns are supplemented by the rod worth minimizer, which prevents rod withdrawals yielding a rod worth greater than permitted by the preselected rod withdrawal pattern. Because of the carefully planned and regulated rod withdrawal sequence, prompt shutdown of the reactor can be achieved with the insertion of a small number of the many independent control rods. In the event that a reactor scram is necessary, the unlikely occurrence of a limited number of stuck rods will not hinder the capability of the control rod system to render the core subcritical.

The second independent reactivity control system is provided by the reactor coolant recirculation system. By varying reactor flow, it is possible to affect the type of reactivity changes necessary for planned, normal power changes (including xenon burnout). In the event that reactor flow is suddenly increased to its maximum value (pump runout), the core will not exceed fuel design limits because the power flow map defines the allowable initial operating states such that the pump runout will not violate these limits.

The control rod system is capable of holding the reactor core subcritical under cold conditions, even when the control rod of highest worth is assumed to be stuck in the fully withdrawn position. This shutdown capability of the control rod system is made possible by designing the fuel with burnable poison (Gd_2O_3) to control the high reactivity of fresh fuel. In addition, the standby liquid control system is available to add soluble boron to the core and render it subcritical, as discussed in Section 3.1.2.3.8.

The redundancy and capabilities of the reactivity control systems for the BWR satisfy the requirements of Criterion 26.

For further discussion, see the following sections:

a.	Principal design criteria	1.2
b.	Reactivity control system	4.3
c.	Functional design reactivity control system	4.6

d.	Reactor trip system	7.2
e.	Process computer system instrumentation and controls (rod worth minimizer)	7.7
f.	Reactor manual control system instrumentation and controls	7.7
g.	Reactor recirculation system	5.4

3.1.2.3.8 Criterion 27 - Combined Reactivity Control Systems Capability

The reactivity control systems shall be designed to have a combined capability, in conjunction with poison addition by the emergency core cooling system, of reliably controlling reactivity changes to assure that under postulated accident conditions and with appropriate margin for stuck rods, the capability to cool the core is maintained (GDC 27).

Evaluation Against Criterion 27

There is no credible event applicable to the BWR which requires combined capability of the control rod system and poison additions by the emergency core cooling network. The BWR design is capable of maintaining the reactor core subcritical, including allowance for a stuck rod, without addition of any poison to the reactor coolant. The primary reactivity control system for the BWR during postulated accident conditions is the control rod system. Abnormalities are sensed and, if protection system limits are reached, corrective action is initiated through automatic insertion of control rods. High integrity of the protection system is achieved through the combination of logic arrangement, actuator redundancy, power supply redundancy, and physical separation. High reliability of reactor scram is further achieved by separation of scram and manual control circuitry, individual control units for each control rod, and fail-safe design features built into the rod drive system. Response by the RPS is prompt and the total scram time is short.

In the event that more than one control rod fails to insert, and the core cannot be maintained in a subcritical condition by control rods alone as the reactor is cooled down subsequent to initial shutdown, the standby liquid control (SLC) system will be actuated to insert soluble boron into the reactor core. The SLC system has sufficient capacity to ensure that the reactor can always be maintained subcritical; and hence, only decay heat will be generated by the core which can be removed by the RHR system, thereby ensuring that the core will always be coolable.

The design of the reactivity control system ensures reliable control of reactivity under postulated accident conditions with appropriate margin for stuck rods. The capability to cool is maintained under all postulated accident conditions; thus, Criterion 27 is satisfied.

For further discussion, see the following sections:

a.	Principal design criteria	1.2
b.	Reactivity control system	4.3
c.	Nuclear design	4.3
d.	Thermal and hydraulic design	4.4
e.	Functional design of reactivity control system	4.6
f.	Reactor trip system	7.2
g.	Reactor manual control system	7.7
h.	Process computer system instrumentation and controls (rod worth minimizer)	7.7
i.	Standby liquid control system	9.3.5
j.	Accident analyses	15

3.1.2.3.9 Criterion 28 - Reactivity Limits

The reactivity control systems shall be designed with appropriate limits on the potential amount and rate of reactivity increase to assure that the effects of postulated reactivity accidents can neither (1) result in damage to the reactor coolant pressure boundary greater than limited local yielding nor (2) sufficiently disturb the core, its support structures, or other reactor pressure vessel internals to impair significantly the capability to cool the core. These postulated reactivity accidents shall include consideration of rod ejection (unless prevented by positive means), rod dropout, steam line rupture, changes in reactor coolant temperature and pressure, and cold water addition (GDC 28).

Evaluation Against Criterion 28

The control rod system design incorporates appropriate limits on the amount and rate of reactivity increase. Control rod withdrawal sequences and patterns are selected to achieve

optimum core performance and low individual rod worths. The rod worth minimizer prevents withdrawal other than by the preselected rod withdrawal pattern. The rod worth minimizer function assists the operator with an effective backup control rod monitoring routine that enforces adherence to established startup, shutdown, and low power level operations control rod procedures.

The control rod mechanical design incorporates a hydraulic velocity limiter in the control rod which prevents rapid rod ejection. This protects against a high reactivity insertion rate by limiting the control rod velocity to less than 5 ft/sec. Normal rod movement is limited to 6 in. increments and the rod withdrawal rate is limited through the hydraulic valve to 3 in./sec.

The accident analyses (Chapter 15) evaluates postulated reactivity accidents as well as abnormal operational transients in detail. Analyses are included for rod dropout, steam line rupture, changes in reactor coolant temperature and pressure, and cold water addition. The initial conditions, assumptions, calculational models, sequences of events, and anticipated results of each postulated occurrence are covered in detail. The results of these analyses indicate that none of the postulated reactivity transients or accidents would result in damage to the RCPB. In addition, the integrity of the core, its support structures or other reactor pressure vessel (RPV) internals, are maintained so that the capability to cool the core is not impaired for any of the postulated reactivity accidents described in the accident analyses.

The design features of the reactivity control system, which limit the potential amount and rate of reactivity increase, ensure that Criterion 28 is satisfied for all postulated reactivity accidents.

3.1.2.3.10 Criterion 29 - Protection Against Anticipated Operational Occurrences

The protection and reactivity control system shall be designed to assure an extremely high probability of accomplishing their safety functions in the event of anticipated operational occurrences (GDC 29).

Evaluation Against Criterion 29

The high functional reliability of the protection and reactivity control system is achieved through the combination of logic arrangements, redundancy, physical and electrical independence, functional separation, fail-safe design, and inservice testability. These design features are discussed in detail in Criteria 21, 22, 23, 24, and 26.

An extremely high reliability of timely response to anticipated operational occurrences is maintained by a thorough program of inservice testing and surveillance. Components important to safety such as CRDs and MSIVs are tested during normal operation. The capability for inservice testing ensures the high functional reliability of protection and reactivity control systems should a reactor variable exceed the corrective action setpoint.

The capabilities of the protection and reactivity control systems to perform their safety functions in the event of anticipated operational occurrences are satisfied in agreement with the requirements of Criterion 29.

For further discussion, see the following sections:

a.	Principal design criteria	1.2
b.	Reactivity control system	4.6
c.	MSIV system	5.4.5
d.	Reactor trip system	7.2

3.1.2.4 Group IV - Fluid Systems

3.1.2.4.1 Criterion 30 - Quality of Reactor Coolant Pressure Boundary

> Components which are part of the reactor coolant pressure boundary shall be designed, fabricated, erected, and tested to the highest quality standards practical. Means shall be provided for detecting and, to the extent practical, identifying the location of the source of reactor coolant leakage (GDC 30).

Evaluation Against Criterion 30

By utilizing conservative design practices and detailed quality control procedures, the pressure retaining components of the RCPB are designed and fabricated to retain their integrity during normal and postulated accident conditions. Accordingly, components that compose the RCPB are designed, fabricated, erected, and tested in accordance with recognized industry codes and standards listed in Table 3.2-1 and Chapter 5. Further, product and process quality planning is provided to ensure conformance with the applicable codes and standards and to retain appropriate documented evidence verifying compliance. Because the subject matter of this criterion deals with aspects of the RCPB, further discussion on this subject is treated in the response to Criterion 14, Reactor Coolant Pressure Boundary.

Means are provided for detecting reactor coolant leakage. The leak detection system consists of sensors and instruments to detect, annunciate, and in some cases, isolate the RCPB from potential hazardous leaks before predetermined limits are exceeded. Small leaks are detected by temperature and pressure changes, increased frequency of sump pump operation, and by measuring fission product concentration. In addition to these means of detection, large leaks are detected by changes in flow rates in process lines and changes in reactor water level. The allowable leakage rates have been based on the predicted and experimentally determined behavior of cracks in pipes, the ability to make up coolant system leakage, the normally expected background leakage due to equipment design, and the detection capability of the various sensors and instruments. The total leakage rate limit is established so that in the absence of normal ac power with loss of feedwater supply, makeup capabilities are provided by the RCIC system. While the leak detection system provides protection from small leaks, the ECCS network provides protection for the complete range of discharges from ruptured pipes. Thus, protection is provided for the full spectrum of possible discharges.

The RCPB and leak detection system are designed to meet the requirements of Criterion 30.

3.1.2.4.2 Criterion 31 - Fracture Prevention of Reactor Coolant Pressure Boundary

The reactor coolant pressure boundary shall be designed with sufficient margin to assure that when stressed under operating, maintenance, testing, and postulated accident conditions (1) the boundary behaves in a nonbrittle manner; and (2) the probability of rapidly propagating fracture is minimized. The design shall reflect consideration of service temperatures and other conditions of the boundary material under operating, maintenance, testing, and postulated accident conditions and the uncertainties in determining (1) material properties, (2) the effects of irradiation on material properties, (3) residual, steady-state and transient stresses, and (4) size of flaws (GDC 31).

Evaluation Against Criterion 31

Brittle fracture control of pressure-retaining ferritic materials is provided to ensure protection against nonductile fracture. To minimize the possibility of brittle fracture failure of the RPV, the RPV was designed to meet the requirements of ASME Code Section III.

The nil-ductility transition (NDT) temperature is defined as the temperature below which ferritic steel breaks in a brittle rather than ductile manner. The NDT temperature increases as a function of neutron exposure at integrated neutron exposures greater than about 1 x 10^{17} nvt with neutron of energies in excess of 1 MeV.

The reactor assembly design provides an annular space from the outermost fuel assemblies to the inner surface of the reactor vessel that serves to attenuate the fast neutron flux incident up on the reactor vessel wall. This annular volume contains the core shroud, jet pump assemblies, and reactor coolant. Assuming plant operation at rated power and availability of 100% for the plant life time, the neutron fluence at the inner surface of the vessel causes a slight shift in the transition temperature. Expected shifts in transition temperature during design life as a result of environmental conditions, such as neutron flux, are considered in the design. Operational limitations assume that NDT temperature shifts are accounted for in the reactor operation. The Technical Specifications describe the mechanism for incorporating temperature shifts caused by the neutron flux.

The RCPB is designed, maintained, and tested such that adequate assurance is provided that the boundary will behave in a nonbrittle manner throughout the life of the plant. Therefore, the RCPB is in conformance with Criterion 31.

For further discussion, see the following sections:

a. Design of structures, components, equipment, and systems 3

b. Integrity of RCPB 5.2

c. Reactor vessel 5.3

3.1.2.4.3 Criterion 32 - Inspection of Reactor Coolant Pressure Boundary

Components which are part of the reactor coolant pressure boundary shall be designed to permit (1) periodic inspection and testing of important areas and features to assess their structural and leaktight integrity, and (2) appropriate material surveillance program for the reactor vessel (GDC 32).

Evaluation Against Criterion 32

The RPV design includes provisions for inservice inspection. Removable plugs in the sacrificial shield and/or removable panels in the insulation provide access for examination of the vessel and its appurtenances. Also, removable insulation is provided on the reactor coolant system safety/relief valves, recirculation system, and on the main steam feedwater systems extending out to and including the first isolation valve outside containment. Inspection of the

RCPB is in accordance with the ASME Code Section XI. Section 5.2.4 defines the Inservice Inspection Program Plan, access provisions, and areas of restricted access.

Vessel material surveillance capsules are located at the 30° and 120°azimuth locations in the vessel adjacent to the wall. Specimens of the base metal, weld metal, and heat-affected zone metal are located in each capsule.

The plant testing and inspection program ensures that the requirements of Criterion 32 will be met.

For further discussion, see the following sections:

a.	Design of structures, components, equipment, and systems	3
b.	Inservice inspection and testing of RCPB	5.2.4
c.	Reactor vessel	5.3
d.	Component and subsystem design	5.4

3.1.2.4.4 Criterion 33 - Reactor Coolant Makeup

> A system to supply reactor coolant makeup for protection against small breaks in the reactor coolant pressure boundary shall be provided. The system safety function shall be to assure that specified acceptable fuel design limits are not exceeded as a result of reactor coolant loss due to leakage from the reactor coolant pressure boundary and rupture of small piping or other small components which are part of the boundary. The system shall be designed to assure that for onsite electric power system operation (assuming offsite power is not available) and for offsite electric power system operation (assuming onsite power is not available) the system safety function can be accomplished using the piping, pumps, and valves used to maintain coolant inventory during normal reactor operation (GDC 33).

Evaluation Against Criterion 33

Means are provided for detecting reactor coolant leakage. The leak detection system consists of sensors and instruments to detect, annunciate, and in some cases isolate the RCPB from potential hazardous leaks before predetermined limits are exceeded. Small leaks are detected by temperature and pressure changes, increased frequency of sump pump operation, and by measuring fission product concentration. In addition to these means of detection, large leaks are detected by changes in flow rates in process lines and changes in reactor water level. The allowable leakage rates have been based on predicted and experimentally determined behavior

of cracks in pipes, the ability to make up coolant system leakage, the normally expected background leakage due to equipment design, and the detection capability of the various sensors and instruments. The total leakage rate limit is established so that in the absence of normal ac power concomitant with a loss of feedwater supply, makeup capabilities are provided by the RCIC system.

The plant is designed to provide ample reactor coolant makeup for protection against small leaks in the RCPB for anticipated operational occurrences and postulated accident conditions. The design of these systems meets the requirements of Criterion 33.

For further discussion, see the following sections:

a.	Detection of leakage through RCPB	5.2.5
b.	RCIC system	5.4.6
c.	ECCS	6.3
d.	Instrumentation and controls	7
e.	Electric power	8

3.1.2.4.5 Criterion 34 - Residual Heat Removal

A system to remove residual heat shall be provided. The system safety function shall be to transfer fission product decay heat and other residual heat from the reactor core at a rate such that specified acceptable fuel design limits and the design conditions of the reactor coolant pressure boundary are not exceeded.

Suitable redundancy in components and features, and suitable interconnections, leak detection, and isolation capabilities shall be provided to assure that for onsite electric power system operation (assuming offsite power is not available) and for offsite electric power system operation (assuming onsite power is not available) the system safety function can be accomplished, assuming a single failure (GDC 34).

Evaluation Against Criterion 34

The RHR system provides the means to remove decay heat and residual heat from the nuclear system so that refueling and nuclear system servicing can be performed.

The major equipment of the RHR system consists of heat exchangers cooled by the service water system and main system pumps. The equipment is connected by associated valves and piping, and the controls and instrumentation are provided for proper system operation.

The RHR system consists of two modes of operation that provide the shutdown cooling function. One mode, the normal Shutdown Cooling Mode, is the preferred operational mode. Although preferred, this mode of RHR does not meet the redundancy/single failure requirements of IEEE 279 and 10 CFR 50 Appendix A, GDC 34. As a result, a second shutdown cooling mode, the Alternate Shutdown Cooling Mode, is available and is the shutdown cooling mode credited to meet the requirements of IEEE 279 and GDC 34. This mode is safety related, Quality Class 1, Seismic Category 1, redundant and single failure proof. Since the normal Shutdown Cooling Mode of RHR is preferred for CGS, the components required for the operation of this mode are maintained as safety related, Quality Class 1. Refer to Section 5.4.7 for a complete discussion of the shutdown cooling modes of RHR.

Both normal ac power and the auxiliary onsite power system provide adequate power to operate all the auxiliary loads necessary for plant operation. The power sources for the plant auxiliary power system are sufficient in number and of such electrical and physical independence that no single probable event could interrupt all auxiliary power at one time.

The plant auxiliary buses which supply power to ESF, RPS, and auxiliaries required for safe shutdown are connected by appropriate switching to the standby diesel generators.

Each power source, up to the connection to the auxiliary power buses, is capable of complete and rapid isolation from any other source.

Loads important to plant operation and safety are split and diversified between switchgear sections, and means are provided for detection and isolation of system faults.

The plant layout is designed to physically separate essential bus sections, standby diesel generators, switchgear, interconnections, feeders, power centers, motor control centers, and other system components.

Standby diesel generators are provided to supply electrical power from within the plant that is not dependent on external sources. The standby generators produce ac power at a voltage and frequency compatible with the normal bus requirements for essential equipment within the plant. Each of the diesel generators has sufficient capacity to start and carry the essential loads it is expected to drive.

The RHR system is adequate to remove residual heat from the reactor core to ensure that fuel and RCPB design limits are not exceeded. Redundant reactor coolant circulation paths are available to and from the vessel and RHR system. Redundant onsite electric power systems

are provided. The design of the RHR system, including its power supply, meets the requirements of Criterion 34.

For further discussion see the following sections:

a.	RHR system	5.4
b.	ECCS	6.3
c.	ESF systems	7.3
d.	Auxiliary power system	8.3
e.	Water systems	9.2
f.	Accident analyses	15

3.1.2.4.6 Criterion 35 - Emergency Core Cooling

A system to provide abundant emergency core cooling shall be provided. The system safety function shall be to transfer heat from the reactor core following any loss of reactor coolant at a rate such that (1) fuel and clad damage that could interfere with continued effective core cooling is prevented, and (2) clad metal-water reaction is limited to negligible amounts.

Suitable redundancy in components and features, and suitable interconnections, leak detection, isolation, and containment capabilities shall be provided to assure that for onsite electric power system operation (assuming offsite power is not available) and for offsite electric power system operation (assuming onsite power is not available) the system safety function can be accomplished, assuming a single failure (GDC 35).

Evaluation Against Criterion 35

The ECCS, consists of the following:

a. High-pressure core spray system (HPCS),

b. Automatic depressurization system (ADS),

c. Low-pressure core spray (LPCS) system, and

d. Low-pressure coolant injection (LPCI) (an operating mode of the RHR system).

The ECCS are designed to limit fuel cladding temperature over the complete spectrum of possible break sizes in the RCPB including a complete and sudden circumferential rupture of the largest pipe connected to the reactor vessel.

The HPCS system consists of a single motor-driven pump, system piping, valves, controls, and instrumentation. The HPCS system is provided to ensure that the reactor core is adequately cooled to prevent excessive fuel clad temperatures for breaks in the nuclear system that do not result in rapid depressurization of the reactor vessel. The HPCS continues to operate when reactor vessel pressure is below the pressure at which LPCI operation or LPCS operation maintains core cooling. A source of water is available from either the condensate storage tank or the suppression pool.

The automatic depressurization system functions to reduce the reactor pressure so that flow from LPCI and the LPCS enters the reactor vessel in time to cool the core and prevent excessive fuel clad temperature. The ADS uses several of the main steam safety/relief valves (MSRVs) to relieve the high pressure steam to the suppression pool.

The LPCS system consists of (a) a centrifugal pump that can be powered by normal auxiliary power or the standby ac power system, (b) a spray sparger in the reactor vessel, above the core (separate from the HPCS sparger), (c) piping and valves to convey water from the suppression pool to the sparger, and (d) associated controls and instrumentation. In case of low water level in the reactor vessel or high pressure in the drywell, the LPCS automatically sprays water onto the top of the fuel assemblies in time and at a sufficient flow rate to cool the core and prevent excessive fuel temperature. The LPCI system starts from the same signals which initiate the LPCS system and operate independently to achieve the same objective by flooding the reactor vessel.

In case of low water level in the reactor or high pressure in the drywell, the LPCI mode of operation of the RHR system pumps water into the reactor vessel in time to flood the core and prevent excessive fuel temperature. Protection provided by LPCI extends to a small break where the ADS has operated to lower the reactor vessel pressure.

Results of the performance of the ECCS for the entire spectrum of liquid line breaks are discussed in Section 6.3. Peak cladding temperatures are well below the 2200°F design basis.

Also provided in Section 6.3.3 is an analysis to show that the ECCS conform to 10 CFR Part 50, Appendix K. This analysis shows complete compliance with the Final Acceptance Criteria with the following results:

a. Peak clad temperatures are well below the 2200°F NRC acceptability limit,

b. The amount of fuel cladding reacting with steam is nearly an order of magnitude below the 1% acceptability limit,

c. The clad temperature transient is terminated while core geometry is still amenable to cooling, and

d. The core temperature is reduced and the decay heat can be removed for an extended period of time.

The redundancy and capability of the onsite electrical power systems for the ECCS are represented in the evaluation against Criterion 34.

The ECCS provided are adequate to prevent fuel and clad damage that could interfere with effective core cooling and limit clad metal-water reaction to a negligible amount. The design of the ECCS, including their power supply, meets the requirements of Criterion 35.

For further discussion, see the following sections:

a.	RHR system	5.4.7
b.	ECCS	6.3
c.	Onsite power systems	8.3
d.	Water systems	9.2
e.	Accident analyses	15

3.1.2.4.7 Criterion 36 - Inspection of Emergency Core Cooling System

The emergency core cooling system shall be designed to permit appropriate periodic inspection of important components, such as spray rings in the reactor pressure vessel, water injection nozzles, and piping, to assure the integrity and capability of the system (GDC 36).

Evaluation Against Criterion 36

The ECCS discussed in Criterion 36 include inservice inspection considerations. The spray spargers within the vessel are accessible for inspection during each refueling outage. Removable plugs in the reactor shield and/or panels in the insulation provide access for examination of nozzles. Removable insulation is provided on the ECCS piping out to and including the first isolation valve outside the drywell. Inspection of the ECCS is in accordance

with the intent of Section XI of the ASME Code. Sections 5.2.4 and 6.6 define the Inservice Inspection Program Plan, access provisions, and areas of restricted access.

During plant operations, the pumps, valves, piping, instrumentation, wiring, and other components outside the primary containment can be visually inspected at any time. Components inside the primary containment can be inspected when the primary containment is open for access. When the reactor vessel is open, for refueling or other purposes, the spargers and other internals can be inspected. Portions of the ECCS which are part of the RCPB are designed to specifications for inservice inspection to detect defects which might affect the cooling performance. Particular attention will be given to the reactor nozzles, core spray, and feedwater spargers. The design of the reactor vessel and internals and the plant testing and inspection program ensure that the requirements of Criterion 36 are met.

For further discussion, see the following sections:

a.	Reactor pressure vessel internals	3.9.5
b.	Inservice inspection and testing of RCPB	5.2.4
c.	Reactor vessel	5.3
d.	ECCS	6.3
e.	Inservice inspection of Class 2 and 3 components	6.6

3.1.2.4.8 Criterion 37 - Testing of Emergency Core Cooling System

> The emergency core cooling system shall be designed to permit appropriate periodic pressure and functional testing to assure (1) the structural and leaktight integrity of its components, (2) the operability and performance of the active components of the system, and (3) the operability of the system as a whole and, under conditions as close to design as practical, the performance of the full operational sequence that brings the system into operation, including operation of applicable portions of the protection system, the transfer between normal and emergency power sources, and the operation of the associated cooling water system (GDC 37).

Evaluation Against Criterion 37

The ECCS consists of the HPCS system, ADS, the LPCI mode of the RHR system, and LPCS system. Each of these systems is provided with test connections and isolation valves to permit periodic pressure testing to ensure the structural and leaktight integrity of its components.

The HPCS, LPCS, LPCI systems, and the ADS are designed to permit periodic testing to ensure the operability and performance of the active components of each system.

The pumps and valves of these systems are tested and flow rate tests conducted periodically to verify operability in accordance with the CGS Inservice Testing Program Plan and Technical Specifications. Flow rate tests are conducted on HPCS, LPCS, and LPCI systems.

The ECCS are tested under conditions as close to design as practical to verify the performance of the full operational sequence that brings each system into operation, in accordance with the Technical Specifications surveillance requirements. The operation of the associated cooling water systems is discussed in the evaluation of Criterion 46. The design of the ECCS meets the requirements of Criterion 37.

For further discussion, see the following sections:

a.	Overpressurization protection	5.2.2
b.	Tests and inspections	6.3.4
c.	ESF systems	7.3
d.	Electric power	8

3.1.2.4.9 Criterion 38 - Containment Heat Removal

> A system to remove heat from the reactor containment shall be provided. The system safety function shall be to reduce rapidly, consistent with the functioning of other associated systems, the containment pressure and temperature following any loss-of-coolant accident and maintain them at acceptably low levels.
>
> Suitable redundancy in components and features, and suitable interconnections, leak detection, isolation, and containment capabilities shall be provided to assure that for onsite electrical power system operation (assuming offsite power is not available) and for offsite electrical power system operation (assuming onsite power is not available) the system safety function can be accomplished, assuming a single failure (GDC 38).

Evaluation Against Criterion 38

In the event of a LOCA within the drywell, the pressure suppression system will rapidly condense the steam to prevent overpressure. An increase in pressure in the drywell from a leak in the RCPB is relieved below the surface of the suppression pool and the steam portion of the gases so vented are condensed by contact with the suppression pool water. Cooling

systems remove heat from the core and from the water in the suppression pool during accident conditions and thus provide continuous cooling of the drywell.

The ECCS provides core cooling in the event of a LOCA. Low water level in the reactor vessel or high pressure in the drywell will initiate the ECCS to prevent excessive fuel temperature. Sufficient water is provided in the suppression pool to accommodate the initial energy which can be released from the postulated pipe failure.

The containment heat removal function is accomplished by the RHR system. Following a LOCA, one or both of the following operating modes of the RHR system would be initiated:

a. Containment spray - condenses steam within the containment, and

b. Suppression pool cooling - limits the temperature within the containment by removing heat from the suppression pool water by way of the RHR heat exchangers. Either or both redundant RHR heat exchangers can be manually activated.

The redundancy and capability of the offsite and onsite electrical power systems for the RHR system are presented in the evaluation against Criterion 34.

For further discussion, see the following sections:

a.	RHR system	5.4.7
b.	Containment systems	6.2
c.	ECCS	6.3
d.	ESF systems	7.3
e.	Electric power	8
f.	Standby service water system	9.2.7
g.	Accident analyses	15

3.1.2.4.10 Criterion 39 - Inspection of Containment Heat Removal System

The containment heat removal system shall be designed to permit appropriate periodic inspection of important components, such as the torus, sumps, spray nozzles, and piping to assure the integrity and capability of the system (GDC 39).

Evaluation Against Criterion 39

Provisions are made to facilitate periodic inspections of active components and other important equipment of the drywell pressure reducing systems. During plant operations, the pumps, valves, piping, instrumentation, wiring, and other components outside the drywell can be visually inspected at any time and will be inspected periodically. The testing frequencies of most components will be correlated with the component inspection.

The suppression pool is designed to permit periodic inspection. The containment heat removal system is designed to permit periodic inspection of major components. This design meets the requirements of Criterion 39.

For further discussion, see the following sections:

a.	RHR system	5.4.7
b.	Containment systems	6.2
c.	ECCS	6.3
d.	ESF systems	7.3
e.	Standby service water system	9.2.7

3.1.2.4.11 Criterion 40 - Testing of Containment Heat Removal System

> The containment heat removal system shall be designed to permit appropriate periodic pressure and functional testing to assure (1) the structural and leaktight integrity of its components, (2) the operability and performance of the active components of the systems, and (3) the operability of the system as a whole, and under conditions as close to the design as practical, the performance of the full operational sequence that brings the system into operation, including operation of applicable portions of the protection system, the transfer between normal and emergency power sources, and the operation of the associated cooling water system (GDC 40).

Evaluation Against Criterion 40

The containment heat removal function is accomplished by the suppression pool cooling mode of the RHR system.

The RHR system is provided with sufficient test connections and isolation valves to permit periodic pressure testing. The pumps and valves of the RHR system are operated periodically to verify operability in accordance with the Inservice Testing Program Plan. The suppression pool cooling mode is not automatically initiated, and the operation of the components of this system is periodically verified. The operation of associated cooling water systems is discussed in the response to Criterion 46. It is concluded that the requirements of Criterion 40 are met.

For further discussion see the following sections:

a.	RHR system	5.4.7
b.	ECCS	6.3
c.	Electric power	8

3.1.2.4.12 Criterion 41 - Containment Atmosphere Cleanup

> Systems to control fission products, hydrogen, oxygen, and other substances which may be released into the reactor containment shall be provided as necessary to reduce, consistent with the functioning of other associated systems, the concentration and quantity of fission products released to the environment following postulated accidents, and to control the concentration of hydrogen or oxygen and other substances in the containment atmosphere following postulated accidents to assure that containment integrity is maintained.
>
> Each system shall have suitable redundancy in components and features, and suitable interconnections, leak detection, isolation, and containment capabilities to assure that for onsite electric power system operation (assuming offsite power is not available) and for offsite electric power system operation (assuming onsite power is not available) its safety can be accomplished, assuming a single failure (GDC 41).

Evaluation Against Criterion 41

A primary containment that provides a barrier to control the release of fission products, hydrogen, oxygen, and other substances to the atmosphere is totally enclosed within the reactor building. Following an accident the reactor building is maintained at a negative pressure with respect to atmosphere to ensure that any leakage from the primary containment does not leak to atmosphere but is retained in the reactor building. The air exhausted from the reactor building to maintain it at a negative pressure is processed through the SGTS, which contains both HEPA and charcoal filters to minimize the release of radioactivity to the environs. The primary containment atmosphere can also be purged through the standby gas treatment for

cleanup prior to entry of personnel. The SGTS is composed of two fully redundant trains of filters and fans, with all active components powered from the emergency diesel buses.

The above described systems meet the requirements of Criterion 41.

For further discussion see the following sections:

a.	Principal design criteria	1.2
b.	Containment functional design	6.2.1
c.	Secondary containment functional design	6.2.3
d.	Combustible gas control in containment	6.2.5
e.	Fission product removal and control systems	6.5
f.	Instrumentation and controls	7

3.1.2.4.13 Criterion 42 - Inspection of Containment Atmosphere Cleanup Systems

The containment atmosphere cleanup systems shall be designed to permit appropriate periodic inspection of important components, such as filter frames, ducts, and piping to assure the integrity and capability of the systems (GDC 42).

Evaluation Against Criterion 42

All components of the SGTS are located in the reactor building and are accessible for inspection during normal plant operation. The design of the system therefore meets the requirements of Criterion 42 (see Section 6.5).

3.1.2.4.14 Criterion 43 - Testing of Containment Atmosphere Cleanup Systems

The containment atmosphere cleanup systems shall be designed to permit appropriate periodic pressure and functional testing to assure (1) the structural and leaktight integrity of its components, (2) the operability and performance of the active components of the systems such as fans, filters, dampers, pumps, and valves, and (3) the operability of the systems as a whole and, under conditions as close to design as practical, the performance of the full operational sequence that brings the system into operation, including operation of applicable portions of the protection system, the transfer between normal and emergency power sources, and the operation of associated systems (GDC 43).

Evaluation Against Criterion 43

As discussed under the evaluation of Criterion 42, all components of the containment atmosphere cleanup system are accessible for tests and inspections during normal plant operation thereby meeting the requirements of Criterion 43. A detailed discussion of the periodic tests that will be performed to verify system operability is given in Section 6.5.

3.1.2.4.15 Criterion 44 - Cooling Water

> A system to transfer heat from structures, systems, and components important to safety, to an ultimate heat sink shall be provided. The system safety function shall be to transfer the combined heat load of these structures, systems, and components under normal operating and accident conditions.
>
> Suitable redundancy in components and features, and suitable interconnections, leak detection, and isolation capabilities shall be provided to assure that for onsite electrical power system operation (assuming offsite electrical power is not available) and for offsite electric power system operation (assuming onsite power is not available) the system safety function can be accomplished, assuming a single failure (GDC 44).

Evaluation Against Criterion 44

The safety-related cooling water system is the standby service water (SW) system, which supplies cooling for the RHR, HPCS, LPCS, fuel pool cooling and cleanup (FPC) system, and the essential HVAC systems.

The redundant SW systems are open loop systems which transfer heat from structures, systems, and safety-related components to the ultimate heat sink.

The ultimate heat sink consists of two man-made Seismic Category I spray ponds and is designed to withstand extreme natural phenomena.

The piping, valves, pumps, and heat exchangers of the SW system are designed and arranged so that the system safety function can be performed assuming a single failure. Electrical power is supplied to the system from offsite or onsite emergency power sources, with distribution arranged such that a single failure will not prevent the system from performing its safety function.

For further discussion, see the following sections:

a. Principal design criteria 1.2

b.	Classification of structures, components, and systems	3.2
c.	Wind and tornado loadings	3.3
d.	Water level (flood) design	3.4
e.	Missile protection	3.5
f.	Design of Seismic Category I structures	3.8
g.	Ultimate heat sink	9.2.5
h.	Standby service water system	9.2.7
i.	Electrical power	8

3.1.2.4.16 Criterion 45 - Inspection of Cooling Water System

The cooling water system shall be designed to permit appropriate periodic inspection of important components, such as heat exchangers and piping, to assure the integrity and capability of the system (GDC 45).

Evaluation Against Criterion 45

The SW system is designed to permit periodic inspection of important components, including pumps, strainers, heat exchangers, and isolation valves, to ensure the integrity and capability of the system.

All important components are located in accessible locations to facilitate periodic inspection during normal plant operation. Suitable manholes, handholes, inspection ports, or other design and layout features are provided for this purpose.

These features meet the requirements of Criterion 45.

For further discussion, see the following sections:

a.	Principal design criteria	1.2
b.	Inservice inspection of Class 2 and 3 components	6.6
c.	Standby service water system	9.2.7
d.	Initial test program	14

3.1.2.4.17 Criterion 46 - Testing of Cooling Water System

> The cooling water system shall be designed to permit appropriate periodic pressure and functional testing to assure (1) the structural and leaktight integrity of its components, (2) the operability and performance of the active components of the system, and (3) operability of the system as a whole and, under conditions as close to design as practical, the performance of the full operational sequence that brings the system into operation for reactor shutdown and for loss-of-coolant accidents, including operation of applicable portions of the protection system and the transfer between normal and emergency power sources (GDC 46).

Evaluation Against Criterion 46

The SW system is designed to permit system operability testing with simulation of emergency reactor shutdown or LOCA conditions and transfer between normal and emergency power sources.

For further discussion, see the following sections:

a.	Principal design criteria	1.2
b.	Standby service water system	9.2.7
c.	Electric power	8
d.	Initial test program	14

3.1.2.5 Group V - Containment (Criteria 50-57)

Although Columbia's design of containment isolation provisions for the lines penetrating containment do not satisfy the requirements of GDC 55 and 56 or 57 or the alternative acceptance criteria in Item II, Section 6.2.4 of the SRP, Columbia's design meets acceptable isolation criteria on other defined acceptance bases as provided by GDC 55 and 56.

As evidenced by Columbia's design documents, Columbia's containment design is as it was described decades ago at original licensing of the plant. Hence, the FSAR crediting of outboard check valves as GDC 55 compliant PCIVs for isolation outside containment remains valid and consistent with the staff conclusion reflected in NUREG-0892.

3.1.2.5.1 Criterion 50 - Containment Design Basis

The reactor containment structure, including access openings, penetrations, and containment heat removal system shall be designed so that the containment structure and its internal compartments can accommodate, without exceeding the design leakage rate and with sufficient margin, the calculated pressure and temperature conditions resulting from any loss-of-coolant accident. This margin shall reflect consideration of (1) the effects of potential energy sources which have not been included in the determination of the peak conditions, such as energy in steam generators and energy from metal-water and other chemical reactions that may result from degraded emergency core cooling functioning, (2) the limited experience and experimental data available for defining accident phenomena and containment responses, and (3) the conservatism of the calculational model and input parameters (GDC 50).

Evaluation Against Criterion 50

The containment structure, including access openings and penetrations, are designed to accommodate, without exceeding the design leak rate, the transient peak pressure and temperature associated with a LOCA up to and including a double-ended rupture of the largest reactor coolant pipe.

The containment structure and ESF systems have been evaluated for various combinations of energy release. The analysis accounts for system thermal energy, chemical energy, and nuclear decay heat energy.

The maximum temperature and pressure reached in the drywell and containment during the worst case accident are shown in Chapters 6 and 15 to be below the design temperature and pressure of this structure.

The cooling capacity of the containment heat removal systems is adequate to prevent overpressurization of the structure and to return the containment to near atmospheric pressure.

For further discussion, see the following sections:

a.	Classification of structures, components, and systems	3.2
b.	Wind and tornado loadings	3.3
c.	Missile protection	3.5
d.	Protection against dynamic effects associated with the postulated rupture of piping	3.6

e.	Seismic design	3.7
f.	Steel containment	3.8
g.	Containment systems	6.2
h.	Containment heat removal systems	6.2.2
i.	Accident analyses	15

3.1.2.5.2 Criterion 51 - Fracture Prevention of Containment Pressure Boundary

The reactor containment boundary shall be designed with sufficient margin to assure that under operating, maintenance, testing, and postulated accident conditions (1) its ferritic materials behave in a nonbrittle manner and (2) the probability of rapidly propagating fracture is minimized. The design shall reflect consideration of service temperatures and other conditions of the containment boundary material during operation, maintenance, testing, and postulated accident conditions, and the uncertainties in determining (1) material properties, (2) residual, steady-state, and transient stresses, and (3) size of flaws (GDC 51).

Evaluation Against Criterion 51

The containment vessel was designed, fabricated, inspected, and tested to meet the requirements of ASME Code Section III Subsection NE (1971 edition through Summer 1972 Addenda). Material for the containment was qualified by impact testing at a temperature which is at least 30°F below the minimum service temperature of +30°F. Means are provided by an auxiliary boiler to maintain the reactor building and consequently the containment temperature at a suitable level during a shutdown of the unit during cold weather.

To demonstrate that the primary containment pressure boundary meets the requirements of Criterion 51, the Class 1, Class 2, and Class MC components of the CGS containment pressure boundary were reviewed according to the fracture toughness requirements of the Summer 1977 Addenda of Section III for Class 2 components and fracture toughness data presented in NUREG-0577, "Potential for Low Fracture Toughness and Lamellar Tearing of PWR Steam Generator and Reactor Coolant Pump Supports." Based on review of the available fracture toughness data and material fabrication histories, and the use of correlations between metallurgical characteristics and material fracture toughness, it was concluded that the ferritic materials in the CGS containment pressure boundary meet the fracture toughness requirements that are specified for Class 2 components by the 1977 Addenda of Section III of the ASME Code. Compliance with these code requirements provide reasonable assurance that the CGS reactor containment pressure boundary materials will behave in a nonbrittle manner,

that the probability of rapidly propagating fracture will be minimized, and that the requirements of Criterion 51 are satisfied.

The preoperational test program and the quality assurance program ensure the integrity of the containment and its ability to meet all normal operating and accident requirements.

The containment design thus meets the requirements of Criterion 51.

For further discussion, see the following sections:

a.	Steel containment	3.8.2
b.	Reactor building ventilation system including spent fuel pool area ventilation system	9.4
c.	Initial test program	14
d.	Quality assurance	17

3.1.2.5.3 Criterion 52 - Capability for Containment Leakage Rate Testing

The reactor containment and other equipment which may be subjected to containment test conditions shall be designed so that periodic integrated leakage rate testing can be conducted at containment design pressure (GDC 52).

Evaluation Against Criterion 52

The containment system is designed and constructed and the necessary equipment is provided to permit periodic integrated leak rate tests during the plant lifetime. The testing program will be conducted in accordance with Appendix J to 10 CFR Part 50.

For further discussion, see the following sections:

a.	Leak rate tests	3.8.2
b.	Containment leakage testing	6.2.6

3.1.2.5.4 Criterion 53 - Provisions for Containment Testing and Inspection

The reactor containment shall be designed to permit (1) appropriate periodic inspection of all important areas, such as penetrations, (2) an appropriate surveillance program, and (c) periodic testing at containment design pressure of

the leaktightness of penetrations which have resilient seals and expansions bellows (GDC 53).

Evaluation Against Criterion 53

The reactor containment design permits periodic inspection of the exposed interior surfaces. It also includes provisions for periodic testing of the leaktightness of all penetrations and inserts in the reactor containment pressure boundary.

The containment design therefore meets the requirements of Criterion 53.

For further discussion, see the following sections:

a.	Steel containment	3.8.2
b.	Containment functional design	6.2.1
c.	Containment heat removal systems	6.2.2
d.	Containment leakage testing	6.2.6
e.	Inservice inspection of Class 2 and 3 components	6.6

3.1.2.5.5 Criterion 54 - Piping Systems Penetrating Containment

Piping systems penetrating primary reactor containment shall be provided with leak detection, isolation, and containment capabilities having redundancy, reliability, and performance capabilities which reflect the importance to safety of isolating these piping systems. Such piping systems shall be designed with a capability to test periodically the operability of the isolation valves and associated apparatus and to determine if valve leakage is within acceptable limits (GDC 54).

Evaluation Against Criterion 54

Piping systems penetrating containment are designed to provide the required isolation and testing capabilities. These piping systems are provided with test connections to allow periodic leak detection tests to be performed.

The ESF actuation system test circuitry provides the means for testing isolation valve operability.

Conformance with Criterion 54 is further discussed in Sections 3.1.2.5.6 (Criterion 55), 3.1.2.5.7 (Criterion 56), and 3.1.2.5.8 (Criterion 57).

3.1.2.5.6 Criterion 55 - Reactor Coolant Pressure Boundary Penetrating Containment

Each line that is part of the reactor coolant pressure boundary and that penetrates primary reactor containment shall be provided with containment isolation valves as follows, unless it can be demonstrated that the containment isolation provisions for a specific class of lines, such as instrument lines, are acceptable on some other defined basis:

(1) One locked closed isolation valve inside and one locked closed isolation valve outside containment; or

(2) One automatic isolation valve inside and one locked closed isolation valve outside containment; or

(3) One locked closed isolation valve inside and one automatic isolation valve outside containment. A simple check valve may not be used as the automatic isolation valve outside containment; or

(4) One automatic isolation valve inside and one automatic isolation valve outside containment. A simple check valve may not be used as the automatic isolation valve outside containment.

Isolation valves outside containment shall be located as close to the containment as practical and upon loss of actuating power, automatic isolation valves shall be designed to take the position that provides greater safety.

Other appropriate requirements to minimize the probability or consequences of an accidental rupture of these lines or of lines connected to them shall be provided as necessary to assure adequate safety. Determination of the appropriateness of these requirements, such as higher quality in design, fabrication, and testing, additional provisions for inservice inspection, protection against more severe natural phenomena, and additional isolation valves and containment, shall include consideration of the population density, use characteristics, and physical characteristics of the site environs (GDC 55).

Evaluation Against Criterion 55

The RCPB [as defined in 10 CFR Part 50, Section 50.2 (v)] consists of the RPV, pressure retaining appurtenances attached to the vessel, valves, and pipes which extend from the RPV up to and including the outermost isolation valve. The RCPB lines which penetrate the

containment have isolation valves capable of isolating the containment to preclude any significant releases of radioactivity. Lines which do not penetrate the containment but which form a portion of the RCPB, can be isolated from the RCPB.

The design of the isolation systems described meet the requirements of Criterion 55.

For further discussion, see the following sections:

a.	Integrity of RCPB	5.2
b.	Containment isolation system	6.2.4
c.	Instrumentation and controls	7
d.	Accident analyses	15

3.1.2.5.7 Criterion 56 - Primary Containment Isolation

Each line that connects directly to the containment atmosphere and penetrates primary reactor containment shall be provided with containment isolation valves as follows, unless it can be demonstrated that the containment isolation provisions for a specific class of lines, such as instrument lines, are acceptable on some other defined basis:

(1) One locked closed isolation valve inside and one locked closed isolation valve outside containment; or

(2) One automatic isolation valve inside and one locked closed isolation valve outside containment; or

(3) One locked closed isolation valve inside and one automatic isolation valve outside containment. A simple check valve may not be used as the automatic isolation valve outside containment; or

(4) One automatic isolation valve inside and one automatic isolation valve outside containment. A simple check valve may not be used as the automatic isolation valve outside containment.

Isolation valves outside containment shall be located as close to the containment as practical and upon loss of actuating power, automatic isolation valves shall be designed to take the position that provides greater safety (GDC 56).

Evaluation Against Criterion 56

Criterion 56 requires that lines which penetrate the containment and communicate with the containment interior must have two isolation valves; one inside the containment, the other outside. It should be noted that this criterion does not reflect consideration of the BWR suppression pool design. For instance, those lines which connect to the suppression pool do not have an isolation valve located inside the containment as this would necessitate placement of the valve underwater. In effect, this would result in introducing a potentially unreliable valve in a highly reliable system thereby compromising design.

The manner in which the containment isolation system meets this requirement is described in the following sections:

a.	Containment isolation system	6.2.4
b.	Instrumentation and control systems	7
c.	Primary containment and reactor vessel isolation control system instrumentation and controls	7.3
d.	Accident analyses	15

3.1.2.5.8 Criterion 57 - Closed System Isolation Valves

Each line that penetrates primary reactor containment and is neither part of the reactor coolant pressure boundary nor connected directly to the containment atmosphere shall have at least one containment isolation valve which shall be either automatic, or locked closed, or capable of remote manual operation. This valve shall be outside containment and located as close to the containment as practical. A simple check valve may not be used as the automatic isolation valve (GDC 57).

Evaluation Against Criterion 57

Each line that penetrates the reactor containment and is neither part of the RCPB nor connected directly to the containment atmosphere has at least one containment isolation valve which is automatic, locked closed or capable of remote manual operation, located outside the containment as close to the containment as practical. Simple check valves are not used as automatic isolation valves on these lines.

Details demonstrating conformance with Criterion 57 are provided in the following sections:

a. Containment isolation system 6.2.4

b. Instrumentation and controls 7

3.1.2.6 Group VI - Fuel and Reactivity Control

3.1.2.6.1 Criterion 60 - Control of Releases of Radioactive Materials to the Environment

The nuclear power unit design shall include means to control suitably the release of radioactive materials in gaseous and liquid effluents and to handle radioactive solid wastes produced during normal reactor operation, including anticipated operational occurrences. Sufficient holdup capacity shall be provided for retention of gaseous and liquid effluents containing radioactive materials, particularly where unfavorable site environmental conditions can be expected to impose unusual operational limitations upon the release of such effluents to the environment (GDC 60).

Evaluation Against Criterion 60

Waste handling systems have been incorporated in the plant design for processing and/or retention of radioactive wastes from normal plant operations to ensure that the effluent releases to the environment are as low as reasonably achievable (ALARA) and within the limits of 10 CFR Part 20. The plant is also designed to prevent radioactivity releases during accidents from exceeding the limits of 10 CFR Part 100.

The principal gaseous effluents from the plant during normal operation are the noncondensable gases from the air ejectors. These gases are exhausted through a hold up system and offgas treatment system including charcoal adsorbers. The effluent from this system is continuously monitored and controlled and the system will be shutdown and isolated in the event of abnormally high radiation levels.

Ventilation air from the various plant areas is continuously monitored and controlled. In the event of an accident inside containment, noncondensable gases are held within the leaktight containment vessel. Release of these effluents will be by controlled purging of the containment.

Liquid radioactive wastes are collected in waste collector tanks, treated on a batch basis through demineralizers, and then either returned to the plant systems or released in a controlled manner to the environment. All discharges to the environment are routed through a monitoring station that continuously monitors and records the activity of the waste and provides an alarm to the operator in the unlikely event of high activity level.

Solid wastes including spent resins, filter sludges, filter cartridges, evaporator bottoms, contaminated tools, equipment, and clothing are collected, packaged, and shipped offsite in approved shipping containers.

The design of the waste disposal systems meets the requirements of Criterion 60.

For further discussion, see the following sections:

f.	Gaseous waste management systems	11.3
g.	Solid waste management system	11.4
h.	Process and effluent radiological monitoring and sampling systems	11.5
i.	Radiation protection	12
j.	Accident analyses	15

3.1.2.6.2 Criterion 61 - Fuel Storage and Handling and Radioactivity Control

The fuel storage and handling, radioactive waste, and other systems which may contain radioactivity shall be designed to assure adequate safety under normal and postulated accident conditions. These systems shall be designed (1) with a capability to permit appropriate periodic inspection and testing of components important to safety, (2) with suitable shielding for radiation protection, (3) with appropriate containment, confinement, and filtering systems, (4) with residual heat removal capability having reliability and testability that reflects the importance to safety of decay heat and other RHR, and (5) to prevent significant reduction in fuel storage coolant inventory under accident conditions (GDC 61).

Evaluation Against Criterion 61

3.1.2.6.2.1 New Fuel Storage. New fuel is placed in dry storage in the new fuel storage vault which is located inside the reactor building. The storage vault within the reactor building provides adequate shielding for radiation protection. Storage racks preclude accidental criticality (see evaluation against Criterion 62). The new fuel storage racks do not require any special inspection and testing for nuclear safety purposes.

3.1.2.6.2.2 Spent Fuel Handling and Storage. Irradiated fuel is stored in the spent fuel pool in the reactor building. Fuel pool water is circulated through the FPC system to maintain fuel pool water temperature, purity, water clarity, and water level. Storage racks preclude accidental critically (see evaluation against Criterion 62).

Reliable decay heat removal is provided by the closed loop FPC system. It consists of two circulating pumps, two heat exchangers, two filter-demineralizers, two skimmer surge tanks, and the associated piping, valves, and instrumentation. The pool water is circulated through the system, suction is taken from fuel pool skimmer surge tanks, flow passes in series through the heat exchangers and filters, and it is discharged through diffusers at the bottom of the fuel pool. Normal source of cooling water to the heat exchangers is from the reactor closed cooling water (RCC) system. When the preferred RCC source is unavailable, the SW system provides cooling water and makeup. The FPC system can also be interconnected with the RHR system to increase the cooling capacity of the FPC system. See Section 9.1.3.

The portion of the system required for cooling of spent fuel after refueling is designed to Seismic Category I requirements and can be isolated by automatic redundant, Seismic Category I isolation valves from the Seismic Category II cleanup portion of the system. Safety-grade cooling water from the SW system is available to the shell side of the FPC heat exchangers by remote-manual operation from the control room. Safety-grade makeup water to the fuel pool is also available from the SW system by remote-manual operation from the control room.

High- and low-level switches indicate pool water level changes in the main control room. Fission product concentration in the pool water is minimized by use of the filter-demineralizer. This minimizes the release of radioactivity from the pool to the reactor building environment.

No special tests are required to ensure system operability, except as noted below, because at least one pump, with a heat exchanger, and filter-demineralizer is routinely in operation while fuel is stored in the pool. Routine visual inspection of the system components, instrumentation, and trouble alarms is adequate to verify system operability.

Service water flow to the shell side of the fuel pool cooling heat exchangers, including operation of the valves that interconnect the service water and RCC systems to the FPC system, are tested in conjunction with testing of the service water system. The service water makeup isolation valves are also tested in conjunction with testing of the service water system.

3.1.2.6.2.3 Radioactive Waste Systems. The radioactive waste systems provide all equipment necessary to collect, process, and prepare for disposal of all radioactive liquids, gases, and solid waste produced as a result of reactor operation.

Liquid radwastes are segregated and treated as equipment drain, floor drain, chemical, detergent, sludges, or concentrated wastes. Processing methods include filtration, ion exchange, neutralization, concentration, solidification, analysis, and dilution. Liquid wastes are also decanted and sludge is accumulated for disposal as solid radwaste. Wet solid wastes and concentrates are normally dewatered and packaged in steel or polyethylene containers as required for disposal. Dry solid radwastes are packaged in steel boxes or other suitable containers. Gaseous radwastes are monitored, processed, recorded, and controlled so that radiation doses to persons outside the controlled area are below those allowed by applicable regulations.

Accessible portions of the refueling and radwaste buildings have sufficient shielding to maintain dose rates within the limits set forth in 10 CFR Part 20 and 10 CFR Part 50. The radwaste building is designed to preclude accidental release of radioactive materials to the environs.

The radwaste systems are used on a routine basis and do not require specific testing to ensure operability. Performance is monitored by radiation monitors during operation.

The fuel storage and handling and radioactive waste systems are designed to ensure adequate safety under normal and postulated accident conditions. The design of these systems meets the requirements of Criterion 61.

For further discussion, see the following sections:

a.	RHR system	5.4.7
b.	Containment systems	6.2
c.	New fuel storage	9.1.1
d.	Spent fuel storage	9.1.2
e.	Spent fuel pool cooling and cleanup system	9.1.3

f. Heating, ventilating, and air conditioning systems 9.4

g. Radioactive waste management 11

h. Radiation protection 12

3.1.2.6.3 Criterion 62 - Prevention of Criticality in Fuel Storage and Handling

Criticality in the fuel storage and handling system shall be prevented by physical systems or processes, preferably by use of geometrically safe configurations (GDC 62).

Evaluation Against Criterion 62

Appropriate plant fuel handling and storage facilities are provided to preclude accidental criticality for new and spent fuel. Criticality in new and spent fuel storage is prevented by the geometrically safe configuration of the new fuel storage racks and by the geometrically safe configuration of the spent fuel racks using fixed poison. There is sufficient spacing between assemblies to ensure that the array when fully loaded is substantially subcritical. Fuel elements are limited to top loading and fuel assembly positions by rack design. The new and spent fuel racks are Seismic Category I components.

Spent fuel and new fuel is stored under water in the spent fuel pool. The racks in which spent fuel assemblies are placed are designed to ensure subcriticality in the storage pool. Fuel is maintained at a subcritical multiplication factor k_{eff} of less than 0.95 under both normal and abnormal conditions. Abnormal criticality conditions may result for abnormal conditions. Abnormal criticality conditions may result from accidental dropping of a fuel assembly to a location adjacent to or on top of a loaded fuel storage rack. Various abnormal loading conditions such as loadings from the operating basis earthquake (OBE) and safe shutdown earthquake (SSE), the dropping of a fuel assembly, or a stuck assembly exerting an upward force on the racks were also considered in the design of the racks.

Refueling interlocks include circuitry which senses conditions of the refueling equipment and the control rods. These interlocks reinforce operational procedures that prohibit making the reactor critical. The fuel handling system is designed to provide a safe, effective means of transporting and handling fuel and to minimize the possibility of mishandling or maloperation.

The use of geometrically safe configurations for new and spent fuel storage, the use of fixed neutron poison in the spent fuel racks, and the design of fuel handling systems precludes accidental criticality in accord with Criterion 62.

For further discussion, see the following sections:

a.	Refueling interlocks system instrumentation and controls	7.7.1.13
b.	New fuel storage	9.1.1
c.	Spent fuel storage	9.1.2
d.	Fuel handling system	9.1.4

3.1.2.6.4 Criterion 63 - Monitoring Fuel and Waste Storage

Appropriate systems shall be provided in fuel storage and radioactive waste systems and associated handling areas, (1) to detect conditions that may result in loss of residual heat removal capability and excessive radiation levels and (2) to initiate appropriate safety actions (GDC 63).

Evaluation Against Criterion 63

Appropriate systems have been provided to meet the requirements of this criterion. A malfunction of the FPC system which could result in loss of RHR capability and excessive radiation levels is alarmed in the control room. Alarmed conditions include high/low level in the fuel pool, cooling water pump discharge pressure low, and high/low level in the fuel storage pool skimmer surge tanks. System temperature is also continuously monitored and alarmed in the control room. The area radiation monitors sense radioactivity in this area and initiate an alarm in the control room on abnormal radiation levels.

Area radiation, tank, and sump levels are monitored and alarmed to give indication of conditions that may result in excessive radiation levels in radioactive waste system areas. These systems satisfy the requirements of Criterion 63.

For further discussion, see the following sections:

a.	Area radiation monitoring system instrumentation	12.3.4
b.	Fuel storage and handling	9.1
c.	Radioactive waste management	11
d.	Radiation protection	12

3.1.2.6.5 Criterion 64 - Monitoring Radioactivity Releases

> Means shall be provided for monitoring the reactor containment atmosphere, spaces containing components for recirculation of loss-of-coolant accident fluids, effluent discharge paths, and the plant environs for radioactivity that may be released from normal operations, including anticipated operational occurrences, and from postulated accidents (GDC 64).

Evaluation Against Criterion 64

Means have been provided for monitoring radioactivity releases resulting from normal and anticipated operational occurrences. The following potential station release paths are monitored:

a. Main plant vent monitor,

b. Turbine building ventilation exhaust,

c. Radwaste building ventilation exhaust,

d. Liquid radwaste system effluent,

e. Standby service water system,

f. Plant service water,

g. Containment monitoring system radiation monitors, and

h. Turbine building sumps.

In addition, offsite monitors are provided.

For further discussion of the means and equipment used for monitoring radioactivity releases, see the following sections:

a.	Detection of leakage through RCPB	5.2.5
b.	Process radiation monitoring system instrumentation and controls	7.6
c.	Process and effluent radiological monitoring systems and sampling systems	11.5
d.	Area radiation and airborne radioactivity monitoring instrumentation	12.3.4

3.2 CLASSIFICATION OF STRUCTURES, COMPONENTS, AND SYSTEMS

Appendix A of 10 CFR Part 50 requires that all nuclear power plants be designed so that, if the safe shutdown earthquake (SSE) occurs, all structures, systems, and components (SSCs) important to safety remain functional.

General Design Criterion 1 (GDC 1) of Appendix A to 10 CFR Part 50 requires that SSCs important to safety be designed, fabricated, erected, and tested to quality standards commensurate with the importance of the safety function to be performed.

3.2.1 SEISMIC CLASSIFICATION

Plant structures, systems, and components important to safety are designed to withstand the effects of an SSE and remain functional if they are necessary to ensure

a. The integrity of the reactor coolant pressure boundary (RCPB),

b. The capability to shut down the reactor and maintain it in a safe shutdown condition, or

c. The capability to prevent or mitigate the consequences of accidents which could result in potential offsite exposure comparable to the exposure limits of 10 CFR Part 50.67.

Plant structures, systems, equipment, and components, including their foundations and supports, designed to remain functional in the event of an SSE are designated as Seismic Category I, as indicated in Table 3.2-1.

All Seismic Category I SSCs are analyzed under the loading conditions of the SSE and the operating basis earthquake (OBE). Since the two earthquakes vary in intensity, the design of Seismic Category I structures, components, equipment, and systems to resist each earthquake and other loads are based on levels of material stress or load factors, whichever is applicable, with margins of safety appropriate for each earthquake. The margin of safety provided for Seismic Category I structures, components, equipment, and systems for the SSE are sufficient to ensure that their design functions are not jeopardized.

For further details of seismic design criteria refer to

Seismic design	3.7
Design of Category I structures	3.8
Systems and components	3.9

Seismic qualification of Seismic Category I instrumentation and electrical equipment	3.10

All SSCs not analyzed under the loading conditions of the SSE and OBE are classified Seismic Category II. Where applicable, the seismic loading conditions as determined from the Uniform Building Code are used for the design of Seismic Category II SSCs.

The OBE, as defined in 10 CFR Part 100, Appendix A, is not incorporated as part of the seismic classification scheme.

The seismic classification indicated in Table 3.2-1 meets the requirements of NRC Regulatory Guide 1.29, Revision 3, except as otherwise noted in the table.

Seismic Category 1M classification denotes systems, structures or components that are designed and constructed to comply with position C.2 of Regulatory Guide 1.29.

3.2.2 SYSTEM QUALITY GROUP CLASSIFICATIONS

System quality group classifications, as defined in NRC Regulatory Guide 1.26, Revision 3, are determined for each water, steam, or radioactive waste containing component of those applicable fluid systems relied on to ensure

a. The integrity of the RCPB,

b. The capability to shut down the reactor and maintain it in a safe shutdown condition, or

c. The capability to prevent or mitigate the consequences of accidents which could result in potential offsite exposure comparable to the exposure limits of 10 CFR Part 50.67.

The quality group classifications for systems and components which meet these definitions are shown in Table 3.2-1.

System quality group classifications, as indicated in Tables 3.2-1 and 3.2-2, meet the requirements of 10 CFR 50.55a and Regulatory Guide 1.26, Revision 3.

Note: Classification of the RWCU system in the Radwaste Building takes exception to Reg. Guide 1.26. Piping, pumps, valves, and supports of the RWCU system in the Radwaste Building have been reclassified as Quality Group D, taking exception to the Reg. Guide 1.26 recommended classification of Quality Group C.

3.2.3 SAFETY CLASSIFICATIONS

Structures, systems, and components were classified as Safety Class 1, Safety Class 2, Safety Class 3, or General Class G in accordance with the ANS-22 definition of their importance to nuclear safety (ANS-22 became ANSI/ANS-52.1-1983). Recognizing that components within a system may be of differing safety importance, a single system may have components in more than one safety class. Supports are designed in accordance with ASME III-Winter 1973 Addenda-Subsection NF and are classified appropriately based on the component supported. Jurisdictional boundaries between NF and other codes were established by the owner as required by the ASME Code. Load combinations and allowable stresses used in support design are in accordance with ASME III-NF as defined in Section 3.9 and are applied to both ASME and the American Institute of Steel Construction (AISC) support members. Modifications and construction practices are controlled by the quality classification of the individual support and by the additional requirements of each applicable code. Table 3.2-1 provides a summary of the safety classes for the principal SSCs of the plant.

Design requirements for components of safety classes are also described in this section. Reference is made to accepted industry codes and standards which define design requirements commensurate with the safety function(s) performed.

3.2.3.1 Safety Class 1

3.2.3.1.1 Definition of Safety Class 1

Safety Class 1 applies to components of the RCPB or core support structure whose failure could cause a loss of reactor coolant at a rate in excess of the normal makeup system or to equipment in which a single failure could cause major fuel damage.

3.2.3.1.2 Design Requirements for Safety Class 1

The design requirements for Safety Class 1 mechanical equipment (i.e., vessel, pipes, pumps, and valves) are described in Section 3.9. The design requirements for the reactor vessel are described in Section 5.3.

The design requirements for Safety Class 1 structures (i.e., reactor pedestal and supports of the RCPB as defined in Section 3.2.3.1.1) are specified in Sections 3.8 and 3.9.

Safety Class 1 SSCs are identified in Table 3.2-1.

3.2.3.2 Safety Class 2

3.2.3.2.1 Definition of Safety Class 2

Safety Class 2 applies to those SSCs, other than service water systems, that are not Safety Class 1 but are necessary to accomplish the safety function of

a. Inserting negative reactivity to shut down the reactor,
b. Preventing rapid insertion of positive reactivity,
c. Maintaining core geometry appropriate to all plant process conditions,
d. Providing emergency core cooling,
e. Providing and maintaining containment, and
f. Removing residual heat from the reactor and reactor core.

3.2.3.2.2 Design Requirements for Safety Class 2

The design requirements for Safety Class 2 mechanical equipment (i.e., vessels including heat exchangers, pipes, pumps, valves, and tanks) are described in Section 3.9.

The design requirements for Safety Class 2 structures (i.e., reactor building including the primary containment) are specified in Section 3.8.

The seismic and environmental design requirements for Safety Class 2 instrumentation and electrical equipment are specified in Sections 3.10 and 3.11.

Safety Class 2 SSCs are identified in Table 3.2-1.

3.2.3.3 Safety Class 3

3.2.3.3.1 Definition of Safety Class 3

Safety Class 3 applies to those SSCs that are not Safety Class 1 nor Safety Class 2 that is relied upon to accomplish a nuclear safety function.

3.2.3.3.2 Design Requirement for Safety Class 3

The design requirements for Safety Class 3 structures, (i.e., standby service water pump houses, diesel generator buildings, radwaste/control building, and spray ponds) are specified in Section 3.8.

The design requirements for Safety Class 3 mechanical equipment (i.e., vessels including heat exchangers, pipes, pumps, valves, and tanks) are described in Section 3.9.

The seismic and environmental design requirements for Safety Class 3 instrumentation and electrical equipment are specified in Sections 3.10 and 3.11.

3.2.3.4 General Class G, Structures, Systems, and Components

3.2.3.4.1 Definition of General Class Structures, Systems, and Components

A boiling water reactor (BWR) has a number of SSCs in the power conversion or other portions of the facility which have no direct safety function but which may be connected to or

influenced by the equipment within the safety classes defined above. Such SSCs are designated as General Class G. For example, portions of the service water systems, the turbine generator auxiliaries, and portions of the heating, ventilating, and air conditioning (HVAC) systems are designated as having no safety classification.

3.2.3.4.2 Design Requirements for General Class G Structures, Systems, and Components

The design requirements for equipment classified as General Class G are specified with appropriate consideration of the intended service of the equipment and expected plant and environmental conditions under which it will operate. Design requirements are based on applicable industry codes and standards.

3.2.4 QUALITY ASSURANCE CLASSIFICATION

Structures, systems, and components are classified in Table 3.2-1 using the following quality class designations

a. Quality Class I - Any nuclear system, structure, subassembly, component, or design characteristics that prevent or mitigate the consequences of postulated accidents that could cause undue risk to the health and safety of the public. All engineered safety features fall within this category. All Quality Class I items meet the applicable provisions of 10 CFR Part 50 Appendix B.

b. Quality Class II+ - Assigned to SSCs having no safety-related function but requiring quality augmentation either as a result of NRC requirements or as committed by CGS. Quality augmentation may include such requirements as environmental qualification, seismic qualification, or other quality affecting activities specifically committed. Augmented quality applies to the following categories of SSCs:

1. Essential fire protection SSCs,

2. Structures, systems, and components that do not perform a safety-related function but must be seismically supported/mounted (seismic 2-over-1) per Regulatory Guide 1.29,

3. Structures, systems, and components required for radwaste management that are subject to Regulatory Guide 1.143,

4. Structures, systems, and components required to cope with a station blackout per Regulatory Guide 1.155 (see Section 8A),

5. Structures, systems, and components required to respond to or mitigate anticipated transients without scram (ATWS) per the requirements of 10 CFR 50.62,

6. Structures, systems, and components required to respond to an electrical separation safe shutdown event (see Section 8.3.1.4.4.1.4),

7. Postaccident monitoring instruments subject to Regulatory Guide 1.97, Category 2, requirements,

8. Remote shutdown items required in response to control room evacuation (10 CFR 50 Appendix A, GDC 19) and,

9. Beyond Design Basis External Event (BDBEE) structures, systems, and components associated with Spent Fuel Level Instrumentation per requirements of NRC Order EA-12-051 and portions of the HCV system per the requirements of NRC Order EA-13-109.

c. Quality Class II - Any system, structure, subassembly, component, or design characteristic that could cause a safety hazard to plant personnel, an extended reduction in unit output, an unscheduled unit trip, or equipment damage. Appropriate quality assurance requirements for these items are assigned in the purchase specifications.

d. Quality Class G - Any nonnuclear system, structure, subassembly, component, or design characteristic to which quality assurance requirements are assigned in accordance with the consequences of failure, operating costs, or procurement costs.

3.2.5 CORRELATION OF SAFETY CLASSES WITH OTHER DESIGN REQUIREMENTS

The design of plant equipment is commensurate with the safety importance of the equipment. Hence, the various safety classes have a gradation of design requirements. The correlation of safety classes with other design requirements is summarized in Table 3.2-3.

3.2.6 IDENTIFICATION OF SAFETY-RELATED SYSTEMS AND COMPONENTS ON FLOW DIAGRAMS AND IN THE MASTER EQUIPMENT LIST

The system classification are shown on the flow diagrams using symbols code group A, B, C, D, D+; Seismic Category I, II; and Quality Class I, II, II+, and G. The Master Equipment List (MEL) uses arabic number designators for quality class and seismic category. The following is a comparison of the classification designators:

Flow Diagram	Table 3.2-1	MEL
Code Group A	Quality Group A	
Code Group B	Quality Group B	
Code Group C	Quality Group C	
Code Group D	Quality Group D	
Code Group D+	Quality Group D+	
Seismic Category I	Seismic Category I*	Seismic Category 1* Seismic Category 1M*
Seismic Category II	Seismic Category II*	Seismic Category 2*
Quality Class I	Quality Class I	Quality Class 1
Quality Class II	Quality Class II	Quality Class 2
Quality Class II+	Quality Class II+	Quality Class A
Quality Class G	Quality Class G	Quality Class G

Flow diagrams which include the seismic and code classifications assigned to each piping system are identified in Table 3.2-1. The flow diagrams delineate the boundary of seismic and code classifications for each system and present the as-built classifications. For the appropriate quality class of specific components, refer to the MEL. In some instances, these classifications reflect voluntary upgrades which may exceed Regulatory Guide 1.26, Revision 3, requirements. For inservice inspection requirements, the appropriate levels of inspection are given in Sections 5.2.4 and 6.6.

Note: Classification of the RWCU system in the Radwaste Building takes exception to Reg. Guide 1.26. Piping, pumps, valves, and supports of the RWCU system in the Radwaste Building have been reclassified as Quality Group D, taking exception to the Reg. Guide 1.26 recommended classification of Quality Group C.

* Table 3.2-1 may indicate Seismic Category I, 1M or II. Clarification of the Seismic 2 over 1 (i.e., 1M) support/mounting requirements is specified in the notes and/or MEL (see Table 3.2-1).

Piping and valves forming part of containment boundary from the containment penetration up to and including Rupture Discs HCV-RD-54 and HCV-RD-60	P	2	R	B	I	I	
Piping and valves forming part of secondary containment from but not including Rupture Discs HCV-RD-54 and HCV-RD-60 to the secondary containment penetrations including the PCIV pneumatic lines between the valves and secondary containment	P	2	R	D	I	I	
Piping and valves from the secondary containment penetration to the exhaust point	P	G	R	D	II+	I	

Table 3.2-1

Equipment Classification (Continued)

[a] A module is an assembly of interconnected components which constitute an identifiable device or piece of equipment. For example, electric modules include sensors, power supplies, and signal processors; and mechanical modules include turbines, strainers, and orifices.

[b] GE - General Electric; P - Plant Owner (Energy Northwest)

[c] 1, 2, 3, G - Safety classes defined in Section 3.2.3.

[d]

A - Auxiliary building
C - Part of or within primary containment
L - Offsite locale
R - Reactor building
S - Service building
T - Turbine building
M - Any other location
O - Outdoors onsite
P - Pump house
W - Radwaste and control building
DG - Diesel generator building
H - Hydrogen Storage and Supply Facility

[e] A, B, C, D - NRC quality groups defined in Regulatory Guide 1.26, Revision 3. The equipment is constructed in accordance with the codes listed in Table 3.2-2, as minimum requirements.

N/A - Quality Group classification not applicable to this equipment.

[f] Quality Classes defined in Section 3.2.4.

Table 3.2-1

Equipment Classification (Continued)

[g] I - constructed in accordance with the seismic requirements of Seismic Category I structures and equipment as described in Section 3.7.
II - constructed in accordance with the requirements of Seismic Category II structures and equipment as described in Section 3.7. The approaches outlined in the Uniform Building Code will be followed where applicable.

N/A - seismic requirements as described for Seismic Category I and II structures and equipment are not applicable to this structure or equipment.

1M - non-safety-related components required to be seismically supported/mounted. This was alternatively called Seismic II⊕ which is Seismic II piping supported on hangers designed to Seismic I loads.

[h] The notes clarify system/component boundaries, design requirements, and/or alternate quality classification applications.

Reactor pressure boundary components (RPBC) and their original applicable code cases are listed in the attachments to Table 3.2-1. Current practices regarding code cases that are adopted for use at CGS (and are approved by Regulatory Guides 1.147, 1.84, 1.85, or other approval authority) requires that they are specified in the component's design specification as required by ASME Section III, NA-3250.

Table 3.2-1

Equipment Classification (Continued)

NOTES

1. This piping has been upgraded from Safety Class 3 to Safety Class 2 and from Quality Group Classification C to Quality Group Classification B.

2. a. Lines 0.75-in. and smaller which are part of the RCPB are Quality Group B or higher and Seismic Category I.

   b. All instrument lines which are connected to the RCPB and are used to actuate and monitor safety systems are Quality Group B from the outer isolation valve or the process shutoff valve (root valve) to the bulkhead of the instrument rack, if rack mounted, or the sensing instrumentation, if locally mounted.

   c. All instrument lines which are connected to the RCPB and are not used to actuate and monitor safety systems are Quality Group D from the outer isolation valve or the process shutoff valve (root valve) to the sensing instrument

   d. All other instrument lines:

      1. Through the root valve are of the same classification or higher as the system to which they are attached;

      2. Beyond the root valve to the instrument rack bulkhead, if rack mounted, or to the sensing instrumentation, if locally mounted, if used to actuate a safety system, are of the same classification as the system to which they are attached;

      3. Beyond the root valve, if not used to actuate a safety system are Quality Group D.

      4. All sample lines from the outer isolation valve or the process root valve through the remainder of the sampling system are Quality Group D.

Table 3.2-1

Equipment Classification (Continued)

NOTES (Continued)

3. The control rod drive insert and withdraw lines from the drive flange up to and including the first valve on the hydraulic control unit (HCU) is in Safety Class 2.

4. Supports for Quality Class II (nonessential) piping systems, HVAC, cable trays, and system components in the reactor building, primary containment, the control building, diesel generator building, the standby service water (SW) pump houses, and the radwaste building corridor are designed and constructed to withstand an SSE per position C.2 of Regulatory Guide 1.29. These supports are constructed to Quality Class II requirements, as a minimum.

5. The HCU is a GE factory assembled engineered module of valves, tubing, piping, and stored water which controls a single control rod drive by the application of precisely timed sequences of pressure and flows to accomplish slow insertion or withdrawal of the control rods for power control and rapid insert ion for reactor scram.

   Although the HCU is field installed and connected to process piping, many of its internal parts differ markedly from process piping components because of the more complex functions they must provide. Thus, although the codes and standards invoked by Quality Groups A, B, C, D pressure integrity quality levels clearly apply to all levels to the interfaces between the HCU and the connecting conventional piping components (e.g., pipe nipples, fittings, simple hand valves, etc.), it is considered that they do not apply to the specialty parts (e.g., solenoid valves, pneumatic components, and instruments).

   The design and construction specifications for the HCU do invoke such codes and standards as can be reasonably applied to individual parts in developing required quality levels, but these codes and standards are supplemented with additional requirements for these parts and for the remaining parts and details. For example, (a) all welds are LP inspected, (b) all socket welds are inspected for gap between pipe and socket bottom, (c) all welding is performed by qualified welders, and (d) all work is done per written procedures. Quality Group D is generally applicable because the codes and standards invoked by that group contain clauses which permit the use of manufacturer's standards and proven design techniques which are not explicitly defined within the codes of Quality Groups A, B, or C. This is supplemented by the quality control techniques described above.

Table 3.2-1

Equipment Classification (Continued)

NOTES (Continued)

6. The standby liquid control (SLC) system is not a safety-related backup to a scram function (RPS/CRD). However, these components of the SLC system are designed to engineering standard greater than those normally applied to Safety Class 2 systems.

7. Only equipment associated with a safety action (e.g., isolation) need conform to a safety function.

8. These lines meet the requirements of Quality Group B except that hydrostatic testing of the containment spray piping is not required.

9. The RCIC turbine does not fall within the applicable design codes. To ensure that the turbine is fabricated to the standards commensurate with its safety and performance requirements, GE has established specific design requirements for this component which are as follows:

   a. All welding is qualified in accordance with Section IX, ASME Boiler and Pressure Vessel Code;

   b. All pressure containing castings and fabrications are hydrotested to 1.5 times design pressure;

   c. All high-pressure castings are radiographed according to:

      1. ASTM E-94
      2. E-142 maximum feasible volume
      3. E-71, 186 or 280 severity level 3;

   d. All-cast surfaces are magnetic particulate or liquid penetrant tested according to ASME, Section III, Paragraph NB-2575 or NB-2576;

Table 3.2-1

Equipment Classification (Continued)

NOTES (Continued)

e. Wheel and shaft forgings are ultrasonically tested according to ASTM-A-388;

f. Butt-welds are radiographed according to ASME Section III, IX-3300, and magnetic particle or liquid penetrant tested according to ASME Section III, IX-3500, or IX-3600;

g. Notification is made on major repairs and records maintained thereof;

h. Record system and traceability according to ASME Section III, NA-4900;

i. Control and identification according to ASME Section III, NA-4400;

j. Procedures conform to ASME Section III, NA-4400;

k. Inspection personnel are qualified according to ASME Section III, Appendix IX, paragraph IX-400.

10. The RCIC turbine exhaust line from the isolation valve to the suppression pool meets all the requirements of Quality Group B except that hydrostatic testing of this portion of piping is not required.

11. Although the refueling bellows are designed to withstand the SSE without rupture, they may be plastically deformed.

12. DELETED.

13. Equipment, piping, and valves that are part of the radwaste system but not used for processing radioactive fluids are designed to Quality Group D standards.

Table 3.2-1

Equipment Classification (Continued)

NOTES (Continued)

14. Equipment, piping, and valves that are part of the radwaste solids handling system are designed to Quality Group D standards.

15. Up to and including the last stop valve, this line meets requirements of Quality Group C.

16. The fuel pool cooling heat exchangers have been upgraded to 270 psig (shell side) and Seismic Category I through several modifications. These heat exchangers are Quality Class II (with the modifications installed as Quality Class I) and ASME Section III Class 3. See Note 13 in Figure 9.1-6.1.

17. Piping and valves of the cooling portion of the fuel pool cooling system have been upgraded to Seismic Category I and are ASME Section III Class 3, Code Group C (with exception of valves listed in Note 16 in Figure 9.1-6.1). See Note 13 in Figure 9.1-6.1 for Quality Classification.

18. The fuel pool cooling circulation pumps have been upgraded to Seismic Category I. Their respective motors have been upgraded to Quality Class I Seismic Category I. The fuel pool cooling pumps are ASME Section III Class 3. See Note 13 in Figure 9.1-6.1 for Quality Classification.

19. The fuel pool cooling system (see Section 9.1.3) normally receives makeup from the Seismic Category II condensate storage tank. Should this normal supply be unavailable, makeup is available from the Seismic Category I SW system. Likewise, the normal source of cooling water to the FPC heat exchangers is from the Seismic Category II RCC system. When this normal supply is unavailable, the Seismic Category I SW system provides the cooling water and makeup. In addition, by means of removable spool-pieces, the RHR system is also available as the supplementary source of cooling during cold shutdown under core offload conditions. The above complies with Regulatory Guides 1.26, Revision 3, and 1.29, Revision 3.

Table 3.2-1

Equipment Classification (Continued)

NOTES (Continued)

The cleanup portion is automatically isolated from the cooling portion of the system by Seismic Category I valves on low fuel pool level (see Section 9.1.3).

20. Piping and valves downstream of valves SGT-V-5A1, SGT-V-5A2, SGT-V-5B1, and SGT-V-5B2 meet the requirements of Quality Group B except that a pneumatic test is not performed.

21. Lavatory exhaust systems are designed to Quality Assurance Class G.

22. Part of the HVAC components are non-safety-related. Non-safety-related equipment and components required to be seismically supported/mounted according to Regulatory Guide 1.29 are designated Seismic Category 1M and Quality Assurance Class II+. Non-safety-related equipment and components not required to be seismically supported/mounted according to Regulatory Guide 1.29 are designated Seismic Category II and Quality Assurance Class II.

23. The condensate storage tanks are designed, fabricated, and tested to meet ASME Code, Section III, Subsection ND-3800. In addition, the specification for this tank requires 100% surface examination of the side wall to bottom joint, and 100% volumetric examination of the side-wall weld joints.

24. The high-pressure core spray (HPCS) suction piping from the condensate storage tank provides the initial source of makeup water to the HPCS system for safety injection. Consequently, this piping has been upgraded by full volumetric examination of every weld.

25. The auxiliary piping systems on the engines are built to the guidelines of ANSI B31.1.

26. These piping systems are liquid penetrant or magnetic particle examined to the acceptance standards of ASME Section III, Class 3, if they are over 4 in. IPS as required by the 1973 Winter Addenda except for the diesel cooling water piping that is on engine skid.

Table 3.2-1

Equipment Classification (Continued)

NOTES (Continued)

27. Piping upstream from the check valves at the inlet of the air receivers is Quality Class II, ANSI B31.1, Seismic Category I. All other piping is Quality Class 1.

28. The piping is supported to Seismic Category I requirements, but is not housed in a Seismic Category I structure. The power conversion system structures are constructed in accordance with applicable codes for steam power plants. The turbine building, interacting with main steam lines and branch lines, is designed as a modified Seismic Category II structure as described in Section 3.8.4.1.3.

29. All cast pressure retaining parts of a size and configuration for which volumetric examination methods are required are examined by radiographic methods by qualified personnel. Ultrasonic examination to equivalent standards may be used as an alternative to radiographic methods. Examination procedures and acceptance standards are at least equivalent to those specified as supplementary types of examination in ANSI B31.1.0 Code, Paragraph 136.4.3.

30. The following qualification is met with respect to the certification requirements:

    a. The manufacturer of the turbine stop valves, turbine governor valves, turbine bypass valves, and mainsteam leads from turbine control valve to turbine casting utilized quality control procedures, and

    b. A certification has been obtained from the manufacturer of these valves and steam leads that the quality control program so defined has been accomplished.

Table 3.2-1

Equipment Classification (Continued)

NOTES (Continued)

31. The makeup water pump house is designed to withstand the design-basis tornado. The design also considers the possible effects of tornado-generated missiles. The tower makeup water piping, valves, and cabling located underground are provided with adequate earth cover to be resistant to tornado-generated missiles or are protected by tornado-resistant structures. The circulating water system also supports the post-tornado operation of the standby service water system. In the event of the loss of the spray headers in the SW spray ponds, tornado-protected underground lines can provide a flow path to provide makeup water from TMU, and to return water to the CW basin. See FSAR Section 9.2.5.3 for additional discussion.

32. Portions of the turbine building that support or interact with main steam piping are designed to Seismic Category I.

33. Those portions of the radwaste and control building that house systems or components necessary for safe shutdown of the reactor are designed to Quality Class I and Seismic Category I requirements. Those portions of the radwaste building housing equipment containing significant quantities of radioactive material are designed to Seismic Category I requirements.

34. Safety-related instrument and control systems are identified in Table 7.1-1.

35. The HSSF liquid hydrogen storage tank, foundations, anchorage (i.e., anchor bolts, slide plates, and the baseplate welding) and the underlying soil are not safety-related, and are designated as Quality Class II+. However, these are designed for Seismic Category I loads and ground motion as defined by Regulatory Guide 1.60. In addition, they were designed to remain in place for both design basis tornado characteristics and maximum probable flood.

36. Piping located between secondary containment isolation valves EDR-V-394, EDR-V-395, FDR-V-219, FDR-V-220, FDR-V-221 and FDR-V-222 is classified as Seismic Category I, Quality Class II+ and Quality Group D.

37. Seismic Category I applies to the motor rotor, bearings and bearing load path parts. The motor is mounted Seismic Category IM.

38. Large bore piping is analyzed to Seismic Category I loading.

Table 3.2-2

Code Group Designations - Industry Codes and Standards
for Mechanical Components[a,b] (Continued)

[b] Components of the reactor coolant pressure boundary meet the requirements of 10 CFR 50, Section 50.55a, "Codes and Standards," except as shown in Table 5.2-1 and discussed in Section 5.2.1.1. All components satisfy codes and addenda in effect at the time of component order or later.

[c] For pumps classified A, B, or C; applicable subsections NB, NC, or ND; respectively, in ASME Code Section III is used as a guide in calculating the thickness of pressure-retaining portions of the pump and in sizing cover bolting.

[d] 100% volumetric examination of the sidewall and roof weld joints for plates over 3/16 in. thick and 100% surface examination of weld joints for plates 3/16 in. thick or less of the sidewall to bottom and sidewall to roof joints. These examination requirements are performed in accordance with the rules of ASME Section III, Class 2.

[e] 100% volumetric examination of the sidewall weld joints for plates over 3/16 in. thick and 100% surface examination sidewall to bottom joints. These examination requirements are performed in accordance with the rules of ASME Code Section III, Class 2.

[f] Nondestructive tests examination requirements per ASME Code, Section VIII, Division 1.

[g] Welds not totally conforming to B31.1 are evaluated and dispositioned on a case-by-case basis considering (a) the function of the systems, (b) the risk of failure, and (c) the consequences of failure for safety and plant availability.

[h] For pumps classified Group D, and operating above 150 psig and 212°F Section VIII, Division 1 is used as a guide in calculating the wall thickness for pressure-retaining parts and in sizing the cover bolting.

[i] Tanks are designed to meet the intent of API, AWWA, and/or ANSI 96.1 standards as applicable.

Table 3.2-3

Summary of Safety Class Design Requirements (Minimum)

Design Requirements	Safety Class			
	1	2	3	G
Quality group classification[a]	A	B	C	D
Quality class[b]	I	I, II+	I, II+	II, G
Seismic category[c]	I	I, 1M	I, 1M	II

[a] The equipment is constructed in accordance with the indicated code group listed in Table 3.2-1 and defined in Table 3.2-2.

[b] I (1 in MEL) - the equipment is constructed in accordance with the quality assurance requirements of 10 CFR 50, Appendix B, and Nuclear Energy Division Boiling Water Reactor Quality System Summary.

II+ (A in MEL) - Non-safety-related equipment for which Columbia Generating Station has made specified commitments to the NRC or others relating to the quality. Some 10 CFR 50, Appendix B, criteria are applied.

II (2 in MEL), G - The equipment is constructed in accordance with the quality assurance requirements as specified in contract documents as described in Section 3.2.3.

[c] I - the equipment of these safety classes is constructed in accordance with the seismic requirements for the safe shutdown earthquake as described in Section 3.7.

1M - The equipment does not perform a safety-related function but must be seismically supported/mounted per Regulatory Guide 1.29.

II - The seismic requirements for the safe shutdown earthquake are not applicable to the equipment of this classification. The approaches outlined in the Uniform Building Code are followed where applicable.

Deleted

3.3 WIND AND TORNADO LOADINGS

3.3.1 WIND LOADINGS

3.3.1.1 Design Wind Velocity

All Seismic Category I structures are designed to withstand a basic wind velocity (fastest mile), including gusts, of 100 mph at an elevation of 30 ft above the site grade. This wind velocity exceeds the basic wind velocity having a statistically derived probable period of recurrence of 100 years in this geographical area, as specified in the American Society of Civil Engineers Task Committee Report (Reference 3.3-1).

The Hanford region experiences high wind speeds due to squall lines, frontal passages, strong pressure gradients, and thunderstorms. The Hanford Reservation has experienced only one recorded tornado (June 1948) and has not been known to be affected by typhoons. No complete statistics are readily available which present frequency of occurrence of high winds produced or accompanied by a particular meteorological event. However, the highest winds produced by any cause are tabulated for the Hanford Meteorological Station (HMS) in Tables 2.3-5 and 2.3-6. Figure 2.3-4 indicates the return probability of any peak wind gust again due to any cause. The 100-mph design wind speed is conservative for the CGS site for the following reasons:

a. Peak wind gusts measured at the 50-ft HMS tower level, as reported in Tables 2.3-5 and 2.3-6, have never exceeded 80 mph, and

b. The statistically derived 100-year return period peak gust (Figure 2.3-4) at an elevation of 50 ft is 86 mph based on HMS records.

Recurrence intervals, data sources, and the history of occurrence of high winds, hurricanes, and tornadoes in the vicinity of the site are discussed in the CGS Environmental Report.

3.3.1.2 Determination of Applied Forces

The basic wind velocity of 100 mph is applied in accordance with Table 1(a) of Reference 3.3-1, including the variation in wind velocity with height and drag coefficients. Considering a gust factor of 1.0 and drag coefficient of C_D and V as the specific wind velocity at a particular height above grade given in Table 1(a) of Reference 3.3-1, the total combined average wind pressure p is given by

$$p = C_D \times 0.002558\ V^2$$

For example, at a height of 30 ft with V = 100 mph, C_D = 1.3, p = 33 psf

The above chosen gust factor is adequate for the CGS site for the following reasons. In Reference 3.3-1, the wind gust factor is defined as gust velocity divided by the velocity of the fastest mile of wind. Whereas the gust factor can not be less than 1.0, it is implied in Section 3.3.1.1 that the factor is unity since the 100-mph fastest mile wind accounts for wind gusts. A factor greater than 1.0 is not warranted at CGS since the statistically derived peak wind gust considered is less than the assumed site basic wind velocity. Additional considerations regarding gust factors and fastest mile velocities are presented in Section 2.3.1.2.1.4.

The following wind velocities are used in the design of structures at various elevations:

Height Above Grade (ft)	Wind Speed, V (mph)*
Less than 50	100
50 to 149	120
150 to 400	140

The wind pressures are applied as static forces. The translation of wind velocities into applied static forces, the wind force distribution, and the drag coefficients are in accordance with published values such as Reference 3.3-1. *The italicized information is historical and was provided to support the application for an operating license. The magnitude and distribution of the applied static forces originally calculated for structures are as follows:*

Height Above Grade	*Windward Side 0.8q (psf)*	*Leeward Side 0.5q (psf)*
Less than 50 ft	*20*	*13*
50 to 150 ft	*30*	*18*
150 to 400 ft	*0*	*25*

The term q, as described in Reference 3.3-1, is designated as the dynamic pressure of a free wind stream at a point on the surface of a structure immersed in the wind stream and when multiplied by the pressure coefficient, Cp, characteristic of the building types defined in Reference 3.3-1, gives the pressure on the structure's surfaces.

The original reactor building membrane roofing system has been replaced with a modern elastic sheet membrane system in accordance with the Factory Mutual system for Class I Fire and I-90 windstorm rating. Local wind uplift forces at the roof perimeter and corners would result in local failure of the existing controlled release fasteners during a gale or squall windstorm.

* *Table 1(a), Reference 3.1-1.*

3.3.2 TORNADO LOADINGS

3.3.2.1 Applicable Design Parameters

The original tornado design criteria provided for wind speeds of 300 mph rotational and 60 mph translational velocity, with a pressure drop of 3 psi to occur in 3 sec as discussed in Section 2.3.1.2.1.3, Tornados. The tornado design criteria were updated in January 1996 based on the design basis tornado characteristics in NUREG-1503 (Reference 3.3-2), which were found acceptable by the NRC (References 3.3-3 and 3.3-4).

Since January 1996, the updated design basis tornado is one having a maximum horizontal component of tangential (or peripheral rotational) wind velocity of 160 mph and a constant translational velocity of 40 mph. The resultant wind velocity (the sum of the maximum horizontal component of tangential velocity and the translational velocity) is 200 mph. The atmospheric pressure at the center of the tornado is 0.9 psi below ambient. The 0.9 psi external pressure drop is assumed to occur at a rate of 0.3 psi/sec. The nonventing structures are designed for the worst combination of wind velocity and associated atmospheric pressure drop in accordance with the load combinations contained in Section 3.3.2.2. The venting structures are designed for the worst combination of wind velocity and associated difference of the pressure within and the atmospheric pressure outside. The effects of a design basis tornado are considered in combination with other loads, including tornado-generated missiles, in Section 3.5.

3.3.2.2 Determination of Forces on Structures

Design static pressures, drag coefficients, and wind pressures are selected in accordance with published values such as Reference 3.3-1. The provisions for gust factors and variation of wind velocity, noted therein, are not applied for the following reasons.

The wind velocity may vary with the height of the structures but, for conservatism, the wind force due to tornado loadings is applied as a uniform static load invariant with the height above grade.

The total wind velocity occurs only in a localized area but is used in the design over the full height of the projected area of the structure. The total wind velocity is in effect the gust wind velocity, since by definition a tornadic gust wind velocity is a high localized wind velocity of very short duration. Therefore, no additional gust factor is applied.

The procedure used to transform the design-basis tornado wind velocity into an effective pressure applied to exposed surfaces of structures is described in Reference 3.3-1.

The following is an example of how Reference 3.3-1 was applied in the original calculations:

The same procedure as that used to transform the basic design-basis wind velocity in Section 3.3.1.2 is used with the exception that the velocity and velocity pressure are assumed not to vary with height.

The equivalent uniform tornado wind velocity used on the structure due to a tangential component of 300 mph and a transitional component of 60 mph is 360 mph. The pressure loads are calculated on the basis of a uniform 360 mph wind velocity.

a. The dynamic pressure on the structure is:

$q = 0.002558 \times (360)^2 = 331.5$ psf

b. The applied static pressures are:

1. Windward pressure on walls:

$p = 0.8 \times 331.5 = 265$ psf

2. Leeward suction on walls:

$p = 0.5 \times 331.5 = 166$ psf

3. Total design pressure on the structure is the sum of 265 psf and 166 psf, or 431 psf.

The differential pressure loading is calculated using the following pressure-time function: The differential pressure is assumed to vary from zero to 0.9 psi at a rate of 0.3 psi/sec and then return to zero at 0.3 psi/sec.

The procedure used for transforming the tornado-generated missile loadings into effective static loads is described in Section 3.5.3.

Mathematical models for the design-basis tornado take into consideration the phase relationship between the wind load and the differential pressure effects.

The tornado load, W′, in the load combinations in Tables 3.8-9 and 3.8-10 constitutes the combined effect of the three separate loads a, b, and c generated by the design basis tornado. The three loads are combined in the following manner to obtain the combined effect:

a. $W' = W_w$

b. $W' = W_p$

c. $W' = W_m$

d. $W' = W_w + 0.5W_p$

e. $W' = W_w + W_m$

f. $W' = W_w + 0.5W_p + W_m$

where:

W' = Total tornado load

W_w = Tornado wind load

W_p = Tornado differential pressure load

W_m = Tornado-generated missile load

3.3.2.3 Additional Design Features

Except for the steel superstructure atop the refueling floor, the reactor building remains sealed through the tornado event and a differential pressure of 0.9 psi across the exterior and interior is bounded by the design. All other Seismic Category I structures are provided with adequate openings to relieve a differential pressure of 0.9 psi in 3 sec or are designed to withstand an external pressure drop of 0.9 psi.

The structural steel frame superstructure atop the refueling floor of the reactor building is designed to withstand the design basis tornado. However, all the siding and roof decking enclosing the steel superstructure is designed for a maximum differential pressure of approximately 0.5 psi. The siding and girts are designed to blow off the steel frame when a differential pressure of approximately 0.5 psi is exceeded. The roof decking and roof purlins are designed to blow off the steel frame when a differential pressure of approximately 0.5 psi is exceeded. This value considers the dead weight loading from the roof membrane, roofing insulation, roof decking, and roof purlins. This is ensured by the use of controlled release type fasteners connecting the girts to the columns and roof purlins to the roof trusses. The release of the girts, siding, roof purlins, and roof decking from the structural steel frame will not affect the ability to shut down the reactor, the integrity of the primary containment or other Seismic Category I structures, or the capability of the essential heat removal systems to perform their intended design functions.

The design of the reactor building crane and its support system considers tornado effects in addition to normal loads to eliminate the possibility of generating internal missiles which may endanger the primary and secondary containment structures. The trolley is provided with

latches to engage tornado racks attached to the bridge girder to prevent horizontal movement of the trolley due to tornado loadings. The bridge trucks are provided with latches to engage tornado racks attached to the crane runway girders to prevent horizontal movement of the bridge due to tornado loadings. See Figure 3.8-44.

Based on the General Electric publication, (Reference 3.3-5), there is no credible mechanism by which a significant amount of water could be sucked from the fuel pool by a tornado.

The design of hardened containment vent system considers tornado effects in addition to normal loads to eliminate the possibility of creating a tornado generated missile.

The design considers the possible effects of tornado-generated missiles discussed in Section 3.5. Primary containment and components, equipment, and systems essential to a safe shutdown are protected from tornado-generated missiles by enclosing structures.

The diesel generator building and the radwaste and control building are designed to withstand the effects of tornado-generated missiles that might be released, such as girts and roof purlins. The results of analyses determining the effects of missiles are discussed in Section 3.5.

Piping and cabling required for safe shutdown and which penetrate exterior walls of the tornado-resistant structures are located below grade or are protected, as in the case of the standby service water (SW) piping at the service water pump houses, by tornado-resistant structures. Piping and cabling required for safe shutdown, which is provided with less than adequate earth cover for tornado protection, is protected with a tornado-resistant concrete slab or other structure. For information concerning protection provided for the SW system see Section 9.2.5.

3.3.2.4 Effect of Failure of Structures or Components Not Designed for Tornado Loads

The two reinforced-concrete spray pond structures have the capability to tolerate tornado generated missiles. Each pond is made up of four perimetral walls, 1 ft 3 in. at the top and 2 ft 0 in. at the bottom, and a floor slab of 7-in. thickness placed on top of a 2-in.-unreinforced-concrete subgrade leveling slab, as described in Section 3.8.4.1.5. Finish grade around the perimetral walls of the spray ponds is 1 ft 0 in. below the top of the walls, and the normal pond water level is at 6 in. below the top of the walls. The walls and slab are bounded by Quality Class I high relative density backfill. On this basis, missile protection is provided for the pond structures. A direct hit by a tornado-generated design basis missile resulting in localized floor and wall penetration is unlikely because of the protection provided by the backfill and the water in the pond.

Damage to the spray pond concrete structure due to tornado-generated missiles would be localized cracking in the area of impact. The structure will remain intact and any leakage will be made up by the cooling tower makeup system which pumps water directly from the river.

The makeup water pump house is a non-Seismic Category I structure impervious to tornado damage. The pump house and structures associated with the cooling tower makeup system, such as valve boxes, are designed to withstand the design basis tornado, including tornado-generated missiles. Piping, valves, and electrical equipment are protected in a similar way. Exterior wall and roof penetrations are designed and anchored to withstand the design basis tornado and the effects of tornado-generated missiles. Tornado-generated missiles are discussed in Section 3.5. Section 9.2.5.3 provides a discussion on the makeup water system and ultimate heat sink interaction if tornado damage to the spray headers require a feed-and-bleed mode of operation.

The availability of essential electrical power to the makeup water pump house systems is ensured. The electrical lines are underground with sufficient earth cover to resist tornado-generated missiles.

The electrical lines are installed in such manner as to provide two redundant electrical systems from the power source to the makeup water pump house. The two electrical systems are physically separated to provide adequate missile protection of one system from the other. At one end of each system, redundant power source transformers, associated switchgear, and cabling are provided on the ground floor of the turbine building where, for the trajectories required to cause damage to this equipment, they are protected against missile impact and spalling by the exterior walls of the turbine building and the floor slabs overhead. The terminal ends and transformers at the makeup water pump house are enclosed within the tornado-resistant pump house. Manholes within each system are also designed to withstand tornado-generated missiles.

The spray pond piping and supports are designed to withstand the effects of the design basis tornado. The piping system cannot be protected from the impact of tornado-generated missiles. In the event of missile damage to one of the pond spray headers, the alternate spray system which is 100% redundant is placed in operation. (In the event that both spray systems are rendered inoperative, the cooling tower makeup water system is placed into operation to provide continuous water supply to the spray ponds using Columbia River water which based on historical data has not exceeded 70°F.) The cooling tower makeup water system is provided with sufficient protection to prevent its loss of function in the event of a design-basis tornado passing over the project site. Since the makeup water flow rate exceeds that of the SW systems, and since the makeup water temperature is lower than the SW system design temperature of 85°F, the continuous availability of cooling water is ensured. Procedures for alternate spray pond use is described in Section 9.2.5.

Failure of nontornado-resistant cooling towers due to tornado loads does not endanger Seismic Category I structures since the plant arrangement provides sufficient distance between the cooling towers and Seismic Category I structures.

The liquid nitrogen storage tank located at the corner of the diesel generator building will not fail due to tornado wind loads. However, if the design-basis tornado missile were to strike the tank straight on near the top of the tank, it could be toppled. Toppling of the liquid nitrogen storage tank due to the impact of a tornado missile can cause the entire contents of the tank to be rapidly emptied in the vicinity of the inerting system skid. There is no safety-related equipment in the vicinity of the tank that would be affected by the cryogenic temperatures associated with liquid nitrogen. In addition, due to the turbulent mixing produced in close proximity to a tornado, no oxygen deficiency condition could be sustained outdoors at the diesel generator intake structures.

Failure of nontornado-resistant structures and components will not affect the ability to shut down the reactor, the integrity of the primary containment or other Seismic Category I structures, the capability of the essential heat removal systems to perform their intended design functions, nor result in the release of radioactivity.

3.3.2.5 Conformance with Regulatory Guide 1.76, Revision 0

The discussion of conformance with Regulatory Guide 1.76, Revision 0, is in Section 1.8.3.

3.4 WATER LEVEL (FLOOD) DESIGN

3.4.1 FLOOD PROTECTION

3.4.1.1 External Flood Levels

3.4.1.1.1 Design Basis Flood

From the flooding conditions considered in Section 2.4, the design basis flood (DBF) condition arrived at for use in the protection of Seismic Category I structures and safety-related systems and components is that flood which results from the probable maximum precipitation (PMP) event. The PMP event results in a flood elevation of 433.3 ft mean sea level (msl). This event includes an additional 2.2 ft to account for wind wave action.

3.4.1.1.2 Breach of the Grand Coulee Dam

Floods associated with breaches of the Grand Coulee Dam are discussed in Section 2.4.4. The associated highest flood level is at el. 424 ft msl with wave action included.

3.4.1.1.3 Acceptance Criteria

The facility design and equipment locations are in accordance with General Design Criterion 2, as related to systems and components withstanding flood conditions, and Regulatory Guide 1.59, Revision 1, dated April 1976.

3.4.1.2 Groundwater Levels

3.4.1.2.1 Design Basis Groundwater

The design basis groundwater conditions are defined in Section 2.4.13. From the groundwater conditions considered in Section 2.4.13, the design-basis groundwater condition for use in the protection of Seismic Category I structures and safety-related systems and components is a rise of the present groundwater table with the possible construction of Ben Franklin Dam as discussed in Section 2.4.13.

The design-basis groundwater is el. of 420 ft msl. The normal groundwater table is at approximately el. 380 ft msl.

3.4.1.2.2 Breach of the Grand Coulee Dam

The effects on the groundwater table due to a breach of the Grand Coulee Dam is discussed in Section 2.4.4. This flood would peak for a short time and would not affect the design-basis groundwater level of 420 ft msl due to its short duration.

3.4.1.2.3 Design Basis Flood Probable Maximum Precipitation

As stated in Section 3.4.1.1.1, the worst DBF condition results from the PMP event. Due to the short duration of this flood and its confines, groundwater level at the site would not be affected.

3.4.1.3 Identification of Structures, Systems, and Components

Seismic Category I structures and safety-related systems and components are identified in Section 3.2. Figures 1.2-1 through 1.2-24 show locations and elevations for systems and components. See Section 2.4.2 for discussion of flood protection of safety-related systems and components.

3.4.1.4 Description of Structures, Systems, and Components

3.4.1.4.1 Flood Protection Requirements

3.4.1.4.1.1 External Flood Protection Requirements. The plant site elevation at Seismic Category I structures and safety-related systems and components is approximately 441 ft msl, except at the spray ponds where the finish grade elevation is 434 ft msl and the spray pond overflow weirs are at 434.5 ft msl. These elevations are sufficient to protect the plant site and, therefore, Seismic Category I structures and the safety-related systems and components housed therein against the DBF. Exterior and access openings to all Seismic Category I structures are located above the plant site grade and, therefore, above the DBF level. Flood protection measures are not provided since they are not required.

3.4.1.4.1.2 Internal Flood Protection Requirements. Section 3.4.1.5.2 discusses internal flood protection measures provided for safety-related systems, equipment, and components.

Figures 1.2-2, 1.2-7 through 1.2-17, and 1.2-22 illustrate plant arrangement and layout and show that safety-related equipment is located within individual rooms or compartments. The pump rooms located on the 422 ft 3 in. elevation are enclosed by reinforced-concrete walls. Penetrations and doors in these walls are provided with seals that minimize the effects of flooding between rooms should a break occur in one of the rooms.

The potential flooding and environmental effect attributable to postulated through-wall leakage cracks in moderate-energy fluid piping systems and postulated rupture of high-energy fluid piping systems are evaluated and discussed in Section 3.6.1.

Section 6.3 addresses single failure of the emergency core cooling systems (ECCS) piping, including leak detection requirements for ECCS passive failures, ECCS passive failures during long-term cooling, and potential flooding attributable thereto.

Section 9.3.3 discusses the design bases, system descriptions, safety evaluation testing and inspection requirements, and the instrumentation requirements relative to equipment and floor drainage systems. The design bases used ensure equipment and floor drainage systems integrity during normal plant operation and preclude any danger to health and safety of plant personnel, the environs and the general public. Five independent sumps are provided in the reactor building at floor el. 422.25 ft. These sumps serve pump rooms as shown on Figures 1.2-6 and 1.2-7. There is a single equipment drain sump for the reactor building (see Figure 9.3-9) located in the CRD/Condensate pump room. This sump also connects to the RCIC pump room through an unisolable drain header. The other four sumps are floor drain sumps serving the ECCS pump rooms. A single floor drain sump serves no more than two rooms. A sump located in one room is connected to a second room by a drain header containing a single isolation valve. Each sump is equipped with a level monitoring system, which automatically actuates the sump pump when high water level is reached in the sump. Each sump pump discharges to the Radwaste System. The isolation valve located in the header between connected rooms automatically closes on high water level in the sump to isolate the room with the leak.

The sumps collect water from such typical sources as equipment drains from the drywell and from other equipment carrying low purity water and from the drywell floor drain and other floor and pit drains. In the event of a pipe break in one of the pump rooms of sufficient size to exceed the capacity of the sump pump and overflow a sump in one room, the effects of common mode flooding between pump rooms are minimized by the following:

a. The reactor building equipment drain sump, located in the CRD/Condensate pump room, serves only the RCIC and the CRD/Condensate pump rooms. Although both rooms will be affected by a flood occurring in one room, analysis ensures that sufficient safe shutdown equipment remains unaffected by the flood, preserving the ability to safely shutdown the plant. Existing equipment drains located in the RHR pump rooms A and B are capped and, thus, do not connect to each other or to a common equipment drain sump. See Section 9.3.3.2.1.

b. The floor drain sumps serving more than one pump room have a single isolation valve in the drain header between pump rooms. This valve is fail-safe and automatically closes on a high water level in the sump. Accordingly, flooding

in any pump room, exceeding the capacity of the sump pump, will be confined to the room in which the leakage occurs with only minimal leakage through wall penetrations and door seals into other rooms or areas. Analysis is performed to ensure that sufficient safe shutdown equipment remains unaffected by the flood, preserving the ability to safely shutdown the plant. The high sump level also annunciates in the main control room. See Section 9.3.3.2.2.1.

c. Wall-mounted Class 1E level switches are also located in each of the ECCS and RCIC pump rooms and are mounted just above floor level. These level switches ensure that if a failure of the sump pump, the sump header isolation valve, or sump alarm system should occur in any of these rooms during a flood event, prompt operator notification of the event would be received allowing sufficient time for mitigating actions and safe plant shutdown. See Sections 6.3.2.5 and 9.3.3.2.2.1.

Administrative controls ensure that separation criteria is maintained by ensuring the appropriate doors and hatches are closed.

3.4.1.4.2 Groundwater Protection Requirements

Seismic Category I structures house safety-related systems and components and Seismic Category I components. The elevation of the lowest floor surface of these structures is as follows:

Structures	Elevation of Top of Floor
Reactor building	422 ft 3 in.
Radwaste and control room areas of radwaste control building	437 ft 0 in.
Diesel-generator building	441 ft 0 in.
Spray ponds 1A and 1B	420 ft 0 in.
Standby service water pump houses 1A and 1B	408 ft 3 in.
Retaining area for the condensate storage tanks	441 ft 0 in.

Seismic Category I structures and safety-related systems and components are located above the present groundwater el. 380 ft msl and are not subject to any force effects of buoyancy and static water from this groundwater elevation. Uplift and increased lateral hydrostatic pressure are considered in the design of all Seismic Category I structures and safety-related systems and components, to ensure their safety in the event of a rise in the groundwater table to 420 ft msl. Standby service water pump houses 1A and 1B are designed to resist the increased hydrostatic pressure which would result from the rise in the groundwater to el. 420 ft msl. The lowest floor surface in the reactor building is the top of the foundation mat at el. 422 ft 3 in. msl. Since this is above the design basis groundwater level, the structure is unaffected by the force effects of buoyancy and static water due to groundwater at el. 420 ft msl. Groundwater el. 420 ft msl was compared with foundation levels of Seismic Category I structures and it was determined that waterproofing is not required. Seismic Category I piping and electric conduit penetrations that are below grade are above the design basis groundwater table, and sealing against groundwater pressure is therefore not required. However, all pipes penetrating exterior walls are waterproofed sealed by boots installed on both sides of the wall penetration; all electrical conduit penetrations are through-wall waterproof sealed using silicon foam.

The only materials underlying the site that might exhibit unfavorable response to seismic or other events under saturated soil conditions are the loose to medium dense, fine to coarse sand with scattered gravel, in the upper approximate 40 ft of the soil profile. These were removed and recompacted as structural fill, as described in Sections 2.5.4.8 and 2.5.4.12. Structural fill supports the Seismic Category I structures, including the turbine generator building and service building, in the central plant complex. Structural fill, as required, is also utilized below the other Seismic Category I and safety-related structures including underground piping and electrical duct banks. The structural fill is compacted to a minimum of 75% relative density and an average relative density of not less than 85%. The compacted backfill will eliminate the possibility of liquefaction and provide satisfactory foundation performance should the groundwater level at the Columbia Generating Station site rise.

To evaluate the possible effects of a gross rise in groundwater levels, Shannon and Wilson, soil consultants, performed a series of repetitive triaxial tests in identical soils in the dry and saturated states and concluded that saturation would not necessitate changes in allowable bearing pressures or settlement calculations as discussed in Section 2.5.4.10.

To provide conservatism in the design of structures, the seismic dynamic response of the structures and components was examined over a range of soil shear moduli, as discussed in Section 2.5.4.7.

The possibility of soil liquefaction under the effects of the safe shutdown earthquake was evaluated for the conditions found to exist at the Columbia Generating Station site. Soils having high (75% plus) relative densities have been found in the past to be safe against liquefaction. In the soil underlying the foundations at Columbia Generating Station, liquefaction potential can only be assessed on the basis of soil type and general characteristics.

The foundations of all critical structures lie on compacted fill of fine to coarse sand with gravels. The phenomenon of the liquefaction has never been observed in such soils as this, and therefore, liquefaction was not postulated at the Columbia Generating Station site.

3.4.1.5 Flood Protection Measures

3.4.1.5.1 External Flood Protection Measures

As discussed in Section 3.4.1.4.1, external flood protection measures are not provided since they are not required. Equipment is located so that it is not vulnerable. Protection is not required to cope with potential leakage from such phenomena as cracks in structure walls. Since Seismic Category I structures are located at sufficient grade and distance from the Columbia River, as described in Section 2.4, the effects of wind wave action, including spray, do not require flood protection measures.

3.4.1.5.2 Internal Flood Protection Measures

The primary or safety-related functions fulfilled by the reactor building include the capability to withstand the effects of flooding from internal sources. Measures provided are discussed in Sections 3.8.4.1.1, 3.8.4.3.3, and 3.8.4.4.1.1. ECCS and RCIC pump rooms located in the reactor building basement at elevation 422 ft 3 in. are designed to withstand the effects of flooding between and including the top of the foundation mat at el. 422 ft 3 in. and el. 466 ft. Although not watertight, the doors and penetrations in these pump room walls are provided with seals that will minimize flooding between rooms (except for the RCIC and CRD pump rooms that are connected by an unisolable sump pipe) even with significant hydrostatic pressure generated from flooding water levels up to 466 ft. These pump rooms, comprised of exterior walls, interior walls, biological shield wall, isolation valves (when provided), penetrations, and doors are designed so that any one compartment at any one time, flooded to an elevation of 466 ft, can withstand the effects of seismically induced water sloshing loads. Section 3.8.4.3.3 discusses the CRD/Condensate pump room and railroad bay south exterior wall design hydrostatic pressure. Section 3.8.4.1.1 discusses the equipment hatch in the vehicle air lock (railroad bay) floor at el. 441 ft. See Section 3.4.1.4.1.2 for additional nonstructural related internal flood protection measures.

3.4.1.6 Emergency Flood Protection

Emergency flood protection procedures for bringing the reactor to a safe shutdown are unnecessary because flood conditions do not impact safe shutdown operation.

3.4.2 ANALYSIS PROCEDURES

Seismic Category I structures are located at sufficient grade and distance from the Columbia River so that dynamic water forces are precluded. Seismic Category I structures are designed

for the force effects of buoyancy and hydrostatic pressure due to the design basis groundwater in conjunction with loading combinations in Section 3.8.4. Seismic Category I structures are checked for stability and foundation pressures. In all cases, the dead loads of structures maintain stability and a positive soil bearing pressure. Design loads due to groundwater force application are applied to all Seismic Category I structures as follows:

a. A vertical hydrostatic pressure due to the water head below el. 420 ft msl on subgrade surfaces of structures and a lateral hydrostatic pressure on subgrade surfaces of structures. The lateral pressure is treated as an additional triangular loading increasing at the rate of 62.4 lb/ft^2 per vertical foot from el. 420 ft to the bottom of the structure, and

b. A buoyant force equal to the weight of water displaced by the structure.

The loading combinations used in conjunction with hydrostatic pressure due to groundwater, taken from Table 3.8-9, are

a. $U = 1.4D + 1.7L + 1.7\ P_o + 1.4F + 1.7Q$

b. $U = 1.4D + 1.7L + 1.4\ T_o + 1.7\ P_o + 1.4F + 1.7Q$

c. $U = 0.9D + 1.4F + 1.7Q$

d. $U = 0.9D + 1.4\ T_o + 1.4F + 1.7Q$

e. $U = 1.1D + 1.3L + 1.3\ P_o + 1.1F + 1.3Q + 1.3W$

f. $U = 1.1D + 1.3L + 1.1\ T_o + 1.3\ P_o + 1.1F + 1.3Q + 1.3W$

g. $U = 1.4D + 1.7L + 1.7\ P_o + 1.9E + 1.4F^* + 1.7Q$

h. $U = 1.4D + 1.4L + 1.4\ T_o + 1.4\ P_o + 1.4E + 1.4F^* + 1.4Q^*$

In the above load combinations, Q denotes lateral pressure on subgrade surfaces of structures due to either dry or saturated soils; and Q* denotes lateral pressure, including seismic effects, on subgrade surfaces of structures due to either dry or saturated soils. In applying the above loading combinations in conjunction with lateral hydrostatic pressure due to groundwater, the value for saturated soil is used.

In the above load combinations, the vertical hydrostatic pressure due to the water head below el. 420 ft msl and acting on subgrade surfaces of structures is included in D, dead loads, with consideration given to the direction of the hydrostatic pressure. The loading combinations

used in conjunction with hydrostatic pressure due to internal flooding are given in Table 3.8-9. The definitions of load terms used in the load combinations are given in Section 3.8.4.3.3.

3.5 MISSILE PROTECTION

The CGS missile protection design basis conforms to 10 CFR 50, Appendix A, General Design Criteria for Nuclear Power Plants, Criterion 4, Environmental and Missile Design Bases. The objectives of missile protection design are to ensure that the plant can be brought to and kept in a safe shutdown mode and to prevent offsite radiological consequences assuming an additional single component failure.

The primary provisions incorporated into the design of the CGS facility to preclude damage to the systems necessary to achieve and maintain a safe plant shutdown are separation and redundancy. These provisions provide that in the event of an accident plus an additional active component failure, where a system required for safe (cool) shutdown is rendered unavailable, enough systems are left available to bring the plant to a safe (cool) shutdown without allowing any offsite radiological consequences. This redundancy and separation is obtained by the deliberate routing of systems, by the presence of structural floors, walls, structural steel members, and adjacent equipment which serve as barriers.

Design against generated missiles involves an initial selection process to define postulated missiles, an evaluation of postulated missile credibility, then a damage assessment to evaluate the effects of credible missiles, and finally, if necessary, to ensure safe shutdown, the provision of barriers or physical modifications of systems and components to preclude damage.

Structures housing systems and components essential for safe shutdown are designed to withstand externally generated missiles so that essential systems and components are not damaged by such missiles or by the secondary effects of such missiles.

3.5.1 MISSILE SELECTION AND DESCRIPTIONS

3.5.1.1 Internally Generated Missiles (Outside Containment)

3.5.1.1.1 Systems Available for Safe Shutdown

Systems available outside containment to facilitate safe shutdown include: high-pressure core spray (HPCS), low-pressure core spray (LPCS), residual heat removal (RHR), standby service water (SW), reactor core isolation cooling (RCIC), control rod drives (CRD), and the reactor feedwater system (RFW). These systems and their function are described in Sections 4.6, 5.4.9, 7.3, and 7.4.

Figures 3.5-1 through 3.5-15 illustrate the location of these systems. Seismic categories, quality group classifications, and reference sections are provided in Table 3.5-1.

3.5.1.1.2 Missiles Due to Rotating Equipment Failure

The systems located outside the primary containment have been reviewed to identify potential rotating equipment missiles. The design objective is to prevent the generation of missiles and their effects.

All rotating equipment (e.g., pumps, turbines, fans, and compressors) outside the primary containment have been evaluated to determine missile generation potential (postulated missiles), missile credibility, and an analysis of credible missile effects was completed. Credible missiles outside containment, missile sources, safety-related systems requiring protection (if any), and the extent of damage to safety-related systems (if any) are listed in Table 3.5-2. All emergency core cooling systems (ECCS) rotating equipment outside the primary containment are grouped by division in different rooms or areas of the plant, separated by walls or barriers, so that a single missile cannot damage redundant systems. The walls or barriers are designed to contain all missiles.

The RCIC turbine is prevented from reaching a runaway speed, where component failure could occur, by overspeed tripping devices. However, the RCIC turbine, similar to all plant rotating equipment, is also evaluated for credible missile generation at normal full speed operation. In addition, as with the ECCS systems, the RCIC turbine is located in a separate compartment.

3.5.1.1.3 Missiles Due to Pressurized Component Failure

The potential of the following equipment to generate missiles was investigated:

a. High energy piping

Pressurized piping in systems where the service temperature exceeded 200°F and/or the service pressure exceeded 275 psig was evaluated for potential generation of missiles. High energy piping pipe whip is discussed in Section 3.6.

b. Valve bonnets

1. Pressurized seal bonnets

Valves with an American National Standards Institute (ANSI) rating of 900 psig and above are pressurized seal bonnet type valves, constructed in accordance with the American Society of Mechanical Engineers (ASME) Boiler and Pressure Vessel (B&PV) Code Section III. Valve bonnets, on pressure seal bonnet type valves, are prevented from becoming missiles by the retaining ring, which would have to fail in

shear, and by the yoke, which would capture the bonnet or reduce bonnet energy.

The bonnet bolts preload the pressure seal gasket to seal the valve initially. When pressurized, the valve is sealed by process fluid pressure and the bonnet bolts are under no load. All ASME III, Class I, 900# bonnet seal type valves were analyzed per ASME B&PV Code Section III requirements. Valve design pressures used in these analyses were given by the ASME B&PV Code Section III, Division 1, Subsection NB, Figure NB-3545.1-2, for weld-end valves. Using a typical pressure seal valve, the total thrust load on the retaining ring and valve body was calculated. The results demonstrated that both the retaining ring and valve body meet the ASME B&PV Code Section III, Division 1, NB-3227, requirements for pressures much higher than the normal operating pressure of the valve.

The majority of valves inside containment have massive valve operators which are supported by the yoke. For these valves, the valve operators act as an additional limitation to the yoke becoming a missile.

For a yoke clamp to fail, it must be assumed that the retaining ring fails completely and instantaneously so that the bonnet could strike the yoke. The yoke is normally under no load and complete failure of the yoke clamp is not considered credible.

Because of the highly conservative design of the retaining ring of these valves, bonnet ejection is highly improbable, and hence bonnets are not considered credible missiles.

2. Bolted bonnets

Most valves of ANSI rating 600 psig and below are valves with bolted bonnets. Valve bonnets are prevented from becoming missiles by limiting stresses in the bonnet-to-body bolting material by requirements set forth in the ASME B&PV Code Section III and by designing flanges in accordance with applicable code requirements. Even if bolt failure were to occur, the likelihood of all bolts experiencing simultaneous complete severance failure is remote. A study of bolted valve bonnets was made in which 25% of the connective bolts in the circular pattern were assumed missing. The stresses occurring under operating conditions with these bolts missing were found to be within acceptable limits. The widespread use of valves with bolted bonnets and the lack of

historical incidence of complete severance failures of bonnets confirms that bolted valve bonnets need not be considered credible missiles.

3. Screwed-typed bonnets

Some valves in the 1 in. to 1.5 in. size range have coarse threaded bonnets which screw into the valve body. These valves were analyzed and found to have low stress intensities in the bonnet retaining threads. The valve design stress intensities were found to be a minimum of 4.5 times the stress intensities that will be experienced by the valves. Because of the highly conservative design of these valves, they are not considered credible missiles.

c. Valve stems

Valve stems are not considered credible missiles if at least one feature in addition to the stem threads is included in their design to prevent ejection; for example, valves with backseats.

d. Thermowells and sample probes

Temperature or other detectors installed on piping or in wells are evaluated as potential missiles if failure of a single circumferential weld would cause their ejection. This is highly improbable since a complete and sudden failure of a circumferential weld is needed for a detector to become a missile. These circumferential welds were analyzed and found to have yield stress values from six to 20 times the stress intensities that will be experienced in service. Because of their highly conservative design, thermowells and sample probes are not considered credible missiles.

e. Nuts and bolts

Nuts, bolts, nut and bolt combinations, and nut and stud combinations are unlikely to fail because of the low stress intensities for these parts. The ASME and ANSI Codes limit the allowable stresses in bolts and studs to 20% to 30% of yield. These low stress intensities are ensured by measuring the torque of all bolts, studs, and nuts during installation. Because of their highly conservative design, nuts and bolts are not considered credible missiles.

f. Blind flanges

Bolted blind flanges are not considered credible missiles because of the extremely unlikely occurrence of all bolts experiencing simultaneous complete severance failure as discussed in Item b.2 above.

g. Nitrogen tanks and bottles

Nitrogen tanks and bottles in the reactor building provide nitrogen for CRDs, charging of main steam safety/relief valve (SRV), isolation valve accumulator tanks, and instrument nitrogen inside containment. These tanks and bottles have design pressures considerably in excess of their operating pressures. Because of their highly conservative design, installed nitrogen tanks and bottles are not considered credible missiles.

No credible missiles are in a position to impact any of the nitrogen tanks or bottles.

3.5.1.1.4 Evaluation of Postulated Missiles

a. Assessment of postulated missile credibility

Postulated missiles are analyzed to determine if a credible failure mode resulting in a missile exists. Failure modes determined to be credible are then assessed for impact on plant safe shutdown.

b. Assessment of potential credible missile damage

The ability of the plant to achieve safe shutdown is ensured by physical separation and redundancy of safety-related systems. The adequacy of the physical separation and redundancy of safety-related systems was evaluated using the following procedure:

1. Target determination

Based on the missile location and orientation, the target areas are predicted. Trajectories are selected to encompass the most adverse conditions. The essential systems within that region are assumed damaged and not available for a safe shutdown;

2. Evaluation of system damage

The essential systems which are available after the worst postulated missile accident and the most critical additional single failure are determined. An evaluation is then made to determine whether these remaining systems are sufficient to achieve safe reactor shutdown; and

3. Protection of systems

When the separation and redundancy of the essential systems is not adequate, or when a redundant system is not available, one or more of the following measures are taken to ensure safe shutdown:

(a) The orientation of the credible missile is changed so that systems necessary for safe shutdown are not damaged,

(b) Missile barriers are provided, and

(c) It is shown that the essential components will not be damaged by the credible missile.

c. Determination of missile energies

One of the following methods is used to calculate the extent of the damage caused by a credible missile:

1. Piston-type missiles

The velocity of a piston-type missile is calculated by assuming that the work done will be converted into kinetic energy of the missile with no losses of energy due to friction or air resistance.

Work is the integral of force times displacement, while the kinetic energy of the missile is one-half the product of the missile mass times the square of the missile velocity. Assuming the applied force constant (PA_o), the kinetic energy is equated to the work done (Reference 3.5-1). Subsequently, the missile velocity is obtained by the expression:

$$V = \left[\frac{2\,PA_o\,L}{m}\right]^{1/2}$$

(Reference 3.5-1)

where:

V = the initial velocity at the end of a piston stroke (ft/sec)

P = pressure of the fluid (psi)

A_o = cross-sectional area of the piston ($in.^2$)

L = length of the stroke in ft

m = mass of missile ($lb\text{-}sec^2/ft$)

2. Jet-propelled missiles

Postulated jet-propelled missiles are propelled by fluid escaping from a pressurized system in which there is essentially no lateral containment of the fluid. The escaping jet will not only impinge on the missile, but will also flow around and past the missile.

The velocity of this type of postulated missile is estimated by (Reference 3.5-1):

$$\left(1 - \frac{V}{V_f}\right) - \text{Log}_e\left(1 - \frac{V}{V_f}\right) = K_1 - \frac{K_2}{N_o + X \text{ Tan } B}$$

where:

$$K_1 = \left(1 - \frac{V_o}{V_f}\right) - \text{Log}_e\left(1 - \frac{V_o}{V_f}\right) + \frac{K_2}{N_o}$$

$$K_2 = \frac{A_o A_m P_b}{m\pi(\text{Tan } B)}$$

V = missile velocity at distance X (fps)

V_f = jet velocity = (fps)

N_o = radius of throat (ft)

P_f = density of the jet fluid ($lb\text{-}sec^2/ft^4$)

X = distance traveled (ft)

B = angle of jet expansion, degrees from normal

V_o = initial velocity of missiles

A_o = throat area (ft^2)

A_m = cross-sectional area of missile (ft^2)

m = mass of missile ($lb\text{-}sec^2/sec$)

3. Stored strain energy missiles

Stored strain energy missiles are assumed to convert all the strain energy at which they fail into kinetic energy. The velocity is calculated from the following formula (Reference 3.5-1):

$$V = \left[\frac{g}{EW}\right]^{1/2} S$$

where:

V = missile velocity (ft/sec)

E = modulus of elasticity (lb/ft^2)

W = specific weight of missile (lb/ft^3)

S = ultimate stress in the missile before failure (lb/ft^2)

g = acceleration of gravity (ft/sec^2)

4. Rotating Machinery

A variety of missiles from rotating machinery can be treated by considering each as a rotating block. Because it is part of a rotating structure, the block is considered to be initially rotating about its axis of revolution at a speed, ω, radians per second. The kinetic energy (KE) of the block is given by (Reference 3.5-4):

$$KE = \frac{1}{2}\left[Rcg^2 + K^2\right]\left(\frac{w}{g}\right)(\omega)^2, \text{ ft} - \text{lb}$$

where:

Rcg = radius to the center of gravity (CG) of the rotating block, measured from the initial axis of rotation in the machinery, ft

K = radius of gyration of the rotating block, about the cg axis of the rotating block

w = block weight, lb

g = acceleration of gravity, ft/sec^2

ω = angular velocity, rad/sec

In this expression the Rcg term gives the kinetic energy due to translation, while the K term gives the kinetic energy due to rotation of the block about its cg axis.

3.5.1.1.5 Example of Postulated Missile Evaluation

a. Assessment of postulated missile credibility

The reactor protection system motor generator sets in the critical dc switchgear rooms in the reactor building (el. 467 ft 0 in.) were analyzed to determine their credibility as missiles. A structural failure of the 1800 rpm flywheel during the normal operation of the motor generator would produce high energy missiles with the potential to damage systems, components, or structures in their paths. Motor generator set modification to eliminate or contain the flywheel missiles was evaluated, but a feasible modification was not practical. The flywheels were, therefore, credible missiles.

b. Assessment of potential credible missile damage

The flywheel missiles were postulated to exit the motor generator sets along a plane perpendicular to the motor generator set, with the missile exiting a maximum of 10 degrees from the perpendicular plane.

1. Target determination

The potential targets for the flywheel missiles were determined by reviewing the applicable drawings and visual inspection of the target area in the switchgear rooms. It was determined that safety-related cables in these rooms could potentially be damaged.

2. Evaluation of system damage

The safety-related cables which could be damaged by the flywheel provide dc power to instrument panels in the control room and to isolation valves inside containment. Damage to these cables was determined to be unacceptable.

3. Protection of systems

It was determined that there was not a feasible method of providing that the cables would not be damaged by the flywheel missiles. To preclude damage to the safety-related cables, the following alternatives were investigated:

(a) The motor generator sets were analyzed to determine if a change in orientation was feasible. This was not a feasible alternative.

(b) The feasibility of constructing a barrier around the flywheel was investigated. This was a feasible alternative.

c. Barrier design

A missile barrier proved to be the only feasible alternative. The barrier was designed to contain the highest energy missile that could be produced by the flywheel. The barrier was constructed of steel and energy-absorbing aluminum honeycomb material and firmly anchored to the concrete floor. This eliminated the effects of the credible missile. A tabulation of plant systems protected by missile barriers is provided in Table 3.5-3.

3.5.1.2 Internally Generated Missiles (Inside Containment)

3.5.1.2.1 Systems Available for Safe Shutdown

Figures *3.5-16* through 3.5-32 describe the mechanical and instrumentation locations of systems available for a safe shutdown. Each system (LPCS, HPCS, RHR, ADS, CRD, and primary containment) is color coded to specify the location of structures, systems, or

components. In addition, the reactor protection system and containment isolation valves inside containment are available for safe shutdown of the plant and to prevent offsite radiological consequences. Information pertaining to applicable seismic category, quality group classification, and reference sections where these systems are described is provided in Table 3.5-4. The evaluation of credible missile kinetic energies and missile target determinations is discussed in Section 3.5.1.1.4. Target and barrier damage evaluations are discussed in Section 3.5.3.

3.5.1.2.2 Missiles Due to Rotating Equipment

Rotating equipment inside containment consists of the following:

a. Recirculation pump and motor

The most substantial piece of nuclear steam supply system (NSSS) rotating machinery is the recirculation pump and motor. This potential missile source is discussed in Reference 3.5-4.

It is concluded in Reference 3.5-4 that destructive pump overspeed is highly improbable. If it occurred, it could result in failure of certain pump and motor components having the potential to become missiles. A careful examination of the pump and motor structure shows that rotor or shaft failure will not result in ejection of motor-generated missiles, and impeller missiles cannot penetrate the pump case. Reference 3.5-4 concludes that in the unlikely event of impeller failure resulting in ejection of missiles through ruptured pipe, penetration of containment by missile fragments is highly improbable. Evaluation of the effects on safety-related systems of impeller fragments that might be ejected from openings in ruptured pipe is not evaluated because of the extreme improbability of this event and because the effects would not be more severe than the assumed consequences of jet impingement due to pipe inside containment as discussed in Section 3.6. The recirculation pump and motor are, therefore, not considered to be credible missile sources.

b. Fans as potential missiles

The fans inside primary containment are designed such that the casing will restrain any possible missile. Therefore, fans and parts thereof are not considered as possible sources of missiles.

3.5.1.2.3 Missiles Due to Pressurized Component Failure

A discussion of the potential for missile generation from the failure of pressurized components, e.g., valve stems, valve bonnets, and temperature element assemblies, is presented in

Section 3.5.1.1.3. That discussion is also applicable to pressurized components inside containment. In addition, SRV and main steam isolation valve (MSIV) accumulators are particular to inside containment.

Pressurized ASME III vessels, such as SRV and MSIV accumulators, are not considered credible missiles. These vessels have low stresses and operate in the "moderate energy" range and, therefore, any failures would be a crack-type and not of concern for missile generation.

All potential sources of postulated missiles inside the primary containment were analyzed to determine missile credibility utilizing the criteria discussed above and in Section 3.5.1.1.3, as required by General Design Criterion 4, "Environmental and Missile Design Basis." It was determined that all postulated missiles inside the primary containment incorporated design features that eliminated their credibility as potential sources of missiles.

3.5.1.2.4 Falling Objects

Structural elements, equipment, and components inside containment which could be considered as potential falling objects are evaluated in accordance with Section 3.7.2.8.

3.5.1.2.5 Secondary Missiles Generated by Postulated Credible Primary Missiles

Secondary missiles are not considered credible missiles due to their low probability of occurrence and their low kinetic energy levels. The probability of damage due to a secondary missile is the probability of occurrence of a primary missile times the probability of hitting a part that can become a secondary missile times the probability that the part will actually become a missile. This probability is very low.

The level of stored kinetic energy in a secondary missile will be low because of the large energy required to produce a secondary missile. In addition, no reliable method to predict secondary missile characteristics is known, other than those characteristics in common with primary missiles.

3.5.1.3 Turbine Missiles

In April 1992, the original Westinghouse shrunk-on-disc type LP rotors were removed and new Westinghouse Fully Integral LP rotors were installed. The LP turbine missile analysis is based on Fully Integral rotors using a probabilistic method (Reference 3.5-27).

It is concluded that the probability of damage to safety-related systems by turbine missiles is acceptably low, due to (a) the protection provided by reinforced-concrete structural barriers, (b) the calculated probability of turbine missile generation, and (c) periodic testing and inspection of turbine overspeed protection systems with associated corrective action as required.

3.5.1.3.1 Safety-Related Targets

Target areas which are evaluated for capability to protect safety-related equipment, components, and systems from postulated turbine missiles consist of the following:

a. Vertical targets

1. Reactor building north exterior wall,

2. Control room north wall, and

3. North wall of vertical cable chase, between reactor building and control room.

b. Horizontal targets

1. Reactor building refueling floor,

2. Roof over vertical cables chase, and

3. Floor slab above control room.

3.5.1.3.2 Turbine Placement and Orientation

Figure 3.5-33 shows the turbine generator layout relative to safety-related plant structures and turbine missile target areas. Also shown on this drawing is the reinforced-concrete shield wall which acts as a barrier for protection of some safety-related targets from postulated low trajectory turbine missiles. A cross-sectional view through the turbine building and reactor building is shown in Figure 3.5-34 to indicate relative elevations of the turbine and target areas. See Figures 1.2-4, 1.2-8 and 1.2-16 for a general arrangement drawing of the turbine building, reactor building, and control building at the turbine operating floor elevation. CGS has an "unfavorable oriented" turbine generator in relation to the identified safety-related targets.

3.5.1.3.3 Missile Identification and Characteristics

3.5.1.3.3.1 High Pressure Turbine. Postulated missiles from the high pressure turbine (HPT) are shown in Reference 3.5-22 to have insufficient energy to penetrate the casing at normal operating speed. At 20% overspeed (120% of normal, or rated speed), HPT missiles are postulated to penetrate the casing, but at velocities too low to reach safety-related targets. The minimum bursting speed of the high pressure turbine rotor, based on minimum specified mechanical properties of the rotor material, is 300% of the rated speed (Reference 3.5-6).

The maximum speed at which the unit may rotate is 3200 rpm, which is 178% of rated speed 1800 rpm (Reference 3.5-27). At this speed the highest stressed low pressure turbine disc would fracture, damaging the turbine to the extent that additional overspeed would not be possible. Therefore, high pressure turbine missiles are not considered.

3.5.1.3.3.2 Low Pressure Turbine. Each low pressure turbine consists of a double-flow rotor assembly, an outer cylinder, two inner cylinders, and stationary blade rings. The rotor is a fully integral, single forging consisting of the shaft, disks, and couplings without any shrink fits or keyways and is made with low stress corrosion cracking (SCC) susceptible materials.

Westinghouse Report "Analysis of the Probability of the Generation of Missiles from Fully Integral Nuclear Low Pressure Rotors" (Reference 3.5-27) states

> To assess the probability of missile generation resulting from a burst of a fully integral nuclear low pressure rotor, five potential failure mechanisms are considered:
>
> a. Ductile burst,
>
> b. Fracture resulting from high cycle fatigue cracking,
>
> c. Fracture resulting from low cycle fatigue cracking-startup/shutdown cycles,
>
> d. Fracture resulting from stress corrosion cracking, and
>
> e. Destructive overspeed.
>
> All the listed failure mechanisms demonstrate that the new Fully Integral rotor design significantly reduces the likelihood of missile generation, except for the destructive overspeed mechanism.
>
> The probability of reaching a destructive overspeed for the Fully Integral LPT rotor is primarily dependent on the DEH control system, which functions to avoid this condition.

3.5.1.3.4 Strike and Damage Probability

A probabilistic approach is adopted to assess the possibility of damage to systems required for safe shutdown or of accidents which could result in potential offsite exposure due to high trajectory missiles. The probability of this occurring is represented by combined probabilities of

$$P_4 = P_1 \times P_2 \times P_3$$

where:

P_1 = missile generation probability

P_2 = probability of a missile striking a structure or component required for safe shutdown or whose failure could result in release of radioactivity

P_3 = probability of significant damage to the structure or component

P_4 = combined overall probability

The terms and assumptions applicable to this analysis follow the procedures outlined by S. H. Bush in Reference 3.5-7.

3.5.1.3.4.1 Missile Generation Probability. Missile generation probability is based on the failure probability of the Fully Integral rotor design (installed 1992) and the turbine overspeed protection system. The dominant failure mechanisms of the rotor are SCC and turbine overspeed. The P1 values for SCC were provided by Westinghouse (References 3.5-27 and 3.5-28) and meet the requirements of the NRC Safety Evaluation Report (SER) for specific turbine inspection and testing intervals. However, the SER states the NRC position that the LP rotor operation, maintenance, and inspection programs be based on the P1 values being less than the 1×10^{-5} probability requirement for loading the turbine without inspection or inservice restriction. This value is applicable to the CGS unfavorably oriented turbines.

The P1 values for the CGS low pressure turbine Fully Integral rotors for stress corrosion cracking are

Inspection Interval (years)	P1 at Rated Running Speed	P1 at 20% Overspeed
4	4.0×10^{-14}	1.4×10^{-14}
8	8.8×10^{-11}	2.0×10^{-11}
12	4.3×10^{-9}	7.7×10^{-10}
16	5.1×10^{-8}	7.9×10^{-9}
32	8.3×10^{-6}	8.9×10^{-7}

The probability for SCC at 20% overspeed (120% of normal or rated speed) is lower than the SCC at rated speed condition, and therefore not considered in determining the overall strike and damage probability of turbine-generated missiles (Reference 3.5-28).

As with previous rotor designs (including the CGS original built-up rotors and current Fully Integral rotors), the potential exists for SCC to be the dominant failure mechanism depending on inspection interval (Reference 3.5-29). However, in Fully Integral rotor designs, the probability of failure by the SCC mechanism has been reduced drastically and the analysis shows that at the normal inspection interval established by the preventive maintenance (PM) program of 80,000 to 100,000 running hours (translates to 10-12 years), the contribution from SCC to P1 would be approximately 4.3×10^{-9}. Considering typical use factors for nuclear turbines, and considering that the crack locations are readily observable during routine turbine maintenance and inspection per the PM program, it is concluded that the NRC safety criteria of $P1 \leq 1 \times 10^{-5}$ will not be exceeded.

The methodology developed to calculate the probability of missile generation due to overspeed events identifies three turbine overspeed events that can result from the failure of the turbine valves to close following a system separation or a total loss of load (References 3.5-30 and 3.5-31). These overspeed events are design overspeed (approximately 120% of rated turbine speed), intermediate overspeed (approximately 130%), and destructive overspeed (runaway speed in excess of approximately 180%). Design overspeed is assumed when a system separation occurs and a turbine trip does not occur at event initiation, one or more governor valves or two or more interceptor valves fail to close immediately, and a successful overspeed trip closes the throttle valves and reheat stop valves. Intermediate overspeed is assumed to occur when there is a system separation and one or more alignment of reheat stop valves and interceptor valves fail to close. Destructive overspeed is assumed to occur when a system separation occurs and at least one governor valve and one throttle valve in the same steam chest fail to close.

Missile generation probability analyses (References 3.5-30 and 3.5-31), indicate that the design and intermediate overspeed failure probabilities are not major contributors to turbine missile ejection probability for plants with fully integral low pressure rotors.

The P1 value for turbine overspeed is derived from the probability of failure of the turbine overspeed protection system in a manner that results in destructive overspeed and includes consideration for periodic turbine valve testing. Additionally, the P1 value includes conservatism to account for design and intermediate overspeed missile generation. The overspeed protection system is a fault tolerant, redundant, digital electro-hydraulic turbine control and overspeed protection system (installed-May 2007). The system has the capability of failure detection and on-line repair of critical components. The missile generation probability analysis for potential turbine overspeed yields a missile generation probability of 3.4×10^{-6} for P1 based on a twelve month turbine valve testing interval (Reference 3.5-32).

Combining the SCC mechanism (assuming inspection at 12 year intervals) and the destructive overspeed mechanism to establish a combined P1 value for missile generation, yields a probability of turbine missile generation of 3.4×10^{-6}.

3.5.1.3.4.2 Strike Probability (P2) and Damage Probability (P3). Rather than performing elaborate calculations for site-specific strike and damage probabilities as previously performed for the disc type rotors, generally accepted industry typical values were used for P2 and P3. For CGS, the product of P2 * P3 is 1×10^{-2} for unfavorably oriented turbine generators (Reference 3.5-28).

3.5.1.3.4.3 Combined Overall Probability (P4). Assuming the longest turbine inspection interval of 12 years and a destructive overspeed probability assuming a twelve month turbine valve test interval, the highest overall damage probability for postulated missiles is then calculated by

$$\begin{aligned} P4 &= P1 * P2 * P3 \\ &= (3.4 \times 10^{-6}) * (1 \times 10^{-2}) \\ &= 3.4 \times 10^{-8} \text{ (which is acceptably less than the NRC safety criteria of } P4 \leq 1 \times 10^{-7}) \end{aligned}$$

3.5.1.3.5 Turbine Overspeed Protection System and Testing

A single failure in the overspeed sensing and turbine trip systems will not prevent overspeed protection from operating. The turbine generator is equipped with a fault tolerant and redundant DEH control system.

The DEH control system, with its overspeed protection features and inspection and testing requirements, is described in Sections 7.7.1.5 and 10.2.

3.5.1.3.6 Turbine Valve Testing

Turbine valve testing is discussed in Section 10.2.

3.5.1.3.7 Turbine Characteristics

For information characterizing the Westinghouse turbines used at CGS, refer to Westinghouse report covering the effects of a high pressure turbine rotor fracture (Reference 3.5-6) and low pressure turbine forged integral rotor fractures, (Reference 3.5-27). Therein, the low-pressure disc materials, manufacturing processes, and operating conditions are stated.

3.5.1.4 Missiles Generated by Natural Phenomena

The consideration of potential missiles injected or suspended in a tornado wind stream is based on References 3.5-8 and 3.5-12.

All Seismic Category I and safety-related structures and components are designed to include the effects of missiles generated by the design basis tornado described in Section 3.3.2 except as noted in Sections 3.5.1.4.1 and 3.5.2. Missiles are categorized as either external or internal missiles. External missiles are materials and/or items usually found outside and in the immediate vicinity of the buildings, whereas internal missiles are materials and/or items found inside the buildings. Descriptions, properties, and impact velocities of the design-basis tornado-generated external missiles are shown in Table 3.5-5. Tornado missile protection provided by plant structures is described in Section 3.5.1.4.1. Those structures have adequate thickness to prevent penetration, perforations, and backface spalling. The basis for evaluating missile penetration is discussed in Section 3.5.3. The protection provided for external and internal missiles is discussed in Sections 3.5.1.4.1 and 3.5.1.4.2, respectively.

Figures 1.2-1 through 1.2-24 indicate the location of structures, equipment, and components protected against tornado-generated missiles.

3.5.1.4.1 Tornado-Generated External Missiles

Structures that house systems, equipment, and components essential to safe shutdown are designed to withstand the effects of design-basis tornado-generated missiles described in Section 3.5.1.4. These structures provide protection by the following means:

a. Reactor building

The location of the reactor building with respect to the other plant structures is illustrated in Figure 1.2-1. Portions of the reactor building exterior walls are protected by adjacent structures against direct impact of tornado generated missiles, as indicated in Figure 3.5-35. The exterior walls of the reactor

building, up to the refueling floor at el. 606 ft 10.5 in., are capable of withstanding the impact of the design basis tornado generated missiles. The exterior walls are constructed of 4 ft thick reinforced concrete to el. 471 ft 0 in. which is 30 ft above plant finish grade. From el. 471 ft 0 in. to the refueling floor at el. 606 ft 10.5 in., the exposed exterior walls are constructed of reinforced concrete, 18 in. minimum in thickness. The reactor building exterior wall thickness from plant grade to the refueling floor at el. 606 ft 10.5 in. is adequate to prevent design basis missile penetration and spalling of concrete. (See Figures 3.5-36 through 3.5-38.)

The refueling floor at el. 606 ft 10.5 in. comprises the spent fuel storage pool, dryer/separator pool, and various other items of refueling equipment. The reactor building walls and roof above this floor are constructed of insulated metal siding and insulated metal roof decking erected on a superstructure consisting of a structural steel frame as indicated in Figures 1.2-11 and 1.2-12. The superstructure also supports the overhead bridge crane. The refueling floor at el. 606 ft 10.5 in. is constructed of reinforced concrete of various thicknesses, with a minimum thickness of 18 in. The walls and floor of the pools have a minimum thickness of 5 ft. The equipment on the refueling floor is not required for safe shutdown. The refueling floor and the walls and floor of the pools are sufficiently thick to withstand the effects of the design basis missiles, and to prevent secondary missile effects caused by spalling of concrete. A missile impacting the spent fuel pool does not have sufficient energy to damage the equipment and spent fuel located in the pool, as discussed in Reference 3.5-12.

b. Diesel generator building

The exposed exterior walls of the structure are constructed of reinforced concrete with a minimum thickness of 2 ft 8 in. The roof has a minimum thickness of 1 ft 6 in. The thicknesses of walls and roof are sufficient to withstand the effects of the design-basis tornado-generated missiles. Figures 1.2-22 and 3.5-42 through 3.5-44 illustrate this structure.

c. Radwaste and control building

The exposed exterior concrete walls and roofs, housing safety-related systems, equipment, and components are designed to withstand the effects of the design-basis tornado-generated missiles. Figures 1.2-13 through 1.2-17 illustrate the radwaste and control building and their relative location in the plant complex. The exterior walls that house safety-related equipment have a minimum thickness of 2 ft. The roof of the portion of the building that houses safety-related equipment is 1 ft 6 in. thick (see Figure 3.5-45).

d. Standby service water pump houses and spray ponds

The exterior walls of both pump houses are constructed of reinforced concrete and are 2 ft 4 in. thick, minimum. The roofs of the pump houses are 1 ft thick. These thicknesses are adequate to withstand design-basis tornado-generated missiles. In addition, the two pump houses are redundant to each other. In the event that one pump house is inoperable, the other is capable of providing sufficient service water for safe shutdown. See Figures 3.5-46 and 3.5-47.

The ability of the spray ponds to tolerate the design-basis tornado-generated missiles is discussed in Section 3.3.2.3.

Figure 1.2-20 illustrates the pump houses and spray ponds.

e. Makeup water pump house

The exterior walls and roof of the makeup water pump house are of reinforced concrete and are sufficiently thick to withstand the effects of the design-basis tornado-generated missiles, as discussed in Section 3.3.2.3. The exterior walls, with the exception of the equipment access opening, are 2 ft 4 in. thick and the roof slab is 1 ft 4 in. thick. Figures 1.2-1, 1.2-23 and 1.2-24 furnish its location and arrangement. The 8 ft 0 in. by 10 ft 0 in. equipment access opening is protected by a 14-in.-thick concrete door.

f. Turbine building

Safety-related components in the turbine building are located in areas where tornado missile protection is provided by reinforced-concrete exterior walls, a minimum of 18 in. in thickness, and two reinforced-concrete slabs overhead, at el. 471 ft and 501 ft. Figures 1.2-2 through 1.2-6 illustrate the turbine building.

g. Safety-related systems outside of tornado-hardened structures

The protection provided to the pipe lines and electrical lines located underground between the spray ponds, SW pump houses, makeup water pump houses, reactor building, and the diesel generator building is described in Sections 3.5.2 and 3.5.3. The protection provided to the critical electrical trays in the corridor between the turbine generator building and the radwaste and control building is also described in Sections 3.5.2 and 3.5.3.

3.5.1.4.2 Tornado-Generated Internal Missiles

The tornado-generated internal missiles as mentioned in Section 3.5.1.4 are materials and/or items attached to or found inside a building, but subjected to the design basis tornado described in Section 3.3.2 as a result of a loss of a building exterior wall or roof. The materials and/or items considered as potential tornado-generated internal missiles are discussed below.

a. The reactor building steel framed superstructure uses girts and roof purlins fastened to the building frame by means of controlled release fasteners. The steel girts and purlins are considered to become free falling tornado-generated internal missiles which can strike the roof of the diesel generator building, the radwaste and control building, and main steam corridor slabs, in the event a tornado blows the roofing and/or siding off of the building frame. Structures housing safety-related systems, equipment, and components are designed to withstand the effects of these missiles.

b. In the event that a tornado blows the roof purlins, roof decking, girts, and siding panels off the reactor building frame, the reactor building crane is then exposed to the design basis tornado. The reactor building crane is designed with provisions which preclude it, or any part thereof, from becoming a missile (see Section 3.3.2.3).

3.5.1.4.3 Flood Generated Missiles

The design basis flood el. discussed in Section 3.4 and defined in Section 2.4, exceeds the flood levels associated with breaches of the Grand Coulee Dam. The final plant grade level is higher than the design basis flood. Therefore, flood-generated missiles are not considered in the design of the Seismic Category I safety-related structures and installations.

3.5.1.4.4 Protection and Design

Systems protected from missiles generated by natural phenomena, and barrier design are described in Sections 3.5.2 and 3.5.3 respectively.

3.5.1.5 Missiles Generated by Events Near the Site

Hazards due to missiles postulated in the design basis explosions or accidents at nearby industrial plants, military facilities, pipe lines, or storage facilities can be discounted as discussed in Section 2.2.

The Hydrogen Storage and Supply Facility (HSSF) contains a liquid hydrogen storage tank, ASME tubes (gaseous hydrogen), trailer tubes (gaseous hydrogen) and a hydrogen pipeline to the plant. An analysis shows that an explosion and subsequent missile generation from a

random tank rupture at normal pressure would not affect the plant due to the remote distance of the facility. Another analysis shows that an overpressurization event and subsequent rupture of the liquid hydrogen tank is a credible event. However, the total annual probability of impact for any of the missiles generated is less than 10^{-7} and does not meet the threshold for consideration as a design basis event. The hydrogen storage containers have relief valves to prevent overpressurization.

3.5.1.6 Aircraft Hazards

NUREG-0800, Standard Review Plan, Section 3.5.1.6, "Aircraft Hazards," provides guidance to ensure that the risks from aircraft hazards are low enough for nuclear power plants. If the distance at which aircraft activity occurs meets all the criteria provided in the following, the probability of an aircraft accident resulting in radiological consequences greater than the exposure limits in 10 CFR 50.67 can be considered to be less than about 10^{-7} per year and no additional analysis is required (Reference 3.5-16):

a. The plant-to-airport distance (D) is between 5 and 10 statute miles, and the projected annual number of operations is less than 500 D^2, or D is greater than 10 statute miles and the number of operations is less than 1000 D^2,

b. The plant is at least 5 statute miles from the edge of military training routes, including low-level training routes, except for those associated with a use greater than 1000 flights per year or where activities (such as practice bombing) may create an unusual stress situation, and

c. The plant is at least 2 statute miles beyond the nearest edge of a federal airway, holding pattern, or approach pattern.

Additionally, aviation crashes associated with general aviation (light planes, $<$12,500 lb) may be excluded from this analysis, as tornado design-basis requirements establish structural requirements sufficient to protect safety-related structures, systems, and components against these types of events (Reference 3.5-17).

3.5.1.6.1 Airports

There are no active airports located within 10 statute miles of the CGS site, but there are two commercial airports and six private airports which are active within 20 miles of the site. The annual number of operations of flights from these airports of less than 1000 D^2 is satisfied for all aviation uses at the commercial airports, including general, airtaxi, freight, and commercial traffic.

3.5.1.6.2 Military Airspace Use

The airspace over the Hanford site is periodically used as a marshaling area for military aircraft participating in training missions at the Yakima Training Center. A low-level military training route associated with this training passes above the western edge of the Hanford site about 18 miles west of CGS (Reference 3.5-18). Thus Criterion 2 associated with military use is also satisfied.

3.5.1.6.3 Federal Airways and Airport Approaches

CGS does not satisfy the third criterion identified in Section 3.5.1.6 of being at least 2 statute miles beyond the nearest federal airway, holding pattern, or approach pattern. Therefore, the probability of an aircraft accident resulting in an exposure greater than 10 CFR 50.67 limits has been evaluated.

Figure 2.2-3 shows the commercial airports, low-level federal airways, and airport instrument approaches in the vicinity of the CGS site. Airway V187 (with a minimum altitude of 3500 ft mean sea level) passes over the CGS site. The 14 nautical mile (NM) instrumented approach pattern is also important to the CGS site. Aircraft tend to maintain significant altitude over the Hanford site because of a request by the Federal Aviation Administration (FAA) (Reference 3.5-18).

The Tri-City Airport traffic supervisor provided a conservative estimate of 7500 flights per year that can be expected through airway V187 and the 14 NM approach (Reference 3.5-19). The number obtained is for flights by aircraft that are under instrument flight rule (IFR) flight plans. Aircraft that leave the airport in the general direction of V187 and that are under visual flight rules do not have to file a flight plan and are not required to follow the airway. For the purpose of this evaluation, the total number of aircraft flying through the airspace over CGS is assumed to be those constrained to the airway V187 and those using the 14 NM instrument-approach path (i.e., 7500 per year). Other flight paths are either sufficiently far away (more than 2 miles) with sufficiently low volume or are not currently active.

The aircraft using the Richland Airport may also pass over the CGS airspace. However, the only aircraft over 12,500 lb expected to use this approach would be ambulance (Life-Flight) aircraft using the Richland Airport under adverse weather conditions. Other aircraft activities possibly impacting the CGS site include activities conducted by/for the Department of Energy or their contractors on the Hanford site. These typically consist of less than 10 low-level flights per year over the entire Hanford site airspace (Reference 3.5-19). The additional risk posed by these operations is expected to be very low and is sufficiently bound by the conservatisms used in the above estimates.

The probability per year (P_{PY}) of an aircraft crashing into the plant can be expressed as (Reference 3.5-16) equation 3.5.1.6-1:

$$P_{PY} = C \times N \times A_{eff}/w$$

where:

C = In-flight crash rate per mile for aircraft using airway

N = Number of flights per year along the airway

w = Width of airway in miles

A_{eff} = Effective area of the plant in square miles.

The effective area of the facility is the ground surface area covered by all flight crash trajectories that could impact the surface structure. This area is larger than the facility itself because of the possibility of the aircraft skidding across the ground before hitting the facility as well as the possibility of a direct hit on the structure before striking the ground. The effective area is the sum of the structure's area, the shadow area (behind the structure), and the aircraft skid area (in front of the structure).

3.5.1.6.4 Summary

The probability per year, estimated per Reference 3.5-16, is 9.07×10^{-8}. Thus, the probability of an aircraft accident resulting in radiological consequences exceeding 10 CFR 50.67 limits is below 10^{-7}/year. Therefore, aircraft are discounted as credible missiles and accidents involving aircraft are not considered design basis events.

3.5.2 SYSTEMS TO BE PROTECTED

The structures, systems, and components necessary for bringing the plant to a safe shutdown and the protection provided for these structures, systems, and components from missiles is discussed in Sections 3.5.1 and 3.5.2.

Protection provided for the safety-related structures located outdoors against tornado-generated missiles is described in Section 3.5.1.4 and by turbine missiles in Section 3.5.1.3.

The plant structures, systems, equipment, and components that are required to bring the plant to a safe shutdown condition, or whose failure could lead to offsite radiological consequences under accident conditions, are protected from external (outdoor) missiles by barrier structures or redundant systems as follows:

a. The exposed exterior walls of safety-related structures are designed to protect internal structures, systems, and components. Structures with such exposed exterior walls are described in Section 3.8.4 and shown in figures referred to therein. Figure 3.5-35 illustrates exterior walls subject to tornado-generated missile impact.

b. All openings for heating, ventilation, and air conditioning system fresh air intakes (FAI) and exhausts (EXH), in buildings housing safety-related equipment, are protected against externally generated missiles as indicated in Table 3.5-6. Examples are the louvered openings above the floor at el. 572 ft 0 in. in the north and south walls of the reactor building. These openings are protected by a labyrinth of missile shield walls inside the opening.

c. The SW and the TMU pipelines and electrical lines between the SW pump houses, the TMU pump house, the reactor building, and the diesel generator building are located below grade and are protected from external missiles by sufficient Quality Class I earth cover of high relative density (described in Section 3.5.3). The TMU system is required for safe shutdown only when both spray ring headers are lost to tornado missiles (see Section 3.3.2).

d. The two SW pump houses, the tower makeup water pump house, and the valve boxes along the cooling tower makeup water lines are tornado-hardened (see Section 3.5.3).

e. As described in Sections 3.8.4.1.5 and 3.3.2.3, the spray ponds (except spray headers) are below grade and are protected from external missiles by sufficient Quality Class I earth backfill of high relative density. The spray headers are not required to be protected from tornado missiles.

f. The critical electrical trays in the corridor between the turbine generator building and the radwaste and control building are protected from possible missiles by the cantilever wall on column line 17 (Figure 3.5-48) and the additional 10 ft 0 in. high cantilever barrier wall immediately east of it. The 10 ft 0 in. high barrier wall provides missile protection for the door at el. 441 ft 0 in. on column line 17. Although the trays are above the door level and do not require missile protection provided by the 10 ft 0 in. high wall, the protection is provided, as shown in Figure 3.5-48.

g. The 18 in. CW piping used to provide service water return flow to the CW basin following a tornado has been analyzed to withstand the effects of all postulated tornado missiles, assuming that it is embedded in soil with the surface of the soil flush with the top of the pipe.

h. The tower makeup water (TMU) pipe lines and electrical lines between the TMU pump house and the SW pump houses are located below grade and are protected from external missiles by sufficient Quality Class I earth cover.

i. Portions of the following underground and aboveground piping associated with the diesel oil system are safety related. However, tornado missile protection is not provided to that piping. In the event of damage to the fill and vent connections due to tornado missiles, there are tank pump out connections and unused flanged connections on the storage tank which can be used as fill and vent openings.

1. Diesel oil day tank overflow and drain to storage tanks,
2. Diesel oil storage tank fill and vent lines, and
3. Filter-polisher unit recirculation piping.

3.5.3 BARRIER DESIGN

The barrier design objectives emphasize missile containment and structural integrity without secondary missile generation.

The overall response of barriers subject to impact are investigated by the use of general energy equations given in Reference 3.5-9. On determination of penetration depth and duration of impact, an effective dynamic force is computed. The additional calculation of the natural period of the target structure and the selection of a ductility ratio facilitates the determination of the required structural resistance. In this manner, missile impact is translated to an equivalent static load in an effort to quantify bending moments and shear. The detailed method used for predicting the overall response of missile barriers, including the forcing function method of determining ductility in structural elements and the basis for the ductility ratios used in the calculations, is provided in Appendix C of Reference 3.5-13 that was approved by the NRC.

3.5.3.1 Concrete Barriers

Concrete missile barriers are designed in accordance with penetration equations such as the modified Petry equation (Reference 3.5-2), the Ballistic Research Laboratory formula (Reference 3.5-1), or the modified NDRC formula (Reference 3.5-14). In all cases, except for barriers exposed to turbine missiles, a minimum concrete thickness of 2.2 times the penetration thickness determined for an infinitely thick slab is provided to prevent perforation, spalling, or scabbing. For discussion of turbine-generated missiles, see Section 3.5.1.3.

3.5.3.2 Steel Barriers

The Ballistic Research Laboratories Formula (Reference 3.5-1) is used to determine penetration depths of missiles into steel barriers.

3.5.3.3 Earth Barriers

When the protective barrier is of earthen origin, the soil penetration studies are based on alternate techniques. Buried safety-related piping and electrical systems required for a safe shutdown are ensured adequate protection from tornado-generated missiles. The original embedment depth of 5 ft was calculated to provide acceptable protection for the original design-basis tornado/missile parameters. The current design-basis tornado/missile parameters are now less severe and are used for any required evaluations for protection from postulated missiles. Based on the specific circumstances, the required embedment may be less than the original 5 ft.

3.5.3.4 Applications

Examples of barrier design are as follows:

Steel covers for manholes containing cabling for safety-related equipment required for safe shutdown are designed to withstand tornado-generated missile impact and associated wind pressure. These steel plates are designed using conventional elastic analysis and design methods for determining stress and strain. The design uses two plates of ASTM A 514 steel plate to prevent penetration and blowout.

The reactor building vehicle air lock (railroad bay) exterior doors and the SW pump house exterior equipment doors are designed and certified by the manufacturer to withstand the effects of tornado-generated exterior missiles as described in Section 3.5.1.4.

All other doors in Seismic Category I and safety-related structures are not designed to withstand the effects of the missiles described in Section 3.5.1. These doors are backed up, wherever missile protection is required, with reinforced-concrete walls forming a labyrinth behind the door. Similarly, louvers in exterior walls, which are vulnerable to missile penetration, are backed up by reinforced-concrete plenums or walls.

Based on the selection and description of missiles cited in Section 3.5.1, the interaction of missiles with structural elements is determined and the results are given in Section 3.5.1.4.1. The tabulations assume the missiles to impact at the most vulnerable point of a structure or component (e.g., at the center of a slab).

The reactor protection system motor generator sets flywheels located in the critical dc switchgear rooms at el. 467 ft 0 in. in the radwaste building were analyzed and determined to be credible missile sources, with the potential consequences affecting the safe shutdown of the

plant. Barriers were constructed around these flywheels of steel and aluminum honeycomb material, which were designed to contain the credible missiles (see Section 3.5.1.1.5).

The SW piping between the SW pump houses, the reactor building, and the diesel generator building is provided with sufficient cover for protection from tornado-generated missiles (see Section 3.5.3.3). The SW piping exits the pump houses at a centerline el. of 435 ft 3 in. and immediately turns down at a 45 degree angle to el. 432 ft, where the piping is routed to the reactor building in high relative density Quality Class I backfill. Grade level is at 440 ft 6 in., providing an embedment depth of over 7 ft from the top of the pipe. Where the pipe exits the pump houses, a 1.5-in. asphaltic concrete road with a 6-in. base coarse and 2-in. leveling coarse bed provides additional protection from tornado-generated missiles. Additionally, the two SW loops are separated by at least 20 ft to preclude loss of redundancy.

The tower makeup water piping to the river is embedded in sufficient Quality Class I backfill for protection of tornado-generated missiles (see Section 3.5.3.3).

The control room remote air intake structure piping is embedded a minimum of 5 ft for protection from tornado-generated missiles. The remote air intake structures are also missile-hardened.

F-90	DEA-FN-31	Exhaust fan HPCS diesel generator room	I/I	(b)

RESOLUTION CODE NOTES:

[a] These postulated missiles originate from air conditioning fan coil units. These fan coil units are contained in housings capable of containing any potential fan missile. The air outlets have grating installed to prevent potential missiles from exiting via this route. The air inlets are into the fan impeller eye and thus the fan inlets are not a missile exit path. Missiles originating from this equipment cannot get beyond the protective housing.

[b] These postulated missiles were determined to be credible. A safe shutdown analysis was performed, which determined that the failure of all equipment in the missile path envelope would have no effect on the ability of the plant to safely shut down in the event of an accident.

[c] These postulated missiles are impeller fragments originating from the radwaste building condensate supply pump and the condensate filter demineralizer backwater pump. These missiles were assumed to be credible. A safe shutdown analysis was performed, which determined that the failure of all equipment in the missile path would have no effect on the ability of the plant to shut down in the event of an accident, with the exception of impacts on one 20-in. standby service water pipe with standard (3/8-in.) wall thickness. A worst case missile, which would transmit the maximum energy to a point of contact with the nearest standby service water pipe was analyzed.

This worst-case missile and impact could not penetrate the standby service water pipes. The target pipe would sustain acceptable deformation in which the pressure integrity of the target pipe is not affected.

This analysis demonstrated that these pumps could not generate a missile capable of compromising the safe shutdown functions of the service water pipes.

Table 3.5-2

Internally Generated Missiles
Outside Containment (Continued)

Resolution Code Notes (Continued):

[d] These postulated missiles are pump impeller and turbine blade fragments. Analysis has shown that the impeller and turbine casings have sufficient thickness to contain each postulated missile. Postulated missiles originating from this equipment cannot be ejected beyond the protective casings.

[e] These postulated missiles are flywheel fragments from the RPS motor-generator sets. A safe shutdown analysis was performed which showed critical Division 1 and 2 electrical power and control cables were in the potential missile path that were required to safely shut down the plant in the event of an accident. Missile barriers were designed and installed around both motor-generator flywheels. These barriers ensure that potential missiles originating from the motor generators will have no effect on the ability of the plant to shut down in the event of an accident.

[f] These postulated missiles originate from the air compressors that provide starting air for the diesel generator sets. These four compressors are of the reciprocating three-cylinder piston type. The three cylinder heads cover the upper portion of the crankshaft and preclude any missile exiting the compressor from the upper half of the crankcase. Credible missiles were postulated to exit out the bottom half of the crankcase. A safe shutdown analysis was performed, which determined that the failure of all equipment in the missile path envelope would have no effect on the ability of the plant to safely shut down in the event of an accident.

[g] Pumps purchased or installed prior to Jan 1, 1980 shall be Quality Class II. Pumps purchased or installed after Jan 1, 1980 shall be Quality Class 1.

Columbia Generating Station **Final Safety Analysis Report**	**Cantilever Barrier Structure**		
	Draw. No. 910402.24	Rev.	Figure 3.5-48

3.6 PROTECTION AGAINST DYNAMIC EFFECTS ASSOCIATED WITH THE POSTULATED RUPTURE OF PIPING

This section describes the design bases and design measures that are implemented for Columbia Generating Station to ensure that the primary containment vessel and all essential equipment inside and outside primary containment, including components of the reactor coolant pressure boundary (RCPB), have been adequately protected against the effects of blowdown jet and reactive forces, and pipe whip resulting from postulated rupture of piping located either inside or outside of primary containment. Design measures have been implemented to ensure that any such postulated accident does not result in loss of required functions that are necessary to mitigate the consequences of that particular accident and place the reactor in a cold shutdown condition. The implementation of design measures considered a single, random active component failure.

The implementation of criteria for protection of safety-related systems from the effects of pipe rupture as discussed in this section is based not only on analytic evaluations but also on the walkdown of plant systems, equipment, and components which were performed. Verification of the protection of safety-related systems, equipment, and components from the effects of pipe rupture was provided by means of this final walkdown prior to fuel load.

The power uprate and Maximum Extended Load Line Limit Analysis (MELLLA) projects resulted in changes to the input parameters associated with the pipe break analysis. The evaluation of these changes (see Reference 3.6-10 and 3.6-24) supports the conclusion that the analysis and design presented in this section bounds the power uprate and MELLLA conditions.

3.6.1 PLANT DESIGN FOR PROTECTION AGAINST POSTULATED PIPING FAILURES IN FLUID SYSTEMS OUTSIDE PRIMARY CONTAINMENT

The analysis of piping systems is performed in accordance with Branch Technical Position (BTP) ASB 3-1, Rev. 1, 1981. Systems or components important to plant safety or shutdown, which are located approximate to high- or moderate-energy piping systems and are susceptible to the consequences of failures of these piping systems, were considered during the evaluations described below. The identification is related to the predetermined piping failure locations as described in Section 3.6.2.

A listing of systems containing high- and moderate-energy lines is provided in Tables 3.6-1 and 3.6-2, and the physical arrangements of piping systems are shown in Figures 3.5-10, 3.5-11, and Figures 3.6-1 through 3.6-20B.

The continued habitability of the control room following a postulated fluid system piping failure is addressed in Section 3.6.1.12.

The results of failure mode and effect analyses are provided in accordance with BTP ASB 3-1 to verify that the consequences of failures of high- and moderate-energy lines do not affect the ability to safely shut the plant down. The analyses consider a single active component failure occurring in a required system concurrently with the postulated event. The results of these analyses are presented in Sections 3.6.1.11 and 3.6.1.18.

3.6.1.1 Energy Classification of Fluid Piping Systems Outside Containment

3.6.1.1.1 High and Moderate Energy Criteria

Definitions of high- and moderate-energy fluid piping systems are given in Section 3.6.2.1. Fluid systems which could be classified as high energy during operation, but are required to function only to mitigate the consequences of a loss-of-coolant accident (LOCA), are considered moderate energy as ruptures of these systems during operation would imply a second passive component failure.

Specifically, the low-pressure coolant injection (LPCI) modes of the residual heat removal (RHR) system, the low-pressure core spray (LPCS) system, the high-pressure core spray (HPCS) system, the suppression pool cooling modes of the RHR system and the standby liquid control (SLC) system are considered moderate energy.

Fluid piping systems which are classified as high energy by Section 3.6.2.1, whose temperature does not exceed 200°F, and whose pressure is derived solely by a centrifugal pump instead of a fluid reservoir, are considered moderate energy systems. In these cases the system is depressurized as a subcooled liquid after the break and the pump energy is simply converted to velocity head. The jet force induced by the pump at the break plane is insufficient to cause pipe whip and thus these cases are properly considered as moderate energy systems.

According to the criteria established in Section 3.6.2.1, the shutdown cooling mode of the RHR and the normally unpressurized portions of the reactor core isolation cooling (RCIC) system, are considered moderate energy.

3.6.1.1.2 Systems Subject to Analysis

According to the criteria established in Section 3.6.1.1.1, the high-energy fluid piping systems subject to analysis are listed in Table 3.6-1. The moderate-energy fluid piping systems subject to analysis are listed in Table 3.6-2.

3.6.1.2 Criteria for Establishing the Postulated Design Basis Break Locations

The criteria that define the postulated design basis break locations in high- and moderate-energy fluid piping systems are presented in Sections 3.6.2.1.1 through 3.6.2.1.3.

3.6.1.3 Criteria for Establishing the Postulated Design Basis Break Orientations

The criteria that define the postulated design basis break orientations in high- and moderate-energy fluid piping systems are presented in Section 3.6.2.1.4.

3.6.1.4 Summary of Dynamic Analysis of Category I Piping and Supports

3.6.1.4.1 Design Basis Breaks for the Dynamic Analysis Outside Primary Containment

Table 3.6-3 lists the number of design basis breaks on which the dynamic analysis is based as well as the particular piping system involved, the diameter of the pipe, the plan figure showing the piping system, the maximum blowdown thrust or the thrust versus time figure, and the room or area containing the postulated break.

3.6.1.4.2 Diagrams of Mathematical Models Used in the Dynamic Analysis

3.6.1.4.2.1 Models Used for Pipe Whip Restraint Design. A description of the mathematical models used to design the pipe whip restraints is presented in Section 3.6.2.2.2.

3.6.1.4.2.2 Models Used for Structural Analysis. Descriptions of the mathematical models and procedures used to ensure adequacy of Seismic Category I structures are presented in Sections 3.6.1.6 through 3.6.1.10.

3.6.1.4.2.3 Models Used to Represent Jet Stream Dynamics. Descriptions of the procedure used to model the dynamics of a jet stream caused by a postulated rupture of a high-energy fluid piping system are presented in Section 3.6.2.3.1.

3.6.1.4.3 Effect of Postulated Fluid Piping System Ruptures on Structures, Systems, or Components Necessary for Safe Reactor Operation

A discussion is presented in Section 3.6.1.11 concerning the effects of postulated high- and moderate-energy fluid piping system failures on structures, systems, and components necessary to shut down and maintain the reactor in a cold shutdown condition.

3.6.1.5 Methods to Protect Structures, Systems, or Components Necessary for Safe Reactor Operation From the Dynamic Effects of Postulated Fluid Piping System Ruptures

3.6.1.5.1 Pipe Whip Restraints

A description of the method used to design pipe whip restraints is presented in Section 3.6.2.3.3.

3.6.1.5.2 Protective Provisions for Structures, Systems, and Components Important to Safety

Separation of redundant features is the basic design criteria utilized to protect structures, systems, or components important to safety from the dynamic effects of postulated pipe ruptures including pipe whip impact and blowdown jet impingement.

The emergency core cooling pumps and the RCIC pump are located in individual rooms. The CRD/Condensate pumps are also located in an individual room, but the equipment drain sump located in that room is connected to the RCIC pump room through an unisolable pipe; other rooms that are connected to a common sump are provided with a connecting line isolation valve. In the event of a flood in any pump room, the walls of each room, including penetrations and doors, allow only minimal leakage between rooms and can withstand the dynamic effects of any postulated fluid piping system rupture in their vicinity as well.

The remaining mechanical and electrical equipment, which must function to mitigate the consequences of a postulated fluid piping system rupture outside primary containment, is protected by providing adequate separation of redundant features per the requirements of BTP ASB 3-1, Rev. 1, 1981.

A more detailed discussion of the analysis employed to demonstrate that structures, systems, and components important to safety are adequately protected is provided in Section 3.6.1.11.

3.6.1.5.3 Physical Separation of Systems or Components Important to Safety

Physical separation of systems or components important to safety is provided by maintaining sufficient distance between redundant features, by enclosing high-energy fluid piping systems and systems or components important to safety within protective structures.

3.6.1.5.4 Description, Number, and Location of Pipe Whip Restraints Outside Primary Containment

Typical pipe whip restraints are seen in Figures 3.6-21 and 3.6-22.

A total of 12 restraints are utilized for the main steam and feedwater lines in the main steam tunnel outside of primary containment. These restraints are illustrated in Figure 3.6-24.

3.6.1.6 Procedures to Evaluate the Structural Adequacy of Seismic Category I Structures Under Pipe Break Effects Outside Containment

3.6.1.6.1 General Approach

Structures and structural components important to safety are designed with sufficient strength to resist the effects of postulated pipe breaks in high energy fluid piping systems, such as pipe whip and jet impingement. High-energy fluid piping systems are defined in Section 3.6.1.1. Section 3.6.1.6 discusses the effects of postulated pipe breaks on structures and structural components. Environmental effects of postulated pipe breaks are addressed in Sections 3.6.1.13, 3.6.1.15, and 3.11.

The main component effects of a postulated pipe break include the following:

a. Pipe whip with its impacting energy,
b. Jet impingement and accompanying jet reaction, and
c. Pressurization and temperature effects which accompany pipe break.

Pipe whip effects from circumferential breaks are seen in Figure 3.6-25. Jet impingement effects from circumferential breaks and longitudinal splits are seen in Figure 3.6-26. Circumferential breaks and longitudinal splits are defined in Section 3.6.2.1.4.

In making a structural evaluation of the effects of pipe break accidents, the loads resulting from these pipe break accidents are used in combination with other prevailing loads that occur at the time of the break. For load information and combinations see Sections 3.6.1.6.5 and 3.6.1.6.6.

To make a structural evaluation of the effects of a postulated pipe break, the local damage to the structural element is predicted and the overall structural response is assessed. Local damage is the damage done to a structural element in the immediate vicinity of the pipe whip impact or the jet impingement. Overall structural response concerns the overall response of the entire structural element to the effects of a postulated pipe break. In the following discussion, whipping pipe is described as missiles.

3.6.1.6.2 Local Damage Prediction

Local damage prediction due to whip or jet impingement in the immediate vicinity of the impacted area includes estimation of the depth of penetration and whether, in the case of concrete targets, secondary missiles might be generated by spalling. In general, a whipping pipe is a blunt missile and penetration and spalling are not appreciable for the structural component (e.g., walls) thickness of interest. Such a condition is seen in Figure 3.6-25. Jet impingement local damage is not considered significant because the fluid mass does not have the mass concentration of a solid and because of the divergence of a jet which spreads the load

over a wide area (see Figure 3.6-26). Missile penetration is predicted for reinforced-concrete targets and for steel targets.

3.6.1.6.2.1 Reinforced Concrete Targets.

Penetration

The depth to which a rigid missile penetrates a reinforced-concrete target of infinite thickness is estimated by the following Modified Petry Formula (References 3.6-15 and 3.6-17):

$$X = K_p A_p \quad \log_{10}\left(1 + \frac{V_s^2}{215{,}000}\right) \tag{3.6-1}$$

where

X = depth of missile penetration into concrete element of infinite thickness (ft)

K_p = penetration coefficient for reinforced concrete (4.76×10^{-3} ft^3 /lb. for normal reinforced concrete with a crushing strength of 3200 psi and 1.4% of reinforcement. See Reference 3.6-15.)

$$Ap = \frac{W}{A} = \frac{\text{Missile Weight (lb)}}{\text{Projected Frontal Missile Area (ft}^2\text{)}}$$

V_s = striking velocity of missile (ft/sec)

When the element has a finite thickness, the depth of penetration is (References 3.6-15 and 3.6-17):

$$X_1 = \left[1 + e^{-4\frac{(t-2)}{x}}\right] x, (t = 2x) \tag{3.6-2}$$

where

X_1 = depth of penetration of missile into a concrete element of finite thickness (ft)

e = base of Napierian Logarithms

t = thickness of concrete element (ft)

Perforation

The thickness of a concrete element that will be just perforated by a missile is given as (References 3.6-15 and 3.6-17):

$$T = 2X \text{ (ft)} \qquad (3.6\text{-}3)$$

Spalling

Spalling of concrete from the side opposite the impact surface of the structural element may occur even if the missile does not perforate the element. The estimate of the thickness that will just start spalling is given as (Reference 3.6-20):

$$T_s = 2.2X \text{ (ft)} \qquad (3.6\text{-}4)$$

3.6.1.6.2.2 Steel Targets. The Ballistic Research Laboratories formula is used to determine perforation of a steel target. The thickness, T, of a steel target that will be just perforated by a missile is given as (Reference 3.6-17):

$$T^{3/2} = \frac{0.5MV^2}{17{,}400\ K^2 D^{3/2}} \qquad (3.6\text{-}5)$$

where

T = steel wall thickness to just perforate (in.)

M = mass of the missile (weight/g in lb-sec^2/ft)

V = velocity of missile (ft/sec)

K = constant depending on grade of steel and is usually ≅1

D = diameter of missile (in.). For irregularly shaped missiles, an equivalent diameter is used, taken as the diameter of a circle with the same area as the projected frontal area of the irregularly shaped missile

The recommendation in Reference 3.6-13 to increase the perforation thickness, T, obtained by the Ballistic Research Laboratories Formula by 25% to prevent perforation is observed; that is:

$$t_p = 1.25T \qquad (3.6\text{-}6)$$

where

t_p = thickness of steel barrier required to prevent penetration (in.)

3.6.1.6.3 Overall Structural Response

3.6.1.6.3.1 General. In general, pipe break loads are considered in combination with other loads (see Section 3.6.1.6.6). Dead loads, live loads, operating thermal loads, and earthquake loads may or may not be significant compared to the pipe break load, depending on the severity of the pipe break load. Thermal loadings due to pipe break have only skin effect and are not considered.

Pressure loads due to pipe break do not necessarily peak with pipe whip and jet impingement loads; however, in the analysis, they are considered to act simultaneously.

With regard to pipe break, when high energy pipes under pressure fail, a fluid jet is created. The associated jet impingement force on a target as well as the reaction force exerted on the piping by the fluid jet force have a time history qualitatively presented in Figure 3.6-27. This force is conservatively idealized as a step function load. For the fluid forces associated with these pipe failures, see Table 3.6-3.

To obtain a solution for the actual complex system, the structure is idealized by an equivalent single degree of freedom system (see Figure 3.6-28) following the procedures described by J. M. Biggs in Chapter 5 of Reference 3.6-1. The response of this mathematical idealization to a step function load (jet impingement) or to a step function load concurrently with an impact loading (due to whipping pipe) involves an energy transfer from the impacting object to the impacted structure. The following exposition on how this energy transfer is addressed makes use of procedures that have been presented by the Bechtel Corporation in its report on missile impact, Topical Report BC-TOP-9A, Revision 2 (Reference 3.6-13).

3.6.1.6.3.2 Structural Response to Whipping Pipe Missile Impact Load.

Discussion

A method of energy-balance procedures is used to evaluate the structural response when a missile impacts a target. The method utilizes the strain energy of the target at maximum response to counteract the residual kinetic energy of the target or target missile combination that results from the missile impact.

A missile of mass M_m is postulated to strike a spring-backed target mass, M_e, with a velocity, V_s. Since the actual coupled mass during impact varies, an estimated average effective target mass, M_e, is used to evaluate the inertia effects during impact. The impact of the missile is

considered plastic. This assumes that the missile remains in contact with the target after impact.

Velocity After Impact

The velocities of the missile and target after impact are calculated from the following relationships (Reference 3.6-19):

$$V_m = \frac{V_s(M_m - eM_e)}{M_m + M_e} \quad (3.6\text{-}7)$$

$$V_t = \frac{V_s M_m (1 + e)}{M_m + M_e} \quad (3.6\text{-}8)$$

where

V_m = missile velocity after impact (ft/sec)

V_t = target velocity after impact (ft/sec)

V_s = missile striking velocity (obtained by using basic velocity formulas, knowing the initial thrust force, missile mass, and missile travel before impact) (ft/sec)

M_m = mass of missile (lb-sec^2/ft)

M_e = effective mass of target during impact (lb-sec^2/ft)

e = coefficient of restitution

Plastic Impact

In a plastic impact, the coefficient of restitution becomes zero, and the velocity of the missile and target masses become equal following impact. The strain energy, E_s, required to stop the missile/target combination is the summation of the missile mass kinetic energy and the target mass kinetic energy at the end of the impact duration, as follows.

$$E_s = \frac{M_m V_m^2}{2} + \frac{M_e V_T^2}{2} \quad (3.6\text{-}9)$$

From Equations 3.6-7 and 3.6-8:

$$V_m = V_T = \frac{M_m V_s}{M_m + M_e} \tag{3.6-10}$$

Substituting the value for V_m and V_T from Equation 3.6-10 into Equation 3.6-9, the required target strain energy is:

$$E_s = \frac{M_m{}^2 V_s{}^2}{2(M_m + M_e)} \tag{3.6-11}$$

Target Effective Mass

Due to the complexity of missile-target impact, a determination of an effective coupled mass on a continuous time basis by means of a general analytical solution is not available. However, an estimate of the average effective mass can be approximated from the results of impact tests on reinforced-concrete beams (Reference 3.6-10) in which the measured structural response is used to back-calculate the average mass during impact. Based on these data, the following formulas are used for estimating the target effective mass.

For concrete beams:

$$M_e = (D_x + 2T)\frac{B\gamma_c T}{g}, \text{ if } B \leq (D_y + 2T) \tag{3.6-12}$$

$$M_e = (D_x + 2T)(D_y + 2T)\frac{\gamma_c T}{g}, \text{ if } B \geq (D_y + 2T) \tag{3.6-13}$$

For concrete slabs:

$$M_e = (D_x + T)(D_y + T)\frac{\gamma_c T}{g} \tag{3.6-14}$$

For steel beams:

$$M_e = (D_x + 2d)M_x \tag{3.6-15}$$

For steel plates:

$$M_e = D_x D_y \frac{\gamma_s t}{g} \qquad (3.6\text{-}16)$$

where

M_e = average effective mass of target during impact $\frac{(lb - sec^2)}{ft}$

M_x = mass per unit length of steel beam $\frac{(lb - sec^2)}{ft}$

D_x = maximum missile contact dimension in the direction (longitudinal axis for beams or slabs) (ft)

D_y = maximum missile contact dimension in the y direction (transverse to longitudinal axis for beams or slabs) (ft)

T = thickness or depth of concrete element (ft)

t = thickness of steel plate (ft)

d = depth of steel beam (ft)

B = width of concrete beam (not to exceed D + 2T)(ft)

γ_c = weight per unit volume of concrete (lb/ft^3)

γ_s = weight per unit volume of steel (lb/ft^3)

g = acceleration of gravity (32.2 ft/sec^2)

Structural Response by Energy Balance Method

a. General Procedures

The strain energy, E_s, required to stop the target (or missile-target combination) is determined from the relationships in Section 3.6.1.6.3.2.

The resistance-displacement function, R(x), for a concentrated load at the area of impact is determined from the target structure physical configuration and material properties.

The estimated maximum target response is determined by equating the available target strain energy to the required strain energy and solving for the maximum displacement, x_m, (see Figure 3.6-29).

b. Elasto-Plastic Target Response

For elasto-plastic target response with no other concurrent loads acting:

$$R(x) = Kx, (0 < x \leq x_e)$$

$$R(x) = Kx_e = R_m, (x_e < x \leq x_m)$$

where

R = resisting force of target (lb)

x = displacement of target (ft)

k = elastic Spring constant for target (lb/ft)

x_e = yield displacement (ft) (See Tables 3.6-4, 3.6-5, and Figure 3.6-29)

R_m = plastic resistance (lb) (See Tables 3.6-4, 3.6-5, and Figure 3.6-29)

x_m = maximum displacement of target (ft)

then

$$E_s = R_m\left(x_m - \frac{x_e}{2}\right)$$

or

$$x_m = \frac{E_s}{R_m} + \frac{x_e}{2} \qquad (3.6\text{-}17)$$

The required ductility ratio, μ_r, is obtained from Equation 3.6-17 by dividing both sides of the equation by x_e.

$$\mu_r = \frac{x_m}{x_e}$$

$$\mu_r = \frac{E_s}{x_e R_m} + 1/2 \qquad (3.6\text{-}18)$$

If other loads are present on the target structure which act concurrent with missile impact loads, (see Sections 3.6.1.6.5 and 3.6.1.6.6 and Table 3.6-6), the maximum combined displacement is determined as follows:

Let

x' = $x_e - x_o$ (see Figure 3.6-29) (ft)

x_o = displacement due to other loads (ft)

x_e = yield displacement (ft)

x_m = maximum combined displacement (ft)

R_m = plastic resisting force (lbs)

k = elastic spring constant (lb/ft)

Then

$$E_s = \frac{k(x')^2}{2} + kx'(x_m - x_e)$$

(See Figure 3.6-29)

or

$$x_m = \frac{E_s}{kx'} - \frac{x'}{2} + x_e$$

Substituting $x' = x_e - x_o$ in the above equation gives

$$x_m = \frac{E_s}{k(x_e - x_o)} + \frac{x_e + x_o}{2} \qquad (3.6\text{-}19)$$

The required ductility ratio, μr, is obtained by dividing both sides of Equation 3.6-19 by x_e.

$$\mu_r = \frac{E_s}{R_m(x_e - x_o)} + \frac{1 + x_o / x_e}{2} \qquad (3.6\text{-}20)$$

The values of M_r should be less than the allowable ductility ratios, M, given in Table 3.6-7.

3.6.1.6.3.3 Jet Impingement. Jet impingement loads are loads that emanate from a break in a high energy line. It is postulated that the characteristics of the jet are such that the jet exits from a break opening in the pipe equal in area to the cross sectional area of the pipe itself (see Figure 3.6-26). The jet is postulated to travel conforming to the configuration of the cross sectional area of the pipe for a distance of five pipe diameters and then to diverge at an angle of divergence of 10°. Where piping is restrained and break separation is limited to one-half pipe diameter or less a fan jet is postulated. A fan jet is perpendicular to the pipe centerline and extends 360° around the break at a 10° half angle as shown in Figure 3.6-30. For the jet thrust forces at the postulated breaks, see Table 3.6-3. Jet loads impacting structures are treated as equivalent static loads. A dynamic load factor is applied to the jet force emanating from the pipe and the resulting load is modified by an appropriate load factor according to its use in combination with other loads. The structure impacted is then evaluated for structural capability.

3.6.1.6.4 Allowable Design Stresses and Strains

For allowable design stresses and strains for reinforced concrete and structural steel, see Section 3.8.4.5 and Tables 3.8-11 and 3.8-12, except as modified in Sections 3.6.1.6.4.1 and 3.6.1.4.2.

3.6.1.6.4.1 Pipe Whip Loading With or Without Other Loads. The acceptability of pipe whip loading with or without other loads is considered from two aspects:

a. The overall structural response of the impacted structural element, and
b. The local damage sustained by the impacted structural element.

The overall structural response is considered acceptable if the ductility ratio resulting from the loading does not exceed the maximum allowable ductility ratios as given in Table 3.6-7. The

determination of ductility ratios utilizes the procedures set forth in Section 3.6.1.6.3 and the loading combinations in Section 3.6.1.6.6. In using these procedures, the allowable limit on section strength, M, used in the determination of yield displacement X_e, (Section 3.6.1.6.3.2, Tables 3.6-4 and 3.6-5 and Figure 3.6-29) is computed in accordance with the strength design methods described in ACI 318-71 (Reference 3.6-12) and in the general practices of Part 2 of the AISC specifications (Reference 3.6-11), modified by the dynamic strength increase factors of Table 3.6-8.

The local damage is considered acceptable if the pipe whip impact does not case spalling and excessive penetration in concrete, or perforation in steel, as determined by the procedures described in Section 3.6.1.6.2.

3.6.1.6.4.2 Pipe Break Loads (Excluding Pipe Whip) With or Without Other Loads. Pipe break loads (excluding pipe whip) with or without other loads are considered acceptable if the loading from the loading combinations in Section 3.6.1.6.6 does not result in stresses that exceed the allowable limits on section strength as given in Tables 3.8-11 and 3.8-12, modified by the dynamic strength increase factors in Table 3.6-8.

3.6.1.6.5 Loads, Definition of Terms, and Nomenclature

For loads, definition of terms, and nomenclature, see Section 3.8.4.3.

3.6.1.6.6 Load Combinations

3.6.1.6.6.1 Seismic Category I Concrete Structures. For load combinations for Seismic Category I concrete structures, see Table 3.8-9, load combinations 6, 7, and 8.

3.6.1.6.6.2 Seismic Category I Steel Structures. For load combinations for Seismic Category I steel structures, see Table 3.8-10, load combinations 6, 7, and 8.

3.6.1.7 Structural Design Loads

Structural elements are designed to withstand the loads generated by piping failures outside of primary containment in combination with other loads given in Section 3.6.1.6.6. Table 3.6-6 furnishes the design loads considered in the areas where piping failures occur.

3.6.1.8 Analysis of Load Reversal

Structural elements such as floors, interior walls, exterior walls, and the building as a whole are analyzed for the effects of reversal of load due to the postulated pipe failure accident. They are also analyzed for rebound loads that accompany pipe break accidents. The analysis approach for rebound is seen in Figure 3.6-31.

3.6.1.9 Modified Structures

The capabilities of structures to carry the design loads will be demonstrated for modifications as part of design change process controls.

3.6.1.10 Verification That Failure of Any Structure Does Not Preclude Safe Reactor Shutdown

Structures subject to pipe whip and/or jet impingement loads are investigated and found not to fail under these loads in conjunction with the applicable load combinations, so that there are no cases of structural barriers failing and causing additional structural failures which would adversely affect the mitigation of the consequences of accidents and the capability to bring the plant to a cold shutdown condition.

3.6.1.11 Verification That Adequate Redundancy Exists for All Postulated Fluid Piping System Ruptures

3.6.1.11.1 Approach

The purpose of the study is to ensure that for all postulated ruptures of fluid piping systems, safe reactor operation and shutdown is not precluded. The basis of this approach is that adequate separation of redundant systems or components required to shut down and maintain the reactor in a cold condition provides the level of protection required to ensure safe reactor operation and shutdown.

The input used for this study includes the routing of all cables, cable trays, and conduit necessary to shut down and maintain the reactor in a cold condition. The locations of all motor control centers; instrument racks; sensors; and heating, ventilating, and air conditioning (HVAC) equipment necessary to shut down and maintain the reactor in a cold condition are also included in the input of this study.

The locations of all postulated high- and moderate-energy fluid piping system ruptures dictate where this study is to be performed.

The input described above is coded to indicate the location of the system or component by elevations; the electrical division to which the component belongs; what the function of the component is; the various references, such as the drawings, in which the component is found; devices interconnecting the component and another system; and additional information of this type. This coding facilitates storage of the input for retrieval at any time.

Table 3.6-3 lists the high-energy design-basis break locations outside containment, the piping systems involved, the pipe diameter, the plan figure showing the piping system, and the maximum blowdown thrust or the thrust versus time figure.

Figures 3.6-32 through 3.6-56 illustrate and list the high-energy break locations inside containment and inside the main steam tunnel.

Moderate-energy crack locations are postulated in accordance with Standard Review Plan Sections 3.6.1 and 3.6.2.

3.6.1.11.2 Method of Analysis for Postulated High-Energy Fluid System Ruptures

3.6.1.11.2.1 Effects of Postulated Passive Component Failures. Postulated pipe breaks in high-energy fluid systems are investigated to determine their effects on the ability to bring the plant to a safe shutdown and to limit the offsite radiological consequences to an acceptable level as stated in 10 CFR 50.

On a case-by-case basis, the effects of pipe whip, jet impingement, and the resulting environmental conditions on safety-related equipment necessary for safe shutdown are evaluated. The effects of the postulated pipe break are dependent on the fluid properties of the system, the location and orientation of the pipe break, the proximity to safe shutdown systems, components, and structures, and the individual design limits of the safe shutdown systems, components, and structures.

Pipe breaks in high energy systems are postulated according to the criteria in Section 3.6.2.1. After identifying what equipment becomes inoperable, a worst case single random active component failure is postulated in a system not affected by the postulated high-energy fluid system rupture. Additionally, if the direct consequences of the postulated rupture results in a reactor or turbine trip, or could otherwise cause a loss of offsite power, offsite power is assumed unavailable.

3.6.1.11.2.2 Analytical Procedure. After all the consequences of the postulated pipebreak, passive and active component failures are evaluated, an analysis determines if safe shutdown can be accomplished. The following guidelines are used in this analysis:

a. For postulated ruptures of fluid piping systems, ensure that core cooling and reactivity control is maintained,

b. Demonstrate that redundant components or systems necessary to safely shut down and cool the reactor are not involved in the postulated passive component failure, and

c. Demonstrate that offsite radiological consequences do not exceed relevant standards.

3.6.1.11.3 Method of Analysis for Postulated Moderate-Energy Fluid System Ruptures

3.6.1.11.3.1 Approach. The analysis of moderate energy piping is performed in accordance with BTP ASB 3-1, Rev. 1, 1981. Postulated ruptures in moderate-energy fluid systems do not generate pipe whip. The analysis investigates the effects of the environment that results from such a postulated rupture on safety-related equipment, including the effects of water spray.

The effects of the postulated moderate-energy pipe cracks are dependent on the fluid properties, available fluid reservoir, drain systems, and the location and the individual design limits of the safety-related equipment, components, and structures necessary for safe shutdown.

Where moderate-energy pipe cracks are postulated in close proximity to high energy systems, the environmental analysis compares the effects of both high- and moderate-energy pipe ruptures. The most limiting case is evaluated for safe cold shutdown.

Moderate-energy pipe cracks are postulated according to the criteria in Section 3.6.2.1.

3.6.1.11.3.2 Method of Analysis. The locations of all postulated ruptures, resulting in through wall leakage cracks, are identified for later retrieval. The analysis assumes that the spray resulting from a postulated moderate-energy rupture causes the malfunction of all equipment not enclosed by compartments that minimize the effects of flooding.

Additionally, the most damaging single random active component failure in a system not affected by the postulated moderate energy pipe rupture is assumed. If the direct consequences of the passive component failure results in a turbine or reactor trip or could otherwise cause a loss of offsite power, then offsite power is assumed unavailable.

3.6.1.11.4 Summary of Analysis

In those cases where analysis discussed in Sections 3.6.1.11.2 and 3.6.1.11.3 identified a location where a postulated pipe rupture in a high- or moderate-energy system had impact on a safety-related component, which precluded the safe shutdown and cooling of the reactor, the component was relocated or protected.

This analysis by actual examination of the plant is undertaken to provide results based on as-built conditions.

Piping layouts for areas containing high- and moderate-energy lines, whose failure can affect the performance of safety-related equipment, are presented as Figures 3.5-10, 3.5-11, and Figures 3.6-1 through 3.6-20B.

Section 3.6.1.11 discusses in detail the methods used to demonstrate that no fluid system piping rupture, in conjunction with a single active component failure, precludes safe shutdown of the plant.

The following should serve to further clarify the method of analysis:

a. Analysis is performed to section B.3 criteria (pages 3.6.1-12 and 3.6.1-13) of BTP ASB 3-1, Rev. 1, 1981;

b. The forces developed at each postulated high-energy pipe break are determined by the methods of Section 3.6.2.2. The effects of the resultant pipe whip and jet impingement are evaluated. Credit is taken for automatic isolation and/or operator action to mitigate the consequences of the postulated pipe break, if the equipment required for this function is not affected by the break or included in item d below;

c. As a first step, all equipment with impact from the whipping pipe or jet is assumed to fail. If the equipment is required for safe cold shutdown or accident mitigation, a detailed analysis is performed to determine if the equipment will actually fail. Structures contacted by the whipping pipe or jet are evaluated for structural adequacy by the methods described in Section 3.6.2.2;

   Impact to pipes of smaller nominal diameter than the impacting pipe are assumed to fail, regardless of wall thickness of impacted pipe. Impact to pipe of both larger nominal diameter and thinner wall thickness than the impacting pipe are assumed to develop through wall leakage cracks;

d. The following comprises the minimum set of equipment necessary for safe shutdown following any high-energy or moderate-energy pipe break/crack assuming a worst-case single active failure:

   1. Pipe break/crack detection instrumentation
   2. Automatic, high-energy line break isolation equipment
   3. RPS (scram)
   4. MSIVs
   5. Five (5) SRVs for reactor vessel depressurization
   6. A single RHR loop with a heat exchanger (loop A or B), in the alternate shutdown cooling mode providing reactor vessel inventory makeup (short term cooling) and reactor vessel and suppression pool inventory cooling (long term cooling)
   7. Supporting Service Water
   8. Supporting HVAC
   9. Supporting electrical power sources;

e. After items b, c, and d have been evaluated, the ability to safely shut down is evaluated;

f. If analysis indicates that safe shutdown cannot be accomplished, then

1. Reroute or relocate cable, pipe, or equipment to prevent loss of function, or

2. If this is not feasible, shield the appropriate affected component(s) to prevent loss of function;

g. The flooding and environmental effects of moderate-energy failure are evaluated to determine whether they are more severe than the high-energy breaks. The high-energy breaks are addressed in Sections 3.6.1.11 and 3.6.1.15.

The area temperature is evaluated by determining the limiting postulated pipe break and using RELAP4/MOD5 (Reference 3.6-21) or GOTHIC (References 3.6-25 and 3.6-26). GOTHIC analyses described within Section 3.6 are performed in accordance with the constraints and limitations provided in the River Bend Unit 1 Safety Evaluation (Reference 3.6-27), or have demonstrated results which are essentially the same or conservative. The limiting pipe break for temperature analysis is that pipe break giving the highest energy release rate over the longest blowdown period.

The effects of flooding are evaluated by determining the limiting pipe break and calculating the effects of the fluid release. The limiting pipe break for flooding analysis is that pipe break with the highest mass flow rate over the longest blowdown period.

Peak differential pressure analysis results are provided in Table 3.6-9 and discussed in Section 3.6.1.20.

See Section 3.6.1.13 for electrical equipment environmental qualifications.

3.6.1.12 Control Room Habitability

A postulated rupture of main steam, feedwater, or RWCU piping has no effect on the continued habitability of the control room, since the radiation dose that control room personnel receive as a result of a postulated rupture is below the allowable limits.

The nuclear steam supply system (NSSS) piping outside of primary containment within the reactor building is enclosed by the main steam tunnel. The main steam tunnel, provided with pressure-relieving blowout panels, is designed to withstand the worst postulated piping system rupture attributable to the NSSS within the steam tunnel.

The high energy piping in the main steam tunnel is provided with pipe whip restraints as described in Section 3.6.1.5. These restraints limit the motion of the free ends of the ruptured NSSS piping to preclude the impact of the NSSS piping with the main steam tunnel structure.

The remaining high energy piping outside the primary containment is not routed in the vicinity of the control room, or does not possess sufficient energy to adversely affect the structural integrity of the control room wall.

Additionally, a remote shutdown panel is provided to permit safe reactor shutdown to a cold condition in the event the control room must be evacuated.

3.6.1.13 Electrical Equipment Environmental Qualifications

All electrical systems necessary for safe shutdown and necessary to maintain the plant in a safe shutdown condition are designed to remain functional in the general area environment resulting from a high-energy line break or from leakage cracks in moderate-energy piping. Specific equipment is either of the following:

a. Designed to remain functional as long as necessary in the general area environment, or

b. Isolated from the general area environment in compartments capable of maintaining normal equipment operating conditions.

Certain rotating equipment cannot be designed to function in the more severe, local steam environment. However, due to physical separation, rotating equipment of not more than one system is exposed to the local conditions which exceed the general area accident environment. Required redundancy is thus maintained for safety equipment.

See Section 3.11 for a more complete description of environmental design of electrical equipment.

3.6.1.13.1 Identification of Equipment

Safety equipment required to mitigate the consequences of an accident and place the reactor in a cold shutdown condition is listed in Table 3.11-2. The table also indicates the required duration following an accident that equipment is required to operate.

3.6.1.13.2 Environmental Design

See Section 3.11 for a discussion of environmental design and an analysis of safety-related electrical components. The section identifies the safety-related equipment that must operate in a hostile environment, and Table 3.11-2 indicates the postulated environmental enveloping conditions for both the general and local accident areas.

3.6.1.13.3 Jet Impingement Barriers

For results of the steam system study, see Section 3.6.1.11.4. Jet impingement barriers have been provided where analysis indicates they are needed to protect components required for reactor safe shutdown. In addition, some room wall, floors, and ceilings act as jet impingement barriers.

3.6.1.13.4 Control Room Equipment

Control room environmental effects, resulting from pipe break accidents, are discussed in Section 3.6.1.12. The postulated pipe breaks have no effect on the control room environment. All control room equipment, therefore, remains functional following a break.

3.6.1.13.5 Onsite Power Distribution System Equipment

See Section 3.11.

3.6.1.14 Design Diagrams of Nuclear Steam Supply System Piping

Figures 3.6-58 to 3.6-60 show the routing of NSSS piping from the outboard end of the containment penetrations to the turbine building.

3.6.1.15 Flooding Analysis

A study investigating the potential flooding attributable to the postulated rupture of high-energy fluid piping systems outside primary containment is provided below.

3.6.1.15.1 Postulated Rupture of the Reactor Feedwater Piping

The reactor feedwater piping outside primary containment, inside the reactor building, is completely enclosed by the main steam tunnel to provide protection against the dynamic effects of postulated fluid piping system ruptures. The main steam tunnel is provided with a blowout panel to discharge steam, to the atmosphere, above the turbine building. A second blowout panel provides for water drainage from the main steam tunnel into the turbine building. A flooding evaluation of the turbine building from any feedwater line break has been completed which shows that no safety-related equipment located within the turbine building would be adversely affected.

3.6.1.15.1.1 Consequences. The postulated rupture, of the feedwater piping in the main steam tunnel, would scram the reactor on low water level.

The isolation valves on the reactor pressure boundary would close to prevent loss of reactor coolant. A postulated active component failure could prevent the inboard isolation valve from

closing, while the dynamic effects of the passive component failure could prevent the outboard isolation valve from closing. The inboard check valve would close to prevent coolant loss, effectively stopping the reactor feedwater flow into the main steam tunnel.

Although a loss of offsite power is assumed, sufficient equipment remains available to safely shut down the reactor to a cold condition.

3.6.1.15.2 Postulated Ruptures of Reactor Water Cleanup System

Since the reactor water cleanup (RWCU) system has no safety function, postulated ruptures of this system have no effect on safe reactor operation, except the effect these postulated ruptures have on structures, systems, or components important to safety. As the analyses discussed in Sections 3.6.1.11 and 3.6.1.20 indicate, postulated ruptures of the RWCU system have no effect on the ability to safely shut down the reactor to a cold condition.

3.6.1.15.3 Postulated Ruptures of the Auxiliary Steam, Heating Steam, Auxiliary Condensate, and Heating Steam Condensate Systems

Since these systems have no safety function, postulated ruptures of these systems, as described in Sections 3.6.1.11 and 3.6.1.20, have no unacceptable consequences, except the effect these postulated ruptures have on structures, systems, or components important to safety. Ruptures in the auxiliary steam (AS), heating steam (HS), auxiliary condensate (CO), or HS condensate (HCO) systems do not prevent safe reactor shutdown to a cold condition. In the case of an AS line break in the reactor building, redundant isolation valves are automatically closed by temperature elements. There are no dynamic effects from the rupture, but the equipment environment (temperature and humidity) would exceed the qualified limits if the AS line to the reactor building was not isolated.

3.6.1.15.4 Additional Considerations

Postulated ruptures of high-energy fluid piping systems are not considered to cause flooding if the contained fluid is in the vapor phase. The main steam and reactor core isolation coolant systems are not considered sources of flooding incidents for this reason.

3.6.1.16 Quality Control and Inspection Programs

The quality control and inspection programs, required for the design and construction of piping systems outside containment, were given in Section 17.1. For the operational phase, the Inservice Inspection (ISI) Program and the Operational Quality Assurance Program Description (OQAPD) are applicable.

3.6.1.17 Leak Detection System Capabilities

The floor and equipment drain headers drain into five sumps in the reactor building at el. 422 ft 3 in. Four sumps are provided for floor drains and one for equipment drains. These sumps contain level switches which activate the sump pumps on high water level. This allows the operator to determine the severity of the leak and take corrective action.

In addition, wall-mounted Class 1E level switches are provided in each pump room in the reactor building at the basement (422 ft 3 in.) level. See Sections 3.4.1.4, 6.3.2.5, and 9.3.3 for more details.

3.6.1.18 Emergency Procedures to Mitigate the Consequences of a Postulated Fluid Piping System Rupture Outside Primary Containment

Shutdown modes available to the operator are determined by whether or not the reactor is isolated.

3.6.1.18.1 Reactor Not Isolated

For those classes of postulated ruptures which do not result in isolation of the RCPB, a normal shutdown is accomplished by using the main condenser and reactor feedwater system.

3.6.1.18.2 Reactor Isolated

With the reactor isolated from the main condenser, a variety of shutdown modes are available to the operator. A single postulated pipe rupture does not preclude the availability of all of them.

3.6.1.18.2.1 Reactivity Control. Before a shutdown can be accomplished, the core must be prevented from generating additional power. Two methods of reactivity control are utilized on the Columbia Generating Station reactor.

The CRD system is the normal means of controlling core reactivity.

The SLC system can be used to shut down the reactor by means of injected sodium pentaborate poison. Both of these systems are redundant and driven by either offsite or plant standby power supplies.

No single accident can render both power supplies unavailable.

3.6.1.18.2.2 Core Coolant Level Maintenance. The systems available for core cooling during reactor isolation are RHR, automatic depressurization system (ADS), RCIC, LPCS, and HPCS. The RHR system is comprised of four modes: shutdown cooling, hot standby (see

Section 5.4.7), low pressure cooling injection (see Section 6.3.2.2.4), and suppression pool cooling (see Section 6.2.2). See Section 6.3.1.2.4 for a description of the ADS. See Section 5.4.6 for a description of the RCIC system. See Section 6.3.2.2.3 for a description of the LPCS. See Section 6.3.2.2.1 for a description of the HPCS.

3.6.1.18.3 Methods of Shutdown Following a Postulated Rupture of a Fluid Piping System

3.6.1.18.3.1 Postulated Rupture of Main Steam Piping in the Main Steam Tunnel Vicinity. A postulated rupture of the main steam system does not generate any pipe whip impact on structures in the reactor building, since the main steam lines are supplied with pipe whip restraints.

High pressure differential signals from the main steam flow restrictors (indicating decrease in steam pressure at the turbine inlet) or high temperature indication in the vicinity of the main steam piping initiates automatic isolation of the main steam lines which, in turn, causes a reactor scram. Automatic relief valve operation maintains the reactor vessel pressure within allowable limits.

With the reactor isolated and scrammed, the HPCS or manual initiation of the ADS would be used to depressurize the reactor while either of the two redundant trains of the shutdown cooling mode of RHR systems would be employed to remove decay and sensible heat from the reactor pressure vessel (RPV).

3.6.1.18.3.2 Postulated Rupture of Reactor Feedwater Piping. A postulated rupture of a reactor feedwater pipe does not generate pipe whip impacts on structures outside primary containment within the reactor building since the feedwater piping is restrained.

The resulting blowdown from the feedwater break scrams the reactor when the low water level setpoint is reached. The operator can also initiate manual scram as the instrumentation will indicate a mismatch in main steam flow rate, reactor feedwater flow rate, and RPV inventory.

The scram, due to low water level, initiates emergency core cooling and RCIC operation. Decay heat removal is manually initiated by the operator.

The shutdown modes available after an operator initiated scram are the same as listed in Section 3.6.1.18.3.1.

3.6.1.18.3.3 Postulated Rupture of Reactor Core Isolation Cooling System Piping. Ruptures are postulated in the RCIC system in the turbine steam supply line or the condensate removal line, from the drip pot. A rupture of either line precludes operation of the RCIC system. A rupture of either line does not generate a scram and, therefore, normal shutdown procedures are used. Automatic isolation of the RCIC system occurs if a high pressure drop across the flow restrictor is sensed, high area temperature is sensed, or low line pressure is sensed.

3.6.1.18.3.4 Postulated Rupture of Residual Heat Removal System Piping. The RHR system, except in the hot standby mode, operates at pressures less than 135 psig steam dome pressure. Postulated failures of the RHR system piping at these pressures does not require any particular safety action. Rather shutdown cooling is reestablished using the redundant train of the RHR system.

In the event that the suction line from the RPV to the RHR pumps becomes inoperable, reactor depressurization can be accomplished by using the HPCS or the ADS. Heat can be removed from the suppression pool by use of the suppression pool cooling mode of the RHR system. For a detailed discussion of the possible shutdown modes see Section 15.2.9.

3.6.1.18.3.5 Postulated Rupture of the Control Rod Drive System Piping. Rupture of the CRD piping does not generate any significant pipe whip loads. While rupture of the CRD piping could prevent system operation, reactor scram is possible using either the nitrogen accumulators or reactor pressure. The SLC system could also be used to bring the reactor to a subcritical condition if the CRDs failed to function.

3.6.1.18.3.6 Postulated Ruptures of the Auxiliary Steam, Heating Steam, Auxiliary Condensate, and Heating Steam Condensate Piping. The consequences of a rupture in any of the above, including the dynamic effects of pipe whip and the resulting environmental conditions, are investigated as described in Section 3.6.1.11. In no instance does a postulated rupture of these systems preclude reactor shutdown to a cold condition.

These systems provide no emergency function that would be required to mitigate the consequences of a postulated piping failure. Therefore, normal reactor shutdown as well as the emergency methods described would not be simultaneously impaired.

3.6.1.18.3.7 Postulated Rupture of the Reactor Water Cleanup System Piping. The consequences of a RWCU system piping rupture are investigated as discussed in Section 3.6.1.11. In no circumstance, does the postulated failure of RWCU system piping preclude the availability of all shutdown modes. Since the RWCU system does not fulfill any safety function, nonoperability has no impact on the safe shutdown of the reactor.

3.6.1.19 Seismic and Quality Classifications of Piping Used in the Dynamic Analysis

See Table 3.2-1 for the seismic and quality classifications of piping systems identified in Table 3.6-3. See Section 3.2 for the definitions of the various seismic and quality classifications.

3.6.1.20 Method Used to Predict Blowdown Rates and Subcompartment Pressure Transient After a Postulated Pipe Break

3.6.1.20.1 Blowdown Analysis for a Postulated Pipe Break Outside the Primary Containment

The analytical approach used to determine the blowdown mass and energy rates from a postulated pipe break outside the primary containment are described in Sections 3.6.1.20.1.1 through 3.6.1.20.1.3.

3.6.1.20.1.1 Method of Analysis for a Postulated Pipe Break in Larger Pipes. For larger pipes, the blowdown mass and energy release are predicted by using the computer programs RELAP3 (Reference 3.6-9) or RELAP4/MOD5 (Reference 3.6-21) or GOTHIC (References 3.6-25 and 3.6-26). In the computer model, the piping system is nodalized into a number of volumes connected by flow junctions (or flow paths in GOTHIC). A multiplier of 1.0 is used with the choked flow correlation. Except in special cases, all breaks are assumed to be the double-ended circumferential type which open instantaneously. Initial conditions and other assumptions necessary for the analysis are such that the result is on the conservative side.

3.6.1.20.1.2 Method of Analysis for a Postulated Pipe Break in Smaller Pipes. For smaller pipes, a constant blowdown profile with an applicable choked flow correlation is used. The initial conditions are chosen to maximize the blowdown mass and energy release rates.

3.6.1.20.1.3 Blowdown Mass and Energy Release Rates for a Postulated Pipe Break in the Main Steam Line and the Reactor Feedwater Line in the Main Steam Tunnel. See Section 3.6.1.20.3.2 for a description of the arrangement and features of the main steam tunnel. For subcompartment analysis in the main steam tunnel, the postulated break in the main steam line and in the feedwater line is assumed to be a crack with the flow area equivalent to the flow area of a single-ended pipe. The blowdown mass and energy release rates are computed by the RELAP3 Program or GOTHIC (References 3.6-25 and 3.6-26).

Figures 3.6-61 and 3.6-62 show the mass and energy release rates after a postulated crack in the main steam line in the main steam tunnel. Figures 3.6-63 and 3.6-64 show the mass and energy release rates after a postulated crack in the reactor feedwater line in the main steam tunnel.

3.6.1.20.2 Subcompartment Analysis for Postulated Pipe Break Outside the Primary Containment Excluding the Main Steam Tunnel, Ventway, and Tunnel Extension

3.6.1.20.2.1 Method of Analysis. The pressure transient in the reactor building after a postulated pipe break is analyzed with the computer programs RELAP3 (Reference 3.6-9) or RELAP4/MOD5 (Reference 3.6-21) or GOTHIC (References 3.6-25 and 3.6-26). In the computer model, subcompartments are represented by nodes (or volumes in GOTHIC), and flow paths between two nodes are represented by flow junctions (or flow paths in GOTHIC). Volumes, vent areas, flow resistances, initial atmospheric conditions, as well as the blowdown mass and energy release rates from the pipe breaks, are input to the computer program. Since

the absolute pressure within the subcompartments after a pipe break outside the primary containment is low in all cases, no significant pressure gradient exists within a subcompartment itself. Therefore, a subcompartment is not nodalized in the analysis and a sensitivity study is not performed.

Table 7.6-2 lists leak detection system instrumentation. Table 6.2-16 lists valve closure times for automatic isolation functions tied into the leak detection system. Credit is taken for automatic isolation if the system capability is not affected by the postulated pipe break or assumed as a single active component failure. Check valves close on reversal of flow in a fraction of a second. In all cases, the blowdown terminates when the inventory of fluid in the line is exhausted.

Where blowdown flow is not automatically terminated by isolation valves or check valves as described above, the duration of the blowdown event as the inventory of fluid in a line is exhausted is not considered in the analysis of peak compartmental pressure and temperature. To evaluate the peak pressures and temperatures in compartments and structures following a postulated break of the high energy pipes inside the structures, the blowdown analysis is extended far beyond the initial transient until the blowdown flow becomes steady or decreases continuously. The duration of the analysis is therefore sufficient to correctly predict the peak pressures and temperatures in these compartments and structures.

For a postulated pipe break or leakage crack in the main steam lines outside the primary containment, the flow from the reactor side of the break is terminated by the closing of the main steam isolation valves (MSIVs) located in each of the four main steam lines. The MSIVs start to close at 0.5 sec after the break and are fully closed at or prior to 5.5 sec after the break, as given in Table 15.6-5.

For a postulated break or leakage crack in the reactor feedwater lines outside primary containment, the flow from the reactor side of the break is terminated by closing of the check valves in each of the two reactor feedwater lines. The check valves start to close when the direction of flow reverses, and the flow from the reactor side of the break is therefore terminated within a fraction of a second.

3.6.1.20.2.2 Initial Atmospheric Conditions. The initial atmospheric conditions within the subcompartments used for the analysis are

Reactor Building:

a. Pressure = 14.7 psia,
b. Temperature = 110°F, and
c. Relative humidity = 0.0%.

Radwaste Building:

a. Pressure = 14.45 psia,
b. Temperature = 80° F, and
c. Relative humidity = 60%.

These conditions are simulated in the RELAP computer analysis as a homogeneous saturated steam-water mixture at 14.7 psia with an average density equivalent to the density of air at the above conditions. When using GOTHIC, the initial conditions are as described using air and water vapor.

3.6.1.20.2.3 Vent Flow. In the RELAP analyses, the vent flow between the subcompartments is assumed to be a homogeneous steam-water mixture with 100% water entrainment. For choked flow, a multiplier of 0.6 is used for Moody two-phase flow correlations. In the GOTHIC analyses, vent flow is modeled as air, steam and water with choked flow as described in References 3.6-25 and 3.6-26. For unchoked flow, the flow resistance consists of an entrance loss, an exit loss, and frictional losses. For conservatism, an entrance loss of approximately 0.5 and an exit loss of 1.0 are assumed for most of the vents.

3.6.1.20.2.4 Results of Subcompartment Analyses. Subcompartment analyses are performed for all subcompartments containing high energy piping. The results are summarized in Table 3.6-9 for subcompartments containing safety related SSCs.

3.6.1.20.2.5 Verification of Structural Adequacy. Verification of structural adequacy of compartments or of structural elements thereof subject to pressure generated by a postulated pipe break and to the local effects in the structure generated by the postulated pipe break; namely, a broken pipe reaction, jet impingement, and pipe whipping impact are discussed in Sections 3.6.1.6 through 3.6.1.10.

3.6.1.20.3 Subcompartment Analysis for a Postulated Pipe Break in the Main Steam Tunnel

See Section 3.6.1.20.3.2 for a description of the arrangement and features of the main steam tunnel. Subcompartment analysis in the main steam tunnel, ventway, and tunnel extension is performed for a postulated crack in the main steam line (see Section 3.6.1.20.1.3). Comparison of mass and energy release rates for the postulated crack in the main steam line to that of a postulated crack in the reactor feedwater line (Figures 3.6-61 through 3.6-64) shows that the main steam line crack is the limiting case. Other lines inside the main steam tunnel or its extension are of smaller sizes and a break in those lines is less severe.

3.6.1.20.3.1 General Approaches. The pressure and temperature transients in the main steam tunnel, ventway, and tunnel extension after a postulated crack in the main steam line are computed by the RELAP4/MOD5 program (Reference 3.6-21) or GOTHIC (References 3.6-25 and 3.6-26). The general approaches discussed in Sections 3.6.1.20.2.1 through 3.6.1.20.2.3 also apply to this case.

3.6.1.20.3.2 Description of the Main Steam Tunnel, Ventway, and Tunnel Extension. Descriptive information of the main steam tunnel, ventway, and tunnel extension is provided in Section 3.8.4.1.1.4. Figures 3.6-65 and 3.6-66 show a sectional plan view and a sectional elevation view, respectively, of the main steam tunnel, ventway, and tunnel extension.

In plan, the main steam tunnel is located at 0° azimuth of the north side of the reactor building; in elevation, it extends from el. 501 ft 0 in. to el. 522 ft 0 in. At the interface of the reactor building and the turbine generator building, the main steam tunnel continues for a short distance into the turbine generator building; the portion in the turbine generator building is referred to as the tunnel extension. The ventway starts at the same level as the main steam tunnel and extends horizontally from the main steam tunnel in the easterly direction and continues upward to the underside of the corridor floor above at el. 548 ft 0 in., where a blowout panel in the north wall of the ventway provides a ventilating path to the atmosphere.

Four blowout panels are used, as shown in Figures 3.6-65 and 3.6-66:

a. Panel A, vertical, part of secondary containment, located between the north end of the main steam tunnel (in the reactor building) and the tunnel extension (in the turbine generator building), bolted in place, of sheet steel,

b. Panel B, vertical, part of secondary containment, located in the east wall of the main steam tunnel, bolted in place, of sheet steel,

c. Panel C, horizontal, part of secondary containment, located at the top of the main steam tunnel, the north edge of panel is hinged, other edges are free and not bolted in place, of sheet steel, and

d. Panel D, vertical, not part of secondary containment, located in the north exterior wall of the ventway, bolted in place, of insulated metal siding.

The fasteners of the blowout panels which are bolted in place (namely, panels A, B, and D) are designed to fail in single shear, and all blow-off panels (namely, panels A, B, C, and D) are designed to blow-off and permit venting when the pressure generated in the main steam tunnel, ventway, and tunnel extension by a postulated pipe break within the main steam tunnel or tunnel extension exceeds 0.5 psi.

3.6.1.20.3.3 Analysis for a Postulated Pipe Break in the Main Steam Tunnel. The analysis for a postulated pipe break in the tunnel extension is discussed in Section 3.6.1.20.3.4.

Figure 3.6-67 shows the nodalization scheme for a postulated pipe break in the main steam tunnel. For conservatism blow-out panels A and B are assumed to remain in place during the pressure transient. Therefore, the tunnel extension and the turbine generator building are not modeled in this case. Nodes 1 and 2 represent the main steam tunnel. Nodes 3, 4, 5, and 6 represent the ventway. Tables 3.6-10 and 3.6-11 provide the volume and flow junction data, respectively.

The hinged panel C is modeled as an inertia valve in the RELAP4/MOD5 analysis (see Reference 3.6-21). The differential equation of motion for the valve gate is:

$$I\,\ddot{\theta}\,(t) = \overline{A}\,P\,(t) - K\,\dot{\theta}\,(t) \qquad (3.6\text{-}21)$$

where

θ = opening angle (radians)

t = time (sec.)

$\dot{\theta} = \frac{d\theta}{dt}$

$\ddot{\theta} = \frac{d_2\theta}{dt^2}$

I = moment of inertia (lb_{mass} - ft^2)

A = area X moment arm (ft^3)

P = differential pressure (lb/ft^2)

K = damping constant $\left(\frac{lb_{mass} \text{ - } sec^2}{ft}\right)$

Let ω= angular velocity in radians/sec. and substituting $\omega = \dot{\theta}$ and $\omega = \theta$ in Equation 3.6-21.

$$I\dot{\omega} + K\omega = \overline{A}P$$

It has the solution

$$\theta = \theta_o + \omega_o t + \left(\frac{AP}{K} + \omega_o\right)\left[t\frac{I}{K}\left(1 - e^{\frac{-Kt}{I}}\right)\right] \qquad (3.6\text{-}22)$$

where θ_o and ω_o are values for θ and ω at $t = O$.

For panel D, the differential equation of motion is

$$M\ddot{s}(t) + AP(t) \qquad (3.6\text{-}23)$$

where

M = mass of panel $\left(\frac{lb_{mass} - sec^2}{ft}\right)$

s = displacement (ft)

v = velocity (ft/sec)

s = linear acceleration (ft/sec^2)

A = area of panel (ft^2)

P = average pressure (lb/ft^2)

t = time (sec)

The frictional force is neglected. The solution of the above equation is:

$$s = s_o + (v_o + \frac{F}{2m} t)\, t \qquad (3.6\text{-}24)$$

where s_o and v_o are values for s and v at t = O.

The displacement, s, of the panel and the opening area as functions of time are determined by iterative procedures.

Pertinent properties of blow-out panels C and D are seen in Table 3.6-12.

Figures 3.6-68 and 3.6-69 are plots of the pressure transients and Figures 3.6-70 and 3.6-71 are plots of the temperature transients for a postulated pipe break in Node 1.

Figures 3.6-72 and 3.6-73 are plots of the pressure transients and Figures 3.6-74 and 3.6-75 are plots of the temperature transients for a postulated pipe break in Node 2.

Blow-out panels C and D are assumed to blow off at the differential pressure noted in Section 3.6.1.20.3.2.

3.6.1.20.3.4 Analysis for a Postulated Pipe Break in the Tunnel Extension. Figure 3.6-76 shows the nodalization scheme for a postulated pipe break in the tunnel extension. Nodes 1 and 2 represent the tunnel extension. The vertical pipe restraint (see Figure 3.6-24) divides

Node 1 and 2. Nodes 3, 4, and 5 represent the following portions of the turbine generator building:

a. Node 3 represents the portion between the mezzanine floor at el. 471 ft 0 in. and the operating floor at el. 501 ft 0 in.,

b. Node 4 represents the portion between the ground floor at el. 441 ft 0 in. and the mezzanine floor at el. 471 ft 0 in., and

c. Node 5 represents the portion between the operating floor el. 501 ft 0 in. and the roof of the turbine generator building.

For conservatism, panel A (in Figures 3.6-65 and 3.6-66) is assumed to remain in place during the pressure transient, and only 10% of the insulated metal siding comprising the exterior walls above the operating floor (see Figure 1.2-5) of the turbine generator building is assumed to blow off the structural steel frame at a differential pressure of 0.5 psi. Tables 3.6-13 and 3.6-14 provide the volume and flow junction data, respectively.

Figures 3.6-77 and 3.6-78 are plots of the pressure transients and Figures 3.6-79 and 3.6-80 are plots of the temperature transients for a postulated pipe break in Node 1.

Figures 3.6-81 and 3.6-82 are plots of the pressure transients and Figures 3.6-83 and 3.6-84 are plots of the pressure transients for a postulated pipe break in Node 2.

3.6.1.20.3.5 Verification of Structural Adequacy. Verification of structural adequacy of the main steam tunnel ventway and tunnel extension, or of structural elements thereof, subject to load combinations involving pressure generated by a postulated pipe break and local effects in the structure generated by the postulated pipe break; namely, broken pipe reaction, jet impingement, and pipe whip impact are discussed in Sections 3.6.1.6 through 3.6.1.10.

3.6.1.20.3.6 Turbine Building Consequences of a Postulated Pipe Break in the Steam Tunnel Extension. The only items with safety-related functions in the turbine building are some reactor protection system (RPS) sensor inputs from the main steam system, MSIV isolation logic inputs from the main steam system, and the tower makeup transformers located on the turbine ground floor which are required to function only for the design basis tornado event. This last item is remote from the steam and feedwater lines (being located on the turbine ground floor) and has been evaluated to have adequate protection from tornado missiles and internal flooding (see Section 3.6.1.15.1). The RPS and MSIV isolation logic sensor inputs due to their nature cannot be made immune from pipe break effects. However, loss of this equipment during a postulated event would not result in loss of capability to bring the plant to a cold shutdown or mitigate the radiological consequences of such an incident even assuming a single failure among the safety systems that remain unaffected.

A pipe break in a main steam or feedwater line in the turbine building or steam tunnel extension could result in transitory pressurization of the corridors between the turbine building, reactor building, radwaste control building, and the diesel generator building. Air and steam would be forced into these corridors through openings in the south wall of the turbine-generator building, and through the seismic gap between the turbine building, reactor building, and radwaste control building. The large volume of the turbine building and because the turbine building metal siding and exterior doors are not leaktight and are not designed to withstand more than a minimal pressure differential, would result in the peak pressures seen by the reinforced-concrete walls of the reactor building and radwaste control building not exceeding the structural capacity of the walls. The doors to the control room are low-range blast doors designed to withstand a pressure differential of 3 lb/in.^{2}, which is considered adequate to maintain control room habitability as discussed in Section 3.6.1.12.

3.6.1.21 Description of Methods of Analyses to Ensure That Primary or Secondary Containment Integrity Is Not Compromised by a Postulated Passive Component Failure

The previous 20 sections present the results of analyses that indicate that postulated piping failures do not adversely affect safe reactor operation. Implicit in these analyses is the necessity of conforming to relevant standards with regard to offsite radiological consequences.

3.6.2 DETERMINATION OF BREAK LOCATIONS FOR DYNAMIC EFFECTS ASSOCIATED WITH THE POSTULATED RUPTURE OF PIPING

Information concerning postulated break and crack location criteria and methods of analysis for evaluating the dynamic effects associated with postulated breaks and cracks in high- and moderate-energy fluid system piping inside and outside of primary containment is presented in this section. The information presented in this section and in Section 3.6.1 confirms that the requirements for the protection of structures, systems, and components relied on for safe reactor shutdown or to mitigate the consequences of a postulated pipe break have been met.

3.6.2.1 Criteria Used to Define Break and Crack Location and Configuration

The following section establishes the criteria for the location and configuration of postulated breaks and cracks in high-energy and moderate-energy piping systems both inside and outside of primary containment.

High-energy fluid systems are defined as those systems or portions of systems that during normal plant conditions* are maintained pressurized under conditions where either one or both of the following are met:

a. Maximum temperature exceeds 200°F
b. Maximum pressure exceeds 275 psig.

Moderate energy fluid systems are defined as those systems, or portions of systems, that during normal plant conditions are pressurized under both of the following conditions:

a. Maximum temperature is 200°F or less, and
b. Maximum pressure is 275 psig or less.

Piping systems are classified as moderate-energy systems, when they operate as high energy piping for only short periods in performing their system function. For the major operational period they qualify as moderate-energy fluid systems. An operational period is considered "short" if the total fraction of time that the system operates, within the pressure-temperature conditions specified for high-energy fluid system, is less than approximately 2% of the time period that the system operates as a moderate-energy fluid system.

A postulated pipe break is defined as a sudden, gross failure of the pressure boundary either in the form of a complete circumferential severance (guillotine break) or as development of a sudden longitudinal crack (longitudinal split). These are postulated for high-energy fluid systems only. For moderate-energy fluid systems, pipe rupture is confined to postulation of leakage cracks in piping and branch runs. These cracks affect the surrounding environmental conditions only and do not cause jet impingement or uncontrolled whipping of the pipe.

A moderate-energy piping system crack is not postulated simultaneously with a high-energy piping system break, nor is any pipe break or crack outside containment postulated concurrently with a pipe break or crack inside containment.

Postulated pipe break locations are selected as described herein and are based on the guidelines provided in Regulatory Guide 1.46, Revision 0; the BTP ASB 3-1, and as expanded in BTP MEB 3-1 for piping inside and outside primary containment.

* Normal plant conditions are defined as the plant operating conditions during reactor startup, operation at power, hot standby, or reactor cool down to cold shutdown, but excluding test modes.

3.6.2.1.1 Postulated Pipe Break Locations in High-Energy Fluid System Piping Not in the Containment Penetration Area

Pipe breaks (not including leakage cracks) are postulated at locations as indicated below:

3.6.2.1.1.1 Postulated Pipe Break Locations in ASME Section III Class I Piping Runs.

The terminal ends* of the pressurized portions of the run.

Intermediate locations of postulated pipe breaks are selected by application of one of the following sets of rules:

a. Pipe break is postulated at each location of significant change in flexibility, such as pipe fittings (elbows, tees, and reducers), and circumferential connections to valves and flanges;

b. Based on stress and fatigue analysis, as calculated according to ASME Code Section III Subarticle NB-3600, no break is postulated if any of the following applies:

1. S_n† does not exceed $2.4S_m$‡,

---

* Terminal ends are extremities of piping runs that connect to structures, components (e.g., vessels, pumps, valves), or pipe anchors that act as rigid constraints to piping motion and thermal expansion. A branch connection to a main piping run is a terminal end of the branch run, except where the branch run is classified as part of the main run in the stress analysis and is shown to have a significant effect on the main run behavior. In piping runs which are maintained pressurized during normal plant conditions for only a portion of the run (i.e., up to the first normally closed valve), a terminal end of such runs is the piping connection to this closed valve.

† S_n is the primary plus secondary stress intensity range, as calculated by use of Equation (10) of ASME Code Section III Subsection NB, Paragraph NB 3653.1, between any two load sets (including the zero load set) for normal and upset plant conditions, including an OBE event transient.

‡ S_m is the design stress intensity, as described in ASME Code Section III Subsection NB, Paragraph NB 3229.

2. S_n exceeds $2.4S_m$ but does not exceed $3S_m$, and the Cumulative Usage Factor (U)* does not exceed 0.1, and

3. S_n exceeds $3S_m$, but S_e† and S_r‡ are each less than $2.4S_m$, and U does not exceed 0.1.

3.6.2.1.1.2 Postulated Pipe Break Locations in ASME Section III Class 2 and 3 Piping Runs.

The terminal ends of the pressurized portions of the run.

Intermediate locations of postulated pipe breaks are selected by applications of one of the following sets of rules:

a. Pipe break is postulated at each location of significant change in flexibility, such as pipe fittings (elbows, tees, and reducers), and circumferential connections for valves and flanges,

b. At each location here the stresses under the loadings resulting from upset plant conditions, including an operating basis earthquake (OBE) event as calculated by the summation of Equations (9) and (10) of ASME Code Section III Subsection NC, Paragraph NC 3652, exceed 0.8 ($1.2S_h + S_A$) where S_h and S_A), are as defined in Paragraph NC 3611.2, or

c. Intermediate breaks are not postulated in sections of straight pipe where there are no pipe fittings, valves, or flanges.

3.6.2.1.1.3 Break Locations in Other Piping Runs. Postulated pipe break locations for piping other than ASME Code Section III Class 1, 2, and 3, are postulated in accordance with pipe whip criteria which conforms to the criteria set forth for ASME Code Section III Class 2 and 3 piping.

---

* U is the Cumulative Usage Factor that indicates the total fatigue damage as calculated by the procedure in ASME Code Section III Subsection NB, Paragraph NB 3653.

† S_e is the nominal value of expansion stress as calculated by use of Equation (12) of ASME Code Section III Subsection NB, Paragraph NB 3653.6(a).

‡ S_r is the range of primary plus secondary membrane plus bending stress intensity, excluding thermal bending and thermal expansion stresses as calculated by use of Equation (13) of ASME Code Section III Subsection NB.

3.6.2.1.2 Postulated Pipe Break Locations in High-Energy Fluid System Piping Between Primary Containment Isolation Valves

Pipe breaks (not including leakage cracks) are postulated in locations as indicated below:

3.6.2.1.2.1 Postulated Pipe Break Locations in ASME Section III Class 1 Piping Between Primary Containment Isolation Valves. No pipe breaks are postulated in the portion of piping between primary containment isolation valves, if any of the following apply:

a. S_n does not exceed $2.4S_m$,

b. S_n exceeds $2.4S_m$ but does not exceed $3S_m$, and the Cumulative Usage Factor (U) does not exceed 0.1, or

c. S_n exceeds $3S_m$, but S_e and S_r are each less than $2.4S_m$, and U does not exceed 0.1.

The stress levels in the ASME Section III Class 1 containment penetration high-energy piping are maintained at or below these limits and therefore, breaks are not postulated.* See Section 3.6.2.1.2.3 for further discussion of containment penetration piping.

Piping systems which may have break exclusion areas between primary containment isolation valves are those determined by examining the list of high-energy piping systems (see Section 3.6.2.1 and Table 3.6-15). Systems which do not pass through primary containment are excluded. In addition, systems which are not pressurized between the isolation valves during normal plant operation (see Table 3.6-15) are excluded. The remaining systems, those which may have break exclusion areas between primary containment isolation valves are listed in Table 3.6-16. Break exclusion areas for these systems are shown in Figures 3.6-85 through 3.6-88.

3.6.2.1.2.2 Postulated Pipe Break Locations in ASME Section III Class 2 and 3 Piping Between Primary Containment Isolation Valves. See Section 3.6.2.1.1.2, for stress criteria applicable to ASME Section III Class 2 and 3 piping between containment isolation valves.

The stress levels are maintained at or below these limits and therefore, breaks are not postulated. See Section 3.6.2.1.2.3 for further discussion of containment penetration piping.

* A program for augmented inservice inspection for high energy line breaks is included in the Inservice Inspection Program Plan.

3.6.2.1.2.3 Primary Containment Penetration Piping. To maintain containment integrity, primary containment penetrations are designed with the following characteristics:

a. They are capable of withstanding the forces caused by impingement of the fluid from the rupture of the largest local pipe without failure, and

b. They are capable of withstanding the maximum reactions that the pipes to which they are attached are capable of exerting.

Piping and electrical penetration details are discussed and shown in Section 3.8.6.

The stress criteria for postulating breaks in containment penetration piping between isolation valves is given in Sections 3.6.2.1.2.1 and 3.6.2.1.2.2.

Welded attachments, for pipe supports or other purposes, to these portions of piping are avoided except where detailed stress analyses or tests are performed to demonstrate compliance with the limits of Section 3.6.2.1.2. In addition, the number of circumferential and longitudinal piping welds and branch connections are minimized.

Any pipe anchors or restraints (e.g., connections to containment penetrations and pipe whip restraints) are designed such that they are not welded directly to the outer surface of the piping except where such welds are 100% volumetrically examinable while in service, and a detailed stress analysis is performed to demonstrate compliance with the limits of Section 3.6.2.1.2.

Tunnel structures surrounding the primary containment penetration piping are designed for the thermal and pressure loads of a through wall leakage crack regardless of crack postulation requirements. See Section 3.6.1.20 for further discussion.

Access for ISI of welds in high-energy (hot type) containment penetration assemblies is described in Section 3.8.6.1.1. All required ISI locations are accessible.

3.6.2.1.3 Postulated Through Wall Leakage Crack Locations in High- and Moderate-Energy Fluid Systems

Cracks in high energy systems, regardless of ASME Code classification, were evaluated at Columbia Generating Station both inside and outside of containment. Inside containment it was found that the circumferential or longitudinal high energy line breaks bounded the structural and environmental consequences produced by a leakage crack at any location in a high energy line. Outside containment analyses were completed or protection was provided to ensure that critical plant systems are not harmed by leakage cracks in adjacent high energy systems.

In moderate-energy piping systems consisting of ASME Code Section III Class 2 and 3 piping and moderate-energy nonnuclear piping, including fluid system piping between primary containment isolation valves, cracks are not postulated provided the stress range of 0.4 ($1.2S_h^*$ + $S_A^\dagger$) is not exceeded for the load combination which includes the effects of pressure, weight, other sustained loads, and occasional loads such as the OBE and thermal expansion loads. Since all piping in structures housing safety-related systems are supported and controlled as Seismic Category I systems regardless of service, the criteria for postulated cracks is the same as above for all systems.

3.6.2.1.4 Types of Breaks and Cracks Postulated in High-Energy and Moderate-Energy Fluid System Piping

3.6.2.1.4.1 Breaks in High-Energy Fluid System Piping. The following types of breaks are postulated in high-energy fluid system piping:

No breaks need be postulated in piping having a nominal diameter less than, or equal to 1 in.

Circumferential breaks are postulated only in piping exceeding a 1 in. nominal pipe diameter.

Longitudinal splits are postulated only in piping having a nominal pipe diameter equal to or greater than 4 in.

Longitudinal splits are not postulated at terminal ends.

At each of the postulated break locations, consideration is given to the occurrence of either a longitudinal split or circumferential break. Both types of breaks are considered if the maximum stress ranges in the circumferential and axial directions are not significantly different. Only one type break is considered as follows:

a. If the result of a detailed stress analysis indicates that the maximum stress range in the axial direction is at least 1.5 times that in the circumferential direction, only a circumferential break is postulated. Where usage factor is a determinant in establishing a postulated break location, the fatigue dominant stresses are

---

* S_h is the allowable stress at maximum (hot) temperatures defined in ASME Code Section III, Article NC 3611.2.

† S_A is the allowable stress range for thermal expansion, as defined in ASME Code Section III, Article NC 3611.2.

examined as indicated above to determine whether longitudinal, circumferential, or both are postulated; or

b. If this type of analysis indicates that the maximum stress range in the circumferential direction is at least 1.5 times that in the axial direction, only a longitudinal split is postulated.

Where break locations are selected without the benefit of stress calculations, circumferential breaks are postulated at the piping welds to each fitting, valve, or welded attachment.

For a longitudinal split, the break area is assumed to be equal to cross-sectional flow area of the pipe.

For circumferential breaks, pipe whipping is assumed to occur in the plane defined by the piping configuration and is assumed to cause pipe movement in the direction of the jet reaction.

A longitudinal break is assumed to result in an axial split without severance and to be oriented at any point about the circumference of the pipe or alternatively at the point(s) of highest stress as indicated by a detailed stress analysis. If a postulated break location is at a nonaxisymmetric fitting, such as a tee or elbow, the split is assumed to be oriented (but not concurrently) on each side of the fitting at its center, perpendicular to the plane of the fitting and is assumed to cause pipe movement in the direction of the jet reaction.

For a circumferential break, the dynamic force of the jet discharge at the break location is based upon the effective cross sectional flow area of the pipe and on a calculated fluid pressure, as modified by an analytically or experimentally determined thrust coefficient. A circumferential break is assumed to result in pipe severance with full separation amounting to at least a one-pipe-diameter lateral displacement of the ruptured piping sections, except as limited by structural design features. The break is assumed to be oriented perpendicular to the longitudinal axis of the pipe. Line restrictions, flow limiters, and the absence of energy reservoirs are accounted for in the calculation of the design jet discharge.

3.6.2.1.4.2 Cracks in High-Energy and Moderate-Energy Fluid System Piping. The following controlled through wall leakage cracks are postulated in high-energy and moderate-energy fluid systems (or portion of systems):

Cracks are postulated in fluid systems or portions of systems whose size exceeds a nominal pipe diameter of 1 in.

Fluid flow from the postulated crack is based on a circular opening of area equal to that of a rectangle one-half pipe-diameter in length and one-half pipe wall thickness in width.

The flow from the postulated crack is assumed to result in an environment that wets all unprotected components within the compartment, with subsequent flooding in the compartment and communicative compartments. Flooding effects are determined on the basis of a conservatively estimated time period required to affect corrective action.

3.6.2.1.5 Protection Criteria for the Effects of Pipe Break

Protection from the effects of a whipping pipe due to a pipe break is provided where necessary. Protection from pipe whip need not be provided if any one of the following conditions exists: The piping is classified as moderate energy piping. Following a single postulated pipe break, piping for which the unrestrained movement of either end of the ruptured pipe, in the direction of the jet reaction about a plastic hinge, formed within the piping, cannot impact any structure, system, or component important to safety. Piping for which the internal energy level associated with the whipping is insufficient to impair the safety function of any structure, system, or component to an unacceptable level. Any line restrictions (e.g., flow limiters) between the pressure source and break location, and the effects of either a single-ended or double-ended flow condition are accounted for in the determination of the internal fluid energy level associated with the postulated pipe break reaction. The energy level in a whipping pipe will be considered insufficient to rupture an impacted pipe of equal or greater nominal pipe size and of equal or heavier wall thickness.

For further discussion of pipe whip protection, see Section 3.6.2.3.3.

Protection of essential systems from the effects of jet impingement is provided where necessary to ensure reactor shutdown to a safe cold condition and to limit the release of radioactivity to within 10 CFR Part 100 limits. For further discussion of criteria for protection against jet impingement, see Section 3.6.2.3.2.

3.6.2.2 Analytic Methods to Define Blowdown Forcing Functions and Response Models

3.6.2.2.1 Analytical Methods to Define Blowdown Forcing Functions

The rupture of a pressurized pipe causes the flow characteristics of the system to change, creating reaction forces which can dynamically excite the piping system. The reaction forces are a function of time and space and depend on fluid state within the pipe prior to rupture, break flow area, frictional losses, plant system characteristics, piping system, and other factors. The methods used to calculate the reaction forces for various piping systems are presented in the following sections.

A rise time, not exceeding 1 msec, is assumed for the initial pulse of the fluid blowdown forcing function, unless longer crack propagation times or rupture opening times are substantiated by experimental data or analytical theory.

Blowdown forcing functions are determined by either of two general methods given below:

a. The predicted blowdown forces on pipes fed by a pressure vessel can be described by transient and steady-state forcing functions. The forcing functions used are based on methods described in References 3.6-3 and 3.6-22. These may be simply described as follows:

1. The transient forcing functions occur at points along the pipe from the propagation of waves (wave thrust) along the pipe and at the broken end from the reaction force due to the momentum of the fluid leaving the end of the pipe (blowdown thrust);

2. The waves cause various sections of the pipe to be loaded with time-dependent forces. It is assumed that the pipe is one-dimensional in that there is no attenuation or reflection of the pressure waves at bends, elbows and the like. Following the rupture, a decompression wave is assumed to travel from the break at a speed equal to the local speed of sound within the fluid. Wave reflections occur at the break end and the pressure vessel end until a steady flow condition is established. Free-space and vessel conditions are used as boundary conditions. The blowdown thrust causes a reaction force perpendicular to the plane of the pipe break, reaching a final steady state value;

3. The initial blowdown force on the pipe is taken as the sum of the wave and blowdown thrusts and is equal to the vessel pressure (P_o) times the break area (A). After the initial decompression period (i.e., the time it takes for a wave to reach the first change in direction), the force is assumed to drop off to the value of the blowdown thrust (i.e., 0.7 P_oA);

4. Time histories of transient pressure, flow rate, and other thermodynamic properties of the fluid can be used to calculate the flowdown force on the pipe using the following equation:

$$F = \{(P - P_a) + \frac{\rho u^2}{g}\}A$$

where

F = blowdown force

P = pressure at exit plane

P_a = ambient pressure

u = velocity at exit plane

ρ = density at exit plane

A = area of break

g = gravitational constant

5. Following the transient period, a steady-state period is assumed to exist. Steady-state blowdown forces are calculated, considering frictional effects. For saturated steam, these effects reduce the blowdown forces from the theoretical maximum of 1.26 P_oA. The method of accounting for these effects is presented in References 3.6-3 and 3.6-22. For subcooled water, a reduction from the theoretical maximum of 2.0 P_oA is found through the use of Bernoulli's and other standard equations, such as Darcy's equation, which account for friction.

b. The following is an alternative method for calculating blowdown forcing functions.

Computer code simulation either by RELAP3 (Reference 3.6-9) or GOTHIC (References 3.6-25 or 3.6-26) is used to obtain exit plane thermodynamic states for postulated ruptures (see Section 3.12.11 for further discussion of the software). Specifically, the software calculates exit pressure, specific volume, and mass rate. From these data the blowdown reaction load is calculated using the following relation:

$$\frac{T}{A_E} = (P_E - P_\infty) + \frac{G_E{}^2 \overline{V}_E}{g_C}$$

$$R = -\frac{T}{A_E} \times A_E$$

where

$\frac{T}{A_E}$ = thrust per unit break area

P_E = exit pressure

P_∞ = receiver pressure

G_E = exit mass flux

$\overline{V}_E$ = exit specific volume

g_c = gravitational constant

R = reaction force on the pipe

3.6.2.2.2 Analytical Methods to Define Response Models

3.6.2.2.2.1 General Description of Analytical Methods. The prediction of time-dependent and steady-thrust reaction loads caused by blowdown of subcooled, saturated, and two-phase fluid from a ruptured pipe is used in the design of piping systems and in the evaluation of dynamic effects of pipe breaks. A detailed discussion of the analytical methods employed to compute these blowdown loads are given in Section 3.6.2.2.1. The analytical methods used to account for this loading are discussed below.

3.6.2.2.2.2 Dynamic Analysis of the Effects of Pipe Rupture.

Criteria

a. Analysis is performed for each postulated pipe break;

b. The analysis includes the dynamic response of all components of the system including the pipe, pipe whip restraints, and all structures required to transmit loading to foundation. The structures are analyzed for a suddenly applied force in conjunction with impact and rebound effects due to gaps between piping and pipe whip restraints;

c. The analytical model adequately represents the mass/inertia and stiffness properties of the system;

d. Pipe whipping is assumed to occur in the plane defined by the piping geometry and configuration and to cause pipe movement in the direction of the jet reaction;

e. Piping contained within the broken loop is no longer considered part of the RCPB. Plastic deformation in the pipe is considered as a potential energy absorber. Limits of strain are imposed similar to pipe whip material (see Section 3.6.2.2.3.2) restraint. Piping systems are designed so that plastic

instability would not occur in the pipe at the design dynamic and static loads, unless damage studies are performed which show that the consequences could not result in the direct damage of any essential system or component; and

f. Components such as vessel safe ends and valves, which are attached to the broken piping system and do not serve a safety function or whose failure would not further escalate the consequences of the accidents, are not designed to meet ASME Code requirements for essential components under faulted loading. However, if these components are required for safe shutdown or if they serve a safety function to protect the structural integrity of an essential component, then these components are designed to code limits for faulted conditions and to the limits necessary to ensure operability.

Analytical Models

a. Lumped-Parameter Analysis Model: Lumped mass points are interconnected by springs to take into account for the effects of inertia and stiffness inherent in the system, and time histories of the responses are computed by numerical integration to account for gaps and inelastic effects. This analytical method is discussed in detail in Reference 3.6-4;

b. Energy-Balance Analysis Model: Kinetic energy, generated during the first quarter cycle movement of the ruptured pipe as imparted to the piping/restraint system through impact, is converted into equivalent strain energy. Deformations of the pipe and the restraint are compatible with the level of absorbed energy; and

c. Pipe whip restraints for the reactor recirculation system are designed by the NSSS supplier. The analytical method utilized for this design is the computer program PDA which is described in Reference 3.6-4 and further discussed in Section 3.12.33.

Pipe whip restraints for all other piping systems requiring such protection are designed by the architect/engineer; the method described below is used for this pipe whip restraint design.

Simplified Dynamic Analysis

a. To simplify dynamic analysis the following conservative assumptions are used:

1. The entire structure including pipe, restraint linkage, support beams, and major structure to foundation connections absorb energy by elastic, elastoplastic, or plastic deformation. To provide a simplified dynamic

mathematical model, one member is generally considered to absorb all the energy. This member is classified as an energy absorbing member and is designed as described in Section 3.6.2.3.3.2. The other components of the structure are assumed as infinitely rigid. These are classified as load transmitting members and are designed as described in Section 3.6.2.3.3.2;

2. The time history of unbalanced forces on the ruptured pipe is reduced to a suddenly applied constantly maintained force, which envelopes the actual force at any particular time, or is based on a more sophisticated blowdown calculation; and

3. Dynamic loading on the pipe whip restraint is reduced to a suddenly applied, constantly maintained force described above, in conjunction with a kinetic energy of impact.

b. Simplified analytical models such as simple beams, structural frames, and ring girders on assumed rigid supports are modeled as single springs. One example of such a typical analytical model is shown in Figure 3.6-89. For these, the required member resistance (R_r) is determined by application of the formula shown in Figure 3.6-90. This derived equation is based on References 3.6-1 and 3.6-2. The following is a description, and discussion of the parameters used in this derivation:

1. The term (R_r) represents the required member resistance (strength) when loaded by a suddenly applied constantly maintained force (F_1), in conjunction with a kinetic energy of impact (K), due to collision of a moving body (i.e., ruptured pipe) with the member in question;

2. The impulse (i) is represented by the area under any load time history having a time of duration (t_d), which is small compared with the natural period of the impacted member;

3. The kinetic energy is represented by $i^2/2M$, where (i) is the impulse and (M) is the mass of the moving body;

4. The kinetic energy of impact (K) is also represented by the product of the Force (F_1) which accelerates the ruptured pipe, and a distance (d) the total distance traveled by the moving body from time zero to time of collision with the member in question. Note that when the resisting member is in direct contact with the ruptured pipe, the distance (d) is zero and the kinetic energy (K) reduces to zero. Likewise, when no

resisting member is required, the ruptured pipe does not collide with anything and therefore no kinetic energy of impact exists. In these events the equation shown in Figure 3.6-90 is applicable with (K) equal to zero;

5. The energy absorbing member is permitted to deform into the plastic region. Thus the member resistance is bilinear. (Y_e) is the deflection of the member at the end of elasticity of the member. (Y_m) is the maximum deflection of the member;

6. The elastic spring constant (k) is the ratio of load on the member divided by the deflection due to this load, where the deflection is equal to or less than the value (Y_e) and the load is compatible with this concept. Thus (k) can be expressed as (R_r/Y_e);

7. For inelastic response the maximum deflection (Y_m) is always larger than the elastic deflection (Y_e). For this case, the ratio (Y_m/Y_e) is defined as the ductility ratio (μ);

8. The maximum deformation of the energy absorbing member is controlled by limiting the ductility ratio (μ).

   Reference 3.6-6 provides the ductility ratio that corresponds to collapse (μ_c). For structural steel members, these values vary with upper limits in the order of 20 to 30 and up (for very ductile structures). For Columbia Generating Station, the maximum permissible ductility ratio is limited to 50% of (μ_c), except that energy absorbing members in direct contact with primary containment are limited to 5% of (μ_c). For Columbia Generating Station, only steel members are utilized as energy absorbing members, as defined in Section 3.6.2.3.3.2. The maximum values of (μ_c), for various structural components, are given in Table 3.6-7; and

9. The equation derived in Figure 3.6-90 accounts for a suddenly applied constantly maintained force in conjunction with a kinetic energy of impact on the resisting member. Total transfer of energy is implied. This is combined with the constantly maintained force (from ruptured piping blowdown) on the restraint structure. This assumption is consistent with a zero coefficient of restitution (full plasticity), and is a conservative assumption.

With regard to rebound, it should be noted that if a coefficient of restitution of unity is assumed (full rebound), there is zero kinetic energy transfer to the restraint structure.

If a coefficient of restitution less than unity is assumed (partial rebound), there is a partial amount of kinetic energy transfer to the restraint structure.

A coefficient of restitution of zero conservatively assumed in the application of the equation mentioned above gives zero rebound with 100% kinetic energy transfer to the restraint structure.

It should also be noted that the assumption of a suddenly applied constantly maintained force as used in the equation mentioned above is conservative with respect to rebound. Rebound implies a finite time of short duration contact with the restraint structure, in contrast to the infinite time assumed.

c. Actual structural resistance for the above structures is determined by methods of limit analysis using a dynamic yield strength, as defined in Section 3.6.2.2.3.1.

3.6.2.2.3 Material Properties Under Dynamic Loads

3.6.2.2.3.1 Dynamic Yield Strength. To account for the rapid strain rate effects, dynamic yield strength is utilized. This phenomenon is documented in References 3.6-6 and 3.6-7. Material tests have shown a consistent increase in yield strength under rapid loading. Under rapid strain rate, carbon steel yield strength consistently improves by more than 40%. High strength alloy steel displays a somewhat smaller improvement. For Columbia Generating Station, a conservative dynamic yield strength of 110% of minimum static yield strength, at the specified operating temperature, is used.

3.6.2.2.3.2 Maximum Strain of Tension Members. Pure tension members, such as U-bars shown in Figure 3.6-21 which act to limit pipe whip are permitted to deform during energy absorption: (a) a maximum of 50% of the minimum uniform strain (at the maximum stress on an engineering stress-strain curve) based on actual restraint material tests or (b) one-half of minimum percent elongation as specified in the applicable ASME Code Section II or ASTM Specifications if demonstrated to be less than 50% of the minimum uniform strain based on representative test results.

The dynamic tensile and impact properties are specified to be not less than (a) 70% of the static percent elongation or (b) 80% of the statically determined minimum total energy absorption.

3.6.2.2.3.3 Maximum Deformation of Flexural Members. Deformations of energy absorbing flexural support members are generally limited to 50% of that deformation which corresponds to structural collapse, except that deformation of energy absorbing members in direct contact with the primary containment vessel is limited to 5% of that deformation which corresponds to structural collapse.

3.6.2.2.3.4 Materials and Proportions of Structural Shapes. The materials and proportions of structural shapes for energy absorbing members are in accordance with recommendations for dynamic member design as documented in References 3.6-6 and 3.6-7.

3.6.2.3 Dynamic Analysis Methods to Verify Integrity and Operability

3.6.2.3.1 Dynamic Analysis Methods for Jet Impingement Effects

The procedure for analyzing the dynamic effects of jet impingement has been extracted from Reference 3.6-8.

Computer simulation using either RELAP3 (Reference 3.6-9) or GOTHIC (References 3.6-25 and 3.6-26) with required geometric input data is run to obtain the exit plane thermodynamic state and mass flow rate. Specifically, the quantities output the computer simulations are

M	= mass flow rate	lb_m/sec
$\overline{V}_E$	= specific volume	ft^3/lb_m
P_E	= exit pressure	lb_f/ft^2

The reaction load on the piping system is given by

$$\frac{T}{A_E} = (P_E - P_\infty) + \frac{G_E{}^2 \overline{V}_E}{g_c} \qquad (3.6\text{-}25)$$

where

$\frac{T}{A_E}$	= thrust per unit area	lb_f/ft^2
P_∞	= receiver pressure	lb_f/ft^2
G_E	= mass flux	$lb_m/sec\ ft^2$

P_E	= exit pressure	lb_f/ft^2
$\bar{V}_E$	= specific volume at exit	ft^3/lb
g_c	= Newton's constant	$32.174 \frac{ft - lb_m}{lb_f\ sec^2}$

(T/AE) yields the thrust reaction load on the piping system subject to the assumption that the vapor to liquid velocity ratio is unity. By conservation of forward momentum, the jet force per unit area (F_j/A_E) equals the thrust force per unit area (T/AE). To determine the effect of the fluid jet on targets located some distance LT from the break, the following procedure is used.

Classify target distance LT as less than, equal to, or greater than the distance required for full jet expansion L_∞. See Figure 3.6-91.

where

$$L_\infty = \frac{D_E}{2}\left[\left(\frac{A_\infty}{A_E}\right)^{1/2} - 1\right] \qquad (3.6\text{-}26)$$

$$\frac{A_\infty}{A_E} = \left[\frac{G_E{}^2}{g_c}\right]\left[\frac{\bar{v}_\infty}{T / A_E}\right] \qquad (3.6\text{-}27)$$

where

A_∞	= area of jet at full expansion	ft^2
A_E	= area of exit	ft^2
D_E	= diameter of exit	ft
G_E	= mass flux	$lb_m/sec\ ft^2$
g_c	= Newton's Constant	$32.174 \frac{ft - lb_m}{lb_f\ sec^2}$
h_E	= exit plant enthalpy	Btu/lb
L_∞	= distance to full expansion	ft

P_∞ = receiver pressure lb_f/ft^2

T = thrust

$\overline{V}_\infty$ = specific volume at full expansion

Assuming the kinetic energy of the fully expanded jet to be insignificant, the following relation holds between vessel stagnation enthalpy and fully expanded jet enthalpy:

$$h_o = h_\infty \tag{3.6-28}$$

Therefore,

$$x_\infty = \frac{h_o - h_{f_\infty}}{h_{fg_\infty}} \tag{3.6-29}$$

where

h_o = stagnation enthalpy at full expansion, Btu/lb

h_{f_∞} = liquid enthalpy at full expansion, Btu/lb

h_{fg_∞} = vaporization enthalpy at full expansion, Btu/lb

X_∞ = quality at full expansion

then,

$$\overline{V}_\infty = \overline{V}_{f_\infty} + X_\infty \overline{V}_{fg_\infty} \tag{3.6-30}$$

where

$\overline{V}_{f_\infty}$ = specific volume of liquid at full expansion, ft^3/lb_m

$\overline{V}_{fg_\infty}$ = specific volume of vaporization at full expansion ft^3/lb_m

$\overline{V}_\infty$ = specific volume at full expansion, ft^3/lb_m

From Equations 3.6-29 and 3.6-30, subject to the assumption of Equation 3.6-28, Equations 3.6-26 and 3.6-27 can be solved for L_∞.

For $L_T < L_\infty$ property variations are assumed linear from A_E to A_∞ for area and from P_E to P_∞ for pressure.

The jet impingement load F_j is as follows with F_j a constant:

$$F_{jT} = F_j \times \frac{A_T}{A_L} \tag{3.6-31}$$

where

A_T = area of target which is intercepted by the jet

A_L = jet area at the target distance calculated as

in Region 1: for $O < L < L_\infty$

$$A_L = \left(A_\infty - A_E\right)\frac{L_T}{L_\infty} + A_E \tag{3.6-32}$$

in Region 2: for $L_\infty \le L \le 1/2\left[\sqrt{\frac{4A_\infty}{\pi}} - D_E\right] \cot 10^\circ$

$A_L = A_\infty$

where

$$L_3 = 1/2\left[\left(\frac{4A_\infty}{\pi}\right)^{1/2} - D_E\right] \cot 10^\circ \tag{3.6-33}$$

in Region 3: for $1/2\left[\sqrt{\frac{4A_\infty}{\pi}} - D_E\right] \cot 10^\circ < L < \infty$

$$A_L = A_E\left(1 + \frac{2_L}{D_E}\tan 10^\circ\right)^2 \tag{3.6-34}$$

for nonflashing/nonexpanding fluids:

$$A_L = A_E \quad (3.6\text{-}35)$$

3.6.2.3.2 Jet Impingement Effect

3.6.2.3.2.1 Physical Separation. The physical separation of different essential systems and components is used to ensure that the plant retains function of sufficient essential systems to ensure safe shutdown in the event of a postulated LOCA and subsequent generation of a jet stream together with an additional single random active component failure and the loss of offsite power.

Where physical separation cannot be used to protect systems, a detailed analysis is performed to determine the effects of jet impingement on their operability. If necessary, barriers are provided to protect structures, systems, and components required for a safe shutdown to prevent offsite radiological consequences and to mitigate the effects of a LOCA.

3.6.2.3.2.2 Jet Impingement Evaluation. The evaluation of the adequacy of physical separation included the inspection of all essential systems and their components that are necessary to start, operate, and control the essential systems required for safe shutdown. The evaluation included the following:

a. Review pipe break locations to provide conservative jet stream orientation and geometry,

b. Review effected equipment by both design drawing examination and plant walkdown,

c. Review signals that result in the actuation of essential systems,

d. Review signals that are necessary to be returned to inside primary containment, to activate the shutdown systems,

e. Review availability of power that is required inside primary containment to operate the essential systems, and

f. Review mechanical engineered safety systems required for safe shutdown.

3.6.2.3.2.3 Postulated Pipe Rupture Locations Inside Containment. The criteria used to define pipe rupture locations is described in Section 3.6.2.1. Figures 3.6-32 through 3.6-56 show the inside containment break locations resulting from the application of the criteria provided in Section 3.6.2.1. Pipe whip restraint locations are also shown in these figures.

3.6.2.3.2.4 Signals From Primary Containment. For instrumentation located inside primary containment, sufficient redundancy is provided such that all signals necessary to cause actuation of essential systems remain functional. Each system that is required to bring the plant to a safe shutdown condition is furnished with two or more sets of redundant instrumentation lines.

In this review, it is conservatively assumed that a jet stream or whipping pipe may damage one of these sets. The redundant system is shown to remain operational by physical separation and barriers, such as the RPV. An example of the above is the location of sets A and B instrumentation lines for the HPCS. Set A and its redundant set B are located at opposite sides of the RPV. Therefore, a jet stream or whipping pipe cannot damage both sets of instrumentation. Function of instrumentation inside primary containment necessary to result in the actuation of the HPCS system is thereby ensured. These conditions as discussed for the HPCS instrumentation lines are typical for all instrumentation lines that support essential systems. The capabilities of redundant instrumentation is discussed in Section 7.3.

3.6.2.3.2.5 Signals to the Primary Containment. No instrumentation signal is necessary to return inside primary containment to operate any of the essential systems. Signals to the ADS valves are provided through their power supply as described in the following section.

3.6.2.3.2.6 Power Requirement Inside Primary Containment. The only essential system that requires power inside primary containment is the ADS.

There are 18 main steam relief valves inside primary containment, seven of which are in the ADS mode. These seven valves will quickly depressurize the RPV in the event of a small break and allow the LPCS or the LPCI to keep the core covered with water, thus permitting the reactor to be brought to a safe shutdown.

There are two independent and redundant electrical systems (divisions) inside primary containment which operate the ADS valves. The divisions are run separately in main paths of conduits, and individual conduits are branched to corresponding ADS valves.

Each ADS valve is equipped with three solenoids and two divisions as noted above. Power to the ADS valves is required to open a solenoid valve connected to the air accumulator, thus allowing the pressurized air to open the ADS valves.

The physical arrangement of the electrical conduits is such that one division runs next to the primary containment vessel wall and the other division runs around the sacrificial shield wall. The conduits for Division 1 (A solenoids) are routed above the platform at el. 541 ft in a horizontal configuration, running toward penetration X-105C. The conduits for Division 2 (B solenoids) are routed below the platform at el. 522 ft in a horizontal configuration, running toward penetration X-105B. The conduits are routed such as to take advantage of the piping

and structure for protection against a possible jet impingement. The ADS supply lines are discussed in Section 7.3.

Six out of the seven furnished ADS valves have to be operational to enable adequate depressurization of the RPV. Jet impingement cannot incapacitate more than three electrical lines. Since four lines would have to be incapacitated to incapacitate more than one valve, safety is ensured.

This condition is typical for all conduits leading to the ADS valves.

3.6.2.3.2.7 Mechanical Engineered Safety Systems. Under conditions involving a LOCA, a loss of offsite power, and the failure of any one diesel generator, the availability of redundant essential systems is determined by study of design drawings and by field walkdown of the physical location of these systems to verify that sufficient separation is provided between two redundant systems. Specifically, two situations are investigated:

a. The possibility of a jet from an essential system destroying or in any way damaging its redundant system. For example, in the case of failure of Division 2 diesel generator, the possibility of a pipe whip or jet from the HPCS damaging the LPCS and ADS is investigated; and

b. The possibility of a jet, from a high energy line, being capable of damaging an essential system and its redundant system. For example, in the event of Division 2 diesel generator failing, in conjunction with a possible jet or pipe whip from the RCIC, which may be capable of damaging the LPCS, ADS, HPCS, or related systems, thus preventing the plant from being brought to a safe shutdown is investigated.

All essential systems are examined to ensure that they will be capable of performing their required function after a jet impingement.

3.6.2.3.2.8 Jet Impingement on Major Structures Inside Primary Containment. Jet impingement loading on the steel primary containment vessel is discussed in Section 3.8.2. Jet impingement loading on the concrete and steel internal structures of the steel primary containment vessel is discussed in Section 3.8.3. Jet impingement loading on primary containment penetrations is discussed in Section 3.8.6.

3.6.2.3.3 Pipe Whip Restraints

3.6.2.3.3.1 Definition of Function. Pipe whip restraints, as differentiated from piping supports, are designed to function and carry load for an extremely low probability gross failure in a piping system carrying high energy fluid. The piping integrity does not depend on the pipe whip restraints for any loading combination. If the piping integrity is compromised by a

pipe break, the pipe whip restraint acts to limit the movement of the broken pipe to an acceptable distance. The pipe whip restraints (i.e., those devices which serve only to control the movement of a ruptured pipe following gross failure) will be subject to a once in a lifetime loading. The pipe break event is considered to be a faulted condition for the piping system, its restraints, and structure to which the restraint is attached. The design and analysis of these components for this event are described later in this section and in Section 3.6.2.2. Piping is no longer considered to be a part of the RCPB following the break. Plastic deformation of the pipe is considered as a potential energy absorber. Piping systems are designed so that plastic instability would not occur in the pipe under design dynamic and static loads if the consequences of such instability could result in the loss of the primary containment integrity or loss of required plant shutdown capability.

3.6.2.3.3.2 Pipe Whip Restraint Features. The restraints are close to the pipe to minimize the kinetic energy of impact and yet are sufficiently removed from the pipe to permit unrestricted thermal pipe movement.

To facilitate ISI of piping, the restraints are generally located a suitable distance away from all circumferential welds and are of bolted construction so as to be removable.

Pipe whip restraint structures fall into one of the following two categories:

a. Energy absorbing members: These are modeled as elastic, elastoplastic, or plastic springs in a dynamic analysis. The required resistant (strength) of these structures is derived by application of the principles of structural dynamics; or

b. Load transmitting members: These are relatively stiff components and are modeled as rigid members in the dynamic analysis. Their function is to transmit loading from the source to foundation. The load due to the postulated pipe rupture is in the form of an equivalent static load and is derived as a result of the dynamic analysis performed for the energy absorbing members.

Energy absorbing members are ductile structures such as simple beams, frames, and ring girders (including the piping system itself) having the capability to deflect significantly in absorbing the energy imparted to them by a postulated broken pipe. For loading conditions including the effects of postulated pipe rupture, these members are designed within the limits for inelastic systems as stated in Table F1322.2-1 of ASME Boiler and Pressure Vessel (B&PV) Code Section III, 1974 Editions, Summer 1974 Addenda, Appendix F, “Rules for Evaluation of Faulted Conditions” adjusted to account for rapid strain rate effects as discussed in Section 3.6.2.2.3. These members are constructed to meet the requirements of Quality Class I structures.

The U-bar straps, as shown in Figure 3.6-21 and described in Section 3.6.2.2.3.2, act as nonlinear energy absorbing, nonrebounding, plastic springs. The U-bar straps are justified by empirical data, as described in Sections 3.6.2.2.2.2 and 3.12.33.

Load transmitting members are rigid components such as clevises, brackets or pins, rigid pipe whip restraint weldments as shown in Figure 3.6-22, or similar components; as well as major structures such as the drywell diaphragm floor, primary containment vessel, reactor pedestal, reactor building and foundation. For loading conditions, including the effects of postulated pipe rupture, the members in Figure 3.6-22 are designed within the limits stated in Table F1322.2-1 of ASME Code Section III, Appendix F, "Rules for Evaluating Faulted Condition" for components and component supports; except that the members beyond those included in the dynamic analytical model (i.e., reactor pedestal, reactor building, as well as certain steel members assumed to be infinitely rigid) are designed to AISC, ACI, and other appropriate structural component criteria. All these members are constructed to the requirements of Quality Class I structures.

The design limits for connecting members such as clevises, brackets, and pins per Figure 3.6-21 are based on the following stress limits:

a. Primary stresses (in accordance with definitions in ASME Section III) are limited to the higher of

   1. 70% of Su, where Su = minimum ultimate strength by tests or ASTM specification, and

   2. Sy + 1/3 (Su - Sy), where Sy = minimum yield strength by test or ASTM specification; or

b. Recommended stress limits in accordance with ASME Code Section III, Subsection NF, for faulted conditions, if applicable. The design limits for welds of connecting members to steel structures are based on the following stress limits: the maximum primary weld stress intensity (two times shear stress) is limited to three times AWS or AISC building allowable weld shear stress.

The recirculation pump discharge and suction piping utilizes the U-bar strap pipe whip restraints (Figure 3.6-21), while all other systems listed in Table 3.6-15 use rigid types as shown in Figure 3.6-22 or similar configurations.

Typical installations of pipe whip restraints are shown in Figures 3.6-23, 3.6-24, and 3.6-92 through 3.6-95.

3.6.2.3.3.3 Pipe Whip Restraint Loading. For the purpose of predicting the pipe rupture forces associated with the reactor blowdown, the local line pressures are assumed to be those

normally associated with the reactor operating at ≥ 105 % of rated power and with a vessel dome pressure of 1040 psig.

In calculating pipe reaction, credit is taken for any line restriction and line friction between the break and the pressure reservoir. The following represent typical restrictions to flow which are specifically considered:

a. Jet pump nozzles,
b. Core spray nozzles (inside internals shroud),
c. Feedwater sparger, and
d. Steam line flow limiter.

The hydraulic bases and calculational techniques for predicting unbalanced forces on a pipe associated with a postulated instantaneous pipe rupture are as discussed in Section 3.6.2.

The dynamic loading on the pipe whip restraint commences at the effective time of impact of the pipe with the restraint. It includes the following:

a. Unbalanced force on the pipe associated with a postulated instantaneous pipe rupture in the form of a suddenly applied force; and

b. Dynamic inertia load of the moving section of pipe which is accelerated by the unbalanced force associated with the pipe rupture and collides with the restraint. This load is in the form of kinetic energy of impact.

3.6.2.3.4 Pipe Whip Effects on Safety-Related Components

Pipe whip (displacement) effects on safety-related structures, systems, and components can be placed in two categories: (a) pipe displacement effects on components (nozzles, valves, tees, etc.) which are in the same piping run in which the break occurred and (b) controlled pipe whip displacements as they apply to external components such as building structure, other piping systems, cable trays, and conduits.

3.6.2.3.4.1 Pipe Displacement Effects on Components in Same Piping Run. The criteria which is used for determining the effects of pipe displacements on inline components are as follows:

a. Components such as vessel safe ends and valves which are attached to the broken piping system and do not serve a safety function or whose failure would not further escalate the consequences of the accident, need not be designed to meet ASME Code Section III imposed requirements for essential components under faulted loading, and

b. If these components are required for safe shutdown, or serve a safety function to protect the structural integrity of an essential component, the code requirements for faulted conditions and limits to ensure operability, if required, are met.

The methods used to calculate the pipe whip loads on piping components in the same run as the postulated break are described in Section 3.6.2.2.2.

3.6.2.3.4.2 Pipe Displacement Effects on Structures, Other Systems, and Components. The criteria which are used for determining the effects of pipe displacements on structures, other systems, and components are as follows:

a. Systems and components which do not serve a safety function or whose failure would not further escalate the consequences of the accident, need not be designed to meet ASME Code Section III imposed requirements for essential components under faulted loading;

b. Systems and components that serve a safety function but are not required to mitigate the consequences of the postulated accident including consideration of random active component failure, are not required to be designed to meet the ASME Code Section III requirements for essential components under faulted conditions;

c. Systems and components, which do serve a safety function and which are required to mitigate the consequences of the particular postulated accident, are located such that the displaced pipe will not come in contact with these systems and components. In areas where this is not feasible, and contact is possible, the components are designed to meet the ASME Code requirements for faulted conditions; and

d. Pipe whip effects on structures are discussed in Section 3.6.2.3.3.2. Structural deflections resulting from pipe whip are covered in Section 3.6.2.2.2.2c.

The methods used to calculate the pipe whip loads are described in Section 3.6.2.2.2.

3.6.2.4 Guard Pipe Assembly Design Criteria for Dual Barrier Containment

The containment structure does not utilize dual barriers, guard pipes, or other protective devices that limit the pressurization of the space between the two barriers. The use of guard pipes is restricted to type 1 penetration assemblies (see Figure 3.8-54) as described in Section 3.8.6.1.1.

3.6.2.5 Implementation of Criteria for Pipe Whip and Jet Impingement Protection

The effects of jet impingement are discussed in Section 3.6.2.3.2. The implementation of criteria for pipe whip protection is discussed in the following.

3.6.2.5.1 Piping Systems Outside Primary Containment

Studies are performed as described in Section 3.6.1 to ensure that in the event of a postulated pipe rupture, sufficient equipment remains functional to mitigate the consequences of the particular pipe rupture, including considerations of failure of a single random active component. The study indicates that pipe whip supports are required within the main steam tunnel and to protect normally open isolation valves that are required to close. Pipe whip protection requirements in the main steam tunnel are discussed in Section 3.6.2.5.4.11.

Pipe whip protection requirements for isolation valves are discussed in Section 3.6.2.5.3.6.

3.6.2.5.2 Piping Systems Inside Primary Containment

High-energy piping systems inside primary containment subject to postulated pipe rupture are tabulated in Table 3.6-15. Specific criteria for determination of break locations and dynamic effects associated with the postulated rupture of piping are discussed in Section 3.6.2.1. The function and features of pipe whip restraints are discussed in Section 3.6.2.3.3. Equipment and system requirements subsequent to a postulated pipe rupture in a fluid system are discussed in Section 3.6.2.5.3.

Pipe whip restraints are furnished when it is necessary to limit pipe movements resulting from a postulated break, which could otherwise cause unacceptable damage to equipment necessary to mitigate the consequences of the particular postulated pipe rupture, including considerations of a single random active failure. For high-energy piping inside primary containment, this includes the following:

a. Assurance of primary containment leaktightness,

b. Assurance that potential for damage is such that the maximum pipe break areas and/or combinations of pipe break areas do not exceed the values described in Section 3.6.2.5.3.2 so that emergency core cooling systems (ECCS) capability is not impaired,

c. Assurance that the CRD system maintains sufficient function to ensure reactor shutdown,

d. Assurance that there is sufficient capability to maintain the reactor in a safe shutdown condition.

The criteria used to define pipe rupture locations for piping systems discussed in Section 3.6.2.5.4 follows Section 3.6.2.1.1.1.

Figures 3.6-32 through 3.6-56 show the piping configurations for each high energy system inside primary containment and include numerical identification of all significant points of interest in the piping system, locations of pipe whip supports, and postulated pipe break locations. The pipe whip supports are identified by the acronym PWS followed by an identification number on Figures 3.6-32 through 3.6-54 and as noted in Figure 3.6-55.

3.6.2.5.3 System Requirements Subsequent to Postulated Pipe Rupture

3.6.2.5.3.1 Control Rod Insertion Capability. To maintain the ability to insert the control rods in the event of a pipe break, no more than one in any array of nine CRD withdrawal lines may be completely crimped (totally blocked). Complete severance of withdrawal lines does not affect the rod insert function. Protection of the CRD insert lines is not required since a reactor pressure of 450 psig or higher can adequately insert the control rods, and no postulated pipe break resulted in severance or total crimping of the CRD insert or withdrawal lines. (See Reference 3.6-23.)

3.6.2.5.3.2 Core Cooling Requirements. The designed ECCS capability can be maintained provided that dynamic effects consequences do not exceed the following break area, break combination, and maintenance of minimum core cooling requirements.

3.6.2.5.3.3 Maximum Allowable Break Areas. For breaks involving recirculation piping, the total effective area of all broken pipes, including the effective area of the recirculation line break, does not exceed the total effective area of the design-basis double-ended recirculation line break. By limiting the total area of all broken pipes involving recirculation loops to an area less than or equal to that of the design basis accident (DBA) (circumferential break of recirculation loop), no accident can be more severe than the DBA.

For breaks not involving recirculation piping, the total effective area of all broken pipes for a given system shall not exceed the total effective area of the double-ended break of the maximum area pipe connected to the reactor boundary for that system.

3.6.2.5.3.4 Break Combinations. In addition to the pipe break area restrictions, breaks involving one recirculation loop do not result in loss of function or damage to the other recirculation loop or loss of coolant from the other loop in excess of that which can result from a break of the attached cleanup connection on the suction side of the loop.

3.6.2.5.3.5 Required Cooling Systems. To ensure compliance with Appendix A of 10 CFR Part 50, General Design Criteria, the cooling system requirements after an additional single active safety system failure are defined in Table 6.3-3. Cases which do not meet the

requirements in Table 6.3-3 must be assessed on an individual basis to determine compliance with core cooling requirements.

3.6.2.5.3.6 Containment System Integrity. The following were considered in addressing the LOCA dynamic effects with respect to containment system integrity.

Leaktightness of the containment fission product barrier is ensured throughout any LOCA.

For those lines which penetrate the containment and are closed during normal operation, the inboard isolation valves are as close as practicable to the RPV. This arrangement reduces the length of pipe subject to a pipe break.

Pipe whip supports are provided in the vicinity of normally open isolation valves inside and outside primary containment for high energy systems to ensure that operability of these valves remains unimpaired during a postulated pipe rupture event.

3.6.2.5.4 System by System Description of Pipe Whip Protection

3.6.2.5.4.1 Main Steam System.

System Arrangement

The main steam system consists of four 26-in. lines which are arranged inside primary containment with mirror image symmetry about the 0° and 180° north-south azimuth. The lines exit the RPV on opposite sides of primary containment and drop down vertically in two parallel pairs to the main steam relief valve platform at el. 541 ft where they are routed horizontally in parallel in the northeast and northwest quadrants to the 0° north azimuth. At this point, the four lines drop vertically in parallel to an elevation just above the diaphragm floor. The MSIVs are located here. The four lines exit the containment nearest the north azimuth at el. 500 ft (approximately). The two feedwater piping loops are described in Section 3.6.2.5.4.2 and are routed near the main steam lines.

Pipe Whip Protection

The postulated pipe breaks and pipe whip restraints for the four main steam lines are shown in Figures 3.6-32 through 3.6-35. Where pipe breaks are postulated inside primary containment, the main steam lines are restrained to prevent the unacceptable motion of these pipes. These restraints are mounted on the side of the sacrificial shield wall structure, as well as on radial beams which extend from the sacrificial shield wall to the primary containment vessel wall. A sliding beam seat at the primary containment wall, permits the beam to grow axially and also permits the primary containment wall to move relative to the sacrificial shield wall.

A structural steel frame (see Figure 3.6-57) between the drywell diaphragm floor and the containment vessel, in the area of the MSIVs, is provided for mounting of pipe whip restraints. The structure is designed with vertically sliding connections at the containment vessel to allow for differential thermal expansion between the containment vessel and the diaphragm floor.

Verification of Pipe Whip Protection Adequacy

Sufficient pipe whip protection is provided for the main steam system to ensure safety as defined in Section 3.6.2.5.2. The pipe whip restraints limit the pipe whip motion of the main steam lines to prevent impact and rupture of the adjacent feedwater lines which would otherwise result in a break area in excess of the ECCS capability. Impact with the CRD piping is prevented by pipe whip restraints at the main steam relief valve platform and separation. The CRD piping bundles are routed below the el. 541 ft main steam relief valve platform, a considerable distance away from where the main steam lines drop down to the diaphragm floor.

3.6.2.5.4.2 Reactor Feedwater System (Inside Primary Containment).

System Arrangement

The reactor feedwater system inside primary containment consists of two piping loops symmetrically arranged with respect to 0° and 180° north-south azimuth. The two piping loops emerge from each side of the reactor as three 12-in. vertical risers which drop down and join a header at the main steam relief valve platform. The header is routed parallel to and outside of the main steam lines, increasing in diameter from 12 in. to 18 in. and to 24 in. as it approaches the 0° north azimuth. At this location, the two 24-in. feedwater pipes drop down to 12 ft 6 in. above the diaphragm floor. The pipe is furnished with a check valve in each line in the short horizontal run near the primary containment vessel penetration.

Pipe Whip Protection

The postulated pipe breaks and pipe whip restraints for both reactor feedwater loops are shown in Figures 3.6-36 and 3.6-37. The feedwater lines are restrained to provide protection from the results of all postulated pipe breaks. Specifically, protection is provided where the resulting pipe motion would otherwise impact equipment necessary to mitigate the consequences of the break causing unacceptable damage to that equipment. The restraints are mounted on the side of the sacrificial shield wall, on radial beams at the el. 541 ft. main steam relief valve platform, and on a specially designed structure between the containment and diaphragm floor as shown in Figure 3.6-57. Special features of these structures are described in Section 3.6.2.5.4.1.

Verification of Pipe Whip Protection Adequacy

Sufficient pipe whip protection is provided for the reactor feedwater system to ensure safety as defined in Section 3.6.2.5.2.

In all cases the pipe is sufficiently restrained to prevent impact with containment or impact with other piping systems that would result in violation of pipe break area or pipe break combination limitations. Impact with the CRD piping is prevented by pipe whip restraints at the main steam relief valve platform and separation. The CRD piping bundles are routed below the el. 541 ft. main steam relief valve platform at a considerable distance away from the 0° north azimuth where the 24-in. feedwater lines drop to 12 ft 6 in. above the diaphragm floor. In two cases, portions of the 12-in. vertical risers are restrained in only one direction, allowing impact with one main steam relief valve. This constitutes acceptable damage because depressurization can be accomplished with one valve not functioning. Furthermore, the HPCS is available as a redundant system.

3.6.2.5.4.3 Reactor Water Cleanup System.

System Arrangement

The RWCU system consists of two 4-in. lines which branch from the two reactor recirculation cooling (RRC) pump suction lines located near the 0° and 180° north and south azimuths. The two lines are routed along the diaphragm floor at approximate el. 500 ft. to azimuth 67° where they join into one 6-in. pipe. This 6-in. pipe branches off into two segments. One branch rises to el. 538 ft just below the main steam relief valve platform. It is then routed to azimuth 150° where it exits primary containment. An isolation valve is located inside primary containment near the penetrations. The other 6-in. segment reduces to a 4-in. pipe and then rises to el. 514 ft and terminates at the 2-in. RPV drain system.

Pipe Whip Protection

The postulated pipe breaks and pipe whip restraints for the RWCU system are shown in Figure 3.6-38. At all locations where pipe breaks are postulated inside primary containment, the RWCU system is restrained to prevent unacceptable motion of the pipe. Where the pipe is routed along the diaphragm floor, restraints are mounted on special structures built up from the floor. Where the pipe is routed below main steam relief valve platform, restraints are mounted on intermediate structures between radial beams.

Verification of Pipe Whip Protection Adequacy

Sufficient pipe whip protection is provided for the RWCU system to ensure safety as defined in Section 3.6.2.5.2. Pipe whip restraints located above the diaphragm floor are designed to prevent impact with the floor, which might impair steam quenching capability of the

suppression pool. Pipe whip restraints located directly below the main steam relief valve platform prevent impact with CRD piping and also primary containment. Equipment necessary to mitigate RWCU pipe breaks, such as ADS system, core spray, LPCI, is protected by separation.

3.6.2.5.4.4 Standby Liquid Control Piping.

System Arrangement

The SLC system includes a section of 1.5-in. piping connected to a short length of 4-in. piping which is connected to HPCS-V-76. The 1.5-in. piping is routed through check valve SLC-V-7 and then downward to penetration X-13. SLC-V-7 limits the high energy portion of the system to approximately 18 in. of piping.

Pipe Whip Protection

The postulated pipe breaks for the SLC system are shown in Figures 3.6-39 and 3.6-48. Pipe whip restraints are not required for this system.

Verification of Pipe Whip Protection Adequacy

Sufficient pipe whip protection is provided for the SLC system to ensure safety as defined in Section 3.6.2.5.2. In the event of a pipe whip resulting from a pipe rupture at any postulated location, the piping system does not damage equipment or systems required for safe shutdown of the reactor. Therefore, pipe restraints are not required for this system.

3.6.2.5.4.5 Residual Heat Removal System - Shutdown Cooling Supply and Return Piping.

System Arrangement

The RHR shutdown cooling supply and return piping consists of two 12-in. piping loops and one 20-in. loop, with all three branching from the RRC piping at the el. 512 ft platform. All three loops are routed primarily in a horizontal plane below the 512 ft platform from the RRC pipe to its primary containment penetration. There is a normally closed valve in each loop located as close as possible to the high energy source, thereby limiting the portion of each loop considered high energy on the basis defined in Section 3.6.2.1.

Pipe Whip Protection

The pipe whip restraints for the RHR shutdown cooling supply and return system are shown in Figures 3.6-43, 3.6-44, and 3.6-45. Where pipe breaks are postulated inside primary containment, the lines are restrained to prevent the unacceptable motion of these pipes. For the two 12-in. shutdown cooling return loops restraints are mounted on intermediate structures

between the radial beams in the el. 512 ft platform. The radial beams extend from the reactor pedestal to the primary containment wall. A sliding beam seat at the primary containment wall permits differential thermal expansion between the containment vessel and reactor pedestal. Restraints for the 20-in. cooling return loop are mounted on a specially designed structure between the diaphragm floor and radial beams in the el. 512 ft platform as shown in Figure 3.6-95.

Verification of Pipe Whip Protection Adequacy

Sufficient pipe whip protection is provided for the RHR shutdown cooling supply and return system to ensure safety as defined in Section 3.6.2.5.2.

For the two 12-in. shutdown cooling return loops, pipe whip restraints are provided to prevent impact with primary containment wall and the diaphragm floor. The pipe whip restraints also prevent impact with the CRD piping bundles located above the el. 512 ft. platform. The ECCS system and the ADS systems are protected by separation, being located at higher elevations.

For unrestrained sections of this system, analysis shows a plastic hinge does not develop at the recirculation pipe, and pipe whip does not occur.

For the 20-in. shutdown cooling supply loop, pipe whip restraints are provided to prevent impact with primary containment and the diaphragm floor. Impact with the CRD piping is precluded by a 90° separation from both CRD piping bundles.

3.6.2.5.4.6 Reactor Core Isolation Cooling Reactor Pressure Vessel Head Spray System.

System Arrangement

The RPV head spray system is a 6-in. line that originates at the top of the RPV dome. After a 2-ft vertical riser and a 2-ft horizontal run, there is a normally closed valve that limits the high energy portion of this system to a total length of 4 ft.

Pipe Whip Protection

The postulated pipe breaks for this system are shown in Figure 3.6-46. A pipe whip restraint is provided to prevent RCIC head spray line impact on the containment head as a result of the postulated break locations.

Verification of Pipe Whip Protection Adequacy

Sufficient pipe whip protection is provided to ensure safety as defined in Section 3.6.2.5.2. The location of the normally closed valve limits the high energy section of this system as steel

pads welded to the containment vessel head have been provided to distribute the impact load and prevent direct impact with the containment vessel head.

3.6.2.5.4.7 Low-Pressure and High-Pressure Core Spray Piping.

System Arrangement

The LPCS and HPCS are 12-in. piping systems with similar arrangements inside primary containment. They originate at el. 561 ft from the reactor at azimuths 120° and 240° respectively and drop vertically to an elevation just below the main steam relief valve platform where there is an expansion loop in a horizontal plane leading to a penetration through primary containment. In the vertical section, there is a normally closed check valve located as close as possible to the reactor, thereby limiting the portion of piping in both systems considered high energy under the definition given in Section 3.6.2.1.

Pipe Whip Protection

The postulated pipe breaks and pipe whip restraints for the LPCS and HPCS systems are shown in Figures 3.6-47 and 3.6-48. Where pipe breaks are postulated inside primary containment the two lines are restrained to prevent the unacceptable motion of these pipes. These restraints are mounted directly onto the sacrificial shield wall.

Verification of Pipe Whip Protection Adequacy

Sufficient pipe whip protection is provided for the LPCS and HPCS systems to ensure safety as defined in Section 3.6.2.5.2. Pipe whip restraints are provided to limit pipe movement resulting from postulated pipe breaks to prevent impact with primary containment and adjacent RHR/LPCI piping. Impact on safety/relief valves (SRVs) resulting from postulated pipe breaks in the HPCS system, is precluded by sufficient separation between these two redundant depressurization methods. The CRD piping bundles are separated by sufficient distance from the high energy sections of the LPCS and HPCS systems.

3.6.2.5.4.8 Residual Heat Removal Condensing Mode and Reactor Core Isolation Cooling Turbine Steam Supply System.

System Arrangement

The RHR condensing mode has been deactivated. All system piping outboard of containment isolation valve RCIC-V-64 has been deactivated and is no longer in use. RCIC-V-64 has been locked closed and the motor operator disconnected. The piping inboard of RCIC-V-64 remains pressurized during plant operation.

The inboard system consists of a 10-in. piping loop which branches off a main steam line at el. 551 ft 2.25 in. and azimuth 105°. An expansion loop in the horizontal plane leads to a penetration through primary containment at el. 550 ft and azimuth 120°.

The RCIC turbine steam supply system consists of a 4-in. line which branches off the 10-in. inboard RHR condensing mode line at approximately azimuth 125° and drops down to el. 532 ft below the main steam relief valve platform. The line is then routed horizontally to a penetration through primary containment at azimuth 35°.

Pipe Whip Protection

The postulated pipe breaks and pipe whip restraints for the inboard RHR condensing mode and RCIC turbine steam supply systems are shown in Figure 3.6-49. Where pipe breaks are postulated inside primary containment, this piping is restrained to prevent unacceptable motion of the piping. The restraints for these two systems are mounted on specially designed structures which tie into the sacrificial shield wall and/or radial beams of the main steam relief valve platform.

Verification of Pipe Whip Protection Adequacy

Sufficient pipe whip protection is provided for the inboard RHR condensing mode and RCIC turbine steam supply systems to ensure safety as defined in Section 3.6.2.5.2. For the 10-in. inboard RHR condensing mode system, pipe whip restraints are provided at all locations where pipe breaks are postulated. The pipe whip restraints limit pipe motion resulting from postulated break to prevent impact with primary containment vessel wall, the HPCS system, and the main steam SRVs. Protection is required since either the ADS or the HPCS are required to depressurize the reactor subsequent to a pipe break in a line with a cross-section area less than 0.7 ft^2 (see Section 3.6.2.5.3).

For the 4-in. RCIC turbine steam supply, restraints are provided for the portion above the main steam relief valve platform to protect containment and the HPCS and SRVs. For the section of this system below the main steam relief valve platform, the pipe movement resulting from postulated breaks will move radially inward impacting the sacrificial shield or vertically down impacting the el. 512 ft platform. The CRD piping bundle in this area is located above this line precluding impact.

3.6.2.5.4.9 Main Steam Valve Drainage Piping.

System Arrangement

The main steam valve drainage piping consists of four 2-in. pipe lines, each originating at the bottom of the four MSIVs inside primary containment. The four lines are routed above the

diaphragm floor joining into one 3-in. line which then exits containment. Isolation valves are located just inside and just outside of the primary containment penetration.

Pipe Whip Protection

The postulated pipe breaks and pipe whip restraints for this system are shown in Figure 3.6-50. Where pipe breaks are postulated the system is restrained to prevent unacceptable motion of the main steam valve drainage piping. A number of the pipe whip restraints for this system are mounted on specially designed structures built up from the diaphragm floor. The remaining restraints are attached to the structure between primary containment and the diaphragm floor (see Section 3.6.2.5.4.1), which has been designed to support the main steam and reactor feedwater pipe whip restraints.

Verification of Pipe Whip Protection Adequacy

Sufficient pipe whip protection is provided for the main steam valve drainage piping to ensure safety as defined in Section 3.6.2.5.2. Pipe whip restraints are provided for this system to protect primary containment structure and the diaphragm floor. Other required safety systems are protected by separation by being located at considerably higher elevations.

3.6.2.5.4.10 Main Steam Reactor Pressure Vessel Head Vent System.

System Arrangement

The RPV head vent system consists of a 2-in. line which originates at the top of the RPV dome and is routed through the primary containment bulkhead plate at azimuth 237°. The line is then routed below the bulkhead plate, to azimuth 70° where it drops down to el. 570 ft and joins a 26-in. main steam line.

Pipe Whip Protection

The postulated pipe breaks and pipe whip restraints for this system are shown in Figure 3.6-51. For the piping section above the bulkhead plate, the pipe whip restraints are mounted onto a removable lattice framework. For the portion of this line below the primary containment bulkhead plate, the restraints are mounted on structures, which tie into the stiffening beams for the bulkhead plate.

Verification of Pipe Whip Protection Adequacy

Sufficient pipe whip protection is provided for the RPV head vent piping to ensure safety as defined in Section 3.6.2.5.2. There are no safety-related systems in the vicinity of the RPV head vent piping and pipe whip restraints are provided to protect the primary containment structure.

3.6.2.5.4.11 Main Steam and Reactor Feedwater Piping Inside Main Steam Tunnel.

System Arrangement

The four 26-in. main steam and two 24-in. reactor feedwater lines inside the main steam tunnel originate at the primary containment penetrations and run horizontally to the end of the tunnel. At this point the six lines drop vertically and are then routed horizontally within the turbine generator building. An isolation valve is located in each line just beyond the penetration.

Pipe Whip Protection

The postulated pipe breaks and pipe whip restraints for the main steam and reactor feedwater lines inside the main steam tunnel are shown in Figures 3.6-53 and 3.6-54. Where breaks are postulated, the six lines are restrained to prevent unacceptable motion. The restraints are mounted on steel structures which then tie into the concrete walls and floors.

Verification of Pipe Whip Protection Adequacy

Sufficient pipe whip protection is provided for the main steam and reactor feedwater lines inside the main steam tunnel to ensure safety.

Pipe whip restraints are provided to prevent pipe whip impact with the main steam or feedwater isolation valves. In addition, impact with adjacent main steam or feedwater lines is prevented. See Figure 3.6-24.

3.6.2.5.4.12 Residual Heat Removal System - Low Pressure Core Injection.

System Arrangement

The RHR/LPCI piping consists of three 14-in. loops whose arrangement is the same for two loops with the third loop being the mirror image of the other two. The piping originates at the reactor vessel at el. 552 ft, rises vertically to el. 563 ft where there is a horizontal section with a check valve. This valve is normally closed, limiting the high energy portion of each loop. After the valve the normally unpressurized section of piping drops to an elevation just below the main steam relief valve platform where it is routed to a penetration through primary containment at el. 534 ft.

Pipe Whip Protection

The postulated pipe breaks and pipe whip restraints for the three RHR/LPCI mode piping loops are shown in Figures 3.6-40, 3.6-41, and 3.6-42. Where pipe breaks are postulated, the three piping loops are restrained to prevent unacceptable motion. The restraints for this system are

mounted onto the sacrificial shield wall and also on structures which tie back to the sacrificial shield wall.

Verification of Pipe Whip Protection Adequacy

Sufficient pipe whip protection is provided for the RHR/LPCI mode piping to ensure safety as defined in Section 3.6.2.5.2. The pipe whip restraints limit pipe motion resulting from postulated breaks to preclude impact with primary containment and adjacent feedwater or core spray piping. Impact with adjacent feedwater or core spray piping may result in pipe break escalation that can exceed limitations of pipe break area and pipe break combination. The CRD piping bundles are separated by a considerable distance from high energy sections of the RHR/LPCI mode piping.

3.6.2.5.4.13 Reactor Pressure Vessel Drain System.

System Arrangement

The RPV drain system is a 2-in. line that originates at the bottom of the RPV and is routed inside the pedestal to a sleeve which leads through the pedestal. Outside the reactor pedestal the line then joins the RWCU system.

Pipe Whip Protection

The postulated pipe breaks and pipe whip restraint for the RPV drain system are shown in Figure 3.6-52. At postulated pipe break locations inside primary containment, the RPV drain system is restrained to prevent unacceptable motion of the pipe. This system contains only one pipe whip restraint. Where the pipe is routed along the platform at el. 512 ft 8 in., the pipe whip restraint is mounted on a transverse beam which is welded to the top of the radial platform beams.

Verification of Pipe Whip Protection Adequacy

Sufficient pipe whip protection is provided for the RPV drain system to ensure safety as defined in Section 3.6.2.5.2. The single pipe whip support for the RPV drain system serves the dual purpose of providing pipe whip protection and seismic restraint. The pipe whip restraint is located above the platform at el. 512 ft 8 in., and is designed to prevent impact with the Quality Class I electrical conduits in the immediate vicinity of the RPV drain line. Since an annular clearance of only 1/16-in. is maintained between the pipe and the pipe whip support, the pipe whip support is also utilized as a rigid three-way support.

3.6.2.5.4.14 Reactor Recirculation Cooling System.

System Arrangement

The two A and B loops of the recirculation piping system consist of the pump discharge and suction piping as shown in Figure 3.6-55. The recirculation pump A and B discharge lines are arranged in a diametrically opposed manner, in the northern and southern segments, respectively, of primary containment. The A lines exit the RPV in five, equally spaced, 12-in. diameter lines commencing at azimuth 30° and ending at azimuth 150° (for B lines azimuth 210° to 330°). These five lines drop vertically alongside the sacrificial shield wall, from el. 536 ft 0 in. to a 16-in. diameter header at centerline el. 528 ft 0 in. A single 24-in. diameter line then drops vertically from the center of the header to el. 506 ft 3-7/8 in. where it is routed into the discharge nozzle of the recirculation pump.

The recirculation pump B and A suction lines are oriented along the 0° and 180° azimuths, respectively, with respect to the RPV. Each suction line consists of a single 24-in. diameter line which exits the RPV at el. 535 ft 3/4 in. and drops vertically alongside the sacrificial shield wall to el. 502 ft 6-1/8 in. where it is routed to the suction nozzle of the recirculation pump.

Pipe Whip Protection

For the recirculation pump suction and discharge systems, the location of postulated pipe breaks and pipe whip restraints are shown in Figure 3.6-55 which is representative of both recirculation loops. Conformance of the postulated break locations with the criteria of Section 3.6.2.1.1.1 is demonstrated in Figure 3.6-56. Where pipe breaks are postulated inside primary containment, the recirculation system piping is restrained to prevent unacceptable motion. These restraints are generally mounted on the side of the sacrificial shield wall structure or the RPV pedestal immediately below. Four restraints, which are located near the diaphragm floor and are not near the sacrificial shield wall or the RPV pedestal, consist of saddle type structures mounted on the diaphragm floor.

Verification of Pipe Whip Protection Adequacy

Sufficient pipe whip protection is provided for the RRC system piping to ensure safety as defined in Section 3.6.2.5.2. Pipe whip restraints are provided to prevent impact with the diaphragm floor as well as to mitigate the consequences of a pipe rupture with respect to surrounding piping systems, structures, and components required for safe shutdown.

The physical separation of the recirculation system from the containment vessel precludes any damage that could result as a result of postulated pipe break.

Table 3.6-4

Resistance-Yield Displacement
Values for Beams

Description	Resistance	Yield Displacement
1. Cantilever 	$R_m = \frac{M_u}{L}$	$X_e = \frac{R_m L^3}{3EI}$
2. Simply supported 	$R_m = \frac{4M_u}{L}$	$X_e = \frac{R_m L^3}{48EI}$
3. Fixed supports 	$R_m = \frac{4\left(M_u^+ + M_u^-\right)}{L}$	$X_e = \frac{R_m L^3}{192EI}$

where:

M_u^+ = ultimate positive moment capacity (ft-lb)
M_u^- = ultimate negative moment capacity (ft-lb)
I = moment of inertia ($in.^4$)
for reinforced-concrete I = I_a see notes accompanying table

NOTES

The resistance of typical structural elements, whose flexural strength defines the minimum capacity, and their yield displacement approximations are presented in Tables 3.6-4 and 3.6-5. It is preferable that the limiting capacity of an element be in the flexural mode, not in shear. In evaluating the yield displacement with the usual elastic analysis, the moment of inertia must account for cracking of concrete sections. The empirical relation for this type of loading is an average moment of inertia, I_a, calculated as follows.

Table 3.6-4

Resistance-Yield Displacement
Values for Beams (Continued)

NOTES (Continued)

$$I_a = \tfrac{1}{2}\left(I_g + I_c\right) = \tfrac{1}{2}\left(\frac{bt^3}{12} + Fbd^3\right)$$

where

I_g = moment of inertia of gross concrete cross section of thickness t about its centroid (neglecting steel areas) ($in.^4$)

I_c = moment of inertia of the cracked concrete section ($in.^4$)

b = width of concrete sections (in.)

F = coefficient for moment of inertia of cracked section with tension reinforcing only (see Figure 3.6-106)

t = concrete thickness (in.)

d = distance from extreme compression fiber to centroid of tension reinforcing (in.)

The moment of inertia, I_a, as calculated by the above equation must be used in the displacement equation in Tables 3.6-4 and 3.6-5 for all reinforced-concrete members. The ultimate moment capacity of a concrete section is considered as the moment strength:

$$M_u = 0.9A_s f_{dy}\left(d - a/2\right) \quad \text{(in.-lb)}$$

where

A_s = area of tensile reinforcing steel ($in.^2$)

f_{dy} = allowable dynamic yield stress for reinforcing steel ($lb/in.^2$)

d = distance from extreme compression fiber to centroid of tension reinforcing (in.)

a = depth of equivalent rectangular stress block (in.)

Table 3.6-4

Resistance-Yield Displacement
Values for Beams (Continued)

NOTES: (Continued)

If the element has compression steel, the appropriate equation for compression steel applies.

The amount of reinforcing steel in concrete members satisfied the following criteria:

For members with tension steel only:

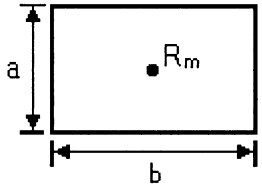
$$\frac{1.4\sqrt{f'_c}}{f_y}\left(\frac{t}{d}\right)^2 \leq \frac{A_s}{bd} \leq \frac{0.25\ f'_c}{f_y}$$

For members with tension and compression steel:

$$\frac{1.4\sqrt{f'_c}}{f_y}\left(\frac{t}{d}\right)^2 \leq \frac{A_s}{bd}$$

$$\frac{A_s - A'_s}{bd}\left(\frac{t}{d}\right)^2 \leq \frac{0.25\ f'_c}{f_y}$$

where



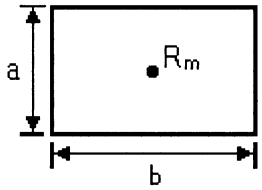
f'_c = compression strength of concrete (lb/in.^{2})
A'_s = area of compressive reinforcement of concrete (in.^{2})

Table 3.6-5

Resistance-Yield Displacement
Values for Slabs and Plates

Description	Resistance	Yield Displacement

1. Simply supported on all four sides with load at center



$$R_m = 2\pi M_u$$

$$X_e = \frac{\alpha R_m a^2}{12EI}\left(1 - \nu^2\right)$$

b/a	1.0	1.1	1.2	1.4	1.6	1.8	2.0	3.0	∞
α	0.1390	0.1518	0.1624	0.1781	0.1884	0.1944	0.1981	0.2029	0.2031

2. Fixed supports on all 4 sides with load at center

$$R_m = 2\pi\left(M_u^+ + M_u^-\right)$$

$$X_e = \frac{\alpha R_m a^2}{12EI}\left(1 - \nu^2\right)$$

b/a	1.0	1.2	1.4	1.6	1.8	2.0	∞
α	0.0671	0.0776	0.0830	0.0854	0.0864	0.0866	0.0871

where

ν = Poisson's ratio
t = thickness (in.)
E = modulus of elasticity (lb/in.^{2})
I = moment of inertia per unit width (in.^{4}/in.)
for reinforced-concrete section I = I_a see notes accompanying Table 3.6-4
M_u^+ = ultimate positive moment capacity (in.-lb/in.)
M_u^- = ultimate negative moment capacity (in.-lb/in.)

Table 3.6-6

Design Load in Areas Where Piping Failures Occur

Notes: For location of pipe break numbers, see Table 3.6-3.
For vertical and horizontal seismic factors, see Section 3.7.
[a] For Node Locations, Refer to FSAR Figures 3.6-38.4 and 3.6-38.5.
[b] Force given as multiple point loads.

Table 3.6-7

Maximum Ductility Ratios Steel
Structural Components

Steel beams (lateral load)	
(Note: To develop this ductility, the flanges must be thick enough to prevent local plastic buckling)	26
Steel beams (lateral and axial load)	8
Welded portal frams (vertical load)	6-16

REINFORCED-CONCRETE STRUCTURAL COMPONENTS

Tension reinforced-concrete beams and slabs, (flexure controls design)	$\frac{0.10}{p^a}$ _ 10
Doubly reinforced-concrete beams and slabs, (flexure controls design)	$\frac{0.10}{p\text{-}p'^b}$ _ 10
Reinforced-concrete columns, walls, and other elements exhibiting brittle fracture (compression controls design)	1.3

[a] p is the ratio of tensile reinforcement.

[b] p' is the ratio of compression reinforcement.

Table 3.6-8

Dynamic Strength of Materials

	Dynamic Increase Factor
Reinforced concrete	
Concrete	
Compression, axial or flexural	1.25
Shear as a measure of diagonal tension and punching shear	1.00
Bond	1.00
Reinforcing steel	
Tension	1.10
Compression	1.10
Shear reinforcement to resist shear as a measure of diagonal tension and punching shear	1.00
Structural Steel	
Flexure and tension	1.10
Compression	1.10
Shear	1.00

Table 3.6-9

Summary of Subcompartment Pressure Analysis[a] (Continued)

Compartment Where Break Occurs			Piping System	Differential Pressure	
Elevation (ft)	Room	Description	Line Designation	Maximum Differential (psi)	Differential Between the Rooms
522	R408	Valve room	6"RWCU (2)-4	1.1	R408/R404
				1.1	R408/R305
				1.1	R408/R509
548	R509	Valve room	6"RWCU (2)-4	0.9	R509/R508, R408
				0.9	R509/R607
548	R510	RWCU HX room	6"RWCU (1)-5SX/SXL	2.7	R510/R504, R508
				2.7	R510/R404, R604
548	R511/ R511A	Valve room	6"RWCU (1)-4	6.3	R511/R404, R504
				2.4	R511/R604
572	R604	El. 572 ft open floor area	4"HS (1)-2	0.07	Reactor building and
			4"AS (11)-2	0.07	Ambient

[a] Table applies to reactor building secondary containment and portions of the radwaste building, exclusive of the main steam tunnel, tunnel ventway, and tunnel extension.

[b] Break could occur in either room; break assumed in R406.N

[c] This differential pressure does not account for hydrostatic pressure due to flooding. With the approximate 9.6 inches of flooding in room C230, the differential pressure across the floor/door C228 is approximately 0.93 psi.

Table 3.6-10

Subcompartment Analysis

Nodal Volume Data for a Postulated Pipe Break in the Main Steam Tunnel[a]

Node	Description	Volume (ft^3)	Elevation (ft)
1	Main steam tunnel, south	7427	501
2	Main steam tunnel, north	4345	501
3	Ventway, el. 501 ft 0 in. to el. 519 ft 0 in.	3629	501
4	Ventway, el. 519 ft 0 in. to el. 532 ft 0 in., west	3672	519
5	Ventway, el. 519 ft 0 in. to el. 532 ft 0 in., east	2340	519
6	Ventway, el. 532 ft 0 in. to el. 548 ft 0 in.	7855	532

[a] For nodalization scheme, see Figure 3.6-67.

Table 3.6-11

Subcompartment Analysis

Flow Junction Data for a Postulated Pipe Break in the Main Steam Tunnel[a]

From Node	To Node	Junction Flow Area (ft^2)	Junction Elevation (ft)	Junction Inertia (ft^{-1})	Form Loss Coefficient[b]		Frictional Loss Coefficient[b]
					Forward Flow	Reverse Flow	
1	2	438.7	509	0.02656	1.06	1.14	0.1
2	3	c					
2	4	218.4	519	0.06044	2.66	2.69	0.1
3	5	170.0	519	0.08014	0.163	0.116	0.1
4	5	84.6	525	0.378	0.6	0.6	0.1
4	6	310.4	532	0.368	0.6	0.6	0.1
5	6	170.0	532	0.0486	0.145	0.206	0.1

[a] For nodalization scheme, see Figure 3.6-67.

[b] These data are dimensionless.

[c] No data furnished since panel B between nodes 2 and 3 is assumed closed during postulated pipe break.

Table 3.6-12

Main Steam Tunnel Subcompartment Analysis
Information for Blowout Panels C and D

Panel C (horizontal, hinged, nonbolted, sheet steel blowout panel)

Total weight:	2060 lb
Area:	230.6 ft^2
Moment arm:	3.375 ft
Moment of inertia:	31,286 lb_{mass}-ft^2
Damping constant:	Neglected

Panel D (vertical, bolted, insulated metal blowout panel)

Total weight:	16,000 lb
Area:	1060.8 ft^2

Reference: Figures 3.6-65 and 3.6-66.

Table 3.6-13

Subcompartment Analysis

Nodal Volume Data for a Postulated Pipe Break in
the Main Steam Tunnel Extension[a]

Node	Description	Volume (ft^3)	Elevation (ft)
1	Main steam tunnel extension, south	2320	501
2	Main steam tunnel extension, north	2799	501
3	Turbine generator building, el. 471 ft 0 in. floor	728610	471
4	Turbine generator building, el. 441 ft 0 in. floor	658938	441
5	Turbine generator building, el. 501 ft 0 in. floor	1270590	501

[a] For nodalization scheme, see Figure 3.6-76.

Table 3.6-14

Subcompartment Analysis

Flow Junction Data for a Postulated Pipe Break in the Main Steam Tunnel Extension[a]

From Node	To Node	Junction Flow Area (ft^2)	Junction Elevation (ft)	Junction Inertia (ft^{-1})	Form Loss Coefficient[b]		Frictional Loss Coefficient[b]
					Forward Flow	Reverse Flow	
1	2	379.0	509	0.01395	0.6	0.56	0.1

3	4	230.0	471	0.1091	1.28	1.49	0.1
3	5	507.0	501	0.01176	1.54	1.55	0.1

[a] For nodalization scheme, see Figure 3.6-67.

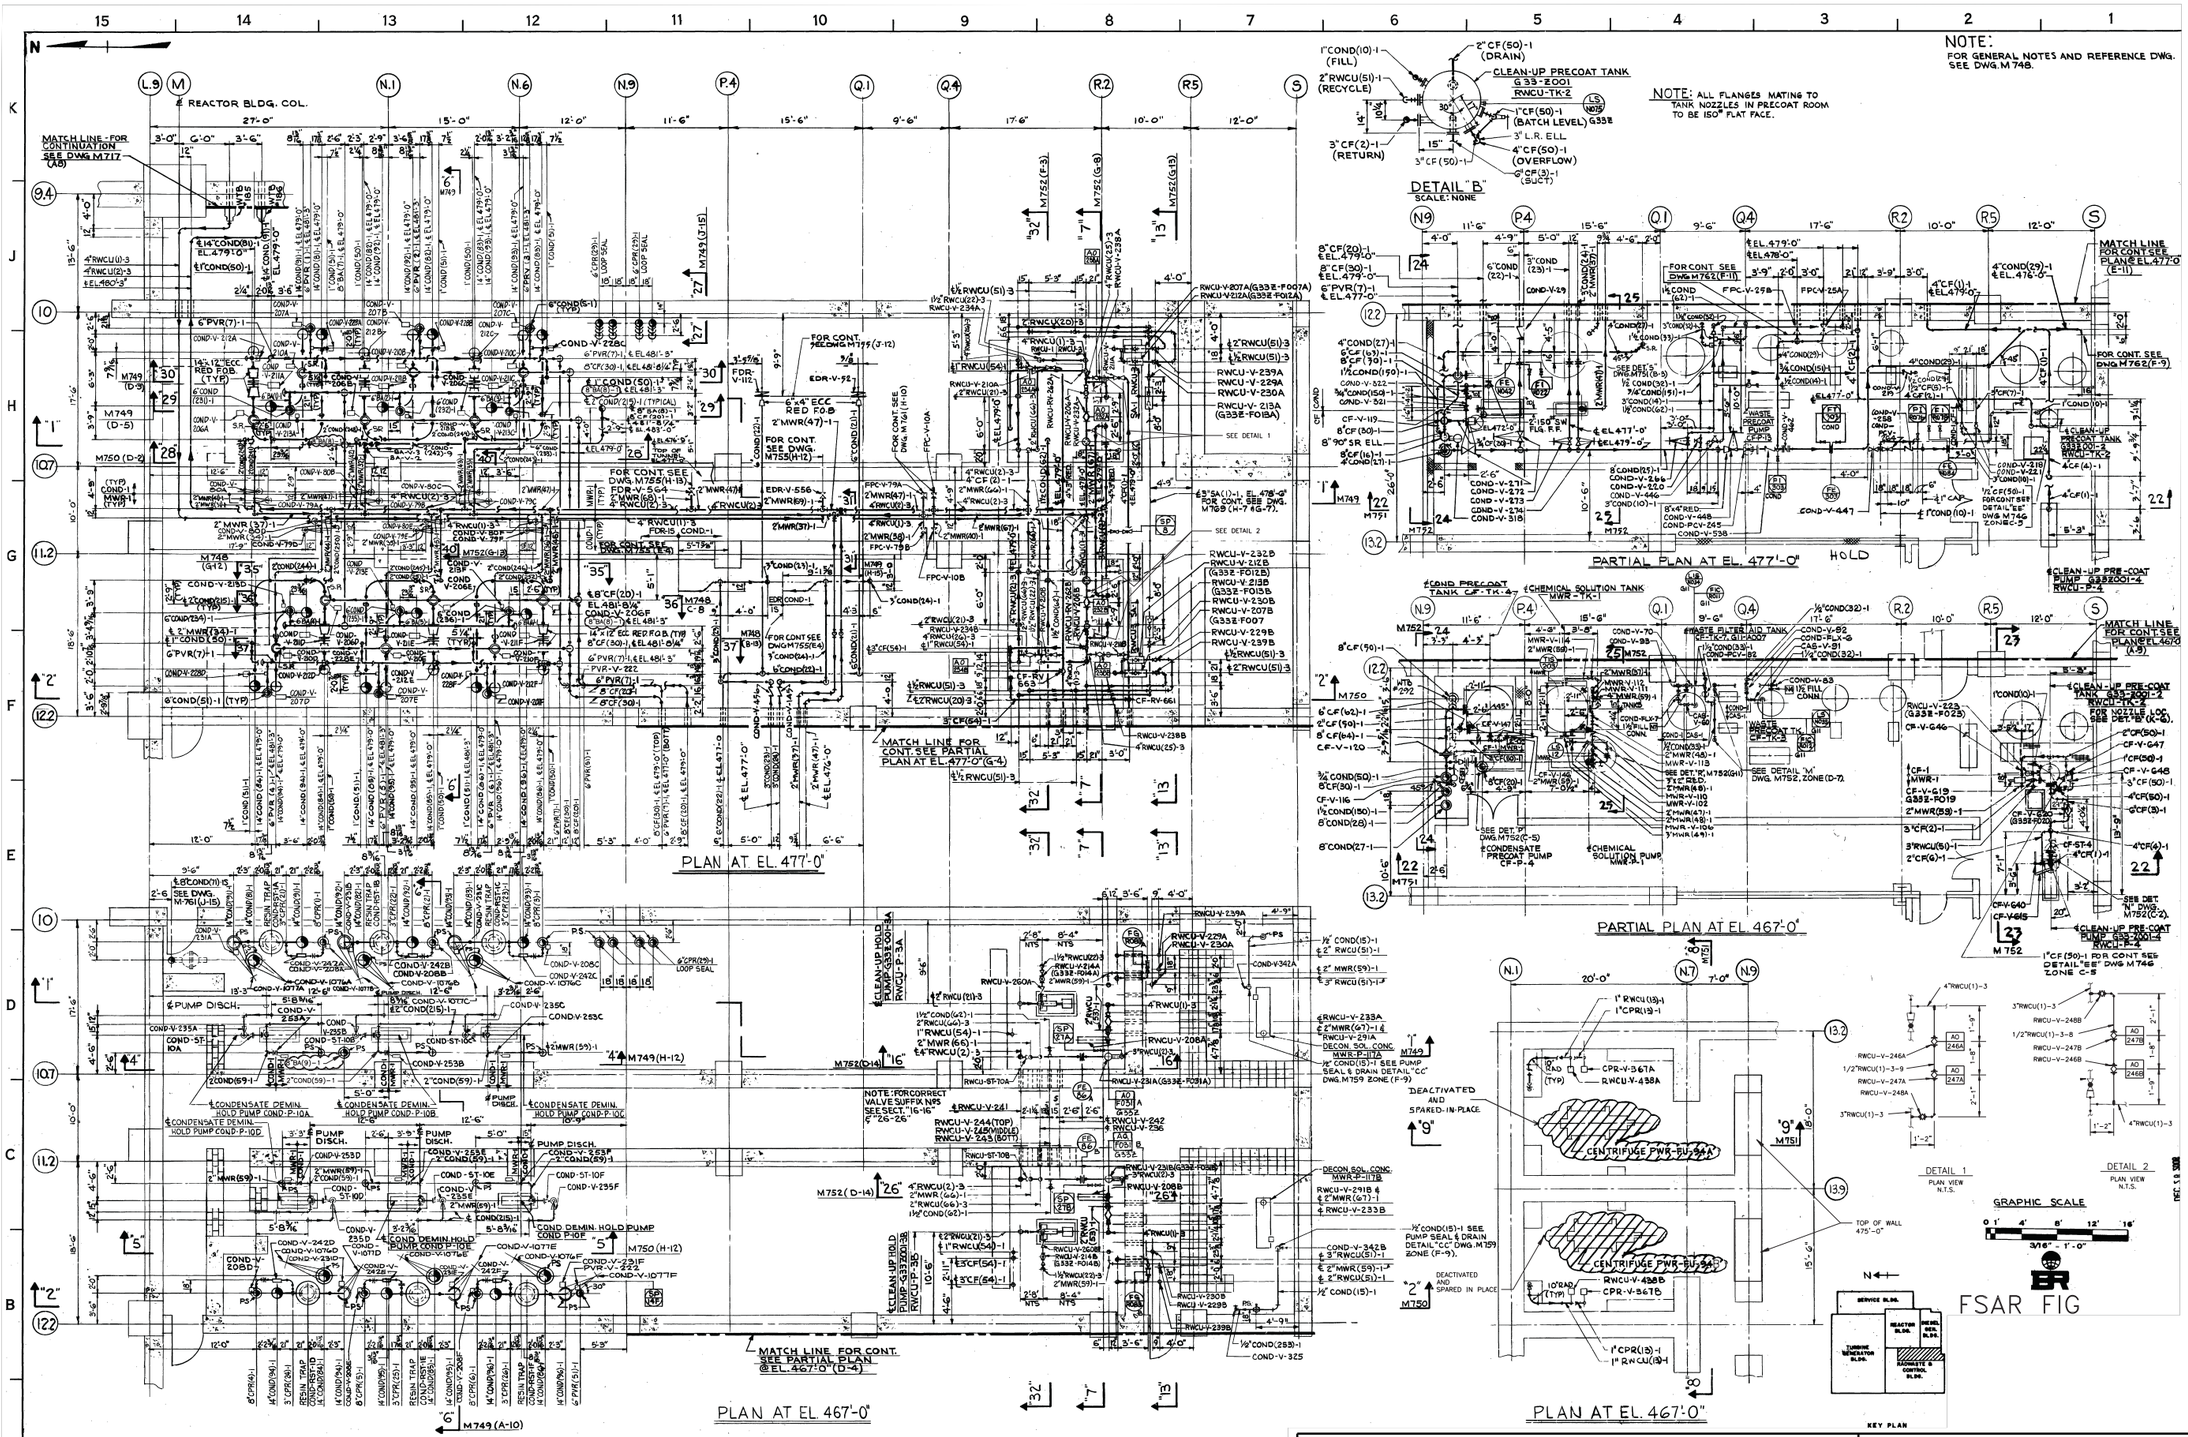
[b] These data are dimensionless.

Table 3.6-15

Piping Systems Inside Containment for Which Design Basis Pipe Breaks are Postulated

System	Portion
Low pressure core spray (LPCS)	RPV to first check valve.
High pressure core spray (HPCS)	RPV to first check valve.
RHR/LPCI mode (loop A)	RPV to first check valve.
RHR/LPCI mode (loop B)	RPV to first check valve.
RHR/LPCI mode (loop C)	RPV to first check valve.
RHR shutdown cooling return (loop A)	Recirculation pump discharge to first check valve.
RHR shutdown cooling return (loop B)	Recirculation pump discharge to first check valve.
RHR shutdown cooling supply	Recirculation pump suction to closed valve RHR-V-9 (MOF009).
Reactor feedwater (RFW) line A	Entire run within primary containment.
Reactor feedwater (RFW) line B	Entire run within primary containment.
RHR condensing mode/RCIC turbine steam	Entire run within primary containment.
Main steam (MS) loop A	Entire run within primary containment.
Main steam (MS) loop B	Entire run within primary containment.
Main steam (MS) loop C	Entire run within primary containment.
Main steam (MS) loop D	Entire run within primary containment.
Standby liquid control (SLC)	RPV to closed valve SLC-V-8, HPCS line to first check valve.
Reactor water cleanup (RWCU)	Entire run within primary containment.
RRC Recirculation pump A discharge	Entire run within primary containment.

Table 3.6-15



Piping Systems Inside Containment for Which Design Basis
Pipe Breaks are Postulated (Continued)

System	Portion
RRC recirculation pump B discharge	Entire run within primary containment.
RRC recirculation pump A suction	Entire run within primary containment.
RRC recirculation pump B suction	Entire run within primary containment.
RRC reactor pressure vessel drain	RPV to three (3) closed valves.
Main steam (MS) valves drainage piping	Entire run within primary containment.
Main steam (MS) RPV head vent	Entire run within primary containment.
RCIC/RPV head spray	RPV to first check valve.

Final Safety Analysis Report

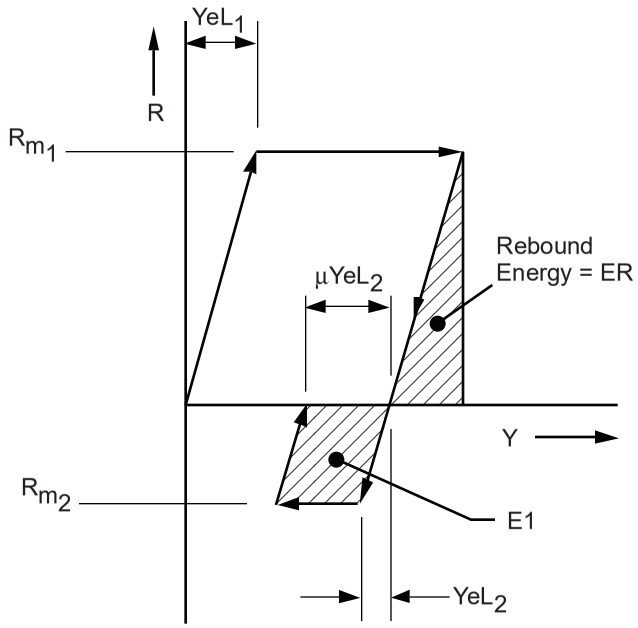
Jet from Circumferential Break with Ends Restrained (Fan Jet)

Draw. No. 020361.14	Rev.	Figure 3.6-30

Note: The wall rebound force is used in a direction opposite to the pipe or pipe jet impact load.

To determine R_m :

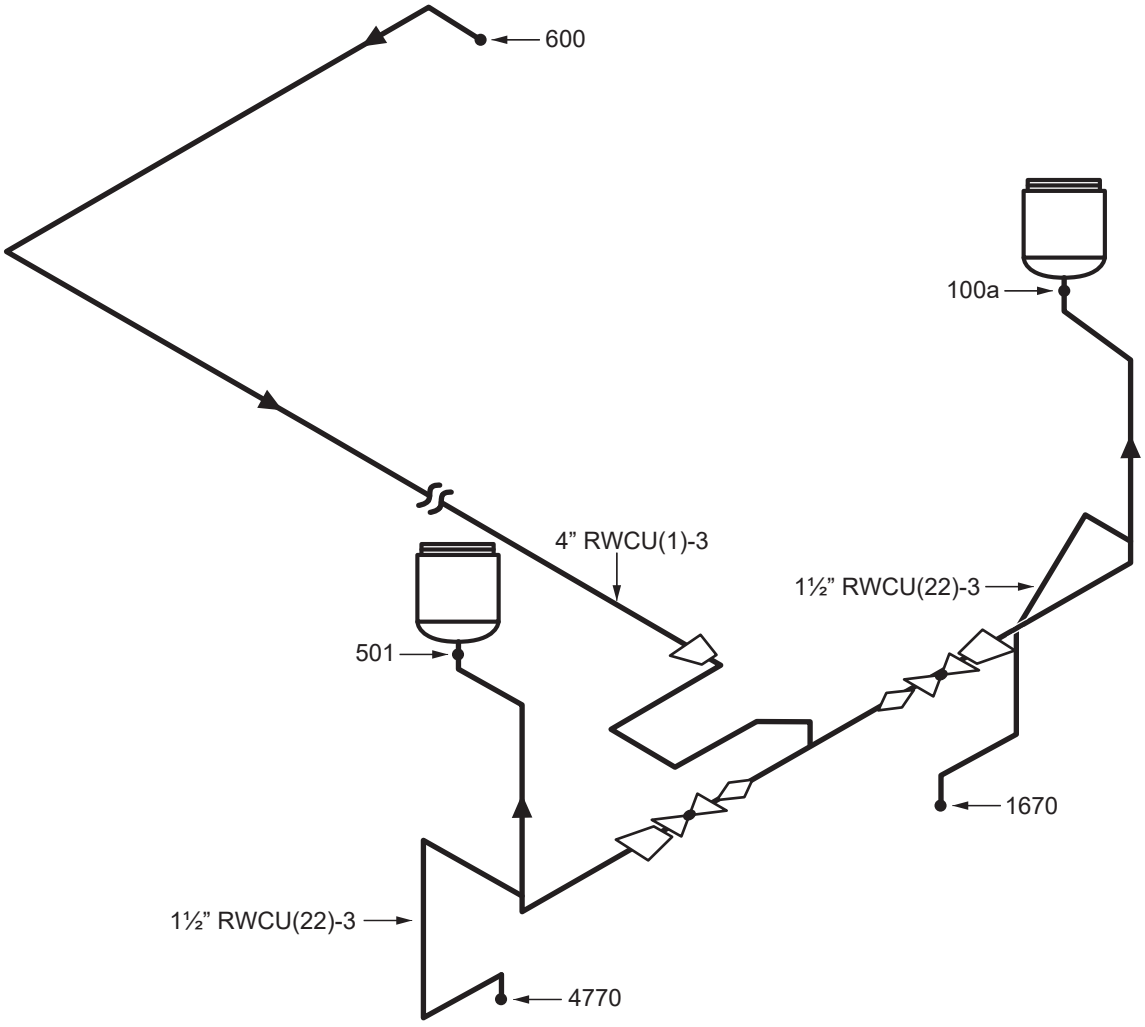
$$\frac{Y_{eL_2}}{R_{m_2}} = \frac{Y_{eL_1}}{R_{m_1}}$$



$$Y_{eL_2} = Y_{eL_1}\left(\frac{R_{m_2}}{R_{m_1}}\right)$$

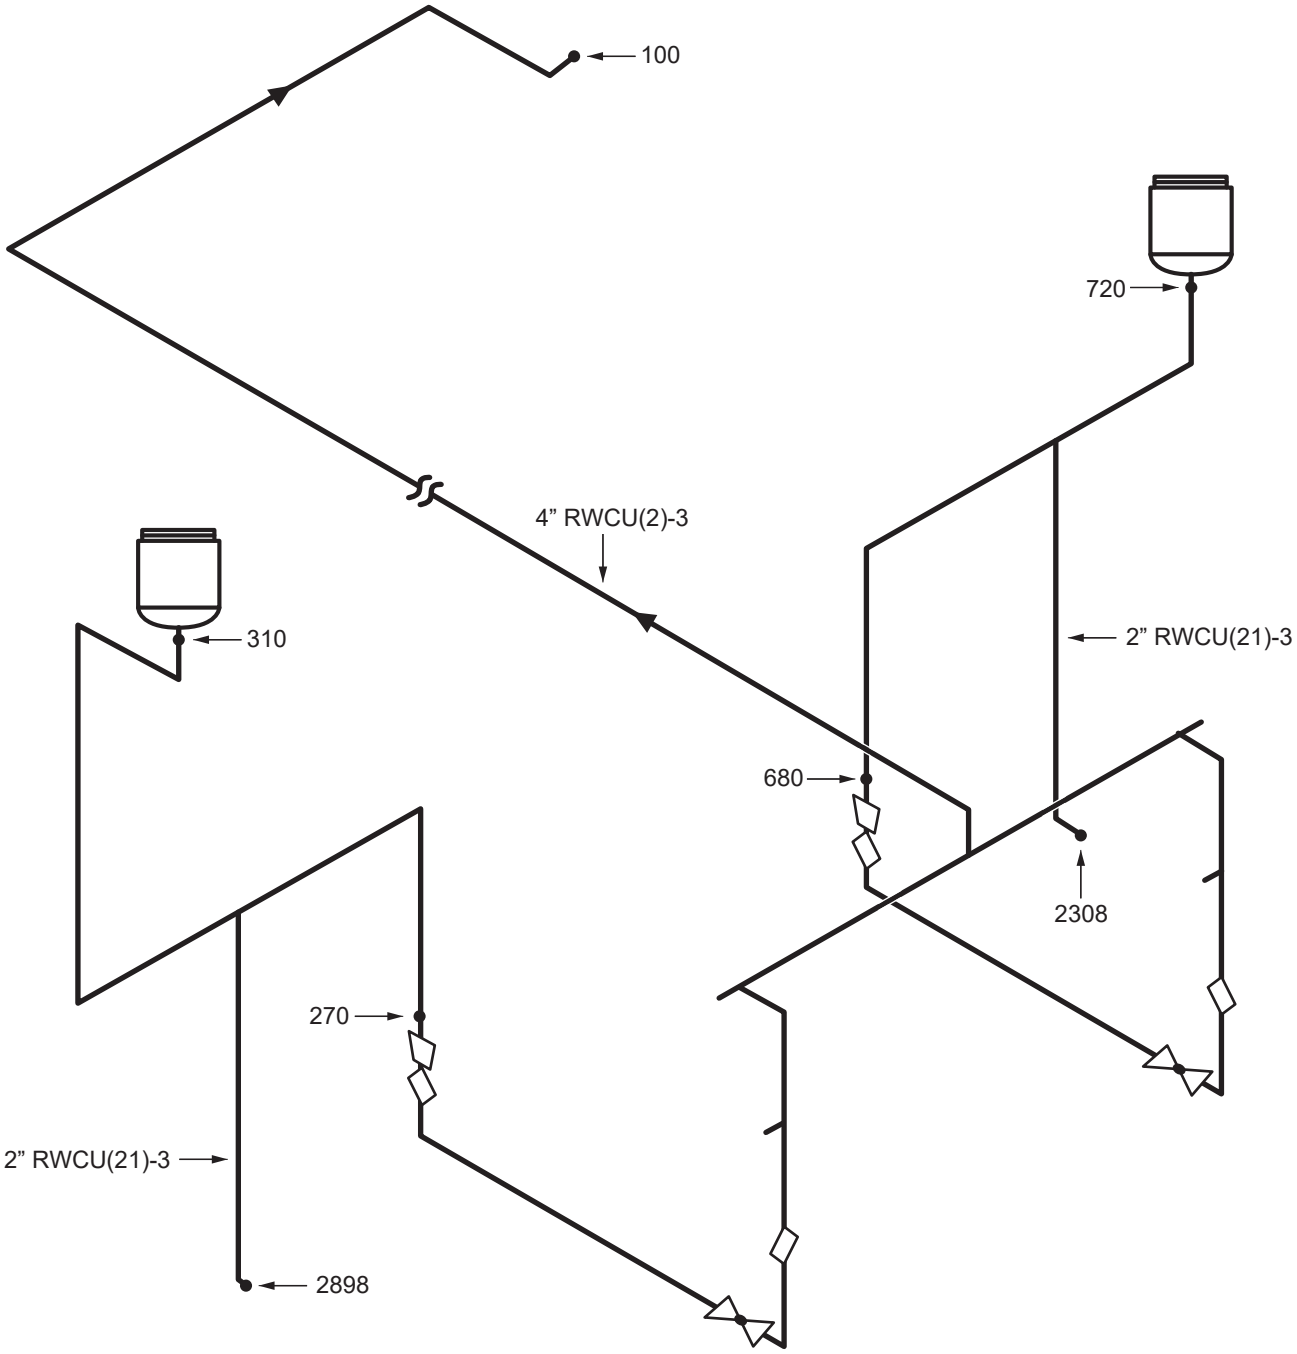
$E1 = \mu Yel_2\ Rm_2 = ER = 1/2\ yel._1\ Rm_1$

$$\text{or } \mu YeL_1\left(\frac{R_{m_2}}{R_{m_1}}\right) Rm_2 = 1/2\ yel._1\ Rm_1$$



Therefore, $Rm_2^2 = 1/2\mu\ (RM_1^2)$

$$\text{or } Rm_2 = \frac{1}{\sqrt{2\mu}}\ Rm_1$$



E1 = ER

3.7 SEISMIC DESIGN

All structures, systems, and components (SSCs) of the facility are defined as either Seismic Category I or non-Category I. The non-Category I seismic features are also referred to in other sections of this report as Seismic Category II. The requirements for Seismic Category I qualification are given in Section 3.2 along with a list of SSCs that are so categorized.

All SSCs related to plant safety are designed to withstand the effects of the safe shutdown earthquake (SSE) and the operating basis earthquake (OBE).

The SSE is that earthquake which is based on an evaluation of the maximum earthquake potential considering the regional and local geology and seismology and specific characteristics of local subsurface material. It is that earthquake which produces the maximum vibratory ground motion for which certain SSCs are designed to remain functional. These SSCs are those necessary to ensure

a. The integrity of the reactor coolant pressure boundary,

b. The capability to shut down the reactor and maintain it in a safe shutdown condition, or

c. The capability to prevent or mitigate the consequences of accidents which could result in potential offsite exposures comparable to the exposure limits of 10 CFR Part 50.67.

The OBE is that earthquake which, considering the regional and local geology and seismology and specific characteristics of local subsurface material, could reasonably be expected to affect the plant site during the operating life of the plant. It is that earthquake which produces the vibratory ground motion for which those features of the nuclear power plant necessary for continued operation without undue risk to the health and safety of the public are designed to remain functional. The OBE amplitude equals 50% the SSE amplitude.

Geological and seismic criteria related to the site are given in Section 2.5. Based on these criteria the characteristics and intensity of the postulated SSE are established.

3.7.1 SEISMIC INPUT

3.7.1.1 Design Response Spectra

The vibratory ground motion produced by the SSE is defined by design response spectra corresponding to the maximum vibratory accelerations at the elevations of the foundations of the nuclear power plant structures. The design response spectra are idealized, smooth curves relating the response of the foundations of the nuclear power plant structures to the vibratory

ground motion, considering such foundations to be single-degree-of-freedom damped oscillators and neglecting soil-structure interaction effects. The vibratory ground motion produced by the OBE is also defined by design response spectra.

Figures 3.7-1 and 3.7-2 show the design response spectra for the horizontal and vertical components, respectively, of ground motion associated with the SSE, for damping coefficients of 0.5, 2.0, 5.0, 7.0, and 10.0% of critical damping. The maximum horizontal ground acceleration for the SSE was selected to equal 0.25g, as described in Section 2.5, where g is acceleration of gravity. The peak ground acceleration in the vertical direction is taken as two-thirds of the horizontal value. The amplification values (and associated frequency ranges) in the design response spectra correspond to those of Newmark and Hall (Reference 3.7-1) with the exception that for 0.5, 2.0, and 5.0% of critical damping the amplification values were set at 4.8, 3.6, and 2.4, respectively. These response spectra correspond to design response spectra considered acceptable for soil sites (References 3.7-1 and 3.7-2).

These design response spectra are not identical to the design response spectra as defined in Regulatory Guide 1.60, Revision 1, scaled to 0.25g maximum horizontal ground acceleration. However, the latter are used with higher damping values as defined in Regulatory Guide 1.61, Revision 0. A response spectrum dynamic modal analysis was performed on the reactor building structure for an SSE input earthquake using (a) the design response spectra defined in Figure 3.7-1 and the damping values of Table 3.7-1, and (b) the design response spectra, scaled to 0.25g maximum horizontal ground acceleration, and damping values defined in Regulatory Guides 1.60, Revision 1, and 1.61, Revision 0, respectively. The structural responses of each of these modal analyses were within 10% of each other at almost all locations.

Figures 3.7-3 and 3.7-4 show the design response spectra for the horizontal and vertical components, respectively, of ground motion associated with the OBE, for damping coefficients of 0.5, 2.0, 5.0, 7.0, and 10.0% of critical damping. The ordinates of these spectra represent one-half of the ordinates of the design response spectra associated with the SSE.

Both earthquakes are of 15 sec duration. This is justified because (a) most records show a short period (10 to 20 sec) of high intensity acceleration, (b) the structural response analysis indicates that the low intensity build-up and phase-out periods preceding and following the high intensity acceleration period have no significant effect on structural response, and (c) the 15 sec duration is long enough to incorporate at least 7.5 cycles of motion at frequencies above 0.5 cps which is considered a representative limit for flexible structures.

3.7.1.2 Design Time History

A synthetic record of strong motion earthquake acceleration which reproduces the frequency content displayed in Figures 3.7-1 through 3.7-4 was developed (see Figure 3.7-5) by using a mathematical model described by Shinozuka (Reference 3.7-3). It consists of a duration T

(T was set at 15 sec) of a stationary Gaussian process with zero mean and a specified auto-correlation function which corresponds to the mean-square spectral density function.

The italicized information is historical and was provided to support the application for an operating license.

$$S_g(\omega) = \frac{S}{\left(\omega^2 - \omega_g^2\right)^2 + 4\zeta_g^2\omega^2\omega_g^2} \qquad \textit{(Eq.3.7.1.2-1)}$$

where ω_g, ζ_g and S are positive parameters which will be determined such as to conservatively represent the frequency content of the ground acceleration displayed in Figures 3.7-1 through 3.7-4. This mathematical model with zero mean and the mean-square spectral density function defined by equation (3.7.1.2-1) was simulated by way of the following series:

$$\ddot{x}_g(t) = s\left(\frac{2}{N}\right)^{1/2} \sum_{k=1}^{N} \cos\left(w_k t + f_k\right) \qquad \textit{(Eq. 3.7.1.2-2)}$$

where, $\ddot{x}_g(t)$ is the mathematical model of earthquake acceleration (a Gaussian random process defined above), and

$$\sigma = \left[\int_{-\infty}^{+\infty} S_g(\omega).\ d\omega\right]^{1/2} \qquad \textit{(Eq. 3.7.1.2-3)}$$

is the standard deviation of the process $\ddot{x}_g(t)$; ω_k (=1,2,…,N) are independent random variables identically distributed with the density function $g(\omega) = g(\omega k)$ obtained by normalizing $S_g(\omega)$

$$g(\omega) = S_g(\omega) / \sigma^2 \qquad \textit{(Eq. 3.7.1.2-4)}$$

and ϕ_K are independent random variables identically distributed with the uniform density $1/2^{\pi}$ between 0 and 2^{π}.

The sample function, $\ddot{x}_g(t)$, which was chosen to represent the random process $x_g(t)$ was corrected and optimized locally.

The response spectra derived from the synthetic record of earthquake acceleration envelope the design response spectra at all damping values used in the design. The comparisons of the synthetic and design response spectra are shown in Figures 3.7-6 through 3.7-10 for the

horizontal component of the OBE. *The spectra were calculated at a set of discrete values for circular frequency (ω_o, $\omega_o r$, $\omega_o r^2$,…, $\omega_o r^{n-1}$) forming a geometric progression. To ensure that the error due to the harmonic component of the simulated earthquake acceleration which contributes most to the response spectrum value is limited to 10%, the ratio of the geometric progression, r, was taken equal to 1.0196 for the damping coefficient of 2.0% of critical damping. This ratio corresponds to a period interval varying from 0.003 sec at a period of 0.03 sec to 0.010 sec at a period of 0.50 sec. The same intervals were used in computing the response spectra at other damping values.*

3.7.1.3 Critical Damping Values

The specific percentage of critical damping values used in dynamic analysis for Category I SSCs are shown in Table 3.7-1 and are based on the recommendations of Reference 3.7-1. Damping values for foundation materials (soils) are also shown in Table 3.7-1.

3.7.1.4 Supporting Media for Seismic Category I Structures

Table 3.7-2 provides a description of the foundation/supporting media for Seismic Category I structures.

All of the buildings/structures shown in Table 3.7-2 have independent foundations. Bedrock was encountered at approximately 525 ft beneath the plant grade (+440 ft 6 in. msl). See Section 2.5 for soil layering characteristics, shear wave velocity, shear modulus, and soil density.

3.7.2 SEISMIC SYSTEM ANALYSIS

Analysis of Seismic Category I SSCs is accomplished by using either the response spectrum method or the time-history method. The results obtained by the response spectrum method of dynamic analysis were used in the design of Seismic Category I structures. Seismic Category I structures were also analyzed by the time-history method of dynamic analysis, using as input a synthetic record of strong motion earthquake acceleration as defined in Section 3.7.1. The results of this analysis are used to generate seismic response spectra for the design and analysis of Seismic Category I systems and components housed in these structures. Alternately, the time histories of structural response at points of attachments/supports of components are used as input in the analysis of systems and components. In the case of Seismic Category I systems and components, the equivalent static load method and dynamic tests are used when conditions allow or require them as described below.

Analysis of Seismic Category I SSCs considers the following stress-producing earthquake effects:

a. Inertia forces determined by a dynamic analysis, and

b. Effects due to differential support displacement, where applicable.

The allowable stress, load combinations, and deformation limits are those set forth in the appropriate codes and design standards which are summarized in Sections 3.8, 3.9, and 3.10.

3.7.2.1 Seismic Analysis Methods

3.7.2.1.1 Introduction

Modeling procedures allow the equations of motion of a system to be written as a finite set of simultaneous ordinary differential equations. There are two approaches to the solution of the equations of dynamic equilibrium: the mode-superposition method and the direct integration method. The former was used in the original seismic analysis. It generally consists of two steps, the solution of the characteristic value problem represented by the free vibration response of the system and the transformation to normal coordinates utilizing the mode shapes of the system. This procedure uncouples the equations of motion so that the response of the system in each individual mode may be evaluated independently. Thus, the problem becomes one of solving independent differential equations rather than a set of simultaneous differential equations and, since the system is linear, the principle of superposition holds, and the total response of the system is determined by summing the responses of the individual modes.

3.7.2.1.2 The Equations of Dynamic Equilibrium

The equations of motion of a multi-degree-of-freedom discrete mass damped system subjected to an arbitrary ground motion assuming velocity proportional damping, are expressed in matrix form as follows:

$$\underline{m}\,\ddot{\underline{v}}(t) + \underline{c}\,\dot{\underline{v}}(t) + \underline{k}\,\underline{v}(t) = -\underline{m}\,\underline{I_O}\ddot{v}_g(t) \qquad \textit{(Eq. 3.7.2.1-1)}$$

where

$\underline{m}$ = *Mass matrix*

$\underline{c}$ = *Damping matrix*

$\underline{k}$ = *Stiffness matrix*

$\underline{I_O}$ = *Unit vector*

$\ddot{v}_g(t)$ = *Ground acceleration*

$\underline{v}(t)$, $\dot{\underline{v}}(t)$, *and* $\ddot{\underline{v}}(t)$ = *Matrices of displacements, velocities. and accelerations, respectively.*

3.7.2.1.3 Solution of the Equations of Dynamic Equilibrium by Direct Integration

The direct integration method was not used.

3.7.2.1.4 Solution of the Equations of Dynamic Equilibrium by Mode-Superposition

The solutions to the dynamic equilibrium equations used *orthogonality relations and expressing the displacements, velocities, and accelerations in terms of generalized coordinates, (i.e.,* $\underline{v(t)} = \underline{\phi}\ \underline{\dot{Y}(t)}$, $\underline{\ddot{v}(t)} = \underline{\phi}\ \underline{\ddot{Y}(t)}$, $\underline{\dot{v}(t)} = \underline{\phi}\ \underline{\dot{Y}(t)}$, *) Equation 3.7.2.1-1 is rewritten as the following uncoupled, normal equations of motion:*

$$M_r \ddot{Y}_r(t) + 2d_r\omega_r \dot{Y}_r(t) + K_r Y_r(t) = \psi_r M_r \ddot{v}_g(t) \qquad \textit{(Eq. 3.7.2.1-2)}$$

where

$M_r = \underline{\phi}_r^T\ \underline{m}\ \underline{\phi}_r$ = *Generalized mass for the r^{th} mode;*

$d_r = \dfrac{\underline{\phi}_r^T\ \underline{c}\ \underline{\phi}_r}{2\omega_r\ \underline{\phi}_r^T\ \underline{m}\ \underline{\phi}_r}$ = *Damping ratio of the r^{th} mode (damping ratio for the r^{th} mode is obtained using a weighted average as described in Section 3.7.1)*

$\psi_r = \dfrac{\underline{\phi}_r^T\ \underline{m}\ \underline{I}_\phi}{\underline{\phi}_r^T\ \underline{m}\ \underline{\phi}_r}$ = *Participation factor for the r^{th} mode;*

ω_r = *undamped circular frequency of the r^{th} mode;*

$\underline{Y(t)}$ = *time dependent normal coordinate vector;*

$\underline{\phi r}$ = *mode shape matrix for the r^{th} mode;*

$\underline{\phi}_r^T$ = *transpose of* $\underline{\phi}_r$.

The undamped circular frequencies, ω, are calculated from

$$\left[\underline{k} - \omega^2 \underline{m}\right] = 0 \qquad \textit{(Eq. 3.7.2.1-3)}$$

and the mode shape matrix for the rth mode is obtained from

$$\left[\underline{k} - \omega_r^2 \underline{m}\right]\underline{\phi}_r = 0 \qquad \textit{(Eq. 3.7.2.1-4)}$$

The solution of the differential equation 3.7.2.1-2, for the case of at-rest initial conditions is

$$Y_r(t) = \frac{\psi_r}{\omega_r\sqrt{1-\lambda_r^2}\int_o^t \ddot{v}_g(\tau)e^{-\lambda r\omega r(t-\tau)} \sin\left[\omega_r\sqrt{1-\lambda_r^2}(t-\tau)\right]d\tau} \qquad \textit{(Eq. 3.7.2.1-5)}$$

For small damping ratios, λ_r, the above solution is approximated by:

$$Y_r(t) = \frac{\psi_r}{\omega_r}\int_o^t \ddot{v}_g(\tau)e^{-\lambda_r\omega_r(t-\tau)} \sin\left[\omega_r(t-\tau)\right]d\tau \qquad \textit{(Eq. 3.7.2.1-6)}$$

There are two methods of dynamic analysis that were used to solve the multi-degree-of-freedom problems: the response spectrum method and the time-history method.

3.7.2.1.5 Response Spectrum Method of Analysis

If the design earthquake is specified in terms of a response velocity spectrum, Equation 3.7.2.1-6 becomes

$$Y_r(t)\,max = \frac{\psi_r S_{vr}}{\omega_r} \qquad \textit{(Eq. 3.7.2.1-7)}$$

where: S_{vr} = Spectral velocity for the r^{th} mode

$$S_{vr} = \left|\int_o^t \ddot{v}_g(\tau)e^{-\lambda_r\omega_r(t-\tau)} \sin\left[\omega_r(t-\tau)\right]d\tau\right| max \qquad \textit{(Eq. 3.7.2.1-8)}$$

The maximum modal displacements, $\underline{v}_{r\,max}$, for the r^{th} mode is

$$\underline{v}_{r\,max} = \underline{\phi}_r \frac{\psi_r S_{vr}}{\omega_r} \qquad \textit{(Eq. 3.7.2.1-9)}$$

where S_{vr} *= spectral velocity for the rth mode.*

If the design earthquake is specified in terms of a response acceleration spectrum instead of a velocity spectrum, the maximum modal displacements, $\underline{v}_{r\,max}$, of the structure for the r^{th} mode are

$$\underline{v}_{r\,max} = \underline{\phi}_r \frac{\psi_r S_{ar}}{\omega_r^2} \qquad \textit{(Eq. 3.7.2.1-10)}$$

where S_{ar} = *Spectral acceleration for the* r^{th} *mode.*

The maximum modal inertia forces, $\underline{F}_{r\,max}$, *for the* r^{th} *mode are computed from*

$$\underline{F}_{r\,max} = \underline{k}\ \underline{v}_{r\,max} \qquad \textit{(Eq. 3.7.2.1-11)}$$

When the maximum modal displacements and modal inertia forces are known, the other modal quantities such as shears and moments are computed for each mode by conventional structural analysis procedures.

3.7.2.1.5.1 Combination of Modal Response. In a response spectrum modal dynamic analysis, if the modes were not closely spaced (i.e., if the frequencies differ from each other by more than 10% of the lower frequency), the modal responses were combined by the square-root-of-the-sum-of-the-squares (SRSS) method as described in Section 3.7.2.1.5.1.1. If two or more frequencies differ from each other by less than 10%, their modal responses were first combined by the absolute sum method and then combined with other individual modal responses by the SRSS method. For some nuclear steam supply system (NSSS) equipment, a double sum method, as described in Section 3.7.2.1.5.1.2 was used to evaluate the combined response. In a time-history method of dynamic analysis, the vector sum at every step was used to calculate the combined response. The use of the time-history analysis method precluded the need to consider closely spaced modes.

3.7.2.1.5.1.1 Square Root-of-the-Sum-of-the-Squares Method. Mathematically, this SRSS method is expressed as follows:

$$R = \left[\sum_{i=1}^{n} (R_i)^2 \right]^{1/2} \qquad \textit{(Eq. 3.7.2.1-12)}$$

where:

R = *Combined response*

R_i = *Response in the* i^{th} *mode*

n = *Number of modes considered in the analysis.*

3.7.2.1.5.1.2 Double Sum Method. This method is defined mathematically as

$$R = \left[\sum_{k=1}^{N} \sum_{s=1}^{N} \left| R_k \; R_s \right| \varepsilon_{ks} \right]^{1/2} \qquad \textit{(Eq. 3.7.2.1-13)}$$

where

R = *Representative maximum value of a particular response of a given element to a given component of excitation*

R_k = *Peak value of the response of the element due to the k^{th} mode*

N = *Number of significant modes considered in the modal response combination*

R_s = *Peak value of the response of the element attributed to s^{th} mode*

where:

$$\varepsilon_{ks} = \left[1 + \left(\frac{(\omega_k - \omega_s)}{(\rho_k \omega_k + \beta_s \omega_s)} \right)^2 \right]^{-1}$$

in which:

$$\omega_k = \omega_k \left[1 - \beta_k^2 \right]^{1/2}$$

$$\beta_k = \beta_k + \frac{2}{t_d \omega_k}$$

where ω_k and β_k are the modal frequency and the damping ratio in the k^{th} mode, respectively, and t_d is the duration of the earthquake.

3.7.2.1.6 Time-History Method of Analysis

The time-history of ground acceleration, $\ddot{v}_g(t)$, is defined at discrete time intervals. *The acceleration is approximated by a segmentally linear function and the solution to Duhamel's Integral (Equation 3.7.2.1-5) is obtained by using a step-by-step integration procedure (Reference 3.7-7).*

$Y_r(t)$ is computed as a function of time for $r = 1,2,3,\ldots,n$, where n is the number of significant modes of the system. The modal displacements, $\underline{v_r(t)}$, at the time t for the r^{th} mode, are then calculated from

$$\underline{v_r(t)} = \underline{\phi_r} Y_r(t) \qquad \textit{(Eq. 3.7.2.1-14)}$$

The total displacements, $\underline{v(t)}$, of the structure at any time, t, are obtained by adding the individual modal displacements at time t:

$$\underline{v(t)} = \underline{v_1(t)} + \underline{v_2(t)} + \cdots + \underline{v_n(t)} \qquad \textit{(Eq. 3.7.2.1-15)}$$

The inertia forces, $\underline{F_r(t)}$, at time t, for the r^{th} mode are determined from

$$\underline{F_r(t)} = \underline{k}\ \underline{v_r(t)} \qquad \textit{(Eq. 3.7.2.1-16)}$$

The total inertia forces, $\underline{F(t)}$, on the structure at any time t, are obtained by adding the individual modal inertia forces at time t.

$$\underline{F(t)} = \underline{F_1(t)} + \underline{F_2(t)} + \cdots + \underline{F_n(t)} \qquad \textit{(Eq. 3.7.2.1-17)}$$

Once the time-histories of the displacements and inertia forces have been determined, the time-histories of internal forces, such as shears and moments, for each mode are determined by conventional structural analysis procedures. The total internal forces are obtained by adding the internal forces from each mode at each increment of time. For example, the matrix of the desired moments, $\underline{M(t)}$, is calculated from

$$\underline{M(t)} = \underline{M_1(t)} + \underline{M_2(t)} + \cdots + \underline{M_n(t)} \qquad \textit{(Eq. 3.7.2.1-18)}$$

where $\underline{M_1(t)},\cdots,\underline{M_n(t)}$ are the time-histories of moments in the individual modes. The maximum values of the internal forces are determined and used for design.

3.7.2.1.7 Analysis for Differential Support Displacements

Certain Seismic Category I systems (piping runs, electrical raceways and supports, duct runs, etc.), and particularly those spanning between different structures are subject to differential support displacements. Seismic Category I system components so effected are analyzed for such effects. The relative support displacements are obtained from the dynamic analysis of structures and are imposed on the systems analyzed thus determining through a static analysis the additional stresses due to relative support displacements.

Stresses due to relative displacements of supports for piping runs are combined with other stresses as described in Section 3.9.3.1.1.7.

For Seismic Category I raceways and cables spanning between different structures subject to differential movements, a flexible transition is made in the system. The transition includes a slack section in cables and a flexible section in the raceways. The slack in the cable sections and flexibility in the raceway sections are sufficient to accommodate the expected differential movements.

Conduit crossing expansion joints or vibration joints in concrete slabs are provided with suitable vibration or expansion fittings to compensate for the building vibration, expansion, and contraction.

For Seismic Category I ductwork spanning between different structures subject to differential movements, a flexible transition is made. The transition includes a slack section in the ductwork and sufficient flexibility in the system to accommodate the expected differential movements.

3.7.2.1.8 Dynamic Analysis of Seismic Category I Structures, Systems, and Components

Seismic Category I SSCs are analyzed for earthquake effects using either response spectrum or time-history methods of analysis.

3.7.2.1.8.1 Dynamic Analysis of Buildings. All Seismic Category I structures were analyzed by the response spectrum method of analysis and the results of the analyses were used in the design of these structures. Modal maxima were combined as described in Section 3.7.2.1.5. Seismic Category I structures for which floor response spectra are required were also analyzed by the time-history method of analysis. The analyses were performed assuming the horizontal ground motion to act in either of two orthogonal directions, North-South and East-West. Maximum stresses resulting from any one horizontal and the vertical excitations were considered to act simultaneously and were added using the absolute sum method.

3.7.2.1.8.2 Dynamic Analysis of Piping Systems. Each pipe line was idealized by a mathematical model consisting of lumped masses connected by elastic members. The stiffness matrix for the piping system was determined using the elastic properties of the pipe. This includes the effects of torsion, bending, shear, and axial deformations as well as change in stiffness due to curved members. The mode shapes and the undamped natural frequencies were determined. The dynamic response of the system was calculated by using either the response spectrum or time-history method of analysis. When the piping system is anchored and supported at points with different excitations, the response spectrum analysis was performed using the envelope response spectrum of all attachment points. Alternatively, the multiple excitation analyses methods may be used where acceleration time histories or response spectra are applied to all piping system attachment points.

The analyses were performed assuming the horizontal ground motion to act in either of two orthogonal directions, North-South or East-West. Any one of the horizontal and vertical excitations were considered to act simultaneously. Moments and forces from each of the horizontal and vertical excitations considered, are added as described in C.3 discussion for Regulatory Guide 1.92.

The relative displacements between anchors were determined from the dynamic analysis of the structures. These relative displacements are then used in a static analysis to determine the additional stresses imposed on the piping system.

An alternate simplified method of dynamic analysis was used for cold and/or limber piping systems. This is the equivalent static load method for piping. This method consists of applying constant horizontal and vertical load factors conservatively derived from seismic floor response spectra.

The description of the method is as follows: Enveloped seismic building response spectra were derived from widened seismic floor response spectra. (The widening of the building response spectra is described in Section 3.7.2.5). The piping system was then supported seismically such that the minimum fundamental frequency was chosen to be above the spectral peak of the enveloped response spectrum for any given span of pipe between adjacent supports. Thus, the initial maximum seismic support spans were analytically determined from this model for the chosen fundamental frequency. The static "g" levels acting on the piping system were then obtained from the enveloped response spectra assuming that the frequencies of the piping system is at or above the chosen frequency. These maximum spans were modified, if required, so that the maximum stresses did not exceed a conservative value of maximum stress based on the American Society of Mechanical Engineers (ASME) Code allowables and a limiting piping deflection between supports.

In the application of the alternate simplified method, a conservative static "g" loading was chosen for all piping systems when this approach was used irrespective of the building or building elevation. This simplified the work and results in different amounts of conservatism for different piping systems. To confirm the adequacy of the alternate simplified method, a study was performed for several representative piping systems. Pipe stress and pipe support loads were calculated for these representative systems using response spectrum analysis method. Results were examined to confirm that both pipe stresses and pipe support loads were calculated using the equivalent static load method.

3.7.2.1.8.3 Dynamic Analysis of Equipment. Equipment is idealized by a mathematical model consisting of lumped masses connected by elastic members or springs. Results for selected Seismic Category I equipment are given in Table 3.9-2. The dynamic response of the system was originally calculated by using the response spectrum method of analysis. When the equipment is supported at two or more points at different elevations, the response spectrum

analysis was performed by using the response spectra at the elevation near the center of gravity of the equipment as the design spectra for the NSSS equipment, and for balance-of-plant using the envelope of response spectra for supports. Modal maxima were combined as described in Section 3.7.2.1.5. The analyses were performed assuming the horizontal ground motion to act in either of two orthogonal directions, North-South and East-West. Maximum stresses resulting from any one horizontal or vertical excitation are considered to act simultaneously and the absolute values are added directly, as described in Sections 3.7.2.6 and 3.7.2.7.

The relative displacements between anchors are determined from the dynamic analysis of the structures. All cases of relative displacement between anchors are considered. If significant, these relative displacements are then used in a static analysis to determine additional stresses imposed on equipment. Further details are given in Section 3.7.2.1.8.3.1 for the NSSS equipment and Section 3.7.3.9 for all other equipment. The cases where the relative displacements between anchors are insignificant and thus neglected in the analysis are those cases where the equipment is supported on a single structural element as a floor slab or wall. Typical examples where relative displacements are considered insignificant are a bank of electrical switchgear located on and anchored to a single floor slab, a diesel generator set located on and anchored to a single isolated foundation, and an air handling unit located on and anchored to a single wall.

3.7.2.1.8.3.1 Differential Seismic Movement of Interconnected Components. The procedure for considering differential displacements for equipment anchored and supported at points with different displacement excitation is as follows.

Relative displacement between the supporting points induces additional stresses in the supported equipment. These stresses can be evaluated by performing a static analysis where each supporting point is displaced a prescribed amount. From the dynamic analysis of the complete structure, the time history of displacement at each supporting point is available. The maximum relative displacements obtained from the time history were used to calculate stresses statistically.

In the static calculation of the stresses due to relative displacements in the response spectrum method, the modal relative displacement was used. The mathematical model of the equipment was then subjected to the modal relative displacement at its supporting points. This procedure was repeated for the significant modes (modes contributing most to the total displacement response at the supporting point) of the structure. The total stress due to relative displacement was obtained by combining the modal results using the method described in Section 3.7.2.1.5.1.

When a component is covered by the ASME Boiler and Pressure Vessel (B&PV) Code, the stresses due to relative displacement as obtained above are treated as secondary stresses.

3.7.2.1.9 Equivalent Static Load Method

This method of analysis is used for design of certain systems:

a. Unless otherwise justified, for systems which can be realistically represented by a simple model, the equivalent static acceleration corresponds to the response spectrum value at the system natural frequency times a factor of 1.5 providing the spectrum is single peaked. If the response spectrum has multiple peaks and the natural frequency lies between two peaks or below a peak, the equivalent static acceleration corresponds to the highest peak located above the natural frequency times a factor of 1.5. If the natural frequency of the system is not known, the equivalent static acceleration corresponds to the response spectrum peak (highest) times a factor of 1.5. If the system natural frequency is at or above the zero period acceleration (ZPA) of the response spectrum, the equivalent static acceleration is the ZPA with no multiplication factor required.

b. Equivalent static load method for piping is described in Section 3.7.2.1.8.2.

3.7.2.1.10 Dynamic Testing

When certain Seismic Category I equipment and components potential functional failure cannot be evaluated analytically (i.e., when structural integrity alone cannot ensure the design intended function), dynamic testing is used to ensure operability. For example, dynamic tests of electrical items are performed in accordance with the requirements of IEEE Standard 344 (Reference 3.7-8). Test performance data and results are obtained either from previously tested comparable equipment or from the actual testing of equipment supplied. When seismic testing is impractical, a combination of test and analysis is used. Other dynamic test procedures which conservatively simulate the seismic conditions for the equipment are also used when found acceptable by the engineer.

Seismic Category I equipment which is difficult to represent by a mathematical model or which is required to demonstrate its ability to remain operating without changing the mode of its operation (such as level switch which should not switch from “on” to “off” or vice versa during the earthquake) was subjected to actual vibration inputs on shake tables. These shake tests were performed by qualified laboratories.

The seismic qualification tests conducted in the laboratory generally consist of the following:

a. The equipment was mounted on the shake table in such a manner as to represent its installed condition;

b. Sine sweep tests were performed covering all practicable frequency ranges with constant or variable acceleration levels to determine the natural resonant

frequencies of the equipment. This procedure enables the determination of the predominant resonant frequencies, by monitoring the output response; and

c. Proof testing was then performed to establish the capability of equipment to function during the particular seismic event and withstand the effects of the particular seismic event, represented by the required response spectra at the appropriate damping level. This was accomplished by using one of the following methods.

1. Sine dwell tests

This test utilizes a sine wave function with one of the equipment natural frequencies and acceleration levels equal to or greater than the corresponding maximum floor acceleration as input. The test duration is generally 30 sec, during which time the behavior of the equipment is observed and recorded. This test is performed at all equipment resonances and at frequencies spaced apart throughout the frequency range. Alternately, the test may be performed only at the equipment resonances when justified.

2. Sine beat tests

A sine beat function with the number of beats and cycles per beat corresponding to the equipment natural frequency and with predetermined acceleration level equal to or greater than the corresponding maximum floor acceleration, is used as input motion to test and record the behavior of the equipment.

3. Random motion tests

A random waveform motion consisting of frequency bandwidths one-third octave apart over the practicable frequency range is used in this test. The amplitude of each frequency bandwidth is independently adjusted in each axis until the test response spectra exceeds the required response spectra. The behavior of the equipment was observed and recorded to ensure its capability to withstand the input vibrations.

3.7.2.2 Natural Frequencies and Response Loads

A summary of natural frequencies, natural mode shapes, and modal responses (displacements, accelerations, moments, and shears) were provided for the significant modes of the reactor building and are shown in Figure 3.7-11 and Tables 3.7-3 through 3.7-15. The modal responses are for the OBE and SSE, for one horizontal (North-South) and the vertical

directions. All Seismic Category I structures were also analyzed by the time-history method of analysis, using as input the synthetic motion obtained as described in Section 3.7.1.2, to develop floor response spectra to be used in design of systems, components, and equipment housed in these structures. Floor response spectrum curves were computed at all lumped-mass points of Seismic Category I structures as described in Section 3.7.1.1. These curves are for the SSE and the OBE, for two horizontal orthogonal (North-South and East-West) and the vertical directions, with equipment damping values of 0.5, 1, 2, and 5 of critical damping and for equipment natural periods ranging from 0.03 to 2.50 sec per cycle. Typical floor response spectra are shown in Figures 3.7-12 and 3.7-15 through 3.7-21 for the reactor building at refueling floor and mat elevations.

3.7.2.3 Procedure Used for Modeling

Seismic Category I SSCs were modeled as a system of lumped masses and springs suitable for mathematical analysis. Each system analyzed is thus replaced by a discrete set of lumped masses, springs, and dashpots, idealizing both the inertia and stiffness properties of the system. The details of the mathematical models are determined by the complexity of the actual structure and the information required for the analysis.

Seismic subsystems, such as equipment and piping [with the exception of the reactor pressure vessel (RPV)], were decoupled from the structure as described in Section 3.7.2.3.1 by lumping their mass contribution to the structural model.

The seismic subsystems were then analyzed separately using the seismic input from the analysis of the structure. Where a subsystem is comparatively rigid and rigidly connected to the primary system, only the mass of the subsystem at the support point is included in the primary system model. Where the subsystem is flexible, such as pipe supported by hangers or equipment mounted on nonrigid supports, a coupled dynamic analysis was performed for both the subsystem and primary system.

The criteria used for decoupling piping systems, other than the NSSS piping systems, to establish the analytical models for seismic analysis are discussed in Section 3.9.3.1.18.5, and have been demonstrated as equivalent to the decoupling criteria outlined by Paragraph II.36 of Reference 3.7-15. The criteria for the NSSS main steam and recirculation piping systems are discussed below.

For NSSS systems and components, the ASME B&PV Code Section III requires that piping systems be designed and analyzed as complete systems from anchor to anchor. A complete piping system must include the subject piping system, all major branch line piping, and all equipment reached to the pipe which influences stresses and movement of the pipe. The piping systems within the General Electric contractual scope for which seismic analysis is performed are as follows:

a. Main steam piping from the RPV in the first anchor at the penetration head fittings, and

b. Reactor recirculation piping bound by the RPV nozzles.

The criteria employed for decoupling the main steam and recirculation piping systems to establish the analytical models for seismic analysis are given below:

a. Small branch lines (6 in. diameter and less) are decoupled from the main steam and recirculation piping systems and analyzed separately; and

b. The stiffness of all the anchors and its supporting steel is large enough to effectively decouple the piping on either side of the anchor for analytic code jurisdiction boundary purposes. The RPV is very stiff compared to the piping system and, therefore, during normal operating conditions, the RPV is assumed to act as an anchor. Penetration assemblies (heat fitting) are also stiff compared to the piping system and are assumed to act as an anchor. The stiffness matrix at the attachment location of the process pipe [i.e., main steam, reactor core isolation cooling (RCIC), residual heat removal (RHR) supply or RHR return] head fitting is sufficient to decouple the penetration assembly from the process pipe. General Electric analysis indicates that a satisfactory minimum stiffness for this attachment point is equivalent to the stiffness in bending and torsion of a cantilever equal to a pipe section of the same size as the process pipe and equal in length to three times the process pipe outer diameter.

Application of above criteria for analyses of the subject piping systems is as follows:

a. The main steam piping upstream of the outboard isolation valve (OBIV) is decoupled from the piping downstream of the OBIV at the first anchor at the penetration head fitting, and

b. The major branch lines which affect the stresses in the main steam and recirculation piping are incorporated in the analytical model for analysis. The system is not decoupled until it reaches the following virtual anchors:

    1. RCIC steam piping upstream of the OBIV is decoupled from the piping downstream of the OBIV at the first anchor at the penetration head fitting.

    2. Safety/relief valve discharge piping originating from the relief valve discharge flange is decoupled at each safety/relief discharge line first anchor at the suppression pool floor.

3. Residual heat removal supply and return piping (connected with the recirculation piping) upstream of the OBIV are each decoupled from the piping downstream of the OBIV at the first anchor at the penetration head fitting.

3.7.2.3.1 Modeling of Structures

In constructing the mathematical model of a structure, the locations for lumped masses were chosen at floor levels and points considered of critical interest such as supports/anchors for equipment and systems. The lumped mass comprises the weight of afferent walls, floors and other dead loads, including weight of systems supported on or hanging from the floor (pipes, ducts, raceways, etc.), and the weight of equipment mounted on the floor. It has been estimated that the equipment load constitutes, generally, less than 10% of the total weight associated with any lumped mass and is not expected to significantly effect the overall behavior of the structure. Between mass points, the structural properties were reduced to uniform segments of cross-sectional area, effective shear areas, and moments of inertia. Thus, the masses of the system were connected by weightless linear elastic springs which account for the axial (direct), flexural, and shear stress effects of the structure. Soil-structure dynamic interaction effects were considered by attaching basemat, assumed rigid, a set of equivalent springs, and dashpots as described in Section 3.7.2.4.

Typical mathematical models for the reactor building soil-structure lumped-mass system for horizontal and vertical input motions and the associated reactor building section are shown in Figures 3.7-13 and 3.8-1.

3.7.2.3.2 Modeling of Piping Systems

The continuous piping system is modeled as an assemblage of beams. The mass of each beam is lumped at the nodes and connected by a weightless elastic member, representing the physical properties of each segment. The pipe lengths between mass points must be sufficiently short, so as not to affect the accuracy of the dynamic analysis. The lengths utilized were determined by parametric studies. The resulting lengths are such that frequencies computed on the basis of a simply supported beam are no less than 33 Hz for all piping including the NSSS systems and components. All concentrated weights on the piping system such as main valves, relief valves, including valve operators with extended structures, and points of significant change in the geometry of the system, are modeled as lumped masses. The torsional effects of the valve operators and other equipment with offset centers of gravity, with respect to centerline of the pipe, are included in the analytical model. If the torsional stress is less than 500 psi, it is considered to be permissible to neglect this effect. Equipment nozzles are generally considered as boundaries for the piping systems. Inline spring-mounted equipment is modeled as a lumped mass.

3.7.2.3.3 Modeling of Equipment

For dynamic analysis, Seismic Category I equipment is represented by lumped mass systems that consist of discrete masses connected by weightless springs. The criteria used to lump masses are

a. The number of modes of a dynamic system is controlled by the number of masses used. Therefore, the number of masses is chosen so that all significant modes are included. The modes are considered significant if the corresponding natural frequencies are less than 33 Hz and the stress calculated from these modes are estimated to amount to a significant percentage (approximately greater than 10%) of the total stresses calculated from lower modes;

b. Mass is lumped at any point where a significant concentrated weight is located. Examples are the motor in the analysis of pump motor stand, or the impeller in the analysis of pump shaft;

c. If the equipment has a free-end overhang span whose flexibility is significant compared to the center span, a mass is lumped at the overhang span; and

d. When a mass is lumped between two supports, it is located at a point where the maximum displacement is expected to occur. This tends to conservatively lower the natural frequencies of the equipment. Similarly, in the case of live loads (mobile) and a variable support stiffness, the location of the load and the magnitude of support stiffness are chosen so as to yield the lowest frequency content for the system. This is to ensure conservative dynamic loads since equipment frequencies are such that the floor spectra peak is in the lower frequency range. If such is not the case, the model is adjusted to give more conservative results.

3.7.2.3.4 Modeling of Reactor Pressure Vessel and Internals

The seismic loads on the RPV and internals were based on a dynamic analysis of an entire RPV-building complex with appropriate forcing function supplied at ground level. For this analysis, the seismic model of the RPV and internals, as shown in Figure 3.7-14, and the mathematical model of the building were coupled together.

This mathematical model consists of lumped masses connected by elastic (linear) members. Using the elastic properties of the structural components, the stiffness properties of the model are determined. This includes the effects of both bending and shear. To facilitate hydrodynamic mass calculations, several mass points (representing fuel, shroud, and vessel) are selected at the same elevation. Mass points are located at all points of critical interest such as anchors, supports, and points of discontinuity, etc. In addition, mass points are chosen such

that the total mass of the structure is generally uniformly distributed over all the mass points, and the full range of frequency of response of interest is adequately represented.

The various lengths of control rod drive (CRD) housings were grouped into two representative lengths. These lengths represent the longest and shortest housings to adequately represent the full range of frequency response of the housings. The high fundamental nature frequencies of the CRD housings result in very small seismic loads. The small frequency differences between the various housings due to the length differences result in negligible differences in dynamic response. Hence, the modeling of intermediate length members becomes unnecessary. Not included in the mathematical model are light components such as jet pumps, in-core guide tubes and housings, spargers, and their supply headers. This reduces the complexity of the dynamic model. If the seismic responses of these components are needed, they can be determined after the system response has been found.

The presence of a fluid or other structural components (e.g., fuel within the RPV) introduces a dynamic coupling effect. Dynamic effects of water enclosed by the RPV were accounted for by a hydrodynamic mass matrix, which links the acceleration terms of the equations of motion of points at the same elevation in concentric cylinders with fluid entrapped in the annulus. The details of the hydrodynamic mass derivation are given in Reference 3.7-11. The seismic model of the RPV and intervals has two horizontal coordinates for each mass point. The remaining translational coordinate (vertical) is excluded because the vertical frequencies of the RPV and internals are well above the significant horizontal frequencies. All support structures, building, and containment walls are negligible. A separate generic and applicable vertical analysis is performed. Dynamic loads due to vertical motion are added to or subtracted from (whichever is more conservative), the static weight of components. The two rotational coordinates about each node point are excluded because of the moment contribution of rotary inertia from surrounding nodes. Since all deflections are assumed to be within the elastic range, the rigidity of some components is represented by equivalent linear springs.

The shroud support plate is loaded in its own plane during a seismic event and hence is extremely stiff. Therefore, the shroud support plate is modeled as a rigid link in the translational direction. The shroud support legs and the local flexibilities of the vessel and shroud contribute to the rotational flexibilities and are modeled as an equivalent rotational spring.

3.7.2.4 Soil/Structure Interaction

Soil/structure interactions were taken into account by coupling the structural model with the foundation medium.

The lumped mass-spring method was used to represent soil/structure interactions; and was obtained from a simplified mechanical analog to the model of a rigid mat resting on the surface of an elastic half space. The resulting compliance functions were approximated by the

frequency independent springs and dashpots (Reference 3.7-5) and are listed in Table 3.7-16. The spring and dashpot constants depend on the geometry of the foundation and on the dynamic properties of the soil. The selected ranges of values for the equivalent dynamic shear modulus, G (which are used in the dynamic analysis), were derived (Reference 3.7-6) by interpreting data from laboratory tests and measurements of seismic velocities adjusted for calculated strains. The ranges of G values are as follows:

Mode	Lower Bound (ksi)	Average Value (ksi)	Upper Bound (ksi)
Horizontal translatory and rocking	50	75	100
Vertical translatory	80	120	160

Based on additional studies performed for CGS, it was found that the use of the elastic half-space/compliance function method and the finite element method for soil/structure interaction analysis yield very comparable results. Therefore, either method is considered acceptable for seismic soil/structure interaction analysis of the CGS plant.

3.7.2.5 Development of Floor Response Spectra

All Seismic Category I structures were analyzed by the time-history method of analysis to obtain time histories of the structural response at points within these structures. The acceleration histories are used to generate floor response spectra.

The floor response spectra are computed for the SSE and the OBE for the two horizontal orthogonal directions and the vertical direction.

Spectral values, (the maximum response of a single degree-of-freedom oscillator) are obtained using a step-by-step integration (Reference 3.7-7). The analytical solution assumed that the acceleration histories of structural response are linear within the time interval of 0.02 sec. The integration was performed at either the 0.02 sec time intervals or at 0.05 times the natural period of the single degree-of-freedom oscillator, whichever was smaller.

The discrete periods or frequencies used in the calculation of the floor response spectra are in compliance with the values suggested in Regulatory Guide 1.122, Revision 0, September 1976.

To account for variations in structural frequencies, the peaks of the computed floor response spectra associated with each of the structural frequencies were widened by no less than +15%

for all Seismic Category I structures analyzed using lumped-mass stick models. The only exceptions were the standby service water pump house (SSWP) spectra where peaks were widened by only +10%. In lieu of performing an analysis to justify the 10% peak broadening of the SSWP spectra, the effects of using a 15% peak broadening of the same response spectra were reviewed. Examination of representative Seismic Category I equipment demonstrates that the equipment meets the 15% broadened curves. In addition, these response spectra are conservative since they are developed using a lumped mass spring model and conservative soil damping values of Table 3.7-1.

For the primary metal containment, the RPV, the RPV pedestal, and the sacrificial shield wall, the response spectra were widened by no less than +10%. However, these spectral data are obtained from the seismic analysis of the finite element building model which included the soil-structure interaction effects. This analysis was performed in accordance with the provisions of Regulatory Guides 1.60, 1.61, 1.92, and 1.122, and Standard Review Plan Section 3.7.2.

3.7.2.6 Three Components of Earthquake Motion

The use of three components of earthquake motion, as described by Regulatory Guide 1.92, Revision 1, was not a requirement for the issuance of the CGS construction permit. The total seismic response was calculated by combining the response calculated from analyses due to one horizontal and one vertical seismic input.

Two sets of seismic results were obtained. First the maximum value of the horizontal component of the earthquake was assumed to act in one horizontal direction simultaneously with the vertical component, and the loads were computed for this combination.

The maximum value of the horizontal component of the earthquake was assumed to act perpendicular to the direction previously assumed and simultaneously with the vertical component, and loads were computed for this combination. The larger of these two loads, at each point in the system, was used for design.

This method of analysis was based on the fact that the maximum resultant value of the horizontal component of the earthquake is determined when the horizontal component of the SSE is specified. This method conservatively assumes that the maximum horizontal and vertical components of the earthquake response occur simultaneously.

In accordance with Regulatory Guide 1.92, Revision 1, an alternative procedure is also acceptable for combining seismic responses, when designing structures, systems, or components submitted to the simultaneous action of three orthogonal earthquake motions. In this case the combined three-dimensional earthquake effect can be obtained for any structural response as the SRSS of the codirectional maximum responses caused by each of the three

earthquake components acting separately. Results of either modal response spectrum or time-history dynamic analyses can be processed this way.

The SRSS method of superposition, as summarized herein, may be used in conjunction with any mathematical model of SSCs, provided a complete set of three earthquake components is utilized as input in the dynamic analysis of that particular model. It should be noted that a comparison of response spectra clearly demonstrates that the original design basis (2-D method ABS) is more conservative than the SRSS/3 component method for all frequencies larger than 1.25 Hz. In the frequency range of interest for the CGS plant (approximately greater than 5 Hz), the margin of conservatism is very significant.

3.7.2.7 Combination of Modal Responses

When the response spectrum method of modal analysis is used, modal maxima are combined as described in Section 3.7.2.1.5.

3.7.2.8 Interaction of Non-Category I Structures With Seismic Category I Structures

The interfaces between Seismic Category I and non-Category I structures and plant equipment have been designed for the dynamic loads and displacements of both Seismic Category I and non-Category I structures and plant equipment. In addition, all non-Category I structures meet one of the following requirements:

a. The collapse of any non-Category I structure does not cause the non-Category I structure to strike a Seismic Category I structure or component,

b. The collapse of any non-Category I structure does not impair the integrity of Seismic Category I structures or components,

c. The non-Category I structures are analyzed and designed to prevent their failure under SSE in a manner such that the margin of safety of these structures is equivalent to that of Seismic Category I structures, and

d. The collapse of non-Category I structures will not prevent the functioning of Seismic Category I structures or components.

3.7.2.9 Effects of Parameter Variations on Floor Response Spectra

Variations in structural properties, damping, soil properties, and soil/structure interaction parameters could result in the shifting of calculated periods to resonant peaks in the floor response spectra. To account for the effects of such variations on the shape of calculated floor response spectra, smooth design envelopes which incorporate a minimum shift of the periods corresponding to calculated resonant peaks were developed and used in seismic design of

systems, equipment and components. The shift in resonant peaks covers at least the calculated variations in natural periods due to the probable variation in soil properties of +33-1/3% (see Section 3.7.2.4) and is never less than 10%. The actual shift in resonant peaks exceeds in some cases 15% as may be seen from Figures 3.7-12 and 3.7-15 through 3.7-21. Less significant variations in peak response values are also expected as a result of variations in structural properties used in dynamic analysis. The use of conservative damping coefficients and of smooth design spectrum envelopes in seismic design of systems, equipment, and components is adequate to account for variations in peak response values.

3.7.2.10 Use of Constant Vertical Static Factors

Seismic Category I SSCs were subjected to a vertical dynamic analysis with the vertical response spectra defining the input, with the exception that a static analysis can be performed in lieu of dynamic analysis as described in Section 3.7.2.1.9.

3.7.2.11 Method Used to Account for Torsional Effects

For nonsymmetrical structures, a stiffness analysis was performed to determine torsional effects on vertical structural elements resisting lateral loads. Inertial forces, determined from dynamic analysis of structures, were applied at the center of mass for each floor. Thus, torsion effects were introduced in each story by applying a twisting moment about the center of rigidity of the story under consideration. This moment is calculated as the sum of the products of the inertial force applied at the center of mass of each floor above and a lever arm equal to the distance from the center of mass of the floor to the center of rigidity of the story. The lever arm was not less than the minimum eccentricity required by the Uniform Building Code (Reference 3.7-9). The torsional moment and story shear were distributed to the resisting elements in accordance with the provisions of the Uniform Building Code.

Symmetrical structures were analyzed in a similar manner for torsional effects using minimum eccentricities between the center of mass and the center of rigidity as defined by the Uniform Building Code.

Calculation of torsional effects using a dynamic analysis that considers coupled translational and torsional degrees of freedom was also performed. The new torsional effects were compared with those loads derived by the design methodology prescribed above. Structures subjected to the new torsional moments were investigated and found to be structurally adequate under the new torsional loads considered in conjunction with the applicable load combinations.

3.7.2.12 Comparison of Responses

Comparisons of structural responses (accelerations) of the reactor building were obtained using (a) the response spectrum method with the site design response spectra, and (b) the time-history method with the simulated time-history of earthquake acceleration described in

Section 3.7.1.2 are presented in Figure 3.7-22. These results demonstrate the conservatism inherent in the simulation process illustrated by Figures 3.7-6 through 3.7-10, and carried over in the calculation of floor response spectra used in seismic design of systems, components, and equipment. A more appropriate comparison was obtained between structural responses (acceleration) of the reactor building obtained using (a) the response spectrum method with response spectra calculated from the simulated earthquake acceleration, and (b) the time-history method. These are also in Figure 3.7-22 and show good agreement between the results obtained using the two methods of dynamic modal analysis.

3.7.2.13 Methods for Seismic Analysis of Dams

No Seismic Category I dams are utilized in this facility.

3.7.2.14 Determination of Seismic Category I Structure Overturning Moments

Overturning and sliding effects of horizontal seismic loadings were considered in combination with the effects of vertical seismic loadings. The seismic loads used consist of two horizontal orthogonal and vertical components of earthquake motions. Each horizontal component was taken separately and is applied concurrently with the vertical component. For Seismic Category I structures, the results of the dynamic analysis were converted to equivalent static loads at the mass points.

Seismic Category I structures are located above the present groundwater elevation of 380 ft msl. However, uplift and lateral hydrostatic pressures are considered, taking into account the maximum groundwater elevation of 420 ft msl in the event the Ben Franklin Dam is constructed, as discussed in Section 3.4. The uplift and hydrostatic pressures, including seismic effects due to dry and saturated soils, as applicable, are applied concurrently.

To calculate the capability of safety-related structures to resist overturning, the following load combinations were considered:

a. D + E + Q* + Uplift
b. D + W + Q + Uplift
c. D + E′ + Q* + Uplift
d. D + W′ + Q + Uplift

Load combination in item c. above is used since the resulting horizontal and vertical forces produce the maximum overturning effects. The load terms in the load combinations are defined in Section 3.8.4.3.3, except as follows:

a. The dead load, D, also includes the weight of dry and saturated backfill, as applicable, and

b. The uplift force, not included in Section 3.8.4.3.3, is taken as the weight of the water displaced by the structure, acting vertically upward and applied to the bottom surface of the basemat.

The overturning moments and the stabilizing moments were calculated about the lower edge (toe) of the basemat. The safety factor against overturning was calculated by dividing the total stabilizing moment by the total overturning moment.

To calculate the capability of safety-related structures to resist sliding, the load combinations considered are the same as those listed above for calculating the capability of safety-related structures to resist overturning. Load combination c was used and produces the maximum sliding effects. The safety factor against sliding was calculated by dividing the frictional force resisting sliding between the basemat and the soil by the summation of horizontal forces causing sliding.

The factors of safety against overturning and sliding for safety-related structures are tabulated in Section 3.8.5.5.

3.7.2.15 Analysis Procedure for Damping

For structures and components, damping coefficients are selected as discussed in Section 3.7.1.3.

For the foundation materials, either internal or radiational damping or both are considered. The horizontal translation, vertical translation, and rocking motion damping values are determined as described in Reference 3.7-5.

The selected design values were significantly smaller than the calculated values. Table 3.7-1 presents the design values of the damping coefficients used. The formulas presented in Table 3.7-16 were used to calculate the realistic damping coefficients.

For composite structures made up from different materials, when the various components cannot be decoupled due to interaction effects, an approximate weighted average damping value was used for each mode of vibration of the structure. This is accomplished by breaking the mode shapes into their various components, then assigning a damping value to each component depending on the principal action of this component. A weighted average value is then determined for the particular mode under consideration. In this manner, a composite damping value is determined for each mode and the total response is calculated in the regular manner.

The method of obtaining weighted average damping values and how they were applied to the original design was obtained from the following relation:

$$D_n = \frac{D_s E_{sn} + D_h E_{hn} + D_r E_{rn}}{E_{sn} + E_{hn} + E_{rn}} \qquad \textit{(Eq. 3.7.2.15-1)}$$

where

D_n = *Weighted average damping for the nth mode*

D_s = *Damping ratio for the superstructure*

D_h = *Damping ratio for the horizontal translation*

D_r = *Damping ratio for the rocking motion*

E_{sn} = *Energy stored in the superstructure*

E_{hn} = *Energy stored in the horizontal spring*

E_{rn} = *Energy stored in the rocking spring*

The basis for Equation 3.7.2.15-1 is presented as Equation (4) in Reference 3.7-15.

In a linear dynamic analysis for the NSSS Systems and components the procedure to be utilized to properly account for damping in different elements of a coupled system model is as follows:

a. *A structural damping of the various structural elements of the model are first specified. Each value is referred to as the damping ratio (B_j) of a particular component which contributes to the complete stiffness of the system;*

b. *Perform a modal analysis of the linear system model. This will result in a modal matrix (ϕ) normalized such that $\phi_i^T K \phi_i W_i^2$, where K is the stiffness matrix, W_i the circular natural frequency of mode i and ϕ_i^T is the transpose ϕ, which is a column vector of ϕ corresponding to the mode shape of mode i. Matrix ϕ contains all translational and rotational coordinates; and*

c. *Using the strain energy of the individual components as a weighting function, the following equation can be derived to obtain a suitable damping ratio (B_i) for the i^{th} mode.*

$$B = \frac{\sum_{j=1}^{N} \phi_{i_j}^{T} B_j K_j \phi_{ij}}{w_i^2} \qquad \textit{(Eq. 3.7.2.15-2)}$$

where

N = *Total number of structural elements*

f = *Mode shape for mode i (f as transpose)*

B_j = *Percent damping associated with element j*

K_j = *Stiffness contribution of element j*

W_i = *Circular natural frequency of mode i*

The original piping design calculations, as indicated in Table 3.7-1, have considered damping values lower than or equal to those permitted by Regulatory Guide 1.61. For piping reanalyses or for snubber support optimization, the following damping values, as stated in ASME Code Case N-411, may be used in both the OBE and SSE spectrum analyses of the ASME Class 1, 2, and 3 piping systems:

Frequency Range (Hz)	Critical Damping (%)
0-10	5
10-20	5 decreasing linearly to 2
Above 20	2

Subject to the requirements of NRC correspondence regarding Regulatory Guide 1.84 (Reference 3.7-13), the code case may be applied to any piping system including those located in the SSWPs. The SSWP spectral peaks shall be broadened by 15% when Code Case N-411 is applied. It may be noted that the seismic spectra for CGS were developed using either the ground response spectra as defined in Regulatory Guide 1.60, Revision 1, or were properly justified by studies to be similar to those which could have been obtained per Regulatory Guide 1.60. Also, the peak broading requirements of Regulatory Guide 1.122 is met in all cases except for SSWP spectra as noted.

The original design basis for CGS required that responses due to inertial loads be combined with seismic anchor motion loads by the absolute sum method. For snubber optimization or any reconciliation work, based on the recommendation of NUREG-1061, Volume 4, the SSRS methodology for the combination of inertial and seismic anchor motion loads is utilized.

3.7.3 SEISMIC SUBSYSTEM ANALYSIS

The general approach to the seismic subsystem analysis is identical to those procedures described in Section 3.7.2 for seismic system analysis, except for the soil/structure interaction effects.

3.7.3.1 Seismic Analysis Methods

The seismic analysis method used to analyze Seismic Category I subsystems is described in Section 3.7.2.1.

3.7.3.2 Determination of Number of Earthquake Cycles

3.7.3.2.1 Number of Cycles for All Items Except Nuclear Steam Supply System Systems and Components

Fatigue evaluation due to an SSE is not required by ASME Code Section III, since it qualifies as a faulted condition. The OBE is an upset condition and therefore, must be included in fatigue evaluations according to ASME Code Section III.

As a minimum, 50 maximum stress cycles due to OBE are used for fatigue evaluations of BOP piping and components.

3.7.3.2.2 Number of Cycles for Nuclear Steam Supply System Systems and Components

3.7.3.2.2.1 Nuclear Steam Supply System Piping. Fifty peak OBE cycles are postulated for fatigue evaluation.

3.7.3.2.2.2 Other Nuclear Steam Supply System Equipment and Components. To evaluate the number of cycles that exist within a given earthquake, a typical boiling water reactor building-reactor dynamic model was excited by three different recorded time histories: (a) May 18, 1940, El Centro NS component 29.4 sec, (b) 1952, Taft N 69° W component, 30 sec, and (c) March 1957, Golden Gate S 80E component, 13.2 sec. The model response was truncated such that the response of three different frequency bandwidths could be studied, (0-10 Hz, 10-20 Hz, and 20-50 Hz). This was done to provide a good approximation to the cyclic behavior expected from structures with different frequency content.

Enveloping the results from the three earthquakes and averaging the results from several different points of the dynamic model, the cyclic behavior, as given in Table 3.7-17, was formed.

Independent of earthquake or component frequency, 99.5% of the stress reversals occur below 75% of the maximum stress level, and 95% of the reversals lie below 50% of the maximum stress level.

In summary, the cyclic behavior number of fatigue cycles of a component during an earthquake is found in the following manner:

a. The fundamental frequency and peak seismic loads are found by a standard seismic analysis,

b. The number of cycles which the component experiences are found from Table 3.7-17 according to the frequency range within which the fundamental frequency lies, and

c. For fatigue evaluation, 0.005% of these cycles are conservatively assumed to be at the peak load and 4.5% are assumed to be at or above three-quarter peak. The remainder of the cycles has negligible contribution to fatigue usage.

The SSE has the highest level of response. However, the encounter probability of an SSE is so small that it is not necessary to postulate more than one SSE during the 40-year plant life. Fatigue evaluation due to the SSE is not necessary since it is a faulted condition and thus not required by ASME Code Section III.

The OBE is an upset condition and, therefore, must be included in fatigue evaluations according to ASME Code Section III. An investigation of seismic histories for many plants shows that during a 40-year life, it is probable that five earthquakes with intensities 10% of the SSE intensity, and one earthquake approximately 20% of the proposed SSE intensity, will occur. To cover the combined effects of these earthquakes and the cumulative effects of even lesser earthquakes, 10 peak OBE cycles are postulated for fatigue evaluation.

Table 3.7-18 shows the calculated number of fatigue cycles and the number of fatigue cycles used in design.

The Fatigue Management Program includes OBE, SRV, and chugging transients, consistent with the recommendations of the GALL Report to include monitoring of all plants transients that cause cycle strains to support a 60-year service life.

3.7.3.3 Procedure Used for Modeling

The procedure used for modeling for the subsystem dynamic analysis is described in Section 3.7.2.3.

The field location of seismic supports and restraints for Seismic Category I piping and piping system components is selected to satisfy the following two conditions:

a. Restraint locations are chosen sufficiently close to each other to limit the stress and strain of the piping system to acceptable values. Spring supports are not a

factor in seismic analysis. Seismic restraints are constructed sufficiently rigid so as to preclude interaction with the piping system; and

b. Structures are provided of sufficient capacity to support the seismic supports and restraints and to withstand the seismic and/or loss-of-coolant accident (LOCA) loads transferred to the supporting structure by the seismic support and/or restraint. The applicable load combinations in Tables 3.8-5, 3.8-6, 3.8-9, and 3.8-10 are used, depending on the loading conditions to which the structure could be subjected.

The final location of seismic supports and restraints for Quality Class 1, Seismic Category I piping, piping system components, and equipment, including the placement of snubbers, is checked against the drawings and instructions issued by the engineer. An additional examination of these supports and restraining devices is made to ensure that the location and characteristics of these supports and restraining devices are consistent with the dynamic and static analyses of the systems.

3.7.3.4 Basis for Selection of Frequencies

All frequencies in the 0.25 to 33 Hz range are considered in the analysis and testing of SSCs. These frequencies cover the natural frequencies of most of the components and structures under consideration. If the fundamental frequency of a component is greater than or equal to 33 Hz, it is treated as rigid and analyzed accordingly. Frequencies less than 0.25 Hz are not usually considered, as they represent very flexible structures and are not normally encountered in this plant.

3.7.3.5 Use of Equivalent Static Load Method of Analysis

When the natural frequency of a structure, equipment, or component is unknown, the item may be analyzed by applying a static force at the center of mass. To account for the possibility of more than one significant dynamic mode, the static force is calculated as 1.5 times the mass times the maximum acceleration from the applicable design response spectra of the point of attachments as described in Section 3.7.2.1.9. For structures, equipment, or components which may be realistically represented by a single degree-of-freedom system, the peak spectral acceleration is used. Equivalent static load method for piping is described in Section 3.7.2.1.8.2.

3.7.3.6 Three Components of Earthquake Motion

The procedure used to consider the three components of earthquake motion for Seismic Category I subsystems is described in Section 3.7.2.6.

3.7.3.7 Procedure for Combining Modal Responses

The procedure used for combining modal responses for Seismic Category I subsystems is described in Section 3.7.2.1.5.

3.7.3.8 Analytical Procedures for Piping

A description of the modeling and analytical procedures applicable to piping systems is described in Sections 3.7.2.3.2 and 3.7.2.1.8.2, respectively.

3.7.3.9 Equipment Components Supported at Multiple Locations with Distinct Inputs

For seismic analysis of equipment and components supported at different elevations and between buildings, the envelope of response spectra, for the points of attachment, is used.

The procedure for considering differential seismic movement effects on equipment/system with interconnected components, supported at different floors of the same structure, or supported by different structures, is as follows:

a. Relative (differential) displacements between different floors of a structure and between different structures during a seismic event are obtained from the dynamic analysis of the structures, and

b. Maximum relative (differential) displacements are imposed on the equipment/system being analyzed and the induced stresses determined through a static analysis.

The allowable stress criteria are defined in Sections 3.8, 3.9, and 3.10.

3.7.3.10 Use of Constant Vertical Static Factors

The use of constant vertical static factors, as applied to Seismic Category I subsystems, is limited, as discussed in Section 3.7.2.10.

3.7.3.11 Torsional Effects of Eccentric Masses

Torsional effects of eccentric masses are discussed in Section 3.7.2.3.2. When the torsional effect of an eccentric mass is likely to have a significant effect on the result of an analysis, the eccentric mass is included in the analytical mode. If the pipe stresses due to an eccentric mass are expected to be insignificant, the offset moment due to the eccentric mass is usually neglected.

3.7.3.12 Buried Seismic Category I Piping Systems and Tunnels

Seismic Category I piping penetrating exterior building foundation walls are furnished with oversized wall sleeves and flexible closure boots.

No buried Seismic Category I tunnels are utilized in this facility.

Underground nuclear safety related piping is designed to safely resist operating loads and loads due to accident conditions which include seismic waves passing through the soil media supporting these elements and relative seismic displacements between building and surrounding soil. Analysis of these underground pipes subject to ground motion is based on their configuration and boundary conditions and the elastic properties of the soil and piping.

For the stress analysis of the portions of the buried pipes penetrating the wall sleeves and connected to the buildings, the relative displacement between the building and soil is imposed on the buried pipe in addition to the pipe internal pressure, pipe dead weight, and seismic and thermal effects on the pipe. When the piping is enclosed in encapsulated sleeves, the supports inside the encapsulated sleeves are also modeled in the analysis of the piping system.

3.7.3.12.1 Procedures for Predicting the Stresses of Buried Pipes in the Free Field

3.7.3.12.1.1 Method of Analysis. The method of analysis developed is based on Reference 3.7-12.

3.7.3.12.1.2 Axial Stresses in Pipe. The method of analysis as suggested by N. M. Newmark in Reference 3.7-12 is used in the analysis of the axial stresses in buried pipes. The value of the maximum particle velocity, Vm, used in the analysis is calculated by following the recommendations of N. M. Newmark et al., in Reference 3.7-2.

3.7.3.12.1.3 Bending Stresses in Pipes. The method of analysis as suggested by N. M. Newmark in Reference 3.7-12 is used in the analysis of the bending stresses in buried pipes.

3.7.3.12.1.4 Buried Piping Encased in Oversized Culvert Sections. Certain portions of buried pipes are encased in oversized culverts. The encasement serves the dual purpose of providing protection against damage of piping under heavily loaded areas such as roads and of accommodating thermal expansion at changes in direction of the piping.

The encased piping does not come in contact with the soil and can thus be analyzed by the same methods used for piping in free space. The dead load, internal pressure, seismic, and thermal stresses are maintained below allowable limits.

3.7.3.12.2 Procedures for Predicting the Stresses of Buried Pipes at Connections to Various Buildings

The relative movement between the soil and buildings is accommodated by encasing the pipe for a sufficient length from the penetration to allow for elastic deformation thereby keeping stress levels below allowable limits. The encased pipe does not come in contact with the soil and can therefore be analyzed using the same methods that are used for piping in free space.

3.7.3.13 Interaction of Other Piping With Seismic Category I Piping

When non-Seismic Category I piping is attached to Seismic Category I piping, that portion of the other piping up to the nearest piping anchor or terminal point is also analyzed as Seismic Category I piping. The non-Seismic Category I piping is designed to withstand the SSE without failing in a manner that would cause the Seismic Category I piping to fail.

3.7.3.14 Seismic Analyses for Reactor Internals

The seismic analysis of the reactor is described in Section 3.7.2.3.4. A comparison of the maximum calculated seismic loads and the allowable seismic loads in the RPV and internals is given in Table 3.7-19. The damping values are given in Table 3.7-1.

3.7.3.15 Analysis Procedure for Damping

Damping values used for Seismic Category I subsystems are discussed in Section 3.7.2.15.

3.7.4 SEISMIC INSTRUMENTATION

3.7.4.1 Comparison With Regulatory Guide 1.12

The seismic instrumentation system for CGS complies with the requirements of Regulatory Guide 1.12, Revision 2.

3.7.4.2 Location and Description of Instrumentation

Triaxial strong-motion accelerographs are installed at appropriate locations to provide data on the seismic input to the free field area, containment, data on the frequency, amplitude, and phase relationship of the seismic response of the containment structure and to provide data on the seismic input to other Seismic Category I SSCs. The criteria for selection of Seismic

Category I structures, components, and equipment to be instrumented, and the location of instrumentation, is that which will enable the evaluation of the following:

a. To determine if the input design response spectra has been exceeded,

b. To determine if the calculated resultant vibratory responses used in the design of the representative Seismic Category I structures and equipment have been exceeded, and

c. The degree of applicability of the mathematical models used in the seismic analysis of the buildings and equipment.

In compliance with Regulatory Guide 1.12 Rev. 2, the seismic monitoring system at Columbia Generating Station is supported by six (6) strong motion recorders (SMR), one (1) Networked Control Center and a personal computer that provides and interface with the Networked Control Center (NCC).

The SMRs are triaxial time-history accelerographs which can operate on a stand-alone basis or be linked as part of the NCC. The accelerographs' internal sensors pickup vibration and transform into an electrical signal, which is proportional to the acceleration. The signal is compared to the trigger threshold. When the threshold is exceeded, an event is created and the data is recorded which is saved on the recorder that is equipped with a portable media drive. The media device can be removed and the data can be read with a standard personal computer (PC) independently.

The first SMR is located on the 422' elevation, which is the reactor building foundation. The second SMR is located on the 522' elevation of the reactor building. The third SMR is located on the 548' elevation of the reactor building. The SMRs located at the foundation and at elevation in the structures measure the seismic response spectra. This response spectra is used to determine the impact on plant equipment or piping in accordance with Regulatory Guide 1.167 (Ref. 6) prior to restart when the plant is shutdown due to OBE exceedance.

The free field SMR is located 1000 feet NE of the reactor building in a covered pit. The free field SMR data will be used to compare measured response to the design spectra to determine whether the OBE has been exceeded in accordance with Regulatory Guide 1.166.

Two additional SMRs are located in the Radwaste Building. The first SMR is located on the 437' elevation, which is the Radwaste Building foundation. The second SMR is located on the 487' elevation. All SMRs located in the free field, Reactor Building, and Radwaste Building are networked as part of the NCC interface and data gathering.

The NCC is a rack mounted unit that is located in the control room. The NCC connects the SMRs in a centralized location where the NCC acts as a primary control and access point for

the SMR. The NCC monitors the on-line operating status of each SMR on the network and performs common trigger and time synchronization for all connected SMRs. Additionally, when the trigger threshold has been exceeded through voting logic, the relay contacts on the NCC acts as a seismic switch to provide remote indication that a specified acceleration has been exceeded. The remote indication are notification to plant operator that the "Miminum Seismic Earthquake Exceeded." As part of the NCC, there are two power supplies with backup batteries, which provides power to the NCC and the SMRs that are connected to the network. The purpose of the batteries is to supply the NCC and SMRs with power to provide 25 minutes of system operation at any time over a 24-hour period without recharging, in combination with a battery charger in accordance with Regulatory Guide 1.12.

Note that when the NCC is connected to a PC, it performs the functions of an operator interface to interpret the collected data on each SMR, monitoring of on-line operating status of each SMR as well as configuring each of the SMR that is on the network. The computer utilizes proprietary software that is used in conjunction with the NCC to monitor, configure, gather and interpret the data from the SMRs. Interpreting the data would aid in the decision to shut down the plant in accordance with Regulatory Guide 1.166.

3.7.4.3 Control Room Operator Notification

The information, which the system makes available to the control room operator, is as described in Section 3.7.4.2.

The bases for establishing predetermined values for activating the readout of the seismic instrumentation to the control room operator are

a. To initiate the triaxial time-history recorders, at a very low level acceleration equal to 0.01g as recommended by Regulatory Guide 1.12, Rev. 2, Section 6.3, and

b. To provide immediate control room annunciation if the OBE has been exceeded.

3.7.4.4 Comparison of Measured and Predicted Responses

In accordance with Appendix A to 10 CFR 100, an orderly and sequential shutdown of the plant will be carried out according to detailed written station procedures if a seismic event with vibratory ground motion equal to or exceeding that of the OBE occurs. Prior to resuming operations, it will be demonstrated to the NRC that no functional damage has occurred to those features necessary for continued operation without undue risk to the health and safety of the public, or that the necessary repairs to those features have been completed.

As per Regulatory Guide 1.166, if the response spectrum check and the cumulative absolute velocity (CAV) check were exceeded, the OBE was exceeded and shutdown is required. If

either check does not exceed the criterion, the earthquake motion did not exceed the OBE. If only one check can be performed, the other check is assumed to be exceeded. In the event that data from the free-field instrumentation is unavailable, then the guidance of Regulatory Guide 1.166, Appendix A, will be followed.

The data from the free-field seismic instrumentation, coupled with information obtained from a plant walkdown, are used to make the initial determination for plant actions due to an earthquake. After an earthquake, a response spectrum check and the CAV will be calculated based on the recorded motions at the free-field instrument within 4 hours in accordance with Regulatory Guide 1.166 to determine if OBE was exceeded. If the OBE ground motion is exceeded or significant plant damage is identified during plant walkdowns, action will be take in accordance with Regulatory Guide 1.166 and plant procedures.

The Reactor Building and Radwaste Building foundation-level instrumentation are used for evaluation of the plant structures when the data from the free-field instrumentation is unavailable. In this case, the determination of OBE exceedance is based on a response spectrum check. A comparison is made between the foundation-level design response spectra and data obtained from the foundation-level instruments. If the response spectrum check at either foundation is exceeded, the OBE is exceeded and plant action is required for evaluation of plant operability. The CAV check is not applicable to the data recorded at the foundation-level instrumentation.

Bolted or riveted structural assemblies	2.0	3.0
Reactor pressure vessel, support skirt, shroud head, separator, and guide tubes	2.0	2.0
Control rod drive housings	3.5	3.5
Fuel	7.0	7.0
Steel frame structures	2.0	3.0
Soil		
Rocking	5	7
Translation (horizontal and vertical)	10	10

[a] The tabulated damping values are used in the seismic analysis in conjunction with the ground response spectra shown in Figure 3.7-1, for the design of all Seismic Category I structures, systems, and components. The original Annulus Pressurization analysis used 3% for all locations except the main steam at RPV nozzle with a 2% damping ratio. The damping ratio for MELLLA is 4% as specified in R.G. 1.61 Rev. 1.

[b] For structures or components, combined stresses are considered below one-half yield for loading combinations including the OBE, and at or near yield for loading combinations including the SSE.

[c] In the event these damping values are found to be too restrictive, the higher damping coefficients cited by Regulatory Guide 1.61 Rev.1 (i.e., 1.0 and 2.0% of critical damping for OBE and SSE events, respectively) may be used.

NOTE: See also Section 3.7.2.15 for the ASME Code Case N-411 damping application to CGS piping systems.

Table 3.7-2

Foundation/Supporting Media for
Seismic Category I Structures

Structure	Average Foundation Embedment Depth (ft)	Width of Structural Foundation (ft)	Total Structural Height (ft)
Reactor building	21.5	147	265
Control room structure and portions of radwaste buildings[a]	15.5	163.5	120
Diesel generator building	4	79.5	40
Standby service water pump houses	12.4	37.5	62
Spray ponds	21	250	16
Turbine generator building[b]	11	192.5	159

[a] See Section 3.8.4.1.2 for a description of the portions of the radwaste and control building designed as Seismic Category I.

[b] The turbine generator building, classified as a modified non-Category I seismic structure, is dynamically analyzed and designed to withstand the effects of an SSE and maintain its structural integrity.

Table 3.7-3

Reactor Building - Seismic Analysis
Natural Frequency and Natural Period

Direction	Mode	Natural Frequency (cps)	Natural Period (sec/cycle)
Horizontal (N-S)	1	1.92	0.519
	2	3.42	0.292
	3	5.17	0.193
	4	5.88	0.170

Table 3.7-16

Lumped Representation of Soil-Structure Interaction

Motion	Equivalent Spring Constant[a]	Equivalent Damping Coefficient[a,b]
	A. For a Rectangular Foundation	
Vertical	$k_v = \frac{G}{1-\nu}\beta_v\sqrt{4cd}$	(c)
Horizontal	$k_h = 4(1+\nu)G\beta_h\sqrt{cd}$	(c)
Rocking	$k_r = \frac{G}{1-\nu}\beta_R \cdot 8cd^2$	(c)
Torsional	(c)	(c)
	B. For a Circular Foundation	
Vertical	$k_v = \frac{4GR}{1-\nu}$	$c_v = 0.85k_vR\sqrt{\rho/G}$
Horizontal	$k_h = \frac{32(1-\nu)GR}{7-8}$	$c_h = 0.575k_hR\sqrt{\rho/G}$
Rocking	$k_R = \frac{8GR^3}{3(1-\nu)}$	$c_R = \frac{0.30}{1+B_R}k_RR\sqrt{\rho/G}$
Torsional	$k_t = \frac{16GR^3}{3}$	$c_t = \frac{\sqrt{k_tI_t}}{1+2B_t}$

[a] In above formulas

2c = width of the rectangular foundation (along axis of rotation for the case of rocking)

2d = length of the rectangular foundation (in the plane of rotation for rocking)

β_v, β_h, and β_R = constants depending on the ratio d/c (See Figure 10-16, p. 351 of Reference 3.7-5)

R = radius of the circular foundation

$B_R = \frac{3(1-\nu)I_R}{8\rho R^5}$

I_R = total mass moment of inertia of structure and foundation about the rocking axis at the base

$B_T = I_T \big/ \rho R^5$

I_T = polar mass moment of inertia of structure and foundation

G = shear modulus of soil material

ν = Poisson's ratio of soil material

ρ = density of soil material

Table 3.7-16

Lumped Representation of Soil-Structure Interaction (Continued)

[b] Conservative values not exceeding those defined in Table 3.7-1 are used for the soil damping in the analytical model for soil-structure interaction.

[c] Use formulas and diagrams for an equivalent circular base with a radius determined by the following:

For translation: $R = \sqrt{\frac{4cd}{\pi}}$

For rocking: $R = \sqrt[4]{\frac{16cd^3}{3\pi}}$

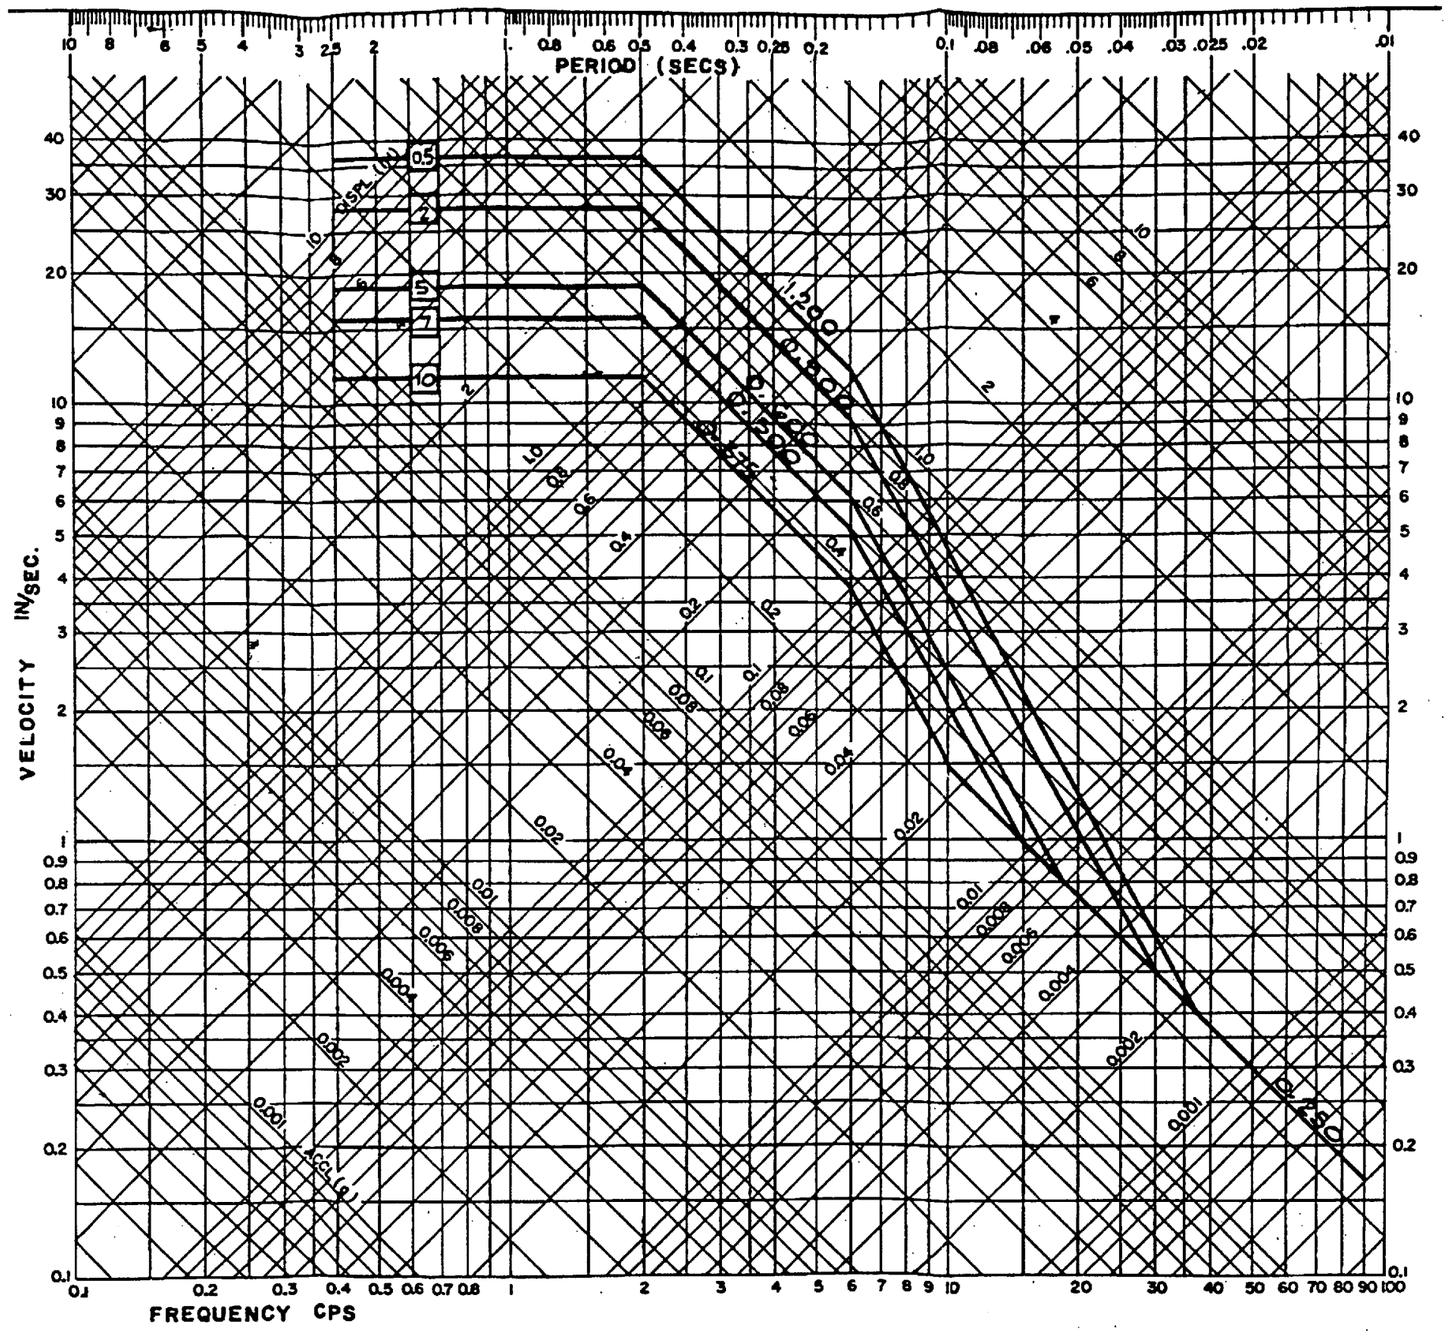
For torsion: $R = \sqrt[4]{\frac{16cd\left(c^2 + d^2\right)}{6\pi}}$

Table 3.7-17

Dynamic Response Cycles Expected During a Seismic Event for Nuclear Steam Supply Systems and Components

Number of Seismic Cycles	Frequency Bandwidth (Hz)		
	0-10	10-20	20-50
Total	168	359	643
Between 75% and 100% of peak loads (0.5% of total)	0.8	1.8	3.2
Between 50% 75% of peak loads (4.5% of total)	7.5	16.2	28.9

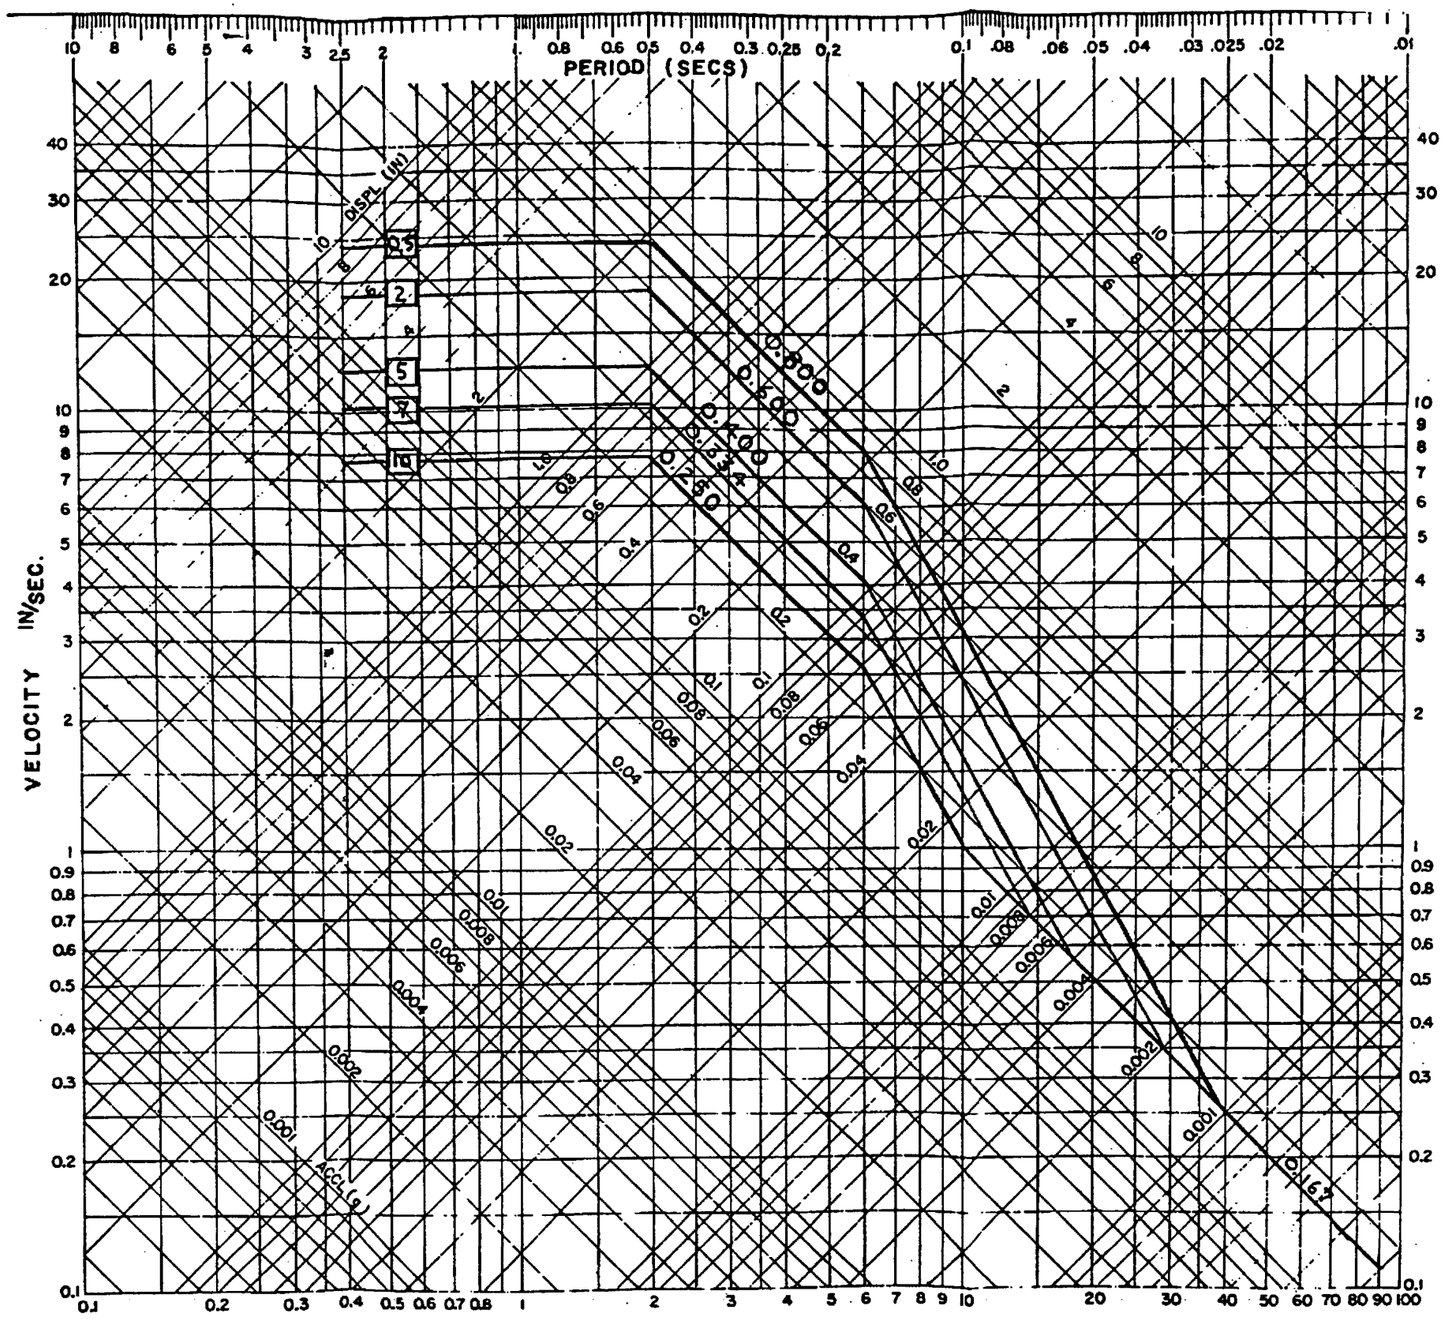
Table 3.7-18



Fatigue Evaluation Due to Seismic Load

Component	Calculated Number of Cycles at Peak Stress	Design Number of OBE Cycles at Peak Stress
1. Reactor pressure vessel		
Vessel	3	10
Shroud support	3	10
Skirt	3	10
2. Category I piping		
Recirculation lines	3	50
Steam lines	3	50

Table 3.7-19



Comparison of the Maximum and Allowable Seismic Loads
of Reactor Pressure Vessel and Internals

Location	Seismic Loads		Allowable Loads
	X-Excitation	Y-Excitation	
Top guide shear (kip)	333	292	860
Core plate shear (kip)	333	290	860
Stabilizer force (total) (kip)	1250	1250	3600
Maximum fuel moment:			
Total (in.-kip)	16,960	14,760	40,300
Per bundle (in.-kip)	22.2	19.3	52.7
Maximum shroud moment (in.-kip)	220,500	218,500	450,900
Maximum shroud shear (kip)	1030	1030	2386
Maximum vessel shirt moment (in.-kip)	204,900	170,700	2,304,000
Vessel skirt shear (kip)	1130	1100	5200

Columbia Generating Station Final Safety Analysis Report	Reactor Building-Seismic Analysis Comparison of Responses		
	Draw. No. 910402.17	Rev.	Figure 3.7-22

3.8 DESIGN OF SEISMIC CATEGORY I STRUCTURES

The nuclear steam supply system (NSSS) is housed in a steel primary containment vessel that has the ability to function as an independent structure. The primary containment vessel is housed in a reactor building also containing fuel storage and handling equipment and equipped with an overhead crane. The primary containment vessel for the NSSS is designed to confine the effects of a postulated nuclear accident and to limit the discharge of radioactive products to within levels specified in 10 CFR Part 50.67.

The Seismic Category I structures, which are part of a complex of buildings in close proximity to each other, are the reactor building, the diesel generator building, and portions of the radwaste and control building. The portions of the radwaste and control building which are Seismic Category I are the radwaste area and the control room tower. The radwaste area encompasses the foundation mat, the walls and all internal structures from the top of mat el. 437 ft to and including the reinforced-concrete slab at el. 467 ft. The control room tower consists of the vertical portion of the building encompassing the area of the control room.

The turbine generator building is a modified non-Category I seismic structure which is dynamically analyzed and designed to withstand the effects of an safe shutdown earthquake (SSE) and maintain its structural integrity thus providing adequate protection for the portions of the steam system designed as Seismic Category I, as defined in Regulatory Guide 1.29, Revision 3.

The reactor building consists of a dual barrier: the steel primary containment vessel and the reactor building which provides secondary containment. The primary containment vessel contains the drywell, suppression chamber, structural floor separating the drywell from the suppression chamber, sacrificial shield wall (SSW), and reactor pedestal. The reactor building secondary containment encloses the biological shield wall, spent fuel storage pool, dryer-separator pool, and the reactor well pool.

Seismic Category I structures that are not part of the building complex are two adjacent spray ponds, each provided with an integrally constructed standby service water pump house, and the condensate storage tank retaining area.

The major structures in the reactor building and principal dimensions are shown in Figures 3.8-1, 3.8-2, and 3.7-13. The seismic analysis methods and models used to obtain seismic loads and floor response spectra, soil/structure interaction, the damping values used, and the seismic input at the base of the buildings are discussed in Section 3.7.

Although the reactor building, radwaste and control building, diesel generator building, and turbine generator building are in close proximity to each other, they are supported on separate foundation mats. No interaction between these mats was considered. Each mat and its

superstructure was analyzed separately for soil-structure interaction due to horizontal and vertical earthquake motions.

The seismic design of the buildings was based on a parametric study for a wide range of soil properties. Thus, uncertainties in the soil properties and frequencies are adequately accounted for in the design.

Each of the Seismic Category I structures in the complex is physically separated from the other, above and below grade, in order to accommodate differential seismic displacements and thermal expansion. Abutting walls between buildings, which are separated by only a few inches, are designed to resist wind forces and tornado effects including tornado-generated missiles and pressure drop. The tornado and wind forces on roofs and external walls were computed as indicated in Section 3.3.

The seismic analysis of the reactor building included interaction between soil, foundation mat, and superstructures using lumped mass-spring, discrete models as described in Section 3.7. Conservative soil and structure damping parameters are included in the model. The response spectrum and time-history methods of analysis were used to determine the responses of the structures.

Time histories of displacements and accelerations at the top of the reactor building mat and at the lumped masses, which usually represent floor slabs, are the main output of the time-history analysis. This output was used as input for time-history analyses, as required, of the main components of the NSSS (the reactor vessel and internals) as well as to generate floor response spectra which were used in the seismic analyses and design of safety-related systems, equipment, and components housed in the Seismic Category I structures. In addition, moments and shears were obtained for comparison with results obtained from response spectrum analyses.

Response spectrum analyses were used for determining shears and moments for the final design of each of the structural components of the reactor building. These are discussed in Sections 3.8.2, 3.8.3, 3.8.4, and 3.8.5.

3.8.1 CONCRETE CONTAINMENT VESSEL (Not Applicable to CGS)

Columbia Generating Station (CGS) has a steel containment vessel (see Section 3.8.2).

3.8.2 STEEL CONTAINMENT VESSEL (ASME Class MC Components)

The capability of the primary steel containment vessel to withstand the hydrodynamic effects resulting from actuation of safety/relief valves (SRV) and specified loads associated with postulated loss-of-coolant accidents (LOCAs), and the applicable modifications were addressed in the Plant Design Assessment Report (DAR) for SRV and LOCA Loads. See Appendix 3A

which identifies the loads and effects which are most important to the design of the CGS plant and describes the CGS plant capability with respect to the hydrodynamic loading phenomena during SRV actuations and postulated LOCA events.

3.8.2.1 Description of the Primary Containment Vessel

The basic safety objective of the primary containment system is to provide the capability in the event of a postulated LOCA of limiting the release of fission products to the plant site environs so that offsite doses are in compliance with the limits specified in 10 CFR Part 50.67.

To meet the basic safety objective, several contributory objectives are achieved by the system or one or more of its components, including

a. Capability to withstand the peak transient pressures and temperatures which could occur due to postulated design basis LOCA; i.e., a mechanical failure of the reactor primary system equivalent to the circumferential rupture of one of the reactor coolant recirculation system pipes,

b. Capability to maintain the functional integrity of the primary containment indefinitely after the postulated design basis LOCA,

c. The primary containment design permits filling the primary containment system drywell with water to a level above the reactor core,

d. The primary containment system is protected against missiles from internal or external sources and excessive motion of pipes, which could directly or indirectly endanger the integrity of the primary containment,

e. Capability to withstand fluid jet forces associated with the flow from the postulated rupture of any pipe within the containment,

f. Capability of limiting leakage during and following the postulated design basis accident to values less than leakage rates which would result in offsite doses greater than the reference doses in 10 CFR Part 50.67,

g. Means of conducting the flow from postulated pipe ruptures, including the design basis rupture of a recirculation line to the pressure suppression pool, to rapidly condense the steam portions of the flow so that the peak transient pressure is less than containment design pressure, to distribute such flow uniformly throughout the pool and to limit pressure differentials between the drywell and the pressure chamber during the various postaccident cooling modes, and

h. Capability for rapid isolation of the primary containment to provide a containment barrier sufficient to maintain leakage within permissible limits.

The primary containment vessel is a free-standing steel pressure vessel. It utilizes the pressure suppression technique through the Mark II over-under configuration. The primary containment vessel and its appurtenances comply with the requirement of the ASME Code, Section III, Subsection NE-Class MC Components, 1971 Edition through Summer 1972 Addenda. It is designed to resist all normal operating loads, loads resulting from the postulated design basis accident as well as those loads associated with the operating basis earthquake (OBE) and SSE. The design also accounts for stresses induced by thermal expansion. The drywell floor which divides the drywell and suppression chamber is a reinforced-concrete slab supported by steel beams and concrete columns. The drywell floor to primary containment vessel gap is closed off by means of a floor seal shown in Figure 3.8-3. This configuration permits unrestrained expansion of the containment shell under differential thermal expansion and pressure loadings. The containment vessel is enclosed in a reinforced-concrete biological shield wall for shielding purposes and is separated from the reinforced concrete by an annulus of compressible isolation material, approximately 2 in. thick. The concrete wall thickness is governed by shielding requirements but also serves as a support for the reactor building floors. Shielding over the top of the drywell is provided by removable, segmented, reinforced-concrete shield plugs. The drywell is located directly above the wetwell. The drywell configuration is basically a frustum of a cone with removable ellipsoidal top closure head. The suppression chamber (wetwell) is cylindrical with an ellipsoidal base. The primary containment vessel is anchored to the concrete mat foundation. The bottom of the suppression chamber is lined on the inside with reinforced concrete. The concrete mat foundation under the suppression chamber is a common foundation supporting the steel primary containment vessel, including all equipment and structures therein, and the reactor building of which the primary containment vessel is a part.

The drywell floor serves as a pressure barrier between the drywell and suppression chamber. The top closure head of the drywell is bolted to a steel flange attached to the top of the containment vessel. The drywell houses the reactor vessel and its associated primary system. The primary function of the drywell is to contain the effects (i.e., mass and radiation) of a LOCA, and to direct the steam released from a primary system pipe break into the suppression chamber pool to limit the total pressure rise during a LOCA.

Under normal operating condition (normal condition) a fatigue analysis is performed in accordance with the requirements of ASME Code Section III.

Under emergency condition, the jet impingement force of 534 kips as outlined in Section 3.8.2.3 might cause local yielding of the drywell shell. An analysis (plastic analysis in accordance with the requirements of the ASME Code Section III) demonstrates that rupture will not occur. Local deformation caused by the jet impingement force does not affect the leak tightness of the containment vessel.

The analysis of the jet impingement effects on the primary containment vessel (Reference 3.8-21) is summarized as follows:

a. Phase 1 - The conical region of the containment shell was modeled and a general shell of revolution analysis was performed using the HYBOS computer program (Reference 3.8-22).

Two critical locations were chosen for independent application of the jet force. One, located approximately in the middle of two box ring stiffeners, is a logical candidate for maximum deflection; the second, located on the thinnest nearly adjacent to a stiffener, is a location where largest curvatures could occur if the shell contacts the concrete biological shield wall spaced 2 in. from the shell.

Since the impinged area (429 $in.^2$) subtends only a small arc of the total periphery, a Fourier harmonic expansion of 11 terms is used to represent the jet forces of 534 kips.

The response to gravity, static seismic, and design pressure loads were also computed. The results of the most severe combinations of the loads (Appendixes C and D of Reference 3.8-21) show that the shell will contact the concrete for either candidate jet force location; consequently the elastic analysis is not valid in the immediate area of the jet load. The largest computer stresses were found for the second location and exceeded yield; therefore, an elastic-plastic analysis was next performed for that critical region;

b. Phase II - A local finite element elastic-plastic model was analyzed using the DYPLAS computer program which is capable of treating nonlinear inelastic materials.

The boundaries of this model as shown in Figure 3.8-4 are structurally remote from the jet-impinged area, indicated by cross-hatching. The displacements from the general shell analysis, therefore, were used as displacement boundary conditions. Inelastic deformation, strains, and stresses were computed for all finite elements during selected steps of load applications; and

c. Stress evaluation was based on the ASME Boiler and Pressure Vessel (B&PV) Code, Section III, Subsection NE, Class MC Components, NE-3131.2 and Appendix F, 1974 edition.

3.1 Code Requirements

$P_m < \sigma_m$

$P_L < 1.5\ \sigma_m$

where

$\sigma m = 0.85 \times 0.7 \times S_u = 0.595\ S_u$

From Table I-1.1, for SA-516, Grade 70 Steel:

S_u - 70,000 psi at 345°F

Therefore:

σm - 41,650 psi

To meet code requirements:

$P_m < 41{,}650$ psi

$P_L < 62{,}475$ psi

3.2 Stress Evaluation

From Appendix J of Reference 3.8-21

$(P_m)max = 29{,}943$ psi $< 41{,}650$ psi

which occurs on upper edge of model (Figure 3.8-4)

$(P_L)max = 36{,}305$ psi $< 62{,}475$ psi

which occurs on the lower portion of the impinged region (Figure 3.8-4)

Therefore code requirements are met.

The ductility ratio is defined as the maximum response of an elasto-plastic structure to a prescribed loading function divided by the response of the same structure to the load at incipient plasticity. The maximum radial displacement at incipient plasticity was computed and is shown in computer Appendix I to Reference 3.8-21 as 0.4335 in. The maximum radial deflection of 2.0 in. was the spacing between shell and shield.

Thus the ductility ratio might be considered to be

$$2.00/0.4335 = 4.6$$

However, since the maximum deflection of the shell is limited by contact with the concrete of the biological shield; the ductility ratio here may not be as meaningful a design parameter as it is in other cases.

A more significant measure of structural integrity against cracking and ultimate leakage may be the most severe local principal cumulative strain.

The most severely strained metal lies on the outside surface of the vessel shell near node 67 as shown in Figure 3.8-4. This strain is the maximum inelastic cumulative strain based on a computed nonlinear strain distribution through the vessel wall. Its value is 4%.

Figure 3.8-5 shows the minimum elongation to failure of ASTM A516 Grade 70 steel as a function of temperature. Over the range of 70°F to 350°F this has a least value of 14.8%.

An estimate of the factor of safety may then be said to be

$$\text{F. S.} = \frac{14.8}{4.0} = 3.7$$

Although failure strains in complex strain fields do not correlate precisely with results of one-dimensional ductility tests, the factor of safety, as computed above, is deemed ample.

The criteria used in the seismic design of the containment system is based on the responses of the containment system to earthquake excitation. The responses are derived from the analysis of a mathematical model developed to represent the containment vessel. Section 3.7 outlines methods of analysis, modeling techniques, the seismic input, and the soil-structure interaction effects.

All ferrous materials of plates, forgings, castings, and pipes for ASME Code, Class MC with thickness greater than 5/8 in. are Charpy V-notch impact tested at 0°F in accordance with the ASME Code, Section III, Paragraph NE-2300. Materials for ASME Code, Class 1 components are impact tested in accordance with NB-2300. The drywell will not be pressurized or subjected to substantial stress at temperatures below 30°F.

The principal containment design parameters are listed in Table 3.8-1.

The physical dimensions of the steel primary containment vessel are

a. The diameter of the cylindrical portion at the base of the cone is approximately 86 ft,

b. The diameter at the top of the cone is approximately 39.5 ft and then narrows to 32 ft to carry the removable head,

c. Ellipsoidal bottom head with a ratio of 2:1 has an inside height of approximately 21.5 ft,

d. The removable ellipsoidal top closure head has an inside height of approximately 15.5 ft,

e. The drywell shell height is approximately 99 ft,

f. The suppression chamber shell height is approximately 72 ft, and

g. Overall shell height is approximately 171 ft.

The primary containment vessel shell plate thicknesses vary. Typical thicknesses are as follows:

a. Bottom ellipsoidal head: from 7/8 in. to 1.5 in.,
b. The suppression chamber cylinder: from 1-5/16 in. to 1.5 in.,
c. The drywell conical section: from 0.75 in. to 1.5 in., and
d. The removable top ellipsoidal head: 15/16 in.

Material thicknesses meet requirements of the ASME Code Section III, Paragraphs NE-3133 and NE-3324.

The primary containment vessel is reinforced with internal vertical and horizontal stiffeners to satisfy design requirements of the various loading combinations and conditions. Fully circumferential rings, attached to the inside face of the primary containment vessel are furnished at el. 516 ft 6 in. and 542 ft 7.25 in. The basic function of these rings is to support pipe whip protection framework and to adequately distribute pipe whip loading into the vessel.

The method used to ensure that there is an adequate clearance between the steel primary containment vessel and the concrete biological shield wall and which will account for differential thermal expansion is illustrated in Figure 3.8-2 and described as follows:

a. A system consisting of approximately 2-in.-thick polyurethane flexible foam sheets, butted at their joints and cemented directly to the containment shell, is

used. The exterior surface sealed with laminated fiberglass reinforced polyester, epoxy jointed, panels which are bonded to the polyurethane sheets;

b. Steel anchor fasteners are attached to the fiberglass reinforced polyester panels, and used for anchoring the inner end of the form ties which extend to the forms on the outside face of the concrete biological shield wall. These fasteners are mounted on the fiberglass reinforced plastic prior to bonding of the flexible foam;

c. The fiberglass panel joints are taped and filled with epoxy so that the entire assembly forms a shell around the containment vessel with the polyurethane material set against and bonded panels thereby are permanent inner forms for the pouring of the concrete structure;

d. Drywell penetrations which extend from the containment vessel shell through the concrete biological wall, are surrounded with concentric sleeves. These pipe sleeves are joined to the fiberglass shell using fiberglass tape and epoxy resins. This technique similarly provides a form for the concrete and maintains adequate clearance between the penetrations and the sleeves to accommodate thermal expansion;

e. The polyurethane foam material is chosen for its resistance to the environmental conditions likely to exist during its service life. Although normal inservice temperature ranges from 95°F to 135°F (average) and 150°F (local), the polyurethane which is used is capable of withstanding temperatures in excess of the LOCA temperature of 340°F. Furthermore, this material is self extinguishing in accordance with ASTM D-1692;

f. The sizing of the expansion gap in which the foam sheet is placed is based on an ultimate steel shell temperature of 340°F and an internal pressure of 45 psig following a postulated reactor LOCA. The external compressive stress applied to the containment vessel by the polyurethane foam, due to vessel thermal expansion from ambient conditions, ranges from 1.2 to 1.5 psi at normal operating and LOCA temperatures. At these temperatures the stress-strain curve for the polyurethane foam is nearly linear between 5% and 60% compression, ranging from approximately 1.2 psi at 5% compression to 1.8 psi at 60% compression. These properties are not significantly affected by the level of radiation exposure received over the plant life; and

g. The above design, materials, and construction of the containment vessel expansion gap provides sufficient space for thermal expansion of the steel containment vessel shell. Moreover, this method of construction prevents either concrete or other foreign material from entering and/or reducing the gap. Local

stress areas are thereby prevented, and the primary containment system is capable of accommodating both normal operating as well as postulate accident conditions.

The steel primary containment vessel, including all penetrations and welded attachments, is designed to act as a structural component within the reactor building as described in Section 3.8.2.4. The general configuration, and elevations are shown in Figures 3.8-1 and 3.8-2. The primary containment vessel is provided with two concentric circular skirts on the bottom ellipsoidal head integral with the vessel. The skirts are anchor bolted to the concrete foundation mat. The bottom ellipsoidal head and the upper portion of the skirts connected to the head are considered part of containment pressure boundary in accordance with the ASME Code Section III. The lower portion of the skirts follow the requirements of the American Institute of Steel Construction (AISC) Code. The skirts are backed up by concrete fill. The concrete fill and the concrete foundation mat discussed in Section 3.8.5 are not part of the containment vessel.

3.8.2.1.1 Description of Penetrations

Penetrations through the primary containment vessel are as follows.

3.8.2.1.1.1 Pipe Penetrations. Two general types of pipe penetrations are provided. The two types differ depending on whether the penetration is subject to a hot or cold operational environment. The cold penetrations pass through the steel primary containment vessel and are welded directly to it. The piping is normally welded directly to the penetration nozzles. The piping design includes the effects of thermal motion of the containment shell at the penetration connections.

The hot penetrations and multiple piping penetrations do not come in direct contact with the steel shell of the primary containment vessel. These penetrations pass through vessel shell nozzles which are welded to the steel shell of the primary containment vessel and function as thermal sleeves. Containment closure is accomplished by means of closure plates or flued head fittings, welded to the penetration nozzle and the piping at a suitable distance outside the containment shell. Detailed descriptions of pipe penetrations are given in Section 3.8.6.

3.8.2.1.1.2 Electrical Penetrations. Containment electrical penetrations are designed to safely accommodate all of the electrical requirements within the containment boundary. These are functionally grouped into low voltage power and control cable penetrations assemblies, medium voltage power cable penetration assemblies, signal cable penetration assemblies and thermocouple cable penetration assemblies. The medium voltage power cable electrical penetrations are canister type assemblies sized to be inserted into the containment vessel penetration nozzles. All other electrical penetrations are a unitized header plate assembly attached to the outboard end of the containment vessel penetration nozzles. Detailed descriptions of electrical penetrations are given in Section 3.8.6.

3.8.2.1.1.3 Traversing In-Core Probe Penetrations. Five traversing in-core probe (TIP) guide tubes pass from the reactor building to the drywell through the primary containment vessel. The penetrations are a Type 2 (see Section 3.8.6.1.2) piping penetration modified with a welding neck flange attached outside the containment. This flange is itself modified with dual concentric O-ring grooves machined into the face, which retain elastomeric O-rings. To this is bolted a blank flange which has been drilled for both a between-O-ring test port and a central hole in which an instrument tubing "bulkhead union" fitting is retained. This single penetration point is sealed by seal welding between the bulkhead union and the blank flange. The TIP guide tubes are attached to both sides of their respective bulkhead unions by flare fittings. These penetrations are also discussed in Section 3.8.6.1.2.

3.8.2.1.1.4 Personnel Access Lock and the (Combined) Equipment Hatch and Control Rod Drive Removal Hatch. The drywell has one manually operated personnel air lock. This air lock consists of a cylindrical shell with two doors, one at each end of the shell. The cylindrical shell is approximately 8 ft 10.5 in. in diameter which is sufficient to provide 6 ft 8 in. high by 3 ft 4 in. wide door openings above the floor. The minimum clear horizontal distance not impaired by the door swing is 5 ft. Each door has double compressible seals with an air space between them so that each door may be individually tested. Each door is hinged and swings toward the drywell.

The air lock doors are designed so as to permit either door to be operated from inside the drywell, inside the air lock, or outside the drywell. In addition, the air lock doors are interlocked to ensure that at least one door is locked when primary containment integrity is required. Signals and controls indicating the status of the doors are provided locally. The locking mechanisms are designed so that tight seals are maintained when the doors are subject to either the design internal or external pressure. A mechanical override is provided to permit temporary bypassing of the door interlock system to permit opening both doors under proper authorization. Quick acting equalizer valves are provided to equalize the pressure in the air lock when personnel enter or leave the primary containment vessel.

The drywell has one equipment removal hatch. The equipment hatch cover is dished and has steel stiffeners. The hatch cover is bolted to a flanged steel sleeve welded to the primary containment vessel shell such that the hatch cover can be removed and reinstalled from outside the drywell. The equipment hatch and cover is entirely supported by the steel containment vessel. Double compressible seals with an air space between them are used to permit leak testing at any time. The inside diameter of the equipment hatch is approximately 12 ft 6 in. which provides a minimum clearance above the floor at the hatch of 10 ft 1.5 in. high by 7 ft 0 in. wide.

Included within the equipment hatch cover is a control rod drive (CRD) removal hatch with its hinged cover. This hatch is provided with leak-testable, double-gasketed seals. The inside

diameter of this hatch is approximately 1 ft 11 in. in diameter which provides a minimum clearance of 11 in. high by 1 ft 4 in. wide at the hatch.

The personnel access lock and the equipment hatch extend radially outward across the annular gap of compressible isolation material and through the biological shield wall and are supported by the primary containment vessel only.

Both the personnel air lock and the equipment removal hatch are designed to withstand the normal environmental conditions which may prevail during normal plant operation and to maintain their functional integrity during a postulated LOCA. The design meets the requirements of the ASME Code Section III, Subsection NE, Class MC Components.

3.8.2.1.1.5 Pressure Suppression Chamber Access Hatch. Access to the pressure suppression chamber is provided at one location in the cylindrical well of the chamber approximately 7 ft 6 in. above the suppression pool operating water level. This access hatch is approximately 3 ft 5 in. in diameter, extends radially outward, is supported by the vessel and has a leak-testable, double-gasketed, bolted cover which is normally closed and is opened only when primary containment is not required. The minimum clearance at the hatch is 2 ft 2.75 in. wide by 2 ft 5.5 in. high. The design meets the requirements of the ASME Code Section III, Subsection NE, Class MC Components.

3.8.2.1.1.6 Access for Refueling Operations. The drywell containment head is removed during refueling operations. This head is held in place by bolts and is sealed with a double seal. It is bolted closed when primary containment is required and is opened only when primary containment is not required. The gasket seal is capable of limiting the leakage to below the design rate and is capable of being independently tested.

3.8.2.1.2 Description of Crane Girder (Not Applicable to CGS)

CGS does not have a crane girder inside containment.

3.8.2.1.3 Description of Vacuum Relief System

See Figure 9.4-8 for an illustration of the vacuum relief system described below.

Three 24-in. reactor building-to-wetwell vacuum relief lines, each containing a 24-in. vacuum breaker valve and an automatic air-operated butterfly valve, are provided between the reactor building and the suppression chamber. These valves prevent excessive vacuum from developing in the primary containment vessel from such causes as inadvertent containment spray actuation.

Each butterfly valve is equipped with a spring-to-open, air-to-close operator which, during normal plant operation is maintained in a closed position by means of a control air supply

through a three-way solenoid pilot valve. The plant control air supply to the valve is backed up by a Quality Class I air supply system, consisting of an accumulator pressurized by the plant control air system and an independent 10 nitrogen bottle manifold located in the vehicle air lock (railroad bay) which will automatically maintain accumulator pressure on loss of air supply from the control air system (see Figure 3.8-7). On venting of air from the air-operators, the spring- actuated butterfly valves open. Venting is accomplished through remote manual deenergization of the solenoid pilot valve or by a signal from the differential pressure switch which deenergizes the solenoid pilot valve when the secondary containment atmospheric pressure is more than 0.5 psi higher (analytical limit) than the suppression chamber atmospheric pressure.

Two limit switches, wired to indicator lights in the control room, are provided with each butterfly valve for position indication. One switch actuates when the valve is fully open and provides an alarm and "open" visual indication in the control room. The other switch actuates when the valve is fully closed and provides a "closed" visual indication in the control room (see Figure 3.8-8).

In series with each butterfly valve is a single disk check valve. The disk is maintained in the closed position during normal operation by means of a spring-actuated lever arm and magnets embedded in the periphery of the disk. The magnetic and spring forces are overcome, and the disk opens when the pressure differential across the valve is within the range of 0.10 to 0.35 psi. The disk is fully open when the pressure difference is 0.5 psi. In addition, pneumatic actuators are provided for remote operation of the disk. Compressed air is supplied by the plant control air system through the pneumatic operator Quality Class I accumulator and backup nitrogen supply as shown in Figure 3.8-7. Each disk pneumatic operator consists of two air cylinders, one to open and one to close the disk. Each air cylinder is actuated through energization of a three-way solenoid pilot valve. The two solenoid pilot valves associated with each disk are operated by a remote manual switch in the control room. During normal operation the remote manual switches are in the neutral position and the solenoids are deenergized. Each valve disk is provided with contact probe sensors for position indication. These sensors are wired to indicator lights in the control room to provide open and closed position indication. An additional sensor is also wired to a light in the control room that indicates when the disk is fully open.

Each reactor building to wetwell vacuum breaker is visually inspected at least once every 30 months.

Nine 24-in. wetwell-to-drywell vacuum relief valves attached to the downcomers in the suppression chamber are provided to return noncondensables from the wetwell to the drywell to prevent too large an upward pressure differential across the diaphragm floor after a LOCA.

Each wetwell-to-drywell vacuum relief valve assembly consists of two discs and seats which operate independently. The operation, controls, and position indication for each disc is as

described above for the single disc check valves. During normal plant operation the control air supply line to these valve assemblies is isolated. Also, residual pressure is vented from the line following vacuum relief valve testing to prevent inadvertent valve opening.

The vacuum breaker valves are sized to ensure that following design conditions are not exceeded.

a. The drywell internal design pressure of 2.0 psi below reactor building pressure,

b. The suppression chamber internal design pressure of 2.0 psi below reactor building pressure, and

c. The upward design pressure difference across the diaphragm floor of 6.4 psi.

The design evaluation for the vacuum relief is discussed in Section 6.2.1.1.4.

The vacuum relief valves are constructed to ASME Section III, Subsection NC for Class 2 components, 1974 Edition through the Summer 1975 Addenda.

Electrical systems associated with the control and position indication for the reactor building to wetwell vacuum breaker valves and the drywell-to-wetwell vacuum breaker valves are not Class 1E since electrical failure or malfunction will not prevent operation or cause inadvertent actuation under postulated accident conditions.

3.8.2.1.4 Containment Pressure Boundaries

The primary containment pressure boundaries for the steel primary containment vessel consist of those defined in Subarticle NE-1130 of the ASME Code Section III and the additional boundaries listed in the following:

a. The steel primary containment vessel shell including the top and bottom heads, and, as defined in the ASME Code Section III, Paragraphs NE-3364 and NE-4431, an upper portion of the skirts supporting the vessel, and

b. The attachment welds fastening pipe whip protection support rings, beam supports, and pads to the vessel for purposes of supporting piping support members, walkways, platforms, monorails, brackets, or other members to the containment vessel.

3.8.2.1.5 Primary Containment Environmental Conditions

The primary containment is designed to operate during all environmental conditions found in Section 3.11. See Table 3.8-2 for specific design conditions.

3.8.2.2 Applicable Codes, Standards, Specifications, and Regulatory Guides

3.8.2.2.1 Codes, Standards, and Specifications

The following describe the applicable codes, standards, specifications, code classification, and code compliance for the steel primary containment vessel.

a. The following sections of the ASME B&PV Code, 1971 Edition, including all addenda through Summer 1972 apply for the steel primary containment vessel.

   Section II, Material Specifications
   Part A - Ferrous
   Part B - Welding Filler Metals

   Section III, Nuclear Power Plant Components
   Subsection NE, Class MC Components
   Section V, Nondestructive Examination
   Section IX, Welding Qualifications;

b. The AISC Specification for the Design, Fabrication, and Erection of Structural Steel for Buildings, February 12, 1969, applies for the steel construction beyond the boundaries established for the steel containment vessel;

c. Steel Structures Painting Manual, Volume 2, Systems and Specifications, 1964 Edition with the 1968 Supplement and the January 1971 Editorial changes.

   Specification SSPC-SP-6, SP-8 and SP-10;

d. Applicable ASTM and AWS Material Standard Specifications permitted by Article NE-2000 of III;

e. Applicable ASTM Standard Specifications for nondestructive methods of examination referenced in Article X-3000 of Section III of the ASME Code;

f. Plant Design Specification 2808-213; and

g. National Electrical Code.

3.8.2.2.2 Code Classification

The steel primary containment vessel is classified Class MC in accordance with Subarticle NA-2130, Section III of the ASME Code, 1971 Edition through the Summer 1972 Addenda.

3.8.2.2.3 Code Compliance

3.8.2.2.3.1 Containment Vessel. The steel shell and the top and bottom heads of the steel primary containment vessel, including all penetrations and attachments within the boundaries defined in Section 3.8.2.1.4, are designed and constructed in accordance with Subsection NE, Class MC Components, including the requirements for quality assurance of the Article NA-4000, and inspection requirements of Article NA-5000 of Section III of the ASME Code.

3.8.2.2.3.2 Code Stamp. The steel primary containment vessel is ASME Code stamped in accordance with requirements of the Code applicable to Class MC containment vessels.

3.8.2.2.3.3 Exceptions. No exceptions are taken to the requirements of Section III of the ASME Code for Class MC containment vessels.

3.8.2.2.3.4 Attachments. Structural steel attachments beyond the boundaries established for the steel primary containment vessel are designed and constructed according to the AISC Specification for the Design, Fabrication, and Erection of Structural Steel for Building, February 12, 1969, where applicable. Nonpressure vessel elements such as catwalks and interior beam connections with hatch floors are designed in accordance with the AISC Code. Stress intensity limits are in accordance with the allowable permitted by the AISC Code with the exception that, for loading combinations including OBE, no increase in allowable stress will be permitted.

The inner and outer skirts for the support of the primary containment vessel are designed in accordance with Subarticle NE-3100 of Section III of the ASME Code.

Supports for pipe whip guide rings are designed as described in Section 3.6.

3.8.2.2.4 Regulatory Guides

The following regulatory guides related to the primary containment vessel are applicable to CGS. Their implementation is discussed in Section 1.8.

a. Regulatory Guide 1.7, Rev. 1 - Control of Combustible Gas Concentrations in Containment Following a LOCA,

b. Regulatory Guide 1.11, Rev. 0 - Instrument Lines Penetrating Primary Reactor Containment,

c. Regulatory Guide 1.28, Rev. 0 - Quality Assurance Requirements (Design and Construction),

d. Regulatory Guide 1.29, Rev. 3 - Seismic Design Classification,

e. Regulatory Guide 1.46, Rev. 0 - Protection Against Pipe Whip Inside Containment,

f. Regulatory Guide 1.57, Rev. 0 - Design Limits and Loading Combinations for Metal Primary Containment System Components,

g. Regulatory Guide 1.63, Rev. 0 - Electric Penetration Assemblies in Containment Structures for Water-Cooled Nuclear Power Plants,

h. Regulatory Guide 1.84 - Code Case Acceptability - ASME Section III Design and Fabrication, and

i. Regulatory Guide 1.85 - Code Case Acceptability - ASME Section III Materials.

3.8.2.3 Loads and Loading Combinations

The primary containment vessel is designed to withstand forces due to

a. Dead load, including permanent equipment loads and hydrostatic loads,

b. Live loads, including movable equipment loads and other loads varying in intensity and occurrence,

c. Thermal effects and loads during startup, normal operating, and shutdown conditions, based on the most critical transient or steady-state conditions,

d. Earthquakes,

e. Wind during construction, and

f. Pressure and temperature effects, jet impingement, and missile impact all due to pipe break accident.

The vessel design includes analyses in the vicinity of the primary containment vessel penetrations for the penetration load combinations given in Section 3.8.6.3.

3.8.2.3.1 Design Pressures and Temperatures

a. Pressure suppression chamber

1.	Internal design pressure (LOCA pressure)	45 psig

	2.	External design pressure (due to negative internal pressure)	2.0 psig
	3.	Design temperature	275°F
b.	Drywell		
	1.	Internal design pressure (LOCA pressure)	45 psig
	2.	External design pressure (due to negative internal pressure)	2.0 psig
	3.	Design temperature	340°F

c.	Pressure suppression chamber and drywell		
	1.	Pneumatic over pressure test (115% of 45 psig)	51.8 psig at ambient temperature
	2.	Initial leak rate test leakage rate of 0.5% of air per any 24 hour period	Maximum permitted total weight of contained at 38 psig test pressure.
d.	Differential design pressure (downward on drywell floor following a LOCA)		25 psid
e.	Differential design pressure (upward on drywell floor following a LOCA)		6.4 psid
f.	Lowest service metal temperature		30°F

3.8.2.3.2 Operating Pressure and Temperature

See Table 3.8-1 for normal operating pressures and temperatures.

3.8.2.3.3 Dead Loads

The following dead loads are transmitted directly through the concrete fill inside the bottom head of the primary containment vessel, through the continuous concrete fill directly under the bottom head and then into the reactor building foundation mat:

a. Concrete fill inside the bottom head of the primary containment vessel,

b. Concrete columns in the suppression chamber and contributory portion of the drywell floor supported by the columns,

c. Contained air in the suppression chamber,

d. Water in the suppression chamber, and

e. Reactor vessel pedestal, reactor pressure vessel (RPV), SSW, and contributory portion of the concrete drywell floor supported by the pedestal.

The following are typical dead loads used in the design of the primary containment vessel:

a. Vessel and appurtenances,

b. Water in the suppression chamber with coincident hydrostatic pressure,

c. Attached equipment and supports, catwalks, platforms and attached piping, air ducts, electrical ducts, conduit and trays,

d. Header loads,

e. Contained air, under test conditions,

f. Weight of the gap filler material applied to the outside face of the shell (used 5 psf.),

g. Design load on welding ring pads of 1500 lb per lineal foot acting in any direction. Welding ring pads are in the drywell and are used for attaching pipe and duct hangers, hoist supports, etc. These pads are welded parallel to the containment vessel surface,

h. Stabilizer truss,

i. Construction dead loads, e.g., scaffolds, and

j. Water in the drywell with coincident hydrostatic pressure, under the flooded condition.

3.8.2.3.4 Live Loads

The following are typical live loads used in the design of the primary containment vessel:

a. Live loads on the drywell floor, platforms and catwalks discussed in Sections 3.8.3.1.3 and 3.8.3.1.4,

b. Monorail live and impact loads,

c. Live loads on floor section of personnel air lock (300 psf), equipment access hatch (1000 psf), and suppression chamber access (150 psf),

d. Live load on temporary construction scaffolds,

e. Operating weight of fluid in attached normally empty piping, headers and penetrations,

f. Head of water, 23 ft 6 in. high, on the refueling bellows seal with the containment vessel head removed and coincident hydrostatic pressure (under the refueling condition), and

g. Same as Section 3.8.2.3.4(f) above except without the containment vessel head removed (under the flooded condition).

3.8.2.3.5 Mechanical Piping Loads

Mechanical piping loads consist of

a. Piping reactions during normal operating or shutdown conditions, based on the most critical transient or steady-state condition,

b. Pipe reactions under thermal conditions generated by a postulated break and including (a) above,

c. Equivalent static load generated by the reaction of a broken high-energy pipe during a postulated break (and including an appropriate dynamic load factor to account for the dynamic nature of the load),

d. Jet impingement equivalent static load generated by the design-basis accident (DBA) postulated break (and including an appropriate dynamic load factor to account for the dynamic nature of the load), and

e. Pipe reactions and thermal conditions during an event causing external pressure.

A description of certain loads included among those listed above follows:

3.8.2.3.5.1 Jet Forces in Drywell. The drywell shell, personnel air lock, equipment hatch, jet deflectors, and the removable top closure head are designed and constructed to withstand, in combination with other loads, jet forces consisting of either steam and/or water at 340°F and applied as follows:

	Jet Force (kips)	Area Subjected (in^2)
From the closure head flange to the top of the head	33	26
From the closure head flange down to the drywell floor	534	429

A jet force is considered to occur in any direction but is not considered to occur simultaneously with another jet force; however, a jet force is considered to occur coincident with the drywell internal design pressure of 45 psig and design temperature of 340°F. Local yielding may take place on the drywell shell from the jet force, but the shell will not rupture. On the top closure head and other areas, where the shell is not backed up by concrete, the primary stresses resulting from this combination of loads do not exceed the values specified in the ASME Code Section III, Paragraph NE-3131(c) at a temperature of 340°F.

3.8.2.3.5.2 Vent Pipe (Downcomer) Thrusts. The vent pipes (downcomers) and their connections to the drywell floor are designed for the following loads:

a. Jet blowdown thrust

A jet force of 20,000 lb acting upward on each of the downcomers is considered to occur simultaneously with an internal design pressure of 20 psig and a design temperature of 275°F;

b. Initial and final test conditions

A force equal to 1.25 times the design pressure multiplied by the flow area of the vent pipe; and

c. Accident conditions

Forces obtained from Section 3.8.2.3.5.2 (a) except that the temperature in the drywell is taken as 340°F and the temperature in the suppression chamber is taken as 275°F. The drywell floor concrete temperature is taken as 95°F.

3.8.2.3.5.3 Pipe Whip. Pipe whip protection support rings, which are fully circumferential rings, are attached to the primary containment vessel at el. 516 ft 6 in. and 542 ft 7.25 in. The basic function of these rings is to support pipe whip protection framework and to adequately distribute pipe whip loading into the vessel.

The pipe rupture loading is applied to the vessel through the support rings during normal operating conditions at normal operating temperature and at atmospheric pressure, as well as during an incident condition at maximum temperature of 340°F and at design pressure. The primary containment vessel analysis include the effects of a pipe rupture at any single location. For further discussion on function and design of load transmitting members see Section 3.6.

3.8.2.3.6 Thermal Loads

The thermal loads in the primary containment vessel steel are produced by the presence of temperature gradients within the containment and its appurtenances. Thermal effects and loads during normal operating conditions are based on the most critical transient or steady-state condition. Thermal loads are also considered under thermal conditions generated by a postulated pipe break.

3.8.2.3.7 Construction Loads

a. Wind load in the projected area of the steel primary containment vessel before the completion of the reactor building in accordance with Reference 3.8-1, with a basic wind of 100 mph as discussed in Section 3.3, and

b. Snow loads before the completion of the reactor building.

3.8.2.3.8 Missile Loads

There are no external missile loads considered since the primary containment vessel is protected by the biological shield wall. Potential internal missiles and protection provisions are discussed in Section 3.5.

3.8.2.3.9 Loss-of-Coolant Accident Loads

The LOCA imposes pressure and thermal loads plus jet forces associated with coolant flow from any ruptured pipe within the containment. This LOCA loading condition is determined

by analysis of the transient pressure and temperature effects which occur during a LOCA. The governing design condition for the LOCA is discussed in Section 6.2.

3.8.2.3.10 Accident Recovery Loads

Among the postulated LOCAs there may be an accident within the drywell that requires a contingency flooding of the pressure suppression chamber and the drywell to an elevation above the top of the active fuel zone in the reactor vessel as indicated in Section 3.8.2.3.12h; and, with the primary containment vessel head not removed, the reactor vessel cavity outside the primary containment vessel and above the refueling bellows seal flooded to a level above the refueling bellows seal noted in Section 3.8.2.3.12.

The structural design criteria for the primary containment vessel are consistent with the provisions of Regulatory Guide 1.57, Revision 0 (issued June 1973) except with respect to the stress limits specified in Section C-1-b (2) of the guide for the load combinations of accident recovery flooding plus OBE.

For the flooded condition loading combination described in Section 3.8.2.3.12h, the various stress categories shown in ASME Code Section III, Figure NB 3222-1 are satisfied, using allowable primary general membrane stress intensities specified in the ASME Code Section III paragraph NE 3131(c)(1) and NE 3131(c)(2).

The stress limits for the primary containment vessel for the accident recovery flooding plus OBE load condition are shown in Section 3.8.2.5.3. Justification for these stress limits, which are higher than those outlined in Regulatory Guide 1.57 is based on the extremely low probability that flooding would ever be required.

3.8.2.3.11 Seismic Loads

Equivalent static loads are developed through a dynamic analysis of Seismic Category I structures subjected to the OBE and the SSE.

3.8.2.3.12 Loading Combinations

The loading combinations considered in the design of the steel primary containment vessel apply to both the drywell and suppression chamber, unless otherwise noted, and include the following typical loads:

a. Initial proof load test condition (at ambient temperature)

This is a normal condition.

1. Dead load

(a) Vessel and appurtenances,

(b) Water in suppression chamber with coincident hydrostatic pressure,

(c) Concrete drywell floor,

(d) Catwalks and platforms,

(e) Contained air, and

(f) Header loads, empty;

2. Live Loads

(a) On drywell floor, and
(b) On catwalks and platforms;

3. Design pressure, internal, in suppression chamber;

4. Test pressure, internal in the drywell;

5. Lateral wind or OBE, horizontal and vertical, whichever is more severe; and

6. Jet blowdown thrusts in the suppression chamber taken at columns, reactor pedestal and penetrations;

b. Final proof load test condition (at ambient temperature)

This is a normal condition.

1. Dead load

Same items as in item a.1, plus:

(a) Drywell equipment, supports, platforms, and attached empty pipe and headers,

(b) Gap fill material, and

(c) Piping, ducts, hoist support loads, etc., on welding ring pads in drywell described in Section 3.8.2.3.3.h.

2. Live load

Same items as in item a.2;

3. Design pressure, internal (drywell and suppression chamber);

4. External pressure of 2 psi (consists of 2 psig restraint due to filler material);

5. Seismic OBE, horizontal, and vertical;

6. Jet blowdown thrusts in suppression chamber (same as item a.6); and

7. Drywell refueling bellows seal loads, namely, the effects of the spring action of refueling bellows seal onto the containment vessel;

c. Normal operating condition (at atmospheric pressure and at operating temperature ranging from 50°F to values specified in Table 3.8-1).

This is a normal condition with OBE and is in conformity with ASME Code, Section III, Paragraph NE-3131(c)(1) or (c)(2) with SSE.

1. Dead load

(a) Vessel and appurtenances,

(b) Water in suppression chamber and coincident hydrostatic pressure,

(c) Concrete drywell floor,

(d) Catwalks in suppression chamber,

(e) Drywell equipment, supports, platforms and attached pipes, headers, air ducts, electrical ducts, conduits, and trays,

(f) Gap filler material, and

(g) Loads on welding ring pads (same as in item b.1);

2. Live load

   (a) On drywell floor,

   (b) On catwalks and platforms,

   (c) Personnel and equipment access openings in the drywell and on personnel access openings in suppression chamber, and

   (d) Operating weight of fluid in normally empty piping and penetrations;

3. External pressure of 2 psi (same as in item b.4);

4. Seismic OBE or SSE, horizontal and vertical, including seismic loads from shear lugs between the drywell floor and the containment vessel and seismic loads from the reactor vessel stabilizers;

5. Jet blowdown thrusts in suppression chamber (same as in item a.6);

6. Drywell refueling bellows seal loads;

7. Drywell floor seal loads; and

8. Thermal loads described in Section 3.8.2.3.6

d. Refueling condition (with containment vessel head removed, at atmospheric pressure and at operating temperature ranging from 50°F to values specified in Table 3.8-1).

This is a normal condition.

1. Dead load

   Same as in item c.1;

2. Live load

   Same items as in item c.2 plus water load due to 23 ft 6 in. head of water on the refueling bellows seal, at the top flange of the drywell, with coincident hydrostatic pressure;

3. External pressure of 2 psi (same as in item b.4);

4. Seismic OBE, horizontal and vertical;

5. Drywell refueling bellows seal loads;

6. Drywell floor seal loads, namely, the effects of spring action on floor seal on to the containment vessel; and

7. Thermal loads described in Section 3.8.2.3.6;

e. Accident condition (at drywell maximum temperature of 340°F and suppression chamber maximum temperature of 275°F). This is a normal condition with SSE in conformance with ASME Code Section III, Paragraph NE 3131(c), or with OBE.

1. Dead load

Same items as in item c.1;

2. Live load

(a) On drywell floor,

(b) On catwalks and platforms, and

(c) Operating fluid weight in normally empty piping and penetrations;

3. Internal design pressure in drywell of 45 psig decaying to a negative pressure of 2 psig at 135°F;

4. Internal design pressure in suppression chamber of 45 psig decaying to a negative pressure of 2 psig at 275°F;

5. External pressure of 2 psi (same as in item b.4);

6. Seismic OBE or SSE, horizontal and vertical, including seismic loads from shear lugs between the drywell floor and the containment vessel, and seismic loads from the reactor vessel stabilizer;

7. Jet blowdown thrusts in suppression chamber (same as in item a.6);

8. Jet forces on drywell shell, personnel air lock, equipment hatch, drywell floor, jet deflectors on the drywell floor over the downcomers and at the floor periphery, and the head of the containment vessel. See Section 3.8.2.3.5.1;

9. Drywell refueling bellows seal loads;

10. Drywell floor seal loads;

11. Effects of header jet nozzle loads; and

12. Thermal loads described in Section 3.8.2.3.6;

f. Accident condition with pipe whip (at drywell maximum temperature of 340°F and suppression chamber temperature of 275°F).

This condition includes pipe whip support load effects onto the containment vessel shell.

Loads are the same as those in item e, with the addition of loads on pipe whip support rings due to main steam or reactor feedwater pipe ruptures;

g. Normal condition with pipe whip (at atmospheric pressure and at operating temperature ranging from 50°F to values specified in Table 3.8-1).

Earthquakes used are OBE or SSE. Stresses are in conformance with ASME Code, Section III, Paragraph NE-3131(c)(1) or (c)(2).

Loads are the same as those in item c, with the addition of loads on pipe whip support rings due to main steam or reactor feedwater pipe ruptures;

h. Flooded Condition (with drywell flooded to el. 552 ft 0 in., which is approximately 1 ft above the top of the active fuel zone in the reactor vessel, suppression chamber and downcomer vent system flooded; and, with the containment vessel head not removed, reactor vessel cavity outside the containment vessel and above the refueling bellows seal flooded to a level 23 ft 6 in. above the refueling bellows seal).

1. Dead load

(a) Vessel and appurtenances,

(b) Concrete drywell floor,

(c) Catwalks in suppression chamber,

(d) Drywell equipment, supports, platforms and attached piping, headers, air ducts, electrical ducts, conduits, and trays,

(e) Gap filler material,

(f) Loads on welding ring pads same as in item b.1,

(g) Suppression chamber filled with water at a maximum temperature of 212°F and with coincident hydrostatic pressure, and

(h) Drywell filled with water to el. 552 ft 0 in. at a maximum temperature of 212°F and with coincident hydrostatic pressure;

2. Live load

(a) Operating weight of fluid in normally empty piping and penetrations, and

(b) Water load on the refueling bellows seal at the top flange of the containment vessel, and coincident hydrostatic pressure, due to the reactor vessel cavity outside the containment vessel above the refueling bellows seal flooded to a level 23 ft 6 in. above the seal, as described in item h;

3. External pressure of 2 psi (same as in item b.4);

4. Seismic OBE, horizontal and vertical, including loads from shear lugs between the drywell floor and the containment vessel, and loads from the reactor vessel stabilizer; and

5. Drywell floor seal loads.

3.8.2.4 Design and Analysis Procedure

The steel primary containment vessel, which consists of a vertical free-standing bell-jar shell, bottom and top ellipsoidal heads and numerous penetrations and attachments, is considered to act as an independent structural component within the reactor building. The bottom head, which is supported by the concrete mat foundation, is designed as a pressure tight and leaktight membrane.

The steel primary containment vessel is designed to the ASME Code Section III, Subsection NE for Class MC components. Those areas of the steel primary containment vessel that are free from structural discontinuities and experience no discontinuity stresses due to thermal and/or mechanical loads are designed in accordance with Subarticle NE-3300 of ASME Code Section III. For the configurations and loadings located throughout the steel primary containment vessel including anchorage, embedment, and all appurtenances which are not explicitly treated in Subarticle NE-3130, the design is in accordance with the applicable references designated in paragraphs (b) and (c) of Paragraph NE-3131 of ASME Code Section III.

The design of nonpressure resisting components within the steel containment vessel that are within the jurisdiction of ASME Code Section III, Subsection NE, is performed in accordance with ASME Code Section III, NE-3131 (e).

The design of nonpressure resisting components within the steel containment vessel which are outside the jurisdiction of ASME Code Section III, Subsection NE, is performed in accordance with the general practices of the AISC Specification for the Design Fabrication and Erection of Structural Steel for Buildings, February 12, 1969.

A comparison of the design pressures to the maximum calculated pressures is shown in Table 3.8-3.

3.8.2.4.1 Description

The following describes the design and analysis procedures required to verify the structural integrity of critical areas present within the steel primary containment vessel.

3.8.2.4.1.1 Bottom Ellipsoidal Head and Bell-Jar Shaped Shell. The 2:1 ellipsoidal head is designed in accordance with Subarticle NE-3300, Vessel Design, of ASME Code Section III.

The compressive stresses within the knuckle region caused by internal pressure are limited to the allowable buckling stress in accordance with Paragraph NE-3133 of ASME Code Section III.

The design of the top and bottom ellipsoidal heads for both external pressure and compressive loadings is in accordance with Paragraph NE-3133 of ASME Code Section III.

The bell-jar shaped shell of the steel primary containment vessel is designed in accordance with Subarticle NE-3300 for internal pressure. For external pressure and mechanical loads which include compressive stresses in the bell-jar shaped shell the design is in accordance with Paragraph NE-3133 of ASME Code Section III.

The bell-jar shaped shell contains the following major structural discontinuities:

a. Steel containment vessel embedment, discussed in Section 3.8.2.4.1.2,

b. Vertical stiffeners on the inside periphery of the suppression pool portion of the steel containment vessel, to increase the longitudinal compression strength of the vessel,

c. Horizontal stiffening rings on the inside periphery of the steel containment vessel to provide capability to resist external pressure,

d. Ring girders attached to the inside periphery of the steel containment vessel at el. 516 ft 6 in. and el. 542 ft 7.25 in., as discussed in Section 3.8.2.3.5.3, and

e. Steel containment vessel closure flange and refueling bellows attachment at el. 583 ft 1.25 in.

3.8.2.4.1.2 Steel Containment Vessel Embedment Region. The anchorage of the steel containment vessel to the concrete foundation mat is facilitated by means of an embedded lower skirt. Analysis for this portion utilizes the computer as described in Section 3.8.2.4.2.

The anchorage itself is accomplished by the use of anchor bolts and embedded plates located at the bottom outer steel skirt of the primary containment vessel. The anchor bolts extend into the concrete mat foundation a distance sufficient to develop the required embedment length. The anchor bolts and embedded plates are designed to resist the moments and vertical shears developed by the axial tensile forces of the steel primary containment vessel shell.

3.8.2.4.1.3 Penetrations. The containment penetrations are designed to withstand the normal environmental conditions which may prevail during plant operation and to retain their integrity during all postulated accidents. Containment penetrations are fully described in Section 3.8.6.

An equipment hatch in the drywell is fabricated from welded steel and furnished with double-gasketed flanged and bolted doors. Provision is made to test pressurize the space between the double gaskets of the door flanges.

The personnel access lock is provided for drywell access. The personnel lock is a double door, latched, welded steel assembly. Quick-acting equalizing valves connect the personnel lock with the interior of the containment vessel for the purpose of equalizing pressure in the two systems when entering or leaving the containment.

The two doors in the personnel access lock are interlocked to prevent both being opened simultaneously and to ensure that one door is completely closed before the opposite door can be opened. An emergency lighting and communication system operating from an emergency supply is provided in the lock interior.

The suppression chamber access hatch is fabricated from welded steel and furnished, on the reactor building side, with a double bolt, horizontal hinged, dished steel closure. The closure is flanged and double gasketed with provisions to test pressure between the double gaskets of the closure flange.

Electrical penetrations are provided with double seals and are separately testable at 45 psig. The test taps and seal are located so that tests of the electrical penetrations can be conducted without entering or pressurizing the drywell or suppression chamber. Gaskets are separately testable at the containment maximum internal pressure of 45 psig to verify leaktightness. The covers on flanged closures, such as the equipment hatch cover, the drywell head, suppression chamber access hatch, and personnel access lock doors are provided with double seals so that these can be tested for leaktightness without pressurizing the entire containment system.

3.8.2.4.1.4 Personnel Access Lock and the (Combined) Equipment Hatch and Control Rod Drive Removal Hatch. The personnel access air lock and the equipment hatch/CRD removal hatch, are supported entirely by the steel containment vessel shell. The lock barrel is welded directly to a thick insert plate which in turn is welded at its periphery to the shell of the steel containment vessel. The barrel in the vicinity of its attachment to the insert plate is also thickened as required. The additional thickness in both the barrel and insert plate is provided to satisfy the area reinforcement requirements as well as to resist the external moments and shears due to the cantilevered construction. The discontinuity stresses induced by the combination of external, dead, and live loads including the effects of earthquake loadings are evaluated. The required analyses and limits for the resulting stress intensities are in accordance with Subarticles NE-3100 and NE-3200 of ASME Code Section III.

The doors for the personnel access air lock are dished. The analyses are in accordance with Paragraphs NE-3325 and NE-3326 of ASME Code Section III.

Additional stiffeners are provided as required around the opening of the equipment hatch.

Analytical methods developed by P. P. Bijlaard for the Welding Research Council and the summarization presented in Reference 3.8-4 are utilized to determine the stresses in a cylindrical shell with openings. With a thick insert plate, a flanged neck around the periphery and gusset plates, the stresses are within the ASME Code allowables.

The required analysis and the stress intensity limits are in accordance with Subarticles NE-3100 and NE-3200 of ASME Code Section III. The hatch cover with the bolted flange is designed in accordance with Paragraph NE-3326 of ASME Code Section III.

The following explains the method of analysis and the strength criteria used for the seismic design of the connections between the personnel access lock and equipment removal hatch and

the drywall shell; the provisions made to take care of shell, and the influence of complete local encasement of the drywell in concrete on the seismic design:

a. The entire containment vessel shell, including the personnel air lock and the equipment hatch, is designed to withstand seismic loading derived by seismic analysis as described in Section 3.7. The method of shell analysis is in accordance with ASME Code Section III, Class MC, utilizing allowable stress intensities required by this code;

b. Further, the containment vessel design also includes the seismic affects due to the inertia of the mass of the personnel access lock and the equipment hatch vibrating as an independent system; and

c. Since the personnel access lock and the equipment hatch are completely separated from the surrounding concrete wall by means of a gap, there is no interaction between these appurtenances and the concrete wall. The gap provided is of sufficient dimension to accommodate all vessel movements.

3.8.2.4.2 Computer Programs Utilized in Design and Analysis

The design and analysis of the steel containment vessel utilized the following three proprietary computer programs of the Pittsburgh-Des Moines Steel Company, Pittsburgh, Pennsylvania:

a. AX1, Analysis of Axisymmetric Solids,
b. AX2, Axisymmetric Shell Program, and
c. AX3, Analysis of Thin-Shell Solids of Revolution.

The italicized information is historical and was provided to support the application for an operating license. The AX1 computer program is a special purpose finite element program for the analysis of axisymmetric solids. Meridional-stiffening cannot be modeled in this program. Circumferential stiffening can be modeled with the axisymmetric finite elements. This program was used exclusively to evaluate jet load effects on the CRD Removal Hatch. All the members analyzed are unstiffened axisymmetric solids. It is capable of determining deformations and stresses within axisymmetric structures of arbitrary shape.

The AX2 computer program is a general purpose program for the analysis of composite shells of revolution loaded axisymmetrically. The shell theory used is for thin, isotropic, elastic shells. Meridional stiffening cannot be modeled. Circumferential stiffening members can be modeled as shell elements or as concentrated stiffnesses at node points. This program was used extensively in the analysis of the primary containment vessel. Meridional stiffening members were neglected in these AX2 analyses. Circumferential stiffening members were modeled as shell elements. It is capable of determining stresses and displacements in shells of revolution that are loaded axisymmetrically.

The AX3 computer program is a general purpose program for the analysis of composite axisymmetric shells. Loads can be applied axisymmetrically or non-axisymmetrically using fourier series representations. Meridional stiffening can be modeled by adding shell layers with zero modulus of elasticity in the circumferential direction. By adding a layer or layers of appropriate thickness' the axial and bending stiffness of the stiffening can be represented. Circumferential stiffening members can be modeled using shell elements or by using the layer method described above. It is capable of determining reactions and deformations for thin shell solids of revolution, such as discs, for axisymmetric loads.

The AX3 program was used to analyze two areas:

1. *The containment shell in the vicinity of the seismic stabilizers (el. 567 ft 5.5 in.) under a non-axisymmetric displacement loading. No meridional or circumferential stiffening exists in the region modeled.*

2. *The Equipment Hatch head/flange intersection under Jet loading. Meridional stiffening on the Equipment Hatch head and barrel was modeled using additional shell layers with zero modulus in the circumferential direction. No circumferential stiffening members exist in the area modeled.*

Computer programs AX1, AX2, and AX3 are further discussed in Section 3.12.

3.8.2.4.3 Seismic Analysis

The evaluation of the structural integrity of the steel primary containment vessel, when excited by seismic motion, is based on a dynamic analysis.

The steel primary containment vessel is designed to interact as a structural component with the reactor building (secondary containment structure) to which it is attached. The primary containment vessel is attached to the reactor building at the stabilizer truss level through the primary containment vessel/biological shield wall shear lug interface, and at the reactor building foundation mat level.

The structural components within the steel primary containment vessel, such as the reactor pedestal, reactor vessel and SSW are designed to interact with the reactor building and the primary containment vessel because of their connections at the reactor building foundation mat level, drywell floor level, and the top of the SSW level, through the reactor vessel shear lug/shear lug stabilizer/SSW stabilizer truss interfaces.

With the formulation of an overall mathematical model which provides for the realistic response of the containment system, response spectra and/or time histories are generated at the component interfaces, and at other desired points. These component response spectra and/or

time histories are used to perform detailed dynamic analyses of the individual components as previously mentioned.

Effects due to the presence of water in the suppression pool under earthquake excitations are established following the procedures described in Reference 3.8-2. The additional loads due to sloshing effect are included as part of the design loads of the primary containment vessel. The analytical results and methods of analysis utilized to determine the seismic sloshing effects in the suppression chamber are discussed in Section 3.8.2.4.3.2.

The model used for the seismic analysis and the method of seismic analysis to obtain the seismic moments, shears, displacements, and floor response spectra are discussed in Section 3.7. To obtain a detailed stress/strain analysis in local areas, the following additional methods are used.

In the dynamic analysis of the steel primary containment vessel component, a dynamic mathematical model is formulated which incorporates the general structural geometry and all significant boundary conditions present. The design of the numerous penetrations is such that any restraining forces on the steel primary containment vessel which could be developed can be considered as negligible. The effects of rotational inertia and shear deformations are also considered as negligible in the response of the steel containment vessel. In the determination of the seismic response of the steel containment vessel, damping effects are considered. The incorporation of damping into the dynamic analysis is facilitated by the use of viscous (velocity proportional) damping. The various damping values for both the OBE and SSE excitations for the steel containment vessel are discussed in Section 3.7.

The resulting equations of motion for the steel containment vessel were solved by the use of a computer program called DACSR. The solution algorithm used depends on the analytical method incorporated to evaluate the equations of motion for the system. A discussion of the solution technique is provided in Section 3.7.

The results of the dynamic seismic analysis contain values for maximum translation and rotational displacements and accelerations, moments and shears, as well as response spectra and/or time histories at desired points throughout the steel containment vessel.

These resultant forces are then combined with the various loading conditions is described in Section 3.8.2.3.12 and in accordance with Paragraph NE-3131 of Section III of the ASME Code. These combined forces are used in the structural analysis of the various critical areas present within the steel primary containment vessel. By using a response spectra and/or time history the cantilevered personnel locks, as well as any other appurtenance, are dynamically analyzed as previously discussed.

The resulting stress intensities due to the addition of seismic loads to the various loading conditions for the steel primary containment vessel and its appurtenances are in accordance

with the stress intensity limits as specified in Paragraph NE-3131 of the ASME Code, Section III.

3.8.2.4.3.1 Computer Program Utilized in the Seismic Dynamic Analysis. The seismic dynamic analysis utilized DACSR, a large capacity computer program discussed in Section 3.12. The program was capable of generating the required mass and stiffness matrices which were required to represent the mass and stiffness of the actual structure.

3.8.2.4.3.2 Seismic Dynamic Analysis of Water in Suppression Chamber (Sloshing Effects). Tests were not performed to arrive at the seismically induced sloshing loads in the suppression chamber. All of the loads were derived by calculations. The calculations provide the basis for the acceptance of these loads.

The method of analysis utilized to determine the seismic sloshing loads in the suppression chamber is taken from Reference 3.8-2 (Chapter 6 and Appendix F).

Two separate analyses were performed, using the formulations given in Reference 3.8-2 as follows:

a. In the first analyses, the entire suppression chamber is taken as a cylindrical rigid tank in plan having a flat bottom as modeled in the above-referenced document, in lieu of the actual 2:1 bottom ellipsoidal head, and supported on the foundation mat. In this analysis the RPV pedestal is excluded from the model, and the tank is considered as containing only the water to the full depth shown in Figure 3.8-1; and

b. In the second analysis, the RPV pedestal is included in the model. To include the pedestal, the suppression chamber is modeled to consist of theoretical rectangular tanks in plan, of the minimum quantity and the maximum size that can be fitted or inscribed adjacent to each other within the annulus formed by the cylindrical wall of the suppression chamber and the concentric cylindrical RPV pedestal. The tanks are each assumed as independent rigid bodies supported on the foundation mat, flat-bottomed and containing water to the full depth shown in Figure 3.8-1.

In both analyses, the structures are subjected to the maximum floor accelerations due to the SSE. The acceleration values are obtained from the time-history analysis performed for the reactor building given in Section 3.7.

Both analyses yield water displacements, velocities, and impulsive and convective water pressures on the walls of the suppression chamber and the reactor building foundation mat.

The first analysis, which considers the RPV pedestal excluded from the suppression chamber, yields the maximum impulsive pressures. The second analysis, which considers the RPV included in the suppression chamber, yields the maximum convective pressures. To obtain conservative values for the forces, bending moments and overturning moments on the suppression chamber and foundation mat, the maximum impulsive forces from the first analysis and the maximum convective forces from the second analysis are assumed to occur together.

The following tabulation gives the analytical results obtained for the additional horizontal wall pressures due to SSE. The additional wall pressures are found to be negligible.

Distance below water surface el. 466 ft 4.75 in. (ft)	Horizontal wall pressure due to SSE induced water sloshing (psi)
0	0.30
5	1.56
10	2.57
15	3.30
20	3.74
Below 20	5.84

The maximum vertical displacement (slosh height) and velocity of the oscillating water surface above the undisturbed equilibrium water surface el. 466 ft 4.75 in. are 9.5 in., and 17.2 in./sec respectively, at the suppression chamber face. This occurs in the second analysis which considers rectangular tanks with the RPV pedestal included.

The period of water oscillation (time required for the water to oscillate one complete cycle) is 6 sec in the first analysis (circular tank) and 3.5 sec in the second analysis (rectangular tanks).

The analytical results used for horizontal pressures in the suppression chamber due to the OBE are one-half of the values obtained for SSE.

3.8.2.4.4 Protective Coatings

Protective coatings are described in Section 6.1.2.

3.8.2.5 Structural Acceptance Criteria

3.8.2.5.1 Primary Stresses

The structural acceptance criteria for the steel primary containment vessel, namely, the basis for establishing allowable stress values, the deformation limits, and the factors of safety, are established by and in accordance with ASME Code Section III.

In addition to the structural acceptance criteria, the steel primary containment vessel is designed to meet minimum leakage rate requirements. The leakage rate requirements are discussed in Section 6.2.

Loading combinations are discussed in Section 3.8.2.4 and buckling criteria is discussed in Section 3.8.2.5.4.

3.8.2.5.2 Primary and Secondary Stresses

For loading combinations described in Sections 3.8.2.3.12 (except for f and h), the stress limits specified in ASME Code Section III, NE-3131(c) are utilized.

3.8.2.5.3 Peak Stresses

For loading combinations described in Sections 3.8.2.3.12f and 3.8.2.3.12h, the stress limits specified in ASME Code Section III, NE-3131(c)(1) and NE-3131(c)(2) are utilized.

3.8.2.5.4 Buckling Criteria for the Primary Containment Vessel

To ensure safety against buckling, the rules set forth in ASME Code Section III, NE-3133, are utilized. The buckling analysis of the containment vessel was performed as follows:

External pressure: The allowable working pressure, P_a, calculated in NE-3133.3 was compared with the specified maximum external pressure, -4 psi. Conical shell elements were analyzed as equivalent cylinders in accordance with NE-3133.7.

Longitudinal compression on unstiffened shell: The maximum allowable compressive stress, B, determined in NE-3133.6, was compared to the maximum longitudinal compressive stress produced under all the loading conditions specified, including the compressive stress due to the SSE overturning moment.

Longitudinal compression meridionally stiffened shell: Two independent checks were made on buckling of stiffened shell lengths:

a. NE-3133.6 was applied as above using an equivalent thickness in bending, $t_e = (12 \times I_s/b)^{1/3}$

   b = meridional stiffener spacing

   I_s = moment of inertia of the composite section comprised of the stiffener and a width of shell, b.

b. Additionally, shell lengths were analyzed by treating the composite stiffener-shell described in item a as a column pinned at the shell ring stiffeners. These columns were evaluated for buckling using the AISC criteria.

3.8.2.6 Materials, Quality Control, and Special Construction Techniques

3.8.2.6.1 Materials

The materials essential to containment integrity (items a through f below) comply with the requirements of Article NE-2000 of the ASME Code Section III. Material for the containment vessel (Section 3.8.2) and vessel penetrations (Section 3.8.6) conforms to but is not limited to the following:

a. Plate

ASME SA-516, Grade 70 (drywell head, flanges, containment vessel, and electrical penetration weld ring collars)	Specification for carbon steel plates for pressure vessels for moderate and lower temperature service
ASME SA-537, Class 2 (containment vessel plates and penetration insert plates)	Specification for carbon-manganese silicon steel plates heat treated for pressure vessels
ASME SA-240 Type 304 (electrical penetration header plates for austenitic pipes or fittings)	Specification for chromium and chromium-nickel stainless steel plate, sheet, and strip for fusion-welded unfired pressure vessels
ASME SA-299 (jet deflectors)	Specification for carbon-manganese-silicon steel plates for pressure vessels;

b. Forgings

ASME SA-350 Grade LF1 or LF2 (flued head fittings or flanges)	Specification for forgings carbon and low alloy steel requiring notch toughness testing for piping components (for low temperature service)

ASME SA-182 F304 (flued head fittings for austenitic stainless steel process piping)	Specification for forged or rolled alloy-steel pipe flanges, forged fittings, and valves and parts for high-temperature service
ASME SA-105, Grade II, (flued heads)	Specification for forgings, carbon steel, for piping components (for ambient and high temperature service);

c. Pipe

ASME SA-333 Grade 1 or 6 (seamless)	Specification for seamless and welded steel pipe for low temperature service
ASME SA-312, Grade TP 304	Specification for seamless and welded austenitic stainless steel pipe
ASME SA-376, Grade TP 304	Specification for seamless austenitic steel pipe for high-temperature central-station service;

d. Bolting

ASME SA-320 Grade 17 (ferritic steels)	Specification for alloy steel bolting materials for low-temperature service
ASME SA-320 Grade B8 (austenitic steels)	Specification alloy steel bolting materials for low-temperature service
ASME SA-193 Grade B7 (ferritic steels)	Specification for alloy-steel and stainless steel bolting materials for high-temperature services
ASME SA-193 Grade B8 (austenitic steel)	Specification for alloy steel bolting materials for high-temperature service
ASME SA-194 Grade 7 (ferritic steels)	Specification for carbon and alloy steel nuts for bolts for high-pressure and high-temperature service
ASME SA-194 Grade 8 (austenitic steel)	Specification for carbon and alloy steel nuts for bolts for high-pressure and high-temperature;

e. Castings

ASME SA-216 Grade WCB	Specification for carbon-steel castings suitable for fusion welding for high-temperature service
ASME SA-352 Grade LCB	Specification for ferritic steel castings for pressure containing parts suitable for low-temperature service
ASME SA-351 Grade CF8	Specification for austenitic steel castings for high-temperature service;

f. Weld fittings, elbows, tees, and reducers

ASME SA-420 Grade WPL 6	Specification for piping fittings of wrought carbon and alloy steel for low-temperature service;

g. Gib material

ASTM A-514 (bearing plate under radial beam)	Standard specification for high-yield strength, quenched, and tempered alloy steel plate, suitable for welding
ASTM B-22, Copper Alloy No. 863 or Lubrite Alloy No. 424 (Material for bearing plates under radial beams, except in suppression pool. Material not required in suppression chamber.)	Standard specification for bronze castings for bridges and turntables

Self-lubricating bearing plates are Lubrite, a manganese bronze material, produced by an established manufacturer of such material. They are provided with trepanned recesses which are filled with a lubricating compound capable of withstanding the design temperature and load and consisting of graphite and metallic substances with a lubricating binder. The compound is pressed into the recesses by hydraulic presses so as to form dense, nonplastic inserts. The lubricating area comprises not less than 25% of the total area. The coefficient of friction does not exceed one-tenth.

This material is not used in the suppression pool where it is classified a detrimental material and therefore prohibited. Such a material, however, is not required in the suppression chamber.

h. Material that does not fall within the scope of the ASME Code conforms to the following ASTM Specification:

ASTM A-36	Standard specification for structural steel;

i. Material for anchor bolts of bottom support skirts and temporary hoist structures conforms to the following ASTM specification:

ASTM A-307	Standard specification for carbon steel externally and internally threaded standard fasteners;

j. Gasketing material - Gaskets are solid and are fabricated in continuous rings of silicone, neoprene, or natural rubber or other material suitable for its intended service. Gaskets have a guaranteed life of not less than 12 months. The sealing pressure on each gasket is constant for the life of the gasket. Results of tests performed by an approved testing laboratory demonstrate satisfactory performance of the gaskets. Gaskets are used at hatches and flanges. Typical applications are described in Section 3.8.2.4.1.3;

k. Concrete fill between the top of the foundation mat and the underside of the primary containment vessel, within the area bounded by the bottom support skirts, is an expansive cement concrete. The minimum compressive strength of the concrete fill is 4000 psi at 28 days; and

l. Grout under bottom support skirts is the non-shrink type. Preparation, mixing and placing of grout is in accordance with the manufacturer's instructions. The design strength of grout is 4000 psi at 28 days.

3.8.2.6.2 Quality Control

Quality control measures used during the construction and installation of the steel primary containment vessel and the penetration assemblies (discussed in Section 3.8.6.6) are

a. *The vessel vendor submitted shop and field quality compliance and quality assurance organization and procedures. These procedures include, as applicable, the methods of documentation of materials, material control, welder identification, and welding electrode handling and distribution; and the vendor's*

methods of qualification of nondestructive testing and welding personnel, procedures, and equipment.

b. The records pertaining to the steel primary containment vessel contain distinct categories; these are material certifications, welding data, test data, vendor drawings, and vendor-certified stress reports. All records are turned over to the Owner on completion of the work.

1. Material certification

(a) Mill Test Reports - mechanical and chemical properties of material used, as detailed within the project specifications.

(b) Nondestructive testing reports.

(c) Plate forming procedures.

2. Welding data

(a) Shop weld data - description of the procedures used, the welding process or processes, the welder or welders performing the welding operations, the type of weld, and the results of the following inspections: visual, radiography, ultrasonic magnetic particles or liquid penetrant, as well as the name of the inspector and date inspection was performed.

(b) Field weld data - the same type of information reported under Shop Weld Data.

(c) As-built drawings - drawings designating structural plate, member or part locations and field welds by number.

(d) Inspection and quality assurance reports.

3. Test data

(a) Cleaning records pertaining to cleanliness inspections.

(b) Pneumatic tests - a record of pneumatic tests performed, including test pressure, hold time, and the results of the test.

(c) Initial leak rate test - a record of leak test, including test pressure, hold time, and an error analysis of the test data.

4. Vendor drawings include outline drawings, assembly drawings, and shop detail drawings.

5. Vendor-certified stress reports contain the structural analysis and design calculations and associated design drawings of the various structural elements and components of the primary containment vessel.

c. All welding procedure qualifications and welder performance qualifications are in accordance with ASME Code Section IX. The welding design, fabrication, inspection, and acceptance, as a minimum, conform to the requirements of Subsection NE of Section III of the ASME Code. For magnetic particle or liquid penetrant inspection, the acceptance criteria conforms to ASME Code Section III, Subsection NE.

d. All procedural requirements for nondestructive testing as a minimum conform to the requirements of Appendix X of ASME Code Section III.

e. Erection tolerances - The steel primary containment vessel erection tolerances meet the requirements of NE-4221 and NE-4222 of ASME Code Section III for fabrication and erection. The tolerance for fabrication of remaining plates are as stated in the AISC Specification for the Design, Fabrication, and Erection of Structural Steel for Buildings, Code of Standard Practice for Steel Buildings and Bridges.

3.8.2.6.3 Special Construction Techniques

No construction techniques unusual to vessel erection methods were required for the steel primary containment vessel.

3.8.2.7 Testing and Inservice Inspection Requirements

3.8.2.7.1 Inspection of Material and Parts for Fabrication

All materials used in constructing pressure retaining parts of the primary containment vessel were examined before fabrication to detect defects affecting functional integrity of the vessel. Materials were inspected to detect defects and cracks introduced during fabrication and to ensure that the work was properly executed and completed. In addition, pressure retaining parts were inspected to ensure that they conformed to the required shape and size after forming.

3.8.2.7.2 Testing of Primary Containment Vessel During Field Erection

During erection of the bottom ellipsoidal head of the primary containment vessel, vacuum box soap bubble tests of longitudinal and circumferential seams were made by placing a vacuum box over the weld areas after application of a soap solution to the test areas and adjacent base material. No leaks were detected in the area by this test and therefore no repairs and retesting were necessary.

On satisfactory completion of soap bubble testing, a halide testing program over the welded seams followed, inasmuch as internal concrete was placed prior to completion of vessel erection. After successful completion of the halide test program, concrete was placed in the interior region of the bottom ellipsoidal head.

3.8.2.7.3 Testing of the Erected Primary Containment Vessel

On completion of field erection of the primary containment vessel and prior to the installation of penetration internals, a test plan was established to outline the tests and inspections to be performed on the primary containment vessel and appurtenances. The tests were performed in accordance with the applicable requirements of the ASME Code to demonstrate the structural integrity and leaktightness of the completed vessel. The tests consisted of an initial and a final reference volume test, an initial and a final soap bubble test, a structural integrity overpressure test for structural acceptability, and an initial leak rate test. The initial soap bubble test was performed at 5 psig, and the final soap bubble test was performed at 45 psig between the 51.8 psig structural integrity test and the 45 psig initial leak rate test.

The initial and final reference volume tests, the first and last of the tests performed in the order of sequence, evaluated and leak tested the reference volumes in accordance with ANSI N45.4-1972.

The following tests and inspections outlined in the test plan were performed in the following order, in accordance with the plan.

a. Test prerequisites

1. *Prior to pressurization of the primary containment vessel, preparatory steps were taken such as installation, calibration, and checking out the operability of all systems and instrumentation equipment including that required for measuring containment pressure, temperature, and humidity.*

2. *Before the tests began, the suppression chamber was filled with water to el. 466 ft 2.75 in.*

b. Initial reference volume test

Before the primary containment vessel was pressurized the reference volume system was evaluated and leak tested in accordance with ANSI N45.4-1972. This test included the helium leak test and the vacuum retention test. The initial reference volume test was successfully completed.

c. Initial soap bubble test

The initial soap bubble test was performed at 5 psig, the first increment of pressure of the structural integrity pressurization test. Soap suds were applied to all weld seams and seals, including seams and seals of all piping and electrical penetrations which were not backed up by water, the equipment hatch, drywell personnel access lock, and suppression chamber access hatch. Where the weld seams of the primary containment vessel penetrations were below the water level of the suppression chamber, visual leak detection was performed. Only the inner door seals of the personnel access lock were soap bubble tested at this time, since the personnel access lock weld seams were tested in the shop. The outer door of the personnel access lock was in the open position and remained open during this test. Weld maps with signoffs for each weld to be soap bubble tested were used for each soap bubble test. This test was successfully completed.

d. Structural integrity pressurization test

This test is also referred to as the structural acceptance overpressure test. The test was performed by pressurizing the primary containment vessel drywell and suppression chamber in increments, holding at pressures of 5, 10, 15, 20, 25, 30, 35, 40, 45, 50, and 51.8 psig. The initial soap bubble test was performed at 5 psig. The outer door of the personnel access lock was left open as it was in the initial soap bubble test. The final test pressure level of 51.8 psig was maintained for at least 1 hr simultaneously in the vessel and on the inner door of the personnel access lock. The increments of holding levels were reached by allowing the pressure to rise 1 psig above the desired level and then reducing the pressure to the desired level. The final holding level of 51.8 psig did not include the 1 psig increase. The final holding test pressure of 51.8 psig is 15% more than the 45 psig design pressure and is in accordance with Subarticle NE-6300 of the Summer 1972 Addenda of ASME Code Section III, Nuclear Power Plant Components, Subsection NE, Class MC components. The structural integrity test was completed successfully.

e. Final soap bubble test

On completion of the structural integrity pressurization test, the primary containment vessel was depressurized from 51.8 psig to 45 psig. A 10 minute hold period at 45 psig was observed and then the inner door seals of the personnel access lock were soap bubble tested. The outer door of the personnel access lock was then closed and the air lock was pressurized to 45 psig. At this point the outer door seals of the personnel access lock were soap bubble tested. When soap bubble testing of the outer door seals was completed, the entire primary containment vessel was soap bubble tested as described in Section 3.8.2.7.3. The final soap bubble test was successfully completed.

f. Initial leak rate test

After the final soap bubble test, an initial leak rate test was performed on the primary containment vessel. During the test, the suppression chamber remained filled with water to el 466 ft 2.75 in. placed therein during the test preparation period described in Section 3.8.2.7.3. During the initial leak rate test, the inner door of the personnel access lock was open and the outer door closed. The primary containment vessel was completely sealed off. Since both the drywell and suppression chamber above the water level at el. 466 ft 2.75 in. are designed for the same pressure, the entire primary containment vessel was tested at the same time without the necessity of providing closures from the drywell.

The test pressure of 45 psig was used. The test pressure was arrived at by depressurizing the vessel from 51.8 psig to 45 psig upon completion of the structural integrity test.

The necessary instrumentation was provided and installed and furnished the data required to calculate and verify the leakage rate. The equipment used was capable of measuring with an accuracy consistent with the measurements made. Continuous hourly measurements were taken until it was shown that the integrated leakage rate from the primary containment vessel did not exceed the specified maximum leak rate of 0.5% of the total weight of contained air in any 24-hr period at test temperature and pressure. Measurements taken were in accordance with procedures outlined in ANSI N45.4-1972.

The leak rate was calculated by the reference volume method and verified by the absolute volume method. The reference volume method followed ANSI N45.4-1972. The leak rate arrived at by both the reference volume and the absolute volume methods was determined by a straight line least-squares fit of the results for the entire period during which data was taken.

g. Final reference volume test

On completion of the initial leak rate test, the primary containment vessel was depressurized to 0 psig and the outer door of the personnel access lock was opened. At this point a vacuum retention test was performed on the reference volume system. The vacuum retention test was successfully completed and the water in the suppression chamber was discharged.

All tests were successfully completed.

3.8.2.7.4 Tests on Electrical and Mechanical Penetrations

All electrical penetration nozzles were pressure tested by two methods. The first test consisted of a shop hydrostatic test of 150 psig prior to shipment of the nozzle to the field. The second pressure test of the electrical penetration nozzles was performed in conjunction with the overall overpressure test of the containment vessel. The pressure for this test was 1.15 times the design pressure of 45 psig as prescribed by ASME Code Section III, Class MC.

All primary containment vessel pipe penetrations were pressure tested by two methods. All internal piping, together with the flued head fitting (if applicable), was initially hydrostatically tested in the shop. Test pressures used were based on the design pressure for the particular system for which the penetration is designed to serve. On completion of the overall containment vessels the penetration was field tested in conjunction with the overall overpressure test of the containment vessel. The pressure of this test was 1.15 times the design pressure of 45 psig as prescribed by ASME Code Section III, Class MC, the same as for the electrical penetrations noted above.

3.8.2.7.5 Tests on Personnel Access Lock

On completion of erection of the primary containment vessel, the air lock was given an operational test consisting of repeated operation of each door and mechanism to determine that all parts operate smoothly without binding or other defects. All defects encountered were corrected and retested. The process of testing, correcting defects, and retesting was continued until no defects were detectable.

Pressure testing of the air lock was performed in conjunction with the containment vessel testing, as described in Section 3.8.2.7.3. During this operation, all double gasketed door seals were tested by pressurizing the space between the gaskets and checking the sealing area for leaks using the test outlined in Section 6.2.6.2.

Design features of the air lock which permit testing are described below:

a. Figures 3.8-10, 3.8-11, and 3.8-12 provide longitudinal and transverse sectional elevations of the personnel access air lock. The figures also identify mechanical and electrical penetrations on the inner and outer faces of both the containment bulkhead and the atmosphere bulkhead;

b. Figure 3.8-13 illustrates the door vacuum relief tube and test connection. This is a design provision which permits between-seal tests on the air lock door seals;

c. Figures 3.8-14 and 3.8-15 illustrate typical mechanical penetrations in the atmosphere and containment bulkheads. The penetration seals and test connections are a design provision that permits between-seal tests on bulkhead penetrations. Each such bulkhead penetration is sealed with a cartridge type seal unit having double dynamic seals, and each bulkhead penetration is provided with the test connection to test these seals;

d. Figure 3.8-16 illustrates a typical electrical penetration in the atmosphere and containment bulkheads. The penetration is accomplished by means of electrical fittings installed into the bulkheads. The fittings pressure seal the electrical leads passing through the bulkhead; and

e. The personnel air lock door seals and the bulkhead penetration seals are tested on a regular post installation periodic basis, subsequent to the tests after erection described in Section 3.8.2.7.3. These tests are of two types: air lock pressure test and individual seal tests.

The air lock design permits pressure testing of the entire air lock at a pressure of P_a. Special air lock features associated with this test include 12 removable test clamp mechanisms on the inner (air lock to containment) door. These clamps prevent the inner door from becoming unseated during leak testing and are located on and are accessible from the inside of the air lock. These clamps are installed for the duration of the internal air lock pressure test.

The air lock is pressurized through the emergency air penetrations. This test confirms sealing capability at a pressure of Pa for all air lock penetrations.

The individual mechanical and door seals are testable as detailed above. The door seals are tested individually on a schedule based on air lock use and as allowed by the containment leakage rate testing program plan as referenced by the Technical Specifications. The door seal pressure test is at 10 psig and is designed to confirm seal integrity.

3.8.2.7.6 Tests on Penetration Field Welds

Leaktightness tests of field welds connecting the penetrations to the primary containment vessel, including welds connecting the penetration sleeves to the vessel shell, were made.

Penetrations welded directly to the containment vessel shell and field welds on the containment vessel shell were tested with the completed containment vessel during the soap bubble, overpressure, and leak rate testing described in Section 3.8.2.7.3.

3.8.2.7.7 Preoperational Leakage Rate Test and Periodic Leakage Rate Tests

On completion of construction of the primary containment system, including installation of all portions of mechanical fluid, electrical and instrumentation systems penetrating the primary containment vessel, and prior to any reactor operating period, preoperational and periodic leakage rate tests are performed. The various leakage rate tests and associated acceptance criteria are in accordance with Option B of Appendix J to 10 CFR Part 50. The steel primary containment system overall leakage rate is tested by the implementation of type A tests. The detection of local leaks and the measuring of leaks across each pressure-containing or leakage limiting boundary is facilitated by the use of type B tests. The steel containment isolation valves and systems are tested by using type C tests. For each of the three types of tests the associated acceptance criteria is as discussed in Appendix J to 10 CFR Part 50. This compliance includes periodic testing, performance of appropriate tests after major modifications, and the initial preoperational tests. A visual inspection of accessible interior and exterior containment surfaces will be performed in conjunction with the leak rate testing. In addition, periodic visual inspections are performed as described in Sections 3.8.3.7 and 3.8.2.7.8. In addition, leakage rate tests will be reported as required in Appendix J. The tests will verify the leaktight integrity of the primary containment vessel and penetrations below the leak rate of 0.5% of the total contained weight of air per day. Type A, B, and C leak rate tests and satisfaction of commitments to 10 CFR 50, Appendix J, are discussed in Section 6.2.6.

Electrical penetrations are provided with double seals and are separately tested at the containment maximum calculated internal pressure (38 psig). The test taps and seals are so located that tests of the electrical penetrations can be conducted without entering or pressurizing the drywell or suppression chamber.

Containment closures which are fitted with resilient seals or gaskets are tested at the containment maximum calculated internal pressure (38 psig) to verify leaktightness. The covers on flanged closures, such as the equipment hatch cover, the drywell head, and personnel access lock doors are provided with double seals so that they can be tested for leaktightness without pressurizing the entire containment system.

In addition, provision is made so that the space between the air lock doors can be pressurized to the full drywell test pressure. Since both doors on the lock swing in toward the drywell

vessel, structural members are provided to brace the inner door during this test. The resilient seals on the personnel access lock are tested at a reduced pressure.

3.8.2.7.8 Examination of Coatings on Immersed Surfaces

Periodic visual examination of concrete structures, structural steel, and the coatings on immersed surfaces inside primary containment will normally be conducted during refueling outages. A continuing examination program has been developed based on the combined observations from the first and successive visual examinations. The frequency of the visual examinations will be based on the findings and apparent degradation rates, and may not necessarily be repeated each refueling outage. If the visual examination of the containment coating indicates that significant deterioration has occurred, the affected areas will be checked to determine the extent of material loss and repairs will be made if necessary.

3.8.3 CONCRETE AND STEEL INTERNAL STRUCTURES OF STEEL CONTAINMENT

3.8.3.1 Description of Internal Structures

The following provides descriptive information of the various internal structures to define the primary structural aspects and elements relied on to perform their safety-related functions. Figure 3.8-1 gives an overall view of the internal structures of the steel containment.

The following internal structures are discussed:

a. Reactor pedestal,

b. SSW,

c. Drywell floor structural system and support elements,

d. Radial beam framing systems,

e. Stabilizer truss,

f. Refueling bellows seals,

g. Reactor steam supply system hangers and supports, and

h. Reinforced-concrete lining inside the bottom head of the steel primary containment vessel.

The safety-related functions of the internal structures include the following:

a. To provide support during normal operation and seismic disturbances and thereby prevent the occurrence of a LOCA, and

b. If a LOCA does occur, to act to mitigate its consequences by protecting the containment and other engineered safety features from the effects induced by the accident such as jet forces and whipping pipes.

The capability of structures internal to the steel containment to withstand the hydrodynamic effects resulting from actuation of SRV and specific loads associated with postulated LOCAs are discussed in Appendix 3A.

3.8.3.1.1 Reactor Pedestal

The general arrangement and principal features of the reactor pedestal are shown in Figure 3.8-17 and 3.8-18.

The reactor pedestal is a vertical cylindrical shell-type reinforced-concrete foundation. This foundation supports the RPV and the SSW. The reactions transmitted by the SSW and the RPV to the pedestal are due mainly to seismically induced loads, pipe break pressures, and pipe rupture restraints attached directly to the SSW and the loads transmitted to the SSW by the radial beam systems. Other pipe rupture restraints are attached directly to the reactor pedestal.

The reactor pedestal is also an important component in the structural system supporting the RPV against seismic disturbances and postulated pipe breaks. This system includes the SSW, reactor pedestal, and the stabilizer truss all in conjunction with the primary containment vessel, the biological shield wall, and the reactor building foundation mat.

In plan, the reactor pedestal is located on the centerline of the RPV and, therefore, on the centerline of the primary containment vessel. In elevation, the reactor pedestal is located directly under the RPV and SSW.

The bottom of the RPV skirt and the SSW are anchor-bolt-connected directly to the top of the reactor pedestal. The bottom of the reactor pedestal is keyed into the reinforced-concrete liner inside the bottom head of the primary containment vessel. Load transmitted from the reactor pedestal to the reactor building foundation mat is by means of the concrete liner inside the containment vessel bottom head, the continuous concrete fill under the containment vessel bottom head and by means of the inner circular skirt attached to the containment vessel bottom head, and anchor-bolted to the reactor building foundation mat. The skirt provides a direct link from the pedestal to the mat. Such load transfer is accomplished without imposing direct load onto the containment vessel bottom head as discussed in Section 3.8.3.4.1.

The features of the reactor pedestal concrete are shown in Figures 3.8-17 and 3.8-18 and include haunches for the support of radial beams and openings for CRDs. Information including plans and sections describing features at the connections of the RPV and SSW to the top of the reactor pedestal are given in References 3.8-5, 3.8-6, and 3.8-7. Information including plans and sections showing the reactor pedestal as part of the drywell floor pressure barrier between the drywell and suppression chamber, and plans and sections showing the monolithic construction at the joint between reactor pedestal and drywell floor, is presented in References 3.8-8 and 3.8-9.

Except at haunches and at any other special features, the reactor pedestal has an inside diameter of 20 ft 3 in., an outside diameter of 30 ft 4 in. and, therefore, a shell thickness of 5 ft 0.5 in. Its height is approximately 84 ft 0 in. The shell is reinforced on both faces by horizontal hoop and vertical meridional reinforcing steel and is designed and constructed integrally with the SSW and RPV, the drywell floor slab, and the reactor building foundation mat.

The inside and outside surfaces of the reactor pedestal are coated with a special decontaminable coating. This coating protects the pedestal surfaces against attack by either aggressive demineralized water or radioactive contamination and facilitates washdown.

3.8.3.1.2 Sacrificial Shield Wall

See References 3.8-5, 3.8-6, 3.8-7, 3.8-23, and 3.8-24 for descriptive information, primary structural functions, structural arrangement, and principal features of the SSW.

3.8.3.1.3 Drywell Floor Structural System and Support Elements

The general arrangements and principal features of the drywell floor structural system and support elements are given in Figures 3.8-17, 3.8-3, 3.8-19, and 3.8-20.

The drywell floor is part of the BWR containment system, utilizing the pressure suppression concept in a Mark II over-under containment configuration. The drywell floor is a leaktight pressure barrier dividing the containment vessel into a drywell portion above the floor and a suppression chamber (wetwell) below the floor and directly under the drywell. The drywell portion, including the drywell floor slab, serve to contain the effects (i.e., mass and radiation) of a LOCA and to direct the steam released from a reactor primary system pipe break into the suppression chamber. The suppression chamber provides a pool of water which serves as a heat sink capable of transforming the energy, in terms of pressure and temperature, that is released from a LOCA following a postulated rupture of the primary coolant piping. The energy transformation is achieved by directing the steam mixture through the drywell floor downcomer vent pipes into the suppression pool where the mixing effect condenses the steam and results in lower pressure and temperature. Noncondensible gases are carried over and

collected in the suppression free space and vented back to the drywell by way of vacuum breaker valves.

See Figures 3.8-1, 3.8-3, 3.8-17, and 3.8-19 and References 3.8-8 and 3.8-9 for information and figures relative to the function of the floor structural system and support elements in providing a leaktight drywell-wetwell pressure barrier.

The drywell floor structural system consists of

a. An outer annulus made of a 2-ft 0-in.-thick reinforced-concrete slab supported by structural steel beams in composite action, by reinforced-concrete columns and by the reinforced-concrete pedestal, and

b. An inner circular reinforced-concrete slab, inside the reactor pedestal, 5 ft 0 in. thick, lower in elevation than the outer slab by approximately 6 ft 10 in., and constructed monolithically with, and supported by, the reactor pedestal.

Additional elements supporting the drywell floor are

a. A continuous circular closure girder embedded in the drywell floor along its outer periphery as shown in Figure 3.8-3;

b. A drywell floor peripheral seal assembly. The seal assembly is discussed in Section 3.8.3.4.3.3; and

c. Shear lugs intermittently located along the outer periphery of the drywell floor and consisting of male lugs welded to the circular flanged girder and female lugs welded to the primary containment vessel.

There are 83 24-in. and 16 28-in. diameter downcomer vent pipes which provide the flow paths for uncondensed drywell steam into the suppression chamber pool. The upper part of each downcomer is embedded in and supported by the reinforced-concrete slab of the drywell floor. A horizontal steel plate ring, welded to each downcomer and embedded in the slab, serves as a downcomer support and as a seal in preventing leakage through the drywell floor. A jet deflector is provided at each downcomer to prevent the direct impingement of a fluid jet onto the downcomer from any pipe break.

A special decontaminable epoxy coating is applied to the drywell floor to reduce the permeability of the concrete slab and to provide additional leaktightness between the drywell and the suppression chamber.

3.8.3.1.4 Radial Beam Framing Systems

Structural steel beams span radially from support points on the SSW and reactor pedestal to the primary containment vessel to form radial beam systems at various levels. The beam seats provided on the primary containment vessel to support the radial beams are designed to support the beams vertically and tangentially and to allow the beams to move freely in the radial direction. The beam seats are also designed to account for differential motions of the primary containment vessel at one end of the beam and the SSW and reactor pedestal at the other end. The radial beam framing systems are erected to serve several purposes. They provide:

a. Supports for mechanical and electrical equipment, such as the recirculation pumps, monorails, valves, air handling units, cable tray runs, and piping systems; during normal operation and seismic disturbances,

b. Platform areas for access to equipment and materials and areas for performing inservice inspection and maintenance, and

c. Supports for pipe whip restraints designed to withstand postulated high energy pipe breaks (see Section 3.6.2).

Various radial beam support systems which are typical are discussed below.

At el. 512 ft 9.5 in. (see Figure 3.8-20) radial beams support the recirculation pump and motor; furnish pipe restraint supports primarily for the residual heat removal (RHR) shutdown cooling supply and return loops; provide support for piping, electrical trays and ventilating duct hung loads; and provide grating floor areas where required for access to material and equipment.

Figure 3.8-21 shows the type of steel framework erected to withstand high-energy pipe rupture loads in the unlikely event of a postulated main steam or feedwater pipe break provides the pipe restraint required to prevent damage to the adjacent redundant main steam and feedwater piping and adjacent structural elements. This framework interfaces with the circumferential pipe whip protection support ring attached to the primary containment vessel at el. 516 ft 6 in. The interface arrangement is one which is comprised of shear lugs which permit the transmission of tangential shear loads and axial loads from the framework and allow for differential vertical motions between the primary containment vessel and the structural framework (see Section 3.6.2).

Figure 3.8-20 shows a radial beam framing system at el. 524 ft 3-7/8 in. provides the platform area required for access to the feedwater valves.

The radial beams at el. 531 ft 0.25 in., shown in Figure 3.8-20, furnish the catwalk needed for inservice inspection of the RPV inlet and outlet nozzles.

The radial beam framing system at el. 541 ft 3.75 in., shown in Figure 3.8-22, is a platform that primarily supports the main steam and reactor feedwater piping at the main steam relief valve location. It also serves as a pipe restraint framework for the main steam and feedwater pipe lines. The steel framework is supported directly by a continuous circular ring girder attached directly to the primary containment vessel at el. 542 ft 7.25 in.

The radial beam platform at el. 557 ft 6.25 in. supports a monorail system used for servicing the main steam relief valves, (see Figure 3.8-23), while another platform at el. 548 ft 6.25 in. provides access to the same valves.

3.8.3.1.5 Stabilizer Truss

The reactor building stabilizer truss in Figure 3.8-24 and the RPV stabilizer in Figure 3.8-25 are important components in the structural system supporting the reactor vessel. This support system includes the reactor pedestal, reactor vessel, and SSW inside the primary containment vessel. The system is designed to interact with the reactor building and the primary containment vessel via their connections at the reactor building foundation mat level, drywell floor level, and the top of the SSW level through the reactor vessel shear lugs/shear lug stabilizers/SSW/stabilizer truss interfaces.

The stabilizer truss is a circular truss with 16 horizontal members hinged at eight panel points at the top of the SSW and at eight panel points at the containment vessel by means of horizontal pin plate/gusset plate connections. The gusset plates are rigidly field-welded to the top of the SSW at one end of each member and to the containment vessel at the other end. The hinges allow vertical translation of the members resulting from differential thermal growth between the SSW and the containment vessel. The reactor vessel, SSW, stabilizer truss, and primary containment vessel are interconnected and as a unit are restrained tangentially but free to move vertically and radially with respect to the biological shield wall. This tangential restraint is accomplished by means of shear lug assemblies at the common panel points on the primary containment vessel and biological shield wall (see Figure 3.8-24). The tangential forces due primarily to earthquake and pipe rupture are in turn transmitted directly to the biological shield wall. Truss restraint to differential radial expansion of the SSW and the containment vessel imposes some load radially at the eight panel points on the containment vessel and is accounted for in the design (see Figure 3.8-24).

The reactor vessel is supported laterally near the top by means of its stabilizer lugs and the stabilizers shown in Figure 3.8-25. The lugs are integral parts of the RPV wall, and the stabilizers are rigidly attached to the top plate of the SSW. Only shear tangential to the vessel is transmitted by this lug and stabilizer arrangement, allowing the vessel to “grow” freely both radially and vertically relative to the SSW.

3.8.3.1.6 Refueling Bellows Seals

The drywell of the primary containment vessel is isolated by means of the drywell floor and its peripheral seal (discussed in Section 3.8.3.1.3) and by means of an inner refueling bellows seal, of flexible stainless steel, at the top head flange of the reactor vessel (see Figure 3.8-26). The inner refueling bellows seal, which is welded to both the reactor vessel and the bulkhead plate, serves to seal the gap between the reactor vessel and the primary containment vessel.

The polyurethane-filled gap between the primary containment vessel and the biological shield wall is kept dry by means of an outer refueling bellows seal at the top head flange of the primary containment vessel. The outer refueling bellows seal is welded between the primary containment vessel and the biological shield wall which seals the space between the primary containment vessel and the biological shield wall.

3.8.3.1.7 Reactor Steam Supply System Hangers and Supports

The steam supply system piping and pumps are supported by various types of hangers which in turn are supported by the structural steel radial beam framing systems; and by pipe supports, the SSW, the drywell floor, and the drywell portion of the reactor pedestal. A description of these supports is found in Section 5.4.

3.8.3.1.8 Reinforced-Concrete Lining Inside the Bottom Head of the Primary Containment Vessel

The reinforced-concrete lining inside the bottom head of the primary containment vessel (Figure 3.8-1 and 3.8-17) facilitates the design and construction of concrete structures in the suppression chamber by providing the means, through a like material for attaching their bases, particularly for attaching the base of the reactor pedestal with a continuous connection to the reactor building foundation mat that transfers all the load directly to the mat, with no residual concentrated load transferred to the bottom ellipsoidal head. In addition, the liner inside the vessel bottom head and the concrete fill on the outside of the bottom head sandwich the bottom head in such manner as to enhance the distribution of uniform type loads. The concrete liner is anchored to the vessel bottom head by means of headed stud shear connectors welded to the vessel bottom head.

3.8.3.2 Applicable Codes, Standards, Specifications, and Regulatory Guides

This section lists the codes, standards, specifications, regulatory guides, and other accepted industry guidelines that were adopted, to the extent applicable, in the original design and construction of the structures inside the primary containment vessel. Modification to these structures may use the latest editions to eliminate repetitious listing for each structure, the codes, standards, specifications, and regulatory guides are listed in Table 3.8-4 and given a

reference number. For each structure inside the primary containment vessel the applicable reference numbers in Table 3.8-4 are given in the following.

3.8.3.2.1 Reactor Pedestal

a. 1A, 2A, 2B, 3, 4, 5A, SB,
b. 6 through 9,
c. 11 through 18,
d. 20 through 25,
e. 30 through 36,
f. 38, 40, 42, 43, 45, and
g. 50 through 54.

3.8.3.2.2 Sacrificial Shield Wall

See References 3.8-5 and 3.8-6 for applicable codes, standards, specifications, and Regulatory Guides. References 3.8-23 and 3.8-24 provide information relative to as-built conditions and compliance to applicable welding codes.

3.8.3.2.3 Drywell Floor Structural System and Support Elements

The structural system and support elements refer to the

a. Reinforced-concrete slab,

b. Reinforced-concrete columns,

c. Reinforced-concrete pedestal,

d. Circular closure girder embedded in the slab along the outer periphery of the floor,

e. Drywell floor peripheral seal and jet deflectors,

f. Shear lugs, and

g. Downcomers and jet deflectors.

3.8.3.2.3.1 Reinforced-Concrete Slab.

a. 1A, 2A, 2B, 3, 4, 5A, 5B,
b. 6 through 9,
c. 11 through 18,

d. 21, 25,
e. 32, 33, 34,
f. 35, 36, 38, 40, 42, 45, and
g. 50 through 54.

3.8.3.2.3.2 Reinforced-Concrete Columns. Same as in Section 3.8.3.2.3.1, except that reference 18 and 21 are not applied.

3.8.3.2.3.3 Reinforced-Concrete Reactor Pedestal. See Section 3.8.3.2.1.

3.8.3.2.3.4 Circular Closure Girder.

a. 1A,
b. 18, 20, 21, 25,
c. 33, 34,
d. 40, 41, 42, and
e. 50 through 54.

3.8.3.2.3.5 Drywell Floor Peripheral Seal.

a. 18, 20, 22, 23, 25,
b. 33, 34,
c. 40, 41, 42, 43, 46, and
d. 50 through 54.

3.8.3.2.3.6 Peripheral Seal Jet Deflectors. Same as Section 3.8.3.2.3.5, except that reference 43 is not applied.

3.8.3.2.3.7 Shear Lugs. Same as Section 3.8.3.2.3.5, except that reference 43 is not applied.

3.8.3.2.3.8 Downcomers

a. 1A,
b. 18, 20, 21, 22A,* 22B,* 23, 25,
c. 33, 34,
d. 40, 41, 42, 46, and
e. 50 through 54.

3.8.3.2.3.9 Downcomer Jet Deflectors. Same as Section 3.8.3.2.3.5, except that reference 43 is not applied.

* See Section 3.8.3.4.9.

3.8.3.2.4 Radial Beam Framing Systems

a. 1A,
b. 18, 20, 25,
c. 33, 34,
d. 40, 41, 42, and
e. 50 through 54.

3.8.3.2.5 Stabilizer Truss

Same as Section 3.8.3.2.4, except that reference 1A is not applied.

3.8.3.2.6 Refueling Bellows Seals

a. 22, 23, 25,
b. 33, 34,
c. 40 through 49, and
d. 50 through 54.

3.8.3.2.7 Reactor Steam Supply System Hangers and Supports

See Section 5.4.14 for the codes and standards applicable to the steam supply system hangers and supports.

3.8.3.2.8 Reinforced-Concrete Lining Inside Bottom Head of Primary Containment Vessel

a. 1A, 2A, 2B, 3, 4, 5A, SB,
b. 6 through 9,
c. 11 through 17,
d. 21, 25,
e. 32, 33, 34,
f. 38, 40, 42, 45, and
g. 50 through 54.

3.8.3.3 Loads and Load Combinations

The following, pertaining to load conditions, load categories, definition of load terms, loads and load combinations, apply to all the major loads encountered and/or postulated for concrete and structural steel internal structures described in Section 3.8.3. All the loads referred to are not necessarily applicable to all structures and their elements. Applicable loads and applicable load combinations for which each structure is designed depends on the conditions to which the particular structure could be subjected.

Hydrodynamic loads resulting from actuation of SRVs and those associated with specific postulated LOCA loads, which were addressed in the DAR are included in Appendix 3A.

Sections 3.8.3.3.1 through 3.8.3.3.3 may be used in conjunction with the appropriate tables on loads and load combinations (Tables 3.8-5 and 3.8-6).

The criteria used for the concrete and steel internal structures of the steel containment complies with the codes, standards, specifications, and regulatory guides listed in Section 3.8.3.2.

3.8.3.3.1 Load Conditions

The load conditions are the following:

a. Service load conditions

Under service load conditions, the loads are those encountered during construction, testing, normal operation, shutdown, and severe environmental such as the OBE and the design basis wind, and

b. Factored load conditions

Under factored load conditions, the loads are abnormal loads due to postulated accidents such as LOCAs due to pipe rupture, shutdown, earthquake, and tornado.

3.8.3.3.2 Load Categories

The load categories for loads under service load conditions and factored load conditions are the following:

a. Service load conditions

1. Construction

All events and loads during structural construction, excluding those during testing;

2. Testing

All events and loads applied during structural integrity tests and preoperational tests such as hydrostatic tests and pressure tests. Each testing event is considered to be mutually exclusive of other testing events;

3. Normal operation and shutdown

   All events and loads that could reasonably be expected during the operation, shutdown, and normal maintenance of the power plant. The magnitude of these events and loads are based on the probability of occurrence of at least once in the design life of the plant;

4. Severe environmental

   All site-related environmental events and loads that could infrequently be encountered during the plant life such as the OBE, design basis wind, and the flood of record;

b. Factored load conditions

1. Extreme environmental

   All loads due to site-related environmental events which are credible but highly improbable. These events include the SSE, design basis tornado, and probable maximum flood;

2. Abnormal

   All loads due to postulated accident events. They include pressure, temperature, pipe whip, jet impingement, and pipe reactions due to each rupture postulated for the design basis pipe accidents. This loading condition also includes plant-related nonenvironmental missiles. The loads from each postulated accident event are considered to be mutually exclusive of other postulated accidents;

3. Abnormal/severe environmental

   Loads due to the highly improbable simultaneous occurrence of abnormal and severe environmental loading categories. Only the specified combination of these categories, as determined by the credible cause-and-effect events, are considered;

4. Abnormal/extreme environmental

   Loads due to the extremely improbable simultaneous occurrence of the abnormal and extreme environmental loading conditions. Only the

specified combinations of these conditions as determined by the credible cause-and-effect events, are considered.

3.8.3.3.3 Load Definitions

The following definitions of load terms apply to the major loads encountered and/or postulated for CGS, under the service load condition and/or the factored load condition, for concrete and structural steel structures:

a. Normal loads

D = Dead loads or their related internal moments and forces, including any permanent equipment loads, hydrostatic loads, and soil loads. For equipment supports, it also includes static and dynamic head and fluid flow effects.

L = Live loads or their related internal moments and forces, including any movable equipment loads such as crane loads, and other loads which vary in intensity and occurrence. For equipment supports, it also includes loads due to vibration and any support movement effects. Appropriate impact factors are included for such moving loads as from trolleys and cranes.

T_o = Thermal effects and loads during normal operating or shutdown conditions, based on the most critical transient or steady-state condition.

See Table 3.8-1 for drywell and suppression chamber temperatures.

R_o = Pipe, cable trays, and duct reactions during normal operating or shutdown conditions, based on the most critical transient or steady state condition. The reactions include

1. Self-weight including contents,

2. Most severe transient or steady-state thermal condition at normal operating or shutdown conditions, and

3. Effects of unbalanced pressure and thrust.

P_o = Normal operating external pressure differential pressure loads resulting from pressure variation either inside or outside the containment;

b. Construction Loads

The definitions for D, L, T_o in Section 3.8.3.3.3 (a) and W in Section 3.8.3.3.3 (d) are applicable, except that the construction load values are used;

c. Testing loads

The definitions for D and L given in Section 3.8.3.3.3 (a) are applicable, except that the test load values are used. In addition, the following loads are also considered:

P_t = Pressure during the structural integrity and leak rate tests. The primary containment vessel test pressure is 51.8 psig. For the drywell floor test pressure see Sections 3.8.3.3.4 and 3.8.3.7.

T_t = Thermal effects and loads during the tests;

d. Severe Environmental Loads

E = Loads generated by the OBE. The seismic effects include loads from structure, equipment, piping, cable trays dynamic soil pressures, hydrodynamic pressures, and all other items that could be considered as inertial forces for seismic analysis. The seismic excitations are discussed in Section 3.7.

W = Loads generated by the design basis wind as discussed in Section 3.3;

e. Extreme environmental loads

E′ = Loads generated by the SSE.

Seismic excitation from the SSE is discussed in Section 3.7. The seismic effects include loads from structures, equipment, piping, cable trays, dynamic soil pressures, hydrodynamic pressures, and all other items that could be considered as inertial forces for seismic analysis;

f. Abnormal loads

Abnormal loads are loads generated by the design basis accident under consideration.

P_a = Maximum differential pressure equivalent static load within or across a compartment generated by the postulated pipe break, and including an appropriate dynamic load factor to account for the dynamic nature of the load and an appropriate margin to account for uncertainty in the calculations. A small break case is also investigated.

1. Internal P_a = 45 psig,
2. External P_a = 2 psig.

T_a = Effects of thermal environment on the structure generated by a postulated pipe break. This includes T_o for all other areas not affected by the pipe break.

1. Peak drywell = 340°F,
2. Peak suppression chamber = 275°F.

R_a = Effects of thermal environment on the pipe reactions on the structure and equipment reactions on the structure generated by a postulated pipe break. This includes R_o for all other areas not affected by the pipe break.

R_r = Local effects in the structure (e.g., pipe support and whip restraints) generated by a postulated pipe break including appropriate dynamic load factors to account for the dynamic nature of the loads. These loads include

1. Reactions from pipe supports and whip restraint, Y_r,
2. Jet impingement, Y_j,
3. Missile impact due to a postulated ruptured pipe, Y_m.

Y_r = Equivalent static load on the structure generated by the reaction on the broken high-energy pipe during the postulated break, and including an appropriate dynamic load factor to account for the dynamic nature of the load.

Y_j = Jet impingement equivalent static load on a structure generated by the postulated break, including an appropriate dynamic load factor to account for the dynamic nature of the load.

Y_m = Missile impact equivalent static load on a structure generated by or during the postulated break, as from pipe whipping, and including an appropriate dynamic load factor to account for the dynamic nature of the load.

3.8.3.3.4 Internal Structures in the Suppression Chamber

The structures are grouped for convenient referencing as either drywell structures or suppression chamber structures. The various internal structures in the steel containment are discussed in Section 3.8.3.1. Of these structures, structures referred to as drywell structures are listed in Section 3.8.3.3.5 and structures referred to as suppression chamber structures are as follows:

a. Reinforced-concrete structures

1. Drywell floor slab,

2. Drywell floor support columns,

3. Reactor pedestal, and

4. Reinforced-concrete lining inside bottom head of primary containment vessel;

b. Structural steel structures

1. Drywell floor support steel immediately on underside of drywell floor slab,

2. Drywell floor continuous circular closure girder,

3. Drywell floor peripheral seal assembly,

4. Drywell floor peripheral seal jet deflectors,

5. Drywell floor peripheral shear lugs,

6. Downcomer vent pipes,

7. Downcomer jet deflectors,

8. Radial beam framing system supporting downcomers against horizontal seismic loads, and

9. Catwalks.

The reinforced-concrete structures are designed using the loads, load combinations and load factors listed in Table 3.8-5.

The structural steel structures are designed using the loads, load combinations and load factors listed in Table 3.8-6. Appropriate dynamic load factors are applied to the calculated dynamic loads in the design of each structural steel element.

See Appendix 3A for a discussion of hydrodynamic loads associated with activation of SRVs and LOCAs.

Structures in the suppression chamber, inclusive of the drywell floor, are designed to resist in combination with other possible concurrent normal and/or accident loads the effects of hydrostatic and hydrodynamic forces associated with water set in motion by seismic disturbances.

Internal structures are designed for the reactions of all other structures or equipment that they may support.

The effects of concrete volume changes are minimized by designing the concrete mix for minimal volume changes and by prescribing construction techniques to minimize differential strains.

The drywell floor is designed for the following differential pressures which may develop across the floor during the containment response following a postulated pipe break accident:

a. During the short term response, a differential pressure equal to +25 psig due to overpressurization of the drywell relative to the suppression chamber and applied to the drywell side in a downward direction, and

b. During the long term response, a differential pressure equal to -6.4 psig due to a partial vacuum in the drywell relative to the suppression chamber and applied to the suppression chamber side in an upward direction.

The drywell floor is designed for a test pressure of +25 psig overpressurization of the drywell relative to the suppression chamber applied to the drywell side.

The drywell floor is also designed for the following loads in addition to its own dead and live loads:

a. The reactor pedestal support reactions (vertical, base shear, and overturning moment),

b. Pipe rupture loads, including jet impingement loads and reactions, transmitted by pipe restraints connected directly or indirectly through radial beam framing systems serving as pipe rupture support truss systems,

c. Thermal and pressure loads imposed during normal operating conditions, and

d. Forces induced during an OBE or SSE.

The reactor support pedestal is designed to resist the following loads, in addition to its own dead load and live leads:

a. Dead and live loads from the reactor vessel, SSW and radial beam framing systems,

b. Thermal and pressure loads under normal operating and accident conditions,

c. Pipe rupture loads transmitted by pipe to the reactor pedestal by pipe restraints connected directly or indirectly through the radial beam framing systems serving as pipe rupture support truss systems,

d. Forces induced during an OBE or SSE, and

e. Thermal, pressure, earthquake, and pipe rupture loads that act on the RPV and SSW and are transmitted to the reactor pedestal via the support reactions.

3.8.3.3.5 Internal Structures in the Drywell

The structures are grouped for convenient referencing as either drywell structures or suppression chamber structures. The various internal structures in the steel containment are discussed in Section 3.8.3.1. Of these structures, structures referred to as suppression chamber structures are listed in Section 3.8.3.3.4; and structures referred to as drywell structures are the following, all of which are treated as structural steel internal structures:

a. SSW,
b. Radial beam framing systems,
c. Stabilizer truss,
d. Refueling bellows seals, and
e. Reactor steam supply system hangers and supports.

The loads, load combinations, and load factors used in the design of the SSW are presented in References 3.8-6 and 3.8-7. Further information relative to the as-built wall is contained in References 3.8-23 and 3.8-24. The loads, load combinations, and load factors used in the design of the structures in the drywell are presented in Table 3.8-6. Appropriate dynamic load factors have been applied to the calculated dynamic loads in the analysis of each structural steel element for load application time.

The radial beam framing systems serving as floor levels and/or pipe restraint supports are designed for the following loads in addition to their own dead loads:

a. A uniform platform live load,

b. Loads from pipe hangers, ventilation ducts, and electrical cable trays,

c. Forces induced during an OBE or SSE,

d. Pipe whip restraint forces, including the jet impingement load, due to a rupture of the supported pipes (see Section 3.6.2), and

e. Temperature and pressure effects during normal operating and accident conditions.

Internal structures are designed for the reactions of all other structures or equipment that they may support including the steam supply system hangers and supports.

The reactor vessel stabilizer truss is designed primarily for lateral seismic loads. However, all the loads associated with a support at the top of the SSW such as pressure and pipe whip loads on the SSW are included in the design of the stabilizer truss. The applicable load combinations are found in Table 3.8-6.

3.8.3.4 Design and Analysis Procedures

3.8.3.4.1 Reactor Pedestal

The general approach in the analysis and design of the reactor pedestal is to determine the values of the controlling stress resultants on the basis of elastic analysis under design loadings and to provide the required capacity of the pedestal in accordance with the strength method of the ACI 318-71 Code (Reference 3.8-10). Design loadings are in conformance with the loads and load combinations of Section 3.8.3.3. The report on design and analysis procedures for the upper portion of the pedestal, including transmission into the pedestal of reactions from the SSW and the RPV, is contained in Reference 3.8-6.

The principal loadings controlling the design of the pedestal are due to seismic action and pipe break effects which include annulus pressurization, pipe reactions, and pipe whip forces. Controlling overall stress resultants are pedestal bending moment, shear, and axial force. The values of these stress resultants due to seismic action are obtained from a dynamic analysis of a discrete mathematical idealization of the entire reactor building structure as described in Section 3.7. For other loadings, the pedestal is analyzed as a cylindrical beam fixed at its base and simply supported at the level of the drywell floor.

The distribution over the cross section of the axial stresses and shearing stresses due to the aforementioned stress resultants is that associated with single flexural theory. The axial force per unit length of arc due to the overall bending moment varies linearly with the distance from the neutral axis. The shearing force per unit length of arc is circumferential (tangential) in direction and varies sinusoidally in magnitude with maxima at the neutral axis. Meridional and hoop steel requirements are determined at the locations of maximum stress; this reinforcement is then provided uniformly around the pedestal.

Specific analyses are made at pedestal discontinuities such as openings and boundaries to determine the radial shears and radial moments. Additional reinforcement consisting of radial ties and meridional steel is provided as required.

At the base of the pedestal, provision is made for transmission of the pedestal reactions. Capacity for the transmission of shear is available due to axial compression, shear friction and the continuous key of the pedestal into its base. The axial tensite forces are transmitted by continuing the meridional reinforcement into the base where the connection to the cadweld ring assembly is made. This assembly, in turn, connects through weldments to the inner steel skirt which is anchored to the basemats.

3.8.3.4.2 Sacrificial Shield Wall

The design and analysis procedures for the SSW are described in Reference 3.8-7. Further information relative to the as-built wall is contained in References 3.8-23 and 3.8-24.

3.8.3.4.3 Drywell Floor Structural System and Support Elements, Including the Peripheral Seal Assembly, Peripheral Seal Jet Deflectors, and Peripheral Shear Lugs

3.8.3.4.3.1 Drywell Floor Slab and Columns. The drywell floor slab and columns are each analyzed elastically to determine the values of controlling stress resultants under the design load combinations for concrete structures as in Section 3.8.3.3. The required capacity for each of these structures is then provided in accordance with the strength method of the ACI 318-71 Code (Reference 3.8-10).

Under vertical loading, the floor slab is considered to act as a one-way slab in the radial direction, supported by tangential beams below, and extending from the support at the pedestal

to the face end at the primary containment vessel. The slab is analyzed as continuous over the supporting beams except for the spans between downcomers which are taken to be simple spans. Significant loads include dead load and differential pressure on the slab (P_a) but the principal load controlling slab design is the pipe break jet impingement force (R_r). Slab capacity is provided to resist the calculated design shears and moments.

The floor slab is also analyzed for the effect of other significant loads besides vertical loads. The effect of differential temperature between drywell and wetwell including slab bending is checked. Also, the connection between the pedestal and the floor slab is checked for capacity to transmit the pedestal horizontal seismic reaction.

The wetwell columns are subjected to a combination of axial (vertical) and lateral (horizontal) loading resulting from the superimposed loads from the drywell floor and seismic action respectively. The significant loads from the drywell floor, which contribute to the design axial load, are the floor dead load, live load, vertical seismic load (E'), differential pressure, and jet impingement. Column flexure due to horizontal seismic action is determined from analysis of the column as an elastic member subjected to lateral inertial forces corresponding to the column seismic acceleration. The capacity of the column to sustain the design stress resultants is determined by the strength method of ACI 318-71 Code. With concurrent axial load and bending moment, the magnified moment due to axial load is utilized in conformance with the Code.

3.8.3.4.3.2 Structural Steel Members. The steel beam structural system of the drywell floor consists of a grid of radial and tangential beams which support the drywell floor slab. The 17 radial beams, which divide the floor area into 17 similar sectors, are supported by the pedestal and the wetwell columns and extend as cantilevers beyond the columns to the vicinity of the primary containment vessel. In each sector, the tangential beams carry the drywell floor slab and span between the radial beams.

Each of the radial and tangential beams is analyzed by conventional elastic methods as an overhanging or simple span beam, as appropriate, to determine the design moments and shears. Loadings for the radial beams and tangential beams are as discussed above for the wetwell columns and the drywell floor slab. The beams are designed as composite beams in conjunction with the slab above. The elastic working stress design method of the 1969 AISC Design Specification (Reference 3.8-11) for composite construction is followed.

3.8.3.4.3.3 Drywell Floor Peripheral Seal Assembly. The drywell floor peripheral seal assembly is shown in Figure 3.8-3. The drywell floor peripheral seal is made of steel and is welded to the primary containment vessel and to the underside of the circular closure girder embedded in the drywell floor. It is a 270 degree segment of a stainless-steel pipe in cross section, circular in plan, and is drained to the floor drain system which is routed to a point outside of primary containment. Design and construction are compatible with primary containment requirements of Class MC components. Assembly of the seal and attachment

thereof to both the floor and the primary containment vessel is by means of welding in accordance with the ASME B&PV Code Section III, Class MC. The floor seal is designed to accommodate the maximum vertical and radial differential thermal movements which may occur during plant startup, normal operation, and shutdown. It is also designed to withstand, in an elastic manner, the effects associated with a LOCA, including temperature changes and pressure differentials ranging from +25 psig to -6.4 psig, and seismic loads. No other loads are applied to this seal. Jet deflectors are provided at the seal to prevent the direct impingement of a fluid jet force on the seal due to any pipe break. To prevent differential lateral and torsional movements, shear lugs are furnished along the outer periphery of the drywell floor to ensure that movements of the interfacing drywell floor, floor seal, and primary containment vessel are in unison during seismic events.

A continuous circular closure girder, which is of structural steel and embedded in the reinforced-concrete drywell (or diaphragm) floor along its periphery, is provided. Its basic function is to complete the drywell floor closure. It consists of a cylindrical vertical web plate extending from the bottom of the radial steel beams supporting the drywell floor slab to the top of the drywell floor slab at el. 499 ft 6 in. and with annular flanges as illustrated in Figure 3.8-3. In addition to its sealing function, the closure girder also provides the means for connecting the drywell floor peripheral seal to the drywell floor, for attaching the male components of the shear lug assembly, and for supporting the concrete floor. The closure girder withstands the design basis accident loads, drywell floor and slab loads, tangential seismic shear loads, and loads from the drywell peripheral seal.

The closure girder is designed according to the 1969 AISC Specification and for normal operating load combinations, extreme environmental, and the abnormal/extreme environmental loading combinations. Among the loads included in the combinations are design basis accident loads, drywell floor and slab loads, tangential seismic shear loads, and loads from the drywell floor seal. The loads are effectively resisted by the girder in flexure, shear, bearing on the concrete slab, and in tension by the way of shear stud connectors and embedded structural steel.

3.8.3.4.3.4 Drywell Floor Peripheral Shear Lugs. Thirty-six male shear lugs, equally spaced around the drywell floor periphery, transmit horizontal load between the drywell floor and the primary containment vessel. Each of these lugs consist of an assembly of steel plates joined by welding and anchored to the concrete floor slab by stud shear connectors. Transmission of load to the primary containment vessel is via female shear lugs welded to the vessel. The joint between male and female lugs affords restraint only in the circumferential direction as relative motion in the vertical and radial directions is permitted.

Analysis and design of the shear lug assembly is in accordance with the elastic working stress design method, Part 1 of the 1969 AISC Design Specification (Reference 3.8-11). The principal load controlling the design of the lug assembly is the horizontal seismic force transmitted by the drywell floor as determined by the method in Section 3.7. In line with

elastic theory, the distribution of the shear force per unit length of periphery is taken to vary sinusoidally with maxima along the diameter perpendicular to the direction of the overall shear force. The maximum value of the distributed shear force per unit length is used to design the shear lugs.

3.8.3.4.4 Radial Beam Framing Systems

The radial beam framing systems considered are those which do not support pipe whip restraints. Analysis and design of those beam systems which do support pipe whip restraints is discussed in Section 3.6.2.3.3.2. The analysis and design of the former radial beam systems is in accordance with the elastic working stress design method, Part 1 of the 1969 AISC Design Specification (Reference 3.8-11). Conventional elastic beam analysis is used. The significant loads in the load combinations are dead, live, reactions under operating conditions, and seismic loads.

3.8.3.4.5 Stabilizer Truss

The stabilizer truss is a pin-connected plane truss which transmits horizontal force between the top of the SSW and the primary containment vessel biological shield wall, as described in Section 3.8.3.1.5. This transmitted force represents reactions from the SSW and the RPV. The supports for the truss joints at the SSW are fixed at the wall so that two components of reaction (radial and tangential) may occur. At the primary containment vessel the truss joint support is constrained only in the circumferential direction so that the only reaction is tangential force.

Analysis and design of the stabilizer truss is in accordance with the elastic working stress design method, Part 1 of the AISC Design Specification (Reference 3.8-11). The principal loads controlling the design of the truss result from seismic action and pipe break effects including pipe whip, pipe jet, and annulus pressurization. The forces transmitted by the stabilizer truss under these loadings are determined by analysis of the overall structural system from the pedestal to the primary containment vessel including the SSW and the RPV. In this regard, the SSW is modeled as a space frame as described in Reference 3.8-7 and the RPV as a beam to give the loads transmitted by the stabilizer truss. Analysis of the stabilizer truss as a pin-connected plane truss with supports as described above is accomplished using the proprietary computer program “McDonnell-ECI, ICES, STRUDL” which is based on MIT’s STRUDL II, Version 2, Update 2 as augmented by McDonnell Douglas Automation Co., St. Louis, Missouri. The computer analysis is described in Reference 3.8-7.

3.8.3.4.6 Refueling Bellows Seals

Design and analysis procedures for the inner and outer refueling bellows seals are based on applicable ASME Code Sections II, VIII, and IX; the Standards of the Expansion Joint Manufacturers Association, and Interpretation Case Number 1177-7 (see Figure 3.8-26).

3.8.3.4.7 Reactor Steam Supply System Hangers and Supports

Design and analysis procedures for the steam supply system hangers and supports are found in Section 5.4. Design and analysis procedures for the General Electric stabilizers are based on applicable ASME pressure vessel codes.

3.8.3.4.8 Reinforced-Concrete Lining Inside Bottom Head of Primary Containment Vessel

The design accounts for strains caused by creep, shrinkage, and elastic shortening. The methods and data used for the analysis are based on the applicable codes, standards, and specifications in Table 3.8-4 and the results of past experience. (See Figures 3.8-1 and 3.8-17).

The concrete lining is analyzed using elastic methods and designed in accordance with ACI 318-71 by the strength method.

The headed stud shear connectors anchoring the concrete liner to the bottom head of the primary containment vessel are capable of transferring horizontal shear from the concrete internal structures to the bottom head of the containment vessel and of resisting relative movements between the concrete liner and the bottom head of the containment vessel. See the discussion of the reactor pedestal in Sections 3.8.3.1.8 and 3.8.3.4.1.

The analysis and design account for any postulated loading conditions that would cause net uplift at the base of certain reinforced-concrete columns.

Uplift on any portion of the pedestal base is transmitted directly into the reactor building foundation mat as discussed in Section 3.8.3.4.1.

3.8.3.4.9 Downcomer Vent Pipes

The downcomer vent pipes are designed to contain and direct uncondensed drywell steam into the suppression pool following a pipe break accident. See Section 3.8.3.1.3 and Reference 3.8-8, and Appendix 3A for further description and the design and analysis procedures used.

Stainless-steel extension pieces were added to the ends of the downcomers to prevent coating damage from plugs which are installed for the preoperational bypass leakage rate tests. Downcomers were originally provided with exit flanges for these tests. These flanges were removed because of concern about the applicability of test data taken on prototype downcomers without flanges. The downcomers are designed and constructed in accordance with ASME Section III Class 2 requirements above 1 in. above the circumferential weld joining the stainless-steel extension pieces to the bottom of the downcomers. Below this point

the downcomers are designed and constructed to ASME Section III Class 3 requirements. The only effect of this code break is to eliminate radiography requirements for the circumferential weld.

3.8.3.5 Structural Acceptance Criteria

3.8.3.5.1 Reinforced Concrete

The maximum permissible stresses and strains used are given in Table 3.8-12. These permissible stresses and strains are used to keep the structures below the range of general yield, both under service load conditions and factored load conditions.

For each of the loading combinations listed in Table 3.8-5, the required sectional strength of concrete (U) is calculated using the strength design method of ACI 318-71 with the applicable capacity reduction factor.

The symbol U denotes the section strength required to resist design loads or their related internal moments and forces based on the strength design methods described in ACI 318-71.

The reinforced-concrete internal structures of the steel containment include the drywell floor, the drywell floor support columns, the reactor pedestal, and the reinforced-concrete lining inside the bottom head of the primary containment vessel. (See Figures 3.8-17 and 3.8-18).

3.8.3.5.2 Structural Steel

See Table 3.8-7 for the criteria used for

a. Required limits of section strength, S and Y, and
b. Section moduli

The symbol S denotes the required section strength based on the elastic design methods and the allowable stresses defined in Part 1 of the AISC "Specification for the Design, Fabrication, and Erection of Structural Steel for Buildings," February 12, 1969 (Reference 3.8-11). The symbol Y denotes the section strength required to resist design loads based on plastic design methods described in Part 2 of the AISC Specifications (Reference 3.8-11). For steel internal structures of steel containments, the elastic working stress design method of Part 1 of the AISC specification (see Table 3.8-4) is used. All the loads considered in the loading combinations are factored loads. The plastic design method of Part 2 of the AISC Specification (see Table 3.8-4) is used as may be required for such structures as pipe restraint supports.

3.8.3.6 Materials, Quality Control, and Special Construction Techniques

Structures internal to the containment, except for the SSW, are not in a region of high-energy neutron flux.

It has been determined that in the 40-year life expectancy of the station the outside face of the SSW will experience a neutron fluence of less than 2×10^{16} nvt. The projected fluence at the SSW outer wall for 60 years of operation, including margin to account for a power uprate, will remain below 2×10^{16} nvt.

The construction materials and material quality control procedures for reinforced-concrete structures internal to the containment conform to the standards set forth in Section 3.8.4.6. Structural steel standards are also found in Section 3.8.4.6.

Materials and quality control programs comply fully with the "Building Code Requirements for Reinforced Concrete," ACI 318-71 (Reference 3.8-10), for concrete and with the AISC Specification (Reference 3.8-11), for steel as applicable.

See Table 6.1-1 for materials for specific components of internal structures in the containment.

Quality control meets the requirements of ANSI N45.2.5 (Reference 3.8-12), and Regulatory Guide 1.55, Revision 0. Reinforcing bars are generally not welded in any structure, except where mechanical cadweld fasteners are not feasible.

No construction techniques unusual to methods used during CGS construction were employed or required for the concrete and steel internal structures of the steel containment.

3.8.3.7 Testing and Inservice Surveillance Programs

All of the structural components in Section 3.8.3 are visually inspected during outages as defined by the inspection program. The frequency of periodic inspections is based on the results from the findings from previous inspections, as defined in the inspection program and summary finding reports. The inspections are made to determine if degradation to structural integrity has occurred. Inspections of concrete structures are conducted to check for possible deterioration, excessive cracking, or spalling of concrete. Similar inspections are made of structural steel members to check for deterioration of surface coatings and abnormal deformations or warpage.

Rigorous inspection was carried out during construction and in conjunction with the quality control assurance procedures for structural materials outlined in Section 3.8.4.6.

The drywell floor metal peripheral seal is designed, procured, fabricated, installed, and inspected in accordance with the 1971 Edition of the ASME Code Section III, Subsection NE, Class MC Components, Winter 1973 Addenda, except that hydrostatic or pneumatic testing of the seal is not performed, and the seal is not N-stamped. Leaktightness of the seal is tested,

however, as described below and in Reference 3.8-14. Butt welds joining the peripheral seal segments are radiographed, and welds joining the peripheral seal to the containment and to the diaphragm slab closure girder are liquid penetrant examined.

Periodic drywell-wetwell leakage tests are performed. See Section 6.2 for details of the periodic testing methods that are included in the containment leakage rate testing program.

The initial bypass leak rate test included tests at 25 psid and 15 psid in addition to the low differential pressure required in the periodic tests. Successful completion of the 25 psid bypass leak rate test served to prove the structural integrity of the drywell floor.

3.8.4 REDACTED

3.8.5 FOUNDATIONS

3.8.5.1 Descriptions of Foundations

All foundations described below are supported by Quality Class I compacted structural backfill as described in Section 2.5.4.5. As a means of providing a level working surface for construction of the mat type foundations, a 4-in. thick unreinforced concrete leveling slab is installed on the compacted subgrade.

The groundwater level at the site is sufficiently lower than the deepest foundation in the complex. For discussion of groundwater levels at the site, see Sections 2.5.4.6 and 3.4.

3.8.5.1.1 Reactor Building

The primary containment vessel and the reactor building enclosing the containment vessel are both supported on a common, reinforced-concrete mat foundation having a thickness of 16 ft. The mat is reinforced with top and bottom layers of reinforcing steel. Reinforcement is placed in an orthogonal grid pattern. The plan of the mat and the corresponding sections through the mat are shown in Figure 3.8-43.

Induced horizontal shears in the mat due to seismic, wind, and tornado disturbances are resisted by frictional resistance between the mat and the supporting media. Shear resulting from shear wall action is transferred to the mat through shear reinforcement. Lateral shears on vertical load-carrying elements are transferred to the mat through keys in the mat.

A gap is provided between the reactor building foundation mat and adjacent building foundations. The gap is of sufficient horizontal dimension to preclude interaction of Seismic Category I foundations with Seismic Category II foundations, during the SSE and the OBE.

The capability of the foundation mat to withstand loads associated with steam relief valve actuation and with vent clearing, and to withstand specified loads associated with postulated LOCAs which act in the drywell and wetwell of the steel containment vessel, are discussed in Appendix 3A.

For additional description of the reactor building foundation mat, see Section 3.8.2.1.

3.8.5.1.2 Radwaste and Control Building

The radwaste areas and the control room area are contained in one building unit supported on a reinforced-concrete mat foundation having a nominal thickness of 8 ft. The control room area occupies approximately 30% of the radwaste and control building plan at the north end of the building. For description of the radwaste and control building, see Section 3.8.4.1.2. The mat has the same structural characteristics as the reactor building mat described in Section 3.8.5.1.1.

The control room portion of the building unit shares common structural elements with the radwaste portion, which is Seismic Category I. Because of this interconnection and the resulting seismic interaction between the building portions, the entire building complex is modeled as a unit for Seismic Category I analysis (see Section 3.7.2).

3.8.5.1.3 Diesel Generator Building

The foundations for the diesel generator building consist of continuous reinforced-concrete wall footings under all building perimeter and interior load bearing walls and reinforced-concrete spread footings under each interior building column. The diesel generator units are each

supported on an individual reinforced-concrete foundation, isolated from the above mentioned building foundations. Induced horizontal shears in the foundations due to seismic, wind and tornado disturbances are transferred to the supporting media through the frictional resistance between the foundations and the supporting media. For a description of the diesel generator building, see Section 3.8.4.1.4.

The diesel oil storage tanks are buried and supported directly on Quality Class I structural backfill as referenced in Section 3.8.5.1. Since the groundwater level is lower than the invert of the tanks (see Section 3.8.5.1), an empty storage tank will not have buoyancy forces acting upon it.

3.8.5.1.4 Standby Service Water Pump House and Spray Pond

The standby service water pump house and spray pond are two structures joined together along one face of the pump house.

The spray pond is an inground water retention structure. The structure consists of reinforced-concrete cantilevered retaining walls, with an independent reinforced-concrete bottom slab on which is supported the spray piping. Spray pipe supports are secured to the slab with bolts screwed into expansion anchors drilled into the concrete slab. The pond is provided with a depressed sump in the bottom slab at one corner, at the pump house pump inlet bay.
A membrane vapor barrier is placed between the structural slab and the leveling slab.

The standby service water pump house foundation consists of three types of foundations. The pump inlet bay portion of the pump house is depressed to the same elevation as the pond sump whose bottom is a reinforced-concrete mat foundation having a thickness of 3.5 ft. The concrete walls which form the pump inlet bay and support portions of the building are also supported on this mat. The face of the pump house which is adjacent to the spray pond is supported by a reinforced-concrete retaining wall common to both the pump house and the spray pond. The balance of the pump house is supported by reinforced-concrete columns and spread footings. For description of the standby service water pump house and spray ponds, see Section 3.8.4.1.5.

Horizontal shears in retaining walls and piers are transmitted to their respective foundations through shear keys. Shears in the foundations are transferred to the supporting media through the frictional resistance between the foundation and the supporting media.

3.8.5.1.5 Condensate Storage Tank Retaining Area

The condensate storage tank retaining area consists of a reinforced-concrete mat foundation, at grade, having a thickness of 2 ft 4 in. The mat provides support to the two condensate storage tanks and the perimeter reinforced-concrete dike walls which are designed to contain the contents of the tanks in the event of their failure. The mat edges are thickened to provide the

strength required to sustain all of the seismic loads acting on the perimeter dike walls. The perimeter dike walls are keyed to the mat foundation to resist the seismically induced lateral horizontal shears in the walls. The mat rests directly on compacted backfill without any membrane waterproofing. Horizontal shears in the mat are transferred to the supporting media through the frictional resistance between the mat and the supporting media.

3.8.5.1.6 Turbine Generator Building

The turbine generator building foundation mat, like the superstructure, is designed to withstand the effects of an SSE and maintain its structural integrity thus providing adequate protection for the main steam lines designed as Seismic Category I, as described in Section 3.8.4.1.3. The turbine generator building is supported on a reinforced-concrete mat foundation having varying thicknesses ranging from 9 ft to 12 ft. For a description of the turbine generator building, see Section 3.8.4.1.3. The mat has the same structural characteristics as the reactor building mat described in Section 3.8.5.1.1.

3.8.5.1.7 Non-Seismic Category I Safety-Related Foundations

The makeup water pump house is a non-Seismic Category I structure but is a safety-related installation designed to withstand the design basis tornado and tornado-generated missiles. For additional description of the pump house, see Section 3.8.4.1.6. The makeup water pump house is supported on two types of foundations. The eastern end of the pump house is supported by a deep, square pump pit which in turn is supported on a reinforced-concrete mat foundation having a thickness of 3 ft. The remainder of the building is supported on continuous reinforced-concrete wall footings.

3.8.5.2 Applicable Codes, Standards, and Specifications

This section lists the codes, specifications, standards of practice, regulatory guides, and other accepted industry guidelines which are adopted to the extent applicable in the design and construction of the foundations for Seismic Category I structures. Modifications to the foundations may use the latest editions. To eliminate repetition, these codes, standards, and specifications are described and discussed in Table 3.8-4 and given a specification reference number. Listed below are the reference numbers for the foundations.

a. 1A through 9,
b. 11 through 17,
c. 25 and 28,
d. 32 through 36, and
e. 38, 41, 42, 43, 45, 49, 52, 53 and 54.

In addition, the "Supplementary Soils Investigation" prepared for Columbia Generating Station by Shannon & Wilson, Inc., soil consultants, is applicable to the design of the foundations (Reference 3.8-20).

3.8.5.3 Loads and Loading Combinations

The loads and loading combinations listed, defined, and discussed in Section 3.8.4.3 are applicable to the design of the foundations. Hydrostatic loads from the flood of record are not applicable to this installation as discussed in Section 3.4.

3.8.5.4 Design and Analysis Procedures

3.8.5.4.1 General

The analysis of Seismic Category I and non-Seismic Category I safety-related foundations is done using conventional elastic techniques. Seismic response coefficients used in the determination of loads applied to the foundations have been determined by mathematical models of the structures. All loads, interior and exterior to the structures, are transferred to their respective foundations through the elastic deformation of slabs, bearing and shear walls and columns. For additional discussion of the design and analysis procedures of the buildings, see Section 3.8.4.4.

The foundations are supported on compacted structural backfill. For discussion of site geology and soils characteristics and criteria, see Section 2.5. All foundation bearing pressures are within the allowables set forth in Appendix 2.5E. Maximum settlements based on allowable bearing pressures on the soil are tabulated in Table 5 contained in Appendix 2.5E.

Structural design of all foundations is in accordance with ACI 318-71.

3.8.5.4.2 Reactor Building Foundation Mat

The reactor building foundation mat is analyzed and designed by the finite element method utilizing NASTRAN, which is an accepted finite element computer program for static and dynamic structural analysis and is discussed in Section 3.12. The exterior building walls and the biological shield wall transmit the lateral loads and forces and overturning moments to the mat foundation, and are included in the model to account for their stiffening effect on the mat.

3.8.5.4.3 Radwaste and Control Building

The radwaste and control building mat foundation is analyzed and designed as a beam on an elastic foundation based on Abbett's "American Civil Engineering Practice" (Reference 3.8-18). The mat is divided into three strips, in each direction, with each strip considered as a beam. The lateral loads and forces acting on the structure are transmitted to

the mat foundation through interior shear walls, and the exterior, perimeter foundation walls. The mat beam strips are computer analyzed by FLXMAT, a proprietary computer program developed by Burns and Roe, Inc., for the analysis of flexible mat foundations on elastic foundations, which is discussed in Section 3.12.

3.8.5.4.4 Diesel Generator Building

Building wall footings and column spread footings are conventionally analyzed utilizing static and seismic loads and forces determined in the mathematical model seismic analysis of the superstructure in combination with other loads. The diesel generator foundations are analyzed utilizing the operating static and dynamic loads determined by the respective diesel generator manufacturers. The diesel generator foundations are seismically analyzed utilizing seismic response coefficients determined by mathematical model analysis.

3.8.5.4.5 Standby Service Water Pump Houses, Spray Ponds, and Condensate Storage Tank Retaining Area

The standby service water pump house building foundations are conventionally analyzed, utilizing seismic loads and forces determined in the mathematical model seismic analysis of the superstructure, in combination with other loads.

The spray pond bottom slab (nominally 7-in. thick) is considered to be a sufficiently flexible structure relative to the underlying supporting soil to essentially follow the displacements and deformations of the soil surface during a seismic event. The horizontal seismically induced shears at the points of pipe supports are resisted by horizontal plate action of the bottom slab which is horizontally constrained by the perimeter retaining wall footings. The spray pond walls are conventionally analyzed as rigid retaining walls subjected to static and dynamic lateral earth pressures.

The bottom slab of the condensate storage tank retaining area is a conventionally analyzed and designed mat foundation subjected to static and seismically induced loads acting on the storage tanks and the perimeter dike walls. The perimeter dike walls are analyzed and designed as vertical cantilever walls keyed and doweled to the thickened edge of the bottom slab mat foundation. The horizontal loads on the walls consist of hydrodynamic forces induced by the retained water within the diked area during a seismic event causing a failure of the condensate tanks, static water pressure of the contained water and the seismic forces acting on the wall itself.

3.8.5.4.6 Turbine Generator Building

The turbine generator building mat foundation is analyzed and designed as a beam on an elastic foundation based on Abbett's "American Civil Engineering Practice" (Reference 3.8-18). The mat is divided into three longitudinal beam strips covering the entire width of the building and

three representative transverse beam strips. The vertical and lateral loads and forces are transmitted to the mat foundation by perimeter foundation walls, interior shear walls, and columns through shear keys and shear friction reinforcement. The mat beam strips are computer analyzed by FLXMAT, a proprietary computer program developed by Burns and Roe, Inc., for the analysis of flexible mat foundations on elastic foundations and is discussed in Section 3.12.

3.8.5.4.7 Makeup Water Pump House

The mat foundation at the bottom of the pump pit and the continuous wall footings are conventionally analyzed. The mat foundation is analyzed as a two-way slab supported on four sides by the pump pit walls.

3.8.5.5 Structural Acceptance Criteria

Foundations are designed in compliance with ACI 318-71 and satisfy the strength and the serviceability requirements specified therein. The structural acceptance criteria for reinforced concrete described in Section 3.8.4.5.1 is applicable to the foundation designs.

The factors of safety against overturning and sliding for safety-related structures are as follows:

Safety-Related Structure	Safety Factors	
	Overturning	Sliding
Reactor building	1.50	1.80
Radwaste and control building	3.13	2.29
Turbine generator building	6.80	2.70
Standby service water pump houses	1.24	2.30

Uplifting of foundation mats occurs for the Seismic Category I structures listed below. Maximum uplift occurs as a result of the combined effects of horizontal and upward SSEs. The maximum uplift conditions are described below.

a. Reactor building - Under maximum uplift, 48% of the mat maintains bearing contact with the soil. Maximum upward deflection is 1.1 in.;

b. Turbine generator building - Under maximum uplift, 89% of the mat maintains bearing contact with the soil. Maximum upward deflection is 0.10 in.; and

c. Radwaste and control building - Under maximum uplift, 84% of the mat maintains bearing contact with the soil. Maximum upward deflection is 0.14 in.

3.8.5.6 Materials, Quality Control, and Special Construction Techniques

The materials, quality control, and special construction techniques for foundations conform to those set forth for Seismic Category I structures and are discussed in Section 3.8.4.6.

3.8.5.7 Testing and Inservice Surveillance Techniques

Tests to evaluate compaction of the Quality Class I structural backfill were performed by determining the relative densities of the compacted soil. Laboratory tests were made in accordance with ASTM D2049 which specifies the use of a vibrating table operating at a stipulated vibrating amplitude. In tests executed for this installation, it was found that the vibrating amplitudes of the tables used were lower than specified in ASTM D2049. Shannon & Wilson, Inc., soil consultants, investigated the relative densities of the compacted soil utilizing various vibrating tables and concluded that the relative density values are valid. The Shannon & Wilson report (Reference 3.8-19) covers their investigation of the foregoing and was submitted to the NRC by Energy Northwest.

In 1984 ASTM replaced ASTM D2049 with ASTM D4253 and D4254. These procedures are equivalent. All three standards are considered acceptable for use.

Routine observations were made of the foundations to determine the extent of cracking and/or imperfections.

Inspections were made during construction in conjunction with the quality control procedures for the structural materials as stated in Section 3.8.4.6. Structural integrity and/or performance tests, other than those described above, were not conducted.

3.8.6 PIPING AND ELECTRICAL PENETRATIONS

To maintain containment integrity, penetration assemblies which penetrate the steel primary containment vessel have the following characteristics:

a. They are capable of withstanding the peak pressures and temperatures encountered during all operating and testing modes,

b. They are capable of accommodating the thermal and mechanical loads which may be encountered during all modes of operation without failure,

c. They are capable of withstanding the forces caused by impingement of fluid from the rupture of the largest local pipe or connection without failure,

d. They are capable of withstanding the maximum piping reactions due to dead weight, seismic excitation, constraint to thermal expansion and other mechanical flow induced effects that may be exerted by the piping, to which they are attached, and

e. To account for the effects of postulated pipe rupture, the penetration assemblies are capable of withstanding the maximum reactions that the pipes to which they are attached are capable of exerting.

The quantities, types, service identifications, sizes, and pertinent data of the primary containment vessel penetrations are given in Figures 3.8-51 and 3.8-52.

The capability of the primary steel containment vessel penetrations to withstand the hydrodynamic effects resulting from the actuation of SRVs and specified loads associated with postulated LOCAs is discussed in Appendix 3A.

3.8.6.1 Description

3.8.6.1.1 Piping Penetrations - Type 1

Process lines traverse the boundary between the inside of the steel primary containment vessel and the outside of the biological shield wall by means of piping penetration assemblies made up of several elements. Two general types of piping penetration assemblies are provided: type 1 (also referred to as "hot" type piping penetration assemblies) and type 2 (also referred to as "cold" type piping penetration assemblies).

Figure 3.8-54 shows a type 1 piping penetration assembly. The type 2 penetration assembly is described in Section 3.8.6.1.2.

All piping is generally attached directly to the penetration nozzle. However, hot piping and multiple piping penetrations pass through the nozzle as type 1 and type 5 penetrations, respectively. The type 5 penetration is described in Section 3.8.6.1.5.

Type 1 penetration assemblies which penetrate the primary containment vessel consist of:

a. Penetration nozzle,
b. Flued head fitting,
c. Process pipe, and
d. Guard pipe, when required.

In all type 1 penetrations, containment closure is accomplished by means of the flued head fitting. The flued head fitting is located at the outer end of the nozzle, guard pipe and process

pipe, at a suitable distance external to the primary containment vessel and biological shield wall. At this location, the flued head fitting is welded to the nozzle. With the exception of the main steam penetrations, the portion of the process pipe, which is within the penetration assembly, is an integral part of the forged flued head fitting thus eliminating pipe welds which would be inaccessible for inservice inspection (See Figure 3.8-54). The main steam fluid heads are constructed from a flued head forging welded to a length of process pipe such that the welded assembly becomes a type 1 penetration (See Figure 3.8-51, Note 7). The flued head to process pipe weld is accessible for inservice inspection.

The inner end of the nozzle is welded to the reinforcing penetration insert plate, which is part of the primary containment vessel shell. The penetrations are designed for long-term integrity.

The guard pipe is provided between the nozzle and the process pipe to form an additional annulus between the nozzle and the process pipe. The additional annulus minimizes thermal stresses at the primary containment vessel shell during normal operation. The guard pipe also prevents direct impingement of hot fluid on to the primary containment vessel shell in the unlikely event of pipe rupture within the penetration, thereby minimizing thermal shock loading. The guard pipe is guided radially, at its inner end, near the primary containment vessel shell, by means of an enveloping sleeve and shims in the annulus between it and the nozzle, to limit seismic movement. Guard pipes are generally furnished with the type 1 penetration assemblies only when the operating process pipe temperature exceeds 300°F.

Pipe insulation is provided when required in the annulus between the process pipe and the guard pipe to reduce thermal stresses and heat losses.

The piping design includes the effects of seismic and thermal motion of the primary containment vessel shell at the penetration connections. Bellows type seals are not used for CGS.

Penetration analysis includes verification of the containment adequacy of the penetrations and of the primary containment vessel in the vicinity of the penetrations. The rupture loads are applied at the outboard interface of the flued head fitting and the process pipe. Analyses are performed to demonstrate that if local contact between the nozzle and the biological shield wall sleeve is possible, the nozzle is capable of maintaining containment.

No equipment or piping is anchored to the biological shield wall. However, lateral restraint assemblies are provided outside the primary containment vessel shell at certain of the type 1 penetrations to provide, where required by a rupture analysis of the penetration nozzle on the vessel side, containment integrity for all postulated maximum nozzle loads due to a self-break of the piping (a guillotine break or side break) as well as an adjacent pipe break (impingement).

The restraint assemblies are in the form of coaxial extensions of and attached to the steel pipe sleeves in the biological shield wall. The steel pipe sleeves are fully anchored into the biological shield wall.

The design loadings and the various load combinations, as well as the allowable stress intensities, are discussed in Sections 3.8.6.3 and 3.8.6.5, respectively.

3.8.6.1.2 Piping Penetrations - Type 2

Process lines for low energy (or cold) fluids utilize penetration assemblies without flued head fittings, to penetrate the primary containment vessel shell. Type 2 penetration assemblies are illustrated in Figure 3.8-55.

The type 2 penetration assemblies consist of a process pipe which also acts as the penetration nozzle in the vicinity of the primary containment vessel wall. The inner end of the nozzle is welded to the reinforcing penetration insert plate, which is a part of the primary containment vessel shell. The piping configuration and supports on both sides of the penetration are designed to preclude overstressing of the steel primary containment vessel nozzle under any loading condition, including postulated accidents.

Five TIP guide tubes pass from the reactor building to the drywell through the primary containment vessel. The penetrations are a type 2 piping penetration modified with a welding neck flange attached outside the containment. This flange is itself modified with dual concentric O-ring grooves machined into the face, which retain elastomeric O-rings. To this is bolted a blank flange which has been drilled for both a between-O-ring test port and a central hole in which an instrument tubing “bulkhead union” fitting is retained. This single penetration point is sealed by seal welding between the bulkhead union and the blank flange. The TIP guide tubes are attached to both sides of their respective bulkhead unions by flare fittings. These penetrations are also discussed in Section 3.8.2.1.1.3.

The design loadings and various load combinations, as well as the allowable stress intensity, are discussed in Sections 3.8.6.3 and 3.8.6.5, respectively.

3.8.6.1.3 Piping Penetrations - Type 3

The primary containment vessel is furnished with a number of spare penetrations of various sizes. These penetrations have a specific possible future use, and may be used as a type 1 or type 2 process pipe penetration or, as an electrical or instrumentation penetration. The type 3 penetration assembly is illustrated in Figure 3.8-55.

Type 3 penetration assemblies consist of a nozzle which penetrates the primary containment vessel and extends outboard beyond the biological shield wall. At the latter location, the

nozzle is furnished with a permanent closure. The inner end of the nozzle is welded to the reinforcing penetration insert plate which is part of the primary containment vessel shell.

Although the type 3 spare penetrations have a specifically intended future use, they are designed so that they can be utilized as any type penetration having more severe loads. Thus, a type 3 penetration which is intended to be a future type 2 penetration is designed for loadings which may be incurred by a type 2 penetration and for loadings which may be incurred by a type 1 penetration. A stipulated pipe rupture load is included in the analysis and is as shown in Figures 3.8-51 and 3.8-52.

The design loadings and various load combinations that may be incurred by either a future type 2 or a future type 3 penetration, as well as the allowable stress intensity, are discussed in Sections 3.8.6.3 and 3.8.6.5.

3.8.6.1.4 Electrical Penetrations - Type 4

The electrical penetration assemblies provide a means for the continuity of power, control and signal circuits through the primary containment vessel while maintaining the leaktight integrity of the vessel. Each penetration assembly is designed to function in the environmental conditions specified in Table 3.8-13. Electrical penetrations are categorized into three classes. Each of the three classes of penetration assemblies is designed to meet the requirements of a particular group of electrical cables (see Reference 3.8-15). The three general classes are

a. Signal penetration assemblies for shielded signal cables for circuits that require high signal integrity (neutron monitoring penetrations), penetrations X-100A, B, C and D;

b. Low voltage penetration assemblies for power, control or instrumentation leads. Penetrations series X-101, X-102, X-105, X-104, and X-107; and

c. Medium voltage penetration for power cables. Penetrations X-103A, B, C, and D.

The basic configuration of each of these three classes of penetration assemblies is a completely enclosed, sealed unit. Each penetration assembly is designed and fabricated so as to permit leak testing of the pressure barrier from a single point outside the primary containment vessel. (See Figures 3.8-56 and 3.8-57.) The penetration assemblies are designed considering the size and physical parameters of the containment vessel penetration nozzles.

The two basic types of electrical penetration assemblies are as follows:

a. The canister type as shown in Figure 3.8-56, and
b. The unitized header plate or noncanister type as shown in Figure 3.8-57.

The canister type electrical penetration (assembly series X-103) is used for medium voltage power cables. The penetration assembly extends the length of the containment vessel penetration nozzle. A plate at each end of the penetration canister provides double barriers between which can be pressurized and monitored for leak testing purposes.

The plates are constructed of stainless steel to eliminate eddy current heating. The containment vessel pressure boundary is established by welding the penetration assembly to the outboard end of the containment vessel penetration nozzle. A weld ring is attached to the inboard end of the containment vessel penetration nozzle to provide lateral support to the penetration assembly. Bolt-on terminal boxes are attached to the inboard weld ring and to the outboard end of the penetration assembly.

The remaining electrical penetration assemblies, series X-100, X-101, X-102, X-104, X-105, and X-107 are the unitized header assembly type. The unitized header assembly consisting of the bulkhead extension and monitoring plate is welded to the outboard end of the containment vessel penetration nozzle. Electrical penetration of the pressure boundary is achieved by the insertion of sealed modules into the monitoring plate. The modules are designed with two sets of dual O-rings between which sets can be pressurized and monitored for leak testing purposes. Modules may be substituted or added to the unitized header assembly as necessary in the future.

Bolt-on terminal boxes are attached to the unitized header assembly on the outboard side of the containment vessel and to a slip-on flange welded to the inboard side of the containment vessel penetration nozzle.

A cable support tray is provided inside the containment vessel penetration nozzle.

3.8.6.1.4.1 Configuration.

a. Neutron monitoring penetration

Shielded signal cables are provided to interconnect low noise circuits between the reactor and the associated control room. Two types of signal circuits are required: Type A service consists of reactor neutron monitoring circuits with a dc analog signal (power range neutron monitoring); type B service consists of reactor neutron monitoring circuits with a pulse output signal (startup neutron monitoring);

For type A service, the wire within the penetration module consists of, at a minimum, No. 18 AWG wires that are connected to the external wiring with insulated crimp splices;

For type B service, the cable within the penetration matches those to which it is connected. The source range monitor (SRM)/intermediate range monitor (IRM) cables consist of two shields which are connected together at the connectors to form a common shield for each cable. Inline connectors mounted on the side of the terminal boxes are used for cable terminations. The connectors are insulated from the penetration.

The concentric geometry of shielded cables is maintained through the penetration assembly without interruption to either shield or conductor.

Type B connectors are insulated from ground by at least 10^8 ohms at room temperature. The insulation resistance, between the center conductor and the shield, is greater than 10^{12} ohms at room temperature;

b. Low voltage control and indication penetration

The low voltage control and indication penetration assemblies (series X-101, X-102, and X-105) are suitable for 600-V ac (or below), whose circuits are designed to supply control power for the plant auxiliary systems.

Cable connections (see Reference 3.8-15 are as follows: (1) multipin connectors mounted on the header plate or box, (2) pigtail with inline pin connector, (3) pigtail and crimp type connector to be routed to a terminal box, or (4) pigtail to be routed to a splice.

Where connectors are furnished, they are the environment-resistant type in accordance with MIL-C-5051D. The insulation resistance between conductors is not less than 10^8 ohms at room temperature. All receptacles and pin contacts for No. 16 AWG and smaller wires are insertion pin types either soldered or gold plated crimp-on;

c. Low voltage power penetration

The low voltage power penetration assembly (X-104 series) is suitable for low voltage, 600-V ac and 250-V dc. The cables used within the penetration have their copper conductors and insulations sized in accordance with the conditions specified in Section 3.8.6.5.4.1 (b).

Wire is switchboard type SIS, stranded, tinned copper with 1000 V, 90°C insulation.

Insulation resistance between conductors is not less than 10^8 ohms at room temperature. The header plates are constructed of a suitable material to minimize eddy current heating. Power penetrations are provided with two copper-constantan thermocouples for temperature monitoring;

d. Medium voltage power penetration

The medium voltage power penetration assembly, (X-103 series) is suitable for three, 8-kV high resistance grounded cable.

The cables used inside the penetration assembly have their copper conductors and insulators sized in accordance with the conditions specified in Section 3.8.6.5.4.1 (c).

Cable terminations are either a mechanical splice (crimp-on lug type) or bushings mounted on the headerplates. Basic impulse level (BIL) is 95 kV. The insulation resistance between conductors is 10^{10} ohms at room temperature. These penetrations are provided with copper-constantan thermocouples for penetration temperature monitoring.

Specific provision is made in the design of the 8-kV penetration assembly to avoid electrical stress on the cable insulation. No part of the shielded cable insulation comes in contact with the ground plane either at the header or in the assembly. Holes in the header have well-rounded edges and are large enough to provide adequate supplementary insulation or bushing for the cable.

The ends of the canister are factory welded to nonmagnetic stainless steel header assemblies containing pressure-tight high-alumina ceramic seals;

e. Low voltage power, control and indication penetration

The low voltage power, control, and indication penetration assembly (X-107 Series), is suitable for 600-V ac and 250-V dc power cables, and 600-V control cable. The cables are used for 120-V ac (or below) circuits that are designed to supply control power for the plant auxiliary systems inside of the suppression chamber.

The cables used within the penetration have their copper conductors and insulations sized in accordance with the conditions specified in Section 3.8.6.5.4.1.

The continuity of shielded cables is to be maintained through the penetration assembly using single, conductor without interruption to either conductor or shield.

Cable connections (for Reference 3.8-15) are as follows: (1) multi-pin connectors mounted on the header plate or box, (2) pigtail with inline pin connector, (3) pigtail and crimp type connector to be routed to a terminal box, or (4) pigtail to be routed to a splice (for drywell wetwell vacuum breakers).

Where connectors are furnished, they are the environment-resistant type in accordance with MIL C-5015D. The insulation resistance between conductors is not less than 10^8 ohms at room temperature. All receptacles and pin contacts for No. 16 AWG and smaller wires are insertion pin types either soldered or gold plated crimp-on.

The header plates are constructed of nonmagnetic austenitic stainless steel to minimize eddy current heating.

3.8.6.1.4.2 Ampacity. The cables through the electrical penetration assembly are sized to ensure the following:

a. Adequate cable current carrying capability (ampacity) of no less than the values indicated in Reference 3.8-15, and

b. After each penetration assembly is installed and operating continuously during normal environmental conditions, the temperature of the concrete adjacent to the containment vessel penetration nozzle does not exceed a maximum of 150°F along the length of the penetration when operating at 100% rated current load on all conductors.

3.8.6.1.4.3 Auxiliary Hardware.

a. Temperature monitoring: Each power penetration (series X-104 and X-103) assembly has two internal temperature monitoring, copper-constantan thermocouples to monitor the temperature within the assembly.

b. Terminal boxes: Terminal boxes and their mounting terminal blocks, connectors and terminal lug connectors are provided at both ends of each penetration. Terminal boxes for unitized header type penetrations are designed to permit installation of the penetration with only the removal of the outer (or front) enclosure cover. The terminal boxes are type National Electrical Manufacturers Association (NEMA) 4 boxes with an environment resistant coating. Boxes are arranged to avoid interference with adjacent penetrations.

All terminal boxes located inside of containment have holes punched in the box to allow equalization of pressure outside to inside the box during a LOCA so that the box will not implode. Plugs are installed in the holes of the boxes to help keep moisture out. These plugs are designed to push into the box during a LOCA. In addition, holes are punched in the bottom of the boxes, as required for moisture drainage.

c. Cables: Cables within penetration assemblies and/or nozzles are restrained by supporting structures to prevent cables from excessive motion due to high electrodynamic or mechanical forces. Cable supports also minimize compressive loading of cable insulation.

d. Radiation shielding: Provision is made for fastening and supporting up to 150 lb of radiation shielding on the inside end of the penetration assembly.

3.8.6.1.4.4 Shop Painting of Electrical Penetrations. All ferrous metal surfaces, interior and exterior, are furnished with a coating to withstand the environmental conditions listed in Table 3.8-13.

3.8.6.1.5 Instrumentation Piping Penetrations - Type 5, 6, and 7

Figure 3.8-58 illustrates the instrumentation penetration assembly. The penetration assembly consists of a penetration nozzle and lengths of instrumentation pipes. The instrumentation pipes pass through the penetration nozzle from the reactor building side, through the containment vessel shell, to the interior of the containment vessel. The inner end (containment vessel end) of the nozzle is welded to the reinforcing penetration insert plate the penetration are designed to preclude over-stressing the steel primary containment vessel nozzle under any loading condition, including postulated accidents.

The penetration of the instrumentation pipes through the primary containment nozzle end plates is sealed by welding which meets the requirements of the ASME Code Section III, Subsection NE, Class MC components.

3.8.6.2 Applicable Codes, Standards, Specifications, and Regulatory Guides

3.8.6.2.1 Codes, Standards, and Specifications

Piping and electrical penetration assemblies are designed and constructed to meet the requirements of the following applicable codes, standards and specifications.

a. The following sections of the ASME B&PV Code, 1971 Edition, including Summer 1972 Addenda and all previous addenda (ASME Code):

Section II, Material Specifications, Part A - Ferrous (ASME Code Section II)

Section III, Nuclear Power Plant Components, Subsection NE, Class MC Components (ASME Code Section III)

Section V, Nondestructive Examination (ASME Code Section V)

Section IX, Welding Qualifications (ASME Code Section IX);

b. Steel Structures Painting Manual, Volume 2, Systems and Specifications, 1964 Edition with the 1968 Supplement and the January 1971 Editorial changes.

Specifications SSPC-SP-6, SP-8 and SP 10;

c. American Society for Testing and Materials

A370 - Standard Methods and Definitions for Mechanical Testing of Steel products

A380 - Recommended Practice for Descaling and Cleaning Stainless Steel Surfaces;

d. Institute of Electrical and Electronics Engineers

IEEE 317-1972 IEEE Standard for Electrical Penetration Assemblies in Containment Structures for Nuclear Power Generating Stations

[NOTE: For the replacement of the electrical penetration modules, use the version of IEEE 317 that is in effect at the time of purchase and documented in the design specification.]

IEEE 336-1971 - Installation, Inspection and Testing Requirements for Instrumentations and Electrical Equipment During the Construction of Nuclear Power Generating Stations

IEEE 344 - (Trial Use) - Guide for Seismic Qualifications of Class I Electric Equipment for Nuclear Power Generating Stations;

e. American Society for Testing and Materials

D635 - Test for Flammability of Self-Supporting Plastics (Fire Resistant);

f. Insulated Power Cable Engineers Association (IPCEA) and NEMA:

S-61-402 - (IPCEA) Standard for Thermoplastic - Insulated Wire WC-5-1968 - (NEMA) - Cable for the Transmission and Distribution of Electrical Energy

S-19-81 - (IPCEA) - Rubber Insulated Wire & Cable for Transmission and Distribution of Electrical Energy

S-66-524 - (IPCEA) - Standard for Cross-Linked Thermosetting

WC-7-1971 - (NEMA) - Polyethylene-Insulated Wire and Cable for the Transmission and Distribution of Electrical Energy

P-32-382 - (IPCEA) - Short Circuit Characteristics of Insulated Cable

S-68-561I - #2 - Cables Rated 5000 Volts and Less and Having Ozone-Resistant Ethylene-Propylene-Rubber Integral Insulation and Jacket

For electrical penetration assembly, use the applicable IPCEA and NEMA Standards that are in effect at the time of purchase;

g. American National Standard for Temperature Measurement Thermocouples C96.1-1964;

h. Military Specification Electric Connector AN Type

MIL-C-5051D - Electric Connector, AN Type;

i. Underwriters Laboratories Standards (UL); and

j. National Electric Code, 1975.

The nozzle, which is part of the containment boundary, is classified as Class MC and designed in accordance with Subsection NE, Section III of the ASME Code. The Type I penetration guard pipe, which is not part of the containment boundary, is designed, tested, and of materials selected in accordance with Subsection NE, Section III of the ASME Code. The part of the

process pipe which is inside the guard pipe and the flued head fitting is of the same code class as the remainder of the process pipe.

3.8.6.2.2 Conformance with Regulatory Guides

The applicable regulatory guides are discussed in Section 3.8.2.2.4.

3.8.6.3 Loads and Loading Combinations

3.8.6.3.1 Loads

The analysis and design of piping and electrical penetrations consider the following loads:

a. Load (a) - Pressure and temperature due to LOCA,

b. Load (b) - Live and dead loads, including the primary loads applied to the containment vessel directly as well as dead weight, seismic inertia loads, and other mechanical and flow induced loads from attached pipes and equipment,

c. Load (c) - OBE,

d. Load (d) - Thermal expansion load, including loads caused by constraint due to thermal expansion of the primary containment vessel, as well as reactions from attached piping due to constraint from thermal expansion of the piping system,

e. Load (e) - SSE, and

f. Load (f) - Jet force or pressure on structures and equipment resulting from a pipe break.

Load (f) includes guillotine type break or longitudinal split of the piping in question, or pressure impingement from adjacent piping. Load (f) for penetration assemblies is tabulated in Figure 3.8-51 under the heading "Flued Head Fitting - Pipe Rupture Loads."

Load (b) includes jet forces resulting from a normal operating effluent discharge of an open-ended pipe.

3.8.6.3.2 Loading Combinations

The loading combinations (of the loads defined in Section 3.8.6.3.1) used in the design of penetrations are as follows:

a. Normal accident: loads (a) + (b) + (c) + (d) (normal condition),

b. Maximum seismic: loads (a) + (b) + (d) + (e),
c. Pipe rupture: loads (a) + (b) + (c) + (d) + (f), and
d. Pipe rupture plus maximum seismic: loads (a) + (b)+ (d) + (e) + (f).

Allowable stresses are discussed in Section 3.8.6.5.4.

All process pipe penetrations, including spare penetrations intended for future process piping, are analyzed for the load combinations defined above.

Electrical penetration assemblies are designed to withstand environmental conditions present during a postulated LOCA including the jet impingement force from a ruptured pipe to the junction boxes. The assemblies are designed to maintain containment integrity for extended periods of time in a postaccident environment.

Electrical penetrations, including penetration nozzles intended for future electrical penetration assemblies, are analyzed for a pipe rupture impingement load [load (f)].

3.8.6.4 Design and Analysis Procedures

3.8.6.4.1 Piping Penetrations

Loads on the piping penetrations due to thermal expansions of the pipes, thermal and pressure movements of the primary containment vessel, and the piping system weight are determined by a flexibility analysis of the piping system and are discussed in Section 3.9.

Seismic loads on piping penetrations are determined by the method described in Sections 3.7 and 3.9. Jet loads on nozzles are analyzed in accordance with Section 3.6.

3.8.6.4.2 Flued Head Fitting Design

The design of the flued head fittings is in accordance with both the ASME Code Section III for Class MC as well as for the same ASME Code Class shown in Figure 3.8-51 for process pipe. The flued head fitting to penetration nozzle weld is excluded from the limit of process pipe classification, and is a Class MC Weld. The flued heads are designed to withstand the loads and combinations thereof noted in Figure 3.8-51, including the containment design pressures and temperatures as noted in Table 3.8-14. The configuration of the flued head is such as to minimize stress concentrations by using gradual transitions from one thickness to another and by shaping the fitting so as to avoid any sudden changes in contour.

The flued head fitting contouring at the process pipe interfaces and the penetration nozzle interface is in accordance with the ASME Code, Section III, Figure NB-4233-1, except that the initial maximum slope of the outside surface adjoining the process pipe is 1-on-4 in lieu of the

1-on-3 slope shown in Figure NB-4233-1. The exterior shape of the fittings is as shown in Figure 3.8-54.

3.8.6.4.3 Thermal Stress Analysis for Flued Head Fittings

Thermal stress due to steady-state and/or transient condition is accounted for.

3.8.6.4.4 Primary Containment Vessel Design at Penetration Nozzle Interface

Influence coefficients are provided for all primary containment vessel penetration nozzles resulting from unit forces and moments applied at the intersection of the centerline of the penetration and the neat inside face of the containment vessel (such as W.P. 1 in Figure 3.8-54). These influence coefficients represent local shell membrane stresses and shell bending stresses at the juncture of the nozzle to shell reinforcing insert plate and the juncture of the reinforcing insert plate to vessel shell plate for unit forces and moments. The primary containment vessel stresses due to applied forces and moments are derived by use of the influence coefficients and proper combination at specified locations. The vessel is designed and analyzed for all loading combinations and satisfies the following design requirements:

a. Penetration assemblies are designed in accordance with the ASME Code Section III, Subsection NE for MC Components. Process piping is designed in accordance with the ASME Code Section III, Subsection NB or NC as required for Class 1 or Class 2 components. The ASME Code Class for each process pipe is indicated in Figures 3.8-51 and 3.8-52;

b. The type, size, and thickness of the penetration nozzle conforms to those indicated in Figures 3.8-51 and 3.8-52. Penetration reinforcement is generally a single plate insert;

c. Loads and loading combinations as described in Section 3.8.6.3;

d. The flued head fittings meet Class MC requirements, as well as the requirements of the ASME Code class specified for the attached process pipes. The flued head fittings are integral with the process pipe at the inboard side of the fitting (W.P. 3 in Figure 3.8-54).

   The flued head fittings are capable of transmitting all applicable loads from the process pipe to the penetration nozzle. Pipe rupture load (f) in Section 3.8.6.3.1 is considered as primary load and is applied at the inner and outer process pipe flued head fitting interface (W.P. 3 and W.P. 2 in Figure 3.8-54) separately.

The flued head fittings are designed in accordance with the allowable stress criteria in Section 3.8.6.5 and meet the allowable stress criteria of the applicable ASME Code Class. When ASME Code Class I is applicable, emergency condition loading criteria is applied for load combination (b) and (c) in Section 3.8.6.3.2 at all locations where the structure can be considered integral and continuous; and upset condition loading criteria is applied at locations where the structure cannot be considered integral and continuous. When emergency condition loading criteria is applicable, the design is based on elastic analysis. Limit analysis is not used.

The analytical procedures utilized for flued head fitting design was performed by means of "ISOFINITE" (see Section 3.12) using the three-dimensional finite element method. The analysis was performed for the normal and emergency conditions described previously. "ISOFINITE" calculates six stress components at the centroid of each element. These stress components are then converted into principal stress and stress intensities. The stress intensities are then compared to 1.5 S_m. The sum of the principal stresses are likewise compared to 1.5 S_m. For maximum primary plus secondary stress intensity, the allowable stress criteria is 3 S_m.

All the flued head fittings satisfy the design criteria of the ASME Code Section III; and

e. The penetration design analysis for pipe rupture and maximum seismic loadings includes verification of containment adequacy of the penetration assemblies and the primary containment vessel in the vicinity of penetrations. For this analysis, the pipe rupture loads utilized are those shown in Figure 3.8-51 for the flued head fitting. The rupture loads are applied at the outboard interface of the flued head fitting and the process pipe (Refer to W.P. 2 in Figure 3.8-54).

Steel pipe sleeves within the biological shield wall provide an annular gap around the penetration nozzles. The analysis includes verification that, if local contact between nozzles and sleeves is possible, the nozzles have sufficient strength to maintain containment. As shown in Figure 3.8-54, lateral restraint assemblies with an annular gap are provided around the flued head fittings, when required.

The steel pipe sleeves are not within the jurisdiction of primary containment and are therefore designed to AISC criteria for Class I structures.

3.8.6.4.5 Electrical Penetrations

All penetration assemblies are a part of the containment system and are capable of meeting the requirements listed in Table 3.8-13. The design, fabrication materials, inspection, and testing of the pressure retaining parts of the penetration assembly are in accordance with the ASME Code Section III, Subsection NE, Class MC components. All assemblies are code stamped in accordance with applicable requirements of the ASME Code Section III.

The power, control and instrumentation wiring complies with the standards listed in Sections 3.8.6.2.1(f) and 3.8.6.6.1 (cable and cable insulation) as applicable to a particular cable construction.

The penetration assemblies are designed to meet the requirements of IEEE Standard 317.

Electric penetration assemblies are designed by analysis, test, and combinations thereof. Design criteria for the penetration seals are as follows:

a. For normal operation, electrical loadings causing heating or electromagnetic forces do not violate primary containment integrity or disrupt the integrity of the electrical circuit,

b. Electrical rated current loadings do not exceed the requirements of the National Electrical Code with regard given to the application of derating factors to account for the effects of ambient temperature and grouping,

c. For seismic loadings, during normal operation, primary containment and electrical circuit integrity are not violated,

d. Jet force impingement may be allowed to disrupt electrical circuits but does not violate primary containment integrity,

e. For LOCA conditions, short circuit faults may disrupt electrical circuits but do not violate primary containment integrity,

f. Motor startup currents produce no detrimental effect on circuit integrity,

g. Gamma radiation exposure produces no detrimental effect on primary containment or circuit integrity,

h. Thermal cycling due to plant startup and shutdown produces no detrimental effect on primary containment nor circuit integrity,

i. The penetration assembly has leak rate less than IEEE 317 leak rate requirements (see Section 3.8.6.7), and

j. Low voltage control, instrumentation, and power operate electrically during LOCA, as specified by the plant specification.

3.8.6.4.6 Protective Coatings

Protective coatings are applied to all exposed steel surfaces of the penetration assemblies, as discussed in Section 3.8.2.4.4.

3.8.6.5 Structural Acceptance Criteria

3.8.6.5.1 Type I Piping Penetrations

The requirements of Article NE-3000 of the ASME Code Section III, as modified by Regulatory Guide 1.57, Revision 0, and discussed in Section 3.8.2.2.4 are met for each of the load combinations and for each component of type 1 penetration assemblies. In addition, the process pipe portion of the assembly is designed to the appropriate piping code class; that is, ASME Code Section III, Code Class 1 or 2.

3.8.6.5.2 Types 2 and 3 Piping Penetrations

The requirements of Article NE-3000 of Section III of the ASME Code are met for each of the load combinations and for each component of types 2 and 3 Piping Penetrations.

3.8.6.5.3 Type 4 Electrical Penetrations and Type 5, 6, and 7 Instrumentation Penetrations

Structural acceptance criteria for the containment penetration assemblies is in accordance with the rules of the ASME Code Section III, Class MC and IEEE 317-1972.

[NOTE: If replacement of the electrical penetration modules is required, the version of IEEE-317 that is in effect at the time of purchase and documented in the design specification is used.]

3.8.6.5.4 Allowable Stresses for Piping, Electrical, and Instrumentation Penetrations

Maximum allowable stress values are in accordance with the ASME Code Section III, Paragraph NE-3131.

Doubler plates (or pads), usually continuous and attached to the pressure boundary by means of fillet welds, and junctures of nozzles to containment vessel, are considered to be structures which are not integral and continuous. Therefore, the rules of the ASME Code Section III,

Paragraph NE-3131(c) (1) are applied. An example of doubler plates or pads is the welding ring discussed in Section 3.8.2.3.3.

Locally thickened vessel shell plates having a properly tapered transition as shown in the ASME Code Section III, Figure NE 3361-1, and full penetration butt weld connections, are considered to be structures which are integral and continuous, and the rules of the ASME Code Section III, Paragraph NE-3131(c) (2) are applied.

3.8.6.5.4.1 Electromagnetic Conditions. Each penetration assembly is designed to meet continuous, short time overload, and fault current conditions (see Reference 3.8-15). The penetration assemblies meet the requirements of IPCEA Standard P32-382.

a. Low voltage control and indication penetration (Nos. X-101 Series, X-102 Series, and X-105 Series): the low voltage control and indication penetration assemblies are designed for the following electromagnetic conditions:

   1. Maximum momentary short-circuit current: 60 x rated amp RMS asym for 0.25 sec, and

   2. Cable and continuous ampacity as tabulated in Reference 3.8-15.

b. Low voltage power penetration (No. X-104 Series in Reference 3.8-15) and low voltage power control and indication penetration (No. X-107 Series in Reference 3.8-15): These two types of penetration assemblies are designed for the following electromagnetic conditions without damaging conductor and insulation:

   1. Maximum short-circuit current: 60 x rated RMS asym for 0.20 sec,
   2. Maximum starting current: 6.5 x rated amp for 15 sec, and
   3. Continuous ampacity as tabulated in Reference 3.8-15.

c. Medium voltage power penetration (No. X-103 Series in Reference 3.8-15): The medium voltage power penetration assemblies are designed for the following electromagnetic conditions without damaging conductor and insulation:

   1. Maximum continuous current: 700 amps,

   2. Maximum inrush current: 4000 amps/phase for 20 sec,

   3. Maximum short-circuits: 66,000 amps asym momentary and 44,000 amp sym. for 75 cycles.

3.8.6.6 Materials, Quality Control, and Special Construction Techniques

3.8.6.6.1 Materials

Materials used comply with the requirements of NE-2000 of Subsection NE of the ASME Code Section III.

Materials used in piping, electrical and instrumentation penetration assemblies are included in Section 3.8.2.6.1. In addition to materials in Section 3.8.2.6.1, the following materials are used in electrical penetration:

a. Conductor

Material for conductor is as specified in Reference 3.8-15 and in Section 3.8.6.1.4.1.

b. Cable insulation

Unless otherwise specified in Reference 3.8-15 and in Section 3.8.6.1.4.1, the cable insulation is of nonmetallic, organic materials as qualified by IEEE-317.

c. The inner and outer bulkheads of each penetration assembly portions of the assembly encircling individual single conductor power cables are made of nonferromagnetic material to eliminate hysteresis heating. Soft metals such as copper, brass, and aluminum are not exposed to the containment environment.

3.8.6.6.2 Quality Control

Quality control measures discussed in Section 3.8.2.6.2 apply to penetration assemblies. The measures include the vessel vendor's submitted shop and field quality compliance and quality assurance organization and procedures, material certifications, weld data, test data, and welding and testing procedures.

The quality control procedures are in accordance with the ASME Code Section III, Appendix X; IEEE-317; and Regulatory Guide 1.63, Revision 0. In summary, steel quality control begins with the selection of basic shapes and with ranges of properties and characteristics defined by industry standards. Quality control extends from testing of specimens sampled from basic shapes to fabrication, installation and joining procedures.

Nondestructive testing for penetration assemblies is in accordance with the ASME Code Section III for the applicable code class, and in accordance with supplemental requirements specified in the plant specifications.

Nondestructive testing requirements include the following:

a. 100% radiography of all welds;

b. Any weld not radiographed because of restricting geometry receive a 100% magnetic particle or liquid penetrant inspection for both root and final surface. If the weld falls into the ASME Code Section III, Category A or B, ultrasonic testing is performed; and

c. Flued head forgings are examined in the finished condition on all accessible surfaces by either the liquid penetrant or the magnetic particle methods.

3.8.6.6.3 Special Construction Techniques

No construction techniques unusual to erection methods used during the original construction were required for the penetration assemblies.

3.8.6.7 Testing and Inservice Inspection Requirements

3.8.6.7.1 Inspection of Material and Parts for Fabrication

The discussion in Section 3.8.2.7.1 applies to penetration assemblies.

3.8.6.7.2 Shop Hydrostatic Testing

Shop hydrostatic tests discussed in Section 3.8.2.7.4 apply to penetration assemblies.

3.8.6.7.3 Shop Tests on Electrical Penetration Assemblies

The following shop tests were performed on the original electrical penetrations in accordance with applicable standards:

[NOTE: If replacement of the electrical modules is required, the version of IEEE 317 that is in effect at the time of purchase and documented in the design specification is used.]

a. Flame resistant tests

All wires successfully pass the "Flame Resistant Test" specified in IPCEA publication No. S-61-402, whether or not other applicable IPCEA Standards require this test.

b. Fire resistance

The electrical penetration assembly meets the requirements of ASTM D635, Test for Flammability of Self-Supporting Plastics, as well as Underwriters Standards (UL).

c. Prototype tests

Qualification tests performed on at least one prototype electrical penetration assembly of each type, namely, low voltage penetration Nos. X-101 Series, X-102 Series, X-105 Series, X-104 Series, and X-107 Series; and medium voltage penetration No. X-100 Series, as specified in IEEE Standard 317, Paragraph 5, demonstrate the suitability of the penetrations, assemblies, design and all materials selected for use with the assemblies.

d. Production test

Prior to shipment, production tests are performed on each penetration assembly as specified in IEEE Standard 317, Paragraph 6.

e. Containment environmental tests

1. Testing to qualify for normal operation

Temperature and moisture resistance: Evidence of qualification for normal operation (see Table 3.8-13) is provided by certified data which demonstrates that cable has been manufactured, tested, and has successfully passed the requirements contained in the applicable IPCEA standards, with regard to the application of derating factors for the ambient temperatures specified.

Thermal and radiation aging: The following test sequence demonstrates that the cable is operational after exposure to the combined effect of thermal and radiation aging (Table 3.8-8):

Test Step #1: Conditioning

The cable under test is conditioned in a circulating air oven for 7 days at 150°C.

Test Step #2

Heat aged samples are exposed to gamma radiation from a nuclear source such as Cobalt 60 to a dosage of 1 x 10^8 rads.

Test Step #3

The samples are subjected to a combined mechanical/electrical proof test consisting of bending around a mandrel maintained at room temperature in accordance with the procedure designated in paragraph 6.19.3 of IPCEA S-19-81, and the cable is subsequently subjected to an AC voltage withstand test equal to 80% of the final factory test voltage called out in the applicable IPCEA standard.

2. *Testing to qualify for operation during the postulated design basis LOCA.*

Test Step #1

A new set of samples is subjected to heat aging as specified in Section 3.8.6.7.3(e) under thermal and radiation aging.

Test Step #2

Test samples are subjected to a radiation dosage of 1 x 10^8 rads.

Test Step #3

Test samples are subjected to environmental conditions as encountered in a LOCA.

The conditioned samples are placed in a pressure vessel so constructed that cables can be operated under rated voltage and load while exposed to the pressure, temperature, and humidity specified in Table 3.8-13.

After conditioned samples are installed inside the pressure vessel, they are energized at rated voltage and loaded with current to the level specified herein. Then the samples are exposed to the environmental extremes specified in Table 3.8-13 and function properly throughout this exposure to environmental extremes.

3. Sampling

The samples tested contain the conductor, insulation, fillers, jacket, binder tape, overall jacket, shielding, which are representative of the cable category being qualified. Table 3.8-8 lists sizes which are considered representative of the categories of cable supplied for electrical penetration assemblies. The sample lengths are sufficient to permit reliable test readings and evaluation consistent with accepted testing practice.

3.8.6.7.4 Field Tests on Electrical Penetration Assemblies

a. Field tests

Field tests made on electrical penetrations in accordance with IEEE 336 demonstrate that the material and equipment meets the specified performance.

b. After installation

All electrical penetration assemblies are installed as an integral part of the primary containment system and meet the requirements of IEEE 317, Paragraph 7.

3.8.6.7.5 Testing of Penetrations After Erected

On completion of field erection of the primary containment vessel and prior to installation of penetration internals, tests of penetrations were performed according to an established test plan discussed in Sections 3.8.2.7.3 and 3.8.2.7.4.

3.8.6.7.6 Tests on Penetration Field Welds

Leaktightness tests of field welds connecting the penetrations to the primary containment vessel, including the welds connecting the penetration nozzle to the vessel shell, are conducted as discussed in Section 3.8.2.7.6.

3.8.6.7.7 Preoperational Leakage Rate Tests and Periodic Leakage Rate Tests

A discussion of the preoperational and periodic leakage rate tests of the primary containment vessel penetrations is provided in Sections 3.8.2.7.7 and 6.2.6.

Table 3.8-1

Primary Containment
Drywell and Pressure Suppression Chamber
Principal Design

Parameters	Characteristics
Pressure suppression chamber	
Internal design pressure	45 psig
External design pressure (due to negative internal pressure)	2.0 psig
Drywell	
Internal design pressure	45 psig
External design pressure (due to negative internal pressure)	2.0 psig
Drywell free volume, including downcomer vent pipes	200,540 ft^3 (maximum)
Pressure suppression chamber free volume	144,184 ft^3 (maximum)
Pressure suppression pool water volume	112,197 ft^3 (minimum)[a]
Submergence of downcomer vent pipe below pressure suppression pool surface	11.67 ft (minimum) 12.0 ft (maximum)
Design temperature of drywell	340°F
Design temperature of pressure suppression chamber	275°F
Downcomer vent pipe pressure loss factor	2.77
Total downcomer vent pipe area	309 ft^2
Break area/total downcomer vent pipe area	0.0105
Calculated maximum pressure after blowdown (no prepurge):	
Drywell	37.4[b] psig
Pressure suppression chamber	30.5[b] psig
Number of downcomer vent pipes	99
Minimum spacing of downcomer vent pipes	4 ft 3 in.

Table 3.8-1

Primary Containment
Drywell and Pressure Suppression Chamber
Principal Design (Continued)

Parameters	Characteristics
Normal operating temperature - suppression chamber pool	90°F (maximum)[c]
Normal operating temperature - suppression chamber air space	95°F[c] (150°F maximum)[d]
Normal operating temperature - drywell	135°F (150°F locally)
Normal operating pressure - drywell and suppression chamber	0 psig to 2 psig

[a] The value for the pool water volume does not include the water within the reactor pedestal (10,065 ft^3) and the 12 ft of water below the downcomer vent pipe exits (15,000 ft^3).

[b] Based on an initial containment pressure of 2.0 psig. The value of P_a to be used for 10 CFR 50 Appendix J testing was conservatively chosen to be 38 psig.

[c] Average or bulk temperature.

[d] Average of two thermocouples located near ceiling.

Table 3.8-2

Containment
Environmental Design Conditions

Parameter	Inside Primary Containment Drywell	Outside Primary Containment
Normal operating environment (capable of continuous operation)		
Temperature	135°F to 150°F	40°F to 104°F
Pressure	2 psig	-0.012 psig to +0.25 psig
Relative humidity	40% to 100%	20% to 90%
Maximum emergency environment (equipment is capable of maintaining containment integrity for not less than 2 hr)		
Temperature	340°F	
Pressure	45 psig	
Relative humidity	100%

Table 3.8-5

Load Combinations and Load Factors
Concrete Internal Structures of Steel Containment

Category ACI 318-71 Strength Design Method	Load	Normal					Severe Environment	Abnormal				Extreme Environment
		D	L	R_o	T_o	P_o	E	P_a	T_a	R_a	R_r	E′
Service load conditions												
Normal	1	1.4	1.7			1.7						
	1b	1.4	1.7	1.4	1.4	1.7						
Severe environmental	2	1.4	1.7			1.7	1.9					
	2b	1.4	1.4	1.4	1.4	1.4	1.4					
Factored load conditions[a,b]												
Extreme environmental	3	1.0	1.0	1.0	1.0	1.0						1.0
Abnormal[c]	4	--	--			--		--	--	--		
Abnormal/severe environmental[d]	5	--	--			--	--	--	--	--	--	
Abnormal/extreme environmental	6	1.0	1.0		1.0	1.0		1.0	1.0	1.0	1.0	1.0

[a] In combination 6, the maximum values of P_a, T_a, R_a, Y_j, Y_r, and Y_m, including an appropriate dynamic load factor, are used unless a time-history analysis is performed to justify otherwise (R_r includes Y_j, Y_r, and Y_m.)

[b] When considering Y_j, Y_r, and Y_m, local section strength capacities may be exceeded under these concentrated loads provided there is no loss of function of any safety-related system.

Table 3.8-5

Load Combinations and Load Factors
Concrete Internal Structures of Steel Containment (Continued)

[c] In abnormal load category, DBA is not considered alone. DBA is considered with E′ as in load combination 6.

[d] In abnormal/severe environmental load category, DBA with E is not considered. DBA is considered with E′ as in load combination 6.

NOTE:

All of the loads listed are not necessarily applicable to all concrete structures in containment. Loads not applicable to a particular structure are deleted. If for any combination, the effect of any load other than D reduces the stress it is deleted from the combination. Combination numbers correspond to those in NUREG-0800, Standard Review Plan for Section 3.8.3. Dashed lines indicate that the load combination is not used. For load definitions, see Section 3.8.3.3.

Table 3.8-6

Load Combinations and Load Factors
Steel Internal Structures of Steel Containment

Load Category	Load	Normal				Severe Environment		Abnormal				Extreme Environment
		D	L	Ro	To	Po	E	Pa	Ta	Ra	Rr	E′
Elastic Working Stress Design Method												
Service load conditions												
Normal	1	1.0	1.0			1.0						
	1a	1.0	1.0	1.0	1.0	1.0						
Severe environmental	2	1.0	--			1.0	1.0					
	2a	1.0	--	1.0	1.0	1.0	1.0					
Factored load conditions[a-c]												
Extreme environmental[d]	3	--	--	--	--	--						--
Abnormal[e]	4	--	--			--		--	--	--		
Abnormal/severe environmental[f]	5	--	--			--	--	--	--	--	--	
Abnormal/extreme environmental	6	1.0	--			1.0		1.0	1.0	1.0	1.0	1.0
Plastic Design Method												
Service load conditions												
Normal	1	1.0	1.0			1.0						
	1b	1.0	1.0	1.0	1.0	1.0						
Severe environmental	2	1.0	--			1.0	1.0					
	2b	1.0	--	1.0	1.0	1.0	1.0					
Factored load conditions[a-c]												
Extreme environmental[d]	3	--	--	--	--	--						--
Abnormal[e]	4	--	--			--		--	--	--		
Abnormal/severe environmental[f]	5	--	--			--		--	--	--	--	
Abnormal/extreme environmental	6	1.0	--			1.0		1.0	1.0	1.0	1.0	1.0

Table 3.8-6

Load Combinations and Load Factors
Steel Internal Structures of Steel Containment (Continued)

[a] In combination 6, the maximum values of P_a, T_a, R_a, Y_j, Y_r, and Y_m, including an appropriate dynamic load factor, are used unless a time-history analysis performed to justify otherwise (R_r includes Y_j, Y_r, and Y_m).

[b] When considering Y_j, Y_r, and Y_m, local section strength capacities may be exceeded under these concentrated loads provided there will be no loss of function of any safety-related system.

[c] Thermal loads for factored load conditions are neglected when it can be shown that they are secondary and self-limiting in nature.

[d] Extreme environmental E′ is considered with DBA as in load combination 6.

[e] Abnormal: DBA not considered alone. DBA is considered with E′ as in load combination 6.

[f] Abnormal/severe environmental: DBA with E not considered. DBA is considered with E′ as in load combination 6.

NOTE:

The drywell floor support steel is considered a steel internal structure in the suppression chamber. All the loads listed are not necessarily applicable to all steel structures. Loads not applicable to a particular structure are deleted. If, for any load combination, the effect of any load other than D reduces the stress, it is deleted from the combination. Combination numbers correspond to those in NUREG-0800, Standard Review Plan, for Section 3.8.3. Dashed lines indicate that the load or load combination is not used. For load definitions, see Section 3.8.3.3.

Table 3.8-7

Section Strength Limits and Section Modulus
for Structural Steel Internal Structures
of Steel Containment

Load Category	Load	Strength Limit[a,b]	Section Modulus of Steel Shapes
Elastic Working Stress Design Method			
Service load conditions			
Normal	1	S	Elastic
	1a	1.5S	Elastic
Severe environmental	2	S	Elastic
	2a	1.5S	Elastic
Factored load conditions			
Extreme environmental	3	1.6S	Elastic
Abnormal	4	1.6S	Elastic
Abnormal/severe environmental	5	1.6S	Plastic[c]
Abnormal/extreme environmental	6	1.7S	Plastic[c]
Plastic Design Method			
Service load conditions			
Normal	1	Y	Plastic
	1b	Y	Plastic
Severe environmental	2	Y	Plastic
	2b	Y	Plastic
Factored load conditions			
Extreme environmental	3	0.9Y	Plastic
Abnormal	4	0.9Y	Plastic
Abnormal/severe environmental	5	0.9Y	Plastic
Abnormal/extreme environmental	6	0.9Y	Plastic

[a] S is the required section strength based on the elastic design methods and the allowable stresses defined in Part 1 of the AISC Specification for the Design, Fabrication, and Erection of Structural Steel for Buildings, February 12, 1969.
[b] Y is the section strength required to resist design loads based on plastic design methods in Part 2 of the AISC Specification for the Design, Fabrication, and Erection of Structural Steel for Buildings, February 12, 1969.
[c] Plastic section modulus may be used.

Table 3.8-8

Radwaste and Control Building
Quality Class and Design Bases Criteria

Location	Materials of Construction[a]	Quality Class	Environmental Disturbances			
			Seismic Category	Design Basis Wind	Design Basis Tornado	Tornado-Generated Missiles
Those portions of the radwaste and control building that house systems or components necessary for safe shutdown of the reactor	Reinforced-concrete	I	I	Yes	Yes	Yes
Those portions of the radwaste building that house equipment containing significant quantities of radioactive material	Reinforced-concrete	I	I	Yes	Yes	Yes
Other portions	Structural steel	II	II	Yes	No[b]	No[b]

[a] See Figure 3.8-42.

[b] "Other portions" denote those portions of the radwaste and control building which are not required to withstand the effects of the design basis tornado and tornado-generated missiles.
