X-energy	X-energy, LLC

Chapter 1 Introduction

This Environmental Report (ER) is prepared and submitted as part of the Duke Energy Carolinas, LLC (DEC), referred to herein as "Duke Energy," a wholly owned subsidiary of Duke Energy Corporation, application for an Early Site Permit (ESP) to the U.S. Nuclear Regulatory Commission (NRC) in accordance with Title 10 of the Code of Federal Regulations (CFR) Part 52 (10 CFR 52), for the Belews Creek, North Carolina (NC) site (Project site). This is separate from the filing of an application for a construction permit or combined license for the facility.

This ESP application (ESPA) is for a new nuclear power generating plant located adjacent to the existing Belews Creek Steam Station (BCSS). The general Project site location is shown in Figure 1.1-1. A detailed site plan is provided on Figure 3.1-1, which illustrates the site boundary, permanently disturbed laydown areas, and the general arrangement of structures including the three proposed nuclear power Plant Complexes (referred to as Plant Complexes). Existing and shared structures and supporting infrastructure are shown on Figure 3.1-2 and Figure 3.1-3, respectively.

In accordance with NRC regulations, this ER evaluates the environmental impacts of constructing, operating, and decommissioning multiple advanced reactors at the Project site as part of the ESPA. Advanced reactors include both light water small modular reactors (SMRs) and non-light water reactors, such as those using gas, liquid metal, or molten salt coolants (NRC, 2023; NRC, 2025). The NRC uses this ER to develop an Environmental Impact Statement or Environmental Assessment, in compliance with the National Environmental Policy Act, to assess the environmental impacts of issuing an ESP.

1.1 APPLICANT AND REACTOR TYPE

1.1.1 APPLICANT

The Applicant is Duke Energy Carolinas, LLC (DEC), referred to herein as "Duke Energy," a wholly owned subsidiary of Duke Energy Corporation.

1.1.2 SITE LOCATION

The Project site is located along Belews Creek and Belews Lake in an unincorporated community of Sauratown Township, Stokes County, and partially in Belews Creek Township, Forsyth County, NC. The proposed nuclear reactors are located in Sauratown Township, Stokes County. The southern portion of the site, which includes additional permanently disturbed land, such as laydown areas, is located in Forsyth County, NC.

The Project site is adjacent to the existing Duke Energy-owned BCSS. It is approximately 14 miles (mi.) (23 kilometers [km]) northeast of Winston-Salem, NC and approximately 19 mi. (31 km) northwest of Greensboro, NC. Figure 1.1-1 shows the general location of the Project site.

Additional information regarding the Project site can be found in Section 2.1, Land Use.

1.1.3 REACTOR TYPE

A specific reactor design has not been selected, but advanced reactors under consideration are noted in Section 1.2.1. The Project site is planned to accommodate up to three nuclear Plant

Complexes, with the specific number of reactors dependent on the technology selected. To assist the NRC in determining the suitability of the site for new nuclear units, Duke Energy utilized a set of bounding plant parameters, referred to as the plant parameter envelope (PPE) described in Section 3.1.2. Technical information from various reactor designs was used to develop a set of bounding parameters that envelop the proposed facility characterization. This approach enables the NRC to assess the suitability of the Project site and allows Duke Energy to select the best technology.

Additional information regarding the reactor technologies considered in the PPE can be found in Section 3.2.1, Reactor Power Conversion System.

1.1.4 COOLING SYSTEM INFORMATION

The cooling water system being considered for the Project site is a closed-cycle recirculating water system with mechanical draft cooling towers. The number of cooling towers is dependent upon the selected reactor technology. A new common intake structure is planned on Belews Lake to service each Plant Complex. The common facility houses pump/motor sets of adequate number and size to supply the selected reactor technology and to overcome pipe routing head losses to each Plant Complex. The system design assumes makeup water for the cooling water system is obtained from the common intake structure on Belews Lake, pumped to the cooling towers, and circulated into and out of the main condenser. Discharge locations are described in Section 3.2.2.4.3, Blowdown Discharge.

Additional information regarding the cooling system and associated structures is provided in Section 3.2.2, Cooling System.

1.1.5 TRANSMISSION SYSTEM INFORMATION

The proposed project involves using the existing BCSS transmission system owned by Duke Energy. Necessary modifications or improvements to the transmission system to support the reactors are limited to the Project site and the existing BCSS 230-kilovolt (kV) switchyard.

Additional information regarding the power transmission system is provided in Section 3.2.4, Power Transmission System.

1.2 DESCRIPTION OF THE PROPOSED ACTION AND PURPOSE AND NEED

1.2.1 PROPOSED ACTION

The proposed action is the issuance of an ESP by the NRC under the provisions of 10 CFR Part 52 for the Duke Energy Project site. This ESP would establish that the proposed site is a suitable location for the potential construction and operation of multiple advanced reactors. This determination would encompass a range of reactor technologies, including SMRs and non-light-water reactor (non-LWR) designs, independent of any future application for a construction permit or combined license for the facility. Issuance of the ESP confirms the site's readiness for nuclear reactor deployment, independent of a specific reactor design or technology. Duke Energy requests the NRC issue an ESP for the proposed site for a period of 20 years from the date of issuance.

The site is being evaluated for its suitability to support the construction and operation of advanced reactors. At this stage, the ESPA does not commit to a specific reactor technology. Instead, it considers a range of potential advanced reactor designs that could be deployed at the site. These technologies include:

- GVH BWRX-300
- NuScale VOYGR
- Holtec SMR-300
- WEC AP300
- TerraPower Natrium
- X-energy Xe-100

As noted in Section 1.1.3, the application employs a PPE approach that integrates characteristics of the technologies under consideration, including reactor safety features, efficiency, and environmental impacts. Given that a specific reactor technology has not been selected at the time of this application, the environmental impacts analyses within this ER consider bounding conditions based on information provided by each vendor. This approach ensures that potential environmental impacts are assessed, irrespective of the final technology selection.

The Project site has a bounding gross electrical output of 2250 megawatts electric (MWe) with a total bounding thermal output of 6250 megawatts thermal (MWt) limited by certain land use, water constraints, and regulatory requirements. These values represent the upper limits for the potential deployment of the technologies being considered. Environmental analyses are performed for up to six units for GVH, Holtec, and WEC reactors; a single 12-unit configuration for NuScale; up to 14 units for X-energy; and up to two units for TerraPower.

This ER analyzes the environmental impacts associated with site preparation, construction, operation, and eventual decommissioning of advanced reactors at the Project site, based on the parameters defined in the PPE. The issuance of the ESP will not authorize construction or operation of any facility but will establish the site's suitability for future licensing decisions, contingent on the selection of the specific advanced reactors.

1.2.2 PURPOSE AND NEED

The purpose of the proposed action, the issuance of an ESP by the NRC, is to resolve identified site safety and environmental issues early in the licensing process. This proactive approach provides stability and clarity for the subsequent development and licensing phases of the project, enabling the deployment of advanced reactors at the Project site.

Duke Energy proposes deploying advanced reactors on a site located adjacent to the existing BCSS, which is scheduled for retirement in the mid-2030s. The site has been selected due to its existing infrastructure, including grid connections; its access to cooling resources; and its proximity to energy demand centers. These factors make the site well-suited for transitioning to advanced nuclear energy generation while minimizing environmental impacts.

The proposed project aims to replace the existing coal and natural gas generation capacity with multiple advanced reactors, which will be integrated into the existing power grid. The total maximum output capacity for the site will not exceed 6250 MWt (2250 gross MWe), consistent with land use, water constraints, and regulatory requirements. This transition to carbon-free energy will help meet growing demand for reliable, baseload power in the region of interest (ROI), while also addressing the critical need for reduced carbon emissions.

Duke Energy Corporation, a regulated rate-based utility, provides electricity to approximately 4.6 million retail customers across 52,000 square miles in NC and South Carolina (SC). As part of its commitment to a sustainable future, Duke Energy is responding to the requirements of NC House Bill 951 (HB951), which mandates net-zero emissions by 2050 (NCGA, 2021). The transition to dispatchable, carbon-free nuclear energy is essential for meeting these state-mandated emission reduction goals, particularly as regulatory pressure on fossil fuel generation increases.

In support of this transition, Duke Energy submitted a Carbon Plan to the North Carolina Utilities Commission (NCUC), which outlines portfolios to achieve the carbon emissions reduction targets set forth in HB951. The NCUC adopted an initial Carbon Plan, providing direction for future planning and authorizing Duke Energy to initiate development activities related to new nuclear facilities. These activities include organizing staff for nuclear development, conducting siting studies, evaluating new nuclear technologies, and preparing an ESPA for the proposed project (NCUC, 2022).

Duke Energy Corporation plans to achieve net-zero carbon emissions by 2050, and as part of this goal, aims to retire over 8400 MW of dispatchable coal-fired generation in the coming decades. This includes the BCSS, a 2220 MWe dual-fuel power generation facility capable of operating on both coal and natural gas. The new nuclear facility at the Project site will provide up to 2250 gross MWe of net generation capacity, replacing the BCSS and ensuring a stable supply of baseload, carbon-free power for the Carolinas service territory. Duke Energy will utilize the existing transmission infrastructure, minimizing additional environmental impacts associated with new transmission line construction. Additional details regarding the transmission lines are described in Section 3.2.4.

Duke Energy strategies and goals for this transition are outlined in its Carolinas Resource Plan (CRP). The CRP is the framework for replacing aging coal plants in a manner that ensures economic benefits for the Carolinas, while meeting growing demand for clean energy. Over the next 15 years, Duke Energy projects a 35,000-gigawatthour increase in electricity demand

within NC and SC, further underscoring the need for reliable, carbon-free power (Duke Energy, 2023).

Duke Energy proposes to deploy multiple advanced reactors with a maximum capacity of 6250 MWt (2250 gross MWe) to replace an existing coal and natural gas plant scheduled for retirement and to meet the demand for clean, reliable, carbon-free power generation in the Carolinas. The Project supports state and regional goals for emission reduction and energy resiliency, and it plays a crucial role in the clean energy transition by enabling continued reliable power generation while meeting the growing energy demand in the ROI.

1.3 PLANNED ACTIVITIES AND SCHEDULES

1.3.1 PREAPPLICATION PUBLIC INVOLVEMENT

Since BCSS began operating in 1974 (Duke Energy, 2025a), Duke Energy has actively participated in the local community and remains a valued member of the community, providing jobs, tax base, community involvement, and volunteer support. Duke Energy has dedicated Local Government and Community Relations staff in the ROI, ensuring a strong connection to the community and its leaders (Duke Energy, 2025b).

The proposed use of nuclear power generation at the Project site has been publicized through various media outlets. The NRC and Duke Energy have engaged in preapplication activities, and public preapplication meetings have been held.

Additionally, Duke Energy has actively engaged with community stakeholders regarding the Project through various efforts including:

- Providing presentations to government, civic, and community leaders.
- Providing tours of the Project site and an operating nuclear power plant.
- Attending community events and distributing information.
- Maintaining communication efforts through traditional media outlets.

As the Project progresses, Duke Energy remains committed to community engagement.

1.3.2 SCHEDULE OF MAJOR ACTIVITIES FOR THE PROPOSED ACTION

Duke Energy has not established a date for preconstruction activities and acknowledges that the ESP does not constitute a decision or approval to build new reactors. A limited work authorization application outlined in 10 CFR 50.10 is not included with this ESPA.

Currently, Duke Energy has not established a date for preconstruction activities. Site preparation activities (preconstruction) are expected to take between six and 18 months. Assuming all necessary licenses are obtained, and based on reactor vendor estimates, the actual construction of each Plant Complex is projected to take between three and five years. Additional information is provided in Section 3.3.

1.4 STATUS OF COMPLIANCE

Federal, state, regional, local, and affected Native American tribal agencies require various environmental protection licenses, permits, reviews, approvals, and consultations (collectively referred to as “authorizations”) to support the preconstruction, construction, and operation phases of the project.

Consultations with federal, state, tribal, and local agencies have been initiated and status noted in Table 1.4-1. Engagement letters sent to government agencies are included as Appendix 1A. However, construction and operation authorizations from these authorities are not yet required, as an ESP solely establishes the Project site’s suitability for future development. Duke Energy will secure any necessary authorizations before starting preconstruction, construction, and operational activities that require approval.

While many agencies are involved, the NRC is ultimately responsible for approving the ESP in accordance with the requirements and procedures outlined in 10 CFR Part 52, Subpart A. Table 1.4-2 lists the permits and other approvals required for construction and operation of the facility.

1.4.1 EARLY SITE PERMIT ISSUANCE

The following statutes summarize the principal agency consultations necessary for the ESP.

The Clean Air Act (CAA) establishes regulatory requirements on federally licensed projects that may affect state and regional air quality during construction and operation. The U.S. Environmental Protection Agency (USEPA) has authorized the North Carolina Department of Environmental Quality (NCDEQ), Division of Air Quality, to implement the provisions of the CAA in NC.

The Clean Water Act (CWA) requires that federal agencies consider the potential impacts to jurisdictional “waters of the United States.” Section 401 of the CWA regulates the issuance of Water Quality Certifications for activities that may result in discharges to these waters. A Section 401 certification is not currently required for the Project site because the ESP, if granted, does not authorize any activities that would result in discharges to jurisdictional waters. This certification is required at a future application phase authorizing construction or operation, when activities with the potential to discharge to such waters are proposed. Section 402 regulates point source and non-point source discharges under the National Pollutant Discharge Elimination System (NPDES). The NCDEQ, Division of Water Resources is the agency responsible for the oversight of CWA Sections 401 and 402. Section 404 of the CWA regulates the placement of fill material in waters of the United States. The U.S. Army Corps of Engineers (USACE) regulates dredge and fill activities in navigable waters pursuant to Section 10 of the Rivers and Harbors Act and Section 404 of the CWA.

The Coastal Zone Management Act (CZMA) imposes regulatory requirements on applicants seeking a federal license to conduct an activity that could affect a coastal zone. The CZMA requires the applicant to certify to the licensing agency that the proposed activity is consistent with the state’s federally approved coastal zone management program. Because the Project site is not located within a coastal zone, it is not subject to the CZMA.

The Endangered Species Act requires federal agencies to ensure that agency action is not likely to jeopardize any species that is listed or proposed for listing as endangered or threatened. The Endangered Species Act requires consultation with the U.S. Fish and Wildlife Service (USFWS).

The National Historic Preservation Act requires federal agencies having the authority to license any major federal action, prior to issuing the license, to consider the effect of the undertaking on historic properties and to afford the Advisory Committee on Historic Preservation an opportunity to comment on the undertaking. Committee regulations provide for establishing an agreement with any State Historic Preservation Officer to substitute state review for Committee review (36 CFR 800.2(c)(4)).

1.4.2 PRECONSTRUCTION, CONSTRUCTION, AND OPERATION ACTIVITIES

Permits and authorizations for future construction and operation of multiple advanced reactors are to be obtained in accordance with applicable statutes and regulations. Applications for these authorizations are to be developed after the reactor technology has been selected and detailed design is initiated. Table 1.4-2 lists authorizations that are anticipated for preconstruction, construction, and operation of advanced reactors. Each authorization includes the jurisdictional agency, the statute, law, or regulation providing authority, the applicant requirement, and the activity that is approved upon issuance of the authorization.

Table 1.4-1
Consultations Required for Early Site Permit
(Sheet 1 of 2)

Agency	Authority	Requirement	Activity	Status
Catawba Indian Nation, Tribal Historic Preservation Office	National Historic Preservation Act, Section 106, 16 United States Code (USC) 470	Consultation.	Consultation regarding presence of historic or prehistoric sites of cultural significance.	• Duke Energy sent a formal notification letter on August 20, 2024. • Formal response from Catawba Indian Nation dated September 24, 2024.
Monacan Indian Nation, Tribal Office	National Historic Preservation Act, Section 106, 16 United States Code (USC) 470	Consultation.	Consultation regarding presence of historic or prehistoric sites of cultural significance.	• Duke Energy sent a formal notification letter on November 7, 2024.
NC Department of Environmental Quality	NC Administrative Code (NCAC) Title 15A Environmental Quality	Consultation.	Concurrence with no potential adverse effects or consultation on appropriate mitigation measures.	• Initial meeting with NCDEQ on June 11, 2024. • Duke Energy sent a formal notification letter to NCDEQ on June 19, 2024. • Virtual meeting with NCDEQ staff on July 19, 2024. • Formal response from NCDEQ dated September 17, 2024.
NC Department of Natural and Cultural Resources (NCDNCR) Natural Heritage Program (NHP)	NC General Statute (GS) Chapter 143B, Article 2	Consultation.	Consultation regarding presence of natural heritage resources.	• Duke Energy sent a formal notification letter on August 20, 2024. • Formal response from NCDNCR NHP dated September 30, 2024.
NCDNCR State Historic Preservation Office (NCSHPO)	NCGS 121-12(a)	Consultation.	Consultation regarding presence of historic or prehistoric sites of cultural significance.	• Duke Energy sent a formal notification letter on July 18, 2024. • Formal response from NCDNCR NCSHPO dated August 14, 2024. • Phase I Archeological Survey sent to NCSHPO dated November 4, 2024. • Formal response from NCSHPO dated January 17, 2025. • Phase II Archeological Survey sent to NCSHPO October 6, 2025.

NCWRC	NC Statutory Authority 113-274 (c)(1a); NCAC Title 15A Subchapter 10B.0105	Special migratory bird permit and consultation.	Removal and relocation of migratory bird nests (Construction Phase).
Local Authorizations			
Duke Energy Lake Services Department	Permits for shoreline activities.	Permit for work at shoreline.	Intake and discharge infrastructure construction and operation.
Forsyth County	Winston-Salem/Forsyth County Unified Development Ordinances	Planning board review.	Board review and approval of land use activity.
Norfolk Southern Railway Company	Utility Accommodation Policy	Railroad crossing authorization (if needed).	Railroad crossing for infrastructure.
Stokes County	Stokes County Environmental Health	Permit to install or abandon.	Install well.
		Permit to install or repair.	Install septic system.
	Stokes County Fire Marshall NC Building Code 105.6.15, Explosives	Blasting/explosive materials permit application.	Use of explosives (Construction Phase).
	Stokes County Zoning Ordinance, Article VIII, Use Requirements by District, 80.2, Conditional Zoning Site Development	Special Use Permit.	Land-clearing and inert debris landfills, and construction and demolition landfills, are permitted as special uses in any zoning district.
	Stokes County Zoning Ordinance 91.2	Conditional zoning approval.	Approval for new electric generation facility.

1.5 METHODOLOGY

In accordance with NRC regulation 10 CFR 52.17, which specifies the required contents of applications for an ESP, this ER has been prepared to meet applicable regulatory requirements.

In preparing this ER, Duke Energy followed the content structure and organizational principles outlined in the NRC's Regulatory Guide (RG) 4.2, Rev. 3, *Preparation of Environmental Reports for Nuclear Power Stations*. The ER was developed using NRC guidance documents such as NUREG-1555, Initial, *Standard Review Plans for Environmental Reviews for Nuclear Power Plants* and NUREG-2249, Initial, *Generic Environmental Impact Statement for Licensing of New Nuclear Reactors—Draft Report for Comment*, which provided further guidance. To facilitate NRC review, Table 1.5-1 lists the applicable regulatory requirements, alongside the corresponding sections of the ER where each requirement is addressed.

Table 1.5-1
Environmental Report Responses to Early Site Permit Regulatory Requirements

No.	Regulatory Requirement (10 CFR)[a]	Responsive Environmental Report Section
1	51.45(a), Signed original	Transmittal letter
2	51.45(b), Description of proposed action	Chapter 3, Site Layout and Project Description
3	51.45(b), Statement of purpose of proposed action	Section 1.2, Description of the Proposed Action and Purpose and Need

GLOSSARY

Term	Definition
7Q10	the lowest 7-day average flow that occurs on average once every 10 years
°C	degrees Celsius
°F	degrees Fahrenheit
AADT	average annual daily traffic
ac.	acre
ac-ft	acre-foot
ACRES	Assessment, Cleanup and Redevelopment Exchange System
ACS	American Community Survey
AGL	above ground level
AMS	ambient monitoring system
AMSL	above mean sea level
ANSI	American National Standards Institute
APE	area of potential effect
ASCE	American Society of Civil Engineers
ASHRAE	American Society of Heating, Refrigerating, and Air-Conditioning Engineers
B.C.E.	Before the Common Era
BCSS	Belews Creek Steam Station

Term	Definition
bgs	below ground surface
BLS	Bureau of Labor Statistics
BLSW	Belews Lake surface water
Blue Ridge	Blue Ridge Physiographic Province
BOD	biological oxygen demand
bya	billion years ago
C-14	carbon-14
C.E.	Common Era
CAA	Clean Air Act
$CaCO_3$	calcium carbonate
CAP	corrective action plan as part of BCSS ash basin closure activities
CBC	Christmas Bird Count
CBG	Census Block Group
CCW	condenser cooling water
CDC	U.S. Center for Disease Control and Prevention
CDP	census-designated place
CFOI	census of fatal occupational injuries
CFR	Code of Federal Regulations

Term	Definition
cfs	cubic feet per second
cm	centimeter
cm/yr	centimeters per year
CO_2	carbon dioxide
CO_2-eq	carbon dioxide equivalent
Coastal Plain	Coastal Plain physiographic province
Corp.	corporation
COVID-19	Coronavirus disease 2019
CPUE	catch-per-unit-effort
CWA	Clean Water Act
dB	decibel
dBA	A-weighted sound level
DBA	design-basis accident
DBT	dry bulb temperature
DPT	dew point temperature
D/Q	Deposition Factor
DRSW	Dan River surface water
E	east

Term	Definition
EAB	exclusion area boundary
EF Scale	Enhanced Fujita Scale
EHS	environmental health and safety
EMF	electromagnetic field
ENE	east-northeast
ESE	east-southeast
FBI	Federal Bureau of Investigation
FDOT	Florida Department of Transportation
FEMA	Federal Emergency Management Agency
FGD	flue gas desulfurization
FHWA	Federal Highway Administration
FRS	Facility Registry Services
ft.	feet
ft^2	square feet
ft/day	feet per day
ft/s	feet per second
$ft.^3/s$	cubic feet per second
FY	fiscal year

Term	Definition
g/cm3	grams per cubic centimeter
gal.	gallon
GHG	greenhouse gases
GIS	geographic information system
GMA	growth management area
gpm	gallons per minute
Gt	gigaton
ha	hectare
HAAs	Haloacetic acids
HCM	Highway Capacity Manual
hr.	hour
HUC	Hydrologic Unit Code
Hz	hertz
I	interstate
ICIS	Integrated Compliance Information System
ih	horizontal hydraulic gradient
in.	inches
in/yr	Inches per year

Term	Definition
Inc.	incorporated
IPaC	Information for Planning and Consultation
IPCC	Intergovernmental Panel on Climate Change
JFD	joint frequency distribution
K	hydraulic conductivity
K-40	potassium-40
KGSO	Piedmont Triad International Airport
KINT	Smith Reynolds Airport
km	kilometers
km^2	square kilometers
kph	kilometers per hour
KRDU	Raleigh/Durham International Airport
kV	kilovolt
kV/m	kilovolts per meter
L	liter
L_{dn}	day-night or community noise level
L_{eq}	equivalent sound level
$L_{eq(1hr)}$	Hourly equivalent noise level

Term	Definition
lb	pound
LCD	local climatological data
LLC	limited liability corporation
LMDCT	linear mechanical draft cooling towers
LOS	level of service
lpm	liters per minute
LPZ	Low Population Zone
LSASD	Laboratory Services and Applied Science Division
LWSP	local water supply plan
m	meter
m^3	cubic meter
m^3/d	cubic meters per day
m^3/s	cubic meters per second
m/s	meters per second
Max	maximum
MCAWW	Methods for Chemical Analysis of Water and Wastes
MDL	method detection limit
MEL	Maximally Exposed Location

Term	Definition
MET tower	Belews Creek, NC site meteorological tower
mg/L	milligrams per liter
mg/m3	milligrams per cubic meter
mgd	million gallons per day
mi.	mile
mi^2	square mile
Min.	minimum
mL	milliliter
mld	million liters per day
mm	millimeter
mph	miles per hour
mpn	most probable number
mpn/100mL	most probable number per 100 milliliters
mrem/yr	millirems per year
MRI	mean recurrence interval
MRLC	Multi-Resolution Land Characteristics
ms/cm	millisiemens per centimeter
mSv/yr	millisieverts per year

Term	Definition
MT	million metric tons
mV	millivolt
MWIS	Makeup Water Intake Structure
mya	million years ago
n	effective porosity
N	north
NAAQS	National Ambient Air Quality Standards
NAICS	North American Industry Classification System
NAVD 88	North American Vertical Datum of 1988
NC	North Carolina
NCOSA	North Carolina Office of State Archaeology
NCOSBM	North Carolina Office of State Budget and Management
NCSHPO	North Carolina State Historic Preservation Office
NCWAM	North Carolina Wetland Assessment Method
NCA	National Climate Assessment
NCAC	North Carolina Administrative Code
NCCSR	North Carolina Climate Science Report
NCDEQ	North Carolina Department of Environmental Quality

Term	Definition
NCDOC	North Carolina Department of Commerce
NCDOR	North Carolina Department of Revenue
NCDOT	North Carolina Department of Transportation
NCDWR	North Carolina Division of Water Resources
NCEI	National Centers for Environmental Information
NCEM	North Carolina Emergency Management
NCES	National Center for Education Statistics
NCGA	North Carolina General Assembly
NCHHS	North Carolina Department of Health and Human Services
NC-IPC	North Carolina Invasive Plant Council
NCNHP	North Carolina Natural Heritage Program
NCWRC	North Carolina Wildlife Resources Commission
n.d.	not dated
NE	northeast
NE	no regulatory standard established for this constituent
NFPA	National Fire Protection Association
NHPA	National Historic Preservation Act
ng/L	nanograms per liter

Term	Definition
NLCD	National Land Cover Database
NM	noise monitoring
NNE	north-northeast
NNW	north-northwest
NOAA	National Oceanic and Atmospheric Administration
NPDES	National Pollutant Discharge Elimination System
NPL	National Priority List
NRC	U.S. Nuclear Regulatory Commission
NRCS	Natural Resources Conservation Service
NRHP	National Register of Historic Places
NS	Norfolk Southern
NTU	nephelometric turbidity units
NUREG	NRC Technical Report designation
NW	northwest
NWI	National Wetland Inventory
NWQMC	National Water Quality Monitoring Council
NWS	National Weather Service
OB	overburden

Term	Definition
OHWM	ordinary high-water mark
ORW	outstanding resource waters
OSHA	U.S. Occupational Safety and Health Administration
pci/L	picocuries per liter
PEM	palustrine emergent
PFAS	perfluoroalkyl and polyfluoroalkyl substances
PFO	palustrine forested
PHFS	Primary Highway Freight System
Piedmont	Piedmont Physiographic Province
$PM_{2.5}$	particulate matter with a diameter of 2.5 microns or less
PM_{10}	particulate matter with a diameter of less than 10 microns
Project	All nuclear site development proposed by the applicant including transmission lines, access roads, utility corridors supporting the facility, etc
Project Region	The area encompassed within a 50-mi. radius of the Belews Creek, NC site bounding limit unless otherwise specified for a particular resource.
Project site	Belews Creek, NC site
Project Vicinity	The area encompassed within a 6-mi. radius of the Project site center point unless otherwise specified for a particular resource.
PSM	process safety management

Term	Definition
PWR	partially weathered rock
PWS	public water supply
QC	quality control
RCP4.5	Representative Concentration Pathway 4.5
RCP8.5	Representative Concentration Pathway 8.5
RCRA	Resource Conservation and Recovery Act
REMP	radiological environmental monitoring program
RH	relative humidity
ROI	region of influence
ROW	right-of-way
RV	recreational vehicle
s	second
S	south
SE	southeast
SEMS	Superfund Enterprise Management System
SM	standard method
SOII	Survey of Occupational Injuries and Illnesses
SPC	Storm Prediction Center

Term	Definition
SR	State Route
SSAR	Site Safety Analysis Report
SSE	south-southeast
SSW	south-southwest
STP	shovel test pit
SW	southwest
TFCSW	Town Fork Creek surface water
TKN	Total Kjeldahl nitrogen
TMDL	total maximum daily load
TRI	Toxics Release Inventory
U.S.	United States
USACE	U.S. Army Corps of Engineers
USC	U.S. Code
USCB	U.S. Census Bureau
USDA	U.S. Department of Agriculture
USDOC	U.S. Department of Commerce
USEPA	U.S. Environmental Protection Agency
USFWS	U.S. Fish and Wildlife Service

Term	Definition
USGCRP	U.S. Global Change Research Program
USGS	U.S. Geological Survey
V	velocity
VDH	Virginia Department of Health
W	west
WBT	wet bulb temperature
WER	water effect ratio
WNW	west-northwest
WOTUS	Waters of the U.S.
WS	water supply
WSP	WSP USA
WSW	west-southwest
WWTP	wastewater treatment plant
yr.	year
ΔT	temperature difference
µg/g	micrograms per gram
µg/L	micrograms per liter
µs/cm	microsiemens per centimeter

Term	Definition
μT	microtesla
χ/Q	atmospheric-dispersion factor

Chapter 2 The Proposed Site and the Affected Environment

2.1 LAND USE

This section describes land use on the Belews Creek, North Carolina (NC) site (Project site), the Project Vicinity (6-mile [mi.] [10-kilometer {km}] radius) and the Project Region (50-mi. [80-km] radius). The Project site is located along Belews Creek and Belews Lake in an unincorporated community of Sauratown Township, Stokes County, and partially in Belews Creek Township, Forsyth County, NC. The site is approximately 14 mi. (23 km) northeast of Winston-Salem, NC, and approximately 19 mi. (31 km) northwest of Greensboro, NC (Section 1.1.2). Land use within the Project site, Project Vicinity, and Project Region are analyzed using the Multi-Resolution Land Characteristics (MRLC) Consortium National Land Cover Database (NLCD) (MRLC Consortium, 2021). The Project site is depicted on Figure 2.1-1. Figure 2.1-2 presents a high oblique aerial photograph of the Project site. Figure 2.1-3 depicts the Project Vicinity and the Project Region.

2.1.1 THE REGION, VICINITY, AND SITE

2.1.1.1 The Region

There are 26 counties within the Project Region which extends to a 50-mi. (80-km) radius of the Project site center point. Eighteen of these counties are in NC and eight are in Virginia (Table 2.1-1, Figure 2.1-3). Additionally, two independent cities (Danville, Virginia, and Martinsville, Virginia) are located within the Project Region. In Virginia, cities are considered an equal level of government as counties. For some counties, the Bureau of Economic Analysis, for statistical purposes, combines any independent cities with the county of which it was once part (Virginia Association of Counties, 2024). Therefore, Danville is included in the statistical data reported within Pittsylvania County, and Martinsville is included in the statistical data reported within Henry County. As stated in Section 2.4.1.2, the largest city in the Project Region is Greensboro, NC. As of the 2020 census, the population of Greensboro was 299,035 persons. The next largest city located within the Project Region is Winston-Salem, NC, with a population of 249,545 (see Section 2.4 for more information on regional demographics).

Major highways, roads, railroads, and airports are shown in Figure 2.1-4. Four interstate highways traverse the Project Region: Interstate (I) 40, I-74, I-77, and I-85. Major rail lines or rail systems include those owned by Norfolk and Western Railroad, Norfolk Southern (NS) Railroad, and Winston-Salem Southbound Railway. There are two major public airports, Piedmont Triad International Airport (KGSO) and Smith Reynolds Airport (KINT). Section 2.4 provides a description of the transportation network in the vicinity of the Project site.

Land cover within the Project Region is predominantly undeveloped forested land and hay/pasture. Large tracts of forested land are located within the northern portion of the Project Region. Developed land within the Project Region is concentrated within major cities located within the south-central portion of the Project Region. Land use and land cover in the Project Region are categorized in Table 2.1-2 and Figure 2.1-5.

The breakdown of agricultural commodity type, acreages, and yield for the counties in the Project Region is included in Table 2.1-3 and Table 2.1-4. The U.S. Department of Agriculture (USDA) 2022 Census of Agriculture indicates that the principal agricultural commodities in the Project Region are corn for grain, corn for silage, forage (hay/haylage), wheat for grain, soybeans, and tobacco (USDA, 2022b and 2022c). The breakdown of forestry commodity by

product for the counties in the Project Region is included in Table 2.1-5 and Table 2.1-6. According to the USDA Forest Service, Halifax County, Virginia, and Chatham County, NC, are among the top producers of wood products, including wood for biofuel, composite panel, poles, posts and pilings, pulpwood, saw logs, veneer logs, and other miscellaneous products.

Major public and trust land areas in the Project Region (areas that are 500 acres [ac.] [202 hectares {ha}]) or larger] are illustrated on Figure 2.1-6. These include the Uwharrie National Forest, Blue Ridge Parkway, North Carolina Zoological Park, several wildlife management areas, nature preserves, game lands, and state parks. Most of these public lands offer camping, fishing, swimming, hiking, and other recreational activities for visitors.

2.1.1.2 The Vicinity

Figure 2.1-3 illustrates the Project Vicinity, defined as a 6-mi. (10-km) radius from the Project site center point. The Project Vicinity spans the southeastern portion of Stokes County, northeastern portion of Forsyth County, southwestern portion of Rockingham County, and the northwestern portion of Guilford County. Figure 2.1-7 illustrates the topography within the Project Vicinity.

Land cover in the Project Vicinity is shown in Table 2.1-2 and Figure 2.1-8. The predominate land cover types include undeveloped forested land, followed by hay/pasture. Evergreen forest is primarily located around Belews Lake with undisturbed pockets of mixed forest, deciduous forest, and hay/pasture dispersed throughout the Project Vicinity. Developed land classified as low intensity or open space is located sparsely throughout the Project Vicinity, whereas most of the high intensity and medium intensity developed lands are found within the Belews Creek Steam Station (BCSS), Walnut Cove, and Stokesdale areas. Belews Lake represents most of the open water within the Project Vicinity.

Prime farmland is defined by the USDA as farmland exhibiting the best combination of physical and chemical soil properties for agricultural production (USDA, 2022d). As shown in Table 2.1-7, approximately 67 percent of soils in the Project Vicinity are identified by the USDA as prime farmland soils. Prime farmland and farmland of statewide importance are found in areas associated with hay/pasture and cultivated cropland adjacent to rivers and streams in the Project Vicinity (see Figure 2.1-8). As illustrated in Figure 2.1-9, prime farmland soils are widespread throughout the Project Vicinity.

Special land uses, 500 ac. (202 ha) or larger, within the Project Vicinity are included on Figure 2.1-6. The Piedmont Land Conservancy consists of three preserves that collectively span 1,716 ac. (694 ha) throughout the Project Region. One of those preserves, the Knight Brown Nature Preserve, is located approximately 3.7 mi. (6 km) northeast of the Project site center point within the Project Vicinity. The Knight Brown Nature Preserve consists of approximately 147 ac. (60 ha) with almost 5 mi. of walking trails, a wooded valley, and two streams (Piedmont Land Conservancy, 2024). Additionally, several recreational areas, parks, marinas, and boat ramps are located adjacent to the Belews Lake. Recreational land use is discussed in detail in Section 2.4.2.6.

Transportation facilities within the Project Vicinity are shown on Figure 2.1-4. Two U.S. highways (U.S Highway 311 and U.S. Highway 158) and one state highway (NC Highway 65) are located within Project Vicinity. A NS railroad line runs to the north of the Project site. The railroad throughline is 2.2 mi. (3.5 km) to the north of the Project site, and a spur line runs to the Project site.

Chapter 160D of the North Carolina General Statutes, Local Planning, and Development Regulations require local governments to adopt and reasonably maintain a comprehensive plan or land use plan (NCGA, 2024). Accordingly, all of the counties within the Project Vicinity (Stokes, Forsyth, Guilford, and Rockingham counties) have adopted countywide comprehensive plans. All four of the county comprehensive plans identify goals for increasing economic growth and attracting businesses, development of a variety of housing options, protection and preservation of natural resources, and improvements to transportation and utilities (Guilford County, 2024a, Rockingham County, 2021, Stokes County, 2015, City-County Planning Board, 2013).

Most of the Project site falls within Stokes County, and according to the Stokes County Comprehensive Plan, Land Use Framework Maps, the Project site and most of Stokes County is designated as "(O-2) Open Space: Rural Community." These designations reflect areas where land uses are designated for very low-density development typically lacking centralized water or sewer infrastructure. The plan notes some of these areas could ultimately transition to O-1 Open Space: Preserved Lands, which are intended for preservation, conservation, or very limited development areas (Stokes County, 2015). A small portion of the Project site falls within Forsyth County. According to the Forsyth County Proposed Land Use Map, the Project site is designated as Growth Management Area (GMA) 5 / Rural Area. This designation identifies land uses in these areas as those intended for preserved agricultural uses, tourism, and recreation opportunities. It also reflects a policy of limited road building, limited expansion of sewer infrastructure, and an intention to avoid rezoning to more intensive land use districts.

2.1.1.3 The Site

As shown on Figure 2.1-1, the Project site is located adjacent to the BCSS on a peninsula surrounded by Belews Lake to the north, east, and much of the western sides. The Project site is accessed from either Pine Hall Road (State Route [SR] 1908) from the west or Craig Road (SR 2042) from the south. Duke Energy Carolinas, LLC (Duke Energy) owns the approximately 1187-ac. (480 ha) Project site and no off-site land acquisition is needed to support project activities.

NC did not adopt the Public Land Survey System; therefore, the Project site is not assigned a section, township, or range (Digital Data Services, Inc., 2016). The Project site is located within the U.S. Geological Survey (USGS) Belews Lake Quadrangle.

Because the layout of the Project site is not finalized, the exact location of the Project site center point is yet to be determined. As a conservative approach, site bounding limit encompass any and all areas in which nuclear facilities could be located. The coordinates of the Project site center point is shown in Table 2.1-8. The Project site center point incorporates a bounding radius around the Project site center point coordinate such that the radius encompasses all safety-related features of the Project. The Project site center point represents the center of the property which is designated for future development of three Plant Complexes. The site center point will remain the same regardless of final site layouts in the final project design. Unless otherwise specified, distance measurements to features within the Project Vicinity and Project Region are measured from the Project site center point.

A topographic map of the Project site is presented on Figure 2.1-10. As shown on the figure, the Project site consists of rolling hills and steep slopes with surface elevations ranging from approximately 725 feet (ft.) (219.5 meters [m]) North American Vertical Datum of 1988 (NAVD 88) near the shoreline of Belews Lake to approximately 890 ft. (271 m) NAVD 88 along the

ridgetops. As described in Section 2.10, the Project site lies within the NC western Piedmont physiographic province (Piedmont), which is characterized by gently rolling, well-rounded hills and long, low ridges ranging in a few hundred feet of elevation difference between the hills and valleys.

Land cover within the Project site is identified in Figure 2.1-8 and summarized in Table 2.1-2. Land cover categories shown are consistent with the land use classification codes listed in MRLC Consortium NLCD. The Project site is primarily undeveloped forested land (deciduous, evergreen, or mixed forest), which accounts for approximately 79 percent of the land cover. Approximately 7 percent of the land cover within the Project site is classified as developed land (high, medium, or low intensity, or open space). These areas represent various land uses to support operation of the BCSS. There are no special land uses within the Project site (Figure 2.1-6).

As shown on Figure 2.1-9 and summarized in Table 2.1-7, approximately 46 percent of soils within the Project site are considered prime farmland and farmland of statewide importance.

Most of the Project site is located in Stokes County, with a small portion located in Forsyth County (Figure 2.1-1). The portion in Stokes County is zoned as “M-1.” Per the Stokes County Zoning Ordinance, M-1 is a light manufacturing district. This zoning district is assigned to areas where the principal use of the land is for light manufacturing and warehousing, uses that normally seek locations on large tracts of land where operations do not detract from the development potential of nearby undeveloped properties. The southern portion of the Project site, located in Forsyth County, is zoned “AG-Agricultural.” The AG-Agricultural District designation was established to maintain agricultural nature uses and scattered non-farm residences on large tracts of land.

There are no known mineral resources within or adjacent to the Project site that are currently being extracted or utilized (USGS NMIC, 2003).

There is an existing natural gas pipeline traversing the Project site that provides natural gas to the existing BCSS. Three double-circuit 230-kilovolt (kV) transmission lines also cross the Project site (Figure 2.1-1). Duke Energy owns and operates the lines.

The Project site is not located within a Coastal Zone and therefore is not subject to requirements in the Coastal Zone Management Act.

Section 2.3.1 provides a further discussion of natural and human-made habitat types within the Project site. Descriptions of floodplains and wetlands within the Project site are discussed in Section 2.2.

2.1.2 TRANSMISSION CORRIDORS AND OTHER OFF-SITE AREAS

The existing BCSS is served by an existing switchyard and established transmission corridors that will serve the needs of the Project site. Therefore, no additional off-site transmission lines or corridors are needed to support the Project. However, the need for a new large 230-kV switchyard or multiple new smaller 230-kV switchyards (in addition to the existing switchyard), has been identified. The new switchyard(s) are located within the existing site boundary. The new transmission lines and any relocation of existing transmission lines are located within the existing Project site, no off-site land acquisition is needed. As such, discussion of land use, special land uses, prime farmland, and natural areas within the Project site, which contains any

new transmission lines, are described above in Section 2.1.1.3. Transmission information is discussed in more detail in Section 3.2.

Portions of the existing wastewater pipeline corridor extends outside the Project site. The existing wastewater pipeline, depicted on Figure 2.1-1, is an associated off-site feature, which is approximately 40 ac. (16 ha), and is currently used by the BCSS to transfer wastewater to its National Permit Discharge Elimination System (NPDES) permitted discharge point to the Dan River. Table 2.1-2 and Figure 2.1-8 identify and categorize the land cover in the existing wastewater pipeline corridor. As shown in Table 2.1-7, approximately 48 percent of soils in the existing wastewater pipeline corridor are identified by the USDA as prime farmland and farmland of statewide or local importance. The existing wastewater pipeline is located within the 6 mi. (10 km) Project Vicinity. Additionally, details of land use, special land uses, and land use plans within the Project Vicinity are described above in Section 2.1.1.2.

2.2 WATER RESOURCES

This section describes the hydrological processes governing the movement and distribution of water in the existing environment at and around the Project site. Sections 2.2.1, 2.2.2, and 2.2.3 describe surface water and groundwater hydrology, water uses, and water quality, respectively. Section 2.2.4 describes water monitoring that characterizes the Project site hydrology.

Sections 4.2 and 5.2 describe the potential impacts to surface water and groundwater resources during plant construction and operation. Water level measurements presented in this section are converted to the NAVD 88, unless otherwise specified.

2.2.1 HYDROLOGY

This section describes the hydrologic characteristics of surface water and groundwater resources that could be affected by building activities or operation of the Project. Site-specific and regional data for the physical and hydrologic characteristics of surface water and groundwater are summarized below.

2.2.1.1 Surface Water

2.2.1.1.1 Regional Surface Water Resources

Figure 2.2-1 presents surface water resources in the 50-mi. (mi.) (80-km [km]) Project Region surrounding the Project site. The Project Region encompasses the Piedmont Ecoregion of NC and Virginia, which is characterized by gently rolling hills with many stream-cut valleys and only a few level floodplains (see Section 2.3.1.1.1). Major surface water features in the Project Region include streams, rivers, and reservoirs that were constructed for flood control, water supply, and power generation. There are no natural lakes in the Piedmont region. Major watersheds in the Project Region are associated with river systems that include the Upper Dan, Lower Dan, Haw, Deep, Lower Yadkin, and Upper Yadkin. Watersheds that are less well represented within the region include those of the South Yadkin, Upper New, Upper Roanoke, Banister, Upper Neuse, and Upper Pee Dee Rivers. Major surface waters in the Project Region include the Dan River, Haw River, Yadkin River, High Rock Lake, and Belews Lake (Figure 2.2-1). Table 2.2-1 summarizes drainage areas and the related flow characteristics of notable streams in the Project Region.

Figure 2.2-2 presents the surface water resources in the 6-mi. (10-km) Project Vicinity. Watersheds in the Project Vicinity include the Upper Dan (Hydrologic Unit Code [HUC] 03010103) and Haw (HUC 03030002); however, the Project has the potential to affect only those surface waters within the Upper Dan River watershed (Figure 2.2-2).

Surface waters in the Project Vicinity include Belews Lake, Belews Creek, East Belews Creek, West Belews Creek, Dan River, Lick Creek, Town Fork Creek, Watershed Lake Two (on Town Fork Creek), Boy Scout Pond, Eurins Creek, and Hogans Creek (Figure 2.2-2).

The Project site drains to Belews Lake via the main Belews Creek arm and the West Belews Creek arm. Water flows from Belews Lake north to the Dan River via a spillway located at the dam (Figure 2.2-3) and short segment of Belews Creek channel. The Project may affect Belews Lake, the Dan River, Belews Creek downstream of the Belews Lake spillway, and smaller tributary streams on the Project site. These surface water resources are discussed in more detail below.

2.2.1.1.2 Dan River

The Dan River is located generally north of the Project site and flows southeasterly from uplands within the Piedmont Ecoregion (see Section 2.3.1.1.1 for a description of the Piedmont Ecoregion), then progresses in a northeasterly direction (Figure 2.2-2). The Dan River receives water from the Belews Lake spillway (Figure 2.2-3). As described in Section 2.2.1.1.2.3, the Dan River also provides source water for the Belews Lake storage augmentation system via a pumping station (i.e., the makeup water intake structure [MWIS]) located near the confluence with Belews Creek (Figure 2.2-3).

2.2.1.1.2.1 Normal Hydrologic Conditions

The Dan River is a free-flowing, unchanneled river system with no associated levees or major flow modifications (Figure 2.2-2). No upstream hydroelectric projects are on the Dan River, and therefore there are no dam-related fluctuations in flow. Potential flow diversions are associated with the MWIS located on the Dan River at the confluence with Belews Creek that provides makeup water to Belews Lake (see Section 2.2.1.1.2.3). No other known flow modifications are located near the Project site.

A USGS streamflow gaging station on the Dan River at Pine Hall (USGS Station No. 02069000) is located approximately 1.2 mi. (1.9 km) upstream of the confluence with Belews Creek (Figure 2.2-3). The Dan River drainage area at the Pine Hall station is 501 square mi. (mi.^{2}) (1297.6 square kilometers [km^2]). Information on representative drainage areas of the Dan River and Belews Lake watersheds are summarized in Table 2.2-2.

Streamflow measurements at the Pine Hall station are periodic; however, official USGS records are available from October 1923 to April 1926, from April 1986 through December 1990, , and from December 2008 through current time. Approved USGS streamflow values from 1986 through early 2024 represents 21 years of approved average annual flow values, 22.1 years of average monthly flows, and 23.4 years of mean daily flow available to characterize the Dan River at Pine Hall. Data from the 1920s were not included due to potential impacts of watershed development and representative data that better capture current watershed conditions.

Table 2.2-3 presents the mean and median daily flow characteristics of the Dan River at Pine Hall stream station for available data. The mean daily flow in this section of the Dan River from 1987 to 2024 is 677 cubic feet per second (cfs) (19.2 cubic meters per second [m^3/s]) and the median flow is 474 cfs (13.4 m^3/s). Table 2.2-4 summarizes mean monthly discharges from available data spanning 1986 through 2024. The highest average flows normally occur in February (959 cfs [27.1 m^3/s]), and the lowest average flows occur in August (421 cfs [11.9 m^3/s]), which corresponds to a typical late summer to fall low-flow period.

Figure 2.2-4 presents annual peak flow exceedance probabilities for the Dan River at Pine Hall. A peak flow of 14,780 cfs has an annual probability of exceedance of 50 percent (i.e., 2-year return period); the 1 percent annual probability (100-year return period) peak discharge is 29,864 cfs; and the 0.2 percent annual probability (500-year return period) peak discharge is 32,245 cfs). Flood stage (i.e., threshold for minor flooding) of the Dan River at the Pine Hall station is 586.3 feet (ft.) (178.7 meters [m]) or 23.0 ft. (7.0 m) gage height (NOAA, n.d.). The peak instantaneous flow was 27,800 cfs (787.2 m^3/s) recorded on January 25, 2010, and corresponded to a maximum river stage of 25.8 ft. (7.9 m).

2.2.1.1.2.2 Drought Conditions

Table 2.2-5 presents annual average low-flow data for durations from one to 60 days for the Dan River at Pine Hall from 1986 through 2024. In July of 1986, USGS estimated and approved a low-flow value of 65 cfs (1.8 m^3/s). The lowest 60-day average flow was 141 cfs (4.0 m^3/s) in 1986. The Dan River has an estimated summer 7-day duration, 10-year return period average low flow (7Q10) of 80 cfs (2.3 m^3/s), and a winter 7Q10 of 160 cfs (4.5 m^3/s) (NCDEQ, 2025a).

2.2.1.1.2.3 Supplemental Pumping to Belews Lake

The Dan River has occasionally provided the source water for a Belews Lake storage augmentation via two separate pumping systems. Prior to 2010, diversions from the Dan River to Belews Lake occurred via a temporary pumping system authorized by the North Carolina Division of Water Quality (predecessor to the North Carolina Department of Environmental Quality [NCDEQ] Division of Water Resources [NCDWR]). This temporary system consisted of 12 8.0-cfs (0.23 m^3/s) pumps (i.e., 96 cfs [2.63 m^3/s] total pumping capacity) supplying six force mains to Belews Lake. Water was pumped from the Dan River into Belews Lake via the temporary system over three periods: December 23, 2002 to February 28, 2003; January 22 to March 31, 2008; and January 12 to March 23, 2009. In 2010, a permanent pumping system (the MWIS) subject to conditions outlined in the BCSS NPDES permit was constructed near the Belews Creek confluence with the Dan River (Figure 2.2-3). Section 2.2.2.1.3 further describes the MWIS.

Duke Energy's BCSS operations plan for Belews Lake determined the need for supplemental pumping from the Dan River. This spillway operational plan established target water level control points of 724.50 ft. (220.8 m) during summer, 724.45 ft. (220.80 m) during fall, and 724.70 ft. (220.88 m) during winter and spring (Table 2.2-7).The MWIS operation plan includes initiating pumping when the lake level falls below 722.5 ft. The current NPDES permit prohibits pumping when the lake level is above 724.5 ft.

2.2.1.1.2.4 Physical Characteristics

Stream channel and flow characteristics of the Dan River and Belews Creek were collected on October 25, 2024. Representative cross sections were characterized at established water quality sampling sites as described in Section 2.2.3. Figures 2.2-5 to 2.2-8 present cross sections at each of the three sampling locations on the Dan River and one location on Belews Creek.

Measurements of the local channel width and mid-channel depths were obtained from the water quality sampling sites, which are further described in Section 2.2.4.1, on October 25, 2024. The local measurements indicated the channel width of the Dan River is less than approximately 100 ft. (30.5 m) with mid-channel depths that range from less than 1 ft. (0.3 m) to approximately 3 ft. (0.9 m) (Figures 2.2-5 to 2.2-7). Near the confluence with the Dan River, Belews Creek has a width of approximately 55 ft. (16.8 m) and depth of approximately 2 ft. (0.6 m) (Figure 2.2-8). Velocity values along cross sections in the Dan River ranged from 0.0 feet per second (ft/s) (0.0 meters per second [m/s]) within slack-water habitats (i.e., slow-moving water) to 2.7 ft/s (0.8 m/s) in faster flowing chute habitats. Flows at the Belews Creek sampling location were less than 0.03 ft/s (0.01 m/s)—essentially slack-water.

Additionally, Dan River channel information available from the USGS Dan River at Pine Hall streamflow station provides a robust characterization of the channel dimensions as well as the

hydraulic characteristics over a range of flow conditions. To supplement the field measurements, a review of the existing field conditions at the USGS station are provided for comparison. The following Dan River channel characteristics were determined based on the available Pine Hall streamflow station field measurement data:

- The gage height varies from 0.41 ft. (0.12 m) at a measured low-flow rate of 83.9 cfs (2.38 m^3/s) to 3.04 ft. (0.93 m) at a measured median flow of 584 cfs (16.54 m^3/s);
- The channel width varies from 97 ft. (29.57 m) at a measured low-flow rate of 83.9 cfs (2.38 m^3/s) to 137 ft. (41.76 m) at a measured median flow of 584 cfs (16.54 m^3/s);
- Bank heights are typically in the range of 13 to 19 ft. (3.96 to 5.79 m);
- The average channel velocity varies from 0.49 ft/s (0.15 m/s) to a median velocity of 1.83 ft/s (0.56 m/s).

Other physical characteristics estimated for the Dan River near the Project site include stream gradient, sediment type, and sediment transport. Near the Project site, the Dan River has a gradient of approximately 3.1 ft/mi (0.6 m/km) and stream slope of 0.06 percent. Stream sediments observed in the Dan River were primarily sand and gravel with mud shorelines. Some areas of bedrock and woody debris were also present. Sediment transport was not directly measured; however, Simmons (1993) summarized regional sediment transport in NC streams including in the Dan River. Simmons (1993) estimated the annual suspended sediment loads in the Dan River near Franscisco, NC (upstream of the Project site), and near Wentworth, NC (downstream of the Project site), as 35,000 tons (270 tons/mi^2) and 460,000 tons (440 tons/mi^2), respectively. Median suspended sediment concentrations were 33 milligrams per liter (mg/L) and 98 mg/L, respectively. Maximum suspended sediment concentration measured 1520 mg/L in the study.

2.2.1.1.3 Belews Lake

2.2.1.1.3.1 Hydrology

2.2.1.1.3.1.1 Hydrologic Overview

Belews Lake is a man-made reservoir formed in 1970 following construction of an earthen embankment dam across Belews Creek. The lake was constructed to serve as a condenser cooling water (CCW) source for the BCSS. Three named streams flow into Belews Lake: Belews Creek, West Belews Creek, and East Belews Creek (Figure 2.2-3).

Belews Lake is oriented in a generally north-northeasterly direction with two primary arms of the reservoir formed by Belews Creek and West Belews Creek (Figure 2.2-3). Figure 2.2-3 shows inflows and flow directions throughout Belews Lake. The BCSS CCW flow influences lake circulation patterns. East Belews Creek flows into the southern end of Belews Lake near the main Belews Creek channel. The West Belews Creek arm is separated into two hydraulically distinct waterbodies by an earthen plug that Duke Energy installed when the BCSS CCW system was constructed. The BCSS CCW canal was then excavated through the ridge that separated West Belews Creek from Belews Creek (Figure 2.2-3). This modification altered the natural flow of West Belews Creek, allowing water from the CCW discharge to flow through the CCW canal and into the lake, upstream of its natural confluence with the main Belews Creek arm.

The normal full pond elevation of Belews Lake is 725 ft. (221.0 m). The average depth of the lake is approximately 49 ft. (14.9 m), and the maximum depth is approximately 144 ft. (43.9 m) (HDR, 2023). The lake occupies approximately 3862 ac. (1562.9 hectares [ha]) and has approximately 88 mi. (141.6 km) of shoreline (Duke Energy, 2020). Belews Lake drains to the Dan River downstream of the dam spillway (Figure 2.2-3).

The upland drainage area into Belews Lake consists of several drainage basins, including East Belews Creek (8.0 $mi.^2$ [20.7 km^2]), West Belews Creek (9.0 $mi.^2$ [23.3 km^2]), Belews Creek (20.8 $mi.^2$ [53.9 km^2]), and drainage areas from smaller tributaries (Table 2.2-2). The dam impounds a total drainage area of approximately 69.4 $mi.^2$ (179.7 km^2). The CCW canal drains an area of approximately 13.2 $mi.^2$ (34.2 km^2), while the lower West Belews Creek drainage area, downstream of the earthen plug, is approximately 2.4 $mi.^2$ (6.2 km^2) (Table 2.2-2).

As Section 2.2.3.1.4 describes, the BCSS uses water from Belews Lake for CCW. The once-through CCW system has a total maximum flow rate of approximately 2340 cfs (66.2 m^3/s) and returns virtually all CCW intake to the lake. However, the elevated discharge temperature generates increased evaporation, known as forced evaporation, that exceeds natural lake evaporation.

2.2.1.1.3.1.2 Watershed Runoff and Belews Lake Water Balance

A comprehensive hydrologic model evaluates relevant inputs and outputs (i.e., direct precipitation, stream inflow, consumptive losses from water use, natural evaporation, forced evaporation, seepage losses, and supplemental pumping from the Dan River) using average monthly data to evaluate long-term hydrologic characteristics of Belews Lake and the Dan River and to inform potential effects of the proposed action on future hydrological conditions (see Section 5.2.1).

Hydrologic characteristics of Belews Lake were estimated for a 27-year historical period from 1997 to 2024 based on historical operations of BCSS (i.e., BCSS historical condition) to capture a range of meteorological (e.g., extended droughts) and operational conditions. This modeling period encompasses available BCSS operations data and Flue gas desulfurization (FGD) operation and includes a variation in BCSS operations and change in consumptive water use as a result of the FGD systems and a reduction in average power generation and plant capacity factor during the years since 2015. The reduction in power generation reduced the heat load to the lake, and thus the forced evaporation, as well as the FGD system demand. Water inflows and outflows were modeled using available lake elevation data, plant operations data, local precipitation data, and other Belews Lake water budget components. Average monthly watershed runoff data were estimated by the model using regional USGS flow records to inform selection of parameters for water balance components.

Belews Lake receives inflows from the watershed, direct precipitation on the lake surface, and via pumping from the Dan River. Most of the inflows to Belews Lake are from the watershed. As described above, major tributaries to Belews Lake include Belews Creek, East Belews Creek, West Belews Creek, and an unnamed tributary to the northeast of Belews Lake (Figure 2.2-3).

Total inflows to Belews Lake based on the modeling are estimated to be approximately 89.5 cfs (2.53 m^3/s). This flow rate is equivalent to an average annual watershed runoff of approximately 14.6 inches (in.) (36.8 centimeters [cm]). Based on the water budget analysis, Belews Lake received an estimated 76.5 percent of inflows from the contributing watershed. Direct precipitation accounted for an estimated 21.8 percent of inflows, while the remaining 1.7 percent

were from pumping (i.e., supplemental diversions) from the Dan River (Table 2.2-6).

Estimated outflows from Belews Lake over the modeling period include consumptive losses from forced evaporation (18.8 percent) and from the operation of BCSS (11.4 percent). Natural evaporation from the entire surface area of the lake accounts for approximately 18.9 percent of the total losses. Other outflows include releases from the spillway (32.3 percent) and estimated seepage through the dam, spillway gates, or into groundwater (18.6 percent) (Table 2.2-6). The average net seepage loss to groundwater is estimated at 20 inches per year (in/year) (6437 ac-ft/year) averaged over the lake surface area.

Figure 2.2-9 provides a characterization of the varying Belews Lake water levels over the historical modeling period. The end-of-month water levels plotted are measured water levels. This figure also depicts the primary inflow component (i.e., watershed runoff) and outflow component (i.e., spillway releases). Based upon this analysis, water levels demonstrated a regular annual variability of approximately 1.5 ft. (0.46 m) from the lake control elevation (724.5 ft. [220.8 m]) to approximately 723 ft. (220.4 m). The normal water level fluctuation range decreased during the time period from approximately 2015 to 2024 due mostly to the reduced BCSS generation as indicated by the annual capacity factor also indicated on Figure 2.2-9. Several periods of increased water level drawdown are also notable, including the drawdown in 2001 to 2003 during a drought which reduced lake elevation to approximately 717.2 ft. (218.6 m) on October 11, 2002. Pumping water from the Dan River using the temporary pumping system and increased precipitation in late 2002 alleviated the drought and lake-level recession. Other moderate droughts occurred from late 2007 through 2009, during which water levels declined to approximately 720.65 ft. (219.65 m), about 3.85 ft. (1.17 m) below the lake control elevation. Pumping from the Dan River via the temporary pumping system in late 2007 through early 2008 alleviated the drought and lake-level recession.

As described above and in Table 2.2-7, the Belews Lake water balance is also influenced by losses associated with forced evaporation and consumptive use (predominantly associated with FGD operations). As illustrated in Figure 2.2-9, decreases in forced evaporation reflect a reduced level of BCSS power generation and its associated thermal discharges to Belews Lake in the years since 2015. Similarly, the pattern of losses associated with consumptive use reflects a higher amount of variability and a general downward trend over the same period. Together, these trends reflect a reduced capacity factor for the BCSS and contribute to a less variable water surface elevation of Belews Lake in recent years.

2.2.1.1.3.1.3 Belews Lake Residence Time

The hydraulic retention, or residence, time of Belews Lake has been estimated to be 1500 days (4.13 years) (HDR, 2023). The estimate was based on a total full-lake storage of 184,843 ac-ft (2.280×10^8 m^3).

2.2.1.1.3.1.4 The Current Water Level Control (Includes BCSS Belews Lake Operational Considerations)

The Belews Lake spillway and water level control structure is located at the northernmost end of Belews Lake and is operated to achieve target seasonal water levels. The structure includes six flow control gates, including two moveable floodgates, known as Taintor gates (Gate 1 and Gate 2). Each Taintor gate is 20-ft. (6.10-m) wide with a sill elevation of 710.0 ft. (216.41 m). The Taintor gates discharge water during unusually high lake levels. The pier separating the Taintor gates contains four other gates: two 5-ft. by 5-ft. (1.5-m by 1.5-m) sluice gates (Gate 3 and Gate

4), an overflow gate (Gate 5), and a stop-log gate (Gate 6). Gate 5 provides normal lake-level control and releases water from the lake. Specifically, water releases from the surface of the mixing chamber within the center pier of the spillway. Gates 3, 4, and 6 (namely 3 and 4) are opened at subsurface elevations as needed to fill the mixing chamber. Contents of the mixing chamber are then released via overtopping Gate 5 (which opens downward).

The spillway operational plan established target water level control points of 724.50 ft. (220.8 m) during summer, 724.45 ft. (220.80 m) during fall, and 724.70 ft. (220.88 m) during winter and spring (Table 2.2-7). Target lake levels identified in Table 2.2-7 were developed by Duke Energy based on a high BCSS capacity factor and with FGD operation (i.e., high forced evaporation and consumptive use). As described in Section 2.2.1.1.3.1.2, water losses from Belews Lake associated with forced evaporation and consumptive use from BCSS have declined in recent years (notably since 2015) due to reduced capacity factor. Table 2.2-7 summarizes the monthly daily elevation durations of Belews Lake water levels relative to the established target levels.

Historically, Belews Lake water levels have periodically fallen below BCSS operational target elevations. The most extreme instance occurred during the May 2001 to May 2003 drought, when the Belews Lake water level dropped to approximately 717.2 ft. (218.60 m), near the critical elevation for BCSS CCW intake operation, in October 2002.

As described in Section 2.2.1.1.2, the Dan River provides source water for the Belews Lake storage augmentation system via the MWIS located near the confluence with Belews Creek. The MWIS was constructed in 2010. In 2011 and 2012, the pumps diverted approximately 2074 ac-ft (2,558,241 m^3) of water to Belews Lake from December 2011 through March 2012; and about 3388 ac-ft (4,179,036 m^3) from August through December 2012. Prior to 2010, diversions from the Dan River to Belews Lake occurred three times via a temporary pumping system (see Section 2.2.1.1.2.3).

2.2.1.1.3.2 Physical Characteristics

2.2.1.1.3.2.1 Belews Lake Depth, Elevation, and Storage Volume Relationships

Belews Lake elevation, surface area, and storage volume relationship data are summarized in Table 2.2-8 and shown on Figure 2.2-10. Both the table and the figure show the relationship between these three parameters based on the original lake design (i.e., “1970”). Bathymetry of Belews Lake was developed based on pre-impoundment topographic mapping (Figure 2.2-11). Similarly, pre-impoundment topographic mapping within the Belews Creek arm is provided in Figure 2.2-12. These data are based on the original lake design and do not reflect sedimentation or erosion that may have occurred since lake construction in 1970 (see Section 2.2.1.1.3.2.3).

Focused hydrographic surveys were conducted by Duke Energy in 2024 and 2025 to verify depths in the vicinity of proposed intake and discharge locations and are provided in Figures 2.2-13 and 2.2-14, respectively. In the area near the proposed water intake and discharges within the Belews Creek arm, depths range from 80 ft. (24.4 m) to 110 ft. (33.5 m) below the normal surface level of the lake, which corresponds to lakebed elevations of approximately 645 ft. (196.6 m) and 615 ft. (187.5 m). These surveys compared to pre-impoundment mapping indicate some sedimentation has occurred along the Belews Creek valley throughout the lake (see Section 2.2.1.1.3.2.3).

2.2.1.1.3.2.2 Belews Lake Circulation

In general, circulation within Belews Lake is driven by inflow from the watershed that is conveyed through each arm of Belews Lake to the spillway where it is released to the Dan River (Figure 2.2-3). As part of the BCSS construction, a segment of the natural West Belews Creek valley was filled, obstructing flow, and the BCSS CCW discharge canal was excavated (Figure 2.2-3). This results in both natural West Belews Creek flow and BCSS CCW discharge flow to be conveyed to the main Belews Creek arm of the lake through the discharge canal south-southeast (SSE) of the BCSS. During periods of low and normal watershed runoff to Belews Lake, the BCSS CCW system creates a counterclockwise flow circulation pattern with recirculated CCW flowing southwest through the lower West Belews Creek embayment to the BCSS intake (Figure 2.2-3). The BCSS CCW flow rate is normally significantly larger than the Belews Creek watershed inflow which influences whole lake circulation patterns. The CCW flow generally occurs as a surface current because it is warm water with lower density.

2.2.1.1.3.2.3 Belews Lake Sedimentation

2.2.1.1.3.2.3.1 Historical and Current Sedimentation

The Belews Lake elevation, area, and storage volume relationship data from original dam design documents based on pre-dam topography (i.e., “1970”) were used for the water balance model for the historical period (Figure 2.2-10). A detailed assessment of lake sedimentation has not been conducted; however, recent bathymetric data for Belews Lake are available to assess sedimentation at selected locations.

Focused bathymetric data from 2024 and 2025, including detailed survey of selected areas of the lake, indicate some sedimentation has occurred since construction in each area surveyed, including tributary inflow areas and in the downstream, deeper part of the lake (Figures 2.2-13 and 2.2-14). The focused survey data indicates approximately 10 to 15 ft. (3.1 to 4.6 m) of potential sedimentation at these locations when compared to the pre-dam topography.

Belews Lake bed profiles further indicate sedimentation since impoundment. Belews Creek and East Belews Creek bed profiles were developed using recent hydrographic surveys and USGS LiDAR data. These profiles were then compared to pre-lake topographic maps and indicate variable sedimentation throughout the lake. Some areas of the lake show minimal sedimentation where others indicate pronounced sedimentation (i.e., approximately 10 ft. [3.0 m] to 20 ft. [6.1 m]).

Belews Lake has approximately 88 mi. (141.6 km) of shoreline (Duke Energy, 2020). Shoreline erosion conditions are typical of larger lakes in NC and no severe erosion segments exist.

2.2.1.1.3.2.3.2 Future Sedimentation

No sedimentation survey or sediment yield data were developed for Belews Lake; however, to estimate future sedimentation within the lake, whole lake sedimentation from within the watershed was estimated using published rates for other NC reservoirs. Annual sedimentation rates are available for 28 reservoirs in NC (Petryniak and Loveless, 2013). Of the reservoirs investigated, W. Kerr Scott Reservoir had the highest sedimentation rate of 0.52 ac-ft per year per square mi. drainage area (ac-ft/yr/mi^2) (640.0 m^3/yr/km^2) (Petryniak and Loveless, 2013). The median rate for the investigated reservoirs is 0.23 ac-ft/yr/mi^2 (283.7 m^3/yr/km^2) (Petryniak and Loveless, 2013).

The W. Kerr Scott Reservoir sedimentation rate is used as a conservative, representative estimate for the total Belews Lake sedimentation rate and applied over the 53-year period since Belews Lake was constructed. This analysis considered an upland drainage area of 63.8 mi.^{2} (165.2 km^2), exclusive of the Belews Lake surface area. A total sedimentation volume of 1758 ac-ft (2,168,458 m^3) was estimated within Belews Lake using this approach. This is equivalent to a 0.95 percent loss of reservoir volume over the 53-year life, which is a relatively small rate of reservoir storage loss to sedimentation.

Should sediment trapping efficiency not change significantly over the next approximately 50-year period, a similar amount of deposition may be estimated for the future condition, resulting in a total of approximately 3500 ac-ft of storage loss by 2075.

2.2.1.1.3.2.4 Temperature Characteristics of Belews Lake

Water temperatures have been measured and modeled at numerous locations within Belews Lake. Surface water temperatures within Belews Lake are influenced by BCSS operation and the use of Lake water for the once-through cooling system. Figure 2.2-15 shows water temperature profiles at different locations throughout Belews Lake for a modeled period assuming full BCSS generation. The BCSS has demonstrated through 316(a) studies that increased temperatures in the lake have not impacted the ability of the lake to support a balanced and indigenous population. The BCSS maintains an active 316(a) thermal variance for operation (NCDEQ, 2025b). As described in Section 2.2.1.1.3.1.1, the CCW discharge of BCSS is located on the upper West Belews Creek arm and water from the discharge passes through the CCW canal into the central portion of the Belews Creek arm.

Figure 2.2-16 and Figure 2.2-17 illustrate the Belews Lake water surface temperatures from observations in July 2002 and January 2018, respectively. During summer operations, water temperatures are more elevated in the West Belews Creek arm. The CCW canal flow influences surface water temperature within the Belews Creek arm. Temperatures are progressively cooler both downstream and upstream of the CCW canal outlet. By comparison, surface water temperatures in the winter demonstrate a similar distributional trend in temperature, whereby temperatures are more elevated in the upper West Belews Creek arm and progressively cooler both downstream and upstream of the CCW canal outlet. Warmer CCW intrudes upstream (south) along the Belews Creek arm as a result of buoyant spreading of the thermal plume on the surface; however, temperatures in the winter are lower than summer values. The lower, deeper lake water, or hypolimnion, has relatively stable water temperatures with only small seasonal variation (Duke Energy, 2021).

Figure 2.2-18 and Figure 2.2-19 show Belews Lake water temperature profiles within the main lake from August 2002 and January 2018, respectively. August 2002 shows severe drought conditions, evident by the surface elevation of approximately 718 ft. [218.85 m]) and represents a worst-case scenario for lake temperatures. The depth profiles illustrate the vertical temperatures extending from near the dam (Station 416) up the Belews Creek arm to Station 405 and up the West Belews Creek arm to Station 418 near the CCW intake. Belews Lake is thermally stratified most of the time as observed from vertical temperature profiles at various locations (Duke Energy, 2021).

Belews Lake thermal stratification characteristics vary seasonally and with location. Stratification patterns are consistent with other relatively deep reservoirs in the southeastern United States (U.S.), with seasonal stratification setting up in warmer months and mixing occurring during cooler months. The temperature profiles identified in Figure 2.2-18 and Figure 2.2-19 indicate

that the Belews Lake surface layer (i.e., epilimnion) is typically 30 to 60 ft. (10 to 20 m) deep at locations and times of the year when it is well-defined. The thermocline, when clearly defined, is typically 15-ft. (5-m) thick. Meaning, the deeper layer (i.e., hypolimnion) generally extends from approximately 50 to 75 ft. (15 to 25 m) down to the lake bottom (Duke Energy, 2021).

The Belews Lake epilimnion thickness and heat storage is a balance between natural heat sources, including solar radiation, the BCSS CCW heat load, and heat losses, including natural and forced evaporative cooling. The epilimnion thickness is generally variable over the course of the year based on seasonal conditions.

2.2.1.1.3.2.5 Belews Lake Currents

In general, currents within Belews Lake are low, and gradients from inflowing streams, outflows via the spillway, and CCW-induced circulation create them. The long residence time in Belews Lake, as described in Section 2.2.1.1.3.1.3, and the long periods of no spillway discharge indicate extremely low velocities. Water movement generally progresses from the upper arms of Belews Lake toward the dam. However, as described in Section 2.2.1.1.3.1, CCW use modifies water circulation within Belews Lake. In the CCW system, water is drawn from the lower (north) West Belews Creek arm into BCSS for cooling and then discharged to the upper (south) West Belews Creek arm. Then, the water flows via the CCW canal to the Belews Creek arm of the lake. Currents are substantially greater as water is conveyed through the CCW canal to the Belews Creek arm, where currents are reduced.

Density and buoyancy differences may also influence localized currents within Belews Lake. For example, water flowing from a stream into a lake tends to float or sink, depending on the density and buoyancy difference. Density differences may be the result of temperature, dissolved solids, or suspended sediments. Ford and Johnson (1983) provide a summary of density currents associated with stream inflows to reservoirs. Depending on the relative densities and hydrodynamic (flow of water) factors, inflowing streamflow may plunge to the reservoir bottom, float over the reservoir surface, or find a neutral buoyancy level in the reservoir known as *interflow* or *intrusion*. Temperature difference is the primary cause for density differences in most stream and reservoir systems. Inflowing water from tributaries, with seasonally lower temperatures and potentially higher suspended sediment concentrations, is denser and will likely sink and flow along the lake bottom. This flow pattern is referred to as a “density current” and may be expected to occur in conjunction with runoff into Belews Lake.

2.2.1.1.4 Project Site Streams

2.2.1.1.4.1 Identified Project Site Streams

Other surface waters located within the Project site are subject to jurisdiction under Section 401 and Section 404 of the Clean Water Act (CWA) (33 U.S. Code [USC] 1251). The U.S. Army Corps of Engineers (USACE) regulates the discharge of dredged or fill material into Waters of the U.S. (WOTUS) under the CWA Section 404 permit program (33 USC 1344). Under Section 401 of the CWA, a Section 401 Water Quality Certification is required for any project requiring a federal construction permit or license for activities that may result in any discharge into navigable waters. In NC, NCDWR is responsible for issuing Section 401 water quality certifications through the USACE and NCDEQ Joint Pre-Construction Notification application.

Screening of the Project site for the potential occurrence of WOTUS initially involved a review of the USGS topographic map, U.S. Fish and Wildlife Service (USFWS) National Wetlands

Inventory (NWI) data, Natural Resources Conservation Service soil survey data, Federal Emergency Management Agency (FEMA) Flood Insurance Rate Maps, and current and historical aerial photography. The lake features include portions of Belews Lake contained within the Project site and the canal that extends through the middle portion of the Project site.

Field delineation surveys to identify WOTUS were performed April 16 to 19, April 24 to 26, and May 10, 2024, within the Project site. A defined delineation survey area, subject to potential impacts from the Project, includes 1041 ac. (421 ha) adjacent to the BCSS and an existing approximately 3.7-mi. (5.95-km) associated off-site wastewater pipeline corridor (Figure 2.2-20). Following the field survey, Duke Energy submitted a WOTUS report and request for a Jurisdictional Delineation Concurrence to the USACE. The USACE performed a site visit on December 10, 2024, to field verify the WOTUS delineation. On January 16, 2025, the USACE issued a Jurisdictional Delineation Concurrence letter confirming the delineation (as depicted on Figure 2.2-20) is a sufficiently accurate representation of the geographic boundaries of the aquatic resources located on the site within the delineation survey area. No surveys for WOTUS were conducted outside of the defined delineation survey area, as impacts are not anticipated beyond this boundary. Duke Energy will coordinate with the USACE to expand the Jurisdictional Delineation Concurrence request to include any areas outside of the defined delineation survey area, if necessary.

As Table 2.2-9 indicates, 23 jurisdictional streams were delineated within the delineation survey area. Of these 23 streams, six are intermittent, seven are perennial, and ten begin as intermittent and transition to perennial along their reaches. 22 of these streams drain into Belews Lake. The final jurisdictional stream is the Dan River. Stream resources on-site and within the associated off-site areas total 21,671 linear ft. (6,605 linear m). All delineated features are connected with Belews Lake, the Dan River, or downstream surface waters. The USACE verified all of the 23 delineated streams.

2.2.1.1.4.2 Physical Characteristics of Project Site Drainages

Numerous drainage areas are within the Project site. Drainage areas, profile lengths, and slopes vary. Drainage lengths range from 80 ft. (24.4 m) to more than 3440 ft. (1048.5 m) in length (Table 2.2-9). Slopes of drainages are typically steep, ranging from 2.3 to 4.8 percent for selected Project site drainages that Table 2.2-10 and Figure 2.2-21 show. Stream characteristics are somewhat variable but are generally narrow and have evidence of an ordinary high-water mark (OHWM), clear natural shelving, sediment sorting, changes in the character of the soil, a natural bank line, and moderately continuous bed and bank. Figure 2.2-21 illustrates representative valley cross sections for select stream segments.

2.2.1.1.5 Floodplains

Floodplains are relatively level land areas along streams or rivers that are subject to periodic flooding. FEMA maintains and updates floodplain data through regulatory flood maps. FEMA defines any land area subject to inundation by at least a 1 percent annual-chance flood event as a “special flood hazard area.” These recurring events are also known as base floods or 100-year floods. FEMA flood maps include different flood zones defined by type, depth, and frequency of flooding. For example, flood zones A/AE are areas subject to inundation by the 1 percent annual-chance flood event. Other flood zones labeled as B or X are areas between the limits of the base flood and the 0.2 percent-annual-chance (or 500-year) flood event. FEMA also defines a “Regulatory Floodway” as the channel of a river or other watercourse and the adjacent land areas that must be reserved to discharge the base flood without cumulatively

increasing the water surface elevation more than a designated height.

Floodplains and floodways in the Project Vicinity are presented in Figure 2.2-22. In total, there are 11,038 ac. (4467 ha) of regulatory floodplains and 284 ac. (115 ha) of floodway in the Project Vicinity. Only FEMA flood zones A/AE are in the Project Vicinity—no other flood zone types are present. Floodways are present at the headwaters of Belews Creek and two other drainages along the outskirts of the Project Vicinity (Figure 2.2-22).

According to FEMA data, floodplains at the Project site are mostly concentrated along the shorelines and tributaries to Belews Lake and along the Dan River (Figure 2.2-22). However, because of the presence of the Belews Lake Dam, the floodplains of Belews Lake and the Dan River are separate and disjunct such that flooding on the Dan River does not have an effect on Belews Lake. The Dan River contains significant floodplains, specifically floodplain forest. Floodplain forests are found beside most rivers and streams in the Piedmont (NCWRC, 2025). Piedmont floodplain forests are typically smaller, with varying widths depending on the topography of land adjacent to the river, and the transition between floodplain and upland forest is often gradual. Human-influences have altered much of the Piedmont riverine and floodplain habitats. For example, many historical riparian areas were lost to create reservoirs like Belews Lake. The Dan River, conversely, remains as one of the larger tracts of intact forested floodplain left at the Project site and in the wider Piedmont Ecoregion.

2.2.1.1.6 Wetlands

Wetlands in the Project Vicinity and at the Project site are presented in Section 2.3.1.2.

2.2.1.2 Groundwater

Building activities and operation of the Project could affect the regional and local groundwater resources described in this section.

2.2.1.2.1 Hydrologic Setting

As described in Section 2.10, the Project site is situated in the Piedmont, which extends approximately 1000 mi. (1600 km) from Alabama to southern New York and mainly consists of northeast-southwest trending metamorphic and igneous rocks. Gently rolling, well-rounded hills and long, low ridges characterize the Piedmont. The elevation within the eastern Piedmont ranges from 300 to 600 ft. (91 to 183 m) above sea level. To the west, elevations gradually rise to about 1500 ft. (457 m) above sea level.

2.2.1.2.2 Regional Groundwater Hydrology

As described in Section 2.10, the Project Region encompasses two physiographic provinces, the Piedmont and the Blue Ridge.

The principal aquifers identified within the Project Region are crystalline-rock aquifers and aquifers in Early Mesozoic basins (Figure 2.2-23). The crystalline-rock aquifers primarily consist of igneous and metamorphic crystalline rock that trends northeast-southwest within the Piedmont and Blue Ridge. The aquifers in Early Mesozoic basins consist of sedimentary rocks, mainly sandstone and siltstone, and are located west of the Project site (USGS, 1997). Groundwater in the aquifers of the Piedmont and Blue Ridge generally are unconfined and lack a competent confining unit (USGS, 1990).

The Blue Ridge-Piedmont groundwater system consists of four components. These components are the unsaturated zone in the regolith, the saturated zone in the regolith, the lower saturated regolith (which contains the transition zone between the saprolite and bedrock) and the fractured crystalline bedrock system. The regolith is the surficial or uppermost layer and is composed of saprolite, alluvium, and soil. The thickness of the regolith greatly varies throughout the Piedmont and Blue Ridge. The regolith consists of an unconsolidated or semi-consolidated mixture of clay and fragmental material ranging in grain size from silt to boulders (USGS, 2002).

Porosity and groundwater storage are the major differences in the water-bearing characteristics of the regolith and bedrock. The regolith can store water in pore spaces between particles, while the crystalline bedrock does not have any significant intergranular porosity; thus, water is stored in narrow planar openings formed along fractures, known as secondary porosity. Regolith porosities typically range from 35 to 55 percent. The regolith provides the bulk of the water storage within the Piedmont and Blue Ridge groundwater system. Porosity within the regolith decreases with depth in the transition zone as the degree of weathering decreases. Primary porosity within the fractured bedrock ranges from 1 to 10 percent but is more typically between 1 and 3 percent. The abundance of fractures and size of fracture openings in the crystalline bedrock decreases with depth. At depths below 750 ft. (229 m), the pressure of the overlying rock holds fractures closed and the total porosity can be less than 1 percent. Due to its higher porosity, the regolith functions as a reservoir that slowly transports water downward into fractures in the bedrock. These fractures form an intricate interconnected network of conveyances that transmit water to springs, wetlands, streams, and wells (USGS, 2002).

The Project Region receives groundwater recharge through infiltration of precipitation. Recharge and discharge are through porous granular material (clayey soil-saprolite or floodplain deposits), but much of the intermediate flow between recharge and discharge areas is through bedrock openings. Areas of recharge occur at upland areas and slopes, while discharge is concentrated in lowland areas bordering surface water bodies, marshes, and floodplains (LeGrand, 2004).

2.2.1.2.3 Groundwater Hydrology of the Vicinity

As described in Section 2.2.1.1, Belews Lake, Belews Creek, East Belews Creek, West Belews Creek, Dan River, Lick Creek, Town Fork Creek, Watershed Lake Two (on Town Fork Creek), Boy Scout Pond, Eurins Creek, and Hogans Creek are the major surface water bodies in the 6-mi. (10-km) Project Vicinity that may exert an effect on groundwater flow. Local groundwater is also influenced by many perennial and ephemeral streams within the Project Vicinity.

The principal aquifers identified within the Project Vicinity are the same aquifers identified within the Project Region: crystalline-rock aquifers and aquifers in Early Mesozoic basins (Figure 2.2-23). Groundwater systems within most of the Project Vicinity are characterized by the crystalline-rock aquifers.

2.2.1.2.3.1 Groundwater Hydrology Immediately Adjacent to the Project Site

The Craig Road Landfill, which Duke Energy owns and operates, borders the Project site to the southwest and is associated with BCSS, as Figure 2.2-24 shows (Synterra, 2024a). Subsurface data generated for this landfill provides an understanding of the hydrogeology immediately adjacent to the Project site.

During previous geologic investigations for the construction of Craig Road Landfill, soil testing and observation wells identified six hydrostratigraphic units within the subsurface: fill, residuum,

saprolite, weathered rock, partially weathered rock (PWR), and competent rock. Hydraulic conductivities and corresponding horizontal flow velocities were calculated using slug testing data (obtained by others), and Table 2.2-11 summarizes these conductivities and velocities (S&ME, 2011). Calculated velocities range from 54.3 ft/yr (16.6 m/yr) in competent rock to 495.9 ft/yr (151 m/yr) within the partially weathered/fractured rock.

As Figure 2.2-25 shows, groundwater beneath the Craig Road Landfill footprint flows northwest, north, and northeast toward Belews Lake (Synterra, 2024a).

2.2.1.2.4 Groundwater Hydrology at the Project Site

Groundwater at the Project site was characterized through subsurface investigations and aquifer testing techniques as described below.

2.2.1.2.4.1 Groundwater Hydrology of the Project Site

The hydrogeologic setting of the Project site includes crystalline bedrock composed primarily of gneiss with lesser amounts of schist overlain by PWR and overburden (OB). The OB includes silty to clayey sand, weathered in place from the underlying bedrock. Groundwater recharge occurs as direct infiltration of rainfall at land surface that percolates through the unconsolidated OB into fractured bedrock. The Project site bedrock generally has little primary porosity and permeability. Since groundwater is stored and transmitted along secondary fracture openings, the fracture density, orientation, openness, and interconnectivity dictate groundwater flow.

Field activities performed for the Site Safety Analysis Report (SSAR) identified fracture density at the Project site is high with an average of 65 fractures per every 100 vertical ft. (30.4 m) of bedrock. However, most (over 97 percent) of these fractures are tight, closed, or filled and likely produce little water. Many of the identified factures may also represent mineralogical or lithologic discontinuities and are not fractures. Less than 3 percent of the fractures identified were described as open or had a recorded open aperture width. Aperture widths range from 0.2 to 6.8 in. (5 to 172 millimeters [mm]) and average 1.3 in. (32 mm) with a median value of 0.9 in. (23 mm). Fractures with open apertures were only recorded in the upper 250 ft. (76.2 m) below ground surface (bgs).

Groundwater is present in the OB and PWR sediments under unconfined conditions and travel short distances, discharging to nearby tributary streams, springs, or surface water bodies such as Belews Lake.

2.2.1.2.4.2 Monitoring Well Network

To characterize the existing groundwater, multiple groundwater wells were installed at the north, middle, and south portions of the Project site. A total of 27 groundwater monitoring wells were installed at the three proposed Plant Complex locations: north, middle, and south. Fifteen of the monitoring wells (W-1 through W-15) were installed for this environmental report (five wells at each Plant Complex area). These monitoring wells were installed to be screened across or near the water table. Monitoring wells were installed with screen lengths ranging from 10 to 20 ft. (3 to 6 m) in length. Because the aquifer is unconfined and the water table occurs at various stratigraphic depths across the site, monitoring wells are screened in all units: OB, PWR, and bedrock. Eleven of the monitoring wells are installed in shallow bedrock, while wells W-6, W-7, W-11, and W-15 are installed in OB/PWR. Monitoring wells W-1 through W-15 have total depths ranging from 36 to 99 ft. (11.0 to 30.2 m) bgs. Well construction details are summarized in Table

2.2-12.

To complete the SSAR subsurface investigations, 12 additional deeper bedrock wells were also installed in the same three future Plant Complex locations. Aquifer pumping test wells were also installed at each North, Middle, and South Plant Complex sites. These monitoring and test wells are associated with the SSAR investigation and are described in SSAR Section 2.4.12.

The water table generally occurs within the PWR and upper 10 ft. (3 m) to 20 ft. (6 m) of the bedrock. In deeper wells, the potentiometric head rises substantially above the screen interval but generally remains within the fractured bedrock aquifer.

2.2.1.2.4.3 Groundwater Level Monitoring

Monthly groundwater level monitoring was performed for wells W-1 through W-15. Groundwater elevations were recorded monthly from July 2024 to June 2025. Groundwater elevations for wells W-1 through W-5 at the north site ranged from 746 to 780 ft. (226 to 238 m) above mean sea level (AMSL). Groundwater elevations for wells W-6 through W-10 at the center site ranged from 750 to 788ft. (229 to 240 m). Groundwater elevations for wells W-11 through W-15 at the south site ranged from 764 to 810 ft. (233 to 247 m). Groundwater level trends are steady and showed only slight fluctuations over the duration of the monitoring period, increasing slightly in the North Plant Complex and decreasing in the Middle and South Plant complexes. Groundwater elevations are tabulated and shown in Table 2.2-13.

2.2.1.2.4.4 Site-Specific Groundwater Recharge and Discharge

As discussed in Section 2.2.1.2.2 groundwater recharge takes place in areas of high elevation/upland and discharge takes place in areas of low elevation/lowlands. The Project site topography reflects higher elevation in the center with suspected areas of groundwater recharge. Recharge from infiltrating rainfall continually replenishes groundwater. The amount of water that recharges a groundwater system can be estimated by examining stream flow hydrographs and separating the contribution from groundwater, called baseflow. Over long periods of time, groundwater discharge in the form of stream baseflow equals groundwater recharge (Risser et al., 2005). Baseflow measurements and groundwater recharge estimates from various USGS streamflow-monitoring stations within the Dan River subbasin and in the Project Vicinity indicate an effective average groundwater recharge rate of 8.45 inches per year (in/yr) (21.4 centimeters per year [cm/yr]). Belews Lake is the main discharge point for groundwater at the Project site.

Site-specific groundwater recharge and discharge is further discussed in SSAR Chapter 2.4.12.

2.2.1.2.4.5 Groundwater Hydrology at the Flue Gas Desulfurization Landfill

Subsurface data generated for the FGD landfill provide an understanding of the hydrogeology proximate to the Project site. The FGD landfill, which Duke Energy owns and operates, is situated in the center of the Project site and is associated with the existing Duke BCSS, as Figure 2.2-24 shows (Synterra, 2024b). The FGD landfill is scheduled for closure by excavation by 2032. Figure 2.2-26 shows groundwater flow beneath the FGD landfill footprint flowing to the northwest toward Belews Lake (Synterra, 2024b).

2.2.1.2.4.6 Aquifer Characteristics

As part of the SSAR investigation, multiple aquifer tests were performed to characterize the aquifer at the Project site. Aquifer characteristic testing included slug testing, packer testing, and aquifer pumping tests. These test methods are described in detail in SSAR Section 2.4.12.

The following definitions are useful for a discussion of aquifer parameters measured from slug testing, packer testing, and aquifer pumping testing results:

- Hydraulic conductivity is the capacity of a unit cube of rock to transmit water.
- Transmissivity is the capacity of an aquifer to transmit water. It equals the hydraulic conductivity times the aquifer thickness.
- Storativity (storage coefficient) is the volume of water released from storage in a unit prism of an aquifer when the head is lowered a unit distance.

2.2.1.2.4.6.1 Project Site Groundwater Hydraulic Conductivity

Hydraulic conductivity can be estimated from the slug test method, which evaluates the aquifer response to an instantaneous change in water level in the test well. Slug testing was performed in each of the observation wells (W-1 through W-15) and is summarized in Table 2.2-14 below:

- North Plant Complex: The average hydraulic conductivity for the for wells W-1 through W-5 (within bedrock) is 3.31 feet per day (ft/day) (1.01 m/day).
- Middle Plant Complex: The average hydraulic conductivity for wells screened in OB/PWR (W-6 and W-7) is 9.07 ft/day (2.76 m/day). The average hydraulic conductivity for the bedrock wells W-8, W-9 and W-10) is 0.174 ft/day (5.30 x 10^{-2} m/day).
- South Plant Complex: The average K for the wells screened in OB/PWR (W-11 and W-15) is 3.67 ft/day (1.12 m/day). The average K for the bedrock wells (W-12, W-13 and W-14) is 0.270 ft/day (8.23 10 $^{-2}$ m/day).
- Hydraulic conductivity varies across the Project site but overall is moderately low in both OB/PWR and the crystalline bedrock. The moderately low hydraulic conductivity reflects the presence of silty sand OB/PWR and the low fracture permeability in the metamorphosed gneiss and shist bedrock.

2.2.1.2.4.6.2 Project Site Groundwater Hydraulic Gradient

Using groundwater elevation data, potentiometric surface maps were created for summer (July 2024), fall (October 2024), winter (January 2025), and spring (April 2025), as shown on Figures 2.2-27 through Figure 2.2-30, respectively. Groundwater flow direction among the potentiometric surfaces generally follows topography, with flow directions from areas of higher topographic elevations to lower elevations. At the South Plant Complex, groundwater flow is bilinear and radial toward the northwest, northeast, and southeast toward Belews Lake and the CCW discharge canal. At the Middle Plant Complex, groundwater flows toward the west and southwest because of the influence from the CCW discharge canal and, in part, to more limited water level data. At the North Plant Complex, flow is radial toward the northwest, north, and northeast because Belews Lake surrounds the area on these three sides. Overall, groundwater

elevations decrease from the south to the north as distance to the lake (discharge area) decreases, resulting in deeper groundwater at the northern portion of the Project site. Groundwater flow directions and patterns are generally consistent across the seasons.

The potentiometric surface maps were used to estimate horizontal hydraulic gradients at the Project site. For each map, horizontal hydraulic gradients were calculated by drawing a flow line on the potentiometric surface map and determining the head loss over the horizontal projection of the flow path length to determine the horizontal hydraulic gradient. Horizontal hydraulic gradients are presented on the respective potentiometric surface map for each event, Figure 2.2-27 through Figure 2.2-30.

The calculated horizontal hydraulic gradients for the ER wells range from 5.0 X 10^{-3} ft/ft (1.52 x 10^{-3} m/m) at the North Plant Complex to 9.2 x 10^{-2} ft/ft (2.80 x 10^{-2} m/m) at the South Plant Complex with an overall average value of 3.8 x 10^{-2} ft/ft. Horizontal hydraulic gradients from July 2024 to June 2025 are summarized in Table 2.2-15.

Vertical hydraulic gradients were calculated at the Project site from July 2024 to June 2025. Typically, the vertical hydraulic gradient is calculated by comparing differences in water level elevations and screened interval depths from nested monitoring wells. At the Project site, the shallow zone (OB/PWR) and deep zone (bedrock) monitoring wells are not co-located but are spread out among the three different areas of the Project site (North, Middle, and South). Vertical hydraulic gradients were, therefore, modeled using interpolated potentiometric surfaces from the shallow and deep zones and the mid-point of well screen elevation surfaces.

Aquifer systems typically have a downward vertical gradient in groundwater recharge areas that transition to upward vertical gradients in groundwater discharge areas. Vertical gradients measuring greater than zero have a downward flow potential; vertical gradients less than zero have an upward flow potential. Based on the monthly water level data from the Project site, the following vertical gradient trends were observed:

- All but two vertical hydraulic calculations demonstrated downward vertical hydraulic gradients (i.e., all vertical gradients had positive values).
- Modeled vertical hydraulic gradient values ranged from -4.1 x 10^{-2} ft/ft to 0.64 ft/ft (0.01 m/m to 0.2 m/m).
- The average modeled vertical hydraulic gradient value was 0.28 ft/ft (0.9 m/m).

Vertical hydraulic gradients are summarized per month in Table 2.2-16. Information regarding methods and models for vertical hydraulic gradient calculations are described in the SSAR Section 2.4.12.

2.2.1.2.4.6.3 Project Site Groundwater Velocity

Groundwater velocity (V) depends on the hydraulic conductivity (K), horizontal hydraulic gradient (ih), and effective porosity (n) of the water-bearing zone. The mathematical equation for calculating horizontal velocity is:

$$V = K*ih/n \qquad \text{(Equation 2.2-1)}$$

The groundwater velocity was determined by using the arithmetic average of the hydraulic

conductivities from the slug tests performed, the hydraulic gradients determined from site water levels data from monitoring wells, and the effective porosity, which was estimated using available published literature (Kresic, 2006). The published effective porosity values used for PWR and crystalline bedrock are 0.20 and 0.019, respectively. Horizontal travel times and velocities were calculated for the wells screened in OB/PWR and wells screened in the bedrock.

Results indicate an average groundwater velocity of 1.2 ft/day (0.37 m/day), and a maximum groundwater velocity of 2.9 ft/day (0.88 m/day) in the OB/PWR units, an average linear velocity of 3.3 ft/day (1.0 m/day) and a maximum linear velocity if 7.9 ft/day (2.4 m/day) in the shallow bedrock, and an average linear velocity of 0.35 ft/day (0.11 m/day) and a maximum velocity of 0.58 ft/day (0.18 m/day) in the deeper bedrock aquifer. Groundwater velocities are shown in Table 2.2-17.

2.2.1.2.4.6.4 Project Site Groundwater Transmissivity and Storativity

Aquifer pumping tests were performed in the OB/PWR, shallow and deep bedrock units to determine transmittivity and storage coefficient. Based on the results of the pumping tests, the OB/PWR unit has an average transmittivity of 132 square feet per day (ft^2/day) (12.3 square meters per day [m^2/day]) and an average storage coefficient of 1.99 x 10-2. The pumping test results concluded that the shallow and deep bedrock units have an average transmittivity of 8.89 ft^2/day (0.83 m^2/day) and 1.40 ft^2/day (0.13 m^2/day), respectively and an average storage coefficient of 1.06 x 10^{-2}, 1.5 x 10^{-3}, respectively. Aquifer pumping test results are shown in Table 2.2-18.

For the SSAR subsurface investigation, soil samples were collected for bulk density. Dry soil bulk densities ranged from 1.07 grams per cubic centimeter (g/cm^3) to 1.40 g/cm^3. Discussion of soil geotechnical testing is presented in SSAR Section 2.5.

2.2.2 WATER USE

This section describes water uses within the hydrological system of the Project site, Project Vicinity, and Project Region. The Project could impact water users that are located within the Upper Dan River subbasin and withdraw water upstream or downstream of Belews Lake, Belews Creek, and the Dan River. This section describes the types of consumptive and nonconsumptive water uses, identifies their locations, and quantifies water withdrawals, consumptions, and returns, as available. In addition, this section describes statutory and legal requirements on water use.

2.2.2.1 Surface Water

2.2.2.1.1 Surface Water Use Regulatory Setting

Surface water rights within NC are considered riparian rights, meaning they are tied to the ownership of land adjacent to a water resource. As a result, property owners next to water bodies can make reasonable use of the adjacent waters. Reasonable use of water generally includes recreational and navigational access and reasonable diversions of flow for industrial, domestic, and agricultural uses. Reasonable use does not include the right of local governments to withdraw water in amounts needed to supply a municipality for domestic purposes. However, public trust rights allow public use of state-owned waters for fishing and navigation (Poyner Spruill, 2009).

Public water systems are regulated by the NCDEQ under the authority of Title 15A, Subchapter 18C of the North Carolina Administrative Code. North Carolina General Statute Section 143-355(l) requires all units of local government that provide or plan to provide public water service to prepare a local water supply plan (LWSP). All community water systems that regularly serve 1000 or more service connections or serve more than 3000 people are also required to prepare a LWSP. An LWSP is an assessment of the current and future water needs of a water system and its ability to meet those needs to better manage water supplies and prepare for water supply system improvements (NCDEQ, 2024a).

In general, NC does not require permitting for surface water withdrawals; however, registration with the NCDEQ is required for nonagricultural water withdrawals or transfers of 100,000 gallons (gal.) (37,854 liters [L]) or more of water per day, in accordance with the North Carolina Water Withdrawal and Transfer Registration statute. Agricultural water users that withdraw 1,000,000 gal. (3,785,412 L) or more of water per day are also required to register. Registrations must be updated at least every 5 years, and local governments that submit an LWSP are exempt from registration requirements. The existing BCSS has a registered water withdrawal from both the Belews Lake and Dan River supplemental intake (Facility ID 0057-0013).

2.2.2.1.2 Regional Surface Water Use

Figure 2.2-1 identifies major surface water features in the Project Region. The analysis of water use in this section involves the hydrologic system in which the Project is proposed. Regionally, the Project has the potential to affect water use within the hydrologic system of the Dan River, which includes the Upper Dan River Subbasin (HUC 03010103) and the downstream Lower Dan River Subbasin (HUC 03010104). Within the Project Region, the Upper and Lower Dan River Subbasins cover many counties within NC and southern Virginia, including Caswell, Forsyth, Guilford, Rockingham, Stokes, and Surry counties in NC, and Franklin, Henry (including Martinsville City), Patrick, and Pittsylvania (including Danville City) counties in Virginia.

Self-supplied surface water use quantity data from the National Water Information System, provided by the USGS, were obtained and organized by water use category for the counties located within the Project Region and the Upper and Lower Dan River Subbasins. Table 2.2-19 presents these quantities for the most recently reported year of 2015 (USGS, 2018a). Users directly withdraw self-supplied water from a surface water source rather than a public water supply (USGS, 2018b). Uses of self-supplied surface water within the Project Region include public water supply, industrial, thermoelectric power, mining, livestock, aquaculture, and irrigation (Table 2.2-19). Among the reported uses, thermoelectric power generation and irrigation include consumptive uses of water, while all other reported uses are considered entirely nonconsumptive (USGS, 2018a). Section 2.2.2.1.2.1 provides additional information on regional consumptive water use. The National Water Information System did not report self-supplied surface water use data for domestic and commercial uses; however, public water supply sources can also provide water for domestic, commercial, and industrial uses (USGS, 2018a, 2018b).

2.2.2.1.2.1 Regional Public Water Supply

Table 2.2-20 and Figure 2.2-31 identify public water supply sources within the counties of the Project Region that withdraw water from the upper or lower Dan River subbasins. Point data for the public water supply intake locations were available for NC, however, intake location data for

Virginia were only available based on the number of public water supply intakes per service area, as shown using hatching in Figure 2.2-31. Five public water treatment facilities within the Project Region obtain water from tributaries of the Dan River: Mayo River, Smith River, Beaver Creek Reservoir, Farmers Lake, and South Mayo River (NCDEQ, 2024a; City of Martinsville, 2022; Henry County Public Service Authority, 2023; Town of Stuart, 2023). Additionally, three public water treatment facilities within the Project Region withdraw water directly from the Dan River, accounting for a total annual average withdrawal of approximately 3602 million gal. (13,635 million L) in 2023 (NCDEQ, 2024a; Danville and Pittsylvania County Economic Development, 2024; VDH, 2024a). These public water treatment facilities supply water to the Town of Madison, the City of Eden, and Danville. These three water users are downstream of BCSS, with the Town of Madison being the closest downstream user.

Section 2.4.2.8.1 includes more information on public water supply populations, available supply, and service area demand.

2.2.2.1.2.2 Regional Consumptive Use

Data on regional consumptive water use is limited. However, consumptive water use in the Project Region consists of that used in thermoelectric power generation and irrigation (Table 2.2-19) (USGS 2018a). In the Project Region, 1.3 percent of the total water used for thermoelectric power generation is consumptive, whereas all 21.34 million gallons per day (mgd) (97,696 cubic meters per day [m^3/d]) of water used for irrigation is consumptive.

2.2.2.1.2.3 Regional Recreational Water Use

In addition to the uses identified in Table 2.2-19, recreation is prevalent throughout the Project Region and within the Upper and Lower Dan River Subbasins. Approximately 46,000 ac. (18,616 ha) of federal and state land within the Dan River Basin provide opportunities for hunting, fishing, and paddling (Dan River Basin Association, 2023). The Dan River provides opportunities for paddling, canoeing, tubing, and kayaking (Town of Madison, 2013). Section 2.4.2.6.2 provides more information regarding recreational opportunities within the Project Region.

2.2.2.1.3 Surface Water Use in the Project Vicinity

Figure 2.2-2 depicts notable surface water bodies located within the Project Vicinity. These water bodies include the Dan River, Belews Creek, Belews Lake, and Town Fork Creek. There are no public water supply facilities that withdraw water from surface water resources within the Project Vicinity (NCDEQ, 2023a). Walnut Cove and Stokesdale obtain either a portion of or all of their public water supplies from surface water sources, with surface water supplies originating from Salem Lake (Salem Creek) and the W. Kerr Scott Reservoir located within the Yadkin River watershed. Both sources are located outside of the Project Vicinity and in the Upper Yadkin hydrologic system (HUC 03040101) (NCDEQ, 2024a).

There are only two self-supplied surface water withdrawal locations in the Project Vicinity reported under the Water Withdrawal and Transfer Registration Statute (G.S. 143-215.22H) and they are associated with the BCSS, including the MWIS and the CCW intake structure (Figure 2.2-2) (NCDEQ, 2022a). Section 2.2.2.1.4 provides more information on water use by the BCSS in association with the Project site.

2.2.2.1.3.1 Vicinity Recreational Water Use

The Dan River State Trail, a paddle trail that covers the entire 90 mi. (145 km) length of the Dan River within NC, runs through the Project Vicinity (North Carolina Trails, n.d.[a]). The Dan River State Trail is a unit of the state parks system that the Dan River Basin Association sponsors and manages (North Carolina Trails, n.d.[b]). Within the Project Vicinity, boaters occasionally use an unofficial access to the Dan River State Trail under the Pine Hall Road bridge (Figure 2.2-3). This access point is within the North Carolina Department of Transportation (NCDOT) corridor, but is not maintained (Dan River Basin Association, n.d.).

Belews Lake offers many recreational uses, including swimming, tubing, fishing, paddling, boating, and jet skiing (Rockingham County, 2024b). Because Duke Energy owns the riparian area around Belews Lake, the right to permit access to the lake is controlled by Duke Energy (Duke Energy, 2020). There are two public boat accesses located on Belews Lake: one near Pine Hall Road on the northwest side of the lake and one near Belews Creek Road on the southwest side of the lake (Figure 2.2-2 and 2.2-3). The North Carolina Wildlife Resources Commission (NCWRC) maintains both boat accesses (NCWRC, n.d.). Section 2.4.2.6.2 notes that 63 permitted private docks and two commercial docks are on Belews Lake (Duke Energy, 2020). Section 2.4.2.6.2 provides more information on recreational uses of Belews Lake.

2.2.2.1.3.2 Vicinity Consumptive Use

Available consumptive water use data for the Project Vicinity are included as part of the regional consumptive water use, as Section 2.2.2.1.2.2 discusses and Table 2.2-19 shows. In addition, no municipal or non-Duke Energy water withdrawals are allowed from Belews Lake; therefore, Belews Lake is not used for consumptive water uses such as irrigation or thermoelectric power generation associated with entities outside of Duke Energy (Duke Energy, 2020). Section 2.2.2.1.4.1 discusses consumptive water uses associated with current power generation at BCSS.

2.2.2.1.4 Surface Water Use within and Adjacent to the Project Site

BCSS draws water from Belews Lake, located adjacent to the Project site, which was created in the 1970s after damming Belews Creek (HDR, 2023). BCSS withdraws CCW from an intake structure located in a natural cove on the western arm of Belews Lake (Figure 2.2-2) (HDR, 2022). It has a combined pump capacity of approximately 1511 mgd (5,719,680 m^3/d) (Duke Energy, 2021). Heated effluent discharges into West Belews Creek arm (Figure 2.2-2) (HDR, 2023; NCDEQ, 2025b). As Section 2.2.1.1.3 describes, a man-made canal crosses the site peninsula to convey cooling water from the discharge area to the eastern portion of Belews Lake. The canal facilitates the reuse of water for the condenser cooling system, creating a closed-cycle recirculating system. Ultimately, using Belews Lake for cooling reduces cooling water withdrawals relative to a once-through system that does not reuse cooling water (HDR, 2022). The station also minimizes cooling water use by operating fewer pumps during cooler months and during periods of reduced electric demand.

Several factors influence the water surface elevation of Belews Lake, including natural processes (e.g., precipitation, watershed runoff, and meteorological conditions that affect evaporation rates) and operational processes associated with BCSS (e.g., spillway releases, diversions from the Dan River, and fluctuations in power generation capacity of BCSS that are associated with consumptive withdrawal rate). In most years, the runoff from the surrounding Belews Creek watershed sufficiently offsets the losses from Belews Lake due to consumptive

use, evaporation, and releases from the main dam. However, the BCSS can withdraw makeup water from an MWIS located at the confluence of the Dan River and Belews Creek (HDR, 2023).

There are two intake structures equipped with velocity caps at the MWIS location; one that draws water from the Dan River, and one that draws water from Belews Creek (HDR, 2022).

The MWIS is designed to support four pumps, each capable of pumping a nominal 9000 gpm (34,068 lpm) or approximately 20.1 cfs (0.57 m^3/s) (HDR, 2023). Duke Energy's NPDES permit for the MWIS allows for a maximum pumping capacity of up to 100 cfs (2.83 m^3/s) from the Dan River to Belews Lake (NCDEQ, 2025b). Cooling water is not used for process units or for contact-cooling purposes; therefore, all flows withdrawn by the MWIS are used in the closed-cycle recirculating system (HDR, 2022).

Makeup pump operation at BCSS has not been necessary since December 2012. Figure 2.2-9 shows that after 2014, Belews Lake water level elevations became more consistent than prior years despite increases in spillway release volumes and reductions in Dan River diversions. This consistency is due to increases in watershed runoff and precipitation as well as reductions in forced evaporation and consumptive use by BCSS resulting from reductions in BCSS power generation.

The NPDES permit (No. NC0024406) prohibits the operation of the MWIS from April 1 through June 30 to avoid peak spawning for many aquatic species. Additional permit conditions related to Dan River withdrawals that resource agencies requested and to which Duke Energy agreed include the following: at least 80 percent of the flow in the Dan River must be maintained during makeup pumping activities, pumping may occur to a maximum level in Belews Lake of 724.5 ft (220.8 m), and the Dan River flow must not fall below 110 cfs (3 m^3/s) as a result of pumping (NCDEQ, 2025b).

2.2.2.1.4.1 Project Site Consumptive Use

The water balance model, which uses historical BCSS power generation data to calculate consumptive use estimations, estimates average forced evaporation and average consumptive withdrawal for the BCSS historical condition to be approximately 16.8 cfs or 10.9 mgd (41,102 m^3/d) and approximately 10.2 cfs or 6.59 mgd (24,955 m^3/d) respectively as shown in Table 2.2-6. The maximum monthly rate of forced evaporation at BCSS is estimated to be approximately 25.3 cfs or 16.4 mgd (61,898 m^3/d) and the maximum monthly consumptive withdrawal at BCSS is 18.3 cfs or 11.8 mgd (44,772 m^3/d).

2.2.2.2 Groundwater

This section describes the current and anticipated future groundwater use within the Project Region, Project Vicinity, and Project site that the operation or building, including transmission corridors and off-site facilities, could affect.

2.2.2.2.1 Regional Groundwater Use

Section 2.2.1.2 describes the principal aquifers in the Project Region as crystalline-rock aquifers and aquifers within Early Mesozoic basins (USGS, 1997). Well yields for crystalline-rock aquifers are generally low, typically yielding 5 to 35 gallons per minute (gpm) (18.9 to 132.5 liters per minute [lpm]) within the fractured bedrock. Above the fractured bedrock, within the

surficial aquifer, well yields can increase up to approximately 200 gpm (757 lpm) (NCDWR, 2024). Well yield for Early Mesozoic basins is typically low with an average 11 to 12 gpm (41.6 to 45.4 lpm) (Huffman, 1996).

Groundwater use by category data are from the NCDEQ Water Withdrawal and Transfer Registration Annual Data website for the 18 NC counties within the 50-mi. (80-km) Project Region. These categories are industrial, mining, public water supply, recreation, and energy. For 13 of the 18 counties, most of the groundwater withdrawals from 1999 to 2022 were for public water supply. The remaining five counties' groundwater primary withdrawal uses were Alamance (recreation), Davidson (mining), Person (energy), Stokes (energy), and Wilkes (industrial). Annual groundwater withdrawal information was only reported for the year 2004 for Davidson County (NCDEQ, 2024b).

Further groundwater use by category data are from the Virginia Department of Environmental Quality Office of Water Withdrawal Permitting for the eight counties within the Project Region. Public water supply is currently and has historically been the primary groundwater withdrawal use for six of the eight Virginia counties. Manufacturing is currently and has historically been the primary groundwater withdrawal use for the two remaining counties, Patrick and Pittsylvania (VDEQ, 2024).

2.2.2.2.2 Sole-Source Aquifers

The U.S. Environmental Protection Agency (USEPA) has not declared any sole-source aquifers within Project Region, Project Vicinity, or Project site (USEPA, 2024a).

2.2.2.2.3 Vicinity Groundwater Use

The NCDWR Local Water Supply Planning Database was accessed for local water supplies within the Project Vicinity. The database identifies three municipalities (Madison, Stokesdale, and Walnut Cove) that have an LWSP for the year 2023. These LWSPs are designed to outline the current and projected water supply use and demand up to the year 2070 for surface water and groundwater. According to the LWSP, groundwater demand is projected to increase from 0.31 mgd (1.2 million liters per day [mld]) in 2023 to 0.32 mgd (1.2 mld) in 2070. This increase in demand correlates to an increase in overall projected population increases from 1757 in 2023 to 2000 in 2070 (NCDEQ, 2024c). The Madison and Stokesdale LWSPs do not identify groundwater withdrawals for current water use and do not identify groundwater withdrawal use in their projections. Table 2.2-21 summarizes the projected groundwater demands for Walnut Cove.

NC OneMap, a collaborative geographic information system (GIS) website that presents data from local, state, and federal government agencies, identifies public water supplies within the 6-mi. (10-km) Project Vicinity. NC OneMap classifies public water systems into three categories (USEPA, 2023a):

- Community water system: a public water system that supplies water to the same population year-round.
- Non-transient non-community water system: a public water system that regularly supplies water to at least 25 of the same people at least six months per year (e.g., schools, factories, and hospitals).

- Transient non-community water system: a public water system that provides water in a place such as a gas station or compound where people do not remain for long periods of time.

The NC OneMap query identified 47 community, 19 transient non-community, and seven non-transient non-community public water supply systems within the Project Vicinity. Table 2.2-22 tabulates the public water supply wells, and Figure 2.2-32 shows their locations. There are a total of 73 public water supply wells with 59 wells installed within the crystalline-rock aquifer and 19 installed within the Early Mesozoic basin aquifer. Well depths within the Project Vicinity range from 103 to 1504 ft. bgs (31.4 to 458 m bgs) within the crystalline-rock aquifer and range from 175 to 1230 ft. bgs (53 to 375 m bgs) within the Early Mesozoic basin aquifer. Well yields range from 5 to 132 gpm (19 to 500 lpm) within the crystalline-rock aquifer and range from 2 to 200 gpm (7.6 to 757 lpm) within the Early Mesozoic basin aquifer (NCGICC, 2023).

The latest groundwater use by category data (2022) for the four counties within the Project Vicinity (Forsyth, Guilford, Rockingham, and Stokes) from NCDEQ (2024a) is shown in Table 2.2-23 and summarized as follows:

- Forsyth County and Rockingham County reported public water supply as their primary groundwater withdrawal, with total groundwater withdrawals of 0.22 mgd (0.83 mld) and 0.10 mgd (0.38 mld), respectively.

- Stokes County reported 0.10 mgd (0.38 mld) for energy and 0.01 mgd (0.04 mld) for public water supply with a total of 0.11 mgd (0.42 mld).

- Guilford County reported 0.04 mgd (0.15 mld) for industrial, 0.86 mgd (3.3 mld) for public water supply, and 0.05 mgd (0.19 mld) for recreation, for a total of 0.95 mgd (3.6 mld).

Public water supply within Forsyth, Guilford, and Rockingham counties leads the groundwater withdrawal use category data from 2019 to 2022. Historically, Stokes County had public water supply as its primary groundwater withdrawal use; however, starting in 2021, groundwater withdrawals for energy surpassed public water supply as the primary groundwater withdrawal use.

The main groundwater withdrawal use is public water supply use. Therefore, most of the Project Vicinity groundwater use is nonconsumptive. Generally, water supplies are 30 percent consumptive due to outdoor use and water supply leaks. The remaining 70 percent is considered nonconsumptive as the water is returned to the watershed via septic system or wastewater treatment plant (WWTP) (USEPA, 2024b).

Based on the identified well yields within the Project Vicinity and the distance of these wells from the Project site, surrounding commercial groundwater withdrawals do not have an influence at the Project site. The closest existing water supply wells are approximately 0.25 mi. (0.40 km) away from the Project site owned by Humphrey's Ridge, LLC, and are located east of Belews Lake. The natural constant head boundary and groundwater divide represented by Belews Lake prevents groundwater drawdown from existing adjacent water supply wells (Freeze and Cherry, 1979).

A private well search was completed through the respective environmental health departments of the four counties. Private well information was successfully obtained from Guilford and

Rockingham counties; however, private well information was not readily available from Forsyth and Stokes counties.

The Guilford County GIS website identified [[ ]]WI private water supply wells within the portion of the Project Vicinity in Guilford County (Guilford County, 2024b). The Rockingham County search identified [[ ]]WI private water supply wells within the portion of the Project Vicinity in Rockingham County (Rockingham County, 2024c). Most of the well data from Rockingham County did not provide well yields or depths because these data are not readily available. From the private water supply well information provided, the well depths ranged from [[ ]]WI in the crystalline-rock aquifer and [[ ]]WI in the Early Mesozoic basin aquifer. Well yields ranged from [[ ]]WI within the crystalline-rock aquifer and from [[ ]]WI within the Early Mesozoic basin aquifer.

The USEPA 2020 U.S. Private Domestic Well database estimates the total private water supply wells for domestic use in Forsyth and Stokes counties. This database uses land use data combined with housing units within the area to provide a well count estimate. The query results estimate a private water supply well count of 3646 wells in Forsyth County and 3535 wells in Stokes County within the Project Vicinity (USEPA, 2024c). Most wells identified within the Project Vicinity are established within the crystalline-rock aquifer system. Others are established within aquifers of the Early Mesozoic basin. Wells developed within the Early Mesozoic basin exist approximately 3.2 mi. (5.1 km.) northwest of the Project site near Walnut Cove and approximately 1.6 mi. (2.6 km.) north of the Project site in the unincorporated community of Pine Hall and are not in hydraulic connection to the Project site. Table 2.2-24 shows the total private well counts for Guilford and Rockingham counties and estimated private well counts for Forsyth and Stokes counties.

2.2.2.2.4 Duke Energy–Owned Extraction Wells

Other than water withdrawals associated with the Duke Energy groundwater corrective action plan (CAP) remediation system, no groundwater withdrawals currently exist at the operating BCSS. The CAP remediation system was installed as part of BCSS ash basin closure activities. The full-scale CAP system is located approximately 2.2 mi. (3.5 km) northwest of the Project site and consists of 72 extraction wells and 64 clean water infiltration wells. Figure 2.2-32 depicts the location of the groundwater withdrawals used by the CAP remediation system wells owned by Duke Energy. The following outlines the total combined water withdrawal amounts for the 72 extraction wells operating as part of the full-scale CAP system:

- Minimum system flow rate: 72 gpm (273 lpm)
- Maximum system flow rate: 98 gpm (371 lpm)
- Average system flow rate: 81 gpm (307 lpm)

Ranges in individual extraction well flow rates include the following:

- Minimum extraction well flow rate: 0.3 gpm (1.1 lpm)
- Maximum extraction well flow rate: 12.6 gpm (47.7 lpm)
- Average extraction well flow rate: 1.3 gpm (4.9 lpm)

The total combined water infiltration amounts for the 64 clean water infiltration wells as part of the full-scale CAP system:

- Minimum system infiltration rate: 63 gpm (238 lpm)
- Maximum system infiltration rate: 89 gpm (337 lpm)
- Average system infiltration rate: 75 gpm (284 lpm)

Individual infiltration well infiltration rates:

- Minimum infiltration well infiltration rate: 0.02 gpm (0.08 lpm)
- Maximum infiltration well infiltration rate 5.8 gpm (22 lpm)
- Average infiltration well infiltration rate: 1.3 gpm (4.9 lpm)

On average, the monthly CAP system withdrawal rate is 3,541,790 gal. (13,407,815 L) and the average monthly infiltration system rate is 3,258,497 gal. (12,334,753 L). Extraction and infiltration wells are all within the saprolite-bedrock matrix of the crystalline-rock aquifer.

2.2.2.2.5 Site Groundwater Use

There are no current groundwater withdrawals at the Project site other than what Section 2.2.2.2.4 describes.

2.2.2.2.6 Groundwater Use Regulations

The NCDWR regulates groundwater use and withdrawals. The NCDWR Public Water Supply branch oversees the permitting of community and non-community public water supply well systems and large capacity water supply wells that are designed for over 100,000 gpd (378,541 lpd). Public water supply systems are regulated through the Safe Drinking Water Act of 1974 (Public Law No: 93-523) and the North Carolina Drinking Water Act (USEPA, 2024d). The rules and regulations regarding public water supply well systems are specified in North Carolina Administrative Code (NCAC) Title 15A Subchapter 18C, which summarizes the permitting, construction, and requirements for the usage of a public water supply well system.

The North Carolina Division of Health and Human Services, Division of Public Health, Environmental Health Section governs private water supply well laws and regulations and permits water supply wells through the local county health departments. NCAC Title 15A 02C covers the general rules regarding the permitting of private drinking-water wells. NCAC Title 15A 02C offers guidelines for private drinking-water well permitting, construction, abandonment, and distances from potential contamination and private wastewater systems. These rules and regulations protect the health of the local water supply.

NCDEQ requires LWSPs for large public water supply systems that provide water service to the community. At a minimum, LWSPs must include:

- Present and projected population, industrial development, and water use within the service area.
- Present and future water supplies.

- An estimate of the present and future water supplies.
- An estimate of the technical assistance that may be needed at the local level to address projected water needs.
- Current and future water conservation and water reuse programs, including a plan for the reduction of long-term per capita demand for potable water.
- A description of how the local government or large community water system responds to drought and other water shortage emergencies and continues to meet essential public water supply needs during the emergency.

A unit of local government or large community water system must submit a revised plan that specifies how the water system intends to address foreseeable future water needs when 80 percent of the water system's available water supply based on calendar year average daily demand has been allocated to current or prospective water users or the seasonal demand exceeds 90 percent.

2.2.3 WATER QUALITY

This section describes the surface water quality within the Project Vicinity for Belews Lake, the Dan River, and Town Fork Creek. The sections also describe groundwater resources and quality in the Project Region, Project Vicinity, and Project site.

2.2.3.1 Surface Water

The following sections discuss the existing water quality of Belews Lake, the Dan River, and Town Fork Creek within the 6-mi. Project Vicinity.

2.2.3.1.1 Project Site Streams

2.2.3.1.1.1 Preapplication Monitoring Program Results

Section 2.2.4.1 describes the surface water sampling locations, methods, parameters, and analyses included in Duke Energy's preapplication monitoring program.

Section 2.2.1.1.4 describes Project site streams characterized by narrow channels with moderate gradients. Streams on the Project site are largely intermittent, with periods of the year in which they have no flow. Table 2.2-25 compares seasonal water quality parameter values from first order streams on the Project site discharging into Belews Lake with USEPA national recommended water quality criteria (NRWQC) for human health and aquatic life and NC water quality criteria for domestic water and surface water, fish, and aquatic life. It includes the most restrictive water quality criteria values for the applicable designated uses and compares the average, range, and maximum measured values of reported water quality parameters against water quality criteria. Most of the Project site stream water quality constituents did not exceed the aforementioned standards; however, the following constituents are outside the standard range:

- Alkalinity exceedances of the USEPA NRWQC occurred in the on-site streams during the winter sampling at sample location BCSW2. USEPA NRWQC exceedances do not constitute a regulatory exceedance, nor do they indicate that a waterway is impaired.

- Arsenic exceedances of the USEPA NRWQC occurred in the on-site streams during the summer sampling at sample location BCSW3. The USEPA NRWQC exceedance from sample BCSW3 during the summer sampling appears to be an isolated result and does not necessarily indicate a regulatory exceedance. The remaining samples did not have detections of arsenic above their respective laboratory method detection limits (MDLs).

- Dissolved oxygen concentrations were below the NCDEQ NC 2B Standard within the on-site streams during the summer and fall sampling event at sample location BCSW2.

- At least one sample from each location during each sampling event exceeded the NCDEQ water quality standard for fecal coliforms/*E. coli* of >400, the most probable number (mpn)/100 milliliter (mL). However, the standard is not applicable to these sampling events. The *E. coli* standard states that the concentration should not exceed the water quality standard in more than 20 percent of the samples examined during a 30-day period. These samples were taken quarterly and only one sample per location. NCDEQ standards are not applicable for singular, point-in-time, sampling events. These concentrations of *E. coli* are not considered an exceedance.

- Fluoride exceedance of the NCDEQ 2B Standards occurred within the on-site streams at sample location BCSW2 during the summer sampling event.

- Lead sample results for the spring sampling event at locations BCSW1 and BCSW6 were above the chronic NCDEQ 2B Standard for Aquatic Life Freshwater. These samples did not exceed the acute NCDEQ 2B Standard and elevated values were not shown during subsequent sampling events. Therefore, sample results are not considered exceedances.

- Manganese exceedances of the USEPA NRWQC occurred in each of the four sampling quarters at multiple locations. Although manganese concentrations were identified above the USEPA NRWQCs, NCDEQ removed its surface water standards regarding manganese based on higher natural background concentrations (NCDENR, 2015c).

- Values of pH were out of the NC 2B Standard range within on-site streams during the spring sampling event at sample locations BCSW1, BCSW3, BCSW4, BCSW5, and BCSW6, and out-of-range values occurred during the winter sampling event at sample location BCSW1 and BCSW2.

- Turbidity exceedances of the NCDEQ NC 2B Standards within the on-site streams occurred during the summer sampling event at sample location BCSW4.

Temperatures in the on-site streams ranged seasonally from 41.7 to 73.0 degrees Fahrenheit (°F) (5.4 to 22.7 degrees Celsius [°C]). Temperature for NCDEQ is a narrative standard, per 15A NCAC 02B.0211 (18), which states, “Temperature: not to exceed 2.8°C (5.04°F) above the natural water temperature and in no case to exceed 32°C (89.6°F) for lower piedmont and coastal plain waters” (NCDEQ, 2022b). Per 15A NCAC 02B.0101 (b), a revision of this water quality standard is allowed, consistent with the provisions of Section 316(a) of the CWA (NCDEQ, 2022b).

2.2.3.1.2 Belews Lake

Belews Lake consists of distinct regions, which in part relate to its principal tributaries: the West Belews Creek arm; the Belews Creek arm; and the main body of the reservoir. Belews Lake

consists of seven water segments within the Project Vicinity as Table 2.2-26 summarizes and Figure 2.2-33 shows (NCDEQ, n.d. [a]).

2.2.3.1.2.1 Temperature

The upper portion of the West Belews Creek arm currently receives heated effluent from the BCSS once-through CCW system. This area is physically separated from the remainder of Belews Lake, except for a 0.93-mi. (1.5-km), man-made canal that facilitates the return of heated CCW effluent to the Belews Creek arm.

Duke Energy implemented a temperature sampling program in 2017 in which continuous in situ temperature profile loggers recorded hourly temperature data and were deployed from the surface down to 65.7 ft. (20 m) or lake bottom (whichever was less) at 6.6-ft. (2-m) intervals, except for Station 416.0 near the dam. The results of this program provided evidence that Belews Lake, and a major portion of the discharge arm near BCSS, maintains temperatures adequate to support biological communities under adverse lake level and weather conditions (Duke Energy, 2021). As a result of the thermal demonstration, NCDEQ, in agreement with these conclusions, approved the 316(a) thermal variance for operation of the BCSS.

Section 2.2.1.1.3 describes Belews Lake and analyzes its temperature.

2.2.3.1.2.2 Other Water Quality Data

In accordance with the NPDES permit and NCDEQ regulations, Duke Energy prepared an initial 316(a) demonstration in 2020 (Duke Energy, 2021). Duke Energy collected water chemistry samples for laboratory analysis semiannually and field measurements were collected quarterly at 13 stations depicted in Figure 2.2-34 as part of Duke Energy's 316(a) thermal variance study plan.

The 316(a) report for the BCSS compared these 2020 data to both NCDEQ water quality criteria and historical water quality and analytical data from 2001 to 2019. Table 2.2-27 summarizes the 2020 water quality maximum values for the 13 stations that measure water quality data for Belews Lake as part of the 316(a) sampling program. Notable findings from the water quality results are as follows (with the clarification that the "uplake" area is defined as the area starting at the confluence of Belews Creek and West Belews Creek with Belews Lake and "downlake" near the sample location marked "SPILLWAY" in Figure 2.2-34):

- Dissolved oxygen demonstrated seasonal variation and distribution within the reservoir.
- Spatially, total phosphorous exhibited a decreasing trend from uplake to downlake.
- Orthophosphate was low throughout Belews Lake during both the study period and historically.
- Phosphorous concentrations in Belews Lake were sufficient to sustain primary productivity. A ratio of nitrogen to phosphorous supports that the lake was phosphorous-limited.
- Nitrogen concentrations (i.e., ammonia, nitrate - nitrite, and Total Kjeldahl Nitrogen [TKN]) were low in all zones of Belews Lake, with TKN values higher uplake than downlake in 2020.

- The hardness concentrations observed in 2020 characterized the water in Belews Lake as soft, falling below the NC water quality criteria of 100 mg/L.
- Turbidity values generally decreased from uplake to downlake locations, both historically and in 2020. Mean turbidity values were below the NC water quality criteria of 25 nephelometric turbidity units (NTU) for lakes with the exception of two uplake sample station locations, 405.0 and 419.2, closest to the headwaters of the lake and are found on Figure 2.2-34.
- Trace metals concentrations collected during 2020 were below the NC water quality standards.
- Chlorophyll-α samples collected during 2020 had concentrations below the NC water quality criteria of 40 micrograms per liter (µg/L). Higher concentrations were measured uplake due to watershed inputs. Concentrations were generally highest in the winter. The data indicated that there was no trend in concentrations between thermally influenced areas and areas uplake and downlake.

In general, water quality sampling results from the thermal variance study indicate that the seasonal water quality and chemistry of Belews Lake provides a suitable physicochemical environment for sustaining a balanced and indigenous biological community.

2.2.3.1.3 Dan River

The Dan River water segment 22-(8) (listed within the 2024 Draft Integrated Report) is a 25.9-mi. (41.7-km) segment from Big Creek to a point 0.2 mi. (0.32 km) downstream of Town Fork Creek located within the Project Vicinity. The water segment meets quality standards and is not impaired. The uncharacterized section of the Dan River within the Project Vicinity, NC22-(25.5), travels from a point 0.2 mi. (0.32 km) downstream of Town Fork Creek to a point 0.3 mi. (0.48 km) upstream of Reed Creek. Table 2.2-26 and Figure 2.2-33 show the water classifications and locations for both segments (NCDEQ, n.d. [a]).

2.2.3.1.3.1 Preapplication Monitoring Program Results

Section 2.2.4.1 describes the surface water sampling locations, methods, parameters, and analyses included in Duke Energy's preapplication monitoring program.

Table 2.2-28 compares seasonal, quarterly water quality parameter values from the four sample locations within the Dan River with applicable federal NRWQC for human health and aquatic life and NC water quality criteria for domestic water and surface water, fish, and aquatic life. It includes the most restrictive water quality criteria values for the applicable designated uses, and compares the average, range, and maximum measured values of reported water quality parameters against water quality criteria.

Most Dan River water quality constituents did not exceed the aforementioned standards; however, the following constituents are outside the standard range:

- Alkalinity exceedances of the USEPA NRWQC occurred in the Dan River during the winter sampling at sample location DRSW1. USEPA NRWQC exceedances do not constitute a regulatory exceedance, nor do they indicate that a waterway is impaired.
- Samples exceeded the NCDEQ water quality standard for fecal coliforms/*E. coli* of >400 MPN/100 mL in at least one sample from each location during each sampling event.

However, the standard is not applicable to these sampling events. The *E. coli* standard states that the concentration should not exceed the water quality standard in more than 20 percent of the samples examined during a 30-day period. These samples were taken quarterly and only one sample per location. NCDEQ standards are not applicable for singular, point-in-time, sampling events. These concentrations of *E. coli* are not considered an exceedance.

- A lead exceedance of the chronic NCDEQ 2B Standard for Aquatic Life Freshwater was observed in the Dan River at sample location DRSW2 during the winter 2025 sampling. However, this sample did not exceed the acute NCDEQ 2B Standard; therefore, this sample is not considered an exceedance.

- Manganese exceedances of the USEPA NRWQC occurred in each of the four sampling quarters. Although manganese concentrations were identified above the USEPA NRWQCs, NCDEQ removed its surface water standards regarding manganese based on higher natural background concentrations (NCDENR, 2015c).

- pH values were out of the NC 2B Standard range occurred in the spring sampling event at Dan River sample location DRSW3.

Temperatures in the Dan River ranged seasonally from 34.5 to 78.4°F (1.4 to 25.8°C). Temperature for NCDEQ is a narrative standard, per 15A NCAC 02B.0211 (18), which states, “Temperature: not to exceed 2.8°C (5.04°F) above the natural water temperature and in no case to exceed 32°C (89.6°F) for lower piedmont and coastal plain waters” (NCDEQ, 2022b). Per 15A NCAC 02B.0101 (b), a revision of this water quality standard is allowed, consistent with the provisions of Section 316(a) of the Federal Water Pollution Control Act (NCDEQ, 2022b). The measured temperatures did not exceed any NCDEQ water quality standards.

In addition to other upstream and downstream Dan River sampling locations, the preapplication monitoring program location DRSW2 provides water quality information for the Dan River immediately upstream of the existing BCSS Outfall 006 sampling location (Figure 2.2-35).

2.2.3.1.3.2 Existing BCSS NPDES Wastewater Outfall 006

Duke Energy operates the BCSS and maintains NPDES wastewater permit NC0024406, which has an existing outfall (Figure 2.2-34) that currently discharges to the Dan River, which is referred to as Outfall 006 (NCDEQ, 2023b). Duke Energy has performed historical sampling for this outfall per NPDES requirements and the 2023 NPDES permit application includes the results of the historical sampling (NCDEQ, 2023b). As part of the NPDES permit application, BCSS sampled for maximum daily discharge for the following constituents:

- Conventional and nonconventional pollutants (40 CFR 122. 21(g)(7)(iii))
- Toxic metals, cyanide, total phenols, and organic toxic pollutants (40 CFR 122. 21(g)(7)(v))
- Certain conventional and nonconventional pollutants (40 CFR 122. 21(g)(7)(v))

2.2.3.1.3.3 Other Water Quality Data

Quarterly samples from the Dan River are collected as part of the NPDES wastewater permit instream monitoring requirements. Four stations, in addition to Outfall 006, quarterly monitor the

Dan River water body as part of Duke Energy's internal river health monitoring program and are shown in Figure 2.2-34. Outfall 006 also measures NPDES wastewater discharge into the Dan River subject to the permit requirements listed within NPDES permit number NC0024406 (NCDEQ, 2023b). NPDES Outfall 006 discharges comply with NC regulatory requirements.

In 2003, Duke Energy produced a report evaluating the water quality impact of pumping Dan River water into Belews Lake to augment the water level. The report evaluated three sample locations within Belews Lake: Stations 410.0, 416.0, and 418.0 (Figure 2.2-34). The evaluation concluded that measurable water quality impacts in regard to suspended solids and water clarity were localized to the immediate pump outlets in the lake and are both transient and insignificant compared to other natural background effects, such as stormwater runoff (Finley, 2003).

2.2.3.1.3.4 North Carolina Natural Heritage Program Classification

As Section 2.3.2.4 details, the North Carolina Natural Heritage Program (NCNHP) classifies the section of the Dan River within the Project Vicinity as a natural area, with a representational rating of R1 (Exceptional) and collective rating of C1 (Exceptional). Per 15A NCAC 02B.0225, "surface waters of the State shall be classified as outstanding resource waters (ORW) upon finding, on a case-by-case basis, that such waters are of exceptional state or national recreational or ecological significance that require additional protection to maintain existing uses and that the waters meets certain conditions," (NCDEQ, 2022b). A water body is deemed to be of exceptional state, or national recreational or ecological significance, if it received a designation, such as an NCNHP classification, which does not provide any water quality protection. The ORW classification provides additional water quality standards for the designated waterbody.

Even though the segment of the Dan River within the Project Vicinity is classified under the NCNHP, the North Carolina Environmental Management Commission has not classified this segment as an ORW (NCDEQ, n.d. [a]). The segment of the Dan River within the Project Vicinity is classified only as a WS-IV waterbody. Therefore, no additional water quality restrictions are required.

2.2.3.1.4 Town Fork Creek

The 2024 North Carolina Draft Integrated Report included an assessment of the water quality within the immediate 12.1-mi.-long (19.5-km-long) upstream segment, NC22-25b2, from Neatman Creek to the Dan River (NCDEQ, 2024d) located within the Project Vicinity. The current water body condition is meeting quality standards and is not impaired. The water classifications and location for the segment is found in Table 2.2-29 and shown in Figure 2.2-33 respectively (NCDEQ, n.d. [b]).

2.2.3.1.4.1 Preapplication Monitoring Program

As part of the preapplication monitoring program described in Section 2.2.4.1, Duke Energy collected water quality samples at one location within Town Fork Creek, approximately 300 ft. (91.1 m) upstream from its confluence with the Dan River. As Figure 2.2-33 shows, sample location TFCSW1 represents water quality in Town Fork Creek upstream from Dan River. This sample location provides water quality data related to the potential influence of background environmental factors.

Table 2.2-29 compares seasonal, quarterly water quality parameter values from the Town Fork Creek sample location with applicable federal NRWQC for human health and aquatic life and NC water quality criteria for domestic water and surface water, fish, and aquatic life. It also includes the most restrictive water quality criteria values for the applicable designated uses, and compares the average, range, and maximum measured values of reported water quality parameters against water quality criteria.

The majority of Town Fork Creek water quality constituents did not exceed the aforementioned standards; however, the following constituents are outside the standard range:

- Manganese exceedances of the USEPA NRWQC occurred in each of the four sampling quarters. Although manganese concentrations were identified above the USEPA NRWQCs, NCDEQ removed its surface water standards regarding manganese based on higher natural background concentrations (NCDENR, 2015c).

- Samples exceeded the NCDEQ water quality standard for fecal coliforms/*E. coli* of >400 MPN/100 mL during each sampling event. However, the standard is not applicable to these sampling events. The E. coli standard states that the concentration should not exceed the water quality standard in more than 20 percent of the samples examined during a 30-day period. These samples were taken quarterly and only one sample per location, NCDEQ standards are not applicable for singular, point-in-time, sampling events. These concentrations of *E. coli* are not considered an exceedance.

Temperatures in Town Fork Creek ranged from 41.5 to 79.0°F (5.3 to 26.1°C). Temperature for NCDEQ is a narrative standard, per 15A NCAC 02B.0211 (18), which states, “Temperature: not to exceed 2.8 °C (5.04 °F) above the natural water temperature and in no case to exceed 32°C (89.6°F) for lower piedmont and coastal plain waters” (NCDEQ, 2022b). Per 15A NCAC 02B.0101 (b), a revision of this water quality standard is allowed, consistent with the provisions of Section 316(a) of the Federal Water Pollution Control Act (NCDEQ, 2022b). The measured temperatures did not exceed any NCDEQ water quality standards.

2.2.3.1.5 Impaired Waters

NCDEQ monitors water quality and produces water quality reports that satisfy the requirements of the CWA Sections 305(b) and 303(d) (NCDEQ, 2024e). Water bodies are assessed based on their designated best use, which is defined in the surface water classifications in Title 15A of the NCAC and summarized in Table 2.2-27 (NCDEQ, 2017a). Each monitored water body receives a biennial assessment, which is reflected in an Integrated Report to satisfy 305(b) reporting requirements. The biennial 303(d) list and Integrated Report identify impaired water bodies that do not meet water quality standards for one or more of the designated uses. The 303(d) list is made up of Category 5 assessments only; however, Category 4 assessments are still considered impaired.

All states are required to develop total maximum daily loads (TMDLs) for water bodies that are impaired and on the 303(d) list (NCDEQ, n.d. [b]). A TMDL is a calculation of the maximum amount of a pollutant that a water body can receive and still meet water quality standards, which is then used to establish limits on sources of the pollutants (NCDEQ, n.d. [b]).

2.2.3.1.5.1 Belews Lake Temperature Impairment

In 2014, a section of Belews Creek (NC22-27-[7]), “including Belews Lake below elevation 725,”

located from Southern Railroad Bridge to a point 1.8 mi. (2.9 km) downstream of Forsyth-Stokes County Line was identified as a Class C water impaired for water temperature (NCDEQ, 2024d). No TMDL has been developed, nor has a probable source of impairment been identified by the USEPA or NCDEQ (NCDEQ, n.d. [c]).

Duke Energy prepared a 316(a) demonstration in 2020 for Belews Lake. NCDEQ released a draft delisting document on October 9, 2024, which includes changing the previously impaired section of Belews Creek (NC22-27-[7]) from a Category 5 assessed water body to a Category 4v water body, thereby removing it from the 303(d) impaired waters list. A Category 4v water body is defined as one that exceeds criteria, but the parameter is part of a permit variance. The impaired section is officially removed from the 303(d) list once the 2024 draft delisting document is finalized. Section 2.2.1.1.3.2.4 discusses temperature trends within Belews Lake in greater detail.

2.2.3.1.5.2 Historical Selenium Impairment and Sampling

Within Belews Lake, historical selenium loading, occurring in the mid-1970s and exacerbated by the long retention time, was inhibiting fish reproduction (Duke Energy, 2021). Environmental studies were restructured to monitor effects of selenium on Belews Lake biota and water quality from 1976 to 1985. These lake recovery sampling programs evolved over time, and new sampling programs were created when BCSS redirected its regulated ash basin discharge from Belews Lake in October 1985. Belews Lake biota began to recover from the inhibition of reproduction once this redirection occurred. Further discussion of the biota and sampling is found in Section 2.3.2.7. Duke Energy and NCDEQ have acknowledged that macroinvertebrate and fish populations have recovered substantially from the selenium contamination that occurred during early operations of BCSS.

Data from the 2020 monitoring period relevant to this impact and recovery include almost all concentrations from Belews Lake of arsenic, selenium, and zinc were below reporting limits and the mean concentrations of copper and low-level mercury were below NC water quality standards and within historical ranges for the system.

2.2.3.2 Groundwater

2.2.3.2.1 Regional Groundwater Quality

The quality of groundwater from the Piedmont and Blue Ridge aquifers is generally suitable for drinking (USGS, 1997). Bedrock composition and geochemical conditions in the aquifer directly affect the occurrence and distribution of potentially naturally occurring contaminants. It is common for naturally occurring contaminants such as arsenic, iron, manganese, and radionuclides to be present and exceed state and federal drinking-water standards in aquifers within the Piedmont and Blue Ridge (Chapman et al., 2013).

2.2.3.2.2 Vicinity Groundwater Quality

As Section 2.2.1.2 describes, Duke Energy owns and operates the Craig Road Landfill, which is associated with BCSS and borders the Project site to the southwest. Groundwater monitoring is conducted semiannually through sampling of 17 monitoring wells surrounding the landfill. Monitoring wells are screened in different units to assess groundwater quality within the unconsolidated regolith and bedrock units (Synterra, 2024a).

Data from the July 2024 sampling event identifies at least one concentration of cobalt, iron, and manganese above their respective NCDEQ Groundwater Standards, 15A NCAC 02L. 0202, effective April 1, 2022 (NCDEQ 2L Standard) from 7 of 17 groundwater samples collected from monitoring wells screened within the unconsolidated regolith and in the bedrock units. Chromium was identified above its respective NDCEQ 2L Standard from one monitoring well sample in the bedrock unit only. PH values were outside of the NCDEQ 2L Standard range for groundwater samples taken from 16 of 17 monitoring wells screened within the unconsolidated regolith and in the bedrock units. Groundwater at the landfill generally flows to the north, northwest, and northeast toward Belews Lake (Synterra, 2024a). Groundwater flow beneath the Craig Road Landfill is not in hydraulic contact or flowing toward groundwater at the three proposed Plant Complex construction locations and is not a concern regarding groundwater quality for the Project site. Groundwater associated with the Craig Road Landfill is being monitored in accordance with the Water Quality Monitoring Plan (WQMP) accepted by NCDEQ Department of Waste Management Solid Waste Section, January 24, 2024 (Synterra, 2024a).

2.2.3.2.3 Site Groundwater Quality

2.2.3.2.3.1 Flue Gas Desulfurization Residue Landfill

As Section 2.2.1.2 describes, Duke Energy owns and operates the FGD Residue Landfill, which is situated within the center of the Project site. Groundwater monitoring is conducted semiannually through sampling of 31 monitoring wells throughout the landfill. Monitoring wells are screened in units to assess groundwater quality within the unconsolidated regolith and bedrock units (Synterra, 2024b).

Data from the May 2024 groundwater sampling event identifies at least one concentration of beryllium, cadmium, chromium, and/or cobalt above their respective NCDEQ 2L Standards in samples from 7 of 23 monitoring wells screened in the unconsolidated regolith unit. Groundwater sample concentrations of iron, manganese, sulfate, and total dissolved solids were above their respective NCDEQ 2L Standards in 17 of 31 monitoring wells screened in the unconsolidated regolith and bedrock units. PH values were outside of the NCDEQ 2L Standard range for groundwater samples taken from 28 of 31 monitoring wells, in the unconsolidated regolith and bedrock units.

In general, groundwater flow at the FGD landfill is to the northwest towards Belews Lake. A groundwater divide is located along the landfill perimeter road on the southeast side of the FGD landfill. Groundwater on the west side of the divide flows to the northwest towards Belews Lake, while groundwater on the east side of the divide flows to the southeast towards an intermittent stream that discharges to Belews Lake (Synterra, 2024b). The groundwater flow beneath the FGD landfill is not in hydraulic contact with the groundwater at the Project site three Plant Complexes and is not a concern regarding groundwater quality for the Project site. Groundwater associated with the FGD landfill is being monitored in accordance with the WQMP accepted by NCDEQ Department of Waste Management Solid Waste Section, January 24, 2024 (Synterra, 2024b).

2.2.3.2.3.2 Belews Creek Observation Well Groundwater Quality

As Section 2.2.1.2 describes, observation wells were installed throughout the Project site to characterize the groundwater and provide a baseline at the three proposed Plant Complexes

before building or operation of the proposed Project. Groundwater samples were collected quarterly from the observation wells (W-1 through W-15) in June 2024, October 2024, January 2025, and April 2025. Groundwater samples were analyzed for analytes listed in NUREG-1555 along with other voluntary selected parameters. These analytes and their analytical methods are summarized in Table 2.2-30.

The majority of groundwater quality constituents reported in the preapplication monitoring program did not exceed NC 2L Standards or USEPA water quality standards. The exceptions were aluminum, arsenic, cobalt, iron, manganese, nickel, nitrate, nitrite, pH, and total coliforms, detected at concentrations greater than NC 2L Standards and USEPA water quality standards in samples collected from certain monitoring wells.

- Constituents such as aluminum, arsenic, iron, and manganese commonly have elevated naturally occurring groundwater concentrations within the Piedmont, and these should be considered background concentrations (Chapman et al., 2013) (NCDWR, 2025).

- pH was recorded less than the range for both the USEPA maximum contaminant limit (MCL) and NC 2L Standard for the majority of wells sampled for each sampling event. Piedmont groundwater is often slightly acidic, resulting in naturally occurring lower pH measurements (Wang, 2016).

- Cobalt was identified in wells W-2, W-3, W-4, W-5, W-8, and W-9 in at least one sampling event greater than the NC 2L Standard. A background well associated with the FGD landfill has historical concentrations of elevated cobalt. Cobalt concentrations identified within the Project site wells are considered background concentrations.

- Nickel was detected in one well (W-3) greater than the NC 2L in April 2025.

- Nitrate was detected in one well (W-7) greater than the USEPA MCL and NC 2L in samples from the June and October 2024 and the January 2025 sampling events.

- Nitrite was detected in wells W-12 and W-13 greater than the USEPA MCL and NC 2L during the October 2024 and January 2025 sampling events.

- Total coliforms were identified in most samples collected in each sampling event. Coliform bacteria are naturally occurring in the environment and are not an indication of poor groundwater quality. *E. coli* was identified once in well W-11 in October 2024 and was not identified in other samples during the preapplication groundwater sampling.

While a limited number of constituents were detected at concentrations greater than regulatory thresholds, the results reflect site-specific background conditions and are not indicative of anthropogenic impact based on the previous undeveloped land use. Table 2.2-31 summarizes the groundwater analytical results for June and October 2024, January 2025, and April 2025 by range and mean.

2.2.4 WATER MONITORING

This section describes the water monitoring program that is used to characterize the surface and groundwater resources. It also includes details of relevant historical monitoring programs.

2.2.4.1 Surface Water

2.2.4.1.1 Existing Monitoring Locations

As Figure 2.2-36 shows, the NCDEQ has historical monitoring stations located throughout the Project Vicinity as part of the Ambient Monitoring System (AMS). These stations obtained data for areas of Town Fork Creek, Dan River, and Belews Lake from approximately 1973 through 2020 (Table 2.2-32). AMS stations are generally located at fixed points above and below known point source dischargers to monitor their possible effects on surface water quality. With the institution of the NPDES permitting program in the late 1970s AMS stations became redundant and were made inactive (NCDEQ, 2017a). Historical data include biological counts, minor inorganic metals, major inorganic metals, minor inorganic non-metals, biological, microbiological, nutrient, physical characteristics, other organics, organic polychlorinated biphenyls, and stable isotopes. Data is available through the USEPA-managed National Water Quality Monitoring Council (NWQMC). Table 2.2-32 lists the station identifiers, sample periods, and sampled characteristic groups. Figure 2.2-36 shows the locations of the stations.

The USGS maintains an active monitoring station at Dan River Pine Hall shown in Figure 2.2-36. It records daily data for precipitation, gage height, and discharge with data available through the USGS water data for the national inventory (USGS, n.d. [a]). Table 2.2-33 lists the station identifier, sample period, and sample parameters.

Belews Lake water levels are dependent on natural and man-made inflows and outflows. Section 2.2.1.1 describes the monitoring and characterization of these water levels.

Duke Energy regularly samples both the Dan River and Belews Lake and maintains water quality monitoring data in accordance with NPDES regulatory and permitting requirements, 316(a) thermal variance monitoring, and NCDEQ 15A NCAC 02B.0500 water quality instream monitoring requirements (NCDEQ, 2022b). Figure 2.2-34 shows sample locations.

2.2.4.1.2 Preapplication Monitoring Program

Duke Energy sampled 11 surface water quality sampling locations throughout the Project site and Project Vicinity as part of a preapplication surface water quality monitoring program (Figure 2.2-35). Surface water quality sampling locations were chosen to supplement available historical water quality information from the Project site and to characterize seasonal variation in chemical conditions of surface waters. Surface water monitoring of potential source water bodies and receiving streams was conducted on a quarterly basis from April 2024, July 2024, October 2024, and January 2025. Surface water resources and sampling locations are depicted on Figure 2.2-35 and include:

- Six locations on the Project site on unnamed tributaries (i.e., on-site streams) that discharge to Belews Lake
- Four locations on the Dan River
- One location within Town Fork Creek

Each location was sampled once quarterly from April 2024 through January 2025. During the summer 2024 sampling period, one location had a dry riverbed resulting in a total of 43 samples. State-certified laboratories analyzed samples for standard water quality parameters

(temperature, pH, conventional pollutants), metals, and selected radionuclides. Samples were collected in compliance with analytical requirements and met NCDEQ and USEPA requirements.

Grab samples were collected in laboratory-supplied containers, individually wrapped in bubble wrap, placed in a cooler on ice, and delivered to the analytical laboratories for analysis. Surface water grab samples and field water quality parameters (pH, dissolved oxygen, temperature, specific conductance, and turbidity) were measured at each location. The full analytical list and their corresponding laboratory methods are shown in Table 2.2-30.

Duke Energy's preapplication monitoring program included the surface water quality sampling locations, methods, parameters, and analyses that Section 2.2.3.1 describes.

2.2.4.2 Groundwater

Duke Energy's preapplication monitoring program included groundwater quality sampling and analyses, which Section 2.2.4.2 describes. The preapplication monitoring program consisted of sampling 15 groundwater observation wells (Figure 2.2-37). Groundwater sample locations were selected to establish baseline groundwater conditions at each of the three Plant Complexes. These sample locations were each sampled once quarterly from June 2024 to April 2025. Samples were analyzed for standard water quality parameters (temperature, pH, conventional pollutants), metals, and selected radionuclides following the guidance of NUREG-1555 as Section 2.2.3.2 describes.

2.2.4.2.1 Groundwater Quality

Groundwater quality sample collection occurred during each of the four quarters using low-flow (low purge) sampling methodology in general accordance with the procedures described in USEPA Region 4 Laboratory Services and Applied Science Division (LSASD), *Groundwater Sampling*, dated April 22, 2023, and in accordance with the Project site standard operating procedures and quality assurance procedures. Groundwater sampling was completed at the 15 observation wells for the sampling events in June 2024, October 2024, January 2025, and April 2025 with exceptions for wells W-2, W-9, and W-13. Samples were not retrieved from wells W-2 and W-9 in June 2024 because the water level was too low at the time and the wells could not be sampled. W-13 was not sampled in April 2025 due to insufficient water volume.

Prior to collecting groundwater samples, groundwater was purged from the observation wells using a stainless-steel submersible bladder pump. During well purging, water quality field parameters pH, dissolved oxygen, oxidation reduction potential, temperature, and specific conductance were measured using a calibrated YSI Professional Pro Plus and turbidity was measured using a calibrated MicroTPW turbidity meter. Water quality field parameters were measured and recorded during purging and at the time of sampling. Well purging continued until water quality parameters stabilized based on the procedures described in USEPA LSASD, *Groundwater Sampling*, dated April 22, 2023.

After purging, groundwater samples were collected in laboratory-supplied containers, individually wrapped in bubble wrap, placed in coolers on ice, and delivered to Eurofins USA locations in Savannah, Georgia, and Orlando, Florida – and Pace Analytical in Greensboro, NC. Samples for all events were released and transported to the analytical laboratories in accordance with chain of custody procedures. Quality assurance and quality control samples

were collected for each quarterly sampling event that consisted of one duplicate, one matrix spike and one matrix spike duplicate sample.

Before and in between observation well sampling locations, the bladder pump and corresponding sample equipment were decontaminated with an Alconox® and deionized water rinse. The YSI and MicroTPW were calibrated before use each morning and performed a calibration check at the end of each day of sampling.

2.2.4.2.2 Other Groundwater Monitoring

In conjunction with the SSAR field activities, groundwater level readings were taken on a monthly basis. This information was collected under approved work instructions as part of the subsurface investigation scope of work in accordance with nuclear quality assurance (NQA-1) procedures as described in SSAR Section 2.4.12.

Table 2.2-1
Regional USGS Stream Runoff Rates

Station	Drainage Area (mi^2)	Average Flow (cfs)	Median Flow (cfs)	10 Percentile Flow (cfs)	Average Annual Runoff (in./yr)

Average WY (1987 – 2024)[b,c]	677	474
Average POR[b,d]	665	469

Source: USGS, n.d. (a).
Notes:
(a) Water year is from October 1 – September 30.
(b) Data for water years with limited or no data is not included.
(c) Average of USGS annual average flows WY 1987 – WY 2024.
(d) Average of USGS annual average flows WY 1924 – WY 2024.
Key: cfs = cubic feet per second; POR = period of record; WY = water year

Table 2.2-4
Monthly Mean Discharges of the Dan River at Pine Hall from 1986 through 2024

Month	Mean Discharge[(a)] (cfs)
January	822
February	959
March	831
April	861
May	842
June	568
July	437
August	421
September	465
October	525
November	564
December	724

Source: USGS, n.d. (a).
Note:
(a) Based on data April 1986 – November 1990; December 2008 – September 2024.
Key: cfs = cubic feet per second

Table 2.2-5
Annual Average Low-Flow Data (1- through 60-Day Durations) for the Dan River at Pine Hall

Year[a,c]	1-day[b]	7-day[b]	15-day[b]	30-day[b]	60-day[b]
1986	65	91	106	117	141

Notes:
ih = Horizontal hydraulic gradient; calculated by the formula ih = ∆h/L.
∆h = Difference in hydraulic head between contour lines used to calculate ih.
L = Horizontal distance between contour lines used to calculate ih; L measured in ArcMap and rounded to the nearest 10-foot increment.
∆h and L values were obtained from the potentiometric surface maps for the July 2024 through February 2025 events.
Key: NC = not calculated

Table 2.2-16
Vertical Hydraulic Gradients[(a)]

	South	-0.029	0.64	0.19

Note:

(a) i_v - Vertical hydraulic gradient (ft/ft); positive value represents downward gradient, negative values (shaded in gray) represent upward gradient.

Key: ft/ft = feet per foot; NA = Not available, insufficient data

Table 2.2-17
Horizontal Groundwater Flow Velocities

Stratigraphic Unit	Hydraulic Conductivity (K)[a] (ft/day)	Average Horizontal Hydraulic Gradient[c] (i_h)(ft/ft)	Maximum Horizontal Hydraulic Gradient[c] (i_h)(ft/ft)	Specific Yield (Effective Porosity, n)	Average Horizontal Flow Velocity[d] (V_{avg}) (ft/day)	Maximum Horizontal Flow Velocity[d] (V_{max}) (ft/day)
Overburden/Partially Weathered Rock (OB/PWR)[b]	6.37	3.8E-02	9.2E-02	0.20	1.2	2.9
Shallow Bedrock [b]	1.63	3.8E-02	9.2E-02	0.019	3.3	7.9
Deep Bedrock [b]	2.49E-01	2.7E-02	4.4E-02	0.019	0.35	0.58

Notes:

(a) Average K values from slug tests for each stratigraphic unit.

(b) K values for shallow and deep bedrock from all three plant complexes; K values for OB/PWR from middle and south plant complex only.

(c) Represents average or maximum ih for each stratigraphic unit.

(d) Vavg and Vmax calculated using Darcy's Law: V = K*ih/n; Vavg uses average K and average ih and Vmax uses average K and maximum ih.

Key: ft/day = feet per day; ft/ft = feet per foot

Table 2.2-25
On-Site Streams Surface Water Quality Values from the Preapplication Monitoring Program from April 2024 through January 2025
(Sheet 4 of 4)

Notes:

(a) NCDEQ Surface Water Quality Standards Rules 15A NCAC 02B.0100 through.0300 (NCDEQ, 2022b).
(b) National Recommended Water Quality Criteria for aquatic freshwater life and human health (USEPA, 2024e, 2024f).
(c) Surface water criteria are specific to surface water body classifications (NCDEQ, n.d.[a]).
(d) Class IV and V waters.
(e) Not to exceed value in more than 20 percent of the samples examined during a 30-day period in which of five samples are taken. Not to exceed geometric mean of 200/100ml (MF Count).
(f) Mercury water quality standards shall be based upon measurement of the total recoverable metal.
(g) The Water Effect Ratio (WER) shall be assigned a value equal to one unless determined otherwise under Sub-Item (11(b)) of Subchapter 02B – Surface Water and Wetland Standards (NCDEQ, 2022b).
(h) Acute and chronic freshwater aquatic life standards for metals shall be based upon measurement of the dissolved fraction of the metal.
(i) WER·65.
(j) WER·6.5.
(k) WER· [0.316 · e^{0.8190[ln hardness]+3.7256}].
(l) Average hardness of 33.5 mg/L has been used to determine the site-specific NC 2B Water Quality Standards for specific metals.
(m) WER· [0.860 · e^{0.8190[ln hardness]+0.6848}].
(n) not used.
(o) WER· [0.960 · e^{0.8545[ln hardness]-1.702}].
(p) Manganese has been monitored by NCDEQ and has been shown to have elevated background level concentrations that are somewhat flow related and are caused by the geology of the region. NCDEQ removed manganese as a standard as there was no evidence of to conclude that discharges of manganese will impact any beneficial uses of North Carolina's waters (NCDENR, 2015c).
(q) WER· [0.998 · e^{0.8460[ln hardness]+2.255}].
(r) WER· [0.997 · e^{0.8460[ln hardness]+0.0584}].
(s) WER· [0.85 · e^{1.72[ln hardness]-6.59].
(t) WER·0.06.
(u) WER· [0.978 · e^{0.8473[ln hardness]+0.884}].

(cc) The standard for chronic selenium has the following components: fish egg/ovary tissue, fish whole body or muscle tissue, and water column (lentic and lotic). These components shall be used in the following order of preference provided data is available: 1. Fish egg/ovary tissue; 2. Fish whole body or muscle tissue; 3. Water column (NCDEQ, 2022b).
(dd) Alpha Emitters: the average annual gross alpha particle activity (including radium-226 but excluding radon and uranium).
(ee) Beta Emitters: Not to exceed this average annual activity level for strontium-90.
(ff) Beta Emitters: Not to exceed this average annual activity level for tritium.
(gg) Beta Emitters: Not to exceed the average annual gross beta particle activity (excluding potassium-40 and other naturally occurring radionuclides).
(hh) Available or total.

Key: µg/L = micrograms per liter; BRL = Below Reporting Limit; °C = degrees Celsius; MDL = Method Detection Limit; MF = membrane filter procedure for bacteriological analysis; mg/L = milligrams per liter; mg/m3 = milligrams per cubic meter; mpn/100mL= most probable number per 100 milliliters; ms/cm = millisiemens per centimeter; mV = millivolts; NCDEQ = North Carolina Department of Environmental Quality; NE = Regulatory standard not established for this constituent; ng/L = nanograms per liter; NTU = nephelometric turbidity unit; pci/L = picocuries per liter; QC = quality control; WER = Water Effect Ratio.

Table 2.2-26
Surface Water Body Classifications for Belews Lake, Dan River, and Town Fork Creek Water Segments within Project Vicinity

Stream Name	Stream Segment	Freshwater Stream Classification	Protected Uses				
			Aquatic Life	Secondary Recreation[a]	Primary Recreation[b]	Water Supply	Shellfish
Belews Creek (including Belews Lake below elevation 725)	22-27-(7.5)	WS-IV[c]	x	x	–	x	–
Arm of Belews Lake immediately southeast of Belews Lake Dam (Below elevation 725)	22-27-10	WS-IV[c], B	x	x	x	x	–
West Belews Creek (West Belews Creek Arm of Belews Lake below elevation 725)	22-27-9-(4)	WS-IV[c]	x	x	–	x	–
West Belews Creek (West Belews Creek Arm of Belews Lake below elevation 725)	22-27-9-(3)	C	x	x	–	–	–
Belews Creek (including Belews Lake below elevation 725)	22-27-(7)	C	x	x	–	–	–
East Belews Creek (East Belews Creek Arm of Belews Lake below elevation 725)	22-27-8-(2)	B	x	x	x	–	–
Belews Creek (Belews Creek Arm of Belews Lake below elevation 725)	22-27-(6)	B	x	x	x	–	–
Dan River	22-(8)	WS-V[d]	x	x	–	x	–
Dan River	22-(25.5)	WS-IV[c]	x	x	–	x	–
Town Fork Creek	22-25	C	x	x	–	–	–

Source: NCDEQ, n.d. (a), NCDEQ, 2017a
Notes:
(a) Secondary contact recreation means wading, boating, other uses not involving human body contact with water, and activities involving human body contact with water where such activities take place on an infrequent, unorganized, or incidental basis.
(b) Primary contact recreation means swimming, diving, water skiing, and similar uses involving human body contact with water where such activities take place in an organized manner or on a frequent basis.
(c) Water Supply-IV are defined as waters used as sources of water supply for drinking, culinary, or food processing purposes where a WS-I, II or III classification is not feasible.
(d) Water Supply-V are defined as waters protected as water supplies which are generally upstream and draining to Class WS-IV waters or waters used by industry to supply their employees with drinking water or as waters formerly used as water supply.
Key: B = Primary Contact Recreation, Fresh Water; C = Aquatic Life, Secondary Contact Recreation, Fresh Water; WS = Water Supply

Table 2.2-27
Surface Water Quality Values for Belews Lake from 2020 316(a) Sampling Program

Constituent	Units	BLSW (Thirteen Monitoring Locations)	
		Mean	Range
Temperature	°C	21.48	9.4 – 37.6
Dissolved Oxygen	mg/L	8.67	7.2 – 10.6
pH, Field	pH units	7.45	6.9 – 8.5
Specific Conductance	µs/cm	77.5	45 – 83
Phosphorus, Total as P	mg/L	0.0448	0.006 – 0.123
Phosphate as P, Ortho	mg/L	0.028	<0.005 – <0.05
Ammonia	mg/L	< 0.06	<0.02 – <0.10
Nitrite+Nitrate	mg/L	0.139	< 0.02 – 0.282
Total Kjeldahl Nitrogen (TKN)	mg/L	0.306	0.1 – 0.74
Carbon, Total Organic (TOC)	mg/L	3.36	2.7 – 5.6
Chloride	mg/L	5.1	2.7 – 5.9
Sulfate	mg/L	5.64	2.7 – 6.6
Turbidity	NTU	14.398	1.57 – 97

Table 2.2-28
Dan River Surface Water Quality Values from the Preapplication Monitoring Program from April 2024 through January 2025
(Sheet 4 of 4)

Notes:
(a) NCDEQ Surface Water Quality Standards Rules 15A NCAC 02B.0100 through.0300 (NCDEQ, 2022b).
(b) National Recommended Water Quality Criteria for aquatic freshwater life and human health (USEPA, 2024e, 2024f).
(c) Surface water criteria are specific to surface water body classifications (NCDEQ, n.d.[a]).
(d) Class IV and V waters.
(e) Not to exceed value in more than 20 percent of the samples examined during a 30-day period in which of five samples are taken. Not to exceed geometric mean of 200/100ml (MF Count).
(f) Mercury water quality standards shall be based upon measurement of the total recoverable metal.
(g) The Water Effect Ratio (WER) shall be assigned a value equal to one unless determined otherwise under Sub-Item (11(b)) of Subchapter 02B – Surface Water and Wetland Standards (NCDEQ, 2022b).
(h) Acute and chronic freshwater aquatic life standards for metals shall be based upon measurement of the dissolved fraction of the metal.
(i) WER·65.
(j) WER·6.5.
(k) WER· [0.316 · e^{0.8190[ln hardness]+3.7256}].
(l) Average hardness of 25.36 mg/L has been used to determine the site-specific NC 2B Water Quality Standards for specific metals.
(m) WER· [0.860 · e^{0.8190[ln hardness]+0.6848}]
(n) WER· [0.960 · e^{0.9422[ln hardness]-1.700}].
(o) WER· [0.960 · e^{0.8545[ln hardness]-1.702}].
(p) Manganese has been monitored by NCDEQ and has been shown to have elevated background level concentrations that are somewhat flow related and are caused by the geology of the region. NCDEQ removed manganese as a standard as there was no evidence of to conclude that discharges of manganese will impact any beneficial uses of North Carolina's waters (NCDENR, 2015c).
(q) WER· [0.998 · e^{0.8460[ln hardness]+2.255}].
(r) WER· [0.997 · e^{0.8460[ln hardness]+0.0584}].
(s) WER· [0.85 · e^{1.72[ln hardness]-6.59].
(t) WER·0.06.
(u) WER· [0.978 · e^{0.8473[ln hardness]+0.884}].
(v) WER· [0.986 · e^{0.8473[ln hardness]+0.884}].
(w) Class C waters.
(x) WER·[{1.136672-[ln hardness](0.041838)} · e^{0.9789 [ln hardness]-3.443}].
(y) Non-trout waters.
(z) WER·[{1.101672-[ln hardness](0.041838)} · e^{0.7977[ln hardness]-3.909}].
(aa) WER· [{1.46203-[ln hardness](0.145712)} · e^{1.273[ln hardness]-1.460}].
(bb) WER· [{1.46203-[ln hardness](0.145712)} · e^{1.273[ln hardness]-4.705}].
(cc) The standard for chronic selenium has the following components: fish egg/ovary tissue, fish whole body or muscle tissue, and water column (lentic and lotic). These components shall be used in the following order of preference provided data is available: 1. Fish egg/ovary tissue; 2. Fish whole body or muscle tissue; 3. Water column (NCDEQ, 2022b).
(dd) Alpha Emitters: the average annual gross alpha particle activity (including radium-226 but excluding radon and uranium).
(ee) Beta Emitters: Not to exceed this average annual activity level for strontium-90.
(ff) Beta Emitters: Not to exceed this average annual activity level for tritium.
(gg) Beta Emitters: Not to exceed the average annual gross beta particle activity (excluding potassium-40 and other naturally occurring radionuclides).
(hh) Available or total.

Key: µg/L = micrograms per liter; °C = degrees Celsius; BRL = Below Reporting Limit; DRSW = Dan River Surface Water; MDL = Method Detection Limit; MF = membrane filter procedure for bacteriological analysis; mg/L = milligrams per liter; mg/m^3 = milligrams per cubic meter; mpn/100mL= most probable number per 100 milliliters; ms/cm = millisiemens per centimeter; mV = millivolts; NCDEQ = North Carolina Department of Environmental Quality; NE = Regulatory standard not established for this constituent; ng/L = nanograms per liter; NTU = nephelometric turbidity unit; pci/L = picocuries per liter; QC = quality control; WER = Water Effect Ratio.

Chemical Oxygen Demand (COD)	mg/L	6.96 – 8.48	7.72	NE	NE	NE	NE

Table 2.2-29
Town Fork Creek Surface Water Quality Values from the Preapplication Monitoring Program from April 2024 through January 2025 (Sheet 4 of 4)

Notes:
(a) NCDEQ Surface Water Quality Standards Rules 15A NCAC 02B.0100 through.0300 (NCDEQ, 2022b).
(b) National Recommended Water Quality Criteria for aquatic freshwater life and human health (USEPA, 2024e, 2024f).
(c) Surface water criteria are specific to surface water body classifications (NCDEQ, n.d.[a]).
(d) Class IV and V waters.
(e) Not to exceed value in more than 20 percent of the samples examined during a 30-day period in which of five samples are taken. Not to exceed geometric mean of 200/100ml (MF Count).
(f) Mercury water quality standards shall be based upon measurement of the total recoverable metal.
(g) The Water Effect Ratio (WER) shall be assigned a value equal to one unless determined otherwise under Sub-Item (11(b)) of Subchapter 02B – Surface Water and Wetland Standards (NCDEQ, 2022b).
(h) Acute and chronic freshwater aquatic life standards for metals shall be based upon measurement of the dissolved fraction of the metal.
(i) WER·65.
(j) WER·6.5.
(k) WER· [0.316 · e^{0.8190[ln hardness]+3.7256}].
(l) Average hardness of 35.58 mg/L has been used to determine the site-specific NC 2B Water Quality Standards for specific metals.
(m) WER· [0.860 · e^{0.8190[ln hardness]+0.6848}].
(n) WER· [0.960 · e^{0.9422[ln hardness]-1.700}].
(o) WER· [0.960 · e^{0.8545[ln hardness]-1.702}].
(p) Manganese has been monitored by NCDEQ and has been shown to have elevated background level concentrations that are somewhat flow related and are caused by the geology of the region. NCDEQ removed manganese as a standard as there was no evidence of to conclude that discharges of manganese will impact any beneficial uses of North Carolina's waters (NCDENR, 2015c).
(q) WER· [0.998 · e^{0.8460[ln hardness]+2.255}].
(r) WER· [0.997 · e^{0.8460[ln hardness]+0.0584}].
(s) WER· [0.85 · e^{1.72[ln hardness]-6.59].
(t) WER·0.06.
(u) WER· [0.978 · e^{0.8473[ln hardness]+0.884}].
(v) WER· [0.986 · e^{0.8473[ln hardness]+0.884}].
(w) Class C waters.
(x) WER·[{1.136672-[ln hardness](0.041838)} · e^{0.9789 [ln hardness]-3.443}].
(y) Non-trout waters.
(z) WER·[{1.101672-[ln hardness](0.041838)} · e^{0.7977[ln hardness]-3.909}].
(aa) WER· [{1.46203-[ln hardness](0.145712)} · e^{1.273[ln hardness]-1.460}].
(bb) WER· [{1.46203-[ln hardness](0.145712)} · e^{1.273[ln hardness]-4.705}].
(cc) The standard for chronic selenium has the following components: fish egg/ovary tissue, fish whole body or muscle tissue, and water column (lentic and lotic). These components shall be used in the following order of preference provided data is available: 1. Fish egg/ovary tissue; 2. Fish whole body or muscle tissue; 3. Water column (NCDEQ, 2022b).
(dd) Alpha Emitters: the average annual gross alpha particle activity (including radium-226 but excluding radon and uranium).
(ee) Beta Emitters: Not to exceed this average annual activity level for strontium-90.
(ff) Beta Emitters: Not to exceed this average annual activity level for tritium.
(gg) Beta Emitters: Not to exceed the average annual gross beta particle activity (excluding potassium-40 and other naturally occurring radionuclides).
(hh) Available or total.

Key: µg/L = micrograms per liter; BRL = Below Reporting Limit; °C = degrees Celsius; MDL = Method Detection Limit; MF = membrane filter procedure for bacteriological analysis; mg/L = milligrams per liter; mg/m^3 = milligrams per cubic meter; mpn/100mL= most probable number per 100 milliliters; ms/cm = millisiemens per centimeter; mV = millivolts; NCDEQ = North Carolina Department of Environmental Quality; NE = Regulatory standard not established for this constituent; ng/L = nanograms per liter; NTU = nephelometric turbidity unit; pci/L = picocuries per liter; QC = quality control; TFCSW = Town Fork Creek Surface Water; WER = Water Effect Ratio

2.3 ECOLOGICAL RESOURCES

This section describes the terrestrial, wetland, and aquatic ecology of the Project Region, Project Vicinity, and the Project site. Section 2.3.1 describes the potentially affected terrestrial resources and Section 2.3.2 describes the potentially affected aquatic resources. Consultations with the USFWS, USACE, NCDEQ, NCWRC, North Carolina Forest Service (NCFS), and NCNHP were initiated to acquire information regarding ecological resources within and near the Project site. Consultation is used to obtain agency input regarding threatened and endangered species, sensitive habitats, commercial and recreational species, and other ecological characteristics for the Project site and Project Vicinity. This section was prepared using U.S. Nuclear Regulatory Commission (NRC) guidance from NUREG-1555 and NRC Regulatory Guide 4.2 Rev. 3. Supporting terrestrial and aquatic environmental studies were executed in accordance with Regulatory Guide 4.11 Rev.2 and Regulatory Guide 4.24 Rev. 0, respectively.

2.3.1 TERRESTRIAL ECOLOGY

2.3.1.1 Terrestrial Habitats

2.3.1.1.1 Ecoregions

Ecoregions are geographic areas that are generally similar in terms of biotic, abiotic, terrestrial, and aquatic ecosystem components. Ecoregions serve as a spatial framework for the monitoring, research, and assessment of ecosystems and their components. The U.S. Environmental Protection Agency (USEPA) defines ecoregions in hierarchical levels from Level I to Level IV, increasing in detail as the level increases. The USEPA maintains the mapping of ecoregions (USEPA, 2024g).

NC is divided into 27 Level IV Ecoregions nested under four Level III Ecoregions. The Project Region is located within the Piedmont and Blue Ridge Level III Ecoregions, as depicted in Figure 2.3-1. The Blue Ridge Ecoregion is located northwest of the Project site and Project Vicinity. The Blue Ridge extends from southern Pennsylvania to northern Georgia and varies in topography, including narrow ridges, hilly plateaus, and mountainous areas. The Blue Ridge Ecoregion contains a high diversity of flora and fauna. Natural vegetation within this ecoregion in NC includes Appalachian oak forests with hemlock communities, cove hardwoods, and pine communities. Soils are mostly mesic, and elevations range from 1000 ft. (304.8 m) to 5000 ft. (1524 m) (Griffith et al., 2002).

The Project site and the Project Vicinity are located within the Piedmont Ecoregion, as depicted in Figure 2.3-1. The Piedmont Ecoregion is a transitional area between the mountainous Appalachians to the northwest and the relatively flat coastal plain to the southeast. It has an erosional terrain of dissected irregular plains with some hills, comprised of metamorphic and igneous rocks. Rare animals and plants are often found on scattered granitic domes and rock flats. Soils contain more clay and less sand than soils within the coastal plain areas. Land cover has changed over the last 200 years, shifting from forest to farm, then back to forest, and now reflect a greater abundance of developed land cover types resulting from growing urbanization. Historic forests consisted of white oak (*Quercus alba*), southern red oak (*Quercus falcata*), post oak (*Quercus stellata*), and hickory (*Carya* sp.), with some shortleaf pine (*Pinus echinata*) and loblolly pine (*Pinus taeda*). Historic farming for cotton, corn, tobacco, and wheat caused moderate to severe erosion in most Piedmont soils. Much of the area now is planted pine or has reverted to successional hardwood and pine woodlands with some pasture (Griffith et al., 2002).

More specifically, the Project site is located within the Northern Inner Piedmont Level IV Ecoregion (Figure 2.3-1). The Northern Inner Piedmont generally has more isolated small mountains, higher elevations, and more rugged topography than other areas of the Piedmont. It is generally characterized by colder temperatures, increased levels of snowfall and has a shorter growing season than other areas of the Piedmont. Soils within the Northern Inner Piedmont are predominantly mesic, which is different from the mostly thermic soils covering other areas of the Piedmont. Virginia pine (*Pinus virginiana*) is more prevalent within this ecoregion, along with chestnut oak (*Quercus montana*) and disjunct plant communities within the mountainous areas (Griffith et al., 2002).

The associated off-site wastewater pipeline corridor is located partially within the Triassic Basins Level IV Ecoregion (Figure 2.3-1). The Triassic Basins Ecoregion within NC occur in four narrow bands and have unusual Piedmont geology of unmetamorphosed shales, sandstones, mudstones, siltstones, and conglomerates. Triassic Basins contain lower elevations and rocks that erode more easily than those within the Northern Inner Piedmont. Soils are often clayey with poor permeability. Land cover within the Triassic Basins includes a mosaic of mixed and deciduous forest, pasture, cropland, and developed land. Large bottomland forests occurred in the wider floodplains before being covered by reservoir water (Griffith et al., 2002).

2.3.1.1.2 Topography and Land Cover

General topography on the Project site is typical of the Piedmont and the Project Vicinity, characterized by rolling hills and long low ridges with a few hundred feet of elevation difference between ridges and valleys. Figure 2.1-7 shows topography of the Project Vicinity. As discussed in Section 2.1, the Project site consists of rolling hills and steep slopes with elevations ranging from approximately 725 ft. (219.5 m) near the shore of Belews Lake to approximately 890 ft. (271 m) along the ridgetops. Topography is discussed in additional detail in Section 2.1, and a map of the topography of the Project site is found in Figure 2.1-10.

The NLCD data indicate the most prevalent land cover type found within the Project Vicinity is deciduous forest (36,003 ac. [14,570 ha]), followed by hay/pasture (17,088 ac. [6915 ha]), evergreen forest (9578 ac. [3876 ha]), and mixed forest (8497 ac. [3439 ha]).The land cover in the approximately 1187-ac. (480-ha) Project site and the 40-ac. (16-ha) associated off-site pipeline corridor is characterized predominantly by evergreen forest (463 ac. [187 ha]), which is the most prevalent land cover type. Other common land cover types include deciduous forest (330 ac. [134 ha]), mixed forest (151 ac. [61 ha]), and herbaceous land (130 ac. [53 ha]) (Figure 2.3-2 and Table 2.3-1).

Field surveys of vegetation on the Project site were conducted in the spring (April 8 to 12, 2024), summer (July 15 to 18, 2024), and fall (October 21 to 24, 2024). Evergreen forests can be found throughout the site, though they are slightly more common on the northern and southern portions of the site. These areas are not highly diverse and are characterized by near-monoculture stands of pine with little to no herbaceous cover. Approximately 18 percent of evergreen forests are currently composed of planted loblolly plantations, not including other areas of the Project site that have regenerated naturally since being harvested. Deciduous forests and mixed forests, which are the second and third most common land cover types, have a more diverse tree layer along with a slightly more diverse herbaceous layer. Combined forest types make up approximately 77 percent of the Project site land cover. The remaining 23 percent of land cover can be attributed to herbaceous, scrub shrub, open water, and developed or barren lands.

The plant communities found within the Project site are common and well represented throughout the local region. These communities contain substantial populations of non-native plant species and successional communities, which indicate significant past anthropogenic disturbance, non-native species invasion, and a disruption to natural disturbance patterns (e.g., fire). Loblolly pine plantations are scattered throughout the Project site.

Much of the Project site has remained or become forested since Belews Lake was created in the late 1960s to early 1970s. However, human disturbance to vegetation in the area was already prevalent and signatures of agriculture (pastureland) and an extensive patchwork of pine plantations are evident from historical aerial imagery. Since the late 1990s and early 2000s, significant forest clearing has taken place within the northern and western portions of the main Project site footprint and in uplands along the associated off-site wastewater pipeline corridor. These areas have, for the most part, since been allowed to naturally succeed back into forest. Areas currently characterized by herbaceous, scrub shrub, and evergreen land cover comprise the most disturbed portions of the Project site and represent consistently cleared lands, newly regenerated formerly cleared lands, and lands which have remained in pine plantation or naturally regenerated back into pine from logged pine plantations. Deciduous forest within the Project site is typically found in the most mature and undisturbed lands. While considered native, thick stands of young to fairly mature loblolly pine have created near monocultures with little else growing in the canopy, subcanopy, and herbaceous layer in extensive portions of upland found within the Project site.

Mature deciduous-forested, small low-gradient stream valleys located within the Project site contain the highest quality vegetation community and highest number of conservative species, including a number of fern and orchid species. This community is concentrated at stream seep heads and low, rich stream terraces and embankments. During surveys of the Project Vicinity, a higher quality example of this community was visited in the nearby Rock Branch Natural Area in Stokesdale, NC. Small stream valleys in the Rock Branch Natural Area are embedded in a more mature forested matrix and small terraces and embankments contain a more diverse shrub and herb assemblage than are present on the Project site. Species of note include southern wild raisin (*Viburnum nudum*), winterberry (*Ilex verticillata*), mapleleaf viburnum (*Viburnum acerifolium*), yellowroot (*Xanthorhiza simplicissima*), small green wood orchid (*Platanthera clavallata*), showy orchid (*Galearis spectabilis*), cucumber root (*Medeola virginiana*), and Carolina lily (*Lilium michauxii*).

2.3.1.2 Wetlands

As defined in Title 33 of the CFR Part 328.3 (33 CFR 328.3), wetlands are those areas that are inundated or saturated by surface water or groundwater at a frequency and duration sufficient to support a prevalence of vegetation typically adapted for life in saturated soil conditions. Types of wetlands include swamps, marshes, bogs, and similar areas. Wetlands and wetland fringe areas can also be found along the edges of many watercourses and impounded waters (both natural and human-made). Wetland habitat provides valuable public benefits, including flood storage, erosion control, water quality improvement, wildlife habitat, and recreational opportunities (33 CFR 320.4(b)).

2.3.1.2.1 Wetlands within the Project Vicinity

In the Northern Inner Piedmont Ecoregion, where the Project site is located (Section 2.3.1.1) (USEPA, 2024g), wetlands are often located along streams and rivers either as swamps or bottomland hardwood forests or as headwater forests near the origins of streams. They tend to

be mainly forested, although some freshwater emergent features are present. Depressional wetlands and seeps also occur (NC DWR, 2018-2024). In the Northern Inner Piedmont, more rugged topography may contribute to narrower riparian wetlands like those observed on the Project site (USEPA, 2024g). Historically, the greatest disturbance threat to wetlands in the Carolinas was attributable to wetland loss and conversion to agricultural land through ditching and draining. In 2002, the U.S. Forest Service found that the most significant threats to forested wetlands in the Carolinas were development, agriculture, and silviculture (Carolina Wetlands Association, 2022).

According to the USFWS NWI data, approximately 7517 ac. (3042 ha) of wetland, riparian, and deepwater habitats are mapped within the Project Vicinity. Wetland types found in the Project Vicinity include freshwater emergent wetlands (88 ac. [35 ha]), freshwater forested wetlands (1855 ac. [751 ha]), freshwater scrub shrub wetlands (312 ac. [126 ha]), freshwater ponds (438 ac. [177 ha]), lakes (3833 ac. [1551 ha]), and riverine features (992 ac. [402 ha]) (USFWS, 2024a) (Figure 2.3-3). They appear to be characteristic of Northern Inner Piedmont systems, generally confined to narrow areas along river corridors and drainageways.

Additional land uses in the Project Vicinity can be found in Section 2.1.1. No special wetland land uses were noted.

2.3.1.2.2 Project Site Wetlands

Wetlands located within the Project site are subject to jurisdiction under Section 401 and Section 404 of the CWA (33 U.S. Code [USC] 1251). The USACE regulates the discharge of dredged or fill material into WOTUS, including wetlands, under the CWA Section 404 permit program (33 USC 1344). Under Section 401 of the CWA, a Section 401 Water Quality Certification is required for any project requiring a federal construction permit or license for activities that may result in any discharge into navigable waters. In NC, the Division of Water Resources of the NCDEQ is responsible for issuing Section 401 water quality certifications through the USACE and NCDEQ Joint Pre-Construction Notification application (NCDEQ, 2017b).

Screening of habitats on the Project site for the potential occurrence of WOTUS initially involved a review of the USGS topographic map, USFWS NWI data, Natural Resources Conservation Service soil survey data, FEMA flood insurance rate maps, and current and historic aerial photography. Within the Project site, NWI data indicate only the presence of lake (25 ac. [10 ha]) and riverine features (1 ac. [0.4 ha]) (Figure 2.3-4). The lake features include portions of Belews Lake contained within the Project site and the canal that extends through the middle portion of the site. The riverine feature is an unnamed tributary located in the southwestern portion of the Project site which drains to Belews Lake.

Subsequently, field WOTUS delineation surveys were performed April 16 – 19, April 24 – 26, and May 10, 2024, within the Project site, specifically within the delineation survey area as depicted on Figure 2.3-5. Wetland identifications were performed in accordance with USACE methods outlined in the Wetlands Delineation Manual (USACE, 1987a), which requires documentation of hydrophytic vegetation, hydric soils, and wetland hydrology. Field identifications of potential WOTUS were performed according to the Wetlands Delineation Manual (USACE, 1987a) and the Regional Supplement to the Corps of Engineers Wetland Delineation Manual: Eastern Mountains and Piedmont region, Version 2.0 (Regional Supplement) (USACE, 2012).

Eighteen features, totaling 2.94 ac. (1.19 ha), qualify as wetlands in accordance with the Regional Supplement (Table 2.3-2). Each feature was assigned a Cowardin designation (Cowardin et al., 1979) and was evaluated using the North Carolina Wetland Assessment Method (NCWAM), per the methodology outlined in the NCWAM User Manual (Version 5), effective February 2016 (NC Wetland Functional Assessment Team, 2016). NCWAM is a functional assessment which assigns wetlands a score of high, medium, or low based on a field assessment of 22 metrics.

All 18 wetland features were identified as palustrine systems associated with topographic crenulation or streams, in a geomorphic floodplain, or contiguous with an open water 20 ac. or larger. Most are either narrow or small features, due to the degree of topographic relief on the site, and therefore are not a dominant feature of the Project site. Of the 18 total and 2.94 ac. (1.19 ha) of delineated wetland features, 13 features, totaling 1.45 ac. (0.59 ha), were classified as palustrine forested (PFO) systems; four features, totaling 1.27 ac. (0.51 ha), were classified as palustrine emergent (PEM); and one feature, totaling 0.22 ac. (0.09 ha), consists of both forested and emergent vegetation (Table 2.3-2). One PEM system is located in a relict stormwater management pond. The other PEM features are characterized by emergent vegetation due to their full or partial occupation of a maintained overhead utility easement. It is assumed that the natural condition of these features would otherwise be forested.

Common tree species observed within PFO features consisted of tulip poplar (*Liriodendron tulipifera*), American sycamore (*Platanus occidentalis*), mockernut hickory (*Carya tomentosa*), American beech (*Fagus grandifolia*), red maple (*Acer rubrum*), and sweetgum (*Liquidambar styraciflua*). Common sapling and shrub species within the PFO features included smooth alder (*Alnus serrulata*), red maple, musclewood (*Carpinus caroliniana*), mockernut hickory, tulip poplar, spicebush (*Lindera benzoin*) black tupelo (*Nyssa sylvatica*), southern sugar maple (*Acer floridanum*), and sweetgum. Common herbaceous species within PFO features included Gray's sedge (*Carex grayi*), Christmas fern (*Polystichum acrostichoides*), velvet panicgrass (*Dichanthelium scoparium*), cinnamon fern (*Osmundastrum cinnamomeum*), Japanese stiltgrass (*Microstegium vimienieum*), and lizard's tail (*Saururus cernuus*).

PEM features were generally characterized by the following herbaceous vegetation: common rush (*Juncus effusus*), woolgrass (*Scirpus cyperinus*), bladder sedge (*Carex intumescens*), and velvet panicgrass.

Of the 18 identified features, 11 features, totaling 1.37 ac. (0.55 ha), were assigned a function score of high according to NCWAM, five features totaling 0.52 ac. (0.21 ha) were assigned a function score of medium, and two features totaling 1.05 ac. (0.42 ha) were assigned a function score of low (Table 2.3-2). Table 2.3-2 contains relevant information for the 18 identified features, including size, Cowardin and NCWAM designation, potential jurisdictional status, NCWAM functional rating, and location. In addition, the locations of each of these wetland features are shown on Figure 2.3-5.

WOTUS are subject to the regulatory authority of the USACE pursuant to Section 404 of the CWA. Of the 18 wetland features identified within the Project site, all are considered potentially jurisdictional due to direct or indirect surface water connections with Belews Lake and the Dan River; however, these recommendations for potential regulatory features are preliminary and are subject to regulatory jurisdictional determination by the USACE. A delineation survey area, subject to potential impacts from the Project, includes 1041 ac. (421 ha) adjacent to the BCSS and an existing approximately 3.7-mi. (5.95-km) associated off-site wastewater pipeline corridor

(Figure 2.3-5). Following the field survey, a WOTUS report and request for delineation concurrence was completed. The delineation concurrence request was submitted to USACE on October 22, 2024. The USACE performed a site visit on December 10, 2024, to field verify the WOTUS delineation. On January 16, 2025, the USACE issued a Jurisdictional Delineation Concurrence letter confirming the delineation (Figure 2.3-5) is a sufficiently accurate representation of the geographic boundaries of the aquatic resources located on the site within the delineation survey area. No surveys for WOTUS were conducted outside of the delineation survey area, as Project impacts are not anticipated beyond this boundary. Duke Energy will continue to coordinate with the USACE to expand the delineation concurrence request to include any areas outside of the delineation survey area, if necessary.

2.3.1.3 Wildlife

To document seasonal wildlife use of the Project site and the immediate Project Vicinity, seasonal pedestrian surveys were conducted during spring (April 8 to 12, 2024), summer (July 15 to 18, 2024), fall (October 21 to 24, 2024), and winter (January 27 to 30, 2025). A pedestrian site reconnaissance survey was conducted each season using a semiquantitative meandering approach within the Project site to record encountered terrestrial faunal species presence (visual, audible, or other signs such as tracks, scat, nests) within each of the on-site habitats (Figure 2.3-6). The field studies for wildlife included surveys for avifauna, mammals, and herpetofauna.

Additionally, a semiquantitative roadside survey approach was used to make observations of terrestrial faunal species along prescribed stops of existing roadways within the Project site and Project Vicinity (Figure 2.3-6). At each of the 17 stops, field biologists recorded birds observed (visible and audible cues) during a 3-minute period for two mornings per seasonal survey period with observations initiated within 1 hour of sunrise each day. The distances between prescribed stops were generally 0.5 mi. (0.8 km) with some stopping points focused on potential habitat features (e.g., vegetation changes, stream corridors, waterbodies). Notable wildlife travel corridors, if any, were also documented.

Incidental observations of wildlife species and habitats outside the Project site were also recorded opportunistically through general reconnaissance within the Project Vicinity. Climatic conditions, such as estimated wind intensity (no wind, slight, gusty, strong wind), temperature (degrees Fahrenheit), and cloud cover, were recorded for each survey event.

As discussed in Section 2.3.1.1, many of the terrestrial communities and associated habitats within the Project site are predominantly composed of disturbed and previously disturbed communities consisting of developed lands or marginal evergreen, herbaceous, and scrub shrub habitat. Wildlife habitat value and associated wildlife communities are considered limited in these areas. However, deciduous forest and associated stream valley habitats, which are more mature and less disturbed, provide higher quality wildlife habitat. Small wetlands on the site provide breeding and nesting areas for wildlife. Belews Lake provides habitat for migratory birds. The sections below summarize relevant information obtained from each survey and provide other data and descriptions of the terrestrial ecology in the area.

2.3.1.3.1 Avifauna

Field studies for avian species included pedestrian meandering on the Project site and general field reconnaissance and roadside survey methods in the Project Vicinity.

In total, 68 species were observed during the spring 2024 surveys, including 45 species observed within the Project Vicinity driving route, 44 species as part of the Project Vicinity general reconnaissance, and 51 species as part of the surveys within the Project site (Table 2.3-3 and Table 2.3-4). Abundant and common bird species observed within the Project site during the spring 2024 Project site field surveys included tufted titmouse (*Baeolophus bicolor*), northern cardinal (*Cardinalis cardinalis*), turkey vulture (*Cathartes aura*), American crow (*Corvus brachyrhynchos*), blue jay (*Cyanocitta cristata*), red-bellied woodpecker (*Melanerpes carolinus*), wild turkey (*Meleagris gallopavo*), brown-headed cowbird (*Molothrus ater*), eastern towhee (*Pipilo erythrophthalmus*), Carolina chickadee (*Poecile carolinensis*), blue-gray gnatcatcher (*Polioptila caerulea*), pine warbler (*Setophaga pinus*), American goldfinch (*Spinus tristis*), chipping sparrow (*Spizella passerina*), Carolina wren (*Thryothorus ludovicianus*), American robin (*Turdus migratorius*), mourning dove (*Zenaida macroura*), and white-throated sparrow (*Zonotrichia albicollis*) (Table 2.3-3).

Fifty-one bird species were observed during the summer 2024 surveys, including 41 species observed within the Project Vicinity driving routes, 34 species as part of the Project Vicinity general reconnaissance, and 38 species within the Project site (Table 2.3-3 and Table 2.3-4). Abundant and common bird species observed within the Project site during summer 2024 Project site field surveys included tufted titmouse, Canada goose (*Branta canadensis*), northern cardinal, yellow-billed cuckoo (*Coccyzus americanus*), eastern wood-pewee (*Contopus virens*), blue jay, red-bellied woodpecker, osprey (*Pandion haliaetus*), indigo bunting (*Passerina cyanea*), eastern towhee, Carolina chickadee, blue-gray gnatcatcher, American goldfinch, Carolina wren, American robin, red-eyed vireo (*Vireo olivaceus*), and mourning dove (Table 2.3-3).

Fifty bird species were observed during the fall 2024 surveys, including 38 species observed within the Project Vicinity driving routes, 34 species as part of the Project Vicinity general reconnaissance, and 34 species within the Project site (Table 2.3-3 and Table 2.3-4). Abundant and common bird species observed during fall 2024 Project site field surveys included northern cardinal, turkey vulture, American crow, blue jay, hairy woodpecker (*Dryobates villosus*), red-bellied woodpecker, wild turkey, song sparrow (*Melospiza melodia*), Carolina chickadee, golden-crowned kinglet (*Regulus satrapa*), eastern bluebird (*Sialia sialis*), brown-headed nuthatch (*Sitta pusilla*), mourning dove, and white-throated sparrow (Table 2.3-3).

Fifty bird species were observed during the winter 2025 surveys including 36 species observed within the Project Vicinity driving routes, 31 species as part of the Project Vicinity general reconnaissance, and 35 species within the Project site (Table 2.3-3 and Table 2.3-4). Abundant and common bird species observed during the winter 2025 Project site field surveys included tufted titmouse, northern cardinal, turkey vulture, American crow, dark-eyed junco (*Junco hyemalis*), song sparrow, Carolina chickadee, golden-crowned kinglet, brown-headed nuthatch, and mourning dove (Table 2.3-3).

While much of the Project site is previously disturbed and in varying stages of secondary growth, large trees typically used for raptor nesting are primarily limited to areas near the shoreline of Belews Lake within the Project site. No raptor nests were observed in trees within the Project site during seasonal ecology field surveys; however, an actively used osprey nest platform was observed in the north portion of the Project site (Figure 2.3-7). Waterfowl and water dependent bird species were observed in close association with Belews Lake. Belews Lake provides valuable habitat for migratory birds. Waterfowl noted as using Belews Lake for foraging, swimming, or wading in 2020 included double-crested cormorant (*Nannopterum auritum*), Canada goose, osprey, great blue heron (*Ardea herodias*), killdeer (*Charadrius*

vociferus), wood duck (*Aix sponsa*), common loon (*Gavia immer)*, great egret (*Ardea alba*), and belted kingfisher (*Megaceryle alcyon)* (Duke Energy, 2021).

The complete list of birds observed within the Project Vicinity and Project site for each seasonal survey is recorded in Tables 2.3-3 and 2.3-4. No bird species federally listed under the Endangered Species Act were identified on the Project site or in the Project Vicinity. Bald eagle (*Haliaeetus leucocephalus*), identified by USFWS as a migratory bird of conservation concern and protected under the Bald and Golden Eagle Protection Act, was observed within the Project Vicinity during spring 2024 and observed in the Project site in the fall of 2024 and winter of 2025. No bald eagle nests were observed within the Project site; however, a bald eagle nest was previously observed at the BCSS, which is located in close proximity to the Project site, adjacent to the Craig Road Landfill (Duke Energy, 2023a). Grasshopper sparrow (*Ammodramus savannarum*), also identified by USFWS as a migratory bird of conservation concern, was observed within the Project Vicinity during summer 2024. Red-headed woodpecker (*Melanerpes erythrocephalus*), also identified by USFWS as a migratory bird of conservation concern, was observed within the Project Vicinity during fall 2024. Information about important terrestrial species is found in Section 2.3.1.5.

Regional data concerning occurrence of birds during the breeding season are derived from the annual North American Breeding Bird Survey, which is a long-term international avian monitoring program. These roadside surveys are conducted in June each year and are 24.5 mi. (39 km) long with 3-minute stops every 0.5 mi. (0.8 km) to document avian species presence within 0.25 mi. (0.40 km) (USGS Eastern Ecological Science Center, 2024a). The closest breeding bird survey route to the Project site is Eden (Number 63126). The Eden route winds through Rockingham County to the northeast of the Project site (USGS Eastern Ecological Science Center, 2024b). Sixty-four avian species were observed during the most recent breeding bird survey (2022) of this route. The most abundant species included northern cardinal, European starling (*Sturnus vulgaris*), tufted titmouse, American crow, and chimney swift (*Chaetura pelagica*) (USGS Eastern Ecological Science Center, 2024c).

The Christmas Bird Count (CBC) is a community science initiative started in 1900 to measure avian diversity during the winter period. CBCs occur between December 14 and January 5 each year, and a compiler chooses a single calendar day to count birds within a predetermined 15-mi. (24-km) diameter circle. Count volunteers follow specified routes through the circle, counting every bird they see or hear all day (Audubon, 2024a). The nearest CBC to the Project site is in Rockingham County, Code NCRO, which is centered on the U.S. 220 Business Bridge over Mayo River, just north of Mayodan, NC. This CBC is to the northeast of the Project site (Audubon, 2024b). The number of avian species observed during the NCRO CBC from 2012 through 2022 ranged from 58 to 78 species per survey (Audubon, 2024c). During the latest CBC (2023), 77 species were recorded. The most abundant species included Canada goose, dark-eyed junco, white-throated sparrow, European starling, and American robin (Audubon, 2024d).

2.3.1.3.2 Mammals

Field surveys for mammals on the Project site consisted of general field surveys and acoustic surveys. General field surveys for mammal species included field reconnaissance and incidental observations during pedestrian surveys.

Mammal species observed within the Project Vicinity include coyote (*Canis latrans*), opossum (*Didelphis virginiana*), groundhog (*Marmota monax*), striped skunk (*Mephitis mephitis)*, white-tailed deer (*Odocoileus virginianus*), raccoon (*Procyon lotor*), eastern gray squirrel (*Sciurus*

carolinensis), and gray fox (*Urocyon cinereoargenteus*). These mammals were also observed on the Project site. Other mammals observed on the Project site include beaver (*Castor canadensis*), eastern mole (*Scalopus aquaticus*), fox squirrel (*Sciurus niger*), eastern cottontail (*Sylvilagus floridanus*), and eastern chipmunk (*Tamias striatus*). Mammal occurrence within the Project site is likely driven by available habitats (developed lands, herbaceous, scrub shrub, open water, and fragmented deciduous, evergreen, and mixed forests) and previous disturbance within and surrounding the Project site. The list of mammals observed within and near the Project site is recorded in Table 2.3-5.

Acoustic surveys for bats were conducted from August 4 to August 15, 2023. Species identified on the Project site included: big brown bat (*Eptesicus fuscus*), eastern red bat (*Lasiurus borealis*), silver-haired bat (*Lasionycteris noctivagans*), evening bat (*Nycticeius humeralis*), Brazilian free-tailed bat (*Tadarida brasiliensis*), and tricolored bat (*Perimyotis subflavus*). Gray bat (*Myotis grisescens*), little brown bat (*Myotis lucifugus*), and eastern small-footed bat (*Myotis leibii*) were considered absent from the Project site (WSP, 2025). The tricolored bat is proposed for federal listing. Information on important terrestrial species is provided in Section 2.3.1.5.

2.3.1.3.3 Herpetofauna

Herpetofauna were recorded based on field reconnaissance and incidental observations during the pedestrian ecological surveys.

Within the Project Vicinity, herpetofauna species observed during surveys were species uncommon to abundant in the Piedmont. Eastern river cooter (*Pseudemys concinna concinna*), uncommon to common in the Piedmont; eastern box turtle (*Terrapene carolina*), common in the Piedmont; and Cope's gray treefrog (*Hyla chrysoscelis*), common to abundant, were observed (LeGrand, H., and Howard, T., 2024) (Table 2.3-6).

Amphibians encountered on the Project site considered abundant or common in the Piedmont included frogs and treefrogs, toads, and salamanders. Specific species were the northern cricket frog (*Acris crepitans*), green frog (*Lithobates clamitus*), spring peeper (*Pseudacris crucifer*), Cope's gray treefrog, southern leopard frog (*Lithobates sphenocephalus*), upland chorus frog (*Pseudacris feriarum*), American toad (*Anaxyrus americanus*), northern dusky salamander (*Desmognathus fuscus*), and southern two-lined salamander (*Eurycea cirrigera*) (LeGrand, H., and Howard, T., 2024). One uncommon to common amphibian, the pickerel frog (*Rana palustris*), was also observed on the Project site (LeGrand, H., and Howard, T., 2024) (Table 2.3-6).

Reptile species encountered on the Project site considered abundant or common in the Piedmont included worm snake (*Carphophis amoenus*), eastern painted turtle (*Chrysemys picta picta*), black racer (*Coluber constrictor*), black rat snake (*Pantherophis alleghaniensis*), eastern fence lizard (*Sceloporus undulatus*), eastern box turtle, and yellow-bellied slider (*Trachemys scripta scripta*) (LeGrand, H., and Howard, T., 2024). The non-native red-eared slider (*Trachemys scripta elegans*) was also observed on the Project site. Table 2.3-6 lists the herpetofauna observed within and near the Project site. As expected, due to the hibernation period for herpetofauna, no herpetofauna were observed during the winter 2025 ecology survey.

Other amphibian species not observed in the Project Vicinity or site but that are common or abundant in the Piedmont include spotted salamander (*Ambystoma maculatum)*, marbled salamander (*Ambystoma opacum)*, eastern newt (*Notophthalmus viridescens),* red salamander (*Pseudotriton ruber*), Fowler's toad (*Anaxyrus fowleri*), and American bullfrog (*Lithobates*

catesbeianus). Other reptile species not observed in the Project Vicinity or site but that are common or abundant in the Piedmont include common snapping turtle (*Chelydra serpentina),* eastern mud turtle (*Kinosternon subrubrum*), Dekay's brownsnake (*Storeria dekayi),* eastern garter snake (*Thamnophis sirtalis),* and copperhead (*Agkistrodon contortrix*) (LeGrand, H., and Howard, T., 2024).

2.3.1.3.4 Insects

No insect studies were conducted as part of site characterization work at the Project site. However, the Project site is expected to support a large diversity of insect species corresponding to the range of habitat types within the Project site. Pollinators are an insect group that is of particular interest in ecosystem management as they perform an important role in ensuring reproductive success of plant communities. Pollinators are also often indicators of healthy, diverse terrestrial ecosystems. Herbaceous and wooded areas around the Project site may provide suitable habitat for common pollinator species such as spicebush swallowtail (*Papilio troilus*), gray hairstreak (*Strymon melinus*), variegated fritillary (*Euptoieta hegesia*), mining bees (*Andrena* sp.), and sweat bees (family Halictidae) (North Carolina Wildlife Federation, 2020).

2.3.1.4 Plant Communities

Vegetation assessment included pedestrian surveys to record plant species encountered within the Project site, characterize plant communities present, and verify land cover. To account for seasonal variability of the vegetation within the site, surveys were conducted in the spring (April 8 to 12, 2024), summer (July 15 to 18, 2024), and fall (October 21 to 24, 2024). No vegetation surveys were conducted during the dormant winter months.

To effectively characterize plant communities in the Project site, the relative abundance of each species occurring within each distinctive NLCD land cover type was assessed. Within individual land cover types, each unique plant community observed was described. Plant community descriptions were based on dominant and characteristic species observed. Species' concepts and nomenclature followed Weakley's *Flora of the Southeastern United States* (2024). Land cover types and parcels assessed as part of the vegetation assessment are illustrated in Figure 2.3-2. The relative abundance of each species recorded through a terrestrial meandering approach within the Project site was assessed qualitatively. The terrestrial meandering approach provided characterization of plant communities within available on-site habitats. Plant species abundance was visually scored for each vegetation layer (overstory, midstory, herbaceous, woody vine) based on the professional judgment of the field biology team using the following commonly used relative abundance scale:

- A: abundant (the dominant plants throughout and near the Project site)
- C: common (locally abundant or frequently encountered)
- O: occasional (occasionally encountered, or locally common but absent or infrequent across much of the study area)
- U: uncommon (infrequently encountered)
- R: rare (very few plants encountered)

Qualitative characteristics of habitats within the Project Vicinity and their associated flora were also recorded opportunistically via windshield surveys where accessible. Particular attention was given to identifying important species and habitats as defined in NUREG-1555 Section 2.4.

As discussed in Section 2.3.1.1, the plant communities found within the Project site are common and well represented throughout the local region. Many of these communities are successional and contain substantial populations of non-native plants, indicating significant past anthropogenic disturbance and a disruption to natural disturbance patterns. Deciduous forests within the Project site are generally less disturbed when compared to other plant communities and stream valleys contain the highest number of conservative species. Vicinity surveys showed habitat and landcover to be similar to those within the Project site although there was one higher quality example of a stream valley embedded in a more mature forested matrix that contained more plant diversity than on the Project site. The key characteristics of land cover types and the diversity of plant associations found within each type identified within the site are described in the sections below. A list of plants documented on the Project site is found in Table 2.3-7.

2.3.1.4.1 Evergreen Forest

Evergreen forest is scattered throughout uplands within the Project site and is represented by two types: loblolly and Virginia pine–dominated forests, although both species were occasionally observed mixing together. Loblolly forest is primarily found in timber plantations where it can be observed growing in rows, and in areas formerly in plantation where it has regenerated naturally since being harvested. Relatively few species are found in association as loblolly was commonly observed growing in near monoculture; however, moderate amounts of tulip poplar, red maple, Virginia pine, and black cherry (*Prunus serotina*) can be found in the canopy. Flowering dogwood (*Benthamidia florida*), tulip poplar, American beech, and musclewood are frequently encountered in the subcanopy. The herbaceous layer is nearly always depauperate but may include a few species such as muscadine (*Muscadinia rotundifolia* var. *rotundifolia*), common greenbriar (*Smilax rotundifolia*), and seedlings from various canopy species. The woody vine layer is also not significantly developed but includes cross vine (*Bignonia capreolata*), Japanese honeysuckle, and Chinese wisteria.

Virginia pine–dominated forest occurs in younger- and older-aged stands. Similar to loblolly forest, Virginia pine forest is typically species poor. However, Virginia pine forest can be found in slightly drier topographic positions and does not occur in planted timber stands. Associated species are consistent with those found in loblolly forests within the Project site, but Virginia pine forests may possess slightly more herbaceous species diversity.

2.3.1.4.2 Deciduous Forest

Deciduous forest represents the most mature land cover type found within the Project site, although it may also be found in more disturbed lands located within suitable landscape positions on side slopes, ravines, creek valleys, and in the floodplain of the Dan River. Several different deciduous forest associations were observed dependent on local site moisture availability, history of disturbance, and underlying geology.

Mature upland deciduous forest found in the southeastern portion of the Project site was characterized by white oak, northern red oak (*Quercus rubra*), tulip poplar, American beech, and red maple. The shrub layer was commonly occupied by beech, sourwood (*Oxydendrum arboreum*), striped wintergreen (*Chimaphila maculata*), deerberry (*Vaccinium stamineum*), hillside blueberry (*Vaccinium pallidum*), strawberry bush (*Euonymus americanus),* and

muscadine. Where this forest association occurred along low-gradient, small stream valleys, additional shrub and herbaceous species were typically accompanying. Low terraces, seep heads, and embankments of these small streams included within the deciduous-forested matrix possessed the highest quality vegetation communities found within the Project site. Additional shrub species observed included pawpaw (*Asimina triloba*), musclewood, spicebush (*Lindera benzoin*), sweetgum, and pink azalea (*Rhododendron periclymenoides*). The herbaceous layer here often included rattlesnake-root (*Nabalus* sp.), mayapple (*Podophyllum peltatum*), star chickweed (*Stellaria pubera*), hooded blue violet (*Viola cucullata*), heartleaf foamflower (*Tiarella cordifolia*), fan clubmoss (*Diphasiastrum digitatum*), dwarf iris (*Iris cristata*), small green wood orchid, showy orchid, and a number of fern species.

Sub-xeric, mature deciduous forest growing along the east and north facing slopes of Belews Lake located north of the transmission corridor of the Project site is characterized by a drier assemblage of species. These species include white oak, chestnut oak, scarlet oak (*Quercus coccinea*), and beech in the canopy. Beech is also found in the sparse shrub layer where it grows over the scant herbaceous layer of hillside blueberry.

Dry, deciduous forest found along exposed south facing ravine slopes north of the transmission line corridor include red maple, beech, chestnut oak, sourwood, and post oak in the canopy with sourwood, red maple, shortleaf pine, and pink azalea in the subcanopy. The herbaceous layer here is mostly absent but infrequently includes tree seedlings and other woody species such as whiteleaf greenbriar (*Smilax glauca*).

Deciduous forest found in the floodplain of the Dan River crossed by the associated off-site pipeline corridor is in various stages of successional regrowth. An area cleared for hay became fallow in the mid-2010s and has since returned to ruderal floodplain forest. As late as 2020, one small adjoining hayfield was allowed to grow over and is still in scrub shrub. The oldest example of deciduous-forested Dan River floodplain in the Project site is located immediately adjacent to the river. This floodplain appears to have been cleared as recently as the early 1980s, and the current species composition reflects its ruderal condition. The canopy here is occupied by box elder (*Acer negundo*), tulip poplar, sweetgum, sycamore, and river birch (*Betula nigra*). Box elder is also found in the shrub layer along with musclewood and spicebush. Wild ginger (*Asarum canadense*), Virginia wildrye (*Elymus virginicus*), wild chervil (*Chaerophyllum procumbens*), sticky willy (*Galium aparine*), creeping Charlie (*Glechoma hederacea*), Japanese honeysuckle, and Japanese stiltgrass were found in the herbaceous layer here.

2.3.1.4.3 Mixed Evergreen – Deciduous Forest

Mixed evergreen-deciduous forest is not significantly abundant across the Project site and typically occurs in the transitional zones between deciduous forest and naturally vegetated pine stands. Species composition varies depending on aspect and moisture availability. Common canopy species include loblolly, Virginia pine, beech, tulip poplar, red maple, black cherry, and various oak species. In the shrub layer, flowering dogwood, beech, sourwood, musclewood, and Chinese privet were frequently observed. The herbaceous layer is scant as within deciduous and evergreen forests on-site and may include fan clubmoss, strawberry bush, Japanese stiltgrass, muscadine, Japanese honeysuckle, and blueberry and huckleberry species.

2.3.1.4.4 Scrub Shrub

Scrub shrub land cover is found in limited areas within the Project site and is most common in areas recently disturbed and in early stages of natural succession. Ruderal upland scrub shrub

is similar throughout the site and resembles disturbed upland herbaceous vegetation in other areas of the Project site, just at a slightly later successional stage. The shrubs found in this landcover type are composed primarily of younger specimens of the evergreen species found throughout the rest of the Project site. These species include Virginia pine, loblolly pine, and eastern red cedar (*Juniperus virginiana*). A majority of this land cover type is localized in the central area of the Project site, directly south of the southernmost section of the associated off-site pipeline corridor. The common species found in these areas include broomsedge (*Andropogon virginicus*), southern crownbeard (*Verbesina occidentalis*), sericea lespedeza, common dog fennel (*Eupatorium capillifolium*), and sawtooth blackberry (*Rubus argutus*).

A small scrub shrub area is located adjoined to the meteorological tower cleared area to its northeast. The trees in this area were cut down but were left lying in this section of the clearing. At the point of observation, not many herbaceous species were growing in this area, and most plants present were young tree species. These tree species included tulip poplar, loblolly pine, red maple, tree of heaven (*Ailanthus altissima*), and persimmon (*Diospyros virginiana*).

2.3.1.4.5 Herbaceous

Herbaceous land cover is predominantly found in upland areas along powerline corridors, reclaimed landfills, roadsides, and recently cleared portions of the Project site. These dry herbaceous communities can be found in old field conditions, regularly maintained turf, and restored tall grass prairie. Old field is the dominant community found in periodically cleared powerline corridors and revegetated landfills, and species composition varies depending on local soil conditions and recency of disturbance. Some of the frequently occurring species in these areas include common dog fennel, Japanese brome (*Bromus japonicus*), sericea lespedeza, tall fescue (*Lolium arundinaceum*), velvet witchgrass, southern crownbeard, silver plume grass (*Erianthus alopecuroides*), and sawtooth blackberry. Young woody species, like eastern red cedar and loblolly pine, which have established since the last clearing events, were occasionally observed.

An approximately 1.2-ac. (0.49 ha) area of warm season and prairie forb dominated upland grassland was found just south of the transmission line corridor bordering the lake on the east side of the Project site. The species recorded here were uncharacteristic of the other herbaceous areas of the Project site as a whole and are common in prairie restoration seed mixes. Signs of a possible pipeline installation at some point in the recent past were observed and may suggest that these species were seeded following land disturbance in the area to restore habitat. Characteristic species observed include rattlesnake master (*Eryngium yuccifolium*), narrow-pod white wild indigo (*Baptisia albescens*), tall white beardtongue (*Penstemon digitalis*), switchgrass (*Panicum virgatum*), and little bluestem (*Schizachyrium scopparium*). This upland grassland may be particularly meaningful as pollinator habitat given the native wildflowers found there. Other herbaceous areas, such as roadsides and most of the powerline corridor, were more dominated by invasive species with fewer native pollinator plant species.

Regularly mowed upland turf occurs along road margins and developed trailer sites of the Project site. These areas are primarily composed of smooth crab grass (*Digitaria ischaemum*), Carolina lovegrass (*Eragrostis pectinacea*), dallis grass (*Paspalum dilatum*), and sericea lespedeza. In some cases, steeper cleared road embankments have been stabilized with weeping lovegrass (*Eragrostis curvula*) plantings. Other species present on these embankments include Japanese stilt grass, sericea lespedeza, and common dog fennel.

An approximately 25.4-ac. (10.3 ha) area of cleared forest surrounding the meteorological tower was observed near the northernmost area of the Project site. The area most immediately surrounding the tower was primarily composed of grasses and forbs that colonized the bare ground after clearing. This included spreading panic grass (*Panicum dichotomiflorum*), tall fescue, sericea lespedeza and smooth crab grass. The rest of this cleared area was covered with a layer of mulch that has discouraged germination in some areas resulting in a widely varied community of weedy species with no clear dominant species. Species present included Japanese stilt grass, fireweed (*Erechtites hieraciifolius*), jimsonweed (*Datura stramonium*), beaked panic grass (*Coleataenia anceps*), and woolly mullein (*Verbascum thapsus*).

2.3.1.4.6 Woody Wetlands

Within the WOTUS delineation survey area (Figure 2.3-5), woody wetlands were identified and are represented by several different vegetation types, varying by local disturbance, water availability, and soil conditions. Of the 18 total and 3.05 ac. (1.25 ha) of delineated wetland features, 13 features, totaling 1.56 ac. (0.63 ha), were classified as PFO systems (Table 2.3-2). WOTUS-delineated wetlands and features are described in Section 2.3.1.2, including common tree species, sapling and shrub species and herbaceous species observed within PFO features.

One quality woody wetland community that possesses intact structure and a unique plant assemblage was observed within the Project site. This woody wetland (Wetland Y; Figure 2.3-5) was observed in the middle portion of the Project site just north of the canal. This wetland is situated in a mixed forest matrix along the low-grade reach of a small stream which has become partly impounded and flooded a small flat valley. No mature trees were observed rooted in the wetland itself and the woody growth was limited to scattered tag alder and red maple shrubs. Although some species indicative of an intact woody wetland system were observed, including rice cut grass (*Leersia oryzoides*), short-fringed sedge (*Carex crinita*), swamp nettle (*Boehmeria cylindrica*), Virginia bugleweed (*Lycopus virginicus*), and starved aster (*Symphyotrichum lateriflorum*), the presence of quick spreading invasives, especially Japanese stilt grass, have impacted the floristic diversity of this on-site isolated, woody wetland.

2.3.1.4.7 Emergent Herbaceous Wetlands

Emergent herbaceous wetland communities were identified during the WOTUS delineation survey. Of the 18 total delineated wetland features, four features, totaling 1.27 ac. (0.51 ha), were classified as PEM (Table 2.3-2). WOTUS-delineated features can be found in Figure 2.3-5. Information on plant communities in these wetlands is included above in Section 2.3.1.2.2.

Three emergent herbaceous wetland communities were observed in the transmission line corridor and within a human-made detention basin just south of the southern terminus of the associated off-site wastewater pipeline corridor. The human-made detention basin wetland (Wetland VVVV; Figure 2.3-5) was composed primarily of common cattail (*Typha latifolia*), woolgrass, swamp nettle, and common rush extending most of the basin and a fringe of black willow (*Salix nigra*). Wetlands observed in the transmission corridor (Wetlands CCC, T, and U; Figure 2.3-5) had similar species and structures, mostly composed of wetland sedge and rush species and a few obligate wetland forbs. Most of the cover in these wetlands can be attributed to swamp nettle, woodland bulrush (*Scirpus expansus*), black bulrush (*Scirpus atrovirens*), and common rush but includes other characteristic species such as Maryland meadow-beauty (*Rhexia mariana* var. *mariana*) and arrowleaf tearthumb (*Persicaria sagittata*).

2.3.1.5 Important Terrestrial Species

NRC guidance (NUREG-1555 and Regulatory Guide 4.2, Preparation of Environmental Reports for Nuclear Power Stations) identifies important species as those that are:

- Federally listed as threatened or endangered.
- Proposed for or candidates for federal listing.
- State listed or have another state status due to rarity.
- Commercially or recreationally valuable.
- Essential to the maintenance and survival of species that are rare and commercially or recreationally valuable.
- Critical to the structure and function of the local terrestrial ecosystem.
- Serving or may serve as biological indicators to monitor the effects of the facilities on the terrestrial environment.

Duke Energy coordinated with several agencies that provided input on important terrestrial species. Duke Energy initially met with NCWRC on May 21, 2024, and the USFWS on May 23, 2024, to provide an initial overview of planned NRC permitting activities for the Project site. Formal agency coordination letters were sent to the NCWRC on June 14, 2024 and the USFWS on June 19, 2024; the NCNHP on August 20, 2024; and the Catawba Indian Nation on August 20, 2024. USFWS provided comments on July 16, 2024, and expressed concerns about potential impacts to tricolored bat, Schweinitz's sunflower (*Helianthus schweinitzii*), monarch butterfly (*Danaus plexippus*), bald eagles, migratory birds, and pollinators (USFWS, 2024b). NCWRC provided comments on July 26, 2024, about tricolored bat, Schweinitz's sunflower, monarch butterfly, and pollinators (NCWRC, 2024a). NCNHP provided comments on September 30, 2024, regarding queries in the NCNHP database for rare species, important natural communities, natural areas, and conservation/managed areas, identifying some of these within 1 mi. (1.6 km) of the Project boundary (NCNHP, 2024). The Catawba Indian Nation responded on September 24, 2024, but did not have any comments related to important species or other terrestrial ecology assets (Catawba Indian Nation, 2024). Comments received that related to ecological resources are included in Appendix 1A; recommendations related to project activities and operations are provided in Chapters 4 and 5.

Prior to the ecological field surveys, a desktop analysis was performed to identify important species and habitats that may be present in the Project site. As part of the desktop analysis for the ecological surveys, biologists reviewed existing literature including information from the USFWS Information for Planning and Consultation (IPaC) system, NCNHP database records, USFWS NWI, and NLCD. During the pedestrian surveys, any observations of such plant or wildlife species were considered important and the habitat that supports them was noted. A list of protected species potentially occurring within or near the Project site was developed and is presented in Table 2.3-8 and summarized in the following sections. Table 2.3-9 summarizes the important species within or near the Project site.

2.3.1.5.1 Federally Listed Species

The USFWS IPaC identified two terrestrial endangered species: gray bat, Schweinitz's sunflower; one terrestrial proposed endangered species: tricolored bat; one terrestrial threatened species (listed threatened due to similarity of appearance to the northern

population): bog turtle (*Glyptemys muhlenbergii*); and one terrestrial proposed threatened species: monarch butterfly (Table 2.3-8).

Gray bats are federally endangered medium-sized insectivorous bats that occur year-round in limestone karst areas of the southeastern and midwestern U.S. However, summer gray bat colonies have been documented using dams, mines, quarries, concrete box culverts, and the undersides of bridges. Gray bats feed on flying insects (such as mayflies, caddisflies, stoneflies, beetles, and moths) over bodies of water. Gray bat females become pregnant in the spring, and pups are born in late May and early June. Newborns are typically able to fly within 21 to 33 days after birth. Threats to this species include human disturbance to roosting bats, environmental contamination, impoundment of waterways, and roost modification or destruction (USFWS, 2024c). Gray bats were considered absent from the Project site during 2023 acoustic monitoring and were not observed during general wildlife surveys on the Project site (WSP, 2025). Suitable gray bat foraging habitat may be present on the Project site in the form of stream corridors, but no suitable roosting habitat is present on the Project site.

Schweinitz's sunflower is a federally endangered perennial plant found in the central Piedmont region of North and South Carolina. Schweinitz's sunflower is usually approximately 6.6 ft. (2.01 m) tall, but stressed plants (such as those that are mowed) tend to be shorter. Schweinitz's sunflower prefers soils known to be poor for agricultural use with increased rock fragments. This species also prefers soils that are shallow and clayey, with increased quantities of slaty rock from weathered metasedimentary rocks. Appropriate soil types include Iredell, Enon, Badin, Cecil, Misenheimer, Gaston, and Zion. This plant typically occurs on upland flats and gentle slopes where plants are in full to partial sun. Many remaining populations of this plant occur along roadsides. The species blooms from late August to when frost begins. Mowing during the summer in August or September limits seed production if the mowed plants cannot flower or fruit (USFWS, 2024d). Schweinitz's sunflower was not observed on-site but suitable habitat does occur along open roadsides in the low-intensity developed areas in prairie-like conditions through the central portion of the Project site, the transmission corridor, and within open wooded areas near Belews Lake shoreline. Figure 2.3-2 illustrates the Project site landcover, including areas along roadsides, the transmission corridor, and the shoreline. This species main range is concentrated to the south of the Project site in the southern portion of the NC Piedmont and reports of it from Stokes, Forsyth, and Guilford counties are only found in the literature and not supported by collections. Additionally, soil types including Cid, Georgeville, Mecklenburg, Secrest, Tatum, Iredell, Enon, Badin, Cecil, Misenheimer, Gaston, Uwharrie, and Zion that have been documented in association with this species are not found within the Project site.

Tricolored bats are proposed for endangered listing. Tricolored bats are small, insectivorous bats that live across the eastern and central U.S. In the winter, these bats inhabit caves and abandoned mines. In the southern U.S., where caves are sparse, tricolored bats roost in road-associated culverts where torpor is shorter, and they forage during warm nights. Summer roosting habitat for this species consists of a wide variety of forested habitats needed for roosting, foraging, and traveling. Tricolored bats roost in a variety of tree species, especially oaks. They often select roosts in tall, large diameter trees but will roost in smaller diameter trees when potential roost substrate is present. Potential roost substrate includes leaf clusters of live and recently dead deciduous trees, Spanish moss, and beard lichen. Tricolored bats commonly roost in the mid to upper canopy of trees. However, males occasionally roost in dead leaves at lower heights, and females occasionally roost in Spanish moss at lower heights (WSP, 2025). A notable threat to this species is white-nose syndrome, which impacts cave-dwelling bats across the country (USFWS, 2024e). The acoustic bat surveys assumed that the Project site consisted of potentially suitable roosting habitat for the tricolored bat, and the species was documented

during acoustic surveys in 2023 (WSP, 2025). Suitable habitat for this species exists on the Project site in deciduous, evergreen, and mixed forest; as well as woody wetlands (Figure 2.3-8).

Bog turtles are listed in NC (part of the southern population) as threatened due to the similarity of appearance to the northern population. The southern population of this species occurs from southwest Virginia through Georgia, while the other distinct northern population of this species is found in Maryland through New England. Bog turtles live in shallow wetland habitats, and are semiaquatic, spending time in both the water and on land. Preferred wetlands for this species are open-canopy herbaceous sedge bogs, fens, or wet meadows. Microhabitats include soft, muddy bottoms, interspersed wet and dry pockets, vegetation dominated by low-growing grasses or sedges, and a low volume of standing or slow-moving water. Bog turtles hibernate from mid-September through mid-April in more densely vegetated areas under the roots of trees, rock walls, or muskrat burrows. They lay eggs in elevated areas, such as on top of hummock-forming tussock sedge, in approximately May to June, and each nest has approximately three to five eggs. Hatching begins in late August or September (USFWS, 2024f). This species is omnivorous, feeding on worms, beetles, snails, and plants including small berries. Threats to this species include habitat destruction due to draining and filling of wetlands for development, watershed and hydrology changes, vehicles, overabundant predators, and illegal collection (Graeter and Weeks, 2018). The bog turtle was not observed on-site but has the potential to occur within the Project site based on the presence of preferred emergent wetlands in the eastern-central corner of the site.

The federally proposed threatened monarch butterfly occurs across the U.S. Monarch butterflies require milkweed (*Asclepias* spp.) and flowering plants: adults feed on the nectar of a variety of flowers during migration and breeding, but they can only lay eggs on milkweed plants. They migrate in the fall to their overwintering sites and then mate at the overwintering sites in early spring. A specific microclimate is required for overwintering monarchs to protect against the elements and prevent freezing (USFWS, 2024g). This species was not documented during on-site wildlife surveys. Suitable breeding habitat is limited on the Project site: milkweed host plant species were rare in occurrence in the southwest portion of the Project site and along the associated off-site wastewater pipeline corridor during surveys (Figure 2.3-8). Suitable foraging habitat for monarchs exists on the Project site in the form of herbaceous areas, especially the grassland found just south of the transmission line corridor bordering the lake on the east side of the Project site. This area hosts native wildflowers (not including milkweed), while other herbaceous areas are dominated by invasive species.

The USFWS IPaC also identified nine migratory birds of conservation concern that have the potential to occur within the Project site: bald eagle, black-billed cuckoo (*Coccyzus erythropthalmus*), chimney swift, eastern whip-poor-will (*Antrostomus vociferus*), grasshopper sparrow, prairie warbler (*Setophaga discolor*), red-headed woodpecker, rusty blackbird (*Euphagus carolinus*), and wood thrush (*Hylocichla mustelina*). Bald eagles and rusty blackbird are considered important species per the definition provided in NUREG-1555 as both are listed as threatened by the NCA. Bald eagles are discussed in Section 2.3.1.5.2, and rusty blackbirds are discussed in Section 2.3.1.5.3. None of these other migratory birds are considered important species.

2.3.1.5.2 Species Protected under the Bald and Golden Eagle Protection Act

Bald eagles are protected under the Bald and Golden Eagle Protection Act and are listed as state threatened. Bald eagles are found throughout NC. These birds inhabit areas near lakes,

large rivers, and bay shorelines. Nesting requires a tall, living tree, as nests are up to 8 ft. (2.44 m) wide and 20 ft. (6.1 m) deep. Bald eagle pairs often return to the same nest each year and add new nest material, growing the nest over time. Bald eagles consume live and dead fish, water birds, rabbit, and carrion (NCWRC, 2024b). At the BCSS, a bald eagle nest has been identified in the top branches of a red oak, adjacent to the Craig Road Landfill. Protective buffers help shield bald eagle nests from activities that may result in detrimental impacts to breeding and successful production of chicks. The standard buffer distance for bald eagle nests during the nesting season is a 660-foot radius measured out from the base of the nest (Duke Energy, 2023a) (Figure 2.3-7). The BCSS bald eagle nest is approximately 0.23 mi. (0.37 km) west of the Project site (Figure 2.3-8). Other suitable bald eagle nesting habitat exists within the Project site along the shoreline of Belews Lake. Duke Energy has developed a Bald Eagle Nest Management Plan for the BCSS, which details general bald eagle nest disturbance guidelines, activity guidelines during vegetation management, activity guidelines during utility structure or electrical maintenance, and guidelines for removal and beneficiation of coal ash (Duke Energy, 2023a).

2.3.1.5.3 State-Listed Species

Rusty blackbirds nest in remote boreal areas but winter across most of NC. They feed within swamps, bottomlands, wet fields, croplands, or feedlots and are seldom far from wooded cover. This species roosts at night with other blackbirds in swamps and wet thickets. In general, rusty blackbirds are uncommon relative to most other blackbird species in the state. Within the Piedmont, rusty blackbirds are winter residents with noticeable migratory movements and mainly occur between early November and early April (LeGrand et al., 2024a). Rusty blackbirds were not observed on-site but have the potential to occur within the Project site based on the presence of preferred hardwood forest along the shoreline of Belews Lake.

Based on the Project site, the NCNHP did not identify any rare species on the Project site. However, several rare species were identified within 1 mi. (1.61 km) of the Project site and may have potential to occur on the Project site if suitable habitat exists. Coppery emerald (*Somatochlora georgiana*), creeping sunrose (*Crocanthemum propinquum*), granite flatsedge (*Cyperus granitophilus*), and marsh St. John's-wort (*Triadenum tubulosum*) were documented within 1 mi. (1.61 km) of the Project site. Potentially suitable habitat exists on the Project site for coppery emerald and marsh St. John's-wort.

The coppery emerald is NCNHP-designated "significantly rare" dragonfly that occurs in the eastern Piedmont and western two-thirds of the coastal plain within NC. This species inhabits creeks and other slow-moving acidic streams in forested areas. Flight occurs between late June and mid-August. Adults are most often seen flying 30 or more feet above the ground, perched on twigs, or patrolling over streams (LeGrand et al., 2023). Suitable habitat for this species exists on the Project site in the form of perennial streams in forested areas spread around the Project site; however, as discussed below in Section 2.3.2.1.1, streams in the Project site are primarily first order small streams and thus, suitable habitat for the coppery emerald is limited on the Project site.

Marsh St. John's-wort is a NCNHP-designated "significantly rare" plant primarily found in the southeastern states, ranging north to Maryland and Missouri and south to western Florida and eastern Texas. The species is widely scattered in the Piedmont and occurs in shallow water or mud, in non-flowing waters such as pond and lake margins, wooded pools, or old river oxbows. Important habitats are drawdown zones of lakes and river sloughs. Marsh St. John's-wort blooms in August and September and fruits shortly thereafter (LeGrand et al., 2024b). Marsh St.

John's-wort was not observed within the Project site; however, suitable habitat does occur within coves and along low, wetland shorelines of Belews Lake.

Creeping sunrose is a state-listed threatened plant found throughout the Appalachian Mountains and on the northeastern coastal plain and ranges from Massachusetts south to northeastern Georgia and eastern Tennessee. It is also found barely into the western Piedmont in the Sauratown Mountains located in Stokes County. Creeping sunrose grows in high elevations on rocky summits, open and rocky woods, and rarely in fields. The species blooms in June and July and fruits from August to October (LeGrand et al., 2024c). Suitable habitat for this species was not observed on the Project site, and site surveys did not document this species.

Granite flatsedge is state listed as threatened and is found in Virginia and Tennessee south to Georgia and Alabama. This species occurs only within the Piedmont and is localized to granitic flatrocks and to a mafic outcrop in Granville County. It is often found at the edges of granitic flatrocks in moss or lichen mats. Granite flatsedge flowers and fruits in July through October (LeGrand et al., 2024d). Suitable habitat is not located on the Project site, and site surveys did not document this species.

In addition, two plant species considered "watch list" W1 (rare but relatively secure) species by the NCNHP were observed on the Project site. Narrow-pod white wild indigo (*Baptisia albescens*) was found within an approximately 1.2-ac. (0.49 ha) grassland just south of the transmission line corridor bordering the lake on the east side of the Project site. As mentioned above in Section 2.3.1.4.5, species within this area may have been seeded following land disturbance in the area to restore habitat. Aloe yucca (*Yucca aloifolia*), another "watch list" species, was observed in several locations within the Project site around what appeared to be old homesites or otherwise previously developed areas. This species is cultivated as an ornamental and is known to persist after introduction; scattered individuals seen within the Project site are almost certainly in this category.

2.3.1.5.4 Species of Commercial or Recreational Value

Most of the Project site has been leased to a hunt club for several years. Three to five deer are harvested from the Project site annually, usually during a youth hunting event.

White-tailed deer, gray fox, opossum, raccoon, fox squirrel, gray squirrel, striped skunk, and eastern cottontail rabbit are recreationally valuable as game species on the Project site, while coyotes are nongame species hunted in NC. Beaver, opossum, groundhog, striped skunk, coyote, gray fox, and raccoon are recreationally valuable as furbearers on the Project site as listed by NCWRC hunting regulations (NCWRC 2024f).

Wood duck, mallard (*Anas platyrhynchos*), Canada goose, wild turkey, and mourning dove were species observed within the Project site that are recreationally valuable because they are game species as listed by NCWRC hunting regulations (NCWRC, 2024f). Species observed in the Project Vicinity that NCWRC hunting regulations indicate are recreationally valuable as game species (NCWRC, 2024f) include mallard, Canada goose, wild turkey, red-breasted merganser (*Mergus serrator*), and mourning dove.

Although not observed, frogs, most commonly bullfrogs, are nongame species hunted and trapped in NC (NCWRC, 2024f) that are expected within the Project site and Vicinity.

No commercially valuable species, species essential to the maintenance and survival of rare or

commercially or recreationally valuable species, species critical to the structure and function of local ecosystems, or species that could serve as biological indicators of effects on local ecosystems were observed in the Project site.

2.3.1.6 Important Habitats

NRC guidance (NUREG-1555 and Regulatory Guide 4.2) identifies important terrestrial habitats as the following:

- Federally designated or proposed critical habitat.
- Wildlife sanctuaries, refuges, and preserves.
- Wetlands, floodplains, or other resources specifically protected by federal or state regulations.
- Habitats identified by federal or state agencies as unique, rare, or a priority for protection.
- Other habitats of known or indicated interest.

As indicated by a review of the IPaC database, no federally designated or proposed critical habitat for terrestrial species is found on the Project site. Discussion of critical habitat for aquatic species is provided in Section 2.3.2.4.

Wetlands are considered an important terrestrial habitat on the Project site, and discussion is included in Section 2.3.1.2.

As determined by the NCNHP, there are no natural areas documented within a 1-mi. (1.61 km) radius of the Project site. There is one managed area within 1 mi. (1.61 km) of the Project area, which is located south of the Project site along Craig Road. As discussed in Section 2.4.2.6.2, this managed area (Belews Lake Park) is a planned park being developed by Forsyth County and will have trails, fishing piers, a shelter, a playground, and natural areas.

Coordination was initiated with the NCFS on January 23, 2025. The NCFS is planning the development of an Educational State Forest on the Shoebuckle property adjacent to the Dan River, northeast of the Project site. Currently, this Dan River Educational State Forest is unstaffed, but the future goal is to provide educational programs for children and provide hiking trails for the general public.

The only other important habitat of interest within the Project Vicinity is the Knight Brown Nature Preserve, as discussed in Section 2.1.1.2. This preserve contains a wooded valley and two streams.

2.3.1.7 Disease Vector and Pest Species

Disease vectors and pest species on the Project site include disease-carrying wildlife species, nuisance wildlife species, and invasive plant species.

2.3.1.7.1 Disease-Carrying and Nuisance Wildlife Species

The Project site contains potential disease vectors such as ticks and mosquitoes. While there are no known vector-borne diseases resulting from these species reported on the Project site,

ticks may carry diseases. Ticks feed on a wide variety of animals and are most common along trails and feeding and resting areas of their hosts. Dog ticks and lone star ticks can both carry Rocky Mountain Spotted Fever, which causes a skin rash and high fever in humans. Black-legged ticks transmit Lyme disease which initially has flu-like symptoms and a bull's-eye red rash at the bite site. However, Lyme disease can invade the neurological system, cardiovascular system, or joints of the body months or years after the initial bite. Imbedded ticks need 12 to 24 hours to transmit Rocky Mountain Spotted Fever or Lyme disease (Sparks and Gray, 2022).

Other pest wildlife species potentially present on the Project site include bees, fire ants, caterpillars with venomous spines, fleas, and chiggers (Sparks and Gray, 2022).

Nuisance species, such as groundhogs, have been observed on the Project site during surveys. While not observed on the Project site or within the Project Vicinity during surveys, a problematic nuisance species in the state is feral swine. Feral swine cause significant damage to wildlife habitat and plant communities during rooting activities. They prey on native ground nesting birds and white-tailed deer fawns. Feral swine damage crops, landscaping, and cultural sites. They carry a variety of diseases and are considered invasive and undesirable as free-ranging animals in the state (NCWRC, 2024c). Trapping is used on the Project site to remove some nuisance animal species.

2.3.1.7.2 Invasive Plants

Invasive plants in NC have a variety of detrimental effects to the economy, environment, and human health. Invasive species are often spread by humans through such actions as installation of plants as garden ornamentals, erosion control, habitat enhancement, or not cleaning vehicles or equipment when moving from place to place. Invasive plants can displace native vegetation, such as longleaf pine, and this displacement interrupts fire regimes and modifies soil characteristics. Invasive plants can also change the landscape (NC-IPC, 2024).

Invasion from non-native vascular plant species is extensive and problematic across much of the Project site. Especially problematic species on-site include Chinese wisteria (*Wisteria sinensis*), Chinese privet (*Ligustrum sinense*), Japanese stiltgrass (*Microstegium vimineum*), Japanese honeysuckle (*Lonicera japonica*), and sericea lespedeza (*Lespedeza cuneata*). The North Carolina Invasive Plant Council (NC-IPC) has compiled a list of invasive plants that occur in the state with input from representatives of the NCNHP, U.S. Department of Agriculture Forest Service, North Carolina Botanical Garden, North Carolina Department of Agriculture and Consumer Services, Piedmont Land Conservancy, North Carolina Native Plant Society, and other groups and individuals (NC-IPC, 2023). A number of plants on this list have been documented on the Project site during plant surveys:

- **Rank 1 – Severe Threat:** Exotic plant species that have invasive characteristics and spread rapidly into native plant communities, displacing native vegetation. Plants within this group include some of the most problematic on the Project site, which are denoted with an asterisk. The following species occur in the tree, shrub, herbaceous, and woody vine strata on the Project site:

  Tree of heaven (*Ailanthus altissima*)

  Silktree (*Albizia julibrissin*)

  Sericea lespedeza*

Chinese privet*

Japanese honeysuckle*

Japanese stiltgrass*

Chinese silver grass

Princess tree (*Paulownia tomentosa*)

Bradford pear (*Pyrus calleryana*)

Multiflora rose (*Rosa multiflora*)

Chinese wisteria*

**These are considered some of the most problematic on the Project site*

- **Rank 2 – Significant Threat:** Exotic plant species that display some invasive characteristics, but do not appear to present as great a threat to native communities as the species listed in Rank 1. The following species within this category were observed in the herbaceous or shrub stratum across the Project site and are overall rare or uncommon:

  Field garlic (*Allium vineale*)

  Creeping Charlie

  Leatherleaf mahonia (*Mahonia bealei*)

  Beefsteak plant (*Perilla frutescens*)

  Longbristle smartweed (*Persicaria longiseta*)

  Common chickweed (*Stellaria media*)

- **Rank 3 – Lesser Threat:** Exotic plant species that spread into or around disturbed areas and are considered a low threat to native plant communities. The following species from this category were observed in the herbaceous stratum across the Project site and are overall rare or uncommon:

  Japanese brome

  Bull thistle (*Cirsium vulgare*)

  Korean lespedeza (*Kummerowia stipulacea*)

  Dallis grass

  Yellow foxtail (*Setaria pumila*) – also on the NC Noxious Weed List

- **Watch List A:** Exotic plants that naturalize and may become problematic in the future; includes species that are or could become widespread in NC. At this time, more information is needed. The species listed below were observed in the herbaceous stratum across the Project site and are overall rare:

  Weeping lovegrass (*Eragrostis curvula*)

  Tall fescue

  Woolly mullein (*Verbascum thapsus*)

- **Watch List B:** Exotic plant species that cause problems in adjacent states but have not yet been reported to cause problems in NC. No plants documented on-site are within this group.

No plants on the federal noxious weed list were documented on the Project site. Yellow foxtail, as noted above, is on the NC Noxious Weed List and was documented on the Project site, though it was limited in location.

2.3.1.8 Wildlife Travel Corridors

The peninsula on which the Project site is located is a travel corridor for mobile wildlife species moving through different habitats as well as traveling to Belews Lake in search of water. The man-made canal in the middle of the Project site interrupts this corridor, although wildlife that can swim could travel across. Tracks of wildlife species, such as white-tailed deer, raccoon, opossum, and coyote, were observed throughout much of the Project site during the seasonal field surveys. These common species do not appear to be impacted by the current level of human and industrial activities occurring near the site. These mobile species and others observed on-site, such as eastern cottontail, groundhog, gray fox, gray squirrel, and fox squirrel (and other terrestrial mammals not observed but likely to occur such as rodents), collectively create and use travel corridors across various on-site biotic communities and to and from adjacent properties. White-tailed deer typically establish the longest and most complex travel corridors. Other species may use portions of these regularly traveled trails.

The Project site is located within the Atlantic Flyway migration route, which up to 500 different species of birds use for migration. Birds use this migration route from late July through early December to travel from Greenland to the Caribbean, and Central and South America to overwinter. In the Piedmont, fall migration is most active during September and October (Craps, 2023).

2.3.1.9 Existing Ecological Effects and Environmental Stresses

As mentioned in Section 2.3.1.1, the Project site has been shaped by timber harvesting, wildfires, and non-native plant invasion. Most of the native pine in the Project area was harvested 20 to 30 years ago and replanted with loblolly pine. Areas currently characterized by herbaceous, scrub shrub, and evergreen land cover comprise the most disturbed portions of the Project site and represent consistently cleared lands, newly regenerated formerly cleared lands, and lands which have remained in pine plantation or naturally regenerated back into pine from logged pine plantations.

Two wildfires occurred in 2024 in the Project Vicinity (Figure 2.3-9). The Steam Station Fire occurred on the western part of the Project site on March 20, 2024. The cause of the fire was most likely a worker smoking behind a warehouse, igniting ground material that was adjacent to pallets. The pallets caught on fire and then ignited nearby pine trees. High winds caused the burning materials to be carried across a small cove of the lake to ignite the woods. Approximately Fifty-four ac. (21.9 ha) of timber burned, and the fire was contained within 3 hours of attack. The Belews Lake Big Island Fire occurred on an island on Belews Lake north of the Project site on July 5, 2024. The cause of the fire was an unattended campfire, but only approximately 0.17 ac. (0.07 ha) of hardwood litter burned. The fire was contained within less than an hour of attack.

In addition to fire and timber harvesting, non-native plant invasion has also shaped the Project site. As discussed above in Section 2.3.1.7, the Project site contains a variety of invasive species. Chemicals and prescribed burns are used to manage nuisance plant species (such as wisteria, Japanese stiltgrass, or privet) annually throughout the Project site.

2.3.1.10 Transmission Corridor Habitats and Species

As discussed in Section 1.1.4, additional transmission lines that extend outside of the existing Project site boundary are not required. As described in Section 3.2, transmission improvements within the existing site boundary include a new switchyard and other transmission line improvements. Because these improvements are located within the site boundary, discussion of habitats and species within transmission corridors is included in previous sections of Section 2.3.1.

2.3.2 AQUATIC ECOLOGY

Potentially affected aquatic resources include any reservoirs, ponds, lakes, rivers, and streams on the Project site and in the Project Vicinity. Wetlands and riparian habitats are discussed in conjunction with terrestrial ecology in Section 2.3.1. This section describes the ecological characteristics of the aquatic resources that the Project could affect.

2.3.2.1 Aquatic Habitats

Surface water features present on the Project site and in the Project Vicinity are described in Section 2.2.1 and are shown on Figure 2.2-2. Aquatic habitats with the potential to be affected by the Project include on-site streams and ponds, Belews Lake, and the Dan River. The ecological characteristics of these potentially affected waterbodies are described below.

2.3.2.1.1 On-site Streams

There are approximately 21,733 lineal ft. (6,624 m) of streams on the Project site. On-site streams are characterized as primarily first order streams that are predominately located within forested areas and drain to Belews Lake. These low-flow streams are characterized as having silt to clay substrates, high levels of biological debris (i.e., leaf and woody debris), and generally little to no aquatic vegetation within the stream channel. Most of the on-site streams are characterized by a relatively high gradient. Additional information regarding on-site stream hydrology and physical characteristics is provided in Section 2.2.1.

2.3.2.1.2 Belews Lake

Belews Lake is the primary surface water feature supporting aquatic habitats within the Project Vicinity. Belews Lake is a reservoir constructed principally as a cooling water source for the BCSS and consists of distinct areas that are important in the characterization of aquatic ecosystems. These areas relate to tributaries (i.e., West Belews Creek, Belews Creek, and East Belews Creek) and their proximity to the Belews Dam. The term “uplake” is used to refer to the area nearest the tributary headwaters and the term “downlake” is the area nearest the dam. A transitional “midlake” area encompasses the area between the uplake and downlake areas on the Belews Creek arm (Duke Energy, 2021).

West Belews Creek receives heated effluent from the BCSS once-through CCW system. This area is physically separated from the remainder of Belews Lake, except for a 0.9 mi (1.5 km), man-made canal that facilitates the return of heated CCW effluent to the main Belews Creek arm (Figure 2.2-3). A forced circulation pattern is induced in Belews Lake by the operation of the combined 2337.8-ft.^{3}/s (66.2-m^3/s) capacity BCSS CCW pumps, which significantly exceed typical tributary inflow rates. Station pumping effectively maintains a circulation pattern within the epilimnion of the downlake region, particularly during the thermally stratified portion of the

year. Areas near Belews Dam and East Belews Creek lie within the outer areas of the thermal plume (Duke Energy, 2021).

The shoreline of Belews Lake is mostly steep and consists of undeveloped forest with sparse residential development. Habitat formers in the reservoir are primarily made up of sparse aquatic plant communities, including those classified as submerged, floating leaf, free-floating, and emergent. Highly vegetated zones are located in the upper reaches of the arms of Belews Lake. These areas are characterized by relatively shallow water and an expansive littoral zone that is suitable for aquatic plant growth; conversely, poorly vegetated zones are located in the more expansive deepwater portions of the reservoir with less shallow water suitable for aquatic plant growth. Much of the nutrient load from the watershed is also sequestered in the upper reaches of the lake resulting in an in-lake productivity gradient from uplake to downlake areas (Duke Energy, 2021). Large woody debris from the surrounding riparian areas provides some additional aquatic habitat in the reservoir.

A more detailed description of the characteristics of surface water features present on the Project site and in the Project Vicinity is presented in Section 2.2.1. Such information includes Belews Lake bathymetric maps and information regarding on-site stream gradients and stream cross sections.

2.3.2.1.3 Dan River and Belews Creek

Belews Creek is a 1-mi (1.6 km) tributary that flows to the Dan River from the Belews Lake Dam, as described in Section 2.2.1. The creek channel is an excavated feature immediately downstream of the Belews Lake spillway that extends downstream to its confluence with the original Belews Creek channel. Aquatic habitats in Belews Creek are characterized upstream by rocky substrate, while downstream, near the confluence with the Dan River, substrate is characterized by sand and cobble, with smaller substrates (silt, clay) near the shorelines.

The Dan River lies within the Roanoke River basin. The Dan River is approximately 110 mi. (177 km) long and flows from along the NC and Virginia border until its confluence with the Roanoke River. Habitat within the Dan River includes a series of riffle-run complexes typical of a Piedmont River system. Substrates are variable and consist of bedrock, gravel, sand, and woody debris. Shorelines are comprised by patches of mud and woody debris. The water clarity is variable based on location and antecedent rainfall conditions and ranges from clear to turbid (Duke Energy, 2024a). Downstream of the confluence with Belews Creek, habitats are characterized by sand and cobble bars, with increased presence of boulders shallow riffles. A more detailed description of surface water features present on the Project site and in the Project Vicinity can be found in Section 2.2.1.

2.3.2.2 Aquatic Biota

This section characterizes the aquatic biota found on the Project site and in the Project Vicinity within the aquatic habitats described in Section 2.3.2.1.

2.3.2.2.1 On-site Streams

Aquatic biota in on-site streams were characterized during seasonal surveys in 2024. Macroinvertebrates were surveyed in spring and fall 2024. On-site streams were sampled using USEPA's Benthic Macroinvertebrate Protocols (USEPA, 2012a). Locations sampled are indicated in Figure 2.3-10. In spring 2024 sampling, 1,049 individual macroinvertebrates were

encountered in on-site streams (Table 2.3-10). A total of distinct 74 macroinvertebrate taxa were observed within streams on the Project site. The most abundant taxa on the Project site included a bivalve (*Pisidium* sp.) and a chironomid, (*Polypedilum* sp.). Over 53 percent of macroinvertebrate individuals captured in on-site streams were classified as midges (Chironomids). In fall 2024 sampling, 65 distinct taxa were observed on the Project site (Table 2.3-11). The most abundant taxa on the Project site in the fall were bivalves (*Pisidium* sp.) and snails (*Physa* sp.). In fall sampling, midges only accounted for 22 percent of the total individuals observed. In general, across spring and fall sampling, the presence of pollutant tolerant taxa (i.e., Dipterans) and the low numbers of pollution intolerant taxa (i.e., mayflies [Ephemeroptera]), indicates lower overall water and habitat quality in on-site streams. This may be attributed to the intermittent nature of many on-site stream sampling locations.

Streams were surveyed for fish in the spring, summer, and fall of 2024. Sampling methodologies included backpack electrofishing and seining at on-site sampling locations indicated in Figure 2.3-10. Fish species observed in seasonal sampling are presented in Table 2.3-12. Fish were only observed in four of the six sampled streams on-site. Fish species observed in on-site streams included Eastern Mosquitofish (*Gambusia holbrooki*), Redbreast Sunfish (*Lepomis auritus*), Redear Sunfish (*Lepomis microlophus*), and Bluegill (*Lepomis macrochirus*). Eastern Mosquitofish accounted for 98.9 percent, 97.2 percent, and 96.9 percent of all fish encountered in spring, summer, and fall sampling, respectively. Low fish diversity is attributed to the small size and intermittent nature of many of the on-site streams that are connected to Belews Lake. It is unlikely that there are self-sustaining populations of fishes in on-site streams as fish were only observed near Belews Lake.

2.3.2.2.2 Belews Lake

2.3.2.2.2.1 Macrophytes

Past surveys of aquatic macrophytes in Belews Lake revealed limited growth of submersed and floating leaf aquatic plants. Several locations with varying densities of emergent plants were identified. Relative density of macrophytes in Belews Lake is presented in Figure 2.3-11. The most dominant aquatic plant species was water willow (*Justicia americana*), which was found in each zone of Belews Lake. Other common species included arrowhead (*Sagittaria lancifolia*), arrow-arum (*Peltandra virginica*), button bush (*Cephalanthus occidentalis*), bulrush (*Scirpus* sp.), and umbrella sedge (*Cyperus* sp.). Isolated populations of swamp rose mallow (*Hibiscus moscheutos*), cattail (*Typha* sp.), giant cutgrass (*Zizaniopsis miliacea*), and giant reed (*Arundo donax*) were also identified (Duke Energy, 2021). Aquatic macrophyte density was greatest in the uplake, shallower portions of the reservoir, whereas deeper portions of the reservoir support a reduced density of aquatic macrophyte (Duke Energy, 2021).

2.3.2.2.2.2 Benthic Macroinvertebrates

Benthic macroinvertebrate populations were surveyed in 2011–2015 by Duke Energy as a part of an assessment of the aquatic populations within Belews Lake. Mean annual macroinvertebrate densities ranged from 1325 individuals per square meter in 2013 to 13,457 individuals per square meter in 2011 within the lake. The total number of taxa observed per year varied from 17 to 37 during the 5-year study. During 2011 to 2015, macroinvertebrate samples were comprised primarily of annelid worms (Oligochaeta) and flies and midges (Diptera) at all locations surveyed. Roundworms (Nematoda) and Asiatic clams (*Corbicula* sp.) were abundant in some locations surveyed. Low numbers of the burrowing mayfly (*Hexagenia* sp.*)* were observed during spring and summer sampling periods.

2.3.2.2.2.3 Mussels

A qualitative mussel survey within Belews Lake was conducted by Duke Energy in August 2020. Two species of freshwater mussels were documented in 2020 surveys: Eastern Elliptio (*Elliptio complanata*) and the Paper Pondshell (*Utterbackia imbecillis*). Eastern Elliptio was the most abundant mussel species encountered, representing 99.6 percent of the 4036 mussels collected (Duke Energy, 2021). Young individuals of Eastern Elliptio were observed, indicating that recruitment occurs in this system, and that suitable habitat conditions for this species are present in Belews Lake (Duke Energy, 2021). One non-native bivalve species, the Asiatic Clam (*Corbicula fluminea*) is present in the lake, with areas of comparatively high densities present (Duke Energy, 2016). The low diversity of mussel communities in Belews Lake is expected as mussel communities in reservoirs tend to reflect changes in substrate, with species shifts from those that prefer sand or gravel substrate to those species that are tolerant of silt substrate, primarily as a shift from lotic to lentic condition, with considerable loss of original mussel fauna (Watters, 1999). Hydraulics (Watters, 1999) and host fish also play important roles in mussel fauna distributions (Daniel, W. and Brown, K., 2013).

2.3.2.2.2.4 Fish

A fish community assessment was conducted in Belews Lake in 2020 as a part of Duke Energy's Balanced and Indigenous Community Study Report (Duke Energy, 2021). Sample methods included electrofishing and experimental gill netting in Belews Lake. Fish species collected during the 2020 survey in Belews Lake are shown in Table 2.3-13. Twenty-four distinct species and one hybrid were encountered in the 2020 quarterly sampling of Belews Lake. The most abundant species in electrofishing was Bluegill. and the species with the highest biomass in sampling was Alabama Bass (*Micropterus henshalli*). Catch rates were higher in areas of Belews Lake with higher nutrient levels (i.e., uplake areas). Areas with higher thermal influences (i.e., West Belews Creek arm) did not exhibit catch rates outside of that which would be expected based on nutrient levels present in those areas (Duke Energy, 2021). Largemouth Bass (*Micropterus nigricans*) catch-per-unit-effort (CPUE) was lower in the deeper, clearer portions of the reservoir where they have likely been displaced by Alabama Bass through congeneric competition (Duke Energy, 2021).

Species diversity was similar in all areas of the lake, regardless of thermal influence. The fish community was dominated by indigenous species (73 percent). While non-indigenous species such as Alabama Bass and Redear Sunfish were abundant in areas of the lake that were thermally influenced by operation of the BCSS, these species were found throughout Belews Lake. Some indigenous species, such as Largemouth Bass, exhibited lower CPUE in 2020 than had been observed in historical surveys of Belews Lake, but this change was not related to operation of BCSS (Duke Energy, 2021). Fish communities included multiple trophic guilds. No areas of the lake were dominated by pollution-tolerant species. The overall size-structure of the fish community indicated reproductive, self-sustaining populations in all areas of the Belews Lake. No threatened or endangered species were encountered in Belews Lake during 2020 quarterly sampling (Duke Energy, 2021).

Thermal impacts from BCSS were found to be more pronounced in summer and winter than in fall or spring. The overall mean catch rate was significantly higher in the areas of the lake that were subject to thermal influence from BCSS operation. Some apparent patterns in distribution seemed to be impacted by natural seasonal temperature and nutrient variations. For example, Gizzard Shad (*Dorosoma cepedianum*) catch varied across zones of the lake depending on

season. Additionally, vertical distribution of fish varied throughout the year indicating seasonal changes in optimal habitats and forage throughout the water column (Duke Energy, 2021).

2.3.2.2.2.5 Summary of Belews Lake Aquatic Community

In general, recent monitoring on Belews Lake reflected the presence of a balanced and indigenous aquatic biological community. The presence of macrophytes was limited to shallower areas of the reservoir. Benthic macroinvertebrate communities were dominated by pollution-tolerant species; however, the presence of pollution intolerant mayflies in spring and summer were indicators of moderate to good water quality. The fish community was characterized by multiple trophic guilds, with a size-structure that indicated reproductive, self-sustaining populations.

2.3.2.2.3 Dan River and Belews Creek

2.3.2.2.3.1 Benthic Macroinvertebrates

Benthic macroinvertebrates were sampled in conjunction with the preapplication monitoring program, in the Dan River in spring and fall 2024. Sampling occurred at four locations, as indicated in Figure 2.3-10. Sampling methodology included D net sampling of overhanging vegetation, root wads, benthic substrate, and other appropriate macroinvertebrate habitat, as determined by field personnel.

Macroinvertebrates encountered in spring 2024 sampling in the Dan River are listed in Table 2.3-10. In spring 2024 macroinvertebrate sampling, 69 distinct taxa were observed in the Dan River. The most abundant taxa in the Dan River included a mayfly (*Pseudocloen* sp.), a chironomid (*Polypedilum* sp.), and an annelid worm (Naididae [Tubificidae] spp.). In spring sampling, 29 percent of the individuals captured belonged to the order Ephemeroptera (mayflies), which are, in general, pollutant intolerant and therefore indicators of good water quality. Five stonefly (Plecoptera) individuals were captured in the Dan River, while no caddisfly (Trichoptera) individuals were observed in the Dan River. Dragonflies (Odonata) accounted for approximately 1.5 percent of individuals captured in the Dan River. Diversity within flies and midges (Diptera) was high, with 25 taxa observed within this order.

Macroinvertebrates encountered in fall 2024 sampling in the Dan River are listed in Table 2.3-11. In fall 2024 macroinvertebrate sampling, a total of 86 distinct taxa were observed in the Dan River. The most abundant taxa included flathead mayfly (*Maccaffertium* sp.) and two chironomids (*Polypedilum* sp. and *Tanytarsus* sp.). Pollution intolerant taxa accounted for 28 percent of the total individuals observed in the Dan River in fall sampling, indicating generally good water quality.

2.3.2.2.3.2 Mussels

A mussel survey was conducted in the Dan River in 2014 near Eden, NC downstream of the Project site (Alderman and Alderman, 2014). The 2014 survey consisted of 3-mi. survey reaches throughout the Dan River subbasin, including the reach of the Dan River within the Project Vicinity. Freshwater mussels were collected via visual and tactile survey methods using bathyscopes, snorkeling, and SCUBA, and the widest possible diversity of habitats was surveyed at each site. Nine species of freshwater mussels were identified as extant within the survey area on the Dan River. These species included common Eastern Elliptio, Variable Spike (*Elliptio icterina*), Carolina Lance (*Elliptio angustata*), Roanoke Slabshell (*Elliptio roanokensis*),

Atlantic Pigtoe (*Fusconaia masoni*), Triangle Floater (*Alasmidonta undulata*), Green Floater (*Lasmigona subviridis*), Notched Rainbow (*Villosa constricta*), and Yellow Lampmussel (*Lampsilis cariosa*) (Alderman and Alderman, 2014).

In conjunction with the preapplication monitoring program, an additional mussel survey was conducted on July 31 and August 1, 2024, in the Dan River. A total of three species of freshwater mussels were observed in the four sites (Figure 2.3-10). No mussels were observed at the most upstream sampling location (DRSW1). Mussel species observed at the other three locations included Eastern Elliptio, Green Floater, and Notched Rainbow (represented by only a shell) (Duke Energy, 2024a). Mussels were most abundant at the downstream sampling locations (DRSW4). In general, mussel habitats at the survey locations were dominated by excessive amounts of sand, but patches of suitable mussel habitat were present. Substrate at the upstream sampling location (DRSW1) consisted of bedrock and sand, with excessive amounts of woody debris. Substrate at sites DRSW2 and DRSW3 consisted of sand and gravel with patches of mud along the shoreline. At DRSW4, benthic habitat was dominated by sand and gravel, with woody debris present along the shoreline (Duke Energy, 2024a). In general, mussel habitat was limited at the sampling locations upstream of the BCSS MWIS (i.e., DRSW1 and DRSW2), while at and below the pump station (i.e., DRSW3 and DRSW4), mussel habitat was more widespread.

See Section 2.3.2.3 for additional discussion regarding sensitive mussel species within the Dan River.

2.3.2.2.3.3 Fish

Fisheries surveys on the Dan River were conducted from 2015 to 2017 by Duke Energy upstream and downstream of the BCSS MWIS (HDR, 2022). This MWIS is located at the confluence of Belews Creek and the Dan River. Survey methodologies included boat electrofishing, backpack electrofishing, fyke netting, and seining at two transects. The upstream sampling location was located north of Walnut Cove, NC, at river mi. (RM) 130. The downstream sampling location was located near Leaksville, NC, at RM 93. Species captured during Dan River sampling from 2015 to 2017 are shown in Table 2.3-14 (HDR, 2022).

At the upstream sampling location, 36 fish species representing six families were collected. Four families made up 96.6 percent of the total number collected: Cyprinidae (comprised of Cyprinidae and Leuciscidae) (49.1 percent); Centrarchidae (18.5 percent); Ictaluridae (17.4 percent); and Catostomidae (11.6 percent). Cyprinids (comprised of Cyprinidae and Leuciscidae) collected included ten species. The most dominant cyprinid species were White Shiner (*Luxilus albeolus*) and Bull Chub (*Nocomis raneyi*). Five species of centrarchids were collected, with Redbreast Sunfish as the most numerous species collected. The catfish family (Ictaluridae) was the third most abundant family. Snail Bullhead (*Ameiurus brunneus*) made up 62.3 percent of the catfish species collected. The Catostomidae family (suckers) consisted of nine species with Blacktip Jumprock (*Moxostoma cervinum*) and Golden Redhorse (*M. erythrurum*) as the most abundant species (HDR, 2022).

At the downstream sampling location, 39 fish taxa representing five families were collected. The most abundant family was Catostomidae (39.8 percent) with Golden Redhorse and V-Lip Redhorse (*Moxostoma pappillosum*) as the most abundant sucker species collected. The Centrarchidae family (37.0 percent) was the second most abundant family, with Redbreast Sunfish as the most abundant, followed by Largemouth Bass. The Cyprinidae family (comprised of Cyprinidae and Leuciscidae) (19.2 percent) was the third most abundant family collected with

White Shiner and Comely Shiner (*Notropis amoenus*) as the most abundant species collected (HDR, 2022).

In conjunction with the preapplication monitoring program, seasonal surveys were conducted on the Dan River in 2024 to characterize the aquatic resources. Surveys were conducted in spring, summer, and fall 2024. Sampling methodology included boat electrofishing, backpack electrofishing, and seining. Sampling locations are indicated in Figure 2.3-10. Fish species collected during quarterly sampling in 2024 are shown in Tables 2.3-15 through 2.3-17.

In spring 2024, 34 fish species and one hybrid were observed during fish surveys. A total of 719 fish were observed with abundant species including White Shiner (n=180), Redbreast Sunfish (n=131), and Golden Redhorse (n=62). A summary of fish species observed in the spring 2024 survey is shown in Table 2.3-15. Game fish observed in the spring 2024 survey include Smallmouth Bass (*Micropterus dolomieu*), Largemouth Bass, Bluegill, Redbreast Sunfish, Green Sunfish (*Lepomis cyanellus*), Redear Sunfish, Warmouth (*Lepomis gulosus*), and Black Crappie (*Pomoxis nigromaculatus*). Abundant Leuciscids (i.e., minnows and shiners) included White Shiner, Comely Shiner, Bull Chub (*Nocomis raneyi*), Satinfin Shiner (*Cyprinella analostana*), Redlip Shiner (*Hydrophlox chiliticus*), and Rosefin Shiner (*Lythrurus ardens*). Catastomids (i.e., suckers) were also abundant, with the most abundant species being Golden Redhorse, V-Lip Redhorse, and White Sucker (*Catostomus commersonii*).

A summary of fish species observed in summer surveys is shown in Table 2.3-16. within the Dan River, water levels precluded boat electrofishing at most sites; therefore, boat electrofishing was only employed in one location, DRSW3, while other locations were sampled via backpack electrofishing. Seining was conducted at each location. In the summer 2024 survey, 975 individual fish of 32 distinct species were observed in Dan River. Abundant species observed included Comely Shiner, Redlip Shiner, and Rosefin Shiner. Game fish observed included Largemouth Bass, Smallmouth Bass, Bluegill, Redbreast Sunfish, Green Sunfish, Redear Sunfish, Warmouth, and Black Crappie. Abundant Catastomids (i.e., suckers) included Golden Redhorse and V-Lip Redhorse. The most abundant Ictalurid (i.e., catfishes) was the Margined Madtom (*Noturus insignis*).

A summary of fish species observed in the fall survey are shown in Table 2.3-17. In Dan River, water levels precluded boat electrofishing at all locations. All sites were therefore sampled using backpack electrofishing. Seining was conducted at each location. As the sampling crew were unable to access DRSW4 at the time of the fall aquatic ecology survey, an alternative sampling location (DRSW4-ALT) was identified and sampled. This downstream alternate sampling location was comprised of similar aquatic habitat as those samples at DRSW4 (i.e., riffles and runs). A total of 93 fish of 14 distinct species were observed in Dan River in the fall 2024 survey. Abundant species observed included Comely Shiner and Redbreast Sunfish. The only Catastomid (sucker) observed was Blacktip Jumprock (*Moxostoma cervinum*). Low numbers of observed fish taxa in fall 2024 surveys may be related to sedimentation related to recent flooding associated with Hurricane Helene in September 2024. Game fish observed included Redbreast Sunfish and Bluegill. One non-native species, Goldfish (*Carassius auratus*), was observed at DRSW2.

2.3.2.2.3.4 Summary of Dan River Aquatic Community

In general, recent monitoring of the Dan River suggests the presence of a diverse macroinvertebrate and fisheries community. Macroinvertebrate sampling observed a high presence of pollution intolerant taxa, which serves as an indicator of good water quality (e.g.,

low pollution). High diversity was observed in the Dan River fish community that reflects the presence of a variety of habitat and substrate types throughout the reach in the Project Vicinity. Further, the presence of sensitive species, as described in Section 2.3.2.3 indicates suitable fish conditions for these sensitive species that may include good water quality, suitable foraging, low pollutant loads, and a variety of substrate/habitat types within the Dan River. The mussel community present in Dan River in the Project Vicinity indicates conditions that are conducive to mussel community presence.

2.3.2.3 Important Aquatic Species

According to NUREG-1555, important species may include:

- Rare species, including:
  - Species federally listed as threatened or endangered.
  - Species that are proposed for federal listing.
  - Species that are candidates for federal listing.
  - Species that are state listed as threatened, endangered, or a species of concern.
  - Commercially or recreationally valuable species.
  - Species that are essential to the maintenance and survival of rare or commercially or recreationally valuable species.
  - Species that are critical to the structure and function of the local ecosystem.
  - Species that may serve as biological indicators to monitor the effects of the proposed facility on the environment.
  - Nuisance species that could cause problems for facility operations (as described in Section 2.3.2.6).

2.3.2.3.1 Federally Listed Species

Federally listed aquatic species that may occur on the Project site or in the Project Vicinity include James Spinymussel (*Parvaspina collina*), and Green Floater (Table 2.3-8).

The federally endangered mussel, James Spinymussel, may potentially be present in the Project Vicinity. James Spinymussel is found in the James River basin in Virginia and West Virginia and in the Upper Dan River subbasin of the Roanoke River basin in Virginia and NC. Suitable habitat for James Spinymussel includes free-flowing streams with a variety of flow regimes and water depths. These mussels are typically found in areas with substrate that is free from silt. James spinymussel filter feed on plankton collected from flowing water passed over the gills (USFWS, 2024h). No critical habitat has been designated for James Spinymussel.

Green Floater is a federally proposed threatened mussel species. Habitat for Green Floater consists of small streams and rivers with low-to-moderate gradients in pools and eddies with gravelly and sandy bottoms. Host fish for the larval life stage of this species include Mottled Sculpin (*Cottus bairdii*), Rock Bass (*Ambloplites rupestris*), Central Stoneroller (*Campostoma anomalum*), Blacknose Dace (*Rhinichthys atratulus*), and Margined Madtom. Adults are filter feeders that consume phytoplankton, zooplankton, bacteria, and suspended detritus. Green Floater is found in small and isolated populations with limited recruitment, resulting in reduced genetic variation and increased risk of localized extirpation. Threats to this species include

dams and water withdrawals, invasive species, sedimentation, impacts to water quality, and habitat loss due to climate change (NatureServe, 2024a). As described in Section 2.3.2.2.3.2, Green Floater has been documented within the Dan River in the Project Vicinity. Additionally, critical habitat for this species has been proposed within the Project Vicinity and is described in Section 2.3.2.4.

2.3.2.3.2 State-Listed Species

The NCNHP provides records showing locations where rare species have been observed to occur within the Project Vicinity. Such records indicate observation within the Project Vicinity of one freshwater bivalve and four freshwater fish. The freshwater bivalve is Green Floater, which is state listed as endangered, and federally proposed as threatened. Green Floater is described in Section 2.3.2.3.1. The four state-listed fish species that have the potential to occur within the Project Vicinity are Quillback (*Carpiodes cyprinus*), Riverweed Darter (*Etheostoma podostemone*), Bigeye Jumprock (*Moxostoma ariommum*), and Roanoke Logperch (*Percina rex*) (Table 2.3-8). Roanoke logperch is state listed as endangered and was recently delisted from the Endangered Species Act. Bigeye Jumprock is state listed as threatened, while Quillback and Riverweed Darter are listed as significantly rare species.

The Roanoke Logperch is a state-endangered darter found in larger streams in the upper Roanoke, Smith, Pigg, Otter, and Nottoway River systems, and Goose Creek in Virginia, and in the Dan, Mayo, and Smith River systems and Big Beaver Island Creek in NC. It is a large darter that can grow up to six inches. Habitat for this species includes medium-to-large, warm, usually clear streams and small rivers of moderate-to-low gradient. Adults are typically found in the main body of stream pools, runs, and riffles, and areas with exposed, silt-free gravel substrate. Roanoke Logperch actively feed in warmer months by flipping over stones with their snout and ingesting the exposed prey that consists of bottom-dwelling macroinvertebrates (USFWS, 2024c). Roanoke Logperch have been visually observed in the Dan River in the Project Vicinity.

Bigeye Jumprock is found only in the upper Roanoke River drainage in NC and Virginia. This species is found in warm, generally clear small to medium rivers. They typically congregate in deep runs and heads of pools in rubbles and boulders. Potential threats to populations include impoundments, siltation and runoff, and habitat fragmentation (NatureServe, 2024b). A total of four Bigeye Jumprock were encountered in the Dan River during spring 2024 aquatic ecology surveys.

Quillback are found across eastern North America. They inhabit pools, backwaters, and main channels of creeks and small to large rivers, as well as lakes. They primarily feed on benthic materials such as plant detritus, and invertebrates, including insects, mollusks, and crustaceans (FishBase, 2024a). A total of two Quillback were encountered in the Dan River during spring 2024 aquatic ecology surveys.

Riverweed Darter is a state-listed species in NC identified as a significantly rare species. They occur only in the upper Roanoke River drainage in Virginia and NC. Primary habitat for riverweed darter are rocky riffles in creeks and small rivers (FishBase, 2024b). Thirteen Riverweed Darters were encountered in the Dan River during the spring 2024 aquatic ecology survey, and eight were encountered during the summer 2024 survey.

2.3.2.3.3 Species of Commercial or Recreational Value

Recreationally important species in Belews Lake include Alabama Bass (*Micropterus henshalli*), Black Crappie, Bluegill, Largemouth Bass, Warmouth, Redbreast Sunfish, Redear Sunfish, White Crappie (*Pomoxis annularis*), Common Carp (*Cyprinus carpio*), Blue Catfish (*Ictalurus furcatus*), Flathead Catfish (*Pylodictis olivaris*), Channel Catfish (*Ictalurus punctatus*), White Perch (*Morone americana*), and Yellow Perch (*Perca flavescens*) (Duke Energy, 2021).

Recreationally important species in the Dan River include Brown Trout (*Salmo trutta*), Brook Trout (*Salvelinus fontinalis*), Rainbow Trout (*Oncorhynchus mykiss*), Black Crappie, Bluegill, Largemouth Bass, Warmouth, Redbreast Sunfish, Redear Sunfish, White Crappie, Common Carp, Blue Catfish, Flathead Catfish, and Channel Catfish. Stocking of Brook Trout, Rainbow Trout, and Brown Trout in the Dan River is done annually by the NCWRC. In 2024, stocking occurred in March through June. A total of 2680 brook trout, 2680 rainbow trout, and 1335 brown trout were stocked in the Dan River. Stocking is done from the Virginia border upstream of the Project Vicinity to 200 yards downstream of the end of SR 1421 (NCWRC, 2024d). Stocking is focused upstream where habitat conditions are more conducive to supporting populations of trout.

There is no commercial harvest of aquatic species within Belews Lake or the Dan River.

2.3.2.4 Important Aquatic Habitats

NUREG-1555 identifies important aquatic habitats as follows:

- Wildlife sanctuaries, refuges, and preserves.
- Habitats identified by the State Natural Heritage Program, the USFWS, or the National Marine Fisheries Service as unique, rare, or of priority for protection.
- Wetlands, floodplains, or other resources protected by federal regulations or executive orders or by state regulations.
- Critical habitats designated by the USFWS to protect listed species.

Wetlands are discussed in Section 2.3.1, Terrestrial Ecology, and floodplains are discussed in Section 2.2, Water Resources (Surface Water and Groundwater).

The NCNHP classifies the Dan River as a natural area, with a rating of R1 (Exceptional), as described in Section 2.2.3.1.3.4. This rating indicates a natural area's potential to contribute to a collection of the best locations for biodiversity elements in the state. The exceptional rating is given to natural areas with some of the best examples of critically imperiled, imperiled, or vulnerable endemic species present. As described in Section 2.2.3.1.3.4, the North Carolina Environmental Management Commission has not classified this segment as an outstanding resource water, and therefore, no additional water quality restrictions are required.

Critical habitat for federally listed species are defined under 50 CFR 424.02 as "(1) The specific areas within the geographical area occupied by the species, at the time it is listed in accordance with the Act, on which are found those physical or biological features (a) Essential to the conservation of the species, and (b) Which may require special management considerations or protection; and (2) Specific areas outside the geographical area occupied by the species at the time it is listed, upon a determination that such areas are essential for the conservation of the species."

Critical habitat for Green Floater was proposed in 2023 for approximately 1586 river mi. (2553 river km) across the species range. Within the Dan River, approximately 137.5 river mi. (221.3 river km) have been proposed as critical habitat for Green Floater, including the length of the Dan River in the Project Vicinity. This subunit of critical habitat would encompass the Dan River in Caswell, Rockingham, and Stokes counties in NC, and Halifax, Henry, Patrick, and Pittsylvania counties in Virginia. Critical habitat would include the river channel up to the OHWM (USFWS, 2023).

2.3.2.5 Key Indicator Organisms

Freshwater mussels can be considered key indicator organisms in the Dan River, as they are highly sensitive to changes in water quality and impacts to habitat. The mussel community in the Dan River was characterized in 2024, as described in Section 2.3.2.2.3.2.

2.3.2.6 Nuisance Species

Nuisance species found in Belews Lake and Dan River include Hydrilla (*Hydrilla verticillata*), Asiatic Clam *(Corbicula fluminea)*, Blue Catfish, and Alabama Bass.

Asiatic Clam is an invasive clam that is native to Asia, Africa, and Australia. They are widespread throughout freshwater and some estuarine habitats in the U.S. Their presence is known to directly impact native freshwater mussel species, resulting in reduced growth of native mussels in the presence of Asiatic clams (USDA, 2024a). Asiatic Clams were observed in macroinvertebrate sampling within Dan River.

Hydrilla is an aquatic macrophyte species that is classified as a nuisance species in the U.S. It was introduced through the aquarium trade. Hydrilla has been known to crowd out native species and impede irrigation and boating in waterways (USDA, 2024b). Hydrilla has been observed in Belews Lake.

Non-native fish species found in Belews Lake include Alabama Bass, Green Sunfish, Redear Sunfish, Threadfin Shad (*Dorosoma petenense*), Alewife (*Alosa pseudoharengus*), White Crappie, Common Carp, Grass Carp (*Ctenopharyngodon idella*), Blue Catfish, Channel Catfish, Flathead Catfish, and White Perch. Alabama Bass is considered a threat to native bass fisheries. They compete directly with native bass species and tend to dominate in less productive lake systems with high-water clarity. They are also known to hybridize with other bass species, such as Smallmouth Bass and Largemouth Bass in systems in which they are both found (NCWRC, 2024e). Blue Catfish are native to the Mississippi River Basin. They are considered an aquatic nuisance species in NC as they may displace native catfishes and directly compete with other species for prey items (NCWRC, 2015).

2.3.2.7 Existing Ecological Effects and Environmental Stresses

BCSS has operated on Belews Lake since 1974. Per the requirements of the NPDES operating permit, the plant has a 316(a) thermal variance. NPDES thermal compliance discharge limit for the steam plant is an ambient water temperature of 89.6° Fahrenheit (32° Celsius) and is defined as the daily average discharge water temperature when a discharge from the lake dam occurs. Discharges from the lake dam are primarily used to maintain lake level. Thermal discharge limits were met throughout 2017 through 2024.

To comply with NPDES permit requirements, Duke Energy conducted an initial and comprehensive 1-year demonstration study on Belews Lake in 2020 to support a thermal variance request under §316(a) of the CWA. The goals of this study were to complete a temperature analysis of Belews Lake and to demonstrate a self-sustaining, balanced, and indigenous biological population of fish and shellfish in Belews Lake. The 2020 study determined that under the current thermal compliance point, the survival, reproduction, development, and growth of the fish and shellfish community within Belews Lake have not been appreciably reduced due to operation of the steam plant. Additionally, operations have not blocked or inhibited access to any potential spawning habitat, spawning activities, or the development of early juvenile individuals (Duke Energy, 2021).

Fish and macroinvertebrate contaminant levels were monitored in Belews Lake following a fisheries collapse related to ash basin effluent from BCSS (Duke Energy, 2016). Selenium concentrations in macroinvertebrates during 2011 to 2015 sampling indicated low concentrations of selenium when compared to historical records (Duke Energy, 2016). Annual mean selenium concentrations were measured in the muscle tissue of Redear Sunfish and Largemouth Bass in Belews Lake from 2011 to 2015. Annual mean selenium concentrations in the muscle tissue of Redear Sunfish and Largemouth Bass collected from Belews Lake ranged from 0.83 to 2.96 µg/g (wet weight) and from 0.92 to 2.73 µg/g, respectively. This study indicated that mean selenium concentrations in Redear Sunfish have declined at areas sampled since 1995 and remained consistent in Largemouth Bass since 2007. Concentrations present are below levels considered detrimental for fish reproduction and well below the concentration considered safe for human consumption (Duke Energy, 2016).

Table 2.3-1
Land Cover within the Project Site and Vicinity

Land Cover Class	Project Site (ac.)	6-mi. Vicinity (ac.)
Open Water	8	4,116

Lonicera japonica	Japanese honeysuckle	C
Lonicera sempervirens	coral honeysuckle	R
Lorinsera aureolata	netted chain fern	R
Ludwigia palustris	common water-purselane	U
Luzula echinata	spreading wood-rush	R
Lycopus virginicus	Virginia bugleweed	U
Maianthemum racemosum	eastern Solomon's-plume	R

Table 2.3-7
Plant Species Documented on the Project Site
(Sheet 8 of 11)

Scientific Name	Common Name	Project Site Overall Abundance [(a)]
Medeola virginiana	cucumber root	R
Melica mutica	two-flower medic	R
Menispermum canadense	moonseed	R
Microstegium vimineum	Japanese stiltgrass	A
Mimosa microphylla	eastern sensitive-briar	R
Mimulus alatus	winged monkey flower	R
Mimulus ringens	Allegheny monkeyflower	R
Miscanthus sinensis	Chinese silver grass	U
Mitchella repens	partridge-berry	U
Muscadinia rotundifolia var. *rotundifolia*	muscadine	C
Nabalus sp.	rattlesnake-root	U
Nemophila aphylla	white nemophila	R
Obolaria virginica	pennywort	R
Onoclea sensibilis	sensitive fern	R
Ophioglossum pycnostichum	southern adder's-tongue	R
Osmundastrum cinnamomeum	cinnamon fern	R
Oxalis dillenii	southern yellow wood-sorrel	R
Oxalis stricta	common yellow wood-sorrel	R
Packera anonyma	Appalachian ragwort	R
Panicum dichotomiflorum	spreading panicgrass	R
Panicum virgatum	switchgrass	R
Parthenocissus quinquefolia	Virginia creeper	O
Paspalum dilatum	dallis grass	U
Paspalum laeve	smooth lense grass	R
Passiflora incarnata	purple passionflower	R
Peltandra virginica	green arrow-arum	R
Penstemon digitalis	tall white beardtongue	R
Perilla frutescens	beefsteak plant	R
Persicaria lapathifolia	pale smartweed	R
Persicaria longiseta	longbristle smartweed	R
Persicaria sagittata	arrowleaf tearthumb	R

Table 2.3-7
Plant Species Documented on the Project Site
(Sheet 9 of 11)

Scientific Name	Common Name	Project Site Overall Abundance [(a)]
Persicaria virginiana	jumpseed	R
Phegopteris hexagonoptera	broad beech fern	U
Phoradendron leucocarpum	American mistletoe	R
Phytolacca americana	common pokeweed	R
Pinus taeda	loblolly pine	U
Pinus virginiana	Virginia pine	U
Piptochaetium avenaceum	eastern needlegrass	R
Platanthera clavellata	small green wood orchid	R
Podophyllum peltatum	mayapple	R
Polygonatum biflorum	small Solomon's seal	R
Polystichum acrostichoides	Christmas fern	C
Prunus serotina	black cherry	U
Pseudognaphalium obtusifolium	eastern rabbit-tobacco	U
Pteridium latiusculum	eastern bracken	R
Pycnanthemum tenuifolium	slender mountain-mint	R
Quercus alba	white oak	R
Quercus falcata	southern red oak	U
Quercus montana	chestnut oak	R
Quercus phellos	willow oak	R
Ranunculus recurvatus	hooked buttercup	R
Rhexia mariana	Maryland meadow-beauty	R
Rhododendron periclymenoides	pink azalea	R
Robinia hispida	bristly locust	R
Robinia pseudoacacia	black locust	R
Rosa multiflora	multiflora rose	R
Rubus flagellaris	common dewberry	R
Rumex crispus	curly dock	R
Rhynchospora glomerata	clustered beaksedge	R
Rudbeckia hirta	black-eyed susan	R
Salvia lyrata	lyreleaf sage	R
Sambucus canadensis	common elderberry	R
Sanguinaria canadensis	bloodroot	R

Table 2.3-7
Plant Species Documented on the Project Site
(Sheet 10 of 11)

Scientific Name	Common Name	Project Site Overall Abundance [(a)]
Sanicula canadensis	black snakeroot	U
Sassafras albidum	sassafras	R
Schizachyrium scoparium	little bluestem	R
Scirpus atrovirens	black bulrush	U
Scirpus cyperinus	woolgrass	U
Scirpus expansus	woodland bulrush	R
Scirpus georgianus	Georgia bulrush	R
Scirpus polyphyllus	leafy bulrush	R
Senega verticillata	whorled milkwort	R
Setaria pumila	yellow foxtail	R
Smilax bona-nox	catbriar	R
Smilax glauca	whiteleaf greenbriar	U
Smilax rotundifolia	common greenbriar	U
Solanum carolinense	Carolina horse-nettle	R
Solidago caesia	axillary goldenrod	R
Solidago rugosa var. aspera	rough goldenrod	R
Stellaria media	common chickweed	R
Stellaria pubera	star chickweed	R
Strophostyles umbellata	perennial sand bean	R
Symphoricarpos orbiculatus	coralberry	R
Symphyotrichum lanceolata	panicled aster	R
Symphyotrichum lateriflorum	starved aster	U
Syphyotrichum pilosum	hairy aster	R
Symphyotrichum puniceum	swamp aster	R
Thalictrum thalictroides	rue-anemone	R
Tiarella cordifolia	heartleaf foamflower	R
Tilia americana	basswood	R
Tipularia discolor	cranefly orchid	R
Toxicodendron radicans	poison ivy	U
Tridens flavus	redtop	R
Tripsacum dactyloides	gama grass	R
Typha angustifolia	narrowleaf cattail	R

Table 2.3-7
Plant Species Documented on the Project Site
(Sheet 11 of 11)

Scientific Name	Common Name	Project Site Overall Abundance [a]
Typha latifolia	common cattail	U
Uvularia perfoliata	perfoliate bellwort	R
Vaccinium fuscatum	hairy highbush blueberry	R
Vaccinium pallidum	hillside blueberry	O
Vaccinium stamineum	deerberry	U
Verbascum thapsus	woolly mullein	R
Verbesina alternifolia	common wingstem	U
Verbesina occidentalis	southern crownbeard	C
Viburnum acerifolium	mapleleaf viburnum	R
Viola cucullata	hooded blue violet	R
Viola pedata	bird's foot violet	R
Viola rafinesquei	wild pansy	R
Viola sororria	common blue violet	U
Xanthorhiza simplicissima	yellowroot	R
Yucca aloifolia[b]	Spanish dagger	R
Woody Vine		
Bignonia capreolata	cross vine	U
Lonicera japonica	Japanese honeysuckle	O
Lonicera sempervirens	coral honeysuckle	R
Muscadinia rotundifolia var. *rotundifolia*	muscadine	U
Smilax rotundifolia	common greenbriar	R
Toxicodendron radicans	poison ivy	U
Vitis sp.	grape	U
Wisteria sinensis	Chinese wisteria	O

Notes:
(a) Relative abundance (qualitative) for occurrence in the Project site: A = Abundant; C = Common; O = Occasional; U = Uncommon; R = Rare.
(b) Likely planted. *Baptisia albescens* (W1; S3) presumably from seed mix in restored tallgrass prairie; *Yucca aloifolia* (W1; S2) located near old homesite and developed area and presumable holdover from intentional plantings.

Table 2.3-8
Protected Species Potentially Occurring within or near the Project Site

Common Name	Scientific Name	Status		
		Federal[a]	State[b]	Suitable Habitat Present on Project Site[c]
Reptiles and Amphibians				
Bog turtle	*Glyptemys muhlenbergii*	SAT	T	P
Insects				
Monarch butterfly	*Danaus plexippus*	PT		P
Coppery emerald	*Somatochlora georgiana*		SR	P
Mollusks				
Green Floater	*Lasmigona subviridis*	PT	E	N
James Spinymussel	*Parvaspina collina*	E	E	N
Fish				
Bigeye Jumprock	*Moxostoma ariommum*		T	N
Quillback	*Carpiodes cyprinus*		SR	N
Riverweed Darter	*Etheostoma podostemone*		SR	N
Roanoke Logperch	*Percina rex*		E	N
Mammals				
Gray bat	*Myotis grisescens*	E	E	N[d]
Tricolored bat	*Perimyotis subflavus*	PE	E	P
Birds				
Rusty blackbird	*Euphagus carolinus*		T	P
Bald eagle	*Haliaeetus leucocephalus*	BGEPA	T	P
Plants				
Creeping sunrose	*Crocanthemum propinquum*		T	N
Granite flatsedge	*Cyperus granitohilus*		T	N
Schweinitz's sunflower	*Helianthus schweinitzii*	E	E	P
Marsh St. John's-wort	*Triadenum tubulosum*		SR	P

Notes:
(a) Federal Status Codes: BGEPA = Protected under the Bald and Golden Eagle Protection Act; E = Listed Endangered; PE = Proposed Endangered; SAT = Listed Threatened due to similarity of appearance to the northern population; PT = Proposed Threatened.
(b) State Status Codes: E = Listed Endangered; SR = Significantly Rare; T = Listed Threatened.
(c) Habitat Codes: N = No records of species within the Project site and/or no suitable habitat is present; P = Suitable habitat is present.
(d) Suitable foraging habitat may be present on the Project site in the form of stream corridors, but no suitable roosting habitat is present on the Project site.
(e) Suitable foraging habitat is present on the Project site in the form of herbaceous areas, but suitable breeding habitat is limited. See Section 2.3.1.5.1 for more details.

Table 2.3-9
Important Species within or near the Project Site
(Sheet 1 of 2)

Common Name	Scientific Name	Important Species Rationale[(a)]	Species Documented?	Suitable Habitat Present on Project Site
Reptiles and Amphibians				
Bog turtle	*Glyptemys muhlenbergii*	SAT, ST	No	Yes
American bullfrog	*Lithobates catesbeianus*	Nongame species	No	Yes
Insects				
Monarch butterfly	*Danaus plexippus*	PT	No but host plant documented on Project site	Yes[(b)]
Coppery emerald	*Somatochlora georgiana*	SR	No	Yes
Mollusks				
Green Floater	*Lasmigona subviridis*	PFT, ST	Yes, in Dan River	No
James Spinymussel	*Parvaspina collina*	FE, SE	No	No
Fish				
Bigeye Jumprock	*Moxostoma ariommum*	ST	Yes, in Dan River	No
Quillback	*Carpiodes cyprinus*	SR	Yes, in Dan River	No
Riverweed Darter	*Etheostoma podostemone*	SR	Yes, in Dan River	No
Roanoke Logperch	*Percina rex*	SE	Yes, in Dan River	No
Mammals				
Coyote	*Canis latrans*	Nongame species	Yes, on Project site	Yes
Beaver	*Castor canadensis*	Game species, furbearer	Yes, on Project site	Yes
Opossum	*Didelphis virginiana*	Game species, furbearer	Yes, on Project site	Yes
Groundhog	*Marmota monax*	Nongame species, furbearer	Yes, on Project site	Yes
Striped skunk	*Mephitis mephitis*	Game species, furbearer	Yes, on Project site	Yes
White-tailed deer	*Odocoileus virginianus*	Game species	Yes, on Project site	Yes
Tricolored bat	*Perimyotis subflavus*	PFE, SE	Yes, on Project site	Yes

Table 2.3-9
Important Species within or near the Project Site
(Sheet 2 of 2)

Common Name	Scientific Name	Important Species Rationale[(a)]	Species Documented?	Suitable Habitat Present on Project Site
Mammals (continued)				
Raccoon	*Procyon lotor*	Game species, furbearer	Yes, on Project site	Yes
Gray squirrel	*Sciurus carolinensis*	Game species	Yes, on Project site	Yes
Fox squirrel	*Sciurus niger*	Game species	Yes, on Project site	Yes
Eastern cottontail	*Sylvilagus floridanus*	Game species	Yes, on Project site	Yes
Gray fox	*Urocyon cinereoargenteus*	Game species	Yes, on Project site	Yes
Birds				
Wood duck	*Aix sponsa*	Game species	Yes, on Project site	Yes
Mallard	*Anas platyrhynchos*	Game species	Yes, on Project site	Yes
Canada goose	*Branta canadensis*	Game species	Yes, on Project site	Yes
Rusty blackbird	*Euphagus carolinus*	ST	No	Yes
Bald eagle	*Haliaeetus leucocephalus*	BGEPA, ST	Yes, nest within Project Vicinity and seen on Project site	Yes
Wild turkey	*Meleagris gallopavo*	Game species	Yes, on Project site	Yes
Red-breasted merganser	*Mergus serrator*	Game species	Yes, within Project Vicinity	Yes
Mourning dove	*Zenaida macroura*	Game species	Yes, on Project site	Yes
Plants				
Schweinitz's sunflower	*Helianthus schweinitzii*	FE, SE	No	Yes
Marsh St. John's-wort	*Triadenum tubulosum*	SR	No	Yes

Notes:
(a) BGEPA = Protected under the Bald and Golden Eagle Protection Act; FE = Listed Federally Endangered; PFE = Proposed Federally Endangered; PFT = Proposed Federally Threatened; SAT = Listed Federally threatened due to similarity of appearance to the northern population; SE = Listed State Endangered; SR = State Significantly Rare; ST = Listed State Threatened.
(b) Suitable foraging habitat is present on the Project site in the form of herbaceous areas, but suitable breeding habitat is limited. See Section 2.3.1.5.1 for more details.

2.4 SOCIOECONOMICS

This section describes the socioeconomic characteristics of the areas that could be impacted by construction, operation, and decommissioning of several advanced reactors at the Project site. The analysis focuses on demography and community characteristics in the potentially affected areas.

The demographic region is defined as the Project site and the surrounding area within a 50-mi. (80-km) radius from the Project site center point bounding limit, as described in Section 2.1.1.3. The economic region or "region of influence" (ROI) for the socioeconomic analysis is defined by the areas where the construction and operations workforce and their families reside, spend their income, and use their benefits, thereby affecting the economic conditions of the region.

To determine the ROI for the socioeconomic analysis, it is assumed that the residential distribution of the construction and operations workforce for the Project mimics the residential distribution of the BCSS workforce. This assumption applies in terms of the geographic area from which the workforce would be drawn and accordingly those areas that would experience most social and economic impacts. The BCSS workforce comprises approximately 150 employees from five states and 29 counties. Three employees list mailing addresses in Florida, South Carolina, and West Virigina and are excluded from analysis, bringing the total number of existing on-site BCSS employees to 147. The largest percentage of workers employed by BCSS reside in Rockingham County (28 percent) and Stokes County (25 percent) in NC. The neighboring counties of Forsyth and Guilford in NC provide 11 percent and 10 percent of the total workers employed by BCSS, respectively. Employees from these four counties account for approximately 75 percent of the on-site BCSS workforce. Therefore, Rockingham, Stokes, Forsyth, and Guilford counties represent the ROI and serve as the basis for the assessment of social and economic impacts from the Project.

2.4.1 DEMOGRAPHY

This section describes the current and projected resident population distribution within the demographic region, demographic characteristics of the population residing within the ROI, and a discussion of transient populations. Population data presented are based on 2020 census data from the U.S. Census Bureau (USCB) and, where applicable, more recent data from the USCB 2018–2022 American Community Survey (ACS) five-year estimates. Future populations were projected following guidance in NUREG-0800, Regulatory Guide 1.70, and Regulatory Guide 4.7. These projections are based on state planning agency projections and studies or other appropriate federal agency sources.

2.4.1.1 Population Data by Sector

Current and projected resident population data by sector within 50-mi. (80-km) of the Project site center point are summarized in Table 2.4-1. Current (2020) population data by sector within 20 mi. (32 km) of the Project site center point is shown on Figure 2.4-1 and current population data within 20 to 50-mi. (32 to 80-km) are shown in Figure 2.4-2.

The population distribution in the area up to a 50-mi. (80-km) radius surrounding the Project site is estimated from 2020 USCB decennial census data. The population distribution is divided into distance bands and directional sectors from the established Project site center point at the following distances: 0-0.3 mi. (0-0.5 km); 0.3-1 mi. (0.5–2 km); 1-2 mi. (2-3 km); 2-3 mi. (3-5

km); 3-4 mi. (5-6 km); 4-5 mi. (6-8 km); 5-6 mi. (8-10 km); 6-7 mi. (10-11 km); 7-8 mi. (11-13 km); 8-9 mi. (12.9-14.5 km); 9-10 mi. (15-16 km); 10-20 mi. (16-32 km); 20-30 mi. (32-48 km); 30-40 mi. (48-64 km); and 40-50-mi. (64-80-km). For each sector, the percentage of each Census Block Group's (CBG) land area that falls either partially or entirely within that sector is calculated. The equivalent percentage of each CBG's population is then assigned to that sector. If two or more CBGs fall within the same sector, the proportional population estimates for the CBGs are summed to obtain the total population estimate for that sector.

Projected population levels during the anticipated year of plant approval and start of commercial operation of the first reactor (2034), the start of commercial operation of the last reactor (2039), and for census years over the 40-year plant operating license period (2039 through 2079) are based on state planning agency projections and studies or other appropriate federal agency sources. Where these planning agency projections do not cover the required period, population projections are extrapolated based on calculated growth rates.

2.4.1.2 Demographic Characteristics of the ROI

The following demographic characterization, which includes current, historic, and projected population data, age and sex distribution, income distribution, and racial and ethnic distribution, within the ROI.

Table 2.4-2 shows the 2020 population of each county within the ROI and of each USCB-recognized "place" (i.e., city, town, or census-designated place) within those counties. Where USCB-recognized places intersect multiple counties, the place is listed under the county where most of the population resides. The 2020 resident population of the four counties that compose the ROI was 1,059,505. The closest places to the Project site center point bounding limit are Stokesdale (population 5924), approximately 0.6 mi. (0.95 km) to the southeast in Guilford County, and Walnut Cove (population 1586), approximately 3 mi. (4.9 km) to the west in Stokes County (Figure 2.4-3). Guilford County, to the southeast, is the most populated county in the ROI and also contains Greensboro (population 299,035), the largest population center in the ROI. Three other large population centers (defined as areas with a population greater than 25,000) are located in Forsyth and Guilford counties: Kernersville, Winston-Salem, and High Point. There are no large population centers in Rockingham or Stokes counties.

Historic and projected population within the ROI is shown in Table 2.4-3. The table includes historic data for the three most recent decennial censuses (2000, 2010, 2020) and projections through 2079, the expected end of licensing period, derived from projected population data published by the North Carolina Office of State Budget and Management (NCOSBM) (NCOSBM, 2023a). Stokes County, where the Project site is located, experienced population growth of approximately 0.6 percent annually between 2000 and 2010 and subsequently declined by 0.6 percent annually between 2010 and 2020. Similarly, Rockingham County experienced population growth of approximately 0.2 percent annually between 2000 and 2010 and subsequently declined by approximately 0.3 percent annually between 2010 and 2020. Forsyth and Guilford counties both experienced average annual population growth rates of 1 percent or nearly 1 percent for the same period. The population of Stokes and Rockingham counties is projected to stay relatively consistent over the licensing period. The population in Forsyth and Guilford counties is projected to continue to grow, but at a slower rate, until 2050. Overall, the ROI population as a whole is projected to continue to grow at a rate of approximately 0.8 percent annually throughout the licensing period, led by growth in Guilford and Forsyth counties.

Age and gender distribution within the ROI and NC are shown in Table 2.4-4. The age distribution of the ROI is generally similar to the state, with a slightly younger median age and larger percentage of population ages 15 to 24. However, in Rockingham and Stokes counties, the median age is between 6 and 8 years older than that of the state. Similar to the state of NC, women in the ROI account for slightly more than half of the population.

Table 2.4-5 presents household income and federal poverty level data for the ROI counties and the state of NC. Median household income and the percentage of households with income of $150,000 or more are lower for the ROI counties compared to the state. The percentage of households below the poverty level in the ROI is higher than that of the state. Within the ROI, Rockingham County has the highest percentage of population living below the poverty level.

Racial and minority populations within the ROI and the state of NC are shown in Table 2.4-6. Racial and ethnic minorities within the ROI (46.4 percent) make up a larger percentage of the population compared to the state (39.5 percent). Black or African American residents comprise the largest racial or ethnic minority group in all four ROI counties. Table 2.4-7 presents trends in racial and ethnic population distribution in the ROI counties from 2010 to 2020, and projections for 2030 through 2050. The aggregate minority population in the ROI is projected to surpass the white population by 2040; and by 2050, roughly 54 percent (711,930 people) of the ROI will identify as a racial or ethnic minority. This shift is most evident in Guilford County, where the aggregate minority population is expected to increase by approximately 20 percent between 2010 and 2050 (NCOSBM, 2023b).

2.4.1.3 Transient Population

As described in Regulatory Guide 4.7, Rev. 3, *General Site Suitability for Nuclear Power Stations*, transient populations are defined as “people (other than those just passing through the area) who work, reside part-time, or engage in recreational activities, and are not permanent residents of the area.”

Significant sources of transient populations include airports, major employers, schools, medical facilities, lodging facilities, event venues, and recreation areas. Transient facilities within 20 mi. (32 km) of the Project site center point are shown in Table 2.4-8. Estimates of transient populations associated with the facilities identified in Table 2.4-8 were obtained primarily by reviewing government agency websites and other public sources of information on employers, schools, recreation areas, medical facilities (hospitals and nursing homes), and lodging facilities (hotels, motels, recreational vehicle [RV] parks, and vacation rentals). Employee counts for industrial employers were sourced, if possible, from company websites. If unavailable, estimates were obtained from job resource websites and news sources. Approximately 230,756 transients associated with 631 facilities were identified within a 20-mi. (32-km) radius.

In addition to the transient populations identified in association with the facilities listed above, nonpermanent residents of the area also include migrant laborers whose employment requires travel that prevents the worker from returning to their permanent place of residence the same day. The U.S. Department of Agriculture conducts a census of agriculture that collects information on migrant workers. Results of the 2022 census indicate that there are 83 farms within the ROI that employ 434 migrant workers (USDA, 2022a).

2.4.2 COMMUNITY CHARACTERISTICS

2.4.2.1 Economy

Table 2.4-9 details employment trends for the four counties in the ROI. In 2022, the ROI had a total labor force of 531,242 people, of which 500,924 individuals were employed. In 2022, Guilford County had the largest employed population of the four ROI counties (263,584), followed by Forsyth County (178,260). A total of 28,836 individuals in the ROI were unemployed in 2022, resulting in an unemployment rate of 5.4 percent. All four of the counties in the ROI had similar unemployment rates, ranging from 5.2 percent (Guilford County) to 6.5 percent (Rockingham County). Overall, unemployment in the ROI decreased from 9.7 percent in 2011 to 5.4 percent in 2022, which is similar to NC as a whole, where unemployment decreased from 9.5 percent to 5.0 percent over the same period.

Table 2.4-10 presents total employment levels by industry sector for the four counties in the ROI. In 2022 the educational services, healthcare, and social assistance sector employed 25 percent of the workers in the ROI, followed by manufacturing at 13.3 percent. The transportation, warehousing, and utilities sector experienced the largest employment growth in the ROI from 2011 to 2022 (43.4 percent increase). The information sector experienced the largest employment decline in the ROI from 2011 to 2022 (24.6 percent decrease). Additionally, the construction labor industry within the ROI comprises 5.9 percent of the existing labor force, which is a 3.7 increase from 2011 to 2022.

Table 2.4-11 lists the top employers in the ROI for 2023. Major employers were concentrated in Forsyth and Guilford counties, with a combined 45 employers with over 1000 workers. There were two employers within Rockingham County that employed over 1000 workers: Consolidated School System and Wal-Mart Associates Inc. There were no employers with over 1000 workers within Stokes County; the largest employer in Stokes County was Stokes County Schools with 500 to 999 employees.

Income distribution by household is detailed in Table 2.4-5. In 2022, the median household income ranged from $50,737 (Rockingham County) to $62,880 (Guilford County) and was lower than the state of NC, which was $66,186. Per capita income is the average income for every individual in a particular group and is derived by dividing the total income of a particular group by the total population in that group (USCB, 2024a). Table 2.4-12 details per capita income trends for the four counties in the ROI. Per capita income ranged from $29,239 (Rockingham County) to $36,563 (Guilford County) in 2022. Between 2011 and 2022, Stokes County experienced the greatest increase in per capita income (55.1 percent) among the ROI counties. Forsyth, Guilford, and Rockingham counties experienced lower increases in per capita income than the state during this same time period (49.0 percent).

2.4.2.2 Transportation

This section describes the transportation network serving the Project site, the Project Vicinity, and the Project Region. Available transportation resources in the Project Vicinity and Project Region include a diverse road network, rail lines, airports, waterways, and public transportation. Figure 2.1-4 illustrates the road, highway, railroad, and airports systems in the area.

2.4.2.2.1 Roads

As shown in Figure 2.1-4, there are four interstate highways within the Project Region: Interstate (I) 40, I-74, I-77, and I-85. The closest interstate highway to the Project site is I-40, which runs east to west 9.9 mi. (15.9 km) south of the Project site at its closest border. Large population centers in the ROI are described in Section 2.4.1.2. Winston-Salem, NC, is located along I-40, 9.3 mi. (14.9 km) to the southwest, and Greensboro, NC, is located 8.5 mi (13.7 km) to the southeast. I-74 runs east to west 14.8 mi. (23.9. km) south of the Project site at its closest border. I-77 runs north to south 40.4 mi. (65.0 km) west of the Project site at its closet border and I-85 runs southwest to northeast 20.7 mi. (33.2 km) south of the Project site.

The road and highway transportation systems in the Project Vicinity are shown in Figure 2.4-4. Two U.S. highways and one state highway serve the Project Vicinity and provide access to the Project site. U.S. 311 runs north–south/southwest connecting Stokes and Forsyth counties, 3.9 mi. (6.3 km) northwest of the Project site boundary. U.S. 158 runs northeast-southwest connecting Forsyth and Guilford counties, approximately 2.2 mi. (3.6 km) south of the Project site center point; and NC Highway 65 runs northwest–southeast connecting Guilford, Forsyth, and Stokes counties 1.1 mi. (1.8 km), south of the Project site center point. SRs and local roads in the Project Vicinity include SR-1908/SR-1977 (Pine Hall Road), SR 1965 (Belews Creek Road), SR 2042 (Craig Road), Martin Luther King Jr. Road, and Fisherman Road.

Primary roadways providing access to the Project site are shown on Figure 2.4-4. Pine Hall Road provides direct access to the Project site from the west, and Craig Road provides direct access from the south. The intersection of Pine Hall Road and SR 2034 (Duke Power Steam Plant Road) is stop-controlled for SR 2034 only. Craig Road ends at the BCSS Entrance, which is gate controlled. Commuting workers coming from the surrounding region to the north are likely to take U.S. 311 to Pine Hall Road. Commuting workers traveling from east and west are likely to take U.S. 311 or U.S. 158 to Belews Creek Road to Craig Road. Other commuting workers traveling within Stokes, Forsyth, and Guilford counties are likely to use county and local roads and connect to Pine Hall Road and Craig Road.

2.4.2.2.2 Road Conditions and Mileage

Each of the four counties in the ROI has hundreds of mi. of publicly maintained roadways. Stokes County contains 59 mi. (95 km) of unpaved and 846 mi. (1362 km) of paved state highway system. Guilford County contains 49 mi. (79 km) of unpaved and 1826 mi. (2939 km) of paved state highway system. Forsyth County contains 16 mi. (26 km) of unpaved and 955 mi. (1537 km) of paved state highway system. Rockingham County contains 92 mi. (148 km) of unpaved and 1128 mi. (1815 km) of paved state highway system.

2.4.2.2.3 Traffic Conditions

Vehicle volume on roads is provided by the NCDOT in the form of estimated annual average daily traffic (AADT) counts. AADT is the total volume of motorized vehicle traffic on a highway or roadway segment for 1 year divided by 365 days in the year (Florida Department of Transportation [FDOT], 2023). The AADT counts and functional classification for the primary access roads to the Project site are shown in Table 2.4-13 (NCDOT, 2024a, 2024b).

The primary roadways within the Project Vicinity that are used to access the Project site are listed in Table 2.4-13. These include U.S. 158 which is classified as an “other” principal arterial

roadway in the Project Vicinity. U.S. 311 and NC Highway 65 are classified as minor arterial roadways. Pine Hall Road and Belews Creek Road, west of NC Highway 65, are classified as major collector roadways. Pine Hall Road east of NC Highway 65 is classified as a local roadway and Belews Creek Road west of NC Highway 65 is a minor arterial roadway. Pine Hall Road east of Hawkins Farm Road is classified as a minor collector roadway. Fisherman Road and Hawkins Farm Road are classified as minor collector roadways. Ellisboro Road, running north–south is classified as a minor collector roadway (NCDOT, 2024b). The remaining local roadways in the Project Vicinity are two-lane undivided roadways.

Level of Service (LOS) is a quantitative stratification of a performance measure or measures representing quality of service. The Highway Capacity Manual (HCM) defines six levels of service, ranging from A to F, for each service measure or combination of service measures. LOS A represents the best operating conditions from the traveler's perspective and LOS F represents the worst (FDOT, 2023).

The HCM describes LOS A through F as follows:

- LOS A: free-flow operations on freeway or multilane highways and high operating speeds and little difficulty in passing on two-way highways.
- LOS B: reasonably free-flow operations, and the ability to maneuver within the traffic stream is slightly restricted on freeway or multilane highways; on two-way highways, passing demand and passing capacity are balanced with some speed reductions present.
- LOS C: freedom to maneuver within the traffic stream is noticeably restricted, and lane changes require more care and vigilance on the part of the driver on freeway or multilane highways; speeds are noticeably reduced on two-way highways.
- LOS D: freedom to maneuver within the traffic stream is seriously limited, and drivers experience reduced physical and psychological comfort levels on freeway or multilane highways; platooning increases significantly on two-way highways.
- LOS E: operation is at or near capacity, and there are virtually no usable gaps within the traffic stream on freeway or multilane highways; passing is virtually impossible on two-way highways.
- LOS F: describes unstable flow with queues forming behind bottlenecks on multilane highways; operating conditions are unstable, and heavy congestion exists on two-way highways.

Based on a standard motor vehicle arterial generalized service volume for a two-lane roadway in a rural town having a maximum AADT of 13,800, the AADTs presented in Table 2.4-13 indicate that the primary roadways in the Project Vicinity operate at an acceptable LOS C or better (FDOT, 2023).

2.4.2.2.4 Roadway Freight Network

The National Highway Freight Network in NC includes Primary Highway Freight System (PHFS) and Non-PHFS Interstate roadways. Within the ROI, I-77 and I-40 are part of the PHFS

network. Minor collectors and local roadways are used to directly access the Project site. (Federal Highway Administration [FHWA], 2024)

2.4.2.2.5 Road Improvements

NCDOT maintains and programs the roadway network in the ROI counties. In Forsyth County, NCDOT is building a multilane freeway that loops around the northern part of Winston-Salem (NCDOT, 2024c). This project began in 2014 and is currently under construction. In Forsyth County, NCDOT has two projects in development: Big Mill Farm/Hopkins Road Improvements, scheduled for construction in 2025, and US 158 (Reidsville Road) Improvements, which began construction in 2024. In Guilford County there are also two projects in development: Johnson Street and Sandy Ridge Road Widening and US 220 Widening (Greensboro). There are no high-profile NCDOT projects or studies currently identified in Rockingham or Stokes counties.

2.4.2.2.6 Railroads

The CSX Winston-Salem Yard, which is operated by NS, is located in the Project Region. The NS railroad in the Project Region runs north–south in Forsyth, Stokes, and Rockingham counties and east–west in Forsyth and Guilford counties. The Yadkin Valley Railroad in the Project Region extends east–west across Forsyth County. The Winston-Salem Southbound Railway railroad in the Project Region extends north–south in Forsyth County.

NS is the primary operator of the rail lines within the ROI. Yadkin Valley Railroad and Winston-Salem Southbound Railway have shorter lines located on the outskirts of the ROI. In the Project Vicinity, NS has a 3.4 mi. (5.5 km) spur that branches off to connect to the BCSS (NCDOT, 2024d and 2024e).

2.4.2.2.7 Waterways

Belews Lake is a reservoir in Forsyth, Stokes, Guilford, and Rockingham counties that is primarily used for support of power generation and secondarily used for recreational purposes (Belews Lake, 2024). The Dan River flows north of the Project site and provides opportunities for paddling, canoeing, tubing, and kayaking. These waterways are not used for transportation-related purposes.

2.4.2.2.8 Airports

As shown on Figure 2.1-4, there are two public airports within the Project Region. Piedmont Triad International (GSO) is the only regional airport that offers international services (Piedmont Triad International Airport, 2024). While there are no regularly scheduled passenger services outside of the U.S., the airport had approximately 350 international flights in 2023. Piedmont Triad International (GSO) functions like an independent municipality with its own police force, fire department, operations, parking facilities, and administration. Smith Reynolds (INT) is a general aviation airport that provides operations for corporate aircraft, air charter services, general aviation, and air cargo (Smith Reynolds Airport, NC 2024). The airport facilities include areas for aircraft maintenance, repair, and overhaul and aviation-related industrial and commercial development. There are no public airports located within the Project Vicinity.

2.4.2.2.9 Public Transportation

Several public transit services serve the ROI; however, there are no transit services that provide direct access to the Project site. In Guilford County, there are five transit providers that operate bus/van services: Guilford Transit Authority, High Point Transit System, Piedmont Authority for Regional Transportation, Guilford County Transportation and Mobility Services, and NC Greyhound. In Forsyth County, three transit providers operate bus services: Winston-Salem Transit Authority, Piedmont Authority for Regional Transportation, and NC Greyhound. In Rockingham County, two transit providers operate bus services: Rockingham Community Access Transit Services and Piedmont Authority for Regional Transportation. In Stokes County, two transit providers operate bus services: Yadkin Valley Public Transportation and Piedmont Authority for Regional Transportation.

2.4.2.3 Taxes

Table 2.4-14 presents annual tax revenues from property taxes, sales taxes, occupancy tax, and other taxes for the four counties in the ROI for fiscal year (FY) 2019 through FY 2023. Property tax in NC is locally assessed and collected by the counties. The North Carolina Department of Revenue (NCDOR) supervises the valuation and taxation of property by taxing units throughout the state. Property tax is levied upon real property, personal property, and motor vehicles (NCDOR, 2024a). The 2024 tax rates and levies for each county in the ROI are shown in Table 2.4-15.

For tax year 2023, the NC individual income tax rate was 4.75 percent, which is lower than the rate from the 2022 tax year (4.99 percent). During the next three tax years (2024, 2025, and 2026), the respective individual income tax rates are expected to continue to decrease to 4.5 percent, 4.25 percent, and 3.99 percent, respectively (NCDOR, 2024b).

All domestic and foreign corporations in NC are subject to franchise tax (NCDOR, 2024c). In addition, a 2.5 percent income tax is levied on the net taxable income of certified corporations in NC (NCDOR, 2024d). However, in 2019, NC enacted the 2021 Appropriations Act, which phases out the current 2.5 percent corporate income tax rate over a 5-year period starting in 2025 to reach a zero percent rate by 2030 (EY, 2024).

NC imposes a sales and use tax of 4.25 percent. Individual counties may impose an additional 2.0 to 2.75 percent as a county sales and use tax (NCDOR, 2024e). This tax is applicable to the sale price of each article of tangible personal property (NCDOR, 2024f). In addition, NC also imposes a tax from the sale of electricity at 7 percent (NCDOR, 2024g). In 2023, Duke Energy operations throughout the Carolinas collected $301,759,828 in sales taxes.

The Project site is developed on an existing Duke Energy–owned parcel (see Section 2.1), which had an assessed property value of $27,259,600 in 2024. In 2024, Duke Energy paid Stokes County $6.8 million in property taxes. Duke Energy currently has not entered into or negotiated any special property tax abatements or agreements.

2.4.2.4 Political Structure

There are 50 senate districts and 14 congressional districts within NC. Within the four-county ROI, there are four congressional districts and two state senate districts (NCGA, 2023a, 2024).

The North Carolina General Assembly (NCGA) established the Board of County Commissioners as the governing body of each of the 100 counties. Counties are governed by a board of five or more commissioners whose members are both the legislative and executive leaders of the government.

The incorporated cities and towns within the ROI are shown on Table 2.4-2. The Stokes County seat is Danbury, which is located approximately 11 mi. (18 km) northwest of the Project site. Winston-Salem is the county seat for Forsyth County, Greensboro is the county seat for Guilford County, and Wentworth is the county seat for Rockingham County.

2.4.2.5 Land Use

As stated in Section 2.1, all counties in the ROI have adopted countywide comprehensive plans. Each plan identifies goals for increasing economic growth and attracting businesses, developing a variety of housing options, protecting and preserving natural resources, and improving transportation and utilities.

2.4.2.6 Aesthetics and Recreation

2.4.2.6.1 Aesthetics

As detailed in Section 2.1, the Project site lies within the NC western Piedmont, which is characterized by gently rolling, well-rounded hills and long low ridges ranging in a few hundred feet of elevation difference between the hills and valleys. The immediate area around the Project site features several notable visual resources:

- Belews Lake, a scenic body of water used to support power plant operation and which also allows for recreation uses (see Section 2.4.2.6.2) (NCWRC, 2012).
- Forested land.
- The BCSS, located adjacent to the Project site to the west, encompasses approximately 700 ac. (283 hectares [ha]) (North Carolina Division of Energy, Mineral, and Land Resources, 2016). The coal-fired plant is a significant industrial feature in the area.
- Rural/low-density residential lands to the south and east of the Project site.

These elements together create a diverse visual environment around the Project site.

Sensitive visual receptors, which are potentially affected by visual intrusions of the Project, include recreators on Belews Lake, residences just south of the Project site boundary, and residences to the east of the Project site across Belews Lake. Additional sensitive visual receptors include visitors to the recreation areas within the Project Vicinity and residences and facilities located along access roads to the Project site. Primary roadways in the Project Vicinity are shown on Figure 2.4-4. Pine Hall Road (SR 1908) and Craig Road (SR 2042) provide the best opportunity for the public to view the Project site. Because the surrounding topography consists of rolling hills and steep slopes with forested land, there is visual screening for the Project site from area roadways.

2.4.2.6.2 Recreation

Recreational areas that could be affected by the construction and operation of the Project primarily consist of outdoor, nature-oriented activities, such as boating, fishing, hunting, camping, bicycling, and hiking. The recreation areas within the Project Vicinity are shown on Figure 2.4-5.

Duke Energy owns all the land within and immediately adjacent to Belews Lake. Duke Energy grants shoreline access leases to adjacent property owners for permission to access the lake across Duke Energy property. There are approximately 63 permitted private docks/structures on Belews Lake. Once leased, the shoreline property may be used for access to Belews Lake for recreational use and for other permitted uses as specified in the lease or in the Guidelines for Use of Shoreline Property at Belews Lake. At a full pool elevation of 725 ft. (221 m.) AMSL the lake has approximately 88 mi. (142 km) of shoreline and 3863 ac. (1563 ha) of surface area. Duke Energy provides recreational access to the lake through two public boat launch areas maintained and managed by the NCWRC: Piney Bluff Access Area and Pine Hall Access Area. Additionally, the commercial docks, Carolina Marina and Humphrey's Ridge, provide access to Belews Lake from the eastern side.

Belews Lake is a popular destination for fishing and other water-related activities in the area. Largemouth bass, spotted bass, and Black Crappie are primarily the targeted species for fishing; however, Belews Lake is also fished for white bass, channel catfish, white catfish, Bluegill, and sunfish. Due to its warm temperatures resulting from the BCSS discharge, Belews Lake is one of the state's more productive lakes for fishing in the winter. Since July 2023, NCWRC issued 40 fishing tournament permits involving 1037 boats for two access areas on Belews Lake. However, introduction of non-native species, such as Hydrilla and the Asiatic Clam may negatively affect water-related activities in the lake (see Section 2.3.2.6). Additionally, Duke Energy–owned lands have 11 leases to hunting clubs that cover approximately 5000 ac. (2023 ha) on the Project site and in the vicinity. Together, these clubs have approximately 100 members. Of the 11 hunting leases, the Belews Creek Hunt Club has the largest lease area (approximately 2518 ac. [1019 ha]), which covers most of the Project site. The remaining 10 hunting leases are located adjacent to the lake on Duke Energy–owned property. NCWRC offers hunting permits and licenses for various types of animals, including deer, turkeys, bears, ducks, waterfowl, and small game animals.

The Dan River flows north of the Project site and provides opportunities for paddling, canoeing, tubing, fishing, and kayaking. Among the 214 mi. (344 km) of river, 90 mi. (145 km) were authorized as a state paddle trail in 2021 in Surry, Stokes, and Rockingham counties. There are several public paddle access points located throughout these counties; however, they are located outside of the Project Vicinity (North Carolina Triad Outdoors, 2024). Although not listed as a public access point, river access (Pine Hall Access) near the Project site is located at an unimproved access point within the NCDOT corridor along Pine Hall Road (Dan River Basin Association, 2024).

South of the Project site, Forsyth County is developing Belews Lake Park. Phase 1 of the park completed in early 2025, the 215-ac. (87-ha) park includes natural areas, trails, fishing piers, a shelter, and a playground. Forsyth County is developing the park in multiple construction phases, with the construction of Phase II anticipated to begin as early as 2025.

As stated in Section 2.1.1.2, the Knight Brown Nature Preserve is located within the Project Vicinity (see Figure 2.1-6). The Knight Brown Nature Preserve is approximately 147 ac. (60 ha) with almost 5 mi. (8 km) of walking trails through a wooded valley, which includes two streams.

Additional recreation facilities in the vicinity are several community parks (Walnut Cove Lion's Park, London Park, Dr. Jack Fowler Park, East Walnut Cove Community Park, Stokesdale Town Park at Martin's Meadow, and Stokesdale Community Park); two golf courses (Riverview Golf Course and Pine Knolls Golf Club); a fishing lake (Hilltop Carp Lake); hiking trails (Cascades Preserve, Mountain to Sea Trail, Dan River Trail, Keyauwee Loop Trail, Falling Waters, Atlantic & Yadkin Greenway, and Hogan's Creek Park); and a campground (R&K Campground). R&K Campground is an RV park that offers short-term and long-term stay options.

Popular recreational destinations in the ROI include Hanging Rock State Park, Mayo River State Park, and Haw River State Park (see Figure 2.1-6). Hanging Rock State Park, the largest state park located within the ROI, is located in Stokes County and offers a variety of recreational opportunities including hiking, biking, horseback riding, swimming, paddling, fishing, picnicking, camping, and rock climbing. Old Salem, located in Forsyth County, is a famous historic district in Winston-Salem that is made up of various shops, historic buildings, gardens, and a history museum. The Old Salem history museum serves as an educational museum on the Moravians of NC who established the Central NC community in the late 18th century. As noted in Section 2.6.2, there are four properties listed on the National Register of Historic Places (NRHP) within a 10-mi. (16-km) radius of the Project site.

2.4.2.7 Housing

Table 2.4-16 details total housing units and occupation status in each of the counties within the ROI in 2022. Of the 469,243 housing units within the ROI, most are located in Guilford (233,332) and Forsyth (171,040) counties. Throughout the ROI, occupancy ranges from 88.8 percent (Rockingham County) to 91.2 percent (Guilford County). Within the ROI, 62.3 percent of units are owner occupied and the remaining 37.7 percent are renter occupied. In 2022, the median mortgage in the ROI was $1291 per month and the median rent in the ROI was $886 per month (see Table 2.4-17). Table 2.4-18 details vacant housing within the ROI, including units for rent or sale. In 2022, less than 10 percent of the total housing units in the ROI were vacant. Of the vacant units, 25.1 percent (11,455 units) were available for rent and 7.5 percent (3,047 units) were for sale.

As shown in Table 2.4-19, within the ROI, the largest increase in new home construction occurred between 1990 and 1999 (16 percent). However, housing construction slowed over the next two decades, dropping from 15.6 percent in the 2000s to 8.7 percent in the 2010s. Table 2.4-20 details residential building permits issued for each of the ROI counties in 2010 and 2020 through 2023. Overall, issuance of residential building permits has increased in all four ROI counties from 2010 to 2020, with the largest increase seen in Forsyth County. Building permits issued for multifamily buildings decreased in Forsyth and Guilford counties from 2010 to 2020. However, from 2020 to 2023 building permits for multifamily buildings in Forsyth and Guilford counties increased. From 2010 to 2023, Rockingham and Stokes counties saw little change in the number of multifamily building permits issued, with no permits issued in 2022 and 2023. While the number of permits issued has increased in the ROI, this does not directly correlate to new housing built, only the issuance of a permit for construction.

Temporary housing within the ROI includes hotels, seasonal homes (for long-term rentals), and RV parks and campgrounds (see Section 2.4.2.6.2 for RV parks and campground within the Project Vicinity). Within the Greensboro (Guilford County) and Winston-Salem (Forsyth County) area there are 163 hotels, 25 bed and breakfasts, and 28 camping and RV sites (Economic Development Partnership of North Carolina, 2024). Additionally, Table 2.4-18 shows that within the ROI there were 3908 seasonal, recreation, or occasional use housing units available in 2022.

2.4.2.8 Community Infrastructure

This section describes public water and wastewater treatment systems, police and fire departments, medical facilities, and schools. Schools are described in Section 2.4.2.9. The other infrastructure and service elements are described in the following sections.

2.4.2.8.1 Public Water Supply and Wastewater Treatment Systems

There are 14 public water systems providing potable water to the residents of Stokes, Forsyth, Guilford, and Rockingham counties. Table 2.4-21 summarizes the population served, total available supply, service area demand, total demand (service area demand, sales, future sales), and demand as percentage of supply for each of the water systems in the ROI. Water systems in the four ROI counties operate below capacity.

Wastewater treatment in the ROI is provided by 10 WWTPs. Table 2.4-22 details the public wastewater treatment facilities, their capacities, and the average wastewater flow for Stokes, Forsyth, Guilford, and Rockingham counties, all of which are operating below capacity.

2.4.2.8.2 Police, Fire, Emergency Services, and Medical Services

2.4.2.8.2.1 Police

Information regarding law enforcement officers is based on Federal Bureau of Investigation (FBI) data for full-time sworn officers, current as of 2019 (FBI, 2019) and is shown in Table 2.4-23. Within the ROI counties, the number of law enforcement officers (sworn officers) ranges from 73 to 1276, with a total of 2379. In 2019, the nationwide ratio of law enforcement officers to citizens was approximately 2.4 per 1000 citizens, which is consistent with the ROI ratio of 2.2 per 1000 citizens.

2.4.2.8.2.2 Fire Services

Fire departments staffed by volunteer, career, and paid firefighters provide fire services in the ROI. In 2020, the National Fire Protection Association (NFPA) estimated that there were 1,041,200 career and volunteer firefighters in the U.S. (NFPA, 2024). According to USCB data, the population of the U.S. in 2020 was 331,449,281 citizens (USCB, 2020), resulting in a firefighter-to-citizen ratio of 1 to 318. The number of firefighters and residents in the ROI are listed in Table 2.4-24. Within the counties in the ROI, the ratio of firefighters to residents ranged from 1 to 123 to 1 to 368. The ratio of firefighters to residents in the ROI was 1 to 300. Forsyth County and Guilford County exceed the national average for firefighter-to-resident ratio, while Rockingham County and Stokes County fall under the national average (see Table 2.4-24).

2.4.2.8.2.3 Emergency Management

The North Carolina Emergency Management (NCEM) agency helps oversee disaster recovery, hazard mitigation and risk management, search and rescue, nuclear emergency preparedness, and emergency communications. The NCEM actively collaborates, communicates, and coordinates to prevent, mitigate, respond, and recover from disasters. The agency deploys state resources when needed and coordinates with neighboring states and the federal government to augment staffing and resources (NCDPS, 2024).

2.4.2.8.2.4 Medical

Table 2.4-25 identifies hospitals and number of beds within the ROI. There are 11 medical centers in the ROI with a total of 3595 beds. Most of these medical centers are located in Forsyth and Guilford counties. Adult care homes and nursing home facilities and associated number of beds are identified in Table 2.4-26. There are 18 adult care homes and nursing home facilities with a total of 764 beds in the ROI.

The number of physicians and dentists within the ROI by county and the ratio of these professionals to residents are detailed in Table 2.4-27. Within the ROI, there are a total of 917 physicians and 630 dentists. The ROI has a resident-to-physician ratio of 1169 to 1 and a resident-to-dentist ratio of 1702 to 1.

2.4.2.9 Education

A total of 271 public and 44 private, elementary, middle, and high schools, are located in the ROI, most of which are in Guilford County. A summary of these schools' statistics, including student enrollment and student-to-teacher ratios for the 2023 private school year and 2024 public school year are provided in Table 2.4-28.

The state of NC has limitations on class sizes. Kindergarten classrooms must have 18 or fewer students per teacher. For first grade, there must be one teacher per 16 students. For second and third grade, there must be one teacher per 17 students. There are no class size requirements detailed for grades 4 through 12 (NCGA, 2023b). As shown in Table 2.4-28, student-to-teacher ratios for the public school districts within the ROI are 15.4 to 1 or lower, with the average across public schools being 14.9 to 1. Student–teacher ratios for private schools within the ROI is 10.6 to 1. The average student-to-teacher ratio within the ROI in public schools is lower than that of the state of NC, where the average ratio is 17.2 to 1.

In addition to primary and secondary schools, there are 17 college campuses, with a total student population of 72,768 individuals, located within the ROI (see Table 2.4-29). Most of the colleges and universities are located within Guilford County, which has nine colleges or universities with a total enrollment of 46,306 students. Table 2.4-30 details the number of individuals enrolled in pre-kindergarten, elementary, secondary and post-secondary schools. In the ROI, 274,358 individuals attend various levels of educational institutions.

Table 2.4-31 details the educational attainment of individuals 25 years and older within the ROI in 2022. Of this population, 9.2 percent have achieved an associate's degree, 21.2 percent have achieved a bachelor's degree, and 12.7 percent have a graduate or professional degree. These percentages are similar to those of NC as a whole.

Notes:
(a) Per the USCB, "places" are categorized as cities, towns, or CDP.
(b) Place intersects two counties but is listed under the county where the majority of the population resides.
Key: CDP = Census Designated Place; ROI = region of influence; USCB = U.S. Census Bureau

Notes:
(a) Multifamily housing is defined as residential buildings containing units built one on top of another and those built side-by-side which do not have a ground-to-roof wall and/or have common facilities.
(b) Single-family dwelling is defined as fully detached, semidetached, row houses, and townhouses. In cases of attached units, each must be separated from the adjacent unit by a ground-to-roof wall.
Key: ROI = region of influence; "--" = not available

2.6 HISTORIC PROPERTIES

As defined by the National Historic Preservation Act (NHPA) of 1966, as amended (54 USC §306108) and its implementing regulations 36 CFR 800.16(l)(1), historic properties are those properties deemed eligible for listing or that are already listed in the NRHP. Issuance of an Early Site Permit (ESP) is subject to review and consultation under Section 106 of the NHPA which requires the applicant to "take into account the effect of the undertaking on any historic property" and afford the Advisory Council on Historic Preservation "a reasonable opportunity to comment with regard to the undertaking." This section focuses on a description of the existing archaeological resources and historic properties at the Project site and within the vicinity.

In accordance with 36 CFR 800.16(d) the area of potential effect (APE) means "the geographic area or areas within which an undertaking may directly or indirectly cause alterations in the character or use of historic properties, if any such properties exist. The APE is influenced by the scale and nature of an undertaking and may be different for different kinds of effects caused by the undertaking."

The determination of the APE is based on the potential for both direct and indirect effects. Direct effects are defined as those that result from activities that could damage or destroy the physical integrity of a cultural resource. Direct effects are typically associated with construction activities. Indirect effects are those that do not directly destroy the physical integrity of a cultural resource but would rather adversely affect contributing elements of the cultural resource. For historic structures, this typically consists of visual effects to the viewshed of the cultural resource that may diminish its overall context.

The APE consists of approximately 1080 ac. [437.06 hectares (ha)]. This area includes a contiguous area on the Project site and a wastewater discharge pipeline corridor to the Dan River. Both are located on land owned by Duke Energy as indicated in Section 2.1.1.3 and are shown on Figure 2.6-1 and Figure 2.6-2. Based on consultation with and written confirmation from the North Carolina State Historic Preservation Office (NCSHPO), an architectural viewshed survey was not required; as such, an Indirect APE was not established. No portions of the APE include federal, state or tribal-owned lands.

2.6.1 CULTURAL BACKGROUND

The history of human activity in the Carolina Piedmont spans thousands of years. The earliest groups to leave a definitive material record of their presence were early Paleoindians who entered the region during the Late Pleistocene glacial epoch at least 12,000 years ago. Their descendants and the descendants of other Native American groups who migrated to the area later occupied the region the next 11 millennia. This long precontact era lasted until the arrival of European explorers in the sixteenth and seventeenth centuries.

While cultural change is a slow and continual process, archaeologists and other researchers divide the human history of a region into distinct cultural periods. Archaeologists and historians recognize five broadly defined precontact periods for the Piedmont region: Paleoindian [circa 10,000-8000 Before Common Era (B.C.E.)], Archaic (8000-1000 B.C.E.), Woodland [1000 B.C.E.-Common Era (C.E.) 900], Mississippian (C.E. 900-1540), and Contact/Protohistoric period (C.E. 1540-1672) .

Prior to fieldwork, a cultural resources records review and background study were conducted for the Phase I Investigation, discussed in Section 2.6.3.1, to identify previously documented

cultural resources and archaeological surveys within the Project site APE and within a 2-mi. (3.2-km) buffer surrounding the APE. The background literature search included a review of files at the North Carolina Office of State Archaeology (NCOSA) and was conducted on January 8 and 12, 2024. In addition, appropriate archival sources were examined including historic USGS topographic quadrangles, aerial imagery, and other historic mapping for information regarding unknown possible cultural resources within Project site APE and within a 2-mi. (3.2-km) buffer surrounding the APE. This research aided in developing a historic context for the Project site APE.

2.6.1.1 Historic Overview of Stokes County

Stokes County was established in 1789, from portions of Surry County, NC, following the ratification of the U.S. Constitution by the Fayetteville Convention (North Carolina History Project, 2024; Stokes County Historical Society, 2024). The county lies in the Piedmont region and is bounded by Forsyth, Surry, and Rockingham counties in NC, and Patrick and Henry counties, in southern Virginia. The community of Rockford was chosen as the first county seat in 1790; later, in 1851, Danbury became the county seat. The primary centers of population for the county are Danbury and King (North Carolina History Project, 2024).

2.6.1.2 Historic Overview of Forsyth County

Forsyth County was formed from a southern portion of Stokes County in 1849 and was named after Colonel Benjamin Forsyth who served during the War of 1812 (Fearnbach, 2007). The town of Winston, named after American Revolutionary War veteran, Major Joseph Winston, was appointed as the county seat in 1851 (Vocci, 2006). The county lies in the Piedmont region of NC and is bounded by Davidson, Davie, Guilford, Rockingham, Stokes, Surrey, and Yadkin counties of NC. The primary center of population for the county is the Winston-Salem Metropolitan Area (North Carolina History Project, 2024).

2.6.2 HISTORIC AND CULTURAL RESOURCES AT THE SITE AND IN THE VICINITY

A cultural resources records review and background study at the NCOSA to identify any previously documented cultural resources and archaeology surveys within a 10-mi. (16.1 km) buffer was also conducted. The background research included portions of Forsyth, Guilford, Rockingham, and Stokes counties. The results indicated there were no previously recorded archaeology sites within the APE; however, within the 10-mi. (16.1 km) buffer, there were 412 previously recorded archaeology sites. Of those 412 sites, [[

]][CRI]

Sites [[

]][CRI] The Dan River Navigation System was created in the 1820s as a reliable means of the transportation of goods and people and was critical for the success of NC. The navigation system was constructed by

the Roanoke Navigation Company and stretched 46 mi. (74 km) from the Virginia-NC State Line to Harriston Falls in Stokes County, NC (Clauser, 1983). [[

]]CRI

[[

]]CRI Little information was available for Site [[ ]]CRI other than that the site consisted of Precontact and Historic components. Site [[ ]]CRI is a [[ ]]CRI dating from 1870 to 1964 and consisted of [[

]]CRI

Although nominated for the NRHP, the site was anticipated to be likely destroyed due to road construction in the area. Very little information is available for site [[ ]]CRI as the site was reported by a local resident. The site is recorded as a Precontact site of unknown affiliation but has not undergone professional survey.

Additionally, [[ ]]CRI are identified as being study listed. NC's Study List is a preliminary review of cultural resources. The Study List screens resources which are not likely eligible or are eligible for listing in the NRHP to streamline nomination processes (NCSHPO, 2024). All [[ ]]CRI are within close vicinity to each other [[

]]CRI The Saura were a Siouan branch who inhabited the Dan River Valley as early as the fifteenth century. The [[ ]]CRI were routinely looted until an intensive archaeological investigation began in the 1960s. The [[ ]]CRI yielded a high number of artifacts which included [[

]]CRI

Features uncovered at the sites revealed the town was fortified with multiple home sites within the palisade. The Saura abandoned [[ ]]CRI around 1710 (NCDNCR 2024).

The Historic Preservation Office Web Service maintained by the NCSHPO was consulted for previously recorded historic architecture resources within the APE and a 10-mi. (16.1 km) buffer. According to the background research, there are no previously recorded historic resources within the APE and 1807 historic resources within the 10-mi. (16.1 km) buffer. Of those 1807 resources, 31 are listed in the NRHP, 17 are determined eligible for listing in the NRHP, 60 have been study listed, 919 are undetermined and will require further evaluation, and 780 are ineligible.

The NRHP listed historic resources include six historic districts: South Main Street Historic District (FY0716) and North Cherry Street Historic District (FY2042) in Forsyth County, Oak Ridge Military Academy Historic District (GF0167) and Summerfield Historic District (GF2060) in Guilford County, and Academy Street Historic District (RK0011) and Mayodan Downtown Historic District (RK1646) in Rockingham County. These six historic districts are located in the 10-mi. buffer and are not subject to any potential project impacts.

A review of historic maps of the APE was conducted to identify any resources not previously surveyed or recorded. The only historic maps showing structures prior to the 1970s were the soils maps of Forsyth County (U.S. Bureau of Soils, 1913), Guilford County (Jurney, et al, 1920), Rockingham County (U.S. Bureau of Chemistry and Soils, 1926), and Stokes County

(Davis, 1934). The historic maps depict approximately 34 structures within the APE and these 34 areas were treated as high probability areas to contain historic cultural resources.

2.6.3 CULTURAL RESOURCE SURVEYS

Duke Energy conducted cultural resource surveys within and surrounding the APE to facilitate compliance with the NHPA of 1966, as amended, and to meet the requirements of Section 106 of the NHPA. Cultural resource surveys were conducted by qualified professionals (Myers-Rinehart et al., 2024).

2.6.3.1 Phase I Investigation

The Phase I cultural resource survey was conducted to determine if any unidentified cultural resources were present. The Phase I fieldwork was performed between March 25 and June 26, 2024. A total of 2623 shovel test pits (STPs) were excavated as part of the archaeological survey, which resulted in the identification of [[ ]]^{CRI} within the APE. Table 2.6-1 lists each site with a description of site type and Figure 2.6-3 shows the location of each archaeological site in the APE. Of the [[ ]]^{CRI} sites [[ ]]^{CRI} were determined to be potentially eligible for the NRHP. NCSHPO concurred with the results of the Phase I survey regarding potential eligibility of each of the [[ ]]^{CRI} sites. Accordingly, Duke Energy conducted a Phase II survey of each of the [[ ]]^{CRI} sites as described in the following section.

2.6.3.2 Phase II Investigation

In May and June 2025 WSP conducted Phase II archaeological NRHP evaluation investigations on sites [[ ]]^{CRI} Phase II evaluation excavations were completed to assess the significance and eligibility for inclusion on the NRHP. The investigation included remote sensing on 4.65 acres (18,800 square meters), excavations on all sites, more extensive archival research, artifact analysis, and reporting. Background research was conducted to collect material for use in developing a context for evaluation of recorded resources and to provide background information. The research included online and local resources. Excavations on all sites included 52 test units, 174 STPs, and 36 cultural features.

Recommendations for NRHP eligibility for each site resulting from the Phase II investigation are shown in Table 2.6-2. Based on the preliminary study results, [[ ]]^{CRI} sites were recommended as not eligible for the NRHP under Criterion D and received NCSHPO concurrence. The remaining [[ ]]^{CRI} sites remain in consultation with NCSHPO. Duke Energy has committed to avoidance or mitigation of these sites if they are deemed eligible. If any site is deemed eligible and avoidance is not possible, archaeological mitigation including Phase III data recovery will be required to resolve adverse effects.

2.6.3.3 Regulatory Consultation

Initial coordination with the NCSHPO was submitted on March 19, 2024, the purpose of which was to provide a Scope of Work for the Cultural Resource Survey and request regulatory comment on the project pursuant to North Carolina Archaeological Investigations Standards and Guidelines (NCOSA, 2023). A response from the NCSHPO (ER 24-0833) was received in a

letter dated April 15, 2024 (Appendix 1A). In this letter, the NCSHPO indicated their concurrence with the proposed SOW methodology. Additionally, the NCSHPO determined that the project, as proposed, will not affect any historic structures.

Additional formal coordination with the NCSHPO was conducted on November 7, 2024, to submit the results of the cultural resource survey (Appendix 1A) and initiate Section 106 regulatory review pursuant to the NHPA. In a letter dated January 17, 2025, the NCSHPO concurred with the report of findings; sites [[ ]]^{CRI} have the potential for intact deposits and may contain data that would provide information pertinent to historic research questions, sites [[ ]]^{CRI} do not have the potential to contain information pertinent to prehistoric or historic research questions.

Duke Energy met twice with NRC staff to discuss tribal consultation, with both parties acknowledging that the Catawba Indian Nation was the only federally recognized tribe in need of consultation. This was accomplished in September 2024 through a phone call between Duke Energy and the Catawba Indian Nation's staff followed by a scoping letter sent to the tribe. In a letter dated September 24, 2024, from their THPO, the tribe concurred that the project will not affect Native American archaeological sites but requested to be notified if Native American artifacts or human remains are discovered. In addition to this consultation, NRC staff requested that state recognized tribes also be identified and consulted about the Project; however, there are no state recognized tribes in Stokes or Forsyth counties. As described in the Phase I cultural resources report, the Saura Indians were present along the Dan River prior to European contact; however, they abandoned their settlements by the early eighteenth century and ultimately joined with the Catawba Indians. Duke Energy also initiated correspondence with the Monacan Nation as they have tribal interest in Rockingham County, NC; however, no response was received from the Monacan Nation.

Additionally, site [[ ]]^{CRI}, the Branson Cemetery, is determined to be ineligible for the NRHP. However, cemeteries are protected under North Carolina General Statutes Chapter 14-148 and 14-149 and are afforded consideration under Chapter 65. If a cemetery cannot be avoided the provisions regarding exhumation and repatriation provided by North Carolina General Statute Chapter 65-106 must be followed.

2.7 AIR RESOURCES

This section addresses the local and regional climatology and meteorology, as well as air quality, in the vicinity of the Project site. The information supports independent evaluations and assessments of atmospheric-dispersion characteristics and impacts on the environment.

The Project site is located in north-central NC in the southeastern portion of Stokes County and the northeastern portion of Forsyth County. Guilford and Rockingham counties are adjacent counties to the east of the Project site. The state of NC spans approximately 500 mi. (802 km) east to west and 186 mi. (301 km) north to south. The Project site is in north-central NC in the Northern Piedmont region which is east of the Blue Ridge Mountain Range. The mountain range barriers affect temperature, precipitation, and wind. The Project site is in a humid subtropical climate zone. Figure 2.7-1 shows an aerial view of the Project site with a 50-mi. (80.5 km) radius around the site.

Data sources for the preparation of this section include:

- Data from KGSO (Greensboro, NC), KINT (Winston-Salem, NC), and KRDU (Raleigh, NC) were utilized for the preparation of this section.

- Annual and monthly Local Climatological Data (LCD) summaries from the National Oceanic and Atmospheric Administration (NOAA) National Centers for Environmental Information (NCEI) were utilized. LCD summaries typically are available for meteorological stations located at airports. Summaries include climatic normals and extremes as well as thirty-year monthly historical values for mean temperature, total precipitation, total snowfall, and heating/cooling degree days. The LCD summaries also include a narrative description of the local climate.

- Statistical summaries of climatological data from the American Society of Heating, Refrigerating and Air-Conditioning Engineers, Inc. (ASHRAE) were utilized for the preparation of this section (ASHRAE, 2021). ASHRAE provides climatic information for worldwide locations, including many U.S. airports and other U.S. locations with hourly surface weather stations. Parameters include dry bulb temperature (DBT), wet bulb temperature (WBT), dew point temperature (DPT), statistical design values of DBT with mean coincident WBT, design WBT with mean coincident DBT, and design DPT with mean coincident DBT. ASHRAE also provides a methodology and key inputs for estimating extreme DBT and WBT for various return intervals.

- American Society of Civil Engineers (ASCE) structural design standards (ASCE, 2021) were referenced and utilized for the preparation of this section. These standards provide minimum load requirements for the design of buildings/structures subject to building code requirements. Particularly useful are maps of 100-year, mean recurrence interval (MRI) 3-second wind gusts. ASCE also provides maps and charts of 50-year return-interval snowpack and a methodology for converting 50-year values extracted from those maps to other return intervals.

- Air quality summaries and monitoring data from the USEPA were utilized for the preparation of this section. The USEPA provides summaries of compliance status with the National Ambient Air Quality Standards (NAAQS) (USEPA, 2024h). The USEPA Green Book provides NAAQS designations, classifications, and

attainment/nonattainment status of areas (USEPA, 2024i). State environmental agencies track concentrations from monitors to assess compliance with the NAAQS.

- Weather event statistics from the NCEI Storm Events Database were utilized for the preparation of this section. The NCEI Storm Events Database contains chronological listings by state and county of tornadoes, thunderstorms, hail, lightning, wind, snow, temperature extremes, and other weather phenomena (NOAA NCEI Storm Events Database, 2024).

- NRC NUREG documents and Regulatory Guides are referenced.

- Various meteorological data publications, as cited in the References section.

2.7.1 CLIMATE

Information about regional climatology conditions was obtained from the National Climatological Data Center (NCDC) Storm Events Database and LCD for the cities of Winston-Salem and Greensboro. The Project site is located within the NCDC's NC Northern Piedmont Climate Division, or Climate Division 3. The nearest NWS Station is KGSO, which is approximately 14 mi. (22 km) to the southeast of the Project site. Meteorological Data from KINT and KRDU were also utilized. KGSO is located in Guilford County and is a reliable station for collecting regional meteorological data.

KGSO is centrally located between the mountains to the west and the coastline to the east and south, which provides a temperate climate. The mountains block cold air masses moving eastward; therefore, few days in the winter are below 20°F (-6.7°C]). KINT, located in Winston-Salem, NC, is within 50-miles (mi.) of the Project site, and experiences warm and muggy summers and very cold winters with variable snowfall. It is partly cloudy year-round.

The average minimum extreme annual temperature at KGSO is 11.4 ˚F (-11.4 ˚C) and at KINT the average minimum extreme annual temperature is 12.4 ˚F (-10.9 ˚C) (see Table 2.7-1). Tropical air brings warm temperatures and high humidity to the area during the summer months. During the summer, the average maximum annual temperatures at KGSO and KINT are 95.7 ˚F (35.4 ˚C) and 95.5 ˚F (35.3 ˚C), respectively.

Rainfall is fairly consistent throughout the year but varies significantly from year to year. July and August have the highest rainfall amounts, while October and November have the least. Summer rainfall is usually from thunderstorm activity that can also bring high winds and hail.

Snow, sleet, glaze, and ice accumulation are rare during the winter months and short-lived when experienced. Snowfall amounts vary greatly, with some winters experiencing only trace snowfall amounts. Glazing is more common in the Piedmont area of NC (where the Project site is located) than in the rest of the state.

According to *Estimated Ice and Wind Loads at the Earth's Surface for the Contiguous U.S.* prepared by Tattelman and Gringorten in October 1973, ice thickness greater than or equal to 2.5 cm (0.98 in.) occurred only twice in NC over a fifty-year period. From the Bennett 1959 study referenced in Tattelman and Gringorten's report a total of 9 to 17 glaze storms, without regard to thickness were observed. NC is in Region V in their report, five ice storms in 50 years with accumulation greater than or equal to 2.5 cm (0.98 in.). Since the Tattelman and Gringorton's publication in 1973 there have been multiple ice storms in the region. On December 4-5, 2002,

a high-pressure system over the northeast U.S. created a system in the western Piedmont where snow fell for up to 8 hours in Greensboro before transitioning to sleet and freezing rain. The freezing rain lasted for more than 12 hours with up to an inch of ice accumulation in parts of the Piedmont. Back-to-back ice storms occurred in 2020. The February 12-13 storm had a quarter-inch of ice accumulation in the Greensboro area and then the February 18-19 storm affecting areas along I-40 and U.S. 421 between Burlington and Boone generally received around a quarter-inch of glaze.

Tornadoes, hurricanes, and tropical storms and depressions are infrequent in the area of the Project site (NOAA NCEI, 2022a; NOAA NCEI, 2022b; Tattelman, P. and Gringorten, I.I., 1973; NOAA NCEI Storm Events Database, 2024).

2.7.1.1 Local Meteorology

Short-term site-specific meteorological data, collected from the Project site meteorological tower (MET tower) during February 7, 2024 – February 6, 2025, are the primary basis for this dispersion meteorology analysis. In addition to on-site measurements, data representative of the Project site or indicative of site conditions were also obtained from LCDs recorded at the NWS Stations at KGSO, KINT, and KRDU (NOAA NCEI, 2022a; State Climate Office of North Carolina, NC State University, 2024; NOAA NCEI, 2022b).

KGSO is located in Guilford County and is a reliable station for collecting meteorological data. It is located approximately 14 mi. (22.5 km) SSE of the Project site. The location of the MET tower, in Stokes County (adjacent to Guilford County), is in the same climatic zone as KGSO, therefore, it will experience similar effects from the mountain ranges as well as similar weather conditions. The selected tower location is positioned to provide sufficient and accurate meteorological data, and KGSO can be used as a backup if needed.

Meteorological measurements were made using one on-site tower, as listed in Table 2.7-2. Data from the on-site tower and regional towers were used to evaluate the impact of topography. The principal impact is on wind directions, as further described in Section 2.7.1.5.

Much of the following discussion considers the 10-meter (m) wind data because it is most representative of the local meteorological conditions closest to the ground where releases for dispersion modeling are expected. Local ground-level conditions are most important in evaluating ground-level releases because maximum air concentrations from contaminants released into the atmosphere generally occur close to the release point.

2.7.1.1.1 Normal, Mean, and Extreme Values

Long-term temperature and precipitation records were examined to determine if data collected at the Project site are consistent with regional conditions, both spatially and over time. This section presents the normal, mean, and extreme local meteorological parameters at nearby KGSO compared to the average measurements at Project site during the 2024 – 2025 collection period. Meteorological data collected at nearby KGSO are presented and evaluated in the following sections in more detail. Table 2.7-2 summarizes annual meteorological parameters from KGSO, including normal temperature and relative humidity (RH), mean wind speed, prevailing wind direction, and normal precipitation for the time period of 1991 – 2020.

Comparisons of common measurements for the different data periods have been made to determine if site meteorological conditions are changing significantly over time. Common

variables (except wind direction) can be compared directly, but wind direction is too dependent on topography for direct comparison particularly with off-site data. Comparing data from nearby off-site locations helps to determine if the Project site is consistent with regional conditions.

Comparison of the KGSO, KRDU, and KINT regional airport data to the Project site data in Table 2.7-3 shows that there is generally good agreement between the Project site and off-site regional locations over different data periods. The differences fall within the normally expected variations. Therefore, it is concluded that meteorological characteristics for the Project site have not changed significantly over time. Additionally, data from the Project site appear to be consistent with overall meteorological conditions in the vicinity. This is characteristic of the similarity in controlling synoptic influences throughout the region. Other meteorological parameters are subject to the same synoptic controls.

2.7.1.1.2 Wind

From February 2024 to February 2025, both 10-m and 60-m wind data were collected by the MET tower at the Project site. The meteorological facility generally met criteria for obtaining "data representative of the atmospheric conditions."

The following discussion considers the 10-m wind data from KGSO and the on-site MET tower as representative of potential ground-level releases for air dispersion modeling purposes. Local conditions are important in evaluating ground-level releases because maximum air concentrations from contaminants released into the atmosphere generally occur close to the release point.

2.7.1.1.2.1 Average Wind Direction and Wind Speed

Table 2.7-4 presents the KGSO 10-m wind speed and wind direction joint frequency distribution (JFD) for the 11-year period of January 2013 – December 2023 and Table 2.7-5 presents the Project site 10-m JFD for the 1-year collection period of February 2024 – February 2025. The distribution of 10-m wind direction frequency at KGSO and the Project site range from light to moderate.

Mean wind speeds recorded at KGSO for the 39-year period 1983 – 2022 (Table 2.7-6) were generally moderate with an average annual mean speed of 7.1 mi. per hour (mph) (11.4 km per hour [kph]). Wind gusts were recorded over a 27-year period, 1996 – 2022, with the maximum 2-minute wind speed recorded in May 2000 at 62 mph (100 kph). The maximum 3-second gust recorded was 82 mph (132 kph) on May 25, 2000, when Guilford and Alamance counties were impacted by a severe storm with reports of property damage and tornado sightings (Swoffard, S., 2000; NOAA SPC, 2024).

Wind speeds at the Project site during 2024 – 2025 were generally light with an average 10-m speed of 4.26 mph and prevailing wind direction from the west-southwest (WSW). The daily maximum 10-m (scalar) wind speed was 19.2 mph (Table 2.7-7).

The Project site and KGSO data indicate winds consistent with the SW to NE orientation of the terrain in the region. The geographic orientation of the ridges and valleys generally aligns with the prevailing regional winds from the southwest, but the gaps in the ridges permit wind flow from other directions as well. The local wind patterns are influenced by this terrain, with up-valley (SW-WSW) and down-valley (NE-ENE) flow patterns common and stable conditions with light to moderate winds frequently observed, especially during the summer and fall seasons.

2.7.1.1.2.2 Wind Direction Persistence

Wind roses for KGSO based on ten years of data (2013 – 2023), are presented in Figures 2.7-2 through 2.7-14. The Project site data are presented as wind roses at 10-m in Figures 2.7-15 through 2.7-27, and at 60-m in Figures 2.7-28 through 2.7-40. Wind roses for KGSO were developed using data from the NOAA NCEI Index of Public Data for the years of 2013 to 2023 (NOAA NCEI, 2024).

Generally, the longer the winds blow in the same direction, the lower the dilution potential because effluent is not dispersing significantly to the sides of the plume. Wind direction persistence is an indicator of the duration of atmospheric transport from each direction. For the Project site (Table 2.7-8), the maximum persistence at 10-m is 27 hours from the SW.

The wind data for KGSO and the Project site show a consistent pattern of wind directions with predominant winds from the southwest. There is moderate seasonal variation. Due to the combination of uniformly light to moderate winds speeds and surrounding terrain, there will often be times with little transport away from the site.

2.7.1.1.3 Air Temperature

Table 2.7-9 summarizes normal maximum and minimum temperatures recorded at KGSO for the time period of 1991 – 2020. Maximum temperatures recorded for the 30-year period 1991 – 2020 usually occur between the months of June and September. Minimum temperatures for the 30-year period 1991 – 2020 usually occur from November through March. Mean monthly temperatures range from the lower 30s (°F) (around 0 ˚C) in the winter to the upper 80s (°F) (around 30 ˚C) in the summer.

The extreme maximum temperature recorded at KGSO for the 94-year period 1928 – 2020 was 103°F (39.4 °C) in August 1988 and the extreme minimum temperature for the 94-year period was -8°F (-22.2 °C) recorded in January 1985 (NOAA NCEI, 2022a).

Table 2.7-10 summarizes average, daily minimum, and daily maximum DBT and WBT recorded at the Project site during the collection period from 2024 – 2025. The highest daily maximum temperatures for the collection period occurred during the months of June and July. The lowest daily minimum temperatures occurred in December and January. The average monthly DBTs range from the mid-30s (°F) (around 0˚C) in the winter, to the upper 70s (°F) (around 25 ˚C). The daily maxima recorded at the Project site was 97.3°F (July 2024), while the daily minimum was 15.8 °F (January 2025).

2.7.1.1.4 Atmospheric Moisture

Long-term RH and WBTs for KGSO are presented in Table 2.7-11. The normal annual RH is 69 percent at KGSO and ranges from 61 percent in April to 77 percent in September. Normal mean annual WBT averages are 50.1 °F (10.1 °C) at KGSO (NOAA NCEI, 2022a). Maximum monthly mean WBTs are 69.0 °F (20.6 °C) during July. Minimum monthly mean WBTs are recorded in January; 30.9 °F (-0.6 °C) (NOAA NCEI, 2022a).

Average RH and WBTs for the Project site, is summarized in Table 2.7-12. The average annual RH is 68 percent at the Project site and ranges from 53 percent in January to 80 percent in September. The average annual WBT is 54.7°F (12.6 °C). The highest daily maximum WBT is 71.8°F (22.1 °C) during July. The lowest daily minimum WBT was recorded in January at

30.5 °F (-0.8 °C). The Project site data match well with the long-term KGSO data.

2.7.1.1.5 Precipitation

Table 2.7-13 summarizes the precipitation recorded at KGSO. Precipitation falls an average of about 116 days per year, and the normal annual precipitation is nearly 44 inches (in.) (112 centimeters [cm]). The maximum monthly rainfall in the 94-year period 1928 – 2022 was 13.26 in. in September 1947. The minimum monthly amounts in the 94-year period were trace amounts in September 1985 and June 1990. The maximum precipitation in 24 hours (hr.) was 7.49 in. (19.02 cm) in September 1947. Except for late winter (which is slightly drier), precipitation is fairly uniformly distributed throughout the year. August and September are normally the wettest months of the year, and February is normally the driest.

Approximately 43 thunderstorms occur in a typical year (Table 2.7-13). Thunderstorm activity is greatest during the late spring and summer months, and the maximum frequency of thunderstorm days is normally in July.

The Project site precipitation data for the 2024 – 2025 collection period (Table 2.7-14) indicate drier than normal precipitation. The annual precipitation was 38.07 in. (96.70 cm). The maximum monthly rainfall was recorded in September with 7.08 in. (17.98 cm). The maximum precipitation in 1 hr. was 1.28 in. (3.25 cm) at 1:00 a.m. on July 19, 2024, and the maximum precipitation in 24 hr. was 4.23 in. (10.74 cm) on August 8 – 9, 2024.

2.7.1.1.5.1 Precipitation Wind Roses

Table 2.7-15 shows composite precipitation data for the 2024 – 2025 collection period based on the Project site hourly precipitation and wind directions (vector). The precipitation value used in the analysis is based on the amount that accumulated over the hour. Precipitation is most associated with wind direction from the W. There is a secondary maximum with wind direction from the west-northwest (WNW). The Project site composite precipitation and wind direction data are presented as precipitation wind roses at 10-m in Figures 2.7-41 through 2.7-53.

2.7.1.1.6 Snowfall

Appreciable snowfall is relatively infrequent in the area. Snowfall data are summarized in Table 2.7-16 for KGSO. Normal annual snowfall is about 7 in. (18 cm). Generally, significant snowfalls are limited to December through March. The 24-hr. maximum snowfall was 14.3 in. (36.3 cm) in December 1930. Recorded maximum monthly snowfall was 22.9 in. (58.2 cm) in January 1966.

2.7.1.2 Atmospheric Stagnation

Air pollution episodes are typically the result of persistent surface high-pressure systems that cause light and variable surface winds and stagnant meteorological conditions. In the eastern U.S. there is a relative minimum of stagnation in July, accompanied by a relative maximum stagnation in May-June and August-September. This mid-summer decrease in air stagnation is due to the impact of the Bermuda High-pressure system. The Bermuda High-pressure system plays a significant role in dictating the day-to-day weather in NC. The Bermuda High is a large area of semi-permanent high pressure, usually situated off the southeast U.S. Atlantic coast. This high many times will extend westward across the southeast during the summer. When the Bermuda High is displaced more south and westward, it can stretch its western edges close to and even over the East Coast. If and when this set-up occurs, the eastern U.S. coastline can be

extremely susceptible to hurricanes. The Bermuda High is strongest in July (Wang and Angell, 1999). This high-pressure system has a clockwise circulation, which puts the eastern U.S. in the position to receive south to southeast winds. These winds pump in heat and humid air from the Atlantic Ocean and Gulf of America into the east. It can often lead to many days or even weeks of hot and sticky weather, especially across the southeast. Therefore, the Bermuda High is a unique controlling factor for air stagnation conditions over the eastern U.S., besides the seasonal cycle of minimum wind in summer and maximum wind in winter. Another unique feature of air stagnation in the eastern U.S. is its early onset in May, compared to the onset in June in the west and central U.S. This results in a prolonged, but weaker air stagnation season in the eastern U.S..

Estimates of the stagnation frequency and duration are provided in Wang and Angell, 1999; Figures 1 and 2. Those estimates indicate that, on average, the Project site experiences approximately two to four cases of air stagnation per year. When stagnation occurs, stagnation lasts approximately five days. Wand and Angell also show that May–July have similar monthly occurrences of air stagnation days, with a peak in air stagnation in the fall (August–October).

2.7.1.2.1 Inversions

Atmospheric stability is based on the temperature difference (ΔT) between the 60-m and 10-m measurement levels. The Pasquill (classes A-G) atmospheric stability classes are described in Table 2.7-17 and the frequency occurrence of each class is presented in Table 2.7-18. While neutral lapse conditions (class D) occur most frequently (31.0 percent), stable lapse conditions (i.e., inversions) typically occur over 36.3 percent of the time. The most unstable class (class A) occurs 21.6 percent of the time, while the most stable class (class G) occurs 2.3 percent of the time.

Tables 2.7-19 and 2.7-20 present a summary of on-site persistence data, with a breakdown by stability class, for the 2024 – 2025 collection period. Inversion persistence is defined as two or more consecutive hours of a single stable class (or combination of stable classes). The longest contiguous period of inversion conditions were 19 hours.

2.7.1.3 Mixing Heights

Mixing heights for Greensboro, NC, were obtained from the U.S. Environmental Protection Agency (USEPA) Support Center for Regulatory Atmospheric Modeling (SCRAM).. The USEPA data are more current than the traditional Holzworth reference (Holzworth, George C., 1972) that is often used. Mixing heights vary during the day, with the lowest average mixing heights (approximately 379 m [1243 feet {ft.}]) generally recorded during the morning hours in the fall and the highest readings (approximately 1609 m [5278 ft.]) recorded during the afternoon in the summer for the 7-year period of record (1984-1987 and 1989-1991) used by the USEPA in the SCRAM dataset. (USEPA, 2024j). Approximate seasonal and annual estimates of mixing heights for the Project site, are presented in Table 2.7-21.

2.7.1.4 Severe Weather

2.7.1.4.1 Tornadoes

A tornado is defined as a rapidly rotating column of air extending vertically from the surface to the base of a cumuliform cloud (AMS, 2024). Tornado intensity is classified according to the Enhanced Fujita Tornado Intensity Scale (EF Scale). This scale correlates wind speeds from a tornado event to the magnitude of observed damage according to 28 indicators. The EF Scale

ranks tornadoes in categories EF-1 to EF-5 using more specific structural damage indicators than the original, previously used tornado intensity classification scale, the Fujita Scale, which was established in 1971 (NOAA SPC, 2021).

Tornadoes occur around the Project site, with 52 recorded in Guilford, Stokes, Rockingham, and Forsyth counties from 1950 to 2023. The strongest tornadoes recorded in the area (EF3) occurred in the months of March and May on the following dates and in these counties (NOAA NCEI Storm Events Database, 2024):

- May 1985 Forsyth County
- May 1989 Forsyth County
- March 1998 Rockingham County
- May 1998 Forsyth County
- May 2008 Forsyth County
- March 2010 Guilford County.

2.7.1.4.2 Hurricanes, Tropical Storms, and Tropical Depressions

Hurricanes, also known as tropical cyclones, have 1-minute average surface winds at 10-m (32.8 ft) exceeding 33 m/s (65 knots). Hurricanes originate from tropical depressions with winds up to 17 m/s (34 knots) which can develop into tropical storms, with winds of 18 – 32 m/s (35 – 64 knots) prior to being classified as a hurricane (AMS, 2024).

Other storms have impacted the area, but the centers of those storms remained beyond 50-mi. of the site center point. Twenty-two historical hurricane tracks are reported within 50-mi. of the site center point, by the NOAA Historical Hurricane Tracks website. Of these, only the unnamed 1893 storm-maintained hurricane strength (Category 1) in the area, which is also confirmed by the State Climate Office of North Carolina. Additionally, four tropical storms were recorded from 1859 to 2023. Hurricanes and tropical storms can produce heavy rainfall, severe thunderstorms, hail, high winds, and flooding in the area.

Other storms that impacted the area but not within 50-mi. of the site have centers that did not pass through the 50-mi. radius. The strongest hurricane which was within a 200 mi. radius and had rains impacting Forsyth County and Guilford County was Hurricane Fran (September 5, 1996), a category 3 hurricane (NOAA NWS, 2015; NOAA NCEI Storm Events Database, 2024). Hurricane Floyd made landfall on the NC's eastern coast and the hurricane-related rainfall (September 15, 1999) reached inland as far as Forsyth County and Guilford County (NOAA NWS, 2019; NOAA NCEI Storm Events Database, 2024).

2.7.1.4.3 Wind

The maximum high wind recorded in Forsyth County, Guilford County, Rockingham County, or Stokes County was 50 knots (kts [57.5 mph {92.6 kph}]) which occurred in Stokes County, April 2003 (NOAA NCEI Storm Events Database, 2024). The maximum high wind recorded in those counties was 60 kts (69 mph [111 kph]) which occurred in February 2003 and March 2004 in Rockingham County and Stokes County (NOAA NCEI Storm Events Database, 2024). The

thunderstorm wind maximum was 100 kts (115 mph [185 kph]) in Forsyth County in July 1962 (NOAA NCEI Storm Events Database, 2024). The database was queried from 1950 to 2023 for Forsyth County, Guilford County, Rockingham County, and Stokes County. The 100-year MRI 3-second wind gust is 93 mph (42 m/s) (ASCE, 2021).

The wind patterns are influenced by the local topography, which will affect the severe weather regionally. In the Piedmont region rainfall is modified by the mountain barrier, but to a lesser extent than in areas closer to the Appalachian Range. Shallow cold air masses from the west tend to be stopped or turned aside by the mountains, while deeper masses are lifted over the range, losing moisture and warming during the passage. Summer precipitation is largely from thunderstorms, which signal an unstable atmosphere, mostly local in character. Damaging storms are infrequent in the Northern Piedmont area. The highest winds to occur have been associated with thunderstorms and are of brief duration.

2.7.1.4.4 Thunderstorms and Lightning

Thunderstorms are defined as a local storm, invariably produced by a cumulonimbus cloud, and always accompanied by lightning and thunder, usually with strong gusts of wind, heavy rain, and sometimes hail (AMS, 2024). Lightning is an electrical discharge in the atmosphere that occurs due to strong electric fields between regions of cumulonimbus (thunderstorm) clouds (AMS, 2024).

Thunderstorms and lightning mainly occur in the spring and summer months. Thunderstorms are occasionally accompanied by high winds, heavy rain, and hail. Damaging thunderstorms are infrequent in the area of the Project site, according to the 75-year period reported on the KGSO and KRDU 2022 LCDs (NOAA NCEI, 2022a; NOAA NCEI, 2022b).

2.7.1.4.5 Hail

Precipitation in the form of balls or irregularly shaped lumps of ice is called hail. Hail has a diameter of five millimeters or greater and is always produced by convective clouds (AMS, 2024). Hail can occur with thunderstorms in Forsyth County, Guilford County, Rockingham County, and Stokes County. A total of 553 hail events are recorded in the NCEI Storm Events Database from 1950 to 2023 in these counties. The largest size of hailstones reported were 2.25 in. (5.72 cm) in Stokes County, June 2002; 2.75 in. (6.99 cm) in Guilford County, April 1983; Rockingham County, June 1998; and Forsyth County, March 2005 (NOAA NCEI Storm Events Database, 2024).

2.7.1.4.6 Winter Weather

Normal annual snowfall for the Project site is between 5.2 in. (13.2 cm) and 7.1 in. (18.0 cm). Maximum monthly snowfall ranges from 25.8 in. (65.5 cm) to 22.9 in. (58.2 cm). These measurements were recorded at KRDU and KGSO, respectively. The mountains to the west modify the winter temperatures and weather. This area experiences winter rain or snowfall amounts that are variable from year to year and rarely persist for more than a few days (NOAA NCEI, 2022a; NOAA NCEI, 2022b).

2.7.1.4.7 Droughts and Wildfires

Periods of abnormally dry weather that are long enough to create a serious hydrologic imbalance are called droughts (AMS, 2024). There were 40 drought events recorded in the

NCEI Storm Events Database from 1950 to 2023 in Forsyth County, Guilford County, Rockingham County, and Stokes County. Two weather-related wildfires occurred during that timeframe, one in Rockingham County (February 2011) and the other in Stokes County (December 2021) (NOAA NCEI Storm Events Database, 2024). The two on-site wildfires that occurred in 2024 are discussed in Section 2.3.1.9.

2.7.1.4.8 Fog

Fog is defined as water droplets suspended in the atmosphere in the vicinity of the Earth's surface that affect visibility. Fog reduces visibility below 1 km (0.62 mi.) (AMS, 2024). The number of days with heavy fog (visibility equal to or less than one-quarter mi.) at the Project site, was determined based on data from the KGSO LCD and KRDU LCD (NOAA NCEI, 2022a; NOAA NCEI, 2022b). Fog data for KGSO is presented in Table 2.7-22. These data indicate that heavy fog occurs about 27 days per year, with the winter normally the foggiest season.

2.7.1.4.9 Precipitation

Precipitation events were obtained from the NCEI Storm Events Database for Guilford County and Stokes County. Records indicate heavy rain is mostly associated with thunderstorms and tropical weather (hurricanes and tropical storms). The Storm Events Database defines heavy rain as an unusually large amount of rain which does not cause a Flash Flood or Flood event but causes damage. The AMS [2024h] defines heavy rain as rain at a rate of accumulation exceeding the geographically dependent value. There are a total of three heavy rain events recorded in the NCEI Storm Events Database for Guilford County and Stokes County. The first was the rain event of February 3-4, 1998, when Goldsboro recorded 2.25 in., then on May 18, 2018, the COOP observer at King recorded 2.70 in. over a 24 hr. period, which was the highest daily May rainfall at that station. More recently on February 6-7, 2020, the station at Danbury set a February two-day record with 4.89 in.

Maximum possible precipitation, estimated by statistical analysis of regional precipitation data, is given in Table 2.7-23 for return periods of one to 100 years and for rainfall durations of from five minutes to ten days. Probable maximum precipitation (PMP), sometimes called maximum possible precipitation, for a given area and duration is the depth which can be reached but not exceeded under known meteorological conditions (USACE, 1987b). This data was taken from the NOAA Atlas 14, Volume 2, Version 3 (NOAA, 2006) and the NOAA Atlas 14 Point Precipitation Frequency Estimates (NOAA, 2025) for the area nearest the Project site. For the Project site, using a 100-year return period, the PMP for 6, 12, 24, and 48 hours is 5.1, 6.4, 7.8, and 8.8 in., respectively.

Floods are defined as the overflowing of the normal stream or body of water, or the accumulation of water over areas not normally submerged (AMS, 2024), whereas flash floods are rapidly rising water levels in waterways, usually as a result of intense rainfall (AMS, 2024). The NCEI Storm Events Database recorded a total of 55 flood events and 254 flash flood events for the time period from 1950 to 2023 in Forsyth County, Guilford County, Rockingham County, and Stokes County for a total of 309 flooding events (NOAA NCEI Storm Events Database, 2024). Floods are discussed in further detail in ER Section 2.1.1. Hydrology.

2.7.1.4.10 Ground Snow Load

From the ASCE-7 Hazard Tool (ASCE/SEI 7-22, Figures 7.6-1 and 7.6-2 A-D), the 20-year MRI snow load value for the Belews Lake area is determined to be 9.33 lb/ft^2 (45.55 kg/m^2). The 20-

year MRI value is, on average, 80% of the 50-year MRI ground snow. Using the 80% estimate generates a 50-year MRI of 11.66 lb/ft^2 (56.94 kg/m^2) (ASCE, 2021).

NRC Interim Staff Guidance DC/COL-ISG-007 (NRC, 2009) provides an algorithm that converts a historical maximum snowpack depth to a ground snow load. The algorithm relates the snowpack depth in inches (in.) (D) to the resulting ground snow load (L) in lb/ft^2. The mathematical equation for calculating ground snow load is:

$$L = (0.279)(D^{1.36}) \qquad \text{(Equation 2.7-1)}$$

Using this equation and the maximum snowpack depth recorded at KGSO, 15 in. (38.1 cm), the maximum ground snow load is 11.1 in. (28.2 cm)

NRC Interim Staff Guidance DC/COL-ISG-007 also provides an algorithm that converts a snowfall event to a ground snow load. The algorithm relates the snowfall depth in inches (S) to the resulting ground snow load (L) in lb/ft^2. The mathematical equation is as follows:

$$L = (0.15)(S)(5.2) \qquad \text{(Equation 2.7-2)}$$

In Equation 2.7-2, the constant (0.15) represents the ratio of the volume of melt water derived from a snow sample and the constant (5.2) is the weight of 1 in. of water in lb/ft^2. Using this algorithm and the maximum snowfall in 24 hr. (14.3 in./24-hr. [36.3 cm/24-hr.]) recorded at KGSO, the maximum ground snow load based on the maximum snowfall event in 24 hr. is 1.64 lb/ft^2 (8.01 kilograms per square meter).

2.7.1.4.11 Dry and Wet Bulb Temperature

The mean DBT at KGSO is 58.3 °F (14.6 °C) with a mean maximum of 77.8 °F (25.4 °C) and mean minimum of 39.0 °F (3.9 °C). The mean WBT at KGSO is 50.1 °F (10.1 °C) with a mean maximum of 69.0 °F (20.6 °C) and mean minimum of 30.9 °F (-0.6 °C) (NOAA NCEI, 2022a; NOAA NCEI, 2022b).

Design-basis DBTs and WBTs were estimated for the Project site, using data from KGSO, KRDU, and KINT (Table 2.7-25 for items a-q and Table 2.7-1 for items r and s). These include the following temperatures:

a. Normal DBT

b. Mean DBT

c. Mean WBT

d. Maximum Normal DBT

e. Maximum Mean DBT

f. Maximum Mean WBT

g. Minimum Normal DBT

h. Minimum Mean DBT

i. Minimum Mean WBT

j. DBT with Annual Exceedance Probability of 0.4 percent

k. Mean Coincident WBT With Annual Exceedance Probability of 0.4 percent

l. DBT With Annual Exceedance Probability of 1.0 percent

m. Mean Coincident WBT With Annual Exceedance Probability of 1.0 percent

n. DBT With Annual Exceedance Probability of 2.0 percent

o. Mean Coincident WBT With Annual Exceedance Probability of 2.0 percent

p. WBT (Non-Coincident) With Annual Exceedance Probability of 0.4 percent

q. WBT (Non-Coincident) With Annual Exceedance Probability of 1.0 percent

r. 100-year extreme maximum and minimum DBT

s. 100-year extreme maximum and minimum non-coincident WBT

The 100-year return interval extreme maximum and minimum DBT and WBT ([r] and [s] in the above list) are estimated using a technique described in ASHRAE, 2021. This technique calculates the n-year return interval extreme maximum or minimum temperature using the average and standard deviation of a series of annual maximum and minimum temperatures with the following equation:

$$T_n = M + IF_s \qquad \text{(Equation 2.7-3)}$$

Where:

Tn = n-year return period value of the extreme temperature computed (years)

M = mean annual extreme temperature

I = +1 if the maximum temperature is being computed, -1 if the minimum temperature is being computed

s = standard deviation of the annual extreme temperature

n = return period in years (e.g., n = 100 for a 100-year return interval)

$$F=-\sqrt{6}/\pi \{0.5772+\ln\{\ln[(n/(n-1)]\} \qquad \text{(Equation 2.7-4)}$$

Where:

F = a function that converts the standard deviation of annual extreme temperature parameters to a new variable that is linearly related to the n-year return interval extreme temperature (Tn).

ASHRAE, 2021, provides the mean annual extreme maximum and mean annual extreme minimum temperature (M) and the corresponding standard deviation(s) used in Equation 2.7-3. The 100-year return minimum and maximum annual extreme DBT and non-coincident WBT are computed using Equations 2.7-3 and 2.7-4 for KGSO, KINT, and KRDU and are listed in Table 2.7-1.

Winter Storm Elliott presented a cold event in December 2022 with a minimum temperature of 5 ˚F (-15.0 °C) recorded at KGSO. An arctic cold front swept across the foothills and the Piedmont area of western NC during the morning of December 23, 2022 and introduced the coldest air mass in more than five years. Temperatures in the single digits and lower teens combined with 10 to 20 mph (16.1 – 32.2 kph) winds to produce wind chill values in the 0˚ to -15 ˚F (-18 to -26 ˚C) range from the evening of the December 23, 2022 through December 24, 2022. While winds abated through December 25, 2022, unseasonably cold weather persisted for the better part of four days. There were numerous reports of frozen and burst pipes along with mostly minor damage to infrastructure throughout the area. Using the 5 ˚F (-15.0 °C) minimum temperature in the ASHRAE calculation for return intervals a return interval of nine years is computed.

2.7.1.5 Topographic Description and Potential Modifications

The Project site is located at an elevation of approximately 810 ft. (247 m) AMSL on a peninsula surrounded to the north, east and west by Belews Lake. Most of the terrain in the vicinity of the Project site (Figure 2.7-54), is characterized by Belews Lake and the foothills of the Blue Ridge mountains to the NW. Belews Lake was formed from Belews Creek, a small tributary of the Dan River, under the authorization of the North Carolina Department of Water and Air Resources specifically to provide cooling water to the BCSS. The location is at the southwestern edge of the Dan River Basin. The Dan River runs parallel to the northwest boundaries of Belews Lake. The Dan River rises from springs on Belcher Mountain on the Blue Ridge Plateau in Patrick County, Virginia then flows 214 mi. (344 km) across the state border into Stokes County, NC. The lake sits in the foothills of the Blue Ridge Mountains and the land gradually rises to the NW. Outcroppings southeast of the Blue Ridge rise into peaks occasionally exceeding 2500 ft. (762 m). The Blue Ridge forms a NE to SW barrier about 50-mi. (80-km) from the Project site.

The Sauratown Mountains are located within Stokes and Surry counties and lie WNW of the Project site. The range is home to two state parks located within a 25 mi. (40 km) radius of the Project site. Pilot Mountain State Park, which includes Pilot Mountain, peak elevation 2241 ft. (683 m), is approximately 24 mi. (39 km) west, and Hanging Rock State Park, peak elevation 2159 ft. (658 m), is approximately 14 mi. (23 km) NW of the Project site.

Terrain in the vicinity of the Project site (Figure 2.7-54), is characterized as alternating ridges and valleys oriented along a NE to SW axis. Nearby ridges reach an elevation of 1100 ft. (335 m) AMSL (approximately 300 ft. [91 m] above plant grade). The structures in two of the three areas (North, Middle, South) are located at a distance from the MET tower that would meet the offset requirement in Regulatory Guide 1.23, Rev. 1 that states the sensors should be located over level, open terrain at a distance of at least ten times the height of any nearby obstruction. The MET tower is approximately 1217 ft. (371 m) ENE of the closest turbine and reactor building (the North Plant Complex). Because the turbine and reactor building is 120 ft. (37 m) tall, the tower would meet the 10:1 offset distance requirement for the North Plant Complex to prevent adverse building wake effects. This assumes that the maximum obstruction height is the turbine and reactor building, which is roughly 120 ft. above grade. A topographic map outlining a 5 mi. boundary from the Project site center point is shown in Figure 2.7-54.

Figures 2.7-55 through 2.7-62 provide elevation profiles of the maximum elevation at the 16 compass directions radiating out from the Project site, to a distance of 50-mi. (80.5 km). Figure 2.7-63 provides a topographic map of the elevation profile radials.

The geographic orientation of the ridges and valleys generally aligns with the prevailing regional winds from the SW, but gaps in the ridges permit wind flow from other directions as well.

2.7.1.6 Potential Influence of Plant and its Facilities on Local Air Meteorology

Larger structures on-site would influence wind conditions (wind speed, direction, and turbulence), although these effects are not expected to be significant beyond ten building/structure heights from the building or structure in question, per Regulatory Guide 1.23.

The only nearby feature which may have any noticeable effects on the local meteorology is the new on-site Ash Basin Landfill. The Ash Basin Landfill is planned to:

- be located partially within the former footprint of the ash impoundment, at the BCSS, adjacent to Pine Hall Road.
- be approximately 90 ac.
- be designed to contain approximately 14.1 million cubic yards of coal ash.
- stand 168 ft. tall (from primary liner to top of final closure cap), rising approximately 125 ft. above Pine Hall Road.

The new landfill is approximately 2 mi. (3.2 km) NW of the Project site. While there could be some localized blockage and diversion of winds around the new landfill, the distance of the new landfill from the Project is too far away to produce downstream effects. Impacts on the proposed nuclear facility are expected to be minimal.

Project-related facilities which may have any noticeable effects on the local meteorology is the new cooling tower. The nearest cooling tower is in the North Plant Complex and is 1,061 ft. (324 m) to the MET tower. If linear mechanical draft cooling towers (LMDCTs) are used, they are expected to produce elevated plumes that somewhat alter overall local frequencies of overhead clouds. LMDCTs may also produce small increases of ground-level fog, rime icing, and drift deposition as potential impacts.

Cooling tower impacts are addressed in Section 5.7.1.

There may be some minor impacts on local air quality during construction. Construction impacts are mitigated using construction best management practices according to Duke Energy procedures and state air permits. Sections 4.7 and 5.7 contain information about air quality impacts from constructing and operating the plant.

2.7.1.7 Global Climate Change

Historical long-term meteorological data are considered in the Project's impact on the surroundings of the Project site. Though the impact of global climate change is uncertain, projected trends are discussed in this section. Consistent with NRC Interim Staff Guidance COL/ESP-ISG-026 (NRC, 2014), the project lifetime, decommissioning period, and resources

that may be impacted by climate change are considered. The first unit at the Project site is estimated to be online in 2034 as the earliest possible commercial operation date, with a planned 12-month stagger between units for units 2 – 6 to come online. The initial operating license for each unit is for 40 years and license renewals could extend the operating period an additional 40 years. Thus with the initial license and renewals, the units could operate up to 80 years, with potential in the future to extend the operating life up to a total of 100 years.

The North Carolina Climate Science Report (NCCSR) (Kunkel, K. E., et al., 2020) assesses historical climate trends and potential future climate change in NC under increased GHG concentrations and provides projected changes for the climate of NC for two hypothetical climate futures: a higher scenario (Representative Concentration Pathway 8.5, or RCP8.5), in which GHG emissions continue to increase through the end of the century, and a lower scenario (RCP4.5), in which emissions increase at a slower rate, peak around the middle of the century, and then begin to decrease.

Sea level along the northeastern coast of NC has risen about twice as fast as along the southern half of the coast, averaging 1.8 in. per decade since 1978 at Duck, NC, and 0.9 in. per decade since 1935 at Wilmington, NC (Kunkel, K. E., et al., 2020). A more recent study considered the effect of relative sea level rise; on historical water levels observed along the NC coast and found that under the higher scenario (RCP8.5) after 2050, water levels that currently have a 10% probability of occurring each year would have nearly a 100% probability of occurring each year in Wilmington. Furthermore, water levels that currently have a 1% probability of occurring each year would have nearly a 60% probability of occurring each year from 2050 to 2100. Threats associated with these coastal conditions would not have a direct effect on the Project site, due to its inland location.

The NCCSR projects that it is very likely that NC temperatures and extreme precipitation frequency and intensity will increase, and it is likely that the frequency and severity of inland flooding will increase (Kunkel, K. E., et al., 2020).

The National Climate Assessment (NCA) Report provides detailed information related to the potential effects of climate change on the U.S. by region (U.S. Global Change Research Program (USGCRP), 2023). The Project site is located in the southeast (SE) region of the U.S. as defined by the report. In general, the NCA report states that the SE region is vulnerable to sea level rise and coastal flooding, extreme heat events, hurricanes, and tropical cyclones, and increasing wildfire risk (USGCRP, 2023).

The NCA report found that heatwaves in the SE are happening more frequently and are occurring during a longer heat season, with some cities also showing increasing trends in heatwave duration and intensity:

The number of extreme warm days (above 95 °F [35 °C]) is expected to continue increasing with every increment of global warming. Further, there have been an increasing number of days that exceed 95 °F (35 °C) and nights that exceed 75 °F (24 °C) and a decrease in the number of “extremely cold” days since 1900. (USGCRP, 2023).

Temperatures have steadily increased across the SE since the 1970s. Climate models agree that annual temperatures will continue to increase in the future, with an average annual increase of 3 – 5 °F (approximately 1.7 – 2.8 °C) by 2041 – 2070. Simulated temperature increases for winter and spring are between 2.5 – 5 °F (1.4 – 2.8 °C). For summer the simulated temperature increases from 3.5 – 6 °F (1.9 – 3.3 °C), and during the fall the increase is between 3 – 5 °F (1.7

– 2.8 °C) (USDA, 2024c). These are probabilistic predictions; however, if these numbers are simply interpolated for the next 50 years, results indicate an approximate total increase of 2 °F (1.1 °C) to 4 °F (2.2 °C) during the operating lifetime of the Project site. The report also finds that days with maximum temperatures exceeding 95 °F (35 °C) are predicted to increase, with more than 35 additional days occurring in central Florida and 20 – 30 additional days across the rest of the region, and there is likely to be a decrease in days with freezing temperatures (USGCRP, 2023).

The NCA report states that the SE region is more prone to extreme drought due to higher rates of evapotranspiration than other parts of the eastern U.S.. Longer-term droughts in the region appear to be increasing in severity but do not appear to be occurring more frequently (USGCRP, 2023).

The NCA report states that the SE has received increasing precipitation in the fall, but over the past few decades there has been a decreasing trend in rainfall in summer. Most climate models forecast that the decrease in summer rainfall will continue with mean annual precipitation expected to decrease across the western portion of the SE. Extreme rainfall events have occurred more frequently across the SE in the past 20 years. Average annual precipitation from 2002 to 2021 was 5 percent to 15 percent higher relative to the 1901 – 1960 average in the central and eastern U.S. (USGCRP, 2023).

The NCA has investigated severe weather events including hurricanes, tropical storms, and tornadoes. The NCA report states that warmer temperature projections would result in a decrease in tropical storms globally, however, there has been a slight increase in the frequency of tropical storms in the Atlantic, and the number of major hurricanes (category 3 – 5) has increased over the past few decades (USDA, 2024c). The Project site is located inland and not likely to experience the most severe impacts of hurricanes. However, extreme rain events are a risk with or without tropical systems. The study reports that the number of major tornadoes has increased in the past 50 years, however, there is “no statistically significant trend.” The study indicates that the increase in the number of tornadoes reported may be attributable to expanded and better reporting of tornadoes (USGCRP, 2023).

Based on the NCA report, the greatest potential effects of climate change are increased temperatures and reduced water availability for the Project site, and its surroundings. At the same time, stormwater from extreme precipitation events may increase. As the models used to develop these projections are based on future estimates of population growth, land use, energy consumption, emissions patterns, etc., there is a level of uncertainty associated with the events and meteorological conditions predicted. The Project site is required to continuously monitor meteorological and environmental conditions throughout the life cycle of the project to ensure it remains within its allowable licensed limits of operation.

2.7.2 AIR QUALITY

2.7.2.1 Regional Air Quality

The Clean Air Act (CAA) was enacted in 1970 to protect public health and welfare and authorizes the USEPA to set NAAQS for six common pollutants, called criteria pollutants. There are also provisions to regulate hazardous air pollutants, which are pollutants that are harmful to human health and/or the environment, as well as greenhouse gases (GHGs), primarily carbon dioxide (CO_2) (42 USC §7401 et seq).

The CAA requires the USEPA to set NAAQS for pollutants considered to be harmful to public health and the environment. Primary NAAQS provide public health protection including protecting the health of sensitive populations (asthmatics, children, elderly, etc.). Secondary NAAQS provide public welfare protection against decreased visibility and damage to animals, crops, vegetation, and buildings (USEPA, 2024h).

The USEPA on February 7, 2024, issued its final rule reconsidering the particulate matter NAAQS (40 CFR Parts 50, 53, and 58). USEPA is revising the level of the primary (health-based) annual standard for fine particles (particulate matter with a diameter of 2.5 micrometers or smaller, $PM_{2.5}$) from the current level of 12 micrograms (µg) per m^3 to 9 µg per m^3. The NAAQS are presented in Table 2.7-26. NC reached full attainment with all NAAQS across the entire state in 2015. The most recent pollutant to be redesignated was ozone. On July 28, 2015, the USEPA redesignated to attainment the NC portion of the Charlotte-Rock Hill, NC-SC, nonattainment area for the 2008 8-hour ozone NAAQS, effective August 27, 2015.

2.7.2.2 Class I Areas

The CAA defines Class I areas as national parks greater than 6000 ac., wilderness areas greater than 5000 ac., national memorial parks greater than 5000 ac., and international parks that were in existence as of August 1977. These areas are potentially sensitive to visibility impairment. The USEPA states that a Class I visibility impact analysis is necessary for a major source within 100 km (62.1 mi.) of a Class I area (USEPA, 1990). Discussion of construction impacts are discussed in ER Section 4.7 of this report and operation impacts are in ER Section 5.7.

The USEPA promulgated the Regional Haze Rule to Improve visibility in Class I areas in 1999 with the ultimate goal of restoring natural background visibility by 2064 (Federal Register Vol. 64, 1999). This rule was amended in 2005 to require certain industrial facilities to install emission controls to reduce emissions of air pollutants that reduce visibility (USEPA, 2024k; Federal Register Vol. 70, 2005). These pollutants include particulate matter with a diameter of 2.5 microns or less ($PM_{2.5}$) and compounds that contribute to $PM_{2.5}$ formation, such as nitrogen oxides, sulfur dioxide, certain volatile organic compounds, and ammonia. The USEPA defines all proposed major sources or major modifications within 50 km to 300 km of a Class I area as those with the potential for air quality impacts on a Class I area. There are five Class I areas within NC and one each in South Carolina, Virginia, and Georgia that may be impacted by Prevention of Significant Deterioration (PSD) sources in NC. The closest Class I areas to the Project site, are Linville Gorge Wilderness Area, located in NC roughly 168 km (104.4 mi) to the SW, Shenandoah National Park, located in Virginia approximately 230.5 km (143.2 mi.) to the north-northeast (NNE), and the Great Smoky Mountains National Park, located in NC and Tennessee approximately 280.3 km (174.2 mi.) to the SW. There are no Class I areas within 100 km (62 mi.) of the Project site, therefore, no Class I areas are affected (USEPA, 2024k). The nearest state park is Mayo River State Park located approximately 16.1 km (10 mi.) to the northeast of the Project site. NC's state rules, under 15A NCAC 02D Section .0530 PSD, implements a program for the PSD of air quality as required by 40 CFR 51.166. The minimum requirements of 40 CFR 51.166 are adopted as the requirements of the NC rule. PSD regulations require a single-source impact analysis be conducted for all new major sources or major modification project sources with the potential for air quality impacts on a Class I area. The Class I Area Increment single-source impact analysis evaluates the significant project emissions increase in potential or permitted allowable emissions of a PSD pollutant from a proposed new source. As stated above, no Class I areas are affected by the Project site and air quality dispersion modeling of potential impacts at state parks is not required.

2.7.2.3 Greenhouse Gas Emissions

Global net anthropogenic GHG emissions have been estimated to be 59 ± 6.6 gigaton CO_2-equivalent ($GtCO_2$-eq) in 2019, about 12 percent (6.5 $GtCO_2$-eq) higher than in 2010 and 54 percent (21 $GtCO_2$-eq) higher than in 1990, with the largest share and growth in gross GHG emissions occurring in CO_2 from fossil fuels combustion and industrial processes (IPCC, 2023). At the national level, net GHG emissions in the U.S. in 2022 totaled 6343.2 million metric tons (MT) CO_2-eq after accounting for sequestration from the land sector (USEPA, 2024m). The increase in total GHG emissions was driven largely by an increase in CO_2 emissions from fossil fuel combustion. In 2022, CO_2 emissions from fossil fuel combustion increased by 1 percent relative to the previous year. This increase in fossil fuel consumption emissions was from increased energy use, due in part to the continued rebound in economic activity after the height of the COVID-19 pandemic. GHG emissions in 2022 (after accounting for sequestration from the land sector) were 17 percent below 2005 levels (USEPA, 2024l). At the state level, GHG emissions in NC are 115.6 MT total CO_2 (EIA, 2024).

The impact of estimated GHG emissions resulting from the Project site on air quality is compared to state and national GHG emissions. Emissions from generic 1000-megawatt electric (MWe) reactor lifetime GHG footprint is 10.5 MT CO2eq. (Table A-3. Nuclear Power Plant Lifetime GHG Footprint NRC, 2014). Using the emissions from the generic 1000 MWe reactor provides a conservative estimate. Lifetime GHG emissions from a new power plant are an estimated 9.1 percent of annual 2022 GHG emission in the state of NC (10.5 million to 115.6 MT) and 0.17 percent of the annual 2022 carbon equivalent emissions in the U.S. (10.5 million to 6343.5 MT).

2.7.3 ATMOSPHERIC DISPERSION

Short-term dispersion estimates for use in evaluation of dose from design-basis accidents (DBAs) and long-term dispersion and deposition estimates for evaluation of radiological impacts from normal releases are included in Section 2.7.3.1 and Section 2.7.3.2, respectively. Section 2.7.3.2 provides estimates of annual average atmospheric-dispersion factors (χ/Q) and relative dry deposition factors (D/Q) to a distance of 50 mi. (80 km) from the Project site.

2.7.3.1 Short-Term Diffusion Estimates

This section presents the methodology and results used to evaluate short-term atmospheric-dispersion conditions applicable to a DBA for the Project site. The evaluation supports demonstration of compliance with 10 CFR 100.11 and has been performed consistent with the guidance contained in NRC RG 1.145, Atmospheric-Dispersion Models for Potential Accident Consequence Assessments at Nuclear Power Plants. Atmospheric dispersion consists of two components: (1) atmospheric transport, or the movement of gaseous effluents through the atmosphere, and (2) atmospheric diffusion, or the spread of gaseous effluents through the atmosphere. Atmospheric-dispersion conditions are represented by χ/Q factors at specified receptor distances, primarily at the Exclusion Area Boundary (EAB) and the outer boundary of the Low Population Zone (LPZ). The evaluations support the siting requirements by demonstrating that appropriate protective measures can be taken in response to a postulated accidental release.

2.7.3.1.1 Calculation Methodology and Assumptions

Atmospheric-dispersion calculations are performed using the PAVAN computer program,

NUREG/CR-2858, PAVAN: An Atmospheric-Dispersion Program for Evaluating Design-Basis Accidental Releases of Radioactive Materials from Nuclear Power Stations. The PAVAN program implements the guidance provided in NRC RG 1.145. PAVAN is designed to calculate χ/Q factors using JFDs of wind direction, wind speed, and atmospheric stability class.

Meteorological data is collected and processed in accordance with NRC RG 1.23. Wind direction and speed data are measured at 10 m above ground level, and temperature data is collected at appropriate vertical levels for determining atmospheric stability. JFDs are compiled into 16 cardinal sectors with wind speed and stability classifications. As noted in Section 2.7.3 of RG 4.2, two consecutive annual cycles of meteorological data should be provided at the time of submittal; however, if two years of on-site data are not available at the time the application is submitted, at least one annual cycle of meteorological data collected on-site should be provided at submittal.

JFDs for each stability class, consistent with NUREG/CR-2858 and RG 1.23, are included as Tables 2.7-27 through 2.7-34, and 2.7-35 through 2.7-42, respectively.

Dispersion factors are calculated for various time intervals post-accident, typically 0-2 hours for the EAB and 0-8 hours and 4-30 days for the LPZ. The analysis uses a ground-level release assumption for conservatism, as defined by RG 1.145 and excludes credit for building wake effects.

For each receptor (EAB and LPZ), χ/Q factors are calculated using both directionally dependent (maximum sector) and directionally independent (overall site) methods. The bounding χ/Q factor is the greater of the two values, consistent with RG. 1.145 guidance. In the directionally dependent approach, χ/Q factors are determined for each sector and the 0.5 percent exceedance value is used. For the directionally independent approach, a site-wide cumulative distribution is compiled, and the 5 percent exceedance value is used. As noted in RG 4.2, RG 1.206 states that the χ/Q factors at the EAB and LPZ for appropriate time periods using realistic (50^{th} percentile) meteorology should be provided. Using the site-wide cumulative distribution and 5 percent exceedance values, the 50^{th} percentile χ/Q factors were determined for each Plant Complex using logarithmic interpolation.

Building wake effects are excluded (building height and cross-sectional area set to zero) for conservatism. Ground-level release is modeled since it results in the highest downwind concentrations. Plume meander is considered for neutral or stable conditions and wind speeds below 6 m/s. For higher wind speeds or unstable conditions, plume meander is neglected.

Effluent release points are represented by a conservatively defined release boundary enclosing all potential sources within each Plant Complexes nuclear power block, determined using the aggregate power block footprint from all technologies being evaluated for implementation. The EAB is determined by assembling a composite of the EAB distances provided as inputs from the selected technologies to have the limiting EAB distance in every direction (limiting in this case meaning nearest to the potential release points). The outer boundary of the LPZ is assumed to be equivalent to the EAB for the purposes of the evaluation. Table 2.7-43 lists the minimum distances from the perimeter of the release envelop (the power block footprint) for each of the 16 downwind direction sectors for each of the three Plant Complexes.

2.7.3.1.2 Results and Conclusions

The PAVAN modeling results provide χ/Q factors for use in accident dose consequence

assessments as required by 10 CFR Part 100. The 50th percentile EAB and LPZ χ/Q values for each plant complex are presented in Tables 2.7-44 through 2.7-46. The bounding 50th percentile χ/Q values for all three Plant Complexes are documented in Table 2.7-47.

2.7.3.2 Long-Term Diffusion Estimates

This section presents the methodology and provides the χ/Q and D/Q factors for routine releases associated with the Project site. The Project site is separated into three Plant Complexes: the North Plant Complex, Middle Plant Complex, and South Plant Complex. Each complex will include multiple advanced reactors. The analysis is prepared in accordance with the guidance provided in NRC RG 1.111, Methods for Estimating Atmospheric Transport and Dispersion of Gaseous Effluents in Routine Releases from Light-Water-Cooled Reactors and uses site-specific meteorological data.

The χ/Q and D/Q factors are calculated at locations as a function of downwind distance from the Project site effluent release points that are located within the North, Middle, and South Plant Complex areas. The χ/Q and D/Q locations include receptors on the EAB or property line (i.e., site boundary) for each Plant Complex in each of the 16 directional sectors and at two off-site locations, i.e., the nearest resident and nearest vegetable garden (greater than 50 m^2 [538 ft^2]). The minimum distance between the release point and the receptor on the unrestricted area boundary, i.e., the distance to the EAB or to the site boundary, is used as the distance in each sector for χ/Q and D/Q determination. The longest distance from the EAB or site boundary to the Plant Complex boundary is used to determine what unrestricted area boundary is used. In addition, general and segmented χ/Q and D/Q factors are calculated radially out to 50 mi. (80.5 km) from the Project site. For all the locations considered, the χ/Q factors are calculated as a ground-level release considering scenarios of no depletion/no decay, no depletion/2.26-day half-life, and depletion/8-day half-life. The χ/Q and D/Q factors are calculated as average values over a period of one year.

2.7.3.2.1 Calculation Methodology and Assumptions

The site-specific meteorological data is collected and processed for a time period of one year from February 7, 2024 to February 6, 2025 to evaluate routine releases at the Project site. As noted in Section 2.7.3.1, two consecutive annual cycles of meteorological data should be provided at the time of submittal; however, if two years of on-site data are not available at the time the application is submitted, at least one annual cycle of meteorological data collected on-site should be provided at submittal.

The wind data consists of an hourly JFD of speed, direction, and Pasquill stability class derived from the MET tower location at the Project site.

The XOQDOQ code module of the NRCDose, version 2.3.10, computer code is used to calculate the χ/Q and D/Q factors. Using XOQDOQ module contained in the NRCDose computer code implements the assumptions outlined in Section C (excluding C.1.a and C.1.b) of RG 1.111.

The XOQDOQ code module of NRCDose is based on the theory that material released to the atmosphere will be normally distributed (Gaussian distribution) about the plume centerline. In predicting concentrations for longer time periods, the horizontal plume distribution is assumed to be evenly distributed within the directional sector. A straight-line trajectory is assumed between the point releases and all receptors in the models.

The XOQDOQ code uses the JFD to estimate the χ/Q and D/Q factors for each of the 16 sectors (22.5°), relative to the release location envelope, extending 50 mi. (80.5 km) radially outward at 16 radial distances for each sector. In the analysis, the release location envelope is at ground level over an area that covers the release point for each Plant Complex at the Project site. The unrestricted area boundary χ/Q and D/Q factors for the 16 sectors for each Plant Complex are conservatively estimated using the minimum distance from the Plant Complexes boundary to the unrestricted area boundary. Figures 2.7-64 through 2.7-66 present the shortest distances from the Plant Complexes boundary to the unrestricted area boundary for each directional sector for the North, Middle, and South Plant Complexes, respectively. Table 2.7-48 presents the distances from the Plant Complexes boundary to the unrestricted area boundary (i.e., EAB or site boundary) for each directional sector and each plant complex.

Many of the dose consequence analyses utilizing the χ/Q and D/Q factors determined in the analysis are prepared to address regulations applicable to the entire project site. Using the bounding χ/Q and D/Q factors for each Plant Complex is overly conservative because the bounding χ/Q and D/Q factors determined for each Plant Complex are not located at the same geographical location. Therefore, it is reasonable to determine χ/Q and D/Q factors for the three Plant Complexes at an unrestricted area boundary Maximally Exposed Location (MEL) that provides less conservative combined χ/Q and D/Q factors than the combined bounding χ/Q and D/Q factors for each Plant Complex. The unrestricted area boundary MEL is a fixed point for a receptor and could be in different sectors for each Plant Complex.

For the analysis, a sensitivity was performed to determine the unrestricted area boundary MEL that results in the maximum combined χ/Q and D/Q factors from all Plant Complexes at the Project site. The unrestricted area boundary MEL is determined to be located along the North Plant Complex EAB, in the northeast sector. The distances from the Middle and South Plant Complex power block boundary to the unrestricted area boundary MEL are shown in Table 2.7-48.

For conservatism, the MEL χ/Q factors for the Middle and South Plant Complexes are those for the directional sector that provides the largest χ/Q factors at a distance equal to the MEL distance from the Middle and South Plant Complexes. Tables 2.7-56 through 2.7-59 show the bounding χ/Q direction for distances of 0.25 mi. (0.40 km) and greater for the Project site is in the north directional sector. Therefore, the χ/Q factors for the Middle and South Plant Complexes are those in the north directional sector. The bounding D/Q direction for the Project site for distances 0.25 mi. (0.40 km) and greater is the northeast directional sector, which is the sector of the unrestricted area boundary MEL.

In addition, the χ/Q and D/Q factors are estimated for off-site receptor locations from the power block boundary of each Plant Complex. The off-site receptor locations are determined using the guidance from NUREG-1555. As such, per Section 5.4: Radiological Impacts of Normal Operation of NUREG-1555, off-site receptors that are to be considered for evaluation up to 5 mi. (8 km) from the site include the nearest residence, milk animals, meat animals, and vegetable gardens larger than 50 m^2 (538 ft^2). These receptors (nearest resident and nearest vegetable garden) and the associated data are listed in Table 2.7-49. No milk animals or meat animals are identified within 5 mi. (8 km) of the Project site; therefore, locations of milk animals or meat animals are not evaluated.

In accordance with RG 1.111, radiological decay and dry deposition are considered. For conservative estimates of radioactive decay, an overall half-life of 2.26 days is acceptable for short-lived noble gases released to the atmosphere and an overall half-life of eight days is

acceptable for iodines released to the atmosphere. In accordance with Regulatory Position 3.c of RG 1.111, wet deposition usually does not have a significant effect on the associated doses. Plume depletion via wet deposition is therefore not modeled in the analysis.

The maximum wind speed utilized in the analysis is 13 meters per second (m/s) (42.65 feet per second [ft/s]). The JFD information provides the highest wind speed interval that is not closed, referring to any wind in excess of 8 m/s (26.25 ft/s) without specifying the maximum value. The XOQDOQ code requires the minimum and maximum values for the wind speed interval to be specified (closed interval). Per NUREG/CR-2919, XOQDOQ: Computer Program for the Meteorological Evaluation of Routine Effluent Releases at Nuclear Power Stations (NRC, 1982), the maximum speed of an open interval can be assumed to be capped with a value that is five units greater than the largest specified interval limit. As such, use of 13 m/s (42.65 ft/s) is appropriate.

No building wake effect is credited in the XOQDOQ model (i.e., the building cross-sectional area for the dispersion analysis is assumed to be zero). Consistent with NUREG/CR-2919 (NRC, 1982), no credit for building wake reduces dispersion and is therefore conservative.

The XOQDOQ release model is developed assuming all routine effluent releases occur at ground level. No plume rise is calculated, and no elevated terrain corrections are applied. This assumption is conservative because the receptors are located at the ground level, and the ground release model for this scenario provides the bounding values for the χ/Q and D/Q values. The following parameters are utilized in the XOQDOQ model for ground release:

- The vent average velocity is 0 m/s (0 ft/s), consistent with Table 2.1 of NUREG/CR-2919 (NRC, 1982) for ground release.
- The vent inside diameter is 0 m (0 ft.), consistent with Table 2.1 of NUREG/CR-2919 for ground release.
- The height of the vent release point is 10-m (32.81 ft.) above plant grade level because XOQDOQ treats a ground release as a release that is 10 m (32.81 ft.) above ground level.
- The height of the vent's building is 10-m (32.81 ft.) above plant grade level, which is the same as the release height (for a ground release).
- The wind height used for the vent elevated release is 10-m (32.81 ft.) above plant grade level, consistent with Table 2.1 of NUREG/CR-2919 for ground release.
- The vent heat emission rate is 0 cal/s because this results in no additional plume rise due to buoyancy of the effluent.
- Default open terrain (e.g., recirculation) factors are utilized to represent plume recirculation in calm or light wind conditions.
- The option to correct χ/Q and D/Q values using standard correction factors for open terrain correction is used in the absence of site-specific diffusion test data. This is consistent with NUREG/CR-2919.

2.7.3.2.2 Summary of XOQDOQ Results

The χ/Q and D/Q factors for the Project site unrestricted area boundary for each Plant Complex are provided in Tables 2.7-50 through 2.7-52. The Project site unrestricted area boundary χ/Q and D/Q factors at the MEL for the North, Middle, and South Plant Complexes are provided in Table 2.7-53.

The off-site receptor χ/Q and D/Q factors for the nearest resident and nearest vegetable garden are provided in Tables 2.7-54 and 2.7-55, respectively.

The general χ/Q and D/Q factors as a function of distance from the release point for each Plant Complex at the Project site, extending to a distance of 50 mi. (80.5 km), are provided in Table 2.7-56 through Table 2.7-59. The largest values for the χ/Q and D/Q factors, for all 16 sectors within 50 mi. (80.5 km) of the envelope, are in the N sector for χ/Q factors and in the NE sector for D/Q factors. χ/Q and D/Q factors for segmented distances out to 50 mi. (80.5 km) from the Project site release envelope are provided in Tables 2.7-60 through 2.7-63.

The χ/Q and D/Q factors will be used to determine the radiological consequences of routine airborne releases from the Project site.

2.7.4 METEOROLOGICAL MONITORING

The primary source of meteorological data during early site permitting through construction is an on-site multi-level MET tower. The meteorological parameters measured at the on-site MET tower are listed below. The Meteorological Monitoring System at the Project site meets Regulatory Guide 1.23.

- Wind speed and direction – measured on an open-lattice tower at approximately 10 m (33 ft.) and 60 m (197 ft.) above ground level (AGL).
- Sigma-theta, the standard deviation of wind direction. Calculated for both the 10 m and 60 m level wind direction.
- Vertical temperature gradient, DeltaT is used to determine the Pasquill atmospheric stability class for air dispersion modeling.
- Ambient temperature – monitored at approximately 10 m (33 ft.) AGL. Temperature is also measured on the MET tower at the 60m level to determine the vertical temperature gradient and stability class.
- Precipitation – measured near ground level near the base of the MET tower.
- Atmospheric moisture based on DPT and RH measured at 10m AGL.

Table 2.7-24 shows that the specifications of the meteorological instruments installed on the MET tower comply with the guidance contained in Regulatory Guide 1.23.

Per Regulatory Guide 1.23, the tower or mast utilized to obtain these measurements should be placed in a location that can provide data representative of the atmospheric conditions into which material may be released and transported. The MET tower is located at latitude 36˚ 17’

10.067” N and longitude 80˚ 2’ 39.038” W at elevation 810 ft (246.9 m) and at the approximate grade level of the plant. The location of the on-site tower is shown in Figure 2.7-54.

In accordance with Regulatory Guide 1.23, Rev 1 meteorological instrument calibration and maintenance procedures support meeting a data recovery rate of at least 90 percent on an annual basis for each meteorological variable and annual JFDs of wind speed, wind direction, and stability class. Meteorological data are available in real-time for analysis. Time average accuracies for digital systems meet the criteria listed in Table 2 of Regulatory Guide 1.23.

Calibration of instruments and maintenance of the MET tower is performed or overseen by Duke Energy technical staff. The MET tower instrumentation maintenance and service scheduling intended to support compliance with Regulatory Guide 1.23, Rev 1 are summarized below (Duke Energy, 2024b).

- Instrument maintenance and servicing schedules. Semi-annual calibrations, daily data review, and monthly site checks.
- Data reduction and compilation. The ESC 8864 data logger meets the digital sampling and display rate requirements.
- Guy wires are inspected annually, and the guy wire anchors are inspected once every three years.

Table 2.7-17
Classification of Pasquill Atmospheric Stability

Stability Classification	Pasquill Categories	Temperature change with height (°C/100m)
Extremely unstable	A	$\Delta T \leq -1.9$
Moderately unstable	B	$-1.9 < \Delta T \leq -1.7$
Slightly unstable	C	$-1.7 < \Delta T \leq -1.5$
Neutral	D	$-1.5 < \Delta T \leq -0.5$
Slightly stable	E	$-0.5 < \Delta T \leq 1.5$
Moderately stable	F	$1.5 < \Delta T \leq 4.0$
Extremely stable	G	$\Delta T > 4.0$

Notes:
(a) This table is listed as Table 1 in Regulatory Guide 1.23.
(b) ΔT is the 60-10 m temperature differential (Delta-T). Actual DeltaT data must be normalized to a standard 100m vertical separation distance between instrument levels to compare to RG 1.23 ranges for determining stability categories. This may be referred to as the normalized lapse rate, derived from the DeltaT measurements.

Table 2.7-18
Total Distribution in Each Stability Class for the Project Site

Stability Class	Hours	Percentage
A	1,860	21.6%
B	466	5.4%
C	494	5.7%
D	2,671	31.0%
E	2,343	27.2%
F	589	6.8%
G	200	2.3%
Unstable (Classes A-C)	2,820	32.7%
Neutral (Class D)	2,671	31.0%
Stable (Class E-G)	3,132	36.3%

Table 2.7-24
Summary of Meteorological Equipment Used at the Project Site

Meteorological Equipment Upgrade	Specifications	Measurement Levels	Meets Guidance[c]	
			Yes	No
RM Young 05305V Wind Monitor-AQ (wind speed)	±0.2 m/s (±0.45 mph) or 5% of observed wind speed starting threshold < 0.4 m/s (0.89 mph)	60 m and 10 m	X	
RM Young 05305V Wind Monitor-AQ (wind direction)	±5 degree starting threshold < 0.4 m/s (0.89 mph)	60 m and 10 m	X[d]	
RM Young 41342VC Temperature Probe Delta[a]	±0.1 °C (±0.18 °F)	60 m and 10 m	X	
RM Young 41342VC Temperature Probe	±0.5 °C (±0.9 °F)	60 m and 10 m	X	
RM Young 52202-20 Rain Gage	±10% for a volume equivalent to 2.54 mm (0.1 in.) of precipitation at a rate < 50 mm/hr (<2 in/hr)	Ground	X	
RM Young Aspirated Radiation Shield	Required for NIST	60 m and 10 m	X	
ESC 8864 Data Logger	N/A	N/A	X	
Sierra Wireless Modem – Duke Energy Approved	N/A	N/A	X	
RM Young Model 41382VC Relative Humidity / Temperature[b]	±4%	10 m	X	

Notes:
(a) Delta-T is derived from the ambient temperature measurements between 60 m and 10 m. The two temperature probes are matched and calibrated together to achieve higher accuracy for Delta-T (i.e., ±0.1 °C or ±0.18 °F) than would be achievable from using individual temperature readings.
(b) For computation of the dewpoint temperature.
(c) Applicable guidance is RG 1.23 Rev 1 or ANS-3.11-2024.
(d) The RM Young specs state that the starting threshold for the wind direction sensor (05305V) is 0.5 m/s at 10-degree displacement, but incorrectly states that 0.5 m/s would be equivalent to 1 mph (0.5 m/s =1.12 mph, so it does not completely meet RG 1.23 guidance for starting threshold). However, the RM Young wind direction does meet guidance in ANS-3.11-2024 for a starting threshold of 0.5 m/s (ref. Section 3.1.2 in ANS-3.11-2024) and accuracy of 5 degrees. It would, however, meet the ANS-3.11-2024 guidance for accuracy and starting threshold.
Key: mm = millimeter, N/A = not applicable, NIST = National Institute of Standards and Technology

2.8 NONRADIOLOGICAL HEALTH

This section describes aspects of the environment at the Project site and within the Project Vicinity with respect to existing nonradiological human health. The section also provides the basis for evaluation of impacts on nonradiological human health from the building and operation of advanced reactors at the Project site.

2.8.1 PUBLIC AND OCCUPATIONAL HEALTH

The Occupational Safety and Health Administration (OSHA) is responsible for developing and enforcing workplace safety regulations. OSHA was created by the Occupational Safety and Health Act of 1970 (29 USC 651 et seq.), which was enacted to safeguard the health of workers. With regard to nuclear power plants, plant conditions that result in an occupational risk but do not affect the safety of licensed radioactive materials are under the statutory authority of OSHA rather than the NRC, as set forth in a Memorandum of Understanding between the NRC and OSHA (OSHA, 2013). OSHA regulations regarding public and occupational health that are applicable to the Project site include Occupational Health and Safety Standards (29 CFR Part 1910), Safety and Health Regulations for Construction (29 CFR Part 1926), and Identification Classification and Regulation of Potential Occupational Carcinogens (29 CFR Part 1990). These regulations establish a federal framework to protect and promote the safety and health of employees working under the authority of the Department of Labor and certain state agencies across the United States.

In 2020, approximately 91,393 people lived within 10 mi. (16 km) of the Project site. Population distribution details are provided in Section 2.4.1. The resident population is primarily concentrated in the cities of Greensboro and Winston-Salem. The nearest residence is approximately 44 feet (13.4 meters) from the Project site at its closest point and approximately 1.1 mi. (1.8 km) from the Project site center point. As described in Section 2.1.1.2, much of the land in the vicinity of the site is undeveloped forest or pastureland; however, concentrated areas of developed land are associated with BCSS and surrounding municipalities such as Walnut Cove and Stokesdale. Stokes County, which contains most of the Project site, is designated by the Stokes County Comprehensive Plan as being “Open Space: Rural Community”; and, the Project Vicinity is characterized by rural, low-density residential lands and recreational areas, with pockets of commercial and industrial areas of relatively higher densities. BCSS is the closest industrial facility to the Project site with approximately 147 on-site employees and Belews Lake is the closest recreational facility with 63 private lake access leases and two public boat ramps.

People and communities most vulnerable to nonradiological health impacts from construction and operation-related activities include those within proximity to the Project site. Occupational injuries, chemical hazards, and etiological agents primarily impact people in the immediate vicinity of a hazardous activity or material, such as employees and construction workers within the Project site; however, chemical hazards have the potential to transport outside of the Project site, within the Project Vicinity, and could make nearby residents and recreational visitors potentially vulnerable to nonradiological health impacts.

2.8.1.1 Occupational Injuries

In general, occupational health risks to workers and on-site personnel engaged in activities related to building and operating nuclear power plants would be predominantly occupational injuries (e.g., falls, electric shock, asphyxiation) or occupational illnesses. The Bureau of Labor

Statistics (BLS) collects information from U.S. companies on occupational injuries, illnesses, and fatalities. BLS defines nonfatal incidence rates as the number of recordable cases per 100 full-time equivalent workers and fatal incidence rates as the number of recordable cases per 100,000 full-time equivalent workers (BLS, 2023a, 2023b). Nonfatal occupational illness and injury data from the Survey of Occupational Injuries and Illnesses (SOII), as well as fatality data from the Census of Fatal Occupational Injuries (CFOI), are often organized by industry; in such cases, nuclear electric power generation is classified under the North American Industry Classification System (NAICS) code for utilities (BLS, 2024a). The industry classification for nuclear electric power generation consists of occupations associated with the construction, operation, and maintenance of nuclear facilities, including management, engineering, office and administrative support, construction, installation, maintenance, production, and transportation (BLS, 2024b).

Table 2.8-1 summarizes the national and state incidence rates of nonfatal occupational injuries and illnesses in 2022 for industries applicable to the construction and operation of nuclear facilities. The nonfatal occupational injury and illness incidence rate for construction in NC is less than that of the U.S. (BLS, 2023a, 2023c).

Unlike nonfatal incidence rates calculated by BLS with data from the SOII, fatal incidence rates calculated by the BLS with data from the CFOI use different methodologies between the national and state rates, meaning state industry rates are not directly comparable with national industry rates (BLS, 2020). Tables 2.8-2 and 2.8-3 provide national and state incidence rates of fatal occupational injuries in 2022 for industries applicable to the construction and operation of nuclear facilities. The national fatal injury incidence rate for the utilities industry is 3.4 recordable cases per 100,000 full-time equivalent workers. No further breakdown of the utilities industry was reported (BLS, 2023b). In NC, the fatal injury incidence rate for the utilities industry is grouped into the estimate of the incidence rate for transportation, leading to a higher reported incidence of fatal injury for the transportation and utilities industry category than that for the utilities industry alone. The transportation and utilities incidence rate in NC was 13.3 recordable cases per 100,000 full-time equivalent workers, higher than the construction industry category (BLS, 2023d).

Duke Energy maintains an Environmental Health and Safety (EHS) manual that outlines EHS-related policies, employee responsibilities, and management systems specific to Duke Energy employees and contractors. Additional supplements are provided by Duke Energy business units for the supplemental requirements of contractors. Duke Energy's EHS manual includes policies and guidance on a variety of health and safety topics aimed at preventing and minimizing occupational health and safety risks to employees and contractors, including fall protection, fire prevention and protection, hazard awareness, heat and cold exposure, natural gas and fuel gas safety, office safety, safety sign and barricades, and personal protective equipment. Additionally, the EHS manual includes policies and guidance on a variety of environmental topics, including air permitting, containment systems, fugitive dust, chemical management, spill plans, and waste management, to help prevent and minimize health and safety risks to the environment, (Duke Energy, 2023b).

The USEPA Facility Registry Service (FRS) is a centrally managed database that identifies facilities or sites subject to environmental regulation. Sources of facility information come from a variety of USEPA programs, including the Assessment, Cleanup and Redevelopment Exchange System (ACRES), Integrated Compliance Information System (ICIS), Superfund Enterprise Management System (SEMS), National Priority List (NPL), and Toxics Release Inventory (TRI), which tracks compliance with the NPDES and the CAA. The USEPA's Envirofacts Multisystem

Search Form allows users to search multiple environmental databases for facility information, including toxic chemical releases, water discharge permit compliance, hazardous waste handling processes in compliance with the Resource Conservation and Recovery Act (RCRA), Superfund status, and air emission estimates. USEPA's Enforcement and Compliance History Online tool within Envirofacts allows users to access integrated site-specific compliance data from a variety of the USEPA data systems compiled in one location.

A search of the Project site was conducted using the FRS GIS data from the ACRES, SEMS, NPDES, ICIS-Air, NPL, RCRA Info, and TRI databases to identify potential sources of existing issues involving hazardous chemicals on or near the site, including brownfields, superfund sites, and toxic releases (Figure 2.8-1). No superfund sites, or brownfields are located within the Project Vicinity. The BCSS is the nearest site identified as being a toxic release site and includes water discharges regulated by the NPDES, air releases regulated by the CAA, and chemical handling and storage regulated under RCRA (USEPA, 2024m, 2024n).

In addition to the current regulated chemical discharges identified using the FRS, BCSS also stores and utilizes [[
]]SRI, which is regulated under OSHA's *Process Safety Management of Highly Hazardous Chemicals* (PSM) Standard, is a chemical that OSHA considers to be highly hazardous (29 CFR 1910.119). [[

]]SRI Because BCSS stores more than the threshold quantity of [[ ]]SRI, Duke Energy is required to complete a process hazard analysis report, consistent with 29 CFR 1910.119 and USEPA's Risk Management Program Rule (40 CFR Part 68). In 2023, Duke Energy completed a revalidation of the 2016 process hazard analysis for the [[
]]SRI The purpose of revalidating the process is to help Duke Energy identify possible deviations from the process design, maintenance, inspection, or operating practices. These deviations could potentially lead to toxicity from [[ ]]SRI and could potentially result in impacts to personnel (on-site), the public (off-site), property damage (on-site), and the environment. The analysis considered various causes of potential hazard events and their frequency, process safeguards, and hazard event severity, likelihood, and consequences. Overall, BCSS uses the strategies in 29 CFR 1910.111 and 29 CFR 1910.119 to avoid and minimize the occurrence and severity of hazardous events, including the establishment of operating procedures for [[ ]]SRI, training for personnel involved in the operation and maintenance of [[ ]]SRI the implementation of management-of-change procedures, the investigation of incidents that could potentially result in a hazardous event, and the implementation of emergency response procedures.

2.8.1.2 Etiological Agents and Emerging Contaminants

2.8.1.2.1 Etiological Agents

Etiological agents are infectious substances or materials known or reasonably expected to contain a pathogen or disease-causing microorganism that affects human health (CDC, 2009). Etiological agents associated with nuclear power plant operations can be found in cooling ponds or towers or thermal discharges. Microorganisms of concern include enteric pathogens (such as *Salmonella* spp. and *Pseudomonas aeruginosa*), bacteria (including *Legionella* spp. and *Vibrio* spp.), free-living amoeba (such as *Naegleria fowleri* and *Acanthamoeba* spp.), thermophilic fungi, blue-green algae, and dinoflagellates (*Karenia brevis*).

Information from the CDC National Outbreak Reporting System was reviewed to identify the number and nature of cases associated with non-foodborne related etiological outbreaks within NC from 2011 to 2021. The statistics for NC are summarized in Table 2.8-4 and Figure 2.8-2. *Campylobacter* spp., *Clostridium* spp., *Cryptosporidium* spp., *E. coli*, *Legionella* spp., *Norovirus* spp., *Salmonella* spp., *Sapovirus* spp., *Shigella* spp., and *Rotavirus* spp., are enteric pathogens with recorded outbreaks throughout the state from 2011 to 2021 (CDC, 2023). These enteric pathogens can cause intestinal infection, or enteric disease, and can be spread through contact with contaminated water, animals, people, or contaminated soil (Kolling et al., 2012; State of West Virginia, 2024; Center for Health Protection, 2023; CDC, 2024a, 2024b). The pathogen responsible for the most non-foodborne related outbreaks within the state is *Norovirus* spp., which is a virus transferred mostly through human contact or contact with contaminated water sources. Based on data from the CDC, water sources within NC known to act as exposure pathways of enteric pathogens include treated recreational water, such as that found in waterparks and swimming pools, untreated recreational water, such as that from a river or stream, and drinking water from community drinking-water facilities (CDC, 2023).

Of the known enteric pathogen outbreaks within NC, *Legionella* spp. is associated with the most outbreaks from contact with contaminated water sources. Waterborne pathogens like *Legionella* spp. can grow in water, whereas *Norovirus* spp. and *Cryptosporidium* spp. do not grow in water but are able to persist in it. Water quality characteristics, such as warm temperatures, permit the growth of *Legionella* spp. (WHO, 2022). The temperature range that supports the growth of *Legionella* spp. falls between 77°F (25°C) and 109°F (43°C) (NASEM, 2019). The Project site is surrounded by Belews Lake. From May to October 2017, water temperature in the Belews Creek arm of Belews Lake fell between 54°F (12°C) and 100°F (38°C), which is within the range of temperatures that permit the growth of *Legionella* spp. (Duke Energy, 2021).

Thermophilic fungi are fungi species that can grow in temperatures above 68°F (20°C), with a maximum growth temperature at or above 122°F (50°C) (Salar and Aneja, 2007). They are known to occur naturally in soil and habitats comprised of decomposing plant material where warm, humid, and aerobic conditions comprise the basic environment for their development (Salar and Aneja, 2007). Although uncommon, multiple species of thermophilic fungi have been known to cause allergic reactions or infections in humans, specifically from the repeated inhalation of fungal spores released during habitat disturbances; however, the most commonly infectious species of thermophilic fungi, *Aspergillus fumigatus,* is viewed as a weak pathogen, primarily impacting immunocompromised individuals and those with an allergy (e.g., Farmer's lung) (Hutchinson et al., 2019; Mares et al., 2019; Latge, 1999). The existence of thermophilic fungi within the Project site is not well documented; however, due to their naturally widespread presence, it is likely that thermophilic fungi are present within the Project site, particularly within the undisturbed wooded areas that provide leaf litter and organic material suitable for growth.

Blue-green algae, commonly referred to as cyanobacteria, can quickly grow out of control, or "bloom," in waterbodies, particularly those with warm, slow-moving, and nutrient-rich conditions (CDC, 2024c). Various types of blue-green algae are known to produce toxins, called "cyanotoxins," which can make algal blooms harmful to people and animals. Consumption or contact with cyanotoxins can impair liver function or cause respiratory failure, paralysis, neurological disease, or death (Wiltsie et al., 2018). The presence of blue-green algae was confirmed in Belews Lake in 2012, and the genes of one type of cyanotoxin were also found; however, the toxin itself was not confirmed (Grubbs, 2014).

Similar to blue-green algae, many species of dinoflagellates can bloom and produce toxins (Canion, 2004). For example, the species *Karenia brevis* is known to produce brevetoxins,

which can cause a variety of neurological and gastrointestinal symptoms in people when ingested, as well as respiratory problems if inhaled as an aerosol (Woods Hole Oceanographic Institution, 2019). Dinoflagellates can be found in both marine and freshwater environments with *Karenia brevis* only capable of surviving in marine habitats (Canion, 2004; State of Florida, 2024). Unlike marine species, freshwater species are less dangerous and are not as well documented as marine species. However, the presence of various dinoflagellate species has been found in freshwater lakes throughout the U.S. (Canion, 2004). Currently, no known records exist of the presence of dinoflagellates in Belews Lake.

2.8.1.2.2 Emerging Contaminants

The USEPA has recognized the growing concern surrounding emerging contaminants in drinking water and has launched a new initiative to address perfluoroalkyl and polyfluoroalkyl substances (PFAS) and other emerging contaminants, particularly in small or disadvantaged communities. In April 2024, USEPA issued the PFAS National Primary Drinking Water Regulation to protect communities from exposure to harmful PFAS, also known as “forever chemicals.” Exposure to PFAS has been linked to adverse health impacts that include some cancers, liver and heart disease, and immune and developmental damage to infants and children (USEPA, 2024t). Other contaminants of concern are trihalomethanes (TTHMs) and Haloacetic acids (HAAs) which are formed as byproducts of water treatment disinfection processes (USEPA, 2024u).

The Town of Madison is located downstream of the Project site and obtains drinking water from the Dan River (Section 2.2.2.1.2.1). Madison monitors water quality and includes testing for TTHMs and HAAs. Annual drinking water quality reports indicated that TTHM and HAAs concentrations were below the established maximum contaminant level (Town of Madison, 2024).

2.8.2 NOISE

Noise is defined as the intensity, duration, and character of sounds from all sources. Sound waves are characterized by frequency, measured in hertz (Hz), and sound pressure is expressed as decibels (dB). The human threshold of audibility ranges from about 60 dB (at a frequency of 31 Hz) to less than about 1 dB (between 900 Hz and 8000 Hz). For regulatory purposes, noise levels for perceptible frequencies are weighted to provide an A-weighted sound level (A-weighted decibels [dBA]) that correlates highly with individual community response to noise. Sound levels outside the range of human hearing are not considered noise in a regulatory sense, even though wildlife may hear sounds at these frequencies (PNNL, 2007).

Noise levels are often reported as the equivalent sound level (L_{eq}). The L_{eq} is the equivalent steady sound level that, if continuous during a specified time period (usually 1 hour or 24 hours), would contain the same total energy as the actual time-varying sound over the monitored or modeled time period (PNNL, 2007).

As noted in Section 2.1, the Project site consists of rolling hills and steep slopes ranging in elevation from approximately 725 feet (ft.) (219.5 meters [m]) NAVD 88 near the shoreline of Belews Lake to approximately 890 ft. (271 m) NAVD 88 along the ridgetops. Although a portion of the Project site supports the BCSS, most is composed of undeveloped forested land. Additional details regarding land uses in the Project Vicinity are described in Section 2.1.

Noise-sensitive receptors typically include residences, recreational areas, public buildings or other developed sites where frequent public use occurs. The nearest noise-sensitive receptor to the Project site is a residence located along Craig Road, approximately 44 ft. (13.4 m) south of Project site at its closest point and approximately 1.1 mi. (1.8 km) from the Project site center point. The nearest recreational area is Belews Lake, located adjacent to the Project site. The BCSS is the nearest industrial site; however, it is not publicly accessible, and high noise levels at this facility are consistent with its industrial land use. Additional sensitive receptors nearby include recreational areas on Belews Lake, a mobile home park to the east, and Belews Lake Park.

2.8.2.1 Ambient Noise Survey

An ambient noise survey was conducted in June 2024. Environmental sound monitors were placed at eight locations around the Project site. The noise monitoring (NM) locations were chosen to characterize the baseline acoustical conditions at the Project site and at the nearest noise-sensitive receptors. The NM locations are described below and shown on Figure 2.8-3:

- NM-1 is located near the middle-west portion of the Project site along Duke Power Steam Plant Road. This location provides representation of activity along one of the roadways accessing the existing BCSS.
- NM-2 is on the west side of the Project site near the existing BCSS. Noise levels captured at this location represent typical noise emissions from the BCSS.
- NM-3 is near the northern boundary of the Project site and is representative of the residential receptors to the east across Belews Lake.
- NM-4 is near the middle-eastern boundary of the Project site near a high-voltage transmission line crossing. This location is also representative of the residential receptors to the east across Belews Lake.
- NM-5 is adjacent to the eastern boundary of the Project site located near Belews Lake. This location is wooded and represents boaters and other lake users.
- NM-6 is adjacent to the southern boundary of the Project site, near Windswept Drive, and represents the single-family residential community to the south of the Project site.
- NM-7 is located to the west of plant access road near the southern gate entrance to BCSS and provides a representation of activity at the southern end of the Project site.
- NM-8 is located on the southwestern portion of the Project site, near the BCSS Fly Ash Landfill and is representative of noise levels from the existing BCSS on the adjacent portion of Belews Lake.

2.8.2.1.1 Methodology

Ambient noise measurements were collected using a sound-level meter that complies with the requirements of the American National Standards Institute (ANSI) Methods for Electroacoustics Sound-Level Meters (ANSI, 2019). The sound-level meter was calibrated within the previous 24 months by a certified laboratory and was field calibrated prior to and after the field measurements. Instrument settings were selected to use the hourly equivalent noise level ($L_{eq[1hr]}$) averaging routine in the dBA scale prior to the field measurements. The sound-level meters were secured to elevated locations, such as trees, to prevent tampering, and windscreens were used during all readings.

Ambient noise levels were sampled in 1-hour intervals, recording the $L_{eq(1hr)}$ maximum, minimum, and percentile levels over the measurement period. A minimum of a 24-hour measurement period was collected at each location. The noise levels were measured between Thursday, June 6 and Monday, June 10, 2024.

2.8.2.1.2 Weather Conditions during the Sound Survey

Based on field observations, the weather conditions at the Project site during the field survey were mostly clear to partly cloudy, with winds ranging from relatively calm to occasional gusts up to 20 mph (32 km per hour). Temperatures ranged from 60 to 85°F (15.6 to 29.4°C). Some light precipitation occurred on the last day of the survey.

Monthly and annual summaries of meteorological data and a description of the regional climate are provided in Section 2.7. Ambient noise levels are somewhat variable based on seasonal changes and weather conditions; however, the results of the noise survey are generally representative of typical ambient conditions due to the absence of precipitation or other weather extremes during the NM survey period.

2.8.2.1.3 Sources of Noise Observed

Natural and human-generated noise sources were observed during the ambient noise survey. The dominant noise sources recorded during the survey included the noise from the existing BCSS, vehicles on roadways, boats on Belews Lake, and natural noises (e.g., birds, insects, and trees).

2.8.2.1.4 Monitoring Results

Ambient NM results for each monitoring location are shown in Table 2.8-5. The calculated community noise levels remained relatively consistent over the duration of the noise measurement survey, with the greatest variation occurring during the last 24-hour period (Sunday to Monday). The increase in noise level at the monitoring locations is attributed to an event that occurred around 6:00 p.m. on Sunday (June 9, 2024). The source of the event is unknown, but it caused an approximate 20-dBA increase in the $L_{eq(1hr)}$ at some of the monitoring locations. Overall, average ambient community noise levels at the Project site varied between 49 and 53 dBA day-night or community noise level (L_{dn}).

While there may have been short-term noise events that caused an increase in noise level at the monitoring locations, the L_{dn} at all but NM-1 remained below 55 dBA during each 24-hour period recorded. The L_{dn} at NM-1 only exceeded 55 dBA over the last 24-hour period (Sunday to Monday). NM-1, as well as NM-2 and NM-7, are located along Duke Power Station Plant Road and are more representative of noise generated by the BCSS operations, including traffic on Duke Power Station Plant Road. Consequently, noise levels at these locations were generally greater than other locations over the same time period. Locations NM-3, NM-4, NM-5, and NM-6 are located further from the existing BCSS and are more representative of noise environments associated with the residences near the Project site and recreational activity on Belews Lake.

2.8.2.2 Sound-Level Regulations

There are no municipal, county, or state-level regulations that establish quantitative noise level limits applicable to the Project site. USEPA guidelines recommend outdoor noise levels do not

exceed L_{dn} of 55 dBA, which is sufficient to protect the public from the effect of broadband environmental noise in typical outdoor and residential areas. This level is not a regulatory requirement but is intentionally conservative to protect the most sensitive portion of the American population with an additional margin of safety (USEPA, 1974). The average measured sound level at each monitoring location is below the USEPA public health and welfare L_{dn} of 55 dBA for outdoor residential areas and other places where quiet is a basis for use (USEPA, 1974).

2.8.3 TRANSPORTATION

Section 2.4.2.2 includes a description of the roadway network within the Project Region. Interstates (I) I-40, I-74, I-77, and I-85 provide the regional access to the Project site. Primary access to the Project site within the Project Vicinity is provided by several minor arterials and other principal arterials, including U.S. Route 311, U.S. Route 158, and NC Highway 65, as well as SRs and local roads, including SR 1908/SR 1977 (Pine Hall Road), SR 1965 (Belews Creek Road), SR 2042 (Craig Road), Martin Luther King Jr. Road, Hawkins Farm Road, and Fisherman Road (see Figure 2.4-4).

As described in Section 2.4.2.2.2, each of the four counties in the ROI have hundreds of mi. of publicly maintained roads. The county crash statistics of each of these four counties from the past 5 years (2019 to 2023) are shown on Table 2.8-6. Guilford County has the lowest ranking (26 in 2023) and Stokes County has the highest (best) ranking (57 in 2023).

Crash data from a 5-year period (September 2019 to August 2024) were obtained from the NCDOT for the roadways around the Project site and in the Project Vicinity. Crash data on these roadways were analyzed to determine the total crashes, crash severity, and crash rates. As shown in Table 2.8-7, no crashes occurred on the Fisherman Road and Hawkins Farm Road segments. There were 55 crashes on Pine Hall Road during this period. The crash-level severity is the most severe injury sustained by any individual involved in a crash. The severity index of 8.4 was used as a benchmark per the state of NC Traffic Engineering Accident Analysis System. Locations with a severity index above 8.4 are likely to experience more serious crashes with more severe injuries than other locations. All the roadways analyzed in the Project Vicinity are below the severity index threshold (8.4), indicating that they tend to have less severe crashes compared to locations with a higher severity index (see Table 2.8-7). The crash rates shown in Table 2.8-8 are the total number of crashes per 100 million vehicle mi. traveled and are all below NCDOT's statewide average total crash rate of 308.11.

AADT and planned roadway improvements in the ROI are identified in Section 2.4.2.2. As noted in Section 2.4.1, the ROI population is projected to continue to grow at a rate of approximately 0.8 percent over the licensing period. Given this relatively small growth rate, it is not expected that associated increases in AADT will notably affect roadways in the Project Vicinity. Impacts to area roadways resulting from the proposed Project are discussed in Sections 4.4.1 and 4.8.3.

2.8.4 ELECTROMAGNETIC FIELDS

All nuclear power plants have power transmission systems associated with them. Operation of power transmission systems generates both electrical and magnetic fields, referred to collectively as electromagnetic fields (EMFs). Public and worker health can be compromised by acute and chronic exposure to the EMFs produced by transmission lines.

EMFs vary in time as the current and voltage change, so that the frequency of the EMF is the same (e.g., 60 Hz for standard alternating current). Electrical fields can be shielded by objects such as trees, buildings, and vehicles. Magnetic fields, however, penetrate most materials, but their strength decreases with increasing distance from the source (NRC, 2024a).

Power lines associated with nuclear power plants usually have voltages of 230 kilovolts (kV), 345 kV, 500 kV, or 765 kV (a voltage used primarily in the eastern U.S.). EMF strength at ground level varies greatly under these lines, generally being stronger for higher voltage lines, a flat configuration of conductors, relatively flat terrain, terrain with no shielding obstructions (e.g., trees or shrubs), and a closer approach of the lines to the ground. At locations where the field strength is at a maximum, the measured values under 500 kV lines often average about 4 kilovolts per meter (kV/m) but sometimes exceed 6 kV/m. Maximum electric field strengths at ground level are 9 kV/m for 500 kV lines and 12 kV/m for 765 kV lines (NRC, 2024a).

Potential hazards associated with transmission lines include both acute and chronic effects. Acute effects are related to the potential for shock hazard. The potential for shock hazard is addressed by referencing the National Electric Safety Code, which provides practical safeguards of persons during the installation, operation, or maintenance of electric supply and communication lines and associated equipment (NRC, 2024a).

The EMFs resulting from 60 Hz power transmission lines fall under the category of nonionizing radiation. Much of the general population has been exposed to power line fields since near the turn of the 20th century. There was little concern about health effects from such exposures until the 1960s. A series of events during the 1960s and 1970s heightened public interest in the possibility of health effects from nonionizing radiation exposures and resulted in increased scientific investigation in this area. Epidemiological studies have suggested a correlation between proximity to high-current wiring configurations and incidence of childhood leukemia. However, no consistent evidence linking harmful effects with 60 Hz exposures has been presented. Many studies have been conducted on the safety of the electric field, but no health effects have been associated with the magnitude of the electric fields that are associated with electrical power usage (NRC, 2024a).

More recently, the National Cancer Institute provided a summary of research on the health effects from EMFs, including potential effects associated with exposure from power lines. Several studies have analyzed the data from multiple studies of power line exposure and childhood leukemia:

- A pooled analysis of nine studies reported a twofold increase in risk of childhood leukemia among children with exposures of 0.4 microteslas (μT) or higher. Less than 1 percent of the children in the studies experienced this level of exposure.
- A meta-analysis of 15 studies observed a 1.7-fold increase in childhood leukemia among children with exposures of 0.3 μT or higher. A little more than 3 percent of children in the studies experienced this level of exposure.
- More recently, a pooled analysis of seven studies published after 2000 reported a 1.4-fold increase in childhood leukemia among children with exposures of 0.3 μT or higher. However, less than one-half of 1 percent of the children in the studies experienced this level of exposure.

For the two pooled studies and the meta-analysis, the number of highly exposed children was too small to provide stable estimates of the dose-response relationship. This means that the

findings could be interpreted to reflect linear increases in risk, a threshold effect at 0.3 or 0.4 μT, or no significant increase. Therefore, as stated in the National Cancer Institute analysis, the interpretation of the finding of increased childhood leukemia risk among children with the highest exposures (at least 0.3 μT) is unclear (National Cancer Institute, 2022).

The existing transmission corridors at the Project site are described in Section 3.2. Long-term or chronic exposure to power transmission lines has been extensively studied. The scientific evidence regarding the chronic health effects from EMFs, including the potential effects associated with exposure of electrical fields that are associated with electric power usage, does not conclusively link EMF exposure to adverse health impacts.

NM-8	48.3	46.9	45.5	53.1	48.5

Notes:
The noise measurement data at locations NM-1, NM-3, NM-4, NM-5, and NM-8 represent data recorded over the entire four-day period, whereas location NM-6 represents a two-day period, and NM-2 and NM-7 represent one 24-hour period. This was due to equipment limitations.
Daytime events occur between 7:00 a.m. and 10:00 p.m.
Nighttime events occur between 10:00 p.m. and 7:00 a.m. A 10 dBA penalty was added to the measured nighttime noise levels in calculating the average community noise level to reflect the sensitivity of receptors during those hours.
Key: dBA = A-weighted decibel; L_{dn} = day-night average community noise level

2.9 ENVIRONMENT AND RADIOLOGICAL MONITORING

This section discusses the preoperational radiological environmental monitoring program (REMP) and discusses the background radiological characteristics at the Project site.

2.9.1 PREOPERATIONAL RADIOLOGICAL ENVIRONMENTAL MONITORING PROGRAM

The preoperational REMP is used to establish the baseline for the local radiation environment, measuring background levels and their variations along the anticipated critical pathways in the area surrounding the Project site. Baseline radiological conditions are used to identify and assess radiological environmental impacts resulting from plant operation. Programs for radiological environmental monitoring are based on the guidance provided in the NRC RG 4.1, Rev. 2, Radiological Environmental Monitoring for Nuclear Power Plants, and the requirements of 10 CFR 20.1501. Preoperational monitoring programs are implemented two years before initial facility operation.

The elements for both the preoperational and operational REMP phases are essentially the same. As such, Section 5.9.6, Radiological Monitoring, provides a description of both preoperational and operational REMP, including exposure environmental pathways, number and location of proposed sample collection points and measuring devices for direct radiation and effluents, sample collection frequency, type of analysis, reporting requirements, and the quality assurance program.

2.9.2 BACKGROUND RADIATION EXPOSURE

Section 2.9 of RG 4.2, Rev. 3, Preparation of Environmental Reports for Nuclear Power Stations, requires a characterization of the background radiation at the Project site.

The average background radiation dose to the public is 620 millirem per year (mrem/yr) (6.2 millisievert per year [mSv/yr]) in the U.S., with approximately half from medical procedures and man-made sources and half from natural sources (USEPA, 2024q).

2.9.2.1 Natural Sources

The NRC separates natural sources of radiation into three categories: cosmic, internal, and terrestrial. Cosmic radiation is the result of radiation received from extraterrestrial sources, such as the sun and other stars, that penetrate the Earth's atmosphere. Internal radiation is the result of naturally occurring potassium-40 (K-40) and carbon-14 (C-14) in all humans. Lastly, terrestrial radiation is the result of radiation received from naturally occurring uranium, thorium, and radium found in soil and rock. In addition to these three categories, there is radon and thoron gas which seeps through the ground and into the air where it is inhaled. The inhaled radon and thoron gas represents about two-thirds of the natural background radiation dose for an average member of the public whereas, cosmic, internal, and terrestrial radiation account for the rest (NRC, 2024b).

Based on information in the following sections, there are no natural features in the vicinity of the Project site that would result in natural background radiation at levels higher than the U.S. average. Therefore, the estimated radiation dose from natural background radiation at the Project site is taken to be the national average of 310 mrem/yr (3.1 mSv/yr). Natural background

radiation doses attributed to cosmic, internal, and terrestrial radiation, and inhalation of radon and thoron gases are discussed in the following sections.

2.9.2.1.1 Cosmic Radiation

Cosmic radiation exposure depends on the site elevation. As stated in Section 2.7, the Project site is located at an elevation of approximately 810 ft (247 m) AMSL on a peninsula surrounded to the east and west by Belews Lake. The annual dose due to cosmic radiation at elevations up to 1000 ft (305 m) AMSL is 28 mrem/yr (0.28 mSv/yr) (USEPA, 2024p). Therefore, it is appropriate to use the average annual dose due to cosmic radiation of 33 mrem/yr (0.33 mSv/yr) (USEPA, 2024q).

2.9.2.1.2 Internal Radiation

The average annual dose due to internal radiation, 29 mrem/yr (0.29 mSv/yr), is applicable to the Project site (USEPA, 2024q).

2.9.2.1.3 Terrestrial Radiation

The national average for terrestrial radiation of 21 mrem/yr (0.21 mSv/yr), which includes uranium, thorium, and radium found in soil and rock, is applicable to the Project site (USEPA, 2024q).

2.9.2.1.4 Radon and Thoron Gas

As mentioned in Section 2.9.2.1, the average annual dose due to radon and thoron gas is estimated to be two-thirds of the natural background dose or 228 mrem/yr (2.28 mSv/yr). The estimated annual dose from radon and thoron gas at the Project site is 211 mrem/yr (2.11 mSv/yr) (USEPA, 2024p). Therefore, it is appropriate to use the average annual dose associated with radon and thoron gas.

2.9.2.2 Man-Made Sources

A portion of background radiation comes from human activities. Man-made sources of radiation to the public include medical sources, consumer products, nuclear reactor facilities, and ash wastes from coal-fired power plants as discussed below. Trace amounts of radioactive elements have dispersed in the environment from nuclear weapons tests and accidents like the one at the Chernobyl nuclear power plant in Ukraine. Background dose due to fallout from nuclear weapons tests contribute about 1 mrem/yr (1E-02 mSv/yr) (USEPA, 2024p). Normally operating nuclear reactors emit small amounts of radioactive elements (USEPA, 2024q).

Based on the information in the following sections, there are no abnormal sources of radiation located in the vicinity of the Project site; therefore, the estimated radiation dose from man-made radiation sources at the Project site is taken to be the national average of 310 mrem/yr (3.1 mSv/yr) (NRC, 2024b).

2.9.2.2.1 Medical Sources

Medical procedures like X-rays and CT scans provide the majority of man-made radiation exposure to the public. Medical personnel may receive a higher radiation dose than the non-medical public. Radiation exposures from diagnostic medical examinations are generally low

and are almost always justified by the benefits of accurate diagnosis of possible disease conditions. There is no direct evidence of radiation causing any harm at the exposure levels encountered with diagnostic radiological examinations. Therapeutic uses of radiation naturally involve higher exposures and physicians will consider the risks of the treatment against the potential benefits. In diagnostic uses, there are theoretical models that suggest the possibility of cancer risks, but these models all extrapolate results from higher exposures to these low levels, and no one is certain about whether or not any real risks are involved. The exposures are usually comparable to those that we receive routinely from natural radiation all around us, and the benefits of the medical exams are of course very significant (HPS, 2024). Medical exposures are about 48% of the average background dose, which is estimated at 310 mrem/yr (3.0 mSv/yr) and are therefore comparable to doses received routinely from natural sources of radiation.

2.9.2.2.2 Consumer Products

Radiation dose from the use of consumer products (i.e., tobacco, fertilizer, welding rods, exit signs, luminous watch dials, and smoke detectors) will fluctuate based on the lifestyle of the individual population. As such, a best estimate of the average annual dose due to consumer products of 13 mrem/yr (0.13 mSv/yr) is used (USEPA, 2024q).

2.9.2.2.3 Nuclear Reactor Facilities

The McGuire Nuclear Station and the Shearon Harris Nuclear Power Plant are located approximately 76 mi. (122 km) southwest and 80 mi. (129 km) southeast of the Project site, respectively. As documented in their respective 2023 annual radioactive effluent release reports on the NRC website, the radiation exposure at the Project site from the McGuire Nuclear Station and the Shearon Harris Nuclear Power Plant is expected to be lower than 1.07 mrem/yr (1.07E-02 mSv/yr) and 8.22E-01 mrem/yr (8.22E-03 mSv/yr) due to the distance between the site and the nuclear reactor facilities mentioned previously.

As mentioned in Section 2.1, U.S. Highway 311, U.S. Highway 158, and NC Highway 65 are located within 5 mi. of the Project site. U.S. Highway 311, U.S. Highway 158, and NC Highway 65 are all located approximately 4.35 mi. (7 km) northwest, 3.0 mi. (4.8 km) south, and 1.6 mi. (2.6 km) south from the Project site, respectively. Additionally, a NS railroad line runs to the north of the Project site. The railroad throughline is 2.2 mi. (3.5 km) to the north of the Project site. As stated in 49 CFR 173.441, the maximum dose rate at any point 6.6 feet (2 m) from the outer lateral surfaces of a vehicle transporting radioactive material is limited to 10 mrem/hr (0.1 mSv/hr). As such, there could be trace and insignificant amounts of radiation exposure to the public from the transportation of radioactive material along the pathways discussed above.

2.9.2.2.4 Coal-Fired Power Plants

Coal is a fossil fuel used to produce power in the U.S. Coal contains trace amounts of naturally occurring radioactive elements (i.e., uranium, thorium, radium, and radon). The process of burning coal at coal-fired power plants, called combustion, produces waste that contains small amounts of naturally occurring radioactive material. The three main types of ash waste (fly ash, bottom ash, and boiler slag) are only slightly more radioactive than the average soil in the U.S. The amount of natural radiation in waste from coal-fired power plants is so small that no precautions need to be taken (USEPA, 2024r).

As discussed in Section 2.1, the Project site is located adjacent to the BCSS. Section 2.7 states that the BCSS's new on-site ash landfill is being constructed partially within the former footprint of the ash impoundment at the BCSS. Additionally, the ash landfill is planned to be approximately 90 ac. (36 hectares), contain roughly 14.1 million cubic yards (10.8 million cubic meters) of coal ash, and is expected to be closed with a geosynthetic closure cap. In addition to the new ash landfill, the BCSS site contains other existing landfills that contribute to the estimated dose from the BCSS.

The expected contribution from the BCSS within 50-mi. is estimated to be roughly 0.03 mrem/yr (3.0E-04 mSv/yr) (USEPA, 2024p).

2.10 GEOLOGY

2.10.1 GEOLOGICAL CONDITIONS

The geological conditions at the Project site are summarized in this section. The Project site information is subdivided into three categories: physiography, stratigraphy, and structural geology. Geological conditions are described for the Project site, Project Vicinity, and Project Region.

Section 2.5 of the SSAR presents detailed geology, seismologic, and geotechnical information for the Project site and surrounding area.

2.10.2 PHYSIOGRAPHY

The two physiographic provinces represented within the Project Region are the Piedmont physiographic province (Piedmont) and the Blue Ridge physiographic province (Blue Ridge) (Figure 2.10-1). The Piedmont extends approximately 1000 mi. (1600 km) from Alabama to southern New York and consists mainly of metamorphic and igneous rocks that have been thoroughly weathered over time. The metamorphic rocks are primarily schist and gneiss, and the igneous rocks are mainly granites, commonly slightly metamorphosed. Structural basins, which are the result of faulting, are filled with sedimentary Mesozoic sediments. These basins, commonly called “Triassic-Jurassic basins,” are present within the Piedmont (NPS, 2018a).

The Blue Ridge is a mountainous belt stretching from Pennsylvania southwest to Georgia. The mountains are made of highly deformed metamorphic rocks of largely Precambrian ages. These include schists, gneisses, slates, and quartzites, and are extensively intruded by igneous bodies (NPS, 2018b).

The Project site and Project Vicinity lie within the NC western Piedmont (Golder, 2007). The NC Piedmont lies between the Coastal Plain physiographic province (Coastal Plain) and the Blue Ridge. The Piedmont occupies about 45 percent of the land area in the state. Along the border between the Piedmont and the Coastal Plain, elevations range from 300 to 600 feet (ft.) (91 to 183 meters [m]) above sea level. To the west, elevations gradually rise to about 1500 ft. (457 m) above sea level at the foot of the Blue Ridge. The Piedmont is characterized by gently rolling, well-rounded hills and long, low ridges with a few hundred feet of elevation difference between the hills and valleys (NCDENR, 2015a).

Major streams and rivers draining the Blue Ridge flow west into the Mississippi River, and east across the Piedmont and Coastal Plain into the Atlantic Ocean (USGS, 2018c). Rivers within the Piedmont typically flow to the southeast, toward the Atlantic Ocean (Golley, 2004).

The Project site drains to Belews Lake via the main Belews Creek arm and the West Belews Creek arm. Belews Lake then flows into Belews Creek, which discharges to the Dan River (HDR, 2014). The Dan River originates along the eastern slopes of the Blue Ridge Mountains in Patrick County, Virginia, and flows east until it empties into the Roanoke River at the John H. Kerr Reservoir, near Clarksville, Virginia (VDWR, 2024). The Roanoke River eventually drains into the Albemarle Sound of NC (NCDEQ, 2018).

As stated in Section 2.1, the Project site consists of rolling hills and steep slopes with surface elevations ranging from approximately 725 ft. (221 m) NAVD 88 near the shoreline of Belews

Lake to approximately 890 ft. (271m) NAVD 88 along the ridgetops. These steep slopes act as preferential pathways for drainage into Belews Lake as unnamed tributaries, shown on the Surface Water Map in Section 2.2. Topography is discussed in additional detail in Section 2.1.

2.10.3 STRATIGRAPHY

2.10.3.1 Regional Stratigraphy

The geologic framework of the Piedmont and Blue Ridge is complex. The Blue Ridge is generally faulted over Paleozoic strata of the Valley and Ridge physiographic province, while the rocks of the Piedmont continue in the subsurface beneath the Coastal Plain. Mesozoic rift basins overlie parts of the Piedmont crystalline rocks and contain hundreds to thousands of meters of Early Triassic to Jurassic sediment and igneous rocks. The oldest rocks, Grenville basement, were formed 1.3 to 1.0 billion years ago (bya) as crystalline gneisses and granitoids. The Grenville basement is exposed in mountain ranges within the Blue Ridge and Piedmont. Neoproterozoic to Paleozoic metasedimentary and metavolcanic rocks compose most of the different Appalachian terranes, both Laurentian and exotic, and record the Mesoproterozoic to Paleozoic accretion and collision of different terranes to the Laurentian margin (USGS, 2018c).

The Piedmont is predominantly an erosional terrain with narrow, elongated, and ridge-like landforms between valleys that range from 0.3 to 1.2 mi. (0.5 to 2 km) wide and are convex upward. Valleys are as narrow as 0.06 to 0.31 mi. (0.1 to 0.5 km) and generally V-shaped in cross section. Alluvial terraces are rare and discontinuous. Soils in the Piedmont typically have less sand and more clay than coastal plain soils. Infiltration rates for Piedmont soils are low at 2.4 to 5.9 inches (in.) (6 to 15 centimeters [cm]) per hour. The soil/saprolite, soil/rock, and saprolite/rock boundaries are characterized by ponding and lateral movement of water (Markewich et al., 1990).

The geology which makes up the water-bearing zones of the Piedmont and Blue Ridge can be composed of bedrock only, regolith-bedrock, or regolith, transition zone, and bedrock, depending on whether weathered material (regolith) overlies the bedrock and whether a local transition zone has developed between the shallow regolith and deeper bedrock (USGS, 2013). The transition zone lies between the regolith and bedrock and consists of coarse fragments of partially weathered bedrock and lesser amounts of saprolite (LeGrand, 2004). In the Blue Ridge, little if any regolith may be present. If present, regolith is often debris flow, colluvium, or alluvium in stream valleys. In the Piedmont, generally there is at least a two-part system with the weathered regolith overlying fractured bedrock. The regolith consists of soil, residuum, saprolite, and possibly colluviums, alluvium, and debris flow. Residuum and saprolite from in situ weathering of the bedrock creates a blanket of decomposed or partially decomposed rock that is usually thick and clayey. Saprolite retains the texture and structure of the parent bedrock from which it is derived. The regolith is more porous and more permeable than the underlying bedrock. Because the crystalline bedrock formed under intense heat and pressure during metamorphism and igneous intrusion, the bedrock has few primary pore spaces, and the porosity and permeability of the unweathered and unfractured bedrock is extremely low (USGS, 2013).

Groundwater at the Project Region, Project Vicinity, and Project site is described further in Section 2.2.

2.10.3.2 Project Vicinity and Project Site Stratigraphy

Within the Project Vicinity, the geology is diverse and complex, reflecting the multiple phases of compressional and extensional deformation experienced in this area (Golder, 2007). As shown on Figure 2.10-2, four main geologic terranes/features lie within the Project Vicinity (from the southeast to the northwest): the Late Paleozoic intrusives, the Milton terrane, the Triassic basin-Dan River basin, and the Sauratown Mountains anticlinorium (NCDENR, 2015b).

The Late Paleozoic intrusives comprise igneous rocks granite and granodiorite. These rocks intruded as giant blobs of molten rock during the formation of the Appalachian Mountain chain (approximately 280 to 320 million years ago [mya]) (NCDENR, 2015b). As shown in Figure 2.10-2, geologic dikes intrude the Late Paleozoic intrusives, Milton terrane, and Triassic basin-Dan River basin. These dikes are ultra-mafic Jurassic diabase dikes that trend north-northwest and are typically steeply to vertical dipping (Golder, 2018).

The Milton terrane comprises nearly two-thirds of the Project Vicinity and is situated northwest of the Late Paleozoic intrusives. The Milton terrane consists of gneiss, schists, and metamorphosed intrusive rocks. The rocks are about 460 to 470 mya. Generally, the rocks of the Milton terrane are interpreted to have been part of a chain of volcanic islands (NCDENR 2015b).

Sedimentary rocks of the Triassic basin-Dan River basin occur northwest of the Milton terrane and trend northeast toward Danville, Virginia. The Chatham Fault Zone separates the Triassic rocks from the metamorphic rocks of the Sauratown Mountain anticlinorium and the Milton terrane. The Pinehall Formation, Cow Branch Formation, and Stoneville Formations are present in the Triassic basin-Dan River basin and occur northwest of the Milton terrane (Golder, 2007).

The Pinehall Formation is generally composed of red to brown basin margin sandstones and conglomerates that interfinger with sandstones and mudstones of the Cow Branch and Stoneville Formations. The Cow Branch Formation ranges in thickness between 180 to 1,000 ft. (55 to 305 m) and largely consists of black and gray cyclically and rhythmically bedded lake sedimentary deposits of shale, mudstones, and sandstones, with thin coal seams at the base of the unit. The Stoneville Formation is an approximately 500-foot-thick (152-meter-thick) sequence of fluvial to alluvial red and brown sandstone and mudstones, with rhythmic fining upward sequences of trough cross bedded sandstones, grading upward into ripple cross laminated finer sandstones and mudstones (Golder, 2007).

The geological feature that is furthest northwest within the Project Vicinity is the Sauratown Mountain anticlinorium (Figure 2.10-2). Within Stokes County, the Sauratown Mountain anticlinorium comprises the Miller Creek Complex, Pilot Mountain Gneiss, Volunteer Gneiss, and Hogan Creek Formation (Golder, 2007).

The Miller Creek Complex comprises calc-silicate granofels. The granofels predominantly comprise bladed amphibole, quartz, feldspar, chlorite, and epidote. The Pilot Mountain Gneiss is made up of medium-grained muscovite biotite quartz feldspar gneiss with minor amounts of garnet, calcite, and epidote. The Volunteer Gneiss is part of the lowermost thrust sheet of the Sauratown Mountain anticlinorium. This unit comprises granitic gneiss with minor augen gneiss and biotite granitic gneiss predominately (Golder, 2007). The Hogan Creek Formation consists of metagraywacke interlayered with muscovite schist (USGS, 2024).

As shown in Figure 2.10-2, the Project site is located entirely within the Milton terrane. Figure 2.10-3 shows the rock units within the Project site are predominantly biotite gneiss and schist. Subsurface investigations identified the vadose zone thickness to range from approximately 10 ft. (3 m) to 65 ft. (20 m) and is comprised mainly of unconsolidated overburden OB sediment (residual soil, saprolite, and regolith) PWR, and fractured crystalline bedrock. OB sediments consist of soil and saprolite formed from in-place weathering of the underlying bedrock parent material. At the Project site, the regolith is generally described as a moist, yellowish/reddish to brown silty medium-grained sand to a sandy silt. Clay layers are common within the upper portion (upper 5 ft. [1.5 m]) of the vadose zone. Trace amounts of gravel-sized rock fragments are commonly observed in the deeper portions of the vadose zone. Relic rock structure and cobble-sized and larger intact rock fragments are observed in the PWR. Most of the crystalline bedrock encountered is gneiss and schist, with lesser amounts of granofels. texture. As regolith grades downward into PWR, both porous- and fracture-medium characteristics may exist because some of the textural features of the bedrock, including stratigraphic layering, foliation, and fractures are retained.

Detailed information regarding the stratigraphy of the Project site is provided in Section 2.5.1 of the SSAR. A geologic cross section from the Project site stratigraphy is shown on Figure 2.10-4.

2.10.4 STRUCTURAL GEOLOGY

The Piedmont and Blue Ridge are made of various lithostratigraphic terranes assembled during multiple orogenies (USGS, 2018c). Collectively, the orogenies experienced by the Blue Ridge and Piedmont include Grenville orogeny (1.3 to 1.0 bya), Taconic orogeny (460 to 450 mya), Acadian/Neoacadian orogeny (395 to 340 mya), and Alleghenian orogeny (335 to 260 mya). These orogenic events were punctuated by periods of extension, including intracontinental rifting (780 to 750 mya), the breakup of supercontinent Rodinia and the opening of the Iapetus ocean (approximately 570 mya), and finally the breakup of supercontinent Pangea and the opening of the modern Atlantic Ocean (approximately 200 mya).These orogenic events are responsible for the crustal structure, fracture and fault zones, mineralization and ore deposits, geochemical, and geophysical properties of the Piedmont and Blue Ridge. Major faults, which bound these terranes, developed highly foliated or fractured rocks that are weak and more susceptible to landslides and other forms of mass wasting (USGS, 2018c). The major rock units in the Piedmont and Blue Ridge occur as northeast-southwest-trending belts that correspond to the trend of the regional geologic structure (LeGrand, 2004). These geologic belts are predominantly bounded by thrust faults (Thigpen et al., 2022).

The Milton terrane, Late Paleozoic intrusives, Triassic basin-Dan River basin, and the Sauratown Mountain anticlinorium are northeast-trending geologic features, as shown in Figure 2.10-2. The Sauratown Mountain anticlinorium is characterized by a nearly symmetrical distribution of basement rocks. Within the Sauratown Mountain anticlinorium, there are stacked thrust sheets or units of Middle Proterozoic basement rocks that have been pushed one on top of the other through the mountain-building processes that formed the Appalachian Mountains. The erosion of these “stacked rock sheets” reveals the structural relationships between each of the thrust sheets (Golder, 2007).

Southeast of the Sauratown Mountains anticlinorium is the Triassic basin-Dan River basin, which is an asymmetric graben bounded to the north by the Chatham fault (Horton, 1994). The Triassic basin-Dan River basin is one of a series of continental rift basins that formed during the breakup of Pangea from the Permian to Early Jurassic (Olson, et al., 2015).

Further discussion regarding the geologic conditions within the Project site can be found in Section 2.5 of the SSAR.

GLOSSARY

Term	Definition
°C	degree Celsius
°F	degree Fahrenheit
ac.	acre
ACSR	aluminum conductor steel reinforced
ALARA	as low as is reasonably achievable
API	American Petroleum Institute
BCSS	Belews Creek Steam Station
BIL	basic insulation level
Btu	British thermal unit
Btu/hr	British thermal unit per hour
B/W	Black and White
CFR	Code of Federal Regulations
cfs	cubic feet per second
Ci/yr	Curies per year
COL	Combined License
CP	Construction Permit
CWA	Clean Water Act
CWS	circulating water system

Term	Definition
dBA	A-weighted scale decibel
Duke Energy	Duke Energy Carolinas, LLC
EAB	exclusion area boundary
ESF	engineering safety features
ESP	Early Site Permit
ESPA	Early Site Permit Application
FGD	Flue Gas Desulfurization
ft.	feet
ft/s	feet per second
gpd	gallons per day
gpm	gallons per minute
GVH	GE Vernova Hitachi Nuclear Energy
ha	hectare
HALEU	high-assay, low-enriched uranium
Holtec	Holtec International
hr.	hour
HVAC	heating, ventilation, and air conditioning
ISFSI	independent spent fuel storage installation

Term	Definition
kg	kilogram
km	kilometer
kV	kilovolt
lb.	pound
LHV	lower heating value
LLW	low-level waste
LRB	Lined Retention Basin
m	meter
mm	millimeter
m/s	meter per second
m^3	cubic meter
m^3/min	cubic meter per minute
m^3/s	cubic meter per second
MDCT	mechanical draft cooling towers
mi.	mile
min.	minute
MMBtu	million British thermal units
MMBTU/hr	million British thermal units per hour

Term	Definition
MW	megawatt
MWD/MTU	megawatt days per metric ton of uranium
MWe	megawatts electric
MWIS	Makeup Water Intake Structure
MWt	megawatts thermal
NC	North Carolina
NCAC	North Carolina Administrative Code
NCDEQ	North Carolina Department of Environmental Quality
NDA	net disturbance area
NEI	Nuclear Energy Institute
NESC	National Electrical Safety Code
NS	Norfolk Southern
NPDES	National Pollutant Discharge Elimination System
NRC	U.S. Nuclear Regulatory Commission
NuScale	NuScale Power, LLC
NUREG	NRC Technical Report designation
PPE	plant parameter envelope
Project	All nuclear site development proposed by the applicant including transmission lines, access roads, utility corridors supporting the facility, etc.

Term	Definition
Project site	Belews Creek, NC site
psig	pound per square inch gauge
RCRA	Resource Conservation and Recovery Act
RG	Regulatory Guide
ROW	right-of-way
SMR	small modular reactor
SQG	Small Quantity Generator
SSCs	structures, systems, and components
TerraPower	TerraPower, LLC
U.S.	United States
USEPA	U.S. Environmental Protection Agency
WEC	Westinghouse Electric Company, LLC
X-energy	X-energy, LLC
yr.	year

Chapter 3 Site Layout and Project Description

3.0 INTRODUCTION

The Belews Creek, North Carolina (NC) site (Project site) proposed plant layout, design, and activities required to build and operate the plant are described in this chapter.

The Project site is located adjacent to the existing Belews Creek Steam Station (BCSS). Because of the proximity to BCSS, the Project site uses some existing infrastructure, including transmission corridors and switchyard, access roads, and water resources. A description of the associated structures and facilities as well as the physical activities involved in building and operating the proposed plant are provided. The chapter is divided into four sections:

- Proposed External Appearance and Plant Layout (Section 3.1)
- Proposed Plant Structures, Systems, and Components (Section 3.2)
- Building Activities (Section 3.3)
- Operational Activities (Section 3.4)

Because the specific reactor technology has not been selected, a plant parameter envelope (PPE) is used to bound key siting-related features. The bounding values and information from the PPE, presented in this chapter, are used as the basis for the evaluation of environmental effects.

3.1 EXTERNAL APPEARANCES AND PLANT LAYOUT

This section describes the overall appearance of the proposed plant layout and all associated facilities. Section 3.1.1 provides an overview of the Project site, while Section 3.1.2 details the PPE. Sections 3.1.3 and 3.1.4 outline the existing units, structures, and facilities, as well as the shared structures and facilities. Section 3.1.5 presents the proposed plant layout and site modifications.

3.1.1 PROJECT SITE

The Project site consists primarily of undeveloped forested land consisting of rolling hills and steep slopes, with surface elevations varying from near the shoreline of Belews Lake to higher ridgetops as described in Section 2.1.1.3. A topographic map of the site is provided in Figure 2.1-10.

Located on a peninsula, the Project site is bordered by Belews Lake to the north, east, and much of the west. It also lies adjacent to the existing BCSS, which is west of the Project site. Section 1.1.2 provides additional details of the site location, while Section 2.1.1 outlines the surrounding region and vicinity.

Belews Lake, described in Section 2.2.1.1.3, serves as a cooling reservoir for the BCSS, a dual-fuel coal and natural gas power generation facility. Duke Energy, Carolinas, LLC (Duke Energy) owns all the land within and immediately adjacent to Belews Lake.

The Project site encompasses approximately 1187 acres (ac.) (480 hectares [ha]) with the general arrangements shown in Figure 3.1-1. It includes the site boundary, Plant Complexes, cooling tower areas, permanently disturbed laydown areas, and other supporting facilities. Space is reserved for a future independent spent fuel storage installation with additional information provided in Section 3.4.2.2.

3.1.2 PLANT PARAMETER ENVELOPE

As described in Chapter 1, Duke Energy is pursuing an Early Site Permit (ESP) to approve the Project site as suitable for deployment of advanced reactors located on up to three nuclear power Plant Complexes (each referred to as “Plant Complex”). The ESP application (ESPA) aims to assess the site’s suitability to accommodate construction and operation of advanced reactors. The ESPA does not specify a specific reactor technology at this stage but rather encompasses several reactor technologies considered that could be deployed on the site. Advanced reactor technologies under consideration are provided in Section 3.2.1.

The PPE was developed using guidance provided in the Nuclear Energy Institute (NEI) document NEI 10-01, Revision 1: *Industry Guideline for Developing a Plant Parameter Envelope in Support of an Early Site Permit*, as well as in Regulatory Guide (RG) 4.27, Revision 0, *Use of Plant Parameter Envelope in Early Site Permit Applications for Nuclear Power Plants*. The bounding value for each parameter identified in NEI 10-01 was determined through a review of vendor supplied information provided for each reactor technology.

The PPE incorporates information from reactor vendors for technologies under consideration to define a bounding surrogate facility. This approach considers all available vendor information to determine the bounding—maximum or minimum—values across parameters. These bounding parameters serve as input for the analyses needed to support the development of the ESPA

(NEI, 2012).

The final reactor technology selected for the Project site will undergo review during the construction permit or license application phase to ensure it falls within the bounds established by the PPE. This approach supports site suitability for a range of reactor technologies without requiring a commitment to a specific design at this stage.

The PPE for the Project site considers the bounding parameters from six different reactor technologies, as listed in Section 3.2.1. The site-related design parameters are provided in Table 3.1-1 and the site characteristics are listed in Table 3.1-2.

3.1.3 EXISTING GENERATION, STRUCTURES, AND FACILITIES

As described in Chapter 1, BCSS began operating in 1974 and is scheduled for retirement in the mid-2030s. Because the Project site is located adjacent to BCSS, existing grid connections and cooling resources will support the Project site. Additionally, there are disturbed areas of the Project site that are used to support BCSS operations. Figure 3.1-2 shows an aerial overlay of the existing generation, structures, and facilities located at and around the Project site.

Belews Lake is a man-made reservoir originally constructed to meet the cooling needs of BCSS as described in Section 2.2.1.1.3. As described in Section 3.4.1.1.2, Duke Energy built the Makeup Water Intake Structure (MWIS) in 2010 at the confluence of the Dan River and Belews Creek, off-site, to function as a lake makeup water system.

The existing wastewater consolidation sump, Lined Retention Basin (LRB), and the associated pipeline corridor extend beyond the Project site. As noted in Section 2.1.2, BCSS uses the wastewater pipeline as a permitted discharge point—referred to as Outfall 006—to discharge into the Dan River under the National Pollutant Discharge Elimination System (NPDES).

An existing 230 kilovolt (kV) switchyard and established transmission corridors currently serve BCSS and will support the Project site. However, a second 230 kV switchyard or multiple smaller 230 kV switchyards are required to fully support the Project. Additional details are provided in Section 3.2.4.

A Duke Energy-owned natural gas pipeline traverses the Project site that provides natural gas to the BCSS, noted in Section 2.1.1.3 and shown on Figure 2.1-1. Three double-circuit 230 kV transmission lines also cross the Project site. Duke Energy owns and operates the lines.

Figure 3.1-2 shows two landfills located on and off the Project site. The off-site Craig Road Landfill is detailed on Figure 2.2-25, while the on-site Flue Gas Desulfurization (FGD) Landfill is depicted on Figure 2.2-26.

The primary access roads into the Project site are already in place with additional smaller on-site and off-site access roads. The primary access to and from the Project site is from the south via Craig Road, as shown on Figure 3.1-3, which connects to State Highway 65 in Forsyth County. Rail lines are also present, which connect to the Norfolk Southern (NS) Railroad (NS, 2025).

3.1.4 SHARED STRUCTURES AND FACILITIES

Figure 3.1-3 provides a graphical representation of the shared structures and facilities listed below.

- 230 kV switchyard (off-site)
- Access roads (on- and off-site)
- Belews Lake (off-site)
- MWIS and associated piping (off-site)
- LRB (off-site)
- Wastewater pipeline to the Dan River (off-site)
- NPDES Outfall 006 (off-site)
- Perimeter security fencing (on- and off-site)
- Rail lines with connection to NS Railroad (on- and off-site)
- Sewage treatment lagoon (on-site)
- Transmission line corridor (on- and off-site)
- Wastewater consolidated sump (off-site)
- Wastewater redirection sump (off-site)

The shared infrastructure limits the overall land use impact and provides economic and beneficial reuse of these structures and facilities.

3.1.5 PROPOSED PLANT LAYOUT

The Project site can accommodate up to three separate, noncontiguous Plant Complexes, each containing multiple advanced reactors depending on the reactor technology selected. Because the layout of the Project site is not finalized, the exact location of the Project site center point and associated boundaries are yet to be determined. The proposed site center point is shown on Figure 3.1-1 and detailed in Table 2.1-8. The Plant site center point incorporates a bounding radius around the Project site such that the radius encompasses all safety-related features as described in Section 2.1.1.3.

The overall Project site layout, including proposed structures, acreages, and EAB is shown on Figure 3.1-1. The Project site spans approximately 1187 ac. (480 ha), with approximately 906 ac. (367 ha) designated for permanent disturbances, such as the power blocks, cooling towers, laydown areas, and switchyards. After completing construction activities, laydown areas used to support construction activities will remain disturbed areas and be used to support operations such as parking lots and related facilities.

The PPE bounding values and parameters for the Project site are listed in Table 3.1-1. The maximum structure height in the power block area, excluding the cooling tower(s) and facility stack(s) is 176 feet (ft.) (53.6 meters [m]) above grade as listed in the PPE. In general, buildings are constructed using standard building materials such as concrete, metal with metal siding, or wood with metal, vinyl, or other acceptable siding. The design and construction of building structures will take into consideration the surroundings to minimize aesthetic impacts.

The circulating water system is anticipated to include mechanical draft cooling towers (MDCT) with makeup water drawn from Belews Lake. The intake, discharge, and circulating water structures and systems are described in Section 3.2.2. Necessary upgrades and modifications to the transmission system noted in Section 3.1.3 are further detailed in Section 3.2.4.

The Project site is located on a primarily forested peninsula and development of this site will alter stormwater flow patterns. As part of site development, engineered stormwater controls are incorporated to manage runoff quantity and quality. Stormwater flow is diverted away from each Plant Complex by an engineered stormwater collection system. It includes a combination of swales, retention and detention basins, pipes, culverts, and sediment and erosion control measures designed to prevent discharge of pollutants to Belews Lake, the Dan River, and its tributaries. The stormwater system will be designed to accommodate site-specific topography, hydrologic conditions, and soil characteristics to ensure compliance with North Carolina Department of Environmental Quality (NCDEQ) NPDES requirements for both construction and post-construction phases.

Access to each Plant Complex is from the south via the existing Craig Road or from the west via Pine Hall Road/Duke Power Steam Plant Road. Duke Energy access roads, shown in Figure 3.1-3, which lead to the existing structures and facilities may require some widening and extending to support the Project site building and operation.

A meteorological tower is located on the northern portion of the peninsula and is further described in Section 2.7.4.

Figures 3.1-4 through 3.1-7 present renderings of the proposed plant layout. The renderings show the proposed Plant Complexes from multiple vantage points within the natural landscape of Belews Creek, NC.

The Project site leverages the use of existing infrastructure and resources to minimize adverse environmental effects. Additional details related to the proposed plant structures, systems, and components are provided in Section 3.2.

Table 3.1-1
Site-Related Design Parameters
(Sheet 1 of 5)

Parameter[(a)]	Definition	PPE Value	ER Section
1. Structures			
1.1 Building Characteristics			
1.1.1 Height	The height from finished grade to the top of the tallest power block structure, excluding cooling towers (excludes stairway towers, elevator, etc.).	176 feet	3.1, 5.4
1.1.2 Foundation Embedment	The depth from finished grade to the bottom of the basemat for the most deeply embedded power block structure.	125 feet	3.3
3. Normal Plant Heat Sink			
3.1 Condenser			
3.1.2 Condenser / Heat Exchanger Duty	Design value for the waste heat rejected to the circulating water system across the condensers.	1.32E+10 Btu/hr	3.2, 5.7
3.2 Nonsafety-Related Service Water Systems			
3.2.2 SW Heat Exchanger Duty	The heat transferred to the nonsafety-related service water system for rejection to the environment.	2.05E+08 Btu/hr (normal) 5.86E+08 Btu/hr (max)	3.2
3.2.3 Miscellaneous Plant Water Uses Intake	The maximum, and normal, water intake of the plant neglecting cooling tower makeup, potable/sanitary water users, and liquid radwaste treatment.	1080 gpm (max) 300 gpm (normal)	3.2, 3.4
3.2.4 Miscellaneous Plant Water Uses Discharge	The maximum, and normal, water discharge of the plant neglecting cooling tower makeup, potable/sanitary water users, and liquid radwaste treatment.	360 gpm (max) 102 gpm (normal)	3.2, 3.4
3.3 Mechanical Draft Cooling Towers			
3.3.1 Acreage	The land required for cooling towers, including support facilities such as equipment sheds, basins, canals, or shoreline buffer areas.	10.8 acres Also see Figure 3.1-1	3.2
3.3.3 Blowdown Constituents and Concentrations	The maximum expected concentrations for anticipated constituents in the cooling water systems blowdown to the receiving water body.	See Table 3.4-3	3.4, 5.2, 5.7
3.3.4 Blowdown Flow Rate	The normal (and maximum) flow rate of the blowdown stream from the cooling water systems to the receiving water body for closed system designs	3852 gpm (normal) 6516 gpm (max)	3.2, 3.4
3.3.5 Blowdown Temperature	The maximum expected blowdown temperature at the point of discharge to the receiving water body.	95°F	3.2, 3.4
3.3.6 Cycles of Concentration	The ratio of total dissolved solids in the cooling water blowdown streams to the total dissolved solids in the make-up water streams.	6 minimum 8-12 normal operating range	3.2, 3.4, 5.7

Table 3.1-1
Site-Related Design Parameters
(Sheet 2 of 5)

Parameter[(a)]	Definition	PPE Value	ER Section
3.3.7 Evaporation Rate	The expected (and maximum) rate at which water is lost by evaporation from the cooling water systems.	26,256 gpm (normal) 32,580 gpm (max)	3.2, 3.4
3.3.8 Height	The vertical height above finished grade of mechanical draft cooling towers associated with the cooling water systems.	50-75 feet	3.2, 5.7
3.3.9 Makeup Flow Rate	The expected (and maximum) rate of removal of water from a natural source to replace water losses from Circulating Water System.	30,109 gpm (normal) 39,117 gpm (max)	3.2, 3.4
3.3.10 Noise	The maximum expected sound level produced by operation of cooling towers, measured at 1000 feet from the noise source.	55.1 dBA	2.8, 4.8, 5.8
3.3.11 Cooling Tower Temperature Range	The temperature difference between the cooling water entering and leaving the towers.	14.8°F - 21.2°F	3.2, 3.4
3.3.12 Cooling Water Flow Rate	The total cooling water flow rate through the condenser/heat exchangers.	676,000 gpm to 1,400,000 gpm	3.2
3.3.14 Maximum Consumption of Raw Water	The expected maximum short-term consumptive use of water by the cooling water systems (evaporation and drift losses).	32,601 gpm	3.2
3.3.16 Stored Water Volume	The quantity of water stored in cooling water system impoundments, basins, tanks and/or ponds.	12,000,000 gallons	3.2
3.3.17 Drift	Rate of water lost from the tower as liquid droplets entrained in the vapor exhaust air stream.	1.2 gpm (normal) 21 gpm (max)	3.2, 3.4
5. Potable Water/Sanitary Waste Systems			
5.1 Discharge to Site Water Bodies			
5.1.1 Flow Rate (Potable/Sanitary Normal)	The expected (normal) effluent flow rate from the potable/sanitary water system to the receiving water body.	11 gpm	3.2
5.1.2 Flow Rate (Potable/Sanitary Maximum)	The maximum effluent flow rate from the potable/sanitary water system to the receiving water body.	19 gpm	3.2
5.2 Raw Water Requirements			
5.2.1 Maximum Use	The maximum short-term rate of withdrawal from the water source for the potable and sanitary wastewater systems.	19 gpm	3.2
5.2.2 Monthly Average Use	The average rate of withdrawal from the water source for the potable and sanitary wastewater systems.	472,500 gallons per month	3.2

Table 3.1-1
Site-Related Design Parameters
(Sheet 3 of 5)

Parameter[(a)]	Definition	PPE Value	ER Section
6. Demineralized Water System			
6.1 Discharge to Site Water Bodies			
6.1.1 Flow Rate	The expected (and maximum) effluent flow rate from the demineralized processing system to the receiving water body.	102 gpm (expected) 360 gpm (max)	3.2, 3.4
6.2 Raw Water Requirements			
6.2.1 Maximum Use	The maximum short-term rate of withdrawal from the water source for the demineralized water system.	1080 gpm	3.2
6.2.2 Monthly Average Use	The average rate of withdrawal from the water source for the demineralized water system.	13,000,000 gallons per month	3.2
7. Fire Protection System			
7.1 Raw Water Requirements			
7.1.1 Maximum Use	The maximum short-term rate of withdrawal from the water source for the fire protection water system (does not include large area fire requirements).	1250 gpm	3.2, 3.4
7.1.2 Monthly Average Use	The average rate of withdrawal from the water source for the fire protection water system.	6 gpm	3.2, 3.4
9. Unit Vent/Airborne Effluent Release Point			
9.4 Source Term			
9.4.1 Gaseous (Normal)	The expected annual activity, by radionuclide, contained in routine plant airborne effluent streams. Provide in Table 7.	See Table 3.4-6	3.4
10. Liquid Radwaste System			
10.2 Release Point			
10.2.1 Flow Rate	The discharge (including minimum dilution flow) flow rate of liquid potentially radioactive effluent streams from plant systems to the receiving water body.	300 - 450 gpm (liquid radwaste discharge flow) 3000 - 9000 gpm (dilution flow)	3.2, 3.4
10.3 Source Term			
10.3.1 Liquid	The annual activity, by radionuclide, contained in routine plant liquid effluent streams, if any.	See Table 3.4-4	3.4
11. Solid Radwaste System			
11.2 Solid Radwaste			
11.2.1 Activity	The annual radionuclide activity contained in solid radioactive wastes generated during routine operations.	See Table 3.4-8	3.4
11.2.2 Volume	The expected volume of solid radioactive wastes generated during routine operations.	38,988 cubic feet per year	6.2

Table 3.1-1
Site-Related Design Parameters
(Sheet 4 of 5)

Parameter[(a)]	Definition	PPE Value	ER Section
13. Auxiliary Boiler System			
13.2 Flue Gas Effluents	The expected combustion products and anticipated quantities released to the environment due to operation of the auxiliary boilers.	See Table 3.4-9	3.4
14. Standby Power System			
14.1 Diesel			
14.1.2 Diesel Exhaust Elevation	The elevation above finished grade of the release point for standby diesel exhaust releases.	9.84 feet	3.4
14.1.3 Diesel Flue Gas Effluents	The expected combustion products and anticipated quantities released to the environment due to operation of the emergency standby diesel generators.	See Table 3.4-10	3.4
15. Plant Layout Considerations			
15.1 Access Routes			
15.1.1 Heavy Haul Routes	The land usage required for permanent heavy haul routes to support normal operations and refueling.	30.12 acres	3.1, 4.1
15.2.1 Acreage to Support Plant Operations	The land area required to provide space for plant facilities.	312.9 acres Also see Figure 3.1-1	3.1, 4.1
16. Plant Operations Considerations			
16.1 Megawatts Thermal	The thermal power generated by one unit (may be the total of several modules). Specify both core thermal power and RCP thermal power (if there are RCPs in the design).	6250 MWt	3.2
16.2 Megawatts Electrical	Best estimate of MWe generator output. Assuming 100% power with 85F circulating water.	2250 MWe	3.2
16.3 Plant Design Life	The operational life for which the plant is designed.	80 years	3.2
16.8 Plant Population			
16.8.1 Operation	The estimated number of total permanent staff to support operations of the plant. Specifically, by responsibility for online operation: Operations Maintenance (including reactor services for online spent fuel work); RP/Health; Physics; Chemistry; Engineering; Security; Training; Other	450	4.4, 4.8, 5.8

Table 3.1-1
Site-Related Design Parameters
(Sheet 5 of 5)

Parameter[(a)]	Definition	PPE Value	ER Section
16.8.2 Refueling/Major Maintenance	The estimated additional number of staff required to conduct refueling and major maintenance activities by responsibility. Operations Maintenance (including reactor services for online spent fuel work); RP/Health; Physics; Chemistry; Engineering; Security.	350	4.4, 4.8, 5.8
17. Construction			
17.2 Acreage			
17.2.1 Laydown Area	The land area required during construction beyond what may be needed for plant operation.	256.2 acres	3.1, 4.1
17.3 Construction			
17.3.1 Noise	The maximum expected sound level due to construction activities, measured at 50 feet from the noise source.	110 dBA	4.8
17.4 Plant Population			
17.4.1 Construction	Maximum number of people on-site during construction.	2096	4.4, 4.8
18. Fuel			
18.1 Maximum Fuel Enrichment	Concentration (weight percent fraction) of U-235 in the fuel uranium.	<5 percent weight (Bounding for LWRs) 15.5 percent weight (Bounding for non-LWRs)	3.2, 6.2
18.4 Maximum Average Assembly Burnup	Maximum assembly average burn-up at end of assembly life.	65,000 (Bounding for LWRs) 169,450 MWD/MTU (Bounding for non-LWRs)	3.2, 6.2
18.8 Peak fuel rod exposure at end of life	Peak fuel rod exposure at end of life	62,000 MWD/MTU (LWRs)	3.2
18.11 Fuel Reload	Mass of uranium in the reload batch.	9.47 MTU/year (Bounding for LWRs) 11.3 MTU/year (Bounding for non-LWRs)	6.1

Notes:
(a) The numbering of the parameters is not intended to be sequential; rather, it reflects the structure of the list developed by industry and refined for this Early Site Permit Application.

Key: °C = degree(s) Celsius; °F = degree Fahrenheit; dBA = A-weighted scale decibels; gpm = gallons per minute; LWR = light-water reactor; MTU/year = metric tons of uranium per year; MWD/MTU = megawatt days per metric ton of uranium; MWe = megawatts electric; MWt = megawatts thermal

Table 3.1-2
Site Characteristics

Parameter[(a)]	Definition	Site Value	ER Section
9. Unit Vent/Airborne Effluent Release Point			
9.1 Atmospheric Dispersion (χ/Q) (Accident)			
9.1.1. 0-2 hour (Exclusion Area Boundary)	The atmospheric dispersion coefficients used in the design safety analysis to estimate dose consequences of accident airborne releases in the limiting two-hour interval.	2.62E-04 sec/m^3	5.11
9.1.2. 0-8 hour (Low Population Zone)	The atmospheric dispersion coefficients used in the design safety analysis to estimate dose consequences of accident airborne releases in the first eight hours.	2.55E-04 sec/m^3	5.11
9.1.3. 8-24 hour (Low Population Zone)	The atmospheric dispersion coefficients used in the design safety analysis to estimate dose consequences of accident airborne releases between hours 8 and 24 after the accident.	2.60E-04 sec/m^3	5.11
9.1.4. 1-4 day (Low Population Zone)	The atmospheric dispersion coefficients used in the design safety analysis to estimate dose consequences of accident airborne releases between the first day and the fourth day after the accident.	2.71E-04 sec/m^3	5.11
9.1.5. 4-30 day (Low Population Zone)	The atmospheric dispersion coefficients used in the design safety analysis to estimate dose consequences of accident airborne releases between day four until the end of the first 30 days after the accident.	2.88E-04 sec/m^3	5.11
9.2 Atmospheric Dispersion (χ/Q) (Annual Average)	The atmospheric dispersion coefficients used in the safety analysis for the dose consequences of normal airborne releases.	2.71E-04 sec/m^3 (Summed total of the three plant complexes)	5.9
	North Plant Complex	2.60E-04 sec/m^3	
	Middle Plant Complex	7.20E-06 sec/m^3	
	South Plant Complex	3.40E-06 sec/m^3	

Notes:
(a) The parameter numbering reflects the structure of the list developed by industry and refined for this Early Site Permit Application.
Key: χ/Q= atmospheric dispersion factor; sec/m^3 = seconds per cubic meter

3.2 PROPOSED PLANT STRUCTURES, SYSTEMS AND COMPONENTS

3.2.1 REACTOR POWER CONVERSION SYSTEM

At this time, Duke Energy has not selected a vendor for the reactor(s) to be constructed at the Project site. Because the reactor technology has not been chosen, a PPE has been developed to evaluate potential environmental impacts. The PPE and related guidance used to establish the surrogate plant is described in Section 3.1.2. The following AR technologies are currently under consideration:

- GVH BWRX-300
- NuScale VOYGR
- Holtec SMR-300
- WEC AP300
- TerraPower Natrium
- X-energy Xe-100

The Project site has the capability to support a total electrical output of 2250 megawatts electric (MWe) of new nuclear power generation. In general, steam generated by the nuclear steam supply system of each unit flows through the steam turbine, creating rotational mechanical work, that rotates the electric generator and produces electricity.

3.2.1.1 Reactor Description

Final arrangement of the Plant Complexes on the Project site is dependent on the reactor technology selected and shall be provided during the construction permit or license application phase. The proposed layout of the Plant Complexes, switchyard, and cooling tower areas is provided in Figure 3.1-1. The design life of the proposed plant is 80 years, but it is dependent on the reactor technology selected.

The maximum thermal output per reactor, based on the technologies being considered, is 1000 megawatts thermal (MWt), with a site maximum of 6250 MWt. The site maximum is based on a bounding electrical output of 2250 MWe at an assumed efficiency of 36 percent. Each reactor, along with its associated power conversion equipment, is estimated to have a maximum gross electrical output of 370 MWe, resulting in a total gross output of up to 2250 MWe for all units. The estimated net electrical efficiency ranges from 30 to 36 percent, depending on the reactor technology selected.

Fuel design is specific to the reactor technology, and all the technologies being considered for the Project site use uranium as their fissile material. For light-water reactor technologies, the maximum fuel enrichment of uranium-235 is less than 5 percent, the maximum average burnup is 65,000 megawatt days per metric ton of uranium (MWD/MTU), and the peak fuel rod exposure is 62,000 MWD/MTU. For non-light-water reactor technologies, the maximum fuel enrichment is 19.75 percent or less of uranium-235, the maximum average burnup is 169,450 MWD/MTU.

3.2.1.2 Engineered Safety Features

Engineered safety feature (ESF) systems are included in the designs being considered and include both active and passive ESF systems. In general, active safety systems rely on powered components, such as valve opening, to supply safety injection water and provide core and containment cooling. In the event of a loss of power, backup power sources like a diesel generator or a gas turbine powers the active systems. Alternatively, passive safety systems rely almost exclusively on natural forces, such as differences in density, gravity, or stored energy, to supply safety injection water and to provide core and containment cooling. Specific details about the ESF system for the reactor technology selected are addressed at the construction permit or license application phase.

3.2.1.3 Power Conversion Systems

The designs under consideration each use a steam turbine to convert the heat energy to mechanical energy. Waste heat from the turbine condensers is rejected to one or more MDCT, which serve as the normal heat sink. Specific details about the power conversion system for the reactor technology selected are addressed at the construction permit or license application phase.

3.2.2 COOLING SYSTEM

Cooling system components used for the planned operation at the Project site are described in Section 3.2.2.1. The cooling system operational modes are described in Section 3.4. The advanced reactor technologies considered do not require a safety-related service water system and instead employ passive containment cooling systems to support safety-related cooling functions. As a result, no external water source is required to support safety-related activities and all aspects of the cooling systems described below are considered non-safety-related.

3.2.2.1 System Description

The circulating water systems (CWS) for the facility are planned as closed-cycle cooling with MDCT as the mechanism for cooling the main condenser. The design assumes makeup water for the CWS is obtained from an intake on Belews Lake, pumped into the cooling towers, and circulated in and out of the main condenser. A portion of the water is lost as evaporation and drift from the cooling towers. The remaining water loss in the CWS is due to blowdown from the MDCT. Blowdown will predominately be returned to Belews Lake through a combined discharge structure or three independent discharge structures but can be diverted to the Dan River for short durations to support liquid radioactive waste dilution or to support operational flexibility.

No modifications to the Belews Lake outfall at the main dam to the Dan River are planned or expected to be required. Operation of the main dam and its existing equipment is maintained and appropriately operated to maintain proper lake levels and conditions. Water is pumped from the Dan River to the northern part of the main lake by the MWIS. The MWIS is planned to operate within the existing permitted limits. Refurbishment, replacement, or modifications may be implemented as needed to improve the facility's efficiency, reliability, and overall operation, while ensuring continued compliance with existing permit conditions.

Other closed-cooling water systems provide cooling water to auxiliary components. A detailed description of these cooling systems is dependent on the reactor technology selected and will be provided at the construction permit or license application phase.

3.2.2.2 Heat Generated, Dissipated to the Atmosphere, and Released in Liquid Discharges

During full power operation, heat generated by the plant is transferred to the CWS via the condensers. The majority of this heat is dissipated to the atmosphere through evaporation in the MDCT, while a smaller portion is discharged as liquid waste (blowdown) to Belews Lake or the Dan River.

As captured in Table 3.1-1, the CWS rejects heat at a rate of 13,200 million British thermal units per hour (MMBtu/hr), with a normal blowdown flow of 3852 gallons per minute (gpm) and a maximum flow of 6516 gpm. The peak blowdown temperature is 95 degrees Fahrenheit (˚F) (35 degrees Celsius [˚C]).

Additionally, blowdown is used as liquid radiological waste dilution and routed to the new outfall near the existing Dan River Outfall 006. Administrative and engineering controls are used to meet the thermal discharge limitations outlined in the NPDES permit for this new outfall. Consistent with thermal discharge requirements for the Belews Lake Dam/Spillway (Outfall 001) to the Dan River, these controls are designed to ensure that the river temperature downstream of the mixing zone remains within 5˚F (2.8˚C) of the upstream river temperature and will not exceed 32°C (89.6˚F) as a result of AR operations.

Heat is also dissipated to the atmosphere by the non-safety-related service water heat exchangers at a normal rate of 2.05E+08 Btu/hr (205 MMBtu/hr) and a maximum rate of 5.86E+08 Btu/hr (586 MMBtu/hr) as noted in Table 3.1-1.

The specific quantities of heat generated, dissipated to the atmosphere, and released in liquid discharges depend on the reactor technology selected and are addressed during the construction permit or license application phase.

3.2.2.3 Water Source and Quantities of Water Withdrawn, Consumed, and Discharged

In full power operation mode, the CWS requires withdrawal of makeup water from Belews Lake. A water balance showing the use of water by the entire Project site, including the CWS, is provided in Figure 3.2-4. The total cooling tower makeup water is withdrawn through the intake at a maximum rate of 41,601 gpm, and a normal rate of 30,109 gpm. Cooling tower water is released to the environment through evaporation, drift, and blowdown. Evaporation and drift are consumptive losses because water is not returned to Belews Lake. The maximum evaporation rate is 32,580 gpm, and the maximum rate of drift is 21 gpm. The normal consumptive water use includes 26,256 gpm from evaporation and 1 gpm from drift. The normal blowdown rate, based on eight cycles of concentration, is 3852 gpm. The maximum blowdown rate, based on six cycles of concentration, is 6516 gpm. Cooling tower blowdown can be used to support dilution of liquid radiological waste releases to the Dan River. When operating to support liquid radiological waste dilution, the blowdown flow can be as high as 9000 gpm.

Miscellaneous plant water is withdrawn from Belews Lake at a maximum rate of 1530 gpm and a normal rate of 600 gpm. As shown in Figure 3.2-4, discharges from the liquid radioactive waste treatment system, 300 gpm normal and 450 gpm maximum, are batch discharges directed to the Dan River with dilution flow (3000 gpm normal, 9000 gpm maximum) provided from cooling tower blowdown. Wastewater generated during the production of demineralized water (at a normal flow of 102 gpm and a maximum of 360 gpm) also discharges to the Dan River. An additional source of water, shown in Figure 3.2-4, is municipal water. This water

services the potable water and sanitary waste systems at a normal flow of 11 gpm and maximum of 19 gpm and is treated and discharged to the Dan River at the same rate with no appreciable water loss. Municipal water, or Belews Lake main intake as an alternate source, provides fire protection water supply at a normal rate of 6 gpm and maximum rate of 1250 gpm.

3.2.2.4 Component Descriptions

Layout and description of various proposed plant structures and components for the CWS, including the intake and discharge, are described in Sections 3.2.2.4.1 through 3.2.2.4.4. Other water systems not described below are dependent on the reactor technology selected and details will be available at the construction permit or license application phase.

3.2.2.4.1 Intake System

Two intake locations are being considered and their approximate locations on Belews Lake are shown in Figure 3.1-1. Section and plan views of the conceptual intake design are shown in Figure 3.2-1.

A single intake structure services all new generation facilities on-site. The intake is a wet well-type structure on the banks of the lake with an adequate number of bays with pump/motor sets to supply the selected technology and support redundancy.

Additional support systems, such as debris removal, and maintenance activities are provided to ensure operational reliability. Debris removal is performed by passive technology screens appropriately sized to meet Clean Water Act 316(b) velocity requirements of less than 0.5 feet per second (ft/s) (0.15 meters per second [m/s]). These passive screens are installed at appropriate depths and in adequate size and quantity to support continuous operation. The common intake structure includes the required electrical switchgear to support intake system operations.

Water intake to the facility is at an adequate depth to not affect full rated power generation capabilities of the facilities during analyzed drought conditions. Current analysis supports an intake depth of up to approximately 60 ft. (18.3 m) for both drought tolerance and thermal stability. Additional water intake design details will be available at the construction permit or license application phase.

Makeup to Belews Lake from the Dan River is available through the MWIS maintained under the existing BCSS NPDES Permit. The existing permit will be updated to include activities associated with nuclear generation. However, no changes to existing limitations associated with operation of the MWIS as outlined in the existing NPDES permit are expected.

3.2.2.4.2 Not Used

3.2.2.4.3 Blowdown Discharge

Conceptual discharge designs being considered for Belews Lake are shown in Figure 3.1-1 and Figure 3.2-2. The base discharge design is one separate discharge for each Plant Complex. The blowdown from each Plant Complex is discharged via gravity to Belews Lake. An alternative design includes collecting the blowdown from each Plant Complex and discharging it through a combined discharge located northeast of the most northern Plant Complex. Discharge piping entering the lake is submerged and routed to the appropriate location and depth to mix

with the bulk waters of the lake. Final discharge location(s) will be based on environmental, technical, and regulatory considerations, with additional details provided during the construction permit or license application phase.

While blowdown is predominantly returned to Belews Lake, blowdown flow can be diverted to the Dan River at an outfall location within the existing corridor, adjacent to Outfall 006. When blowdown is diverted to the Dan River outfall, administrative and engineering controls are used to limit temperature impacts to the river such that the river temperature downstream from the mixing zone remains within the limits required to meet NPDES permit limitations. The blowdown discharge to the Dan River is a submerged discharge. A conceptual discharge design is shown in Figure 3.2-3.

All potential discharge designs for Belews Lake maintain an exit velocity less than approximately 10 ft/s (3.05 m/s) to minimize erosion and corrosion aspects. The Dan River discharge is designed to optimize thermal mixing to minimize environmental impacts. The Dan River consists of five ports spaced at approximately 5-ft. (1.5-m) intervals with a total length of approximately 20-ft. (6.1-m) The maximum port discharge velocity is approximately 10.6 ft/s (3.2 m/s) while the minimum velocity is approximately 5.5 ft/s (1.7 m/s). Thermal discharges are designed and constructed to comply with NPDES permit conditions. Additional discharge design details are available at the construction permit or license application phase once a reactor technology is selected.

3.2.2.4.4 Mechanical Draft Cooling Towers

Heat dissipation for the Project site is planned as a closed-cycle cooling type with MDCT as the mechanism for cooling the main condensers of wasted thermal heat.

Cooling towers being considered are MDCT that utilize evaporative cooling for heat dissipation. Makeup water for the cooling water system is from the common intake structure on Belews Lake, pumped to the cooling towers, and circulated through the main condenser. Drift and evaporation cause the loss of cooling water, while a portion is returned to Belews Lake and Dan River as blowdown from the cooling towers through a planned discharge. The locations of the cooling towers are within the plant areas shown in Figure 3.1-1. The cooling tower locations occupy a maximum area of approximately 10.8 ac. (4.4 ha) with a maximum height of 75 ft. (22.86 m) above plant grade. The maximum volume of water stored in the cooling towers is 12,000,000 gallons, with a maximum circulation rate of 1.4E+06 gpm. The planned cooling towers are designed for a maximum blowdown temperature of 95°F (35°C) at the point of discharge to Belews Lake and an approximate temperature differential of 21.2°F (11.8 °C) between the cooling water entering and leaving the towers. Cooling towers are expected to operate at a minimum of six cycles of concentration, with a typical operating range of 8 to12 cycles of concentration under normal conditions.

3.2.3 PLANT WATER USE

Water is required to support the Project site during building activities and operation. Typical water uses for operation include the CWS, potable and sanitary water system, fire protection system, and other auxiliary systems like demineralized water and liquid radioactive waste treatment systems. Belews Lake is the primary water source for plant operations and water is withdrawn via a new common intake structure. Municipal water is used for fire protection, as well as potable and sanitary purposes for building and operational activities.

3.2.3.1 Water Consumption

A water-use diagram for the conceptual facility is provided in Figure 3.2-4. The diagram shows the normal and maximum flow rates for the intake and discharge from the lake, the rates for consumptive uses, and the relationships between the various water flow systems. All flow values are for all Plant Complexes, not a single Plant Complex. The average values are the expected limiting values for normal plant operation with cooling tower operation at eight cycles of concentration, and the maximum values are those for cooling tower operation at six cycles of concentration.

The source of water for facility operations is Belews Lake. Two potential proposed water intake locations are shown in Figure 3.1-1. A single intake withdraws water at a normal flow of approximately 30,709 gpm, and a maximum flow of approximately 43,131 gpm.

Of the total intake, approximately 30,109 gpm (normal) and 41,601 gpm (maximum with radwaste dilution flow) is directed to serve as makeup water for the CWS. The proposed CWS uses MDCT for heat dissipation. MDCT consume water through evaporation and drift. The normal drift rate is estimated to be 1 gpm and the maximum drift rate is estimated to be 21 gpm. The normal and maximum evaporation rate is estimated to be 26,256 gpm and 32,580 gpm, respectively. The blowdown from the cooling towers discharges water back to Belews Lake through a combined discharge or a specific Plant Complex discharge, or to the Dan River for radwaste dilution or operational flexibility. The blowdown rate to Belews Lake is estimated to be a normal flow of 3852 gpm, and a maximum of 6516 gpm. Maximum blowdown during radwaste dilution is approximately 9000 gpm.

The operational modes (e.g., hot standby, startup, normal operation, etc.), for the cooling water system are to be defined once a specific reactor technology is selected.

Of the total intake withdrawal volume, a normal flow of approximately 600 gpm and a maximum of 1530 gpm is directed to the plants and facilities and then distributed for various auxiliary systems. The consumptive uses of water within these systems are normally 198 gpm and maximum of 720 gpm. The specific water volumes distributed to each of these individual uses have not been defined but are to be developed once the reactor technology has been selected. The effluent generated during the production of demineralized water is discharged to the Dan River at a normal flow rate of 102 gpm and maximum flow rate of 360 gpm. Treated liquid radioactive waste effluent is discharged to the Dan River through the proposed discharge in batch releases maintaining a normal flow rate of 300 gpm and maximum flow rate of 450 gpm with an added dilution flow. During batch releases, the dilution flow has a normal flow of 3000 gpm and a maximum of 9000 gpm.

The source of water for the potable and sanitary water systems is to be from the municipal water system. Consumptive uses of this water are expected to be negligible, and the wastewater is to be discharged through the existing Belews Creek sewage treatment facility to the Dan River. The water supply rate for the potable and sanitary water systems is estimated at 11 gpm normal, with a maximum rate of 19 gpm.

3.2.3.2 Water Treatment

Duke Energy uses a common open cooling water chemistry program that covers cooling tower and once-through systems for waste heat condenser applications and some service water cooling applications. Similarly, Duke Energy has common water chemistry programs for primary,

secondary, and closed-cooling water systems. The programs describe the implementation for treatments, maintenance and testing best suited for the site-specific design and environment. Procedures specific to the Project site will be defined at the construction permit or license application phase once reactor technology is selected, water quality studies are completed, and NC NPDES permitting requirements are established. A representative list of chemicals which may be used at each site for water treatment activities is provided in Table 3.2-1. This list may not be all inclusive and will be determined based on the chosen reactor technology.

The demineralized water treatment system is expected to employ reverse osmosis and additional demineralization processes to further remove dissolved solids from filtered water produced by the raw water treatment system. Specific details for the treatment of demineralized water will be available at the construction permit or license application phase.

3.2.4 POWER TRANSMISSION SYSTEM

An existing 230 kilovolt (kV) switchyard, owned and operated by Duke Energy, serves the BCSS and will support the Project site. Established transmission corridors that serve the BCSS will also support the Project site. Figures 3.1-1 and 3.1-2 present the proposed transmission switchyard and the existing transmission system. Details are provided at the construction permit or license application phase once a reactor technology is selected.

3.2.4.1 Transmission System

The interconnection of the existing Belews Creek 230 kV switchyard to the proposed Project site and switchyard consists of the following activities:

- An extra bay is built at the existing Belews Creek 230 kV switchyard.
- The Pleasant Garden Black and White (B/W) 230 kV lines are rerouted into the northside of the existing Belews Creek 230 kV switchyard.
- The Belews Creek 230 kV lines are shifted down four positions (towards the lake) to terminate into the corresponding new and existing breaker positions.
- Capacitor Banks 1 and 2 have been permanently removed from the Belews Creek 230kV switchyard to accommodate new transmission line connections.
- A new switchyard is constructed.
- The proposed nuclear units are connected to the new switchyard on individual bus lines.
- Four bus lines are constructed to connect the new switchyard to the existing Belews Creek 230kV switchyard.
- Backup emergency power (off-site power) is connected to either open taps off the existing transmission lines or the new switchyard. A small substation may be needed to distribute off-site power to each unit. This decision is dependent on the selection of final reactor technology.

To support this configuration, the Bank 1 and Bank 2 capacitors at the existing Belews Creek 230 kV switchyard must be removed. A new switchyard will be constructed to the east of the

existing Belews Creek switchyard and south of the existing transmission corridor to facilitate the interconnection of the proposed nuclear units. Each nuclear unit will be connected to the new switchyard via dedicated bus lines.

Additionally, four bus lines will be built to connect the new switchyard to the existing Belews Creek 230 kV switchyard. Backup (off-site) emergency power is connected to either open taps on the existing transmission lines or via the new switchyard. A small substation may be needed to distribute off-site power to each unit, depending on the final selection of reactor technology.

3.2.4.2 Existing BCSS and Proposed Transmission Line Corridors

Proposed transmission lines from power blocks, switchyard areas, and the existing Belews Creek switchyard are located within the net disturbance area (NDA). Routes are dependent on the final layout of the site. Corridors associated with the construction of tie-ins and the relocation of the 230kV transmission lines are determined based on Duke Energy standard corridor widths per DE-B-06, shown in Figure 3.2-5. These corridor widths support all necessary National Electrical Safety Code (NESC) requirements.

3.2.4.3 230kV Switchyard

The 230kV switchyard may include transformers, breakers, switches, relays, real-time metering, and dual communication paths. Additional equipment would include connecting bus work, a supporting steel superstructure, ground wire towers, switch house, and equipment storage building. No underground utilities are planned for this switchyard.

The parameters involve ensuring adequate voltage and current handling capabilities, system protection and reliability. The system must be designed with appropriate voltage ratings to manage system voltages under normal and fault conditions, such as Basic Insulation Level (BIL) to withstand surges, current ratings for switchyard equipment to accommodate anticipated load flows and short circuit current to handle fault currents within their allowable ranges. Critical design considerations include clearance requirements to ensure there is sufficient phase to phase and phase to ground distances to prevent flashover and maintain operational safety.

Capacitor Banks 1 and 2 have been removed from the existing Belews Creek 230 kV switchyard to accommodate new transmission connections. Additional details are provided as part of the construction permit or license application phase once final reactor technology has been selected.

3.2.4.4 230kV Structures and Conductors

The proposed 230kV transmission line connections use self-supporting, lattice steel towers. The configuration for the electrical conductors (the cables that carry the electrical current) is yet to be determined, but the existing configuration is single 2156 aluminum conductor steel reinforced (ACSR). Two single ground wires are placed on the two highest points of the structures to provide lightning protection. In some cases, these ground wires may carry fiber optic or other communication circuits. Tower height may vary depending on final grade and land use but normally ranges between 80 and 120 ft. (24.4 and 36.6 m) with standard span lengths typically between 600-800 ft. (182.9-243.8 m). Tower foundations are normally laced-steel grillages, one per leg, buried in the earth. Some towers where the line turns at an angle require foundations of reinforced concrete. Figure 3.2-6 is a sketch of a typical structure with no underbuilt

transmission lines.

3.2.4.5 General Methods of Construction Switchyard

A construction assembly area, referred to as a laydown area, is required for worker assembly, vehicle parking, and material storage during construction. Laydown areas are located within the Project site as shown on Figure 3.1-1. Selection criteria used for locating the potential laydown area include:

- Relatively flat.
- Well drained.
- Previously cleared.
- Preferably graveled and fenced.
- Preferably wide access points with appropriate culverts.
- Sufficiently distant from streams, wetlands, or sensitive environmental features.
- Located adjacent to an existing paved road near the transmission line.

In general, the site is leveled using a cut-and-fill process. Areas of the site that are too high (sloped) or too low are leveled to achieve a consistent elevation. Any fill required is obtained from an approved or permitted borrow area. All activities are conducted in accordance with Duke Energy's Site Clearing and Grading Specifications. Construction activities are conducted in accordance with Duke Energy Transmission Construction Guidelines Near Streams, Duke Energy Quality Protection for Transmission, Substation or Communications Construction, and Duke Energy Substation Lighting Guidelines.

Trailers used for material storage and office space are parked in the laydown area. Following completion of construction activities, trailers, unused materials, and construction debris are removed from the Project site. Additional building activity details are provided in Section 3.3.

3.2.4.6 Transmission Line Tie-Ins

A laydown area is required for assembly, vehicle parking, and material storage during construction. The laydown area within the Project site used for associated transmission line structures is approximately 5 ac. (2.0 ha). Selection criteria described in Section 3.2.4.5 are the same as for the switchyard and substation laydown area. Additional building activity details are provided in Section 3.3.

The transmission structure is the most visible element of the electric transmission system, and functions to keep an adequate distance between the high-voltage conductors and the surrounding area. The transmission line structure type depends on the line voltage, terrain, and whether the line is single circuit or double circuit. Transmission structure heights vary depending on final grade and land use but normally range from 80 to 120 ft. (24.4 to 36.6 m). The Federal Aviation Administration provides guidance for marking and lighting of structures that may affect navigable airspace. The guidance applies to structures that exceed an overall height of 200 ft.

(61 m) above ground level or are located within 3 nautical miles of an airport.

Equipment used during the construction phase may include trucks, truck-mounted augers, drills, tracked cranes, and bulldozers. Low ground-pressure-type equipment is used in specified locations (such as areas with soft ground) to reduce the potential for environmental impacts.

Reels of conductor and ground wire are delivered to various staging areas along the corridor. A small rope is used from structure to structure, connected to the conductor and ground wire, and used to pull them down line through pulleys suspended from insulators. A bulldozer and specialized tensioning equipment are used to pull conductors and ground wires to the proper tension. Crews clamp wires to the insulators and remove the pulleys.

Activities associated with the transmission line tie-ins and relocation are conducted in accordance with Duke Energy procedures.

3.2.4.7 Predicted Noise Levels from Transmission System Operations

High-voltage transmission lines can emit noise when the electric field strength surrounding the lines is greater than the breakdown threshold of the encapsulating air, creating an energy discharge. This discharge is known as corona discharge and is affected by ambient weather conditions such as wind, precipitation, air density, humidity, and energized surface irregularities. Corona results in audible noise, radio, and television interference, energy losses, and the production of ozone and oxides of nitrogen. The sound created from corona discharge can result in a noise that can be heard near the base of the transmission lines. According to NUREG-1437, *Generic Environmental Impact Statement for License Renewal of Nuclear Plants*, noise from corona discharge along a transmission line is low, well below the 65 dBA threshold for perceptible noise.

Table 3.2-1
Representative Water Treatment Chemicals

Chemical use	Chemical
Water treatment (Clarifier)	60% Ferric Sulfate/Ferralyte 8130
Water treatment (Clarifier)	25% Sodium Hydroxide
Water treatment (Clarifier)	12.5% Sodium Hypochlorite
Water treatment (Clarifier and Thickener Tank)	Nalclear 7768
Water treatment (Clarifier and Thickener Tank)	Ferralyte 8130 Ferric Sulfate
Water treatment (Polymer Pumps)	PolyClean 7
Cooling Tower (shared with Chiller Tower)	3D Trasar 3DT187
Cooling Tower (shared with Chiller Tower)	12.5% Sodium Hypochlorite
Cooling Tower (shared with Chiller Tower)	Trasar 3DT199
Cooling Tower	Nalco 7468
Chiller System	DOWFROST HD (propylene glycol)
Chiller System	Dupont SUVA 123
Chiller System	NalPrep IV
Closed Water Cooling	33% Propylene Glycol
Closed Water Cooling	Nalco C-4710
Demineralizer Building (RO and Cooling Tower Blow down)	38% Sodium bisulfite
Demineralizer Building (RO system)	25% Sodium hydroxide
Demineralizer Building (UF system)	50% Citric acid
Demineralizer Building (UF system)	12.5% sodium hypochlorite
Demineralizer Building (RO system)	Antiscalant PC-191T
Demineralizer Building (RO cleaning biocide)	RoCide DB20
Demineralizer Building (RO cleaning)	RoClean P303
Demineralizer Building (RO cleaning)	RoCide IS2
Demineralizer Building (RO cleaning)	RoClean P111
Aux Boiler Building (HRSG Water)	19% Aqueous Ammonia
Aux Boiler Building (HRSG Water)	Eliminox

3.3 BUILDING ACTIVITIES

3.3.1 INTRODUCTION

This section describes the site development activities that form the basis for evaluating environmental impacts and distinguishes between preconstruction and construction activities at the Project site, which can accommodate up to three separate Plant Complexes (each referred to as a Plant Complex).

Construction activities generally involve safety-related structures, systems, and components (SSCs) that require authorization by the United States (U.S.) Nuclear Regulatory Commission (NRC) through a formal review process defined in Title 10 of the Code of Federal Regulations (CFR) Part 50.10(a)(1) (10 CFR 50.10(a)(1)). In contrast, preconstruction activities are non-safety-related and may be performed without NRC authorization.

Because Duke Energy has not yet selected an advanced reactor technology, a PPE, as described in Section 3.1.2, has been developed to evaluate the potential environmental impacts.

As described in Section 3.1.1, the Project site encompasses approximately 1187 ac. (480 ha) with the general arrangements shown in Figure 3.1-1. It includes the site boundary, Plant Complexes with approximate elevations, cooling tower areas, permanently disturbed laydown areas, and other supporting facilities.

Additionally, an aerial view showing the site boundary and the NDA is provided in Figure 3.3-1. The NDA encompasses approximately 906 ac. (367 ha) and includes a vegetative buffer zone along the shoreline. Space is also reserved for a future independent spent fuel storage installation with additional information provided in Section 3.4.2.2.

3.3.2 PRECONSTRUCTION ACTIVITIES

Preconstruction and site preparation activities may proceed without prior NRC approval, provided that the necessary regulatory authorizations for land-disturbing activities, building and infrastructure development, and environmental protection have been obtained from federal, state, and local agencies. These regulatory requirements may include, but are not limited to, stormwater management permits, water quality certifications, and construction-related environmental controls. The Project complies with applicable federal, state, and local regulations governing grading, filling, earthwork, and stormwater discharges. A comprehensive list of anticipated permits and authorizations applicable to the Project is provided in Table 1.4-2.

Site preparation and building activities require the placement of earthen fill, which is sourced primarily from the Project site within the NDA. Land-disturbing activities, including excavation and fill placement, are conducted in accordance with applicable state erosion and sediment control requirements. An approved Erosion and Sedimentation Control Plan (ESCP) is required, and coverage under the applicable state stormwater general permit is obtained from the NCDEQ or local delegation prior to initiating building activities as indicated in Table 1.4-2.

Pursuant to the North Carolina Sediment Pollution Control Act of 1973, any potential fill material needed from an off-site borrow site will be obtained from an approved NCDEQ source. Fill material reused on-site is placed only after determination of its geotechnical suitability for the intended use. Final quantities of fill are determined during detailed design and reflect a balanced cut-and-fill approach planned for the Project. Material not suitable for backfill will either be

reused on-site for ground-maintenance purposes or disposed of in accordance with state or local requirements.

To prevent off-site sedimentation and manage stormwater runoff during building activities, the Project implements a range of best management practices (BMPs) during all phases of building activities. These may include silt fencing, filter socks, stabilized construction entrances (potentially with wheel wash systems), sediment basins, floating turbidity barriers, and similar systems used for managing stormwater during construction activities. Additional environmental protection measures may include containment and spill response kits and systems for construction materials such as oils, paints, and chemicals.

The following is a summary of anticipated preconstruction activities that may be performed in advance of an NRC issued Construction Permit (CP) or Combined License (COL):

- Construction of new roads within the site construction areas to facilitate access to parking and storage areas, and new access roads to remote areas of development such as the cooling and makeup water intake and process wastewater discharge structure locations.

- Construction of rail unloading areas with heavy haul roads and bridges leading from the unloading areas to the construction storage and staging areas.

- Improvements of existing site roads and bridges to accommodate anticipated construction and operational vehicle traffic and to handle anticipated oversized or heavy haul vehicles.

- Site preparation of each Plant Complex, which are eventually enclosed by a Protected Area fence in accordance with 10 CFR Part 73.

    - Site preparation for each Plant Complex includes clearing and grubbing of trees and dense vegetation, topsoil stripping, grading and installation of stormwater management systems. Some areas may be temporarily stabilized with crushed stone for accessibility; however, temporary and permanent stabilization are most likely to be sequenced with the substructure installations comprised of non-safety-related foundations and buried utilities.

    - As presented in Table 3.3-1, the Plant Complexes are planned to be constructed sequentially. It is anticipated that each Plant Complex will be graded to balance earthwork cut-and-fill quantities to the greatest extent practical. Adjacent laydown areas may be adjusted to grade elevations that are different than the power block and permanent plant equipment grades to facilitate a balanced earthwork design. Specialized off-site material, such as crushed stone, will be brought to the site from an approved off-site source.

    - The potable water source for use during building activities may be with a connection to existing water lines that currently serve existing BCSS operations, landfills or material management areas, or a new water line connection to the municipal system located immediately outside of Duke Energy's existing south gate at Craig Road.

  - Water to be used for building activities could be obtained from a municipal city water connection that serve existing plant facilities or obtained from new groundwater production wells or from Belews Lake.

- Site preparation of construction parking and laydown areas, as well as construction trailer locations and other temporary construction facility areas, along with associated utilities and supporting infrastructure.

  - Site preparation includes clearing and grubbing of trees and dense vegetation, topsoil stripping, mass earthwork and grading, installation of stormwater management systems, and stabilizing the completed surfaces with crushed stone, asphalt pavement, or concrete paving. Graded slopes may be surfaced with grass seeded topsoil.

- Site preparation of switchyard and cooling tower areas.

  - Site preparation includes clearing and grubbing of trees and dense vegetation, topsoil stripping, mass earthwork and grading, installation of stormwater management systems and stabilizing the surface with crushed stone.

- Construction of cooling and makeup water intake and discharge systems along the Belews Lake shoreline.

  - The type of disturbance will vary based on the structure types selected; however, it is anticipated that excavation and lakebed dredging will occur to prepare the site for structure construction, and cofferdams may be temporarily installed to perform work in a dry environment. Cooling and makeup water intake and process wastewater discharge piping and electrical power and control cables will comprise utility corridors that will extend from each Plant Complex to their respective intake and discharge structures located along the lake shoreline.

- Installation of preconstruction site security features that include perimeter and interior vehicle and personnel access control points, fencing, site access gates, lighting, physical barriers, and guard houses.

- Installation of utility systems for construction use that would support the entire construction site and associated activities.

  - The utilities and systems may be installed below grade or above grade as needed and may include electrical power, potable and fire protection water, sanitary, and wastewater.

- Installation of permanent, non-safety-related utility systems.

  - The non-safety-related utility systems may be installed below grade or above grade as needed and may include electrical power and communications, potable and fire protection water, sanitary, wastewater, and other balance of plant systems.

- Erection and installation of construction-use facilities such as:

  - Offices, warehouses, equipment storage sheds, fuel and lubricant storage areas, bathrooms and change rooms, first aid and dining trailers, assembly and training areas, and personnel access facilities.
  - Concrete batch plant.
  - Concrete pads for construction cranes and crane assembly.
  - Construction fencing.

- Erection and installation of the switchyard foundation, equipment, and transmission towers.
- Erection and installation of the non-safety-related cooling and makeup water intake and process wastewater discharge structures and ancillary equipment and utilities, including site access roads for inspection and maintenance of these systems. Any work within, along, or near shorelines is typically provided with erosion control measures such as floating turbidity barriers to limit aquatic impacts.
- Erection and installation of the non-safety-related cooling tower system, including makeup water supply and blowdown water discharge pipelines and supporting electrical infrastructure.
- Soil and rock excavation for foundations within the Protected Area, including the power block and other support SSCs. Excavation may require permanent installation of construction aids, such as dewatering equipment. Rock excavation activities will most likely require controlled rock blasting. As captured in PPE Table 3.1-1, the Reactor Building excavation extends to a maximum depth of 125 ft. (38.1 m) below finished grade elevation.
- Transportation of backfill material from off-site sources and on-site stockpiles for backfilling foundations inside the Protected Area, including the power block and other support SSCs. Activities related to installation of safety-related structural backfill for safety-related SSCs are performed as part of the construction phase.
- Procurement or fabrication of components, or portions of the proposed advanced reactors, occurring at other than the final, in-place location, may also be performed. This work includes assembly of the components into complete modules on-site. However, the setting of completed modules does not occur until after the receipt of a CP or a COL and is considered a construction activity.

3.3.3 CONSTRUCTION ACTIVITIES

Activities constituting construction, as defined in 10 CFR 50.10(a)(1), are the driving of piles, subsurface preparation, placement of backfill, concrete, or permanent retaining walls within an excavation, installation of foundations, or in-place assembly, erection, fabrication, or testing, which are for:

(i) Safety-related SSCs of a facility, as defined in 10 CFR 50.2;

(ii) SSCs relied upon to mitigate accidents or transients or used in plant emergency

operating procedures;

(iii) SSCs whose failure could prevent safety-related SSCs from fulfilling their safety-related function;

(iv) SSCs whose failure could cause a reactor scram or actuation of a safety-related system;

(v) SSCs necessary to comply with 10 CFR Part 73;

(vi) SSCs necessary to comply with 10 CFR 50.48 and criterion 3 of 10 CFR Part 50, appendix A; and

(vii) On-site emergency facilities necessary to comply with either § 50.160 or § 50.47 and appendix E to this part, as applicable.

3.3.3.1 Overview of Construction Activities

Construction activities may begin after the NRC issues a CP or a COL. The safety-related SSCs facility types, arrangements, and layout will vary among the reactor technology vendors; however, the nuclear island and power block will generally include the items listed in the subsequent paragraphs that are patterned after the typical SSC facilities that comprise a pressurized water reactor.

As part of each SSC installation, supporting infrastructure includes the installation of mechanical piping and process systems, such as fire protection and heating, ventilation, air conditioning (HVAC) systems. Electrical installations begin at lower elevations and continue progressively to above grade as structures are completed.

3.3.3.2 Reactor Building Construction

The Reactor Building is the central safety-related structure housing the reactor vessel and related components. This heavily reinforced concrete structure includes the following key construction activities:

- Placement of reinforcing steel and concrete for the mat foundation that supports the containment structure. This includes the installation of mudmats, vapor barriers, basemat rebar/dowels, permanent commodities embedded in the basemat (e.g., pipe, conduit), and permanently installed construction aids within the basemat.
- Construction of the containment structure, which includes a steel plate lining system that seals the containment vessel, and structurally reinforced concrete walls and dome.
- Placement of the reactor pressure vessel within the containment structure.
- Construction of internal structures such as interior walls, slabs, platforms, and supports for mechanical and electrical systems.
- Installation of associated piping, valves, and mechanical and electrical equipment.
- Installation of containment structure cranes, including jib and bridge cranes.

- Completion of the reactor containment roof structure.

Outside the reactor containment structure, additional activities include:

- Construction of exterior walls, slabs, and platforms.
- Installation of major mechanical and electrical equipment.
- Installation of refueling machine and diesel equipment.
- Placement of gantry and bridge cranes.

3.3.3.3 Turbine Generator Building Construction

The Turbine Generator Building supports the steam turbine and generator systems and includes the following construction scope:

- Formation and placement of heavily reinforced structural concrete mat foundation and pedestal system to support off-site fabricated turbine and generator units.
- Erection of a multi-story steel frame enclosure with walls constructed of precast concrete panels or steel siding, and a structural roof system.
- Installation of an overhead crane to facilitate turbine and generator erection and future maintenance.

3.3.3.4 Radiological Waste Building Construction

The Radiological Waste Building is designed to process and manage radioactive solid and liquid waste removed from the Reactor Building. Key construction elements include:

- A single story, steel-framed structure with heavily reinforced concrete mat foundation.
- Construction of concrete walls and a concrete roof system lined with steel shielding for radiological protection.
- Installation of internal tanks, process equipment, and waste handling systems required for interim processing and storage prior to final disposal.

3.3.3.5 Additional Safety-Related and Support Facilities

Other key plant facilities anticipated for construction or installation include:

- Auxiliary Building
- Annex Building
- Security Building and Sally Ports
- Control Building

- Water Treatment Building
- Wastewater Treatment Building
- Emergency Diesel Generator Building
- Fire Protection Safety Building and Water Storage Tanks
- Bulk Gas Storage Facilities
- Process Water Storage Tanks
- Vehicle Maintenance and Warehouse Buildings

The common yard area construction spans the full construction duration beginning at the start of site preparation. The necessary permits and authorizations are obtained to ensure compliance with all applicable rules and regulations.

Civil installations include backfill of safety-related foundations and safety-related utilities, concrete formwork and structural modules, concrete foundations with reinforcing steel and steel embedments, structural steel, concrete pipe, and coatings.

Mechanical and HVAC installations include equipment such as vessels, pumps, compressors, tanks, heat exchangers, turbine generators, condensers, cooling towers, HVAC systems, process equipment, process system piping, and valves.

Electrical installations include transformers, electrical panels and instruments, switchgear, cable trays, conduit with cables encased in duct banks or direct buried, control instruments, and instrument trays.

3.3.4 CONSTRUCTION EQUIPMENT

The following construction equipment is anticipated to be used throughout the construction of the Project, categorized by major construction activities.

Clearing and grubbing operations: expected equipment includes excavators, bulldozers, backhoes, small tracked cranes, dump trucks, woodchippers and mulchers, and skid steer loaders.

Mass earthwork activities (excavation, grading, and fill placement): anticipated equipment includes bulldozers, scrapers, backhoes, end loaders, trenching machines, dump trucks, water trucks, graders, roller compactors, and vibratory plate compactors.

Substructure and equipment erection (foundations, utilities, and buried commodities): expected equipment includes backhoes, end loaders, trenching machines, dump trucks, skid steer loaders, wheel-mounted and tracked cranes, concrete trucks, pumper trucks, graders, asphalt pavers, roller compactors, and vibratory plate compactors.

Marine construction work (cooling and makeup water intake, process wastewater discharge structures, and related systems): depending on the selected technology, equipment may include pile drivers, vibratory hammers, hydraulic dredgers, excavators, backhoes, end loaders, dump

trucks, skid steers loaders, forklifts, wheel-mounted and tracked cranes, concrete trucks, pumper trucks, and other specialized equipment required for pump structure erection.

3.3.5 Construction Sequencing

The anticipated sequencing of construction is that the South Plant Complex will be constructed initially, followed by construction on the Middle Plant Complex, and lastly the North Plant Complex.

The timeline/duration for preconstruction and construction activities has not been established; however, a major activities schedule has been used as a basis for sequencing the construction activities presented in Table 3.3-1.

The construction sequence for all Plant Complexes has not been finalized. Nevertheless, concurrent construction of multiple units or multiple site areas remains a possibility, depending on the technology selected. This is especially true for the technologies that have multiple units in each Plant Complex, but less likely where one plant design houses multiple reactors, such as the Holtec dual-unit plant and the NuScale VOYGR.

Table 3.3-1
Conceptual Preconstruction and Construction Activities Schedule

Plant Complex	Preconstruction Activity Duration	Construction Activity Duration	Preconstruction Activity Start Date	Construction Completion Date Unit Online
South	24 months	36 to 42-month duration for Unit 1 Unit 2 starts 12 months after the start of Unit 1	Q3 2028	Q2 2034 Q2 2035
Middle	Starts 24 months after South Plant Complex	Unit 3 starts 12 months after the start of Unit 2 Unit 4 starts 12 months after the start of Unit 3	Q3 2030	Q1 2036 Q1 2037
North	Starts 24 months after the Middle Plant Complex	Unit 5 starts 12 months after the start of Unit 4 Unit 6 starts 12 months after the start of Unit 5	Q3 2032	Q1 2038 Q1 2039

3.4 OPERATIONAL ACTIVITIES

3.4.1 PLANT-ENVIRONMENTAL INTERFACES DURING OPERATION

The Project site will utilize advanced reactors with MDCT for primary heat dissipation at the plant. Bounding values provided throughout this section are for the entire site, not a single unit. Sections 3.4.1.1, 3.4.1.2 and 3.4.1.3 describe the water, land, and air interfaces, respectively. The operational modes of the cooling system such as hot standby, startup, and normal operation are defined upon the selection of a specific reactor technology and addressed during the construction permit or license phase.

3.4.1.1 Water Interfaces

The environmental interfaces with the Project site water systems include the plant intake and discharge structures, the cooling towers, and the sanitary and radwaste systems. Figure 3.2-4 shows normal operational flow rates to and from the various water systems, the source water for each system, and the receiving body of water for liquid discharges. Table 3.4-1 summarizes the normal and maximum operational flow rates that include withdrawals, consumptive uses, and liquid discharges.

3.4.1.1.1 Common Intake Structure

A common intake structure is planned on Belews Lake to serve all Plant Complexes at the Project site. Two potential locations are under consideration for the common intake structure and shown on Figure 3.1-1. Option 1 is located generally north of the canal on the eastern bank of the Project site, in between the North and Middle Plant Complexes. Option 2 is located on the western bank near the proposed North Plant Complex and east of the existing BCSS.

The conceptual design of the common intake structure is shown in Figure 3.2-1. The intake design will include debris screening capabilities, with passive screening technology as the preferred option. The passive screen will be designed and installed at the appropriate depth to ensure continuous operation. The design will include debris removal systems to maintain clean surface areas, ensure low velocity of less than 0.5 ft/s (0.15 m/s) through the screens, and comply with impingement and entrainment requirements of Section 316(b) of the Clean Water Act (CWA).

3.4.1.1.2 Makeup Water Intake Structure

In 2010, Duke Energy built the MWIS to support BCSS operation. It withdraws water from the Dan River and Belews Creek and routes it directly to Belews Lake. The MWIS is designed and permitted to include two 50 cubic feet per second (cfs) (1.42 cubic meters per second [m^3/s]) velocity caps, a permanent settling pond with approximately 6000 square feet of surface area, a four-pump pumping station with a capacity not to exceed 100 cfs, (2.83 m^3/s), force main, an electrical substation with an access road, and a diffuser in Belews Lake.

The MWIS is located north of the Project site at the confluence of the Dan River and Belews Creek as shown on Figure 3.1-3. It is authorized under the existing BCSS NPDES Permit NC0024406 issued by the NCDEQ. The total pumping capacity of the MWIS is defined by the conditions in the NPDES permit and adhered to as follows:

- Pumping will not lower flow in the Dan River below 110 cfs (3.12 m^3/s).

- Pump intakes are positioned above the river bottom with a velocity less than or equal to 0.5 ft/s (0.15 m/s) at the inlet of the velocity caps with a 2 millimeter (mm) fine mesh traveling screen.
- Water withdrawal location is near the confluence of the spillway channel below Belews Lake Dam and the Dan River.
- Semi-annual lake monitoring to assess limnological conditions in Belews Lake.
- Pumping may occur to a maximum water elevation in Belews Lake of 724.5 ft. (220.8 m) Mean Surface Level.
- No pumping will occur between April 1 and June 30 in order to avoid the fish spawning period.
- At least 80 percent of ambient flow will be bypassed, meaning withdrawals will not exceed 20 percent of the river flow.

Routine inspection and cleaning in and around the velocity caps, including the removal of silt, sediment, and debris, ensures reliable makeup water to Belews Lake from the MWIS is maintained.

3.4.1.1.3 Cooling Tower Blowdown

The normal cooling tower blowdown flow rate, based on eight cycles of concentration, is 3852 gpm (14.6 cubic meters per minute [m^3/min]). The maximum blowdown flow rate, based on six cycles of concentration, is 6516 gpm (24.7 m^3/min). The cooling tower temperature range, which is the difference between the cooling water entering and leaving the cooling towers, is 21.2°F (11.8°C). The maximum blowdown temperature at the point of discharge to Belews Lake is 95°F (35°C). Blowdown constituents and concentration in the wastewater at discharge are shown in Table 3.4-3.

The range of water quality including peak constituent concentrations in Belews Lake is detailed in Section 2.2.3 and summarized in Tables 2.2-27 and 2.2-28. This bounds any seasonal variations in water quality for Belews Lake. The blowdown constituents at the discharge are estimated based on the peak Belews Lake constituent concentrations at the intake, assuming the cooling towers operate at the maximum of 12 cycles of concentration. This conservative estimate bounds any seasonal variation and different plant operating modes. Impacts associated with cooling tower blowdown are described in Section 5.2.

Based on the bounding values in the PPE, described in Section 3.1.2, the normal water evaporation rate from the cooling system is 26,256 gpm (99.4 m^3/min), with a maximum evaporation rate of 32,580 gpm (123.3 m^3/min). Drift losses occur at a normal rate of 1 gpm (0.0038 m^3/min), with the maximum drift rate of 21 gpm (0.08 m^3/min). Table 3.2-1 contains a representative list of chemicals that may be used at each Plant Complex for water treatment activities. The specific chemicals and storage quantities are determined by the results of water quality studies and systems required for the chosen reactor technology.

3.4.1.1.4 Discharge Design

The discharge design is dependent upon the reactor technology selected but is designed to ensure compliance with environmental and regulatory standards. The cooling tower blowdown will be directed to multiple discharge points based on operational needs, allowing for flexibility and optimization of water retention and water quality strategies.

The primary discharge route will return the blowdown to Belews Lake, supporting water retention strategies to preserve lake levels and ecosystem health. Alternatively, the blowdown may be diverted to the Dan River outfall, located within the existing corridor adjacent to Outfall 006. This option supports water quality strategies that help manage the constituents returning to Belews Lake and ensure effective contaminant control.

Additionally, the blowdown flow will be used as a dilution flow for treated liquid radioactive waste, which will be directed to a new Dan River outfall adjacent to Outfall 006. Blowdown diversion to the Dan River occurs in short durations. When blowdown is diverted to the Dan River outfall, administrative and engineering controls are used to limit temperature impacts to the river such that the increase in river temperature downstream from the mixing zone does not exceed NPDES permit limitations.

The final configuration will depend on the reactor technology selected. Specific details regarding specific flows, temperature changes, losses, and associated procedures will be addressed in the construction permit or license application phase. Conceptual discharge designs are shown in Figure 3.2-2 and Figure 3.2-3.

3.4.1.2 Land Interfaces

Routine maintenance of the Project site and associated infrastructure is necessary for ensuring its continued operation and upkeep.

3.4.1.2.1 General Site Maintenance

Domestic waste and trash are regularly removed to ensure waste and debris do not impact the environment, facility, personnel, or operational activities. Groundskeeping is performed routinely to maintain the areas surrounding facilities and associated infrastructure, corridors, and parking areas.

3.4.1.2.2 Paved Area Maintenance

Road and paved area maintenance depends on the material used. Asphalt paved roads and parking areas are maintained by filling stress-related cracks with a bitumen sealer on a periodic basis. Asphalt roads generally last ten to twenty years, and surface rehabilitation can be performed to extend the lifespan. Crushed stone surfaced roads and parking areas generally need annual grading. Concrete pavement maintenance includes resealing joints or cracks and replacing sections of pavement with excessive cracking, uplift, or degradation. Changes in road surfaces may occur as site operations evolve potentially affecting grade, runoff, and future maintenance requirements.

3.4.1.2.3 Rail Line Maintenance

Rail line maintenance is infrequent and may include replacing ties in cases of excessive deterioration or failure, as well as reballasting to address track settlement. Switch components will require periodic lubrication and occasional replacement of parts or components.

3.4.1.2.4 Transmission Line Operation and Maintenance

Modifications to the existing Belews Creek 230 kV switchyard, the installation of a new switchyard, the reroute and expansion of the Pleasant Garden B/W 230 kV and Belews Creek

B/W 230 kV lines, and the installation of new individual bus lines to interconnect the existing facilities to each Plant Complex is required.

Additional details on the transmission system and design parameters are described in Section 3.2.4. Impacts to land resources due to the transmission system are addressed in Section 5.1.

3.4.1.2.5 Transmission Corridor Maintenance

Vegetation is cleared to at least the full width of the transmission corridor. Additional clearing is required beyond the corridor for trees that have the potential to fall on the transmission lines. Periodic vegetation maintenance may be required to ensure the reliability of the transmission system.

3.4.1.3 Air Interfaces

Various stacks and vents associated with gaseous effluent release and diesel emissions are used. The MDCT height ranges from 50 to 75 ft. (15 to 22.9 m) above finished grade, and the release point for the standby diesel exhaust is at least 9.84 ft. (3 m) above grade. Location and elevation of other plant vents and exhausts for systems such as the auxiliary boiler system, if needed, are conservatively assumed to exhaust at grade.

3.4.1.4 Summary of Plant-Environmental Interfaces During Operation

A summary of environmental interfaces during operation is provided in Table 3.4-2, which includes section, table, and figure reference numbers where this information is discussed in more detail.

3.4.2 RADIOACTIVE WASTE MANAGEMENT

Radioactive waste is generated through several processes associated with the normal operation and maintenance of nuclear reactors. Radioactive waste contains or emits radioactive particles and can be in a liquid, gas, or solid form (NRC, 2024). This section describes the liquid, gaseous, and solid radioactive waste management systems proposed to be used at the Project site.

3.4.2.1 Radioactive Waste Generation Process

Fission products, from the nuclear reactor process, may enter the reactor coolant by diffusing from the nuclear fuel through fuel cladding leaks. Nonradioactive materials such as metals in the reactor core or primary cooling system can be activated by the neutrons in the reactor core as corrosion products. Contaminated reactor coolant is treated through filtration systems that produce radioactive solid and liquid waste. Gaseous byproducts are generated through fission or released from the reactor coolant. Radioactive waste results from a combination of fission products, activated materials, treatment processes, and contaminated materials used to perform routine maintenance and general repairs. Duke Energy's existing nuclear fleet operates under various administrative procedures to ensure the safe handling and management of radioactive wastes.

3.4.2.2 Independent Spent Fuel Storage Installation

According to 10 CFR Part 72, an independent spent fuel storage installation (ISFSI) is a facility

designed to safely store spent nuclear fuel, which is used fuel that remains after it has been removed from a nuclear reactor. As noted in Section 3.1, an ISFSI is anticipated for the Project site, with its size and design to be determined based on the selected reactor technology. Details of the ISFSI including its layout, capacity, and operational characteristics will be determined during the construction permit or license application phase. The ISFSI will meet the requirements set forth in 10 CFR Part 72, *Licensing Requirements for the Independent Storage of Spent Nuclear Fuel, High-Level Radioactive Waste, and Reactor-Related Greater Than Class C Waste*.

3.4.2.3 Regulatory Compliance and Safety Standards

The radioactive waste management systems are designed to minimize releases from reactor operations to values as low as is reasonably achievable (ALARA). The systems are designed and maintained to meet the requirements of 10 CFR Part 20, *Standards for the Protection Against Radiation* and 10 CFR Part 50, Appendix I, *Numerical Guides for Design Objectives and Limiting Conditions for Operation to Meet the Criterion As Low as is Reasonably Achievable for Radioactive Material in Light-Water Cooled Nuclear Power Reactor Effluents*. Radiation dose impacts from normal operation of the Project site are provided in Section 5.9.

3.4.2.4 Liquid Radioactive Waste Management

Nuclear reactors produce liquid radioactive waste during normal operations. Sources of liquid radioactive waste include leakage from systems, processing systems, and maintenance activities. The liquid radioactive waste system controls, collects, processes, handles, stores, and disposes of liquid radioactive waste generated during normal operation.

The sources and potential sources of liquid radioactive waste are determined following the reactor technology selection and are provided during the construction permit or license application phase. The collection and processing systems are designed to remove the radioactivity to the extent that the system recycles or discharges the processed liquid in accordance with the requirements of 10 CFR Part 20 and the ALARA principles of 10 CFR Part 50, Appendix I.

After treating liquid radioactive waste, it is diluted with cooling tower blowdown water through independent piping from each Plant Complex routed to a common liquid radioactive waste line directed toward the Dan River outfall, adjacent to Outfall 006 shown on Figure 3.1-3 and Figure 3.2-3. The common liquid radioactive waste line is located within the existing corridor, adjacent to the Outfall 006 piping. The discharge is controlled and monitored to ensure compliance with environmental regulations and safety standards. Liquid radioactive waste processing systems are designed to keep radiation exposures of plant personnel ALARA and ensure that discharges to the Dan River stay within the limits set by the NRC and other applicable regulations, which protect public health and the environment from radiological impacts.

The bounding annual release of radioactivity in liquid effluents from the proposed Project site is provided in Table 3.4-4, and the bounding annual liquid effluent release of radioactivity from a single reactor is shown in Table 3.4-5.

3.4.2.5 Gaseous Radioactive Waste Management

Nuclear reactors generate gaseous radioisotopes during normal operation, which may include radioactive aerosols, noble gases, radioiodine, and tritium. Common gaseous radioactive waste

comes from collection tank and processing equipment vents, and non-condensable gases in steam systems.

The processing system collects, processes, and stores gases from multiple sources, to decrease the radioactivity content to a level that allows them to be released to the environment through a controlled and monitored release point (e.g., plant vent). Radioactive gases are usually held for radioactive decay for the purpose of minimizing radioactivity released to the environment. Retention methods may include storage in pressurized tanks, long delay lines, and holdup through adsorption on activated charcoal. Radioactive gases from plant system leakage to the building atmosphere are detected by area radiation monitors. Ventilation systems process these gases through filtration, if needed, and direct releases through the monitored building ventilation system release points.

Gaseous radioactive waste discharges are controlled pursuant to 10 CFR Part 20 and the ALARA principles of 10 CFR Part 50, Appendix I. Gaseous radioactive waste system equipment is designed to ensure occupational exposure to plant personnel are ALARA. Additionally, system safeguards and operational practices ensure radiation doses to members of the public and releases are below established regulatory limits. The bounding annual release of radioactivity in gaseous waste from the Project site is provided in Table 3.4-6, and Table 3.4-7 provides the bounding annual release of radioactivity from a single reactor.

3.4.2.6 Solid Radioactive Waste Management

Nuclear reactors generate various types and quantities of solid (wet or dry) radioactive waste as a byproduct of processing contaminated liquid and gaseous effluent, and through incidental and designed contact with radioactive materials during routine operations. These wastes result from routine operations and maintenance activities within radiologically controlled areas, and from processes that involve direct contact with radioactive materials. Details for the management of high-level waste will be presented in the construction permit or license application phase.

Low-level waste (LLW) consists of items contaminated with radioactive material or made radioactive by exposure to neutron radiation. This waste typically includes protective clothing, shoe covers, wiping rags, mops, filters, reactor water treatment residues, and various tools and equipment. The radioactivity of LLW ranges from levels slightly above natural background radiation to much higher levels on parts from inside the reactor. LLW is stored on-site in a radwaste building, either until it decays and can be disposed of with solid waste, or until the quantity is large enough to ship to a licensed LLW disposal site in compliant containers (NRC, 2024).

The solid radioactive waste management system collects, monitors, segregates, processes, and prepares solid radioactive waste prior to shipment or on-site storage. This system ensures the handling, processing, and storage of solid radioactive waste in a manner that minimizes exposure to plant personnel and the public, in accordance with 10 CFR Part 20. Wastes are packaged to meet the U.S. Department of Transportation (49 CFR Part 173 and 178) and NRC (10 CFR Part 71) regulations for transportation of radioactive materials. Packaged radioactive waste is transported to either a licensed waste processing facility or a licensed low-level radioactive waste disposal facility.

The bounding volume of solid radioactive waste generated at the Project site is listed in Table 3.1-1. The bounding annual radioactivity of solid radioactive waste from the Project site is provided in Table 3.4-8.

3.4.3 NONRADIOACTIVE WASTE MANAGEMENT

Solid and hazardous waste is generated during the construction and operation of advanced reactors on the Project site. This section provides a general discussion of typical nonradioactive solid, liquid, and gaseous waste streams generated on-site. Nonradioactive waste from nuclear power plants includes both hazardous and nonhazardous wastes.

Common waste streams include cooling water that may contain water treatment chemicals or biocides, waste from floor and equipment drains, water treatment residuals, sanitary effluents, stormwater runoff, gaseous effluents, used oils, universal waste, and hazardous waste.

Duke Energy's existing waste management programs comply with federal, state, and local regulations.

3.4.3.1 Effluents Containing Chemicals or Biocides

Biocides and other chemicals are used to treat cooling and process waters to avoid scaling or fouling. Effluents from the plant water systems, described in Section 3.2.3, are processed to minimize the release of these treatments, but may still contain some low-level chemicals or biocides. Chemical concentrations are controlled through engineering, operational, and administrative controls to comply with the conditions in NPDES permit.

Specific chemicals and biocides used depend upon the characteristics of the water to be treated and the design requirements of the reactor technology selected. Duke Energy's nuclear operating fleet uses an established water chemistry program that covers cooling tower and once-through systems for waste heat condenser applications and some service water cooling applications. The program utilizes several administrative procedures to ensure compliance and describes the implementation for treatments, maintenance, and testing best suited for the site-specific design and environment. Table 3.2-1 summarizes representative chemicals that may be used for water treatment at the Project site.

After the reactor technology is selected, site-specific procedures are developed during the construction permit or license application phase, including any necessary revisions to the NPDES permit requirements. The constituents and their concentrations are controlled in accordance with the limits outlined in the NPDES permit and limitations set by federal, state, or local regulatory agencies.

3.4.3.2 Sanitary System Effluents

Sanitary waste is generated during building and operational activities. The Project site is subject to the NPDES program for wastewater discharges (NCDEQ, 2024a). As shown on Figure 3.2-4, sanitary waste from the Project site is pumped to the existing BCSS domestic wastewater treatment plant for treatment prior to discharge.

The BCSS domestic wastewater treatment plant is authorized to treat and discharge under NPDES Permit No. NC0024406. In accordance with the permit, liquid waste from the domestic wastewater treatment plant is discharged via internal Outfall 009. Effluent is subsequently released to the Dan River via Outfall 006.

Under the proposed Project, sanitary effluent limits for internal Outfall 009 will remain in effect as specified in the existing permit. The maximum effluent flow rate from the domestic

wastewater plant is 19 gpm (0.07145 m^3/min) or approximately 27,305 gpd (0.10 m^3/day) as noted on Table 3.4-1 and shown on Figure 3.2-4.

The NPDES permit defines discharge limits for flow volume and water quality to protect receiving surface waters, and the Project site will continue to operate in compliance with these requirements.

3.4.3.3 Other Effluents

Nonradioactive waste streams, separate from the liquid process and sanitary waste systems described above, are described in this section. The following waste streams are included in this section:

- Solid waste management.
- Hazardous and mixed waste management.
- Liquid effluents.
- Gaseous effluents.

3.4.3.3.1 Solid Waste Management

Solid waste consists of hazardous and nonhazardous nonradioactive waste streams and are generated during construction and operation of advanced reactor technologies at the Project site. Solid waste is managed in accordance with existing Duke Energy waste management programs designed to comply with federal, state, and local regulations.

Broadly, Duke Energy Environmental Programs maintain administrative policies and procedures to ensure all employees and contractors properly manage waste. Procedures are tailored to meet site-specific obligations and regulations to ensure compliance. Duke Energy also maintains regional waste subject matter experts as a resource.

To ensure safe handling and minimize environmental impacts, all nonradioactive waste will be segregated based on waste type and its potential hazards and stored in appropriate containers. Waste segregation will occur at the point of generation, and waste will be labeled accordingly to facilitate proper disposal. Duke Energy maintains an approved waste vendor list to ensure waste is recycled or disposed of through an approved facility. Additional details are provided in Section 5.10.

3.4.3.3.2 Hazardous and Mixed Waste Management

3.4.3.3.2.1 Hazardous Waste

Hazardous waste in NC is regulated by the U.S. Environmental Protection Agency (USEPA) and the NCDEQ, Division of Waste Management (NCDEQ, 2024b). The existing BCSS is a Small Quantity Generator (SQG) of hazardous waste issued EPA ID Number NCD000856591 (USEPA, 2024a), and Duke Energy anticipates no change to generator status at the Project site.

A SQG Is a facility that generates more than 100 kg (220 lbs.) but no more than 1000 kg (2200 lbs.) per month of hazardous waste, and less than 1 kg (2.2 lbs.) per month of an acute hazardous waste (USEPA, 2024b). SQGs are subject to enforcement and oversight under the

Resource Conservation and Recovery Act (RCRA) Subtitle C, codified in 40 CFR Part 260 through 280 (USEPA, 2024b), as well as North Carolina Administrative Code (NCAC), Subchapter 13A – Hazardous Waste Management, which adopts RCRA (NCDEQ, 2024b).

SQGs must manage and dispose of hazardous waste in accordance with Subtitle C of RCRA that include requirements for manifesting, labeling, storage limits, hazardous waste determinations, recordkeeping and reporting, employee training, waste minimization, and emergency preparedness.

3.4.3.3.2.2 Mixed Waste

Mixed waste contains both radioactive and hazardous wastes and are generally accumulated in designated areas on-site and then shipped off-site for treatment and disposal. This waste is regulated by both the USEPA through RCRA and by the NRC under the Atomic Energy Act.

Duke Energy maintains procedures for management of hazardous and mixed waste at their facilities. While there is potential for mixed waste generation, all effort to abate this waste stream is implemented through engineering controls and administrative procedures.

Hazardous and mixed waste generated at the Project site are managed in accordance with relevant federal and state regulations. Additional details on hazardous and mixed waste and associated impacts are described in Section 5.10.1.

3.4.3.3.3 Liquid Effluents

The CWA, 33 U.S. Code 1251 establishes the basic structure for regulating discharges into U.S. waters and sets quality standards for surface waters (USEPA, 2024c). Section 402 of the CWA (40 CFR Part 122) authorizes the NPDES program, which requires permits to control point source discharges (USEPA, 2024d). The EPA has delegated permitting authority to the state, administered through the NCDEQ, Division of Water Resources (NCDEQ, 2024c).

Nonradioactive liquid effluents from the Project site include cooling tower blowdown, stormwater discharges, and other conventional liquid discharge streams (e.g., turbine building sumps, groundwater sumps, water treatment discharges), which are authorized and controlled by the Project site NPDES permit.

3.4.3.3.3.1 Cooling Tower Blowdown

Cooling tower blowdown, water that is routinely released from the cooling system to remove impurities and sediment that may degrade performance, is typically discharged to Belews Lake but can be discharged to the Dan River. As described in Section 3.4.1.1.4, blowdown flow is also used for water quality purposes to dilute treated liquid radioactive effluent prior to discharge into the Dan River. Normal and maximum operational flow rates are listed in Table 3.4-1. Section 3.4.1.1 describes the water interfaces, while Section 3.4.1.1.3 details cooling tower blowdown. This effluent contains constituents normally present in Belews Lake but at a higher concentration based on the cycles of concentration assumed for the cooling towers. As described in Section 3.4.3.1, biocides or other chemicals may also be used to prevent biological growth and prevent scaling. A list of blowdown constituents and concentrations is provided in Table 3.4-3.

3.4.3.3.3.2 Stormwater Management System

As described in Section 3.4.3.3.3, the NCDEQ administers the NPDES program. Accordingly, the stormwater management system for the Project site will be designed and permitted in compliance with the requirements set by the state of NC. The system is engineered to meet NCDEQ design standards and will collect and manage stormwater runoff from each Plant Complex through a dedicated stormwater collection and conveyance system.

This system includes drainage swales and trapezoidal ditches in open areas such as construction laydown and use zones, with culverts at road crossings. In the power block and equipment areas, drainage inlets, manholes, and interconnected drainpipes collect and direct runoff. The system channels runoff to Belews Lake when permissible, and to stormwater ponds designed to meet retention requirements and attenuate peak flows to predevelopment conditions, as required.

The stormwater system is designed to comply with relevant federal, states, and local stormwater regulations.

3.4.3.3.3.3 Other Liquid Effluent Sources

The remaining nonradioactive liquid waste discharges (e.g., turbine building sumps, groundwater sumps, and water treatment discharges) are routed to the consolidated sump, where they undergo treatment before discharging to the Dan River Outfall 006. Section 3.4.1.1.4 provides information on the discharge to Outfall 006.

Liquid effluent discharges are managed in accordance with the Project site issued NPDES permit.

3.4.3.3.4 Gaseous Effluents

Operation of a nuclear power reactor emits gaseous effluents during normal operation. This section describes the gas effluents associated with the operation of a nuclear plant utilizing advanced reactor technology. Cooling towers, auxiliary boilers, and fossil fuel-powered equipment, such as generators, pumps, boilers, and compressors are the primary sources of effluents. These effluents commonly include carbon monoxide, hydrocarbons, nitrogen oxides, particulates, and sulfur oxides.

Only one reactor technology being considered includes a fossil fuel-powered auxiliary boiler, with emissions listed in Table 3.4-9. For air modeling purposes, the exhaust elevation is conservatively modeled at grade elevation. The exhaust elevation is to be included in the construction permit or license application phase, if selected. Diesel generators and diesel-driven fire water pumps are used intermittently and for brief durations. The standby diesel generators' exhaust is at a bounding minimum elevation of 9.84 ft. (3 m) above grade, and estimated emissions are provided in Table 3.4-10.

Air emissions from the Project site will comply with applicable federal, state, and local air emission standards.

Table 3.4-1
Normal and Maximum Operational Flow Rates

Withdrawal	**Normal Operational Flow (gpm)**	**Maximum Flow (gpm)**
Intake from Belews Lake (circulating makeup water and miscellaneous plant water uses)	30,709	43,131
Municipal Water for Potable/Sanitary and Fire Protection	17	1269
Consumptive Use	**Normal Operational Flow (gpm)**	**Maximum Flow (gpm)**
Cooling Tower Evaporation	26,256	32,580
Cooling Tower Drift	1	21
Demineralized Water Losses	198	720
Fire Protection	6	1250
Liquid Discharges	**Normal Operational Flow (gpm)**	**Maximum Flow (gpm)**
Treated/Diluted Radwaste (to Dan River)	3300	9450
Treated Domestic (Sanitary) Waste (to Dan River)	11	19
Miscellaneous Plant Water Uses (to Dan River)	102	360
Cooling Tower Blowdown (to Belews Lake)	3852	6516

Key: gpm = gallons per minute

Table 3.4-2
Summary of Plant-Environmental Interfaces During Operations

Resource Type	Operational Interface Point Description	Reference Section Number	Table Number	Figure Number
Water	Normal operational flow rates and maximum flow rates.	Section 3.2.2.3 Section 3.4.1.1	Table 3.4-1	Figure 3.2-4
	Description of intake operation, water intake systems.	Section 3.2.2.4.1 Section 3.4.1.1.1		Figure 3.2-1
	Plant discharge outfall to Belews Lake.	Section 3.2.2.4.3 Section 3.4.1.1.4		Figure 3.2-2
	Plant discharge to the Dan River.	Section 3.4.1.1.4		Figure 3.2-3
	Stormwater discharge.	Section 3.4.3.3.3.2		
	Cooling tower blowdown volume, flow rates, temperature range, number of cycles of concentration assumed for operations.	Section 3.2.2.4.4 Section 3.2.3.1 Section 3.4.1.1.3		Figure 3.2-4
	Description of chemicals for intake and discharge treatment, including temperature and chemical constituent concentration in wastewater at the plant discharge outfall location.	Section 3.2.3.2 Section 3.4.1.1.3 Section 3.4.3.1	Table 3.2-1, Table 3.4-3	
Land	General site maintenance.	Section 3.4.1.2.1		
	Roadway and paved surface maintenance.	Section 3.4.1.2.2		
	Rail line maintenance.	Section 3.4.1.2.3		
	Transmission system and transmission line corridor.	Section 3.2.4.1 Section 3.2.4.2		Figure 3.2-5 Figure 3.2-6
	Transmission voltage, number of transmission facilities, proposed modifications to existing corridors and new transmission lines.	Section 3.2.4.1.1 Section 3.4.1.2.1		Figure 3.1-1 Figure 3.1-2 Figure 3.1-3
	Transmission maintenance procedures and frequency for transmission corridors, switchyards, roads, and other associated infrastructure.	Section 3.2.4.2 Section 3.4.1.2 Section 3.4.1.2.2		
Air	Cooling Tower Emissions.	Section 3.4.1.3		
	Gaseous Effluent Release.	Section 3.4.1.3 Section 3.4.3.3.4	Table 3.4-9

Table 3.4-3
Bounding Blowdown Constituents and Concentrations

Constituent	Maximum Potential Concentration parts per million (ppm)[(a)(b)]
Alkalinity	330
Aluminum	11
Ammonia	1.2
Arsenic	0.0065
Barium	0.23
Boron	0.54
Cadmium	0.0012
Calcium	69
Hardness (as CaCO3)	310
Total Organic Carbon (TOC)	36
Chloride	73
Chromium	0.0073
Copper	0.014
Iron	5.5
Lead	0.0041
Magnesium	32
Manganese	0.35
Mercury	N/A
Nickel	0.012
Nitrite plus Nitrate	2.4
Nitrogen, Total Kjeldahl (TKN)	6.7
pH range	6 – 9
Phosphate, Ortho (as PO4)	0.60
Phosphorus, P	0.60
Potassium, K	34
Selenium	0.012
Silicon, Si	78
Sodium	61
Sulfate	78
Total dissolved solids	940
Total suspended solids	24
Zinc	0.039
Thallium	0.0024
Vanadium, (and Compounds)	0.018

Notes:
(a) Values are calculated based on water quality data from the nearest upstream sample location to the potential intake location option 1 or Sample Location 410, as described in Section 3.4.1.1.1.
(b) The concentration at discharge is based on the assumption of the maximum normal operating value of 12 Cycles of Concentration.

Key: Ci/yr = Curies per year

Table 3.4-9
Bounding Emissions from Auxiliary Boilers

Pollutant	Bounding Value (lb/yr)
Carbon monoxide	5930
Hydrocarbons	465
Nitrogen oxides	33,875
Particulates	7700
Sulfur oxides	41,575

Notes:
The emissions are based on the following inputs:

- Auxiliary boiler operation during each startup: 36 days per year; 864 hours per year.
- Auxiliary boiler size: 75,000 lb/hr at 150 psig, saturation temperature 89.1 MMBtu/hr.
- Quantity one auxiliary boiler operating at 100 percent load.
- Auxiliary boiler without "low NOx" burners.

Key: lb/yr = pound(s) per year; MMBtu/hr = million British thermal units per hour; NOx = nitrogen oxides; psig = pounds per square inch gauge; yr = year

Table 3.4-10
Bounding Emissions from Standby Diesel Generators

Pollutant	Emissions (lb/yr)
Carbon monoxide	18,744
Hydrocarbons	9000
Nitrogen oxides	233,898
Particulates	4830
Sulfur oxides	14,580

Notes:
The bounding emissions are based on inputs as follows:

- Fuel used is Number 2 diesel oil with 35° API and LHV of 18,390 Btu/lb.
- Standby diesel generators operating at 100 percent load.
- Emissions are based on each generator operating fours per month.

Key: ° = degree; API = American Petroleum Institute; Btu/lb = British thermal units per pound; lb/yr = pound(s) per year; LHV = lower heating value

Chapter 4 Environmental Impacts from Construction of the Proposed Project

As described in Section 3.3, construction activities are generally comprised of safety-related structures, systems, and components (SSCs) that require authorization by the United States (U.S.) Nuclear Regulatory Commission (NRC) under an established review process, as defined in 10 Code of Federal Regulations (CFR) 50.10(a)(1). 10 CFR Part 51 contains a substantially similar definition of "construction" at 10 CFR 51.4 (definition of "construction," item (1)(i)). Other building activities that do not require NRC approval may occur before, during, or after NRC-authorized construction activities. These other activities include those explicitly excluded from the definition of construction in 10 CFR 50.10(a)(2). 10 CFR Part 51 contains a substantially similar list of exclusions from the definition of "construction" at 10 CFR 51.4 (definition of "construction," item (1)(ii)) and which are termed "preconstruction" in 10 CFR 51.45(c). As noted in 10 CFR 51.45, an Environmental Report (ER) prepared at the early site permit stage must also include a description of impacts from both "construction" and "preconstruction" activities. Together, these are referred to as "building" activities, which include the preconstruction and construction-related activities that form the basis for analyses in Chapter 4 – Environmental Impacts from Construction of the Proposed Project.

As described in Regulatory Guide (RG) 4.2, Rev. 3, *Preparation of Environmental Reports for Nuclear Power Stations,* assessing the significance of environmental impacts for new reactor applications, the NRC uses the following definitions of significance levels as codified in the footnotes to Table B-1 in Appendix B to Subpart A, "Environmental Effect of Renewing the Operating License of a Nuclear Power Plant," of 10 CFR Part 51:

SMALL: Environmental effects are not detectable or are so minor that they will neither destabilize nor noticeably alter any important attribute of the resource. For the purpose of assessing radiological impacts, the Commission has concluded that those impacts that do not exceed permissible levels in the Commission's regulations are small.

MODERATE: Environmental effects are sufficient to alter noticeably, but not to destabilize, important attributes of the resource.

LARGE: Environmental effects are clearly noticeable and are sufficient to destabilize important attributes of the resource.

The Project site spans approximately 1187 ac. (480 ha) with a net disturbance area (NDA) of approximately 906 ac. (367 ha), as shown on Figure 3.3-1. Impacts from building are assessed within the NDA, which designates up to 906 ac. (367 ha) for permanent disturbances. The NDA excludes an approximate 100-foot (ft.) (31-meter [m]) vegetative buffer along the shoreline of Belews Lake, except in areas where shoreline access is required for building activities. To ensure future impacts are adequately bounded by this application, the entire NDA is defined as the expected area of permanent disturbance for the purposes of impact assessment. Additionally, the associated off-site area of approximately 40 ac. (16 ha), including the portion of the wastewater pipeline that extends outside of the Project site, is designated as permanent disturbance. The impacts presented in this chapter are based on the Plant Parameter Envelope (PPE) that is used to bound key siting-related features, as discussed in Section 3.1.2. Duke Energy Carolinas, LLC (Duke Energy) will consider and implement avoidance, minimization, and other mitigation measures, as appropriate. Subject to future licenses and designs, permanent impacts within the NDA may be reduced.

4.1 LAND USE IMPACTS

This section assesses impacts to land use and land cover at the Belews Creek, North Carolina (NC) site (Project site) and the Project Vicinity (6 miles [mi.] [10 kilometers {km}]) associated with building the Project. The impacts of building the wastewater pipeline at an associated off-site area are discussed in Section 4.1.2. The Project site is not located near a Superfund site.

4.1.1 ON-SITE IMPACTS

As stated in Section 2.1.1.3, the Project site consists of approximately 1187 acres (ac.) (480 hectare [ha]) located adjacent to the Belews Creek Steam Station (BCSS) on a peninsula surrounded by Belews Lake to the north, east, and west. As described in Section 2.1.1.3, the Project site is primarily undeveloped forested land. Approximately 7 percent of the land cover within the Project site is classified as developed land (high, medium, or low intensity, or open space). These areas represent various land uses necessary to support operation of the BCSS, including the Flue Gas Desulfurization (FGD) Landfill, which will be closed through excavation in accordance with state regulations, thereby eliminating the landfill.

Impacts to land use occur within the NDA shown on Figure 3.3-1. Initial building activities described in Section 3.3 include clearing and grubbing of trees and dense vegetation, site grading, and excavation. Figure 4.1-1 illustrates the land area by land cover type that is disturbed by building activities associated with the Project. Table 4.1-1 presents the approximate acreage of each land cover type impacted within the NDA. Of the 906 ac. (367 ha) disturbed, approximately 696 ac. (282 ha) are forested, representing 77 percent of the NDA.

Each Plant Complex is graded to balance earthwork cut and fill quantities to the greatest extent practical. As stated in Section 4.10.1, material generated from clearing, grubbing, and grading activities is stockpiled in a remote location on-site or transported off-site as needed. In addition to earthwork material, building activities generate general waste, metal waste, and equipment waste, which are disposed in accordance with federal, state, and local regulatory requirements. As stated in Section 4.10.1.5, adequate landfill capacity is available to meet the projected demand for waste disposal needs during the building phase.

As detailed in Section 2.1.1.3, most of the Project site is located in Stokes County and is zoned as “M-1 Light Manufacturing District.” The principal use in this zoning district is light manufacturing and warehousing uses on large tracts of land. Electrical power generation facilities including coal, gas, hydroelectric, solar, nuclear, and wind are permitted as conditional zoning uses within this district. All three nuclear power Plant Complexes on the Project site are located in Stokes County. Each complex may contain multiple advanced reactors. Therefore, using the Project site for nuclear power generation complies with the Stokes County zoning regulations. A small portion of the southern end of the Project site located in Forsyth County is zoned “AG-Agricultural.” This portion of the site is used for laydown areas during building activities which is consistent with permitted uses in the AG zoning district. Duke Energy will obtain all county approvals for zoning and development of the Project site, as appropriate.

As discussed in Section 2.1.1.2, Stokes and Forsyth counties have adopted county-wide comprehensive plans. The *Stokes County 2035 Vision Plan: Moving Together* designates most of the county, including an area in the southeastern corner of the county where the Project site is located, as “(O-2) Open Space: Rural Community” for land use planning purposes. The purpose of this designation is to preserve low-density development as it includes many of the rural areas in Stokes County. The Project conforms to existing zoning and is adjacent to the

BCSS and would not preclude preservation of other rural areas in the county included within the O-2 land use planning area. The small portion of the Project site located within Forsyth County is within the county's designated Growth Management Area 5 / Rural Area. Land uses in this designation are intended to remain very low-density residential and agricultural in character. The use of the Forsyth County portion of the site as laydown areas is consistent with low-density development.

As indicated in Section 2.1.1.3, the Project site includes prime farmland, and approximately 67 percent of the land in the Project Vicinity is considered prime farmland (Table 2.1-7). In accordance with the Farmland Protection Policy Act, Duke Energy coordinated with the U.S. Department of Agriculture's Natural Resources Conservation Service (NRCS) regarding impacts to prime and unique farmlands. A Farmland Conversion Impact Rating (Form AD-1006) was completed in consultation with the NRCS to evaluate the potential impacts to prime and unique farmland by county. The impact rating score considers the acreage of converted prime farmland, the relative abundance of prime farmland in the surrounding county, and other criteria such as distance from urban support services and built-up areas, potential effects of conversion on the local agricultural economy, and compatibility with existing agricultural use. Sites with an impact rating score of 160 or greater have the potential to adversely affect prime farmland. The impact rating score developed for the Project site is 99.69 points for the portion of the Project site located in Stokes County (1153 ac. [467 ha]) and 100.51 points for the Forsyth County portion (33.7 ac. [14 ha]). Because the impact rating scores for Stokes and Forsyth counties are less than 160, impacts to prime and unique farmlands are expected to be minor and no further consultation with the NRCS is required.

As stated in Section 2.2.1.1.5, floodplains at the Project site are mostly concentrated along the shorelines and tributaries to Belews Lake. Clearing and grading activities necessary for building the proposed intake and blowdown structures would result in a minor intrusion into the floodplain of Belews Lake. Section 4.2.1.1.6 further discusses impacts on floodplains. Impacts to wetlands on the Project site during construction are described in Section 4.3.1.2. Of the 17 wetlands (totaling 2.68 ac. [1.08 ha]) on the Project site, 14 are completely or partially within the NDA. An additional wetland (0.26 ac. [0.11 ha]) is located in the associated off-site area (wastewater pipeline). To minimize wetland impacts, Duke Energy will implement appropriate avoidance and minimization measures. Where impacts are unavoidable, Duke Energy will obtain the necessary permits for impacts.

As stated in Section 4.4.4.2, hunting leases on the Project site are expected to be discontinued. As shown in Figure 2.4-5, recreational lake facilities such as the Pine Hall Public Boat Ramp, Piney Bluff Boat Launch, and commercial marinas are situated at a considerable distance from the Project site or across Belews Lake. Therefore, building activities do not impact access to these facilities.

Site development disturbs approximately 906 ac. (367 ha), transforming a primarily naturally vegetated and forested area into developed industrial land. This change noticeably alters but does not destabilize land use on and around the Project site. All site preparation and building activities are conducted in accordance with applicable federal, state, and local regulations. Environmental controls, including a site-specific stormwater pollution prevention plan (SWPPP), which is discussed in Section 4.2.3, are implemented to minimize impacts of building activities.

4.1.2 OFF-SITE IMPACTS

As stated in Section 2.1.2, no new off-site transmission line corridors are needed for the Project;

therefore, there are no corresponding changes to off-site land use from transmission line development.

As discussed in Section 2.1.2, portions of the existing associated off-site wastewater pipeline corridor extend outside the Project site. Land cover within the existing associated off-site wastewater pipeline corridor, which is approximately 40 ac. (16 ha), is mostly developed land and forested land (Table 4.1-1). As described in Section 3.3.2, building activities within this corridor are similar to those for the Project site and consist of land clearing and grubbing, grading, trenching, and backfilling. Although building activities within the corridor disturb existing land cover, the overall use of the corridor for the pipeline does not change. As such, impacts to land use in the associated off-site wastewater pipeline corridor are minor.

Impacts to floodplains within the wastewater pipeline corridor are discussed in Section 4.2.1.1.6 and are minor. Impacts to wetlands associated with building activities within the wastewater pipeline corridor are discussed in Section 4.3.1.2. Based on anticipated avoidance and minimization of wetland impacts, landscape perspective of total wetland habitats, adherence to mitigative requirements, and the use of best management practices (BMPs), impacts on wetlands are minor.

4.1.3 SUMMARY OF LAND USE IMPACTS

Overall, noticeable land use impacts from building activities are primarily due to the conversion of up to approximately 696 ac. (282 ha) of forested land within the Project site to developed land for industrial use. Development of the Project site would be compatible with BCSS on the adjacent property and complies with current zoning in Stokes and Forsyth counties. Based on the acreage of land that is converted from forest to industrial use, impacts from building activities on the Project site noticeably alter, but do not destabilize, land use. Therefore, on-site impacts to land use from building activities are MODERATE. Off-site impacts to land use in the associated off-site wastewater pipeline corridor are minor and, therefore, SMALL.

Table 4.1-1
Land Cover Types Disturbed by Building Activities on the Project Site and Associated Off-Site Area

	On-Site Area		Associated Off-Site Area (Wastewater Pipeline)		Total Area in the NDA[(a)]
Land Cover Type	**Ac.**	**Percent**	**Ac.**	**Percent**	**Ac.**
Barren Land	14.0	1.5	1.4	3.5	15.4
Deciduous Forest	270.3	29.8	4.8	12.0	275.1
Developed, Low Intensity	10.8	1.2	4.3	10.6	15.0
Developed, Medium Intensity	19.0	2.1	7.7	19.2	26.7
Developed, High Intensity	11.3	1.2	3.5	8.6	14.8
Developed, Open Space	33.0	3.6	6.2	15.4	39.1
Emergent Herbaceous Wetlands	3.7	0.4	–	–	3.7
Evergreen Forest	335.3	37.0	6.0	15.0	341.4
Hay/Pasture	16.2	1.8	0.2	0.5	16.4
Herbaceous	37.9	4.2	2.7	6.6	40.6
Mixed Forest	90.7	10.0	2.1	5.3	92.8
Open Water	1.2	0.1	0.2	0.5	1.3
Shrub/Scrub	62.3	6.9	1.1	2.8	63.5

Source: MRLC Consortium, 2021
Notes:
(a) The NDA is assumed to be permanently disturbed to ensure future impacts are adequately bounded by this application.
(b) Column total may not equal sum of individual values due to rounding.

4.2 WATER RESOURCES

This section describes water-related impacts that could result from building activities associated with the development of advanced reactors on the Project site. Section 4.2.1 addresses hydrologic alterations. Sections 4.2.2 and 4.2.3 address water-use impacts and water quality impacts, and Section 4.2.4 discusses water monitoring, respectively.

Potential water-related impacts include:

- Direct physical alteration of Belews Lake, streams, rivers, and wetlands.
- Indirect physical alteration of receiving surface water bodies, especially streams, due to changes in runoff volumes and rates.
- Changes in groundwater flow patterns from dewatering and soil retention management practices.
- Alteration of surface water quality as a result of erosion and sedimentation or inadvertent discharges of pollutants.
- Down-gradient groundwater quality changes from inadvertent or accidental spills of fuels and lubricants.

A detailed description of building activities, methods, and durations is provided in Section 1.3 and Section 3.3. Table 1.4-2 provides a list of consultations and permits that may be required prior to initiating building activities.

The following sections describe the building-related effects on both surface water and groundwater resources.

4.2.1 HYDROLOGIC ALTERATIONS

This section identifies and describes hydrologic alterations that result from building activities on surface water and groundwater hydrology. Activities that may produce hydrologic alterations are described in Sections 3.3.2 and 3.3.3 and could include:

- Clearing land and installing infrastructure such as roads and stormwater management systems.
- Altering the surface grade and runoff patterns.
- Building new structures (e.g., reactor containment structure, turbine building, cooling towers, electrical substation, sub-grade piping and systems), roads, rails, and parking lots.
- Building transmission towers.
- Building cooling water intake and discharge structures within Belews Lake and the Dan River.
- Potential changes in surface water and/or groundwater use during building.

4.2.1.1 Surface Water

This section evaluates the potential direct and indirect impacts of building activities on the surface waters present on the Project site and associated off-site areas. Surface water resources potentially affected by building activities are described in detail in Section 2.2.1 and include on-site streams, watershed runoff characteristics, Belews Lake, the Dan River, and floodplains. Potential impacts to on-site wetlands are described in Section 4.3.1.

As described at the beginning of this chapter, impacts from building activities are assessed within the NDA and the associated off-site wastewater pipeline that extends outside the NDA. Surface waters within the NDA and the associated off-site wastewater pipeline area directly impacted by building activities are shown on Figure 4.2-1. As the design progresses, Duke Energy is considering appropriate avoidance, minimization, and mitigation measures to reduce total impacts. Impacts are also being permitted in accordance with applicable regulations.

4.2.1.1.1 Project Site Streams

Jurisdictional streams are described in Section 2.2.1.1.4 and include 22 on-site and one off-site jurisdictional streams (i.e., six intermittent, seven perennial, and ten intermittent streams that transition to perennial) that were verified by the U.S. Army Corps of Engineers (USACE). Section 2.2.1.1.4.2 identifies the lengths of stream channels, which range from 80 ft. (24.4 m) to more than 3440 ft. (1048.5 m).

On-site streams drain into Belews Lake (Figure 4.2-1). Drainage slopes are typically steep, while channel widths are narrow. Project site streams are subject to direct and indirect impacts of building activities. Building activities include site preparation (e.g., clearing, site grading, and installation of stormwater management systems), as described in Section 3.3.2.

Of the 22 Project site streams, all are within or partially within the NDA, with the exception of the Condenser Cooling Water (CCW) Canal (S54). Eleven streams are entirely within the NDA, 10 are partially within the NDA, and the CCW Canal (S54) is outside the NDA. The CCW Canal (S54) is discussed in Section 4.2.1.1.3. Up to approximately 16,875 linear ft. (5144 linear m) of Project site streams are potentially impacted by building activities that result from fill activities, resulting in the loss of surface streams and associated functions. The impacted streams are primarily first order, relatively small streams which are mostly intermittent in nature and do not demonstrate high quality habitat.

An additional approximately 1256 linear ft. (383 linear m) of Project site streams are indirectly impacted. As shown on Figure 4.2-1, the indirect effects are to the portions of the streams that extend outside of the NDA to the confluence with Belews Lake. The remnant portions of these streams are indirectly affected due to the reduction in size, which can affect their degree of functionality. These remnant streams are indirectly impacted by building activities that result in flow alteration and disruption, stream bed and bank erosion, increased sedimentation, and decreased water quality (Figure 4.2-1 and Table 4.2-1). Increased sedimentation alters the flow of water and reduces water depth (MARC, 2025). Water quality impacts are further discussed in Section 4.2.3.1.

BMPs specific to the extent and type of building activity are implemented and maintained at appropriate time intervals throughout building activities. These BMPs stabilize soils, control the off-site movement of sediments, control stormwater flows, and remove construction debris to minimize indirect impacts to streams outside the NDA. Disturbed areas are stabilized in

accordance with design specifications employing good engineering and construction practices. Soil stabilization and sediment control BMPs are further discussed in Section 4.2.3. In addition, the Project is subject to an Erosion and Sediment Control permit that is issued by the NC Department of Environmental Quality (NCDEQ) that ensures protection for affected surface water bodies. Stormwater controls include retention ponds to control rate and volume of overland flow into receiving streams, as described in Section 3.2. Stormwater BMPs are further discussed in Section 4.2.1.1.2. Additionally, as described in Section 3.2, construction debris is properly disposed of to avoid affecting Project site streams.

Unavoidable direct and indirect impacts to jurisdictional streams are subject to regulatory authority of the USACE and NCDEQ pursuant to Sections 404, 401, and 402 of the Clean Water Act (CWA). The USACE issues Section 404 permits, and the NCDEQ manages Section 401 Water Quality Certifications and Section 402 National Pollutant Discharge Elimination System (NPDES) permits through its Division of Water Resources. The USACE requires demonstration of specific avoidance and minimization measures and implementation of specific compensatory mitigation measures in accordance with 33 CFR Part 332 “Compensatory Mitigation for Losses of Aquatic Resources.” Because impacts to Project site streams are mitigated, impacts of building activities are minor.

4.2.1.1.2 Stormwater

As Section 2.1.1.3 describes, the Project site consists of rolling hills and steep slopes, with surface elevations ranging from 725 ft. (219.5 m) North American Vertical Datum of 1988 (NAVD 88) near the shoreline of Belews Lake to 890 ft. (271 m) NAVD 88 along the ridgetops. Extensive grading and earthwork during site preparation results in grading and leveling much of the Project site within the NDA to accommodate a nominal base elevation (Figure 3.1-1). Each of the sequentially built Plant Complexes that are planned as presented in Table 3.3-1 is graded to balance earthwork cut and fill quantities to the greatest extent practical. Adjacent laydown areas may be adjusted to grade elevations that are different from the power block and permanent plant equipment grades to facilitate a balanced earthwork design. Site preparation includes clearing and grubbing of trees and dense vegetation, topsoil stripping, grading and installation of stormwater management systems, and mass earthwork and grading (Section 3.3.2).

In conjunction with grading and leveling activities, stormwater runoff patterns across the NDA are affected as drainage subbasins are recontoured. Additionally, runoff rates are affected due to the change in land cover from a substantially undeveloped and heavily forested landscape to one dominated by developed land surfaces. In accordance with the NPDES construction general permit for stormwater discharge (Section 1.4), a SWPPP is developed for stormwater management and erosion and sediment control within the disturbance area. Stormwater flow is diverted away from the Plant Complexes by an engineered stormwater collection system and may include a combination of swales, retention and detention basins, pipes, culverts, and sediment and erosion control measures designed to prevent discharge of pollutants to Belews Lake, Dan River, and associated tributaries. Sedimentation basins are one component of a system to control sediment discharge from larger disturbed areas. Sedimentation basins may be converted to detention or retention facilities for the permanent stormwater management system. Other building-phase stormwater facilities may be temporary or converted to permanent stormwater management facilities. The total ground area disturbed at any given time is minimized to the extent practicable. Temporary or permanent stabilization is used when areas are not disturbed for an extended time (Table 3.3-1).

The overall Project site runoff potential is coordinated with Belews Lake spillway operations to account for increased storm runoff volume and more rapid timing of runoff (more rapid than the existing condition) and resulting impacts on lake level control.

In summary, structural and non-structural BMPs are implemented throughout the building phase to control and manage stormwater runoff. Phasing during the building process minimizes the extent of ground surface that is disturbed at any given time. With a comprehensive plan to manage stormwater using BMPs, detention basins, and engineered stormwater conveyances, impacts from stormwater are minor.

4.2.1.1.3 Belews Lake

Building activities that directly impact Belews Lake include installation of the Project intake and discharge structures and associated in-lake pipelines. Indirect impacts include an increase in stormwater runoff rates and volumes from the cleared Project site to Belews Lake.

Belews Lake shoreline and the CCW Canal (S54) are depicted on Figure 4.2-1. An approximate 100-ft. (30-m) vegetated buffer extends along the shoreline of Belews Lake and the edges of the CCW Canal. The NCDEQ Erosion and Sediment Control program prohibits land disturbance during building unless a buffer zone is provided along the margin of the watercourse of sufficient width to confine visible siltation within the 25 percent of the buffer zone nearest the land-disturbing activity. This prohibition shall not apply to a land-disturbing activity in connection with building activities located on, over, or under a lake or natural watercourse. Application of this buffer zone guidance is applicable to minimize potential effects to both Belews Lake and the CCW Canal from building activities in the NDA (Figure 4.2-1). The appropriate buffer width can vary depending on-site conditions, soils, topography, and hydrology. Zones of undisturbed vegetation may be used to ensure compliance with this requirement even in the event of failure of other erosion and sedimentation control measures and practices. The NC Erosion and Sedimentation Control Planning Design Manual provides guidance for determining the necessary width of undisturbed vegetation required for compliance (NCDEQ, 2013). Because the NDA is limited by a buffer zone along both Belews Lake and the CCW Canal, effects of erosion and deposition within Belews Lake are minimized.

Section 3.2.2 describes the cooling system that includes intake and discharges. Building activities related to the intake structure include excavation and lakebed dredging to prepare the Project site for building activities. Cofferdams may be temporarily installed to perform work in a dewatered environment. Two optional locations are identified for the intake structure; however, only a single structure is developed for the Project. Cooling tower blowdown discharge options are described in Section 3.2.2.4.3 and include either one common discharge structure for all advanced reactor Plant Complexes or a separate discharge structure for each advanced reactor Plant Complex (Figure 3.1-1). Discharge structure piping extends from the shoreline to the submerged discharge structure(s) in Belews Lake, as described in Section 3.2.2.4.3.

Localized and short-term increases in turbidity and sediment deposition from building activities may occur in the immediate vicinity of both the intake and discharge structures as well as the lakebed piping areas. As described in Section 4.2.3.1, the intake structure is built within an approximate 5000-square-foot (ft^2) (464.5-square-meter [m^2]) area on the shoreline. Dredging for the discharge structure occurs in an approximate 20-ft. (6-m) x 20-ft. (6-m) area to a depth of approximately 3 ft. (0.9 m) for the installation of scour protection. For the discharge conveyance from the Project site elevation to the shoreline, an approximately 45-degree-angle bore hole is required to place the piping directly into Belews Lake. Dredging may be required at the outlet of

the discharge piping to install scour protection. If dredging is required, approximately 1200 cubic feet (ft^3) (111 cubic meters [m^3]) of soil and sediment is disposed of within either an approved upland location that may include a location on-site or at an off-site landfill. Temporary and localized impacts on Belews Lake hydrology are possible adjacent to and downstream of the activities if disturbed sediment extends beyond the immediate area. Within Belews Lake the dredged material is replaced with crushed rock. No significant losses occur to the lake surface area and storage volume as a result of intake and discharge structures installation. As described in Section 3.3.2, cofferdams are temporarily installed as the principal mitigative BMP to contain and control sedimentation as well as allowing dewatering for construction.

Impacts to Belews Lake are limited to the locations of the intake and discharge structures and associated pipelines within the lake. Temporary and localized impacts affect relatively small areas of the lake and are minimized through the use of other BMPs in addition to cofferdams that may include turbidity curtains, shoreline erosion control measures or other measures. Dredging activity is minimized as much as possible, and dredged material is replaced with crushed rock to avoid any changes in hydrology as a result of sediment displacement. Overall direct impacts to water resources of Belews Lake from building activities are localized to the footprint of the intake and discharge structures and associated pipelines within the lake. Impacts are further minimized by incorporating the approximate 100-ft. (30-m) vegetated buffer outside of the NDA. Therefore, impacts from building activities on water resources within Belews Lake are localized and minor.

4.2.1.1.4 Dan River

Project nonradioactive discharges are routed through the existing Outfall 006. Liquid radioactive wastes are routed through a new discharge in a corridor adjacent to existing Outfall 006 and are diluted with cooling tower blowdown discharge. The only anticipated building activity on the Dan River is within the new discharge in the associated off-site corridor that includes the wastewater pipeline located at Outfall 006. While the wastewater pipeline is located within an approximate 100-ft. (30.5-m) wide corridor, building-related disturbances within the Dan River are more localized. As described in Section 3.2.2.4.3, the discharge structure within the Dan River consists of a pipeline buried within the river bottom. In-river excavation is conducted to install the discharge pipeline and results in localized sediment disturbance and localized hydraulic alterations. Riprap is placed in conjunction with the discharge to minimize scour and erosion of the riverbed.

Adherence to federal, state, and local permit conditions reduces direct and indirect impacts to the Dan River. Excavation and fill (e.g., riprap) activities within the Dan River are regulated under Section 404 of the CWA via a permit from the USACE. As indicated in Section 1.4, an NPDES construction general permit authorization for building is required. This permit includes provisions for a site-specific SWPPP and appropriate strategies to reduce erosion and control sedimentation at the Project site. For example, structural and non-structural BMPs in the SWPPP minimize direct and indirect impacts to the Dan River. Therefore, hydrologic alteration impacts from building the discharge in the Dan River are minor.

4.2.1.1.5 Wetlands

Direct and indirect impacts to wetlands within the Project site and the associated off-site wastewater pipeline corridor are presented in Section 4.3.1.2.

4.2.1.1.6 Floodplains

The Federal Emergency Management Agency 100-year floodplains are mostly concentrated along Project site shorelines and tributaries to Belews Lake and along the associated off-site wastewater pipeline corridor at the Dan River, as discussed in Section 2.2.1.1.5 (Figure 4.2-2). Building activity necessitates the use of heavy equipment and increases impervious surfaces. BMPs to mitigate the impacts to floodplains are outlined in the SWPPP and Section 4.2.1.1.2.

Building activity within the Project site directly impacts approximately 6.4 ac. (2.59 ha) of floodplains within the NDA. Impacts on floodplains within the NDA are minor and are mitigated by BMPs and compliance with permits. Floodplains within the Project site represent a minority of floodplains within the 6-mi. (10-km) Project Vicinity (Figure 2.2-22). Therefore, building activities do not destabilize the function of floodplains along the shoreline and tributaries to Belews Lake.

Installing a new discharge outlet and the associated off-site wastewater pipeline within the Dan River directly affects approximately 2.14 ac. (0.87 ha) of floodplain (see Figure 4.2-2).

As described in Section 3.2.2, the discharge structure within the Dan River consists of a pipeline buried below-grade within the river bottom (Figure 3.2-2). In-river excavation is conducted to install the discharge pipeline. BMPs minimize the temporary impacts to floodplains of the Dan River from heavy equipment and ensure the floodplain is not destabilized. Areas impacted during building may be revegetated or rehabilitated after installing the wastewater pipeline to mitigate the localized and temporary impacts on floodplain function and value. The Dan River has approximately 4507 ac. (123 ha.) of floodplains within the Project Vicinity. As there are substantially greater floodplain resources within the Project Vicinity, localized impacts from the wastewater pipeline do not destabilize the overall function of flood storage. Temporary impacts to floodplain areas along the Dan River are minimized by use of BMPs and by the restoration of the disturbed corridor following building activities. Therefore, impacts to floodplains are minor.

4.2.1.1.7 Transmission Corridors

As discussed in Section 1.1.5, additional transmission lines that extend outside of the existing Project site boundary are not required. As described in Section 3.3, transmission improvements within the existing Project site include a second 230-kilovolt switchyard and other transmission line improvements. These improvements are located within the Project site and within the NDA. Accordingly, analysis of impacts on surface waters within transmission corridors is integrated in the preceding sections of Section 4.2.1.1.

4.2.1.1.8 Summary of Hydrologic Alteration Impacts to Surface Waters

Building activities result in potential direct impacts of up to approximately 16,875 linear ft. (5144 linear m) of streams within the NDA and approximately 100 linear ft. (30.5 m) within the associated off-site wastewater pipeline. An additional approximately 1256 linear ft. (383 linear m) of streams on the Project site are indirectly impacted by building activities. Impacts within Belews Lake are localized to the intake, discharge, and associated lakebed piping structures. In conjunction with grading and leveling activities, stormwater runoff patterns across the NDA are affected, resulting in changes in stormwater runoff rates across the Project site. As described in Section 4.2.1.1.2, structural and non-structural BMPs are implemented throughout the building phase to control and manage stormwater runoff and retain sediment.

Impacts to on-site aquatic habitats are mitigated in accordance with Sections 404, 401, and 402

of the CWA and permitted by the USACE and the NCDEQ. Implementation of design measures and BMPs, coupled with adherence to federal, state, and local permit conditions related to Sections 404, 401, and 402 of the CWA, reduce direct and indirect impacts from building activities on stormwater runoff rates, Belews Lake, and the Dan River. For impacts that result from activities subject to permitting under Section 404 of the CWA and cannot be reduced, Duke Energy implements specific compensatory mitigation measures in accordance with 33 CFR Part 332 “Compensatory Mitigation for Losses of Aquatic Resources.” As indicated in Section 1.4, an NPDES construction general permit authorization with site-specific SWPPP is required and includes strategies to reduce erosion and control sedimentation at the Project site.

As discussed above, the overall impacts of hydrologic alterations to surface waters are mitigated and are, therefore, SMALL.

4.2.1.2 Groundwater

This section identifies and describes hydrologic alterations that result from building activities on groundwater hydrology. Groundwater resources potentially affected by building activities are described in detail in Section 2.2.2. Physical characteristics of the groundwater system within the Project site and surrounding area are identified in Section 2.2.1.2.

Potential hydrologic alterations to groundwater that may result from building activities include those associated with dewatering and building of impervious surfaces such as buildings and concrete. As referenced in Section 3.3.2, dewatering may be required to maintain a dry excavation for building structural foundations, including the power block and other support SSCs. Duke Energy has not identified the specific reactor technology to be used on the Project site. Depending on the technology, the building excavation depth of safety-related structures will vary. As detailed in Section 3.3, the deepest building excavation will be 125 ft. (38 m) below finished grade elevation.

Bounding dewatering impacts were evaluated using the deepest excavation depth of 125 ft. (38 m) below finished grade elevation. Dewatering is accomplished by pumping from sumps located around the base perimeter of the excavation area. The radius of influence of the drawdown cone surrounding the foundation excavation is estimated using site-specific aquifer coefficients. The maximum extent of the drawdown cone, based on conservative calculations, is predicted to extend up to 4000 ft (1219 m) during peak dewatering operations. The actual drawdown is expected to be controlled and restricted by recharge and boundary conditions from Belews Lake. Groundwater users within the area are not expected to experience adverse effects from dewatering. Localized changes (decreases) in groundwater elevations may occur during dewatering. Dewatering flows are discharged pursuant to the appropriate regulatory guidelines. Once building activities are completed, dewatering is no longer needed, and the water table is returned to the static baseline conditions described in Section 2.2.1. Groundwater flow patterns may be affected during building and grading activities; however, effects are minor. Structure foundation development does not result in long-term impacts on groundwater availability or flow patterns.

The building activities result in the development of permanent use areas within the NDA. While specific details of site layout within the NDA have not yet been fully designed, it is expected that the permanent use areas consist of land uses that are impervious to groundwater infiltration, such as power blocks, cooling towers, laydown areas, and switchyards. Impervious surfaces from the development of these areas result in reduced infiltration and groundwater recharge in the immediate area of these structures. Other lands within the NDA are expected to allow for

varying degrees of groundwater infiltration and recharge. Surface water that does not infiltrate to groundwater is managed as stormwater runoff and ultimately discharged to Belews Lake. In locations where groundwater recharge is affected, corresponding effects (reductions) in groundwater levels may occur. Overall impacts on groundwater levels are expected to be minor. Therefore, impacts of hydrologic alteration of groundwater during building activities are SMALL.

4.2.2 WATER-USE IMPACTS

Water used for building activities is obtained from a municipal city water connection or from Belews Lake, as described in Section 3.3.2. The potential impacts of water use during building activities are described in this section.

4.2.2.1 Surface Water

Section 2.2.2 describes current surface water usage. Section 3.3 describes the water required to support the Project site during building activities. The impacts from surface water alteration and building activities to recreation are discussed in Section 4.4.4.2.

Water for dust suppression and concrete batch plant operation is withdrawn from Belews Lake. The maximum daily water usage from Belews Lake during building activities is 500,000 gpd (1,892,706 lpd). The current volume of Belews Lake is discussed in Sections 2.2.1.1 and 2.2.2.1 and the effects of water use from Belews Lake are negligible.

As described in Section 2.2.2.1.3, there are no public water supply facilities that withdraw water from surface water resources within the Project Vicinity. The only two self-supplied surface water withdrawal locations in the Project Vicinity are associated with the BCSS. These include the CCW intake structure on Belews Lake, and the existing Dan River make-up water intake structure (Figure 2.2-2). No building-phase water use is obtained from the Dan River.

As described in Section 3.3.2, potable water for building is obtained from either an existing water line connection or a new water line connection with Winston-Salem/Forsyth County Utilities. The maximum expected daily potable water usage is 61,622 gpd (233,264 lpd). The total permitted capacity of Winston-Salem/Forsyth County Utilities is 91 million gallons per day (mgd) (344.5 million liters per day [MLD]), with a maximum daily use during the 2024 annual period of 61.1 mgd (277.8 MLD). Because this supply has excess capacity, the effects of potable water usage are minor.

In summary, the impacts from surface water use during the building phase are SMALL.

4.2.2.2 Groundwater

Groundwater is not used as a source of water for building activities. Therefore, the impacts from groundwater use are SMALL.

4.2.3 WATER QUALITY IMPACTS

Various impacts on water quality may occur because of building activities. Potential impacts include those related to changes in stormwater flow and runoff that result in increased soil erosion or sediment transport, accidental discharges of construction-related chemicals such as fuel, oil, or grease, and changes in water quality parameters. Existing water quality of surface water and groundwater at the Project site is presented in Section 2.3.3. The following sections

discuss the potential impacts of building activities on surface water and groundwater quality.

Compliance with federal, state, and local requirements minimizes potential impacts of construction activities on surface water resources. For example, a site-specific SWPPP outlines guidance as part of the NPDES permit compliance program for managing stormwater and minimizes pollutant loading within receiving waterbodies. Duke Energy will also coordinate with the USACE and NCDEQ regarding compliance with applicable Section 401/404 permits for jurisdictional waters.

4.2.3.1 Surface Water

Direct physical alteration of surface waters from building activities resulting in the filling of streams, results in adverse impacts to surface water quality. Activities such as erosion and sedimentation, accidental spills, or releases of stormwater can result in indirect impacts on surface water quality. Section 4.2.1.1 evaluates the site preparation and building activities that could affect surface water quality. The total area affected by building activities within the Project site and the proposed intake and discharge structures are summarized in Table 4.1-1 and Section 4.1.1. Section 4.10 discusses the anticipated water quality impacts from nonradiological waste releases to surface water resources.

Surface water impacts are regulated by the USACE and the NCDEQ. Ground-disturbing activities that have the potential to affect surface water quality are permitted in accordance with applicable federal, state, and local regulations. On-site streams are subject to regulatory authority pursuant to Sections 404, 401, and 402 of the CWA. Duke Energy will obtain appropriate USACE and NCDEQ permits for impacts on streams and will adhere to USACE and NCDEQ guidelines and mitigative requirements, as applicable to control and minimize impacts on water quality. Requirements that address water quality include but are not limited to an NPDES general construction permit and a site-specific SWPPP that mitigates the impact of building activities on stormwater.

To minimize the impacts of building activities on surface water quality, BMPs are used to control erosion and limit the amount of soil and sediment entering surface waters. These controls include silt fencing, mulching, geotextiles, sod stabilization, flow diversion, buffer strips, detention ponds, and establishment of temporary or permanent vegetation as outlined in the NC Erosion and Sediment Control Planning and Design Manual (NCDEQ, 2013).

To control the discharge of oil spills and limit their effects on surface water, Duke Energy will implement a spill prevention, control, and countermeasure (SPCC) plan pursuant to 40 CFR Part 112 at the Project site. An SPCC plan includes BMP actions such as proper vehicle and equipment maintenance, containment for fuel or oil storage tanks, and the maintenance of spill response equipment and materials. With adherence to permit conditions and implementation of mitigation measures including the use of BMPs, SPCC plan and the SWPPP, impacts of Project building activities on surface water quality are minor.

4.2.3.1.1 On-Site Streams and Stormwater

As described in Section 4.2.1.1.1, building activities result in direct impacts of up to approximately 16,875 linear ft. (5144 linear m) of streams within the NDA and approximately 100 linear ft. (30.5 m) within the associated off-site wastewater pipeline. An additional approximately 1,256 linear ft. (383 linear m) of streams on the Project site are indirectly impacted by building activities. In conjunction with grading and leveling activities, stormwater

runoff patterns across the NDA are noticeably altered resulting in changes in stormwater runoff rates across the Project site. Each of these activities results in water quality alteration in conjunction with erosion, sedimentation, pollutant transport, and potential accidental spills and releases of contaminants during building activities.

Duke Energy has a site-specific SWPPP to mitigate the impact of building activities on off-site stream water quality caused by the permanent impact to streams within the NDA, as discussed in Section 4.2.1.1.1. As described in Section 4.2.1.1.2, structural and non-structural BMPs are implemented throughout the building phase to control and manage stormwater runoff and minimize downstream water quality degradation in Belews Lake. An SPCC plan minimizes and controls the effects of accidental oil-related releases from construction equipment during the building phase.

The on-site streams are not used for either consumptive or recreational purposes, as described in Section 2.2.2.1. Therefore, water quality impacts do not affect water users of on-site streams. Mitigation measures implemented as part of a site-specific SWPPP and SPCC plan minimize impacts of building activities on off-site water quality, specifically within receiving waters.

4.2.3.1.2 Belews Lake

Building activities within Belews Lake entail the development of intake and discharge structures and associated pipelines as part of the cooling system (Section 3.2.2). Impacts within Belews Lake are temporary and localized to the intake and discharge structures on the Project site. Installation of these structures and any associated underwater excavation are compliant with USACE and NCDEQ requirements, including Section 404 permits. As described in Section 4.2.1, dredging activities are minimized through the use of a cofferdam. The intake structure or structures are expected to be within an approximate 5000 ft^2 (464.5 m^2) area on the shoreline. From the site elevation to the shoreline, a 45-degree angled bore hole is required to lay the piping directly into Belews Lake. Dredging may be required at the discharge pipeline outlet to install scouring protection. It is estimated that, if required, approximately 1200 ft^3 (111 m^3) of soil and sediment are dredged. Material dredged in conjunction with building the intake and discharge are stockpiled in an approved upland location and tested for potential constituents of concern. Based on sample analytical results, materials are disposed of within either an approved upland location on the Project site or at an off-site landfill. The dredged material would be replaced with crushed rock. As described in Section 3.3.2, cofferdams may be temporarily installed to perform work in a dewatered environment as the principal BMP to contain and control sedimentation. Sediment disturbed during excavation results in a short-term localized impact on water quality consisting of increased turbidity and suspended solids in the vicinity of the building activity. Section 4.2.4.1.2 describes a sediment monitoring program to monitor potential constituents of concern that may remobilize from sediment disturbed during dredging. Program results will determine whether additional BMPs, engineering controls, or alternative methods are required to maintain water quality and aquatic habitat.

Water quality may be impacted by building activities associated with the intake and discharge structure and discharge pipeline(s). These building activities may result in erosion and sedimentation, accidental spills, releases of stormwater, or changes in runoff volumes resulting in direct and indirect impacts on surface water quality. However, permitting requirements including the implementation of appropriate BMPs and control measures minimize impacts such that impacts to the water quality of Belews Lake are localized and temporary. Additionally, an implemented SPCC plan minimizes and controls the effects of accidental releases from construction equipment during the building phase. Therefore, impacts to Belews Lake are minor.

4.2.3.1.3 Dan River

As described in Section 4.2.1.1.4, project nonradioactive discharges are routed through the existing Outfall 006. Liquid radioactive wastes are routed through a new discharge in a corridor adjacent to existing Outfall 006 and are diluted with cooling tower blowdown discharge. The only anticipated building activity on the Dan River is within the new discharge in the associated off-site corridor that includes the wastewater pipeline located at Outfall 006. While the wastewater pipeline is located within an approximate 100-ft. (30.5-m) wide corridor, building-related disturbances within the Dan River are more localized. As described in Section 3.2.2, the discharge structure within the Dan River consists of a pipeline buried within the river bottom. In-river excavation is conducted to install the discharge pipeline and results in localized sediment disturbance and localized water quality alterations related to turbidity and suspended solids. Riprap is placed in conjunction with the discharge to minimize scour and erosion of the riverbed. Disturbance of riparian vegetation by construction equipment operations within the wastewater pipeline corridor can also indirectly reduce the water quality of the Dan River due to erosion, associated sedimentation, and potential accidental releases from spills.

Adherence to federal, state, and local permit conditions reduce direct and indirect impacts to the Dan River. Placement of fill material (e.g., riprap) below the ordinary high-water mark is regulated by the USACE under Section 404 of the CWA. As indicated in Section 1.4, a NPDES general construction permit with a site-specific SWPPP is required and includes strategies to reduce erosion and sediment at the construction site. BMPs in the SWPPP will be used to minimize direct and indirect impacts to the Dan River. Additionally, an SPCC plan will be implemented to minimize and control the effects of accidental oil-related releases from building equipment during the building phase. Water quality impacts from building the wastewater discharge pipeline to the Dan River are localized and short-term. Therefore, water quality effects on the Dan River are minor.

4.2.3.1.4 Summary of Water Quality Impacts to Surface Water

As a result of mitigative measures and engineering controls (e.g., BMPs, SWPPP, and SPCC) regulated by the NCDEQ and the USACE that are implemented during building activities, impacts to surface water quality are controlled, localized, and temporary. Therefore, the impacts on surface water quality are SMALL.

4.2.3.2 Groundwater

Baseline water quality data for groundwater are provided in Section 2.2.3.2. Dewatering of the power block areas usually occurs within a limited area during the duration of the building of the below-grade nuclear island structures and foundations. Drainage sumps at the bottom of the excavation area discharge water that may have entered the excavation area into surface waters pursuant to permitting conditions and applicable regulations. Dewatering is managed in accordance with BMP procedures and construction stormwater permit.

During building activities, gasoline, diesel fuel, hydraulic lubricants, and other similar products are used for building equipment. Accidental releases or spills of these fluids have the potential to affect groundwater. Pursuant to 40 CFR Part 112, an SPCC plan will be prepared and implemented at the Project site, which would include the use of BMPs to minimize the occurrence of spills and limit their effects on groundwater. These BMPs include actions such as proper vehicle and equipment maintenance, containment for fuel or oil storage tanks, and the maintenance of spill response equipment and materials. BMPs are also used during building

activities to minimize potential discharges to the environment.

In the unlikely event small amounts of oil-related substances are released into the environment, they would have a small, localized, temporary impact on the groundwater. Because engineering controls, as described above, prevent or minimize the release of harmful effluents, and effluent concentrations are maintained at levels below permitted threshold limits that are established to be protective of water quality, impacts to groundwater quality are SMALL.

4.2.4 WATER MONITORING

This section describes the monitoring programs Duke Energy uses to provide protection of waterbodies that may be affected by building activities and to obtain timely and accurate information so that actions can be taken to limit building impacts. This section discusses the thermal and chemical monitoring programs, as applicable, for surface water and groundwater at the Project site, Belews Lake, and the Dan River. Building monitoring programs are compared to baseline conditions to identify potential concerns and take appropriate actions toward limiting the impact on both surface water and groundwater resources.

4.2.4.1 Surface Water

4.2.4.1.1 Preapplication Monitoring Program

Duke Energy's preapplication surface water monitoring program includes surface water quality sampling and analyses, as described in Section 2.2.4.1 and shown on Figure 2.2-35. The preapplication monitoring program consists of six on-site streams within the Project site, four sample locations along the Dan River, and one sample location in Town Fork Creek. These surface water sample locations were selected to establish baseline surface water conditions at each of the proposed advanced reactor locations at the North, Middle, and South Plant Complex areas. The preapplication locations supplement Duke Energy's existing monitoring sampling locations described in Section 2.2.4.1.1 and shown on Figure 2.2-34. The preapplication monitoring sample locations were each sampled once quarterly from April 2024 to January 2025. As described in Section 2.2.3.1, samples were analyzed for standard water quality parameters (temperature, pH, conventional pollutants), metals, and select radionuclides following the guidance of NUREG-1555.

4.2.4.1.2 Building Monitoring Program

Duke Energy will monitor existing locations as described in Section 2.2.4.1.1 throughout the building period outlined in Section 3.3.5. Surface water locations monitored during building may include additional monitoring locations following technology selection and final design. Details of the building monitoring program are defined following technology selection and will include thermal and chemical monitoring as needed. As part of the program, a monitoring plan will be developed to specify locations, sampling frequencies, sampling protocols, and quality assurance procedures for sampling and analysis.

Water discharges to Belews Lake and on-site streams during building activities are monitored in accordance with applicable NPDES permit requirements and NCDEQ water quality requirements (Table 1.4-2). Typical requirements of an NPDES permit include monitoring of stormwater and dewatering discharges. A SWPPP is required as part of the NPDES permit and identifies required inspection methods and BMPs used to detect and limit erosion and provide effective sediment control. Discharges of water during building activities are subject to

monitoring which may include temperature and water quality monitoring. A full radiological monitoring program is not planned to be performed during building activities due to the lack of radiological gaseous emission, liquid effluents, or direct radiation during the building phase.

Through a sediment monitoring program, Duke Energy will monitor potential constituents of concern that may remobilize from sediment disturbed during dredging. Sediment monitoring will occur both before and during building activities. The program results will determine whether additional BMPs, engineering controls, or alternative methods are required.

Requirements for monitoring on-site streams, Belews Lake and the Dan River during building of the intake structure, the discharge pipeline and potential diffuser are specified as part of the USACE Section 404 permit, and the Section 401 water quality certification issued by NCDEQ.

As shown in Table 3.3-1, the advanced reactors are brought online in a phased approach. As such, building monitoring programs described in this section occur in conjunction with operating monitoring programs described in Sections 5.2.4.1.2 and 5.9.

4.2.4.2 Groundwater

4.2.4.2.1 Preapplication Monitoring Program

Duke Energy's preapplication groundwater monitoring program includes groundwater quality sampling and analyses, as described in Section 2.2.4.2. The preapplication monitoring program consists of 15 groundwater observation wells. Groundwater sample locations establish baseline groundwater conditions at each of the proposed advanced reactor locations at the North, Middle, and South Plant Complex areas. These sample locations were each sampled once quarterly from June 2024 to April 2025. Samples were analyzed for standard water quality parameters (temperature, pH, conventional pollutants), metals, and selected radionuclides following the guidance of NUREG-1555 as described in Section 2.2.3.2. Water levels were obtained from each groundwater observation well on a monthly basis.

4.2.4.2.2 Building Monitoring Program

The groundwater wells to be monitored during building are a subset of the wells that exist from the preapplication monitoring program as described in Section 2.2.4.2. The building monitoring program is not defined until a technology is selected and will include water level and chemical monitoring. As part of the program, a monitoring plan is developed to specific locations, sampling frequencies, sampling protocols, and quality assurance procedures for sampling and analysis. The monitoring program will include both water quality sampling and water level monitoring.

A full radiological monitoring program is not planned to be performed during building activities due to the lack of radiological gaseous emission, liquid effluents, or direct radiation during the building phase. Testing of radionuclides is included to compare with the baseline established in the preapplication monitoring program to monitor during building.

As shown in Table 3.3-1, the advanced reactors are brought online in a phased approach. As such, building monitoring programs described in this section occur in conjunction with operating monitoring programs described in Sections 5.2.4.2.2 and 5.9.

4.3 ECOLOGICAL RESOURCES

This section describes the potential effects on terrestrial, wetland, and aquatic ecological resources from building activities associated with the Project.

Building activities associated with the Project could affect terrestrial, wetland, and aquatic ecosystems occurring on and adjacent to the Project site. Potentially affected resources include the habitats and associated ecological communities of upland terrestrial habitats, wetlands, and aquatic habitats. Preconstruction activities, including site preparation (such as land clearing, grading, excavation, and filling), have the greatest potential to result in effects on ecosystems.

Section 1.4 discusses the status of required consultations with federal, state, tribal, and local agencies. Consultations with the U.S. Fish and Wildlife Service (USFWS), USACE, NCDEQ, NC Wildlife Resources Commission (NCWRC), and NC Natural Heritage Program (NCNHP) were initiated to acquire information regarding ecological resources within and near the Project site (Section 2.3). Consultation was used to obtain agency input regarding threatened and endangered species, sensitive habitats, commercial and recreational species, and other ecological characteristics for the Project site and Project Vicinity. For more details on dates and responses from agencies, see Section 2.3.1.5 and Appendix A in Chapter 1. Input from these agencies is included in the sections below, as applicable.

4.3.1 TERRESTRIAL AND WETLAND IMPACTS

As stated in Section 2.1.1.3, the Project site consists of approximately 1187 ac. (480 hectares [ha]) located adjacent to the BCSS on a peninsula surrounded by Belews Lake to the north, east, and west. Section 2.3.1 describes the terrestrial ecosystems of the Project site and includes upland and wetland habitats, associated ecological communities, and important species. Section 2.3.1 also briefly describes these features for the potentially affected areas in proximity to the Project site. This section evaluates the potential effects of building activities on the terrestrial ecosystems that occur on the Project site and associated off-site areas. Additionally, measures to mitigate adverse environmental impacts are proposed, where necessary.

As described at the beginning of this chapter, impacts from building activities are assessed within the NDA and the associated off-site wastewater pipeline that extends outside the NDA. As the design progresses, Duke Energy is considering appropriate avoidance, minimization, and mitigation measures to reduce total impacts.

4.3.1.1 Terrestrial Habitats

The Project site spans approximately 1187 ac. (480 ha), with approximately 906 ac. (367 ha) designated for permanent disturbances such as the power blocks, cooling towers, laydown areas, and switchyards. After completing construction activities, laydown areas used to support construction activities will remain disturbed areas and be used to support operations such as parking lots and related facilities. As described in the Chapter 4 introduction, the 906 ac. (367 ha) represents the NDA, which excludes an approximate 100-ft. (31-m]) vegetative buffer along the shoreline of Belews Lake, except in areas where shoreline access is required for building activities. Additionally, the associated off-site wastewater pipeline corridor results in the conversion of up to an additional 40 ac. (16 ha) to permanent uses. These areas are cleared of vegetation for building activities (Table 4.1-1). Although facilities will not occupy the entire acreages, there are no plans to revegetate or restore disturbed areas such as laydown areas.

Land clearing, grubbing, grading, excavation, and other typical site preparation activities result in the loss of existing vegetation. The types of habitats present at the Project site are shown in Figure 4.3-1, with the affected habitats summarized in Table 4.3-1.

Building on the Project site and associated off-site wastewater pipeline corridor results in the combined conversion of approximately 946 ac. (383 ha) to permanent uses, most of which (approximately 906 ac. [367 ha]) occurs within the NDA. The predominant habitat types impacted by building activities on the Project site are evergreen forest (31.9 percent), deciduous forest (17.0 percent), and mixed forest (9.8 percent). Approximately 85.6 ac. (34.6 ha) of herbaceous lands and 16.4 ac. (6.6 ha) of scrub shrub are also converted by building activities to developed uses. Land cover impacts to wetland areas include both woody (1.2 ac. [ha]) and emergent herbaceous (1.3 ac. [0.5 ha]) wetlands. Section 4.3.1.2 discusses wetland impacts.

Building on the associated off-site wastewater pipeline corridor results in the conversion of approximately 40.1 ac. (16.2 ha) to permanent uses. Impacts on the associated off-site wastewater pipeline corridor primarily affect developed, low-intensity land (11.4 ac. [4.6 ha]), herbaceous land (10.0 ac. [4.0 ha]), evergreen forest (5.5 ac. [2.2 ha]), and deciduous forest (4.3 ac. [1.7 ha]). Permanent uses on the Project site include those associated with power-generating facilities, switchyard, cooling towers, utility systems, and other construction use facilities. More details on the Project site layout and description can be found in Section 3.1.

As discussed in Section 2.3.1.4, plant communities on the Project site are common and well represented throughout the local region. Many of these communities are successional and contain substantial populations of non-native plant species, indicating the effects of past anthropogenic disturbance and disruption to natural disturbance patterns. Approximately 76 percent of the Project site and 100 percent of the associated off-site wastewater pipeline corridor are impacted by building activities (Table 4.3-1). However, most of this land was previously disturbed and generally low-quality, marginal evergreen, herbaceous, and scrub shrub habitat. Other land cover types impacted include developed and barren lands that provided minimal habitat to plant communities and wildlife on the Project site. Deciduous forests on the Project site and associated off-site wastewater pipeline corridor represent higher-quality habitat impacts. Based on the amount of deciduous forest within the on-site and associated off-site areas, as shown in Table 4.3-1, 61.8 percent of on-site deciduous forest is directly impacted, and 100 percent is permanently impacted in the associated off-site area. Although there is a similar habitat within the Project Vicinity (Table 4.3-1), a large amount of forested habitat is lost on the Project site and associated off-site wastewater pipeline corridor due to building activities. Therefore, direct impacts on habitat on the Project site and associated off-site wastewater pipeline corridor are noticeable but not destabilizing.

Habitats outside of the NDA are subject to potential indirect effects from the building activities occurring within the adjacent NDA. Some indirect effects may include encroachment of invasive species and erosion and sedimentation impacts. As discussed in Section 2.3.1.7.2, substantial populations of invasive plant species are present within certain areas on the Project site. Disturbance associated with building activities, such as earth-moving and excavation, creates conditions for opportunistic invasive species to become more widespread and established across the Project site and in habitats adjacent to the NDA. Establishment of invasive species from building activities is minimized by periodic monitoring and control measures, as feasible.

BMPs for erosion and sedimentation control, specific to the extent and type of construction, are developed and installed prior to building activities and are maintained throughout construction.

Based on the area affected, overall impacts on terrestrial habitats are noticeable. However, because of the availability of similar land cover types within the Project Vicinity, the prevalence of low-quality plant communities, and reduced quality of the existing habitats on the Project site and associated off-site area, potential impacts on terrestrial land cover are noticeable but not destabilizing.

4.3.1.2 Wetlands

Wetland communities on the Project site are described in Section 2.3.1.2 and mapped in Figure 2.3-5. Figure 4.3-2 depicts wetlands affected by building activities. Of the 17 wetlands (totaling 2.68 ac. [1.08 ha]) in the Project site, 14 are completely or partially within the NDA. An additional wetland (0.26 ac. [0.11 ha]) is located in the associated off-site area (wastewater pipeline). The total for these wetland areas subject to direct impacts is 2.45 ac. (0.99 ha) within the Project site and 0.26 ac. [0.11 ha] within the associated off-site wastewater pipeline area. As discussed in Section 2.3.1.2.1, based on USFWS National Wetlands Inventory data, approximately 88 ac. (35 ha) of freshwater emergent wetlands, 1855 ac. (751 ha) of freshwater forested wetlands, and 312 ac. (126 ha) of freshwater scrub shrub wetlands (totaling 2255 ac. [913 ha] of wetlands) are mapped within the Project Vicinity. Table 4.3-2 provides a breakdown of Project site direct and indirect wetland impacts by system and also by Cowardin classification. Direct wetland impacts within the associated off-site area are to wetland WJ, a palustrine (freshwater) forested wetland. As summarized in Table 2.3-2, wetlands identified were determined to have functional ratings of low to high. Impacts from filling wetlands result in the permanent loss of all functions within the area affected for each wetland.

Project site wetlands outside of the NDA are subject to indirect effects of building activities. Wetlands AA, R, and X are located entirely outside of the NDA while wetlands S, U, W, and WL are bisected by the NDA (Table 4.3-2). The remnant portions of wetlands S, U, W, and WL are indirectly affected due to the reduction in size which can affect their degree of functionality. Wetlands U, WL, and W are associated with on-site impacted streams. The removal of these associated stream systems results in indirect effects on the hydrology of these systems. Wetlands AA, R, and X are also subject to indirect effects associated with changes in hydrologic inputs due to grading, excavation, or the introduction of impervious surfaces occurring within the NDA. Changes to their hydrologic inputs can impact the function of these wetlands. Wetland systems outside of the NDA are subject to potential indirect effects from the land-clearing and other preconstruction and building activities occurring within the adjacent NDA, such as edge-effect encroachment of invasive species or changes to the shading of remaining wetlands, which could affect the habitat function of these features. Remaining wetland resources retain some landscape connectivity via the forested buffer along the lake edge, thereby sustaining corridors that can support wildlife movement. Wetlands not directly subject to impacts risk indirect erosion and sedimentation impacts from preconstruction and building activities; however, these impacts are mitigated to the extent practicable by the use of BMPs to prevent erosion and the transport of sediment to wetlands via stormwater. Erosion controls can include mulching, geotextiles, sod stabilization, and buffer strips, while sediment control can include silt fences or vegetative buffer strips. These BMPs are designed, installed, and operated to meet all requirements and be acceptable for approval and issuance of both erosion and sediment plans/NPDES permit NCG010000 and post-construction categorical industrial stormwater coverage as required for steam electric generation sites. Building activities comply with federal and state BMPs for erosion control and stormwater management, thereby minimizing the potential for those processes to directly disturb or indirectly impact nearby wetland communities outside the Project site and associated off-site areas.

As Section 2.3.1.2.2 notes, wetlands are subject to regulatory authority pursuant to Sections 401 and 404 of the CWA. The USACE performed a site visit in December 2024 to field verify the streams and wetland delineation, followed by issuance of a Jurisdictional Delineation Concurrence letter in January 2025 confirming the delineation is a sufficiently accurate representation of the geographic boundaries of the aquatic resources located on the site within the delineation survey area. Appropriate NCDEQ (Section 401) and USACE (Section 404) permitting applications for wetlands will be submitted based upon final design, and NCDEQ and USACE guidelines and mitigative requirements will be followed.

Any required mitigation by USACE will comply with the requirements of 33 CFR Part 332 "Compensatory Mitigation for Losses of Aquatic Resources," which promotes the national goal of "no net loss" of wetland acreage and functions as described in the Final Rule. Potential stream and wetland mitigation will be evaluated during later design and permitting phases for any unavoidable impacts to waters of U.S., including wetlands, using a watershed-based approach in the selection of mitigation sites. Mitigation sites will be evaluated and prioritized consistent with the Final Rule's mitigation preference hierarchy: 1) credits from approved mitigation banks, 2) credits from approved in-lieu fee programs, and 3) permittee-responsible mitigation. During the permitting phase, if a mitigation bank is not available within the approved service area for the Project watershed, compensatory mitigation will be coordinated through the NCDEQ's In-Lieu Fee Program administered by the Division of Mitigation Services. Other options will be evaluated if banks or in-lieu fee options are not available. Therefore, impacts on waters of the U.S., including wetlands, will be fully mitigated.

In summary, all wetlands within the Project site are directly or indirectly impacted by building activities, while the associated off-site wetland is directly impacted. Of the approximately 2.94 ac. (1.19 ha) of on-site and off-site total wetland area (approximately 2.68 on-site and approximately 0.26 off-site), approximately 92 percent (2.71 ac. [1.1 ha]) will be directly impacted. The remaining approximately 0.23 ac. (0.09 ha) of on-site wetlands are subject to indirect effects to hydrology, vegetative cover composition, and habitat value from construction activities. However, there are substantially greater wetland resources within the Project Vicinity approximately 2255 ac. (913 ha). Total direct and indirect impacts constitute a negligible impact on total wetland habitats in the Project Vicinity, such that overall impacts on wetlands are not destabilizing.

As the design and permitting processes progress, Duke Energy will consider and implement appropriate avoidance and minimization measures. For impacts that cannot be avoided, Duke Energy will coordinate with the USACE and the NCDEQ to ensure the appropriate mitigation credits will be generated or acquired following the watershed approach and "no net loss" principle. Based on anticipated avoidance and minimization of wetland impacts, landscape perspective of total wetland habitats, NCDEQ and USACE guidelines and mitigative requirements, and the use of BMPs, impacts on wetlands are minor.

4.3.1.3 Wildlife

As described in Section 2.3.1.3, wildlife communities within the Project site and the associated off-site wastewater pipeline corridor are common, well represented, and reflect the composition of associated wildlife communities (Section 2.3.1.4). Wildlife communities using evergreen, herbaceous, or shrub scrub habitat within the Project site and associated off-site wastewater

pipeline corridor are generally characterized as having low diversity and are dominated by common species. However, deciduous forest and associated stream valley habitats provide higher-quality wildlife habitat on the Project site. Impacts on streams are discussed below in Section 4.3.2.1.1. Section 4.3.1.4 provides a discussion of impacts on species of concern and important terrestrial species.

Building activities result in disturbance, displacement, and loss of wildlife because heavy equipment is used for clearing, grading, and excavation. Mobile animals, such as birds and larger mammals, avoid disturbance areas and may relocate to safer areas. However, smaller, less mobile species, such as small mammals, reptiles, and amphibians, are displaced or may suffer mortality during building activities. Based upon the conversion of habitats to developed areas described in Section 4.3.1.1, the overall abundance and composition of wildlife within the Project site is altered from wildlife communities that are characteristic of undeveloped habitats, to those communities that are naturalized or tolerant of developed habitats. Wildlife displaced by building activities can find refuge in undisturbed habitats within the Belews Lake shoreline buffer or within similar habitats within the Project Vicinity. While the shoreline buffer is retained and serves as a refuge area for wildlife and a corridor for wildlife movement during building activities, the narrowness of this shoreline buffer limits the overall capacity to support wildlife diversity. Movement of species through the Project site to Belews Lake in search of water may be similarly impacted by this habitat fragmentation. However, the loss of individuals from these localized impacts is not anticipated to affect regional species populations.

Riparian zones are valued habitats that are used by wildlife. A forested riparian zone of approximately 100 ft. (30 m) within the Project site is retained along most of Belews Lake shoreline, except in the areas where shoreline access is needed. Similar riparian habitat for wildlife is available along Belews Lake and other water bodies in the 50-mi. (80-km) Project Region, and the loss of small segments at the intake and discharge structures does not affect populations of wildlife that use riparian habitats.

As described in Section 2.3.1.8, the Project site and associated off-site wastewater pipeline corridor are located within the Atlantic Flyway migration route. One osprey (*Pandion haliaetus)* nest on a man-made nesting platform was documented on the Project site within the NDA (Figure 4.3-3) and is impacted by building activities. A known bald eagle (*Haliaeetus leucocephalus*) nest is outside the NDA and is not impacted by building activities. Additional discussion on bald eagle impacts is included below in Section 4.3.1.4.1. BMPs to minimize impacts on migrating bird species include minimizing or avoiding tree clearing during nesting season from April to July. If building activities occur during this window, Duke Energy compliance recommendations are in place to reduce effects to nesting migratory birds. These include surveying for active nest sites and establishing avoidance buffers as needed.

Birds flying through the Project site may collide with tall construction equipment or structures that include cranes and transmission lines. During final design, Duke Energy will consider placing new transmission lines in locations that will minimize potential impacts to birds utilizing methods such as those outlined by the Avian Power Line Interaction Committee. NUREG-1437, *The Generic Environmental Impact Statement for License Renewal of Nuclear Plants,* concludes that bird collisions with cooling towers, other nuclear power plant structures, and transmission lines occur at rates that are unlikely to affect local or migratory bird populations (NRC, 2013).

If artificial lighting is used to support nighttime building activities, birds and nocturnal pollinators are subject to impacts. Bird collisions may be more frequent during migration because some

bird species are attracted to artificial lights during migration (Gauthreaux and Belser, 2006). Recent studies have shown that artificial lighting disrupts the natural reproduction and feeding patterns of nocturnal pollinators, such as beetles and moths. As a result, pollination rates in plants and the health and diversity of nocturnal pollinators may be correspondingly reduced. Mitigation measures such as minimizing the number of light structures, installing fully shielded lights that direct light downward, avoiding landscape lighting features for trees or building facades, and using only low-pressure sodium, high-pressure sodium, or light-emitting diode light sources help minimize potential adverse effects of outdoor lighting to wildlife. Therefore, impacts of collisions and effects from artificial lighting on species during building activities are minor.

Section 4.8.2 describes noise that can result from building activities and factors that influence noise effects, such as frequency, intensity, duration, location, and timing. As summarized in Table 4.8-1, noise emissions from most of the construction equipment used on the Project site attenuate to 85 A-weighted scale decibels (dBA) or less at 50 ft. (15 m) from the noise source. The exception is pile-driving activities, which can reach up to 110 dBA at 50 ft. (15 m) from the source. As discussed in Section 4.8.2, pile-driving activities occur periodically within the power block areas and may occur as part of the intake and discharge structure installation. Additionally, as described in Section 3.3.2, rock excavation activities likely require controlled rock blasting, which may produce noise levels of up to 126 dBA. However, the noise emissions of these isolated explosive events are equivalent to a thunderclap at the source and are temporary and short-term. The noise level at which birds and small mammals are startled or frightened is 80 to 85 dBA (Golden et al., 1980). Thus, wildlife within 50 ft. (15 m) during most building activities on the Project site may be startled, move away from the building activities, and avoid feeding or sheltering in nearby habitats. Displacement of small mammals and birds is expected within areas affected by building activities.

While many wildlife communities on the Project site have low diversity and are dominated by common species, there are some higher-quality habitats on the Project site, such as deciduous forest and associated stream valley habitats. All habitat on the Project site within the NDA is permanently converted to developed use which alters the composition of wildlife species. BMPs minimize impacts on common wildlife species, and individual losses of species as a result of building activities do not noticeably affect species populations within the Project Vicinity or Region. Thus, overall impacts on general wildlife as a result of building activities are noticeable but not destabilizing.

4.3.1.4 Important Terrestrial Species and Habitats

4.3.1.4.1 Important Terrestrial Species

As discussed in Section 2.3.1.5, there are important terrestrial species and habitats within or near the Project site. Table 2.3-9 identifies the important terrestrial species that may be impacted by building activities on the Project site. Species that are federally listed as endangered, or species proposed to be listed as endangered, include Schweinitz's sunflower (*Helianthus schweinitzii*), tricolored bat (*Perimyotis subflavus*), bog turtle (*Glyptemys muhlenbergii*), monarch butterfly (*Danaus plexippus*), and gray bat (*Myotis grisescens)*.

As discussed in Section 2.3.1.5.1, the Project site contains suitable habitat for Schweinitz's sunflower in the form of open roadsides, the transmission corridor, and within natural forest openings near the Belews Lake shoreline. However, this species was not documented during vegetation surveys of the Project site in April, July, or October 2024. Surveys during the October event were conducted during the optimal flowering period for this species. While specific habitat

for the sunflower was identified, no specimens were observed, as discussed in Section 2.3.1.5.1. On-site suitable habitat for this species is disturbed by periodic mowing and other general maintenance occurring along transmission lines and roadsides. Further, dense vegetation within the transmission corridor limits growth of this species, which needs partial to full sun. Affected habitats that are suitable for Schweinitz's sunflower include approximately 85.6 ac. (34.6 ha) on the Project site, and 10.0 ac. (4.0 ha) within the associated off-site wastewater pipeline corridor. Impacts on Schweinitz's sunflower are minor because the species was not observed, and suitable habitat is limited on the Project site.

Tricolored bat is proposed for federal listing as endangered, and this species was documented on-site through acoustic surveys in 2023 as detailed in Section 2.3.1.5.1. Roosting and foraging habitat is present on the Project site and is impacted by building activities. Impacts on foraging habitat are limited because habitat types affected, such as forests and open water, are common in the Project Vicinity (Table 4.3-1), and bats are highly mobile and capable of using other, similar foraging habitats nearby. The greatest direct threat to tricolored bats during building activities is associated with the clearing of roost trees within forested habitat on the Project site; however, the forests in the Project Vicinity provide potential roost trees that tricolored bats could use as alternatives to roost trees removed from the Project site. Approximately 698.0 ac. (282.5 ha) of roosting habitat (deciduous forest, evergreen forest, mixed forest, and woody wetlands) is within the NDA, whereas 12.1 ac. (4.9 ha) of roosting habitat is within the associated off-site wastewater pipeline corridor (Figure 4.3-4). To minimize potential effects to tricolored bats, mitigative measures that include tree-clearing restrictions and culvert surveys are used. Clearing trees during the winter when bats are hibernating and not using trees during summer roosting also limit direct impacts on roosting bats. Prior to construction, Duke Energy will consult with the USFWS and adhere to conservation measures, such as tree-clearing time frames and conducting surveys to avoid impacts on roost trees and associated bats, as appropriate. Tricolored bats may also roost in culverts. Culverts greater than 3 ft. (1 m) wide and bridges within or adjacent to the Project are surveyed for bats within 15 days of construction. Based on the limited dependence of tricolored bats on the Project site for foraging habitat and the ability to avoid direct effects on bats in occupied roosting trees if present, the potential for construction impacts on tricolored bats is minor.

Potentially suitable habitat for the bog turtle is present on the Project site, but the species has not been documented in surveys. Furthermore, as noted in Section 2.3.1.2.2, there are only four palustrine emergent wetlands, and one forested and emergent vegetated wetland delineated on the Project site. These are located in a relict stormwater management pond or in the transmission corridor and are therefore in maintained areas that are periodically disturbed. These wetlands are within the NDA (Figure 4.3-2), but suitability for bog turtles within these areas is considered low due to the recurring disturbance. Therefore, impacts on the bog turtle are minor.

Monarch butterfly is a species proposed for federal listing as threatened and is reliant on milkweed species for breeding. USFWS has occurrence records of this species around the Project site. During 2024 surveys, the monarch butterfly was not documented on-site, and its breeding habitat is limited on the Project site. Milkweed was limited to rare in its occurrence during surveys in the southwest portion of the Project site and along the associated off-site wastewater pipeline corridor, as discussed in Section 2.3.1.5.1 and shown in Figure 4.3-4. Suitable foraging habitat exists on the Project site in the form of herbaceous areas, especially the grassland found just south of the transmission line corridor bordering the lake on the east side of the Project site. This area hosts native wildflowers (not including milkweed), while other herbaceous areas are dominated by invasive species. As Figure 4.3-1 shows, the herbaceous

area just south of the transmission line corridor is also within the NDA. Within the Project site, 85.6 ac. (34.6 ha) of herbaceous foraging habitat is impacted by building activities. However, this herbaceous foraging habitat is not unique on the Project site (Table 4.3-1), and transmission corridors established as part of building activities may provide suitable herbaceous foraging habitat within other areas of the Project site for use by this species. Duke Energy will consult with USFWS regarding this species as appropriate if the monarch butterfly becomes federally listed. Based on limited breeding habitat and the presence of other suitable foraging habitat in the Project Vicinity, impacts on monarch butterfly are minor.

As discussed in Section 2.3.1.5, federally endangered gray bats are not expected on the Project site. Gray bats were not documented during 2023 acoustic monitoring and no suitable roosting habitat is present on the Project site; therefore, impacts on these bats are limited. Suitable foraging habitat may be present on the Project site in the form of stream corridors, but bats are highly mobile and capable of using other, similar habitat nearby.

Bald eagles are protected under the Bald and Golden Eagle Protection Act and are state-listed as a threatened species. As discussed in Section 2.3.1.5.2, there is a bald eagle nest at the BCSS adjacent to the Craig Road landfill and approximately 0.23 mi. (0.37 km) west of the Project site. As Section 2.3.1.5.2 describes, Duke Energy has developed a Bald Eagle Nest Management Plan for the BCSS, which details general bald eagle nest disturbance guidelines, activity guidelines during vegetation management, activity guidelines during utility structure or electrical maintenance, and guidelines for removal and beneficiation of coal ash (Duke Energy, 2023a). Protective buffers help shield bald eagle nests from activities that may result in detrimental impacts on breeding and successful production of chicks. The standard buffer distance for bald eagle nests during the nesting season is a 660-ft. (201-m) radius measured from the base of the nest as discussed in the Bald Eagle Nest Management Plan (Duke Energy, 2023a). This buffer is outside of any on-site and off-site disturbance areas, as shown in Figure 4.3-4. Duke Energy will coordinate with the USFWS prior to construction to obtain required permits and implement conservation measures, as appropriate. Based on avoidance of the nest area and implementation of appropriate conservation measures, impacts on bald eagles are minor.

Section 2.3.1.5.3 describes state-listed species with the potential to be present on the Project site including, rusty blackbird (*Euphagus carolinus*), coppery emerald (*Somatochlora georgiana*), and marsh St. John's-wort (*Triadenum tubulosum*). Rusty blackbird, a species state-listed as threatened, was not observed on-site but has the potential to occur due to the species' preferred hardwood forest habitat along the shoreline of Belews Lake. Furthermore, rusty blackbirds do not breed in the Piedmont Ecoregion and are only expected during the winter months. As previously discussed, an approximate 100-ft. (30-m) vegetative buffer around the lake is retained and not impacted by building activities. Rusty blackbirds are highly mobile and hardwood forests by the lake are not unique to the Project Vicinity. Therefore, the impacts on the rusty blackbird are minor.

The coppery emerald is a species designated by NCNHP as significantly rare, and it may occur on the Project site. However, as noted in Section 2.3.1.5.3, habitat for this species is limited due to the small size of on-site streams. Therefore, even though impacts on streams would occur, as discussed in Section 4.3.2.1.1, impacts on this species are minor.

Marsh St. John's-wort is a species designated by NCNHP as significantly rare, and suitable habitat occurs within coves and along low, wetland shorelines of Belews Lake. This species has not been observed on-site. An approximate 100-ft. (30-m) buffer around the lake is retained.

Shoreline impacts are also limited to relatively isolated intake/discharge areas along Belews Lake. Therefore, impacts on marsh St. John's-wort are minor.

As Section 2.3.1.5.4 discusses, species of commercial or recreational value on the Project site include game species (such as gray squirrel [*Sciurus carolinensis*], white-tailed deer [*Odocoileus virginianus*], and wood duck [*Aix sponsa*]), non-game species (coyotes [*Canis latrans]*), and furbearers (such as raccoon [*Procyon lotor*] and opossum [*Didelphis virginiana*]). These species are common in the area and within the Project Vicinity. Therefore, impacts on these species are minor.

Overall, impacts on important terrestrial species are limited because of the low probability of occurrence for the species, the presence of extensive habitat characterized by low-quality plant communities, and the abundance of similar suitable habitat within the Project Vicinity. In addition, Duke Energy will consult as appropriate regarding potential effects to tricolored bat and bald eagle and incorporate relevant conservation measures to minimize effects to these species. Therefore, impacts on important terrestrial species are minor.

4.3.1.4.2 Important Terrestrial Habitats

As Section 2.3.1.6 discusses, the Project site does not include any designated or proposed critical habitat for terrestrial species. Important terrestrial habitats on the Project site or in the Project Vicinity include wetlands, Belews Lake Park, Knight Brown Nature Preserve, and the Dan River Educational State Forest. Building activities do not impact Belews Lake Park, Knight Brown Nature Preserve, or the Dan River Educational State Forest, as these features are outside the Project site NDA and the off-site wastewater pipeline area.

Impacts on wetlands from building activities are described in Section 4.3.1.2. Based on the limited extent of wetlands on the Project site, the impact on wetlands from building activities is minor. Therefore, the overall impact on important terrestrial habitats because of building activities is minor.

4.3.1.5 Transmission Corridors

As discussed in Section 1.1.5, additional transmission lines that extend outside of the existing Project site boundary are not required. Transmission improvements within the existing Project site include a second 230-kilovolt switchyard and other transmission line improvements. These improvements are located within the Project site and substantially within the NDA. Accordingly, analysis of impacts on habitats and species within transmission corridors is integrated in the preceding sections of Section 4.3.1.

4.3.1.6 Summary of Impacts on Terrestrial Ecology

As previously discussed, impacts on plant communities and habitats are noticeable based on the size of the area affected. Much of the habitat on-site is low quality and there is suitable habitat within the Project Vicinity. However, higher-quality habitats on-site are also permanently impacted, and composition of wildlife within the Project site is altered to naturalized communities. Impacts on wildlife are limited because of mitigation measures, BMPs, and the short duration of building activities. The only important habitat on the Project site consists of wetlands, as defined by U.S. NRC guidance and discussed in Section 2.3.1.6. Impacts on these habitats are mitigated by BMPs and required federal or state mitigation. Impacts on important terrestrial species are mostly limited because many of these species are not found on the

Project site or there is limited impact on habitats and populations found within the Project Vicinity and Project Region. Consultation with USFWS and implementing appropriate conservation measures and other mitigative measures reduces impacts on important terrestrial species found on the Project site or in adjacent areas. Overall, the impacts on terrestrial ecology from building activities are MODERATE.

4.3.2 AQUATIC IMPACTS

The aquatic ecosystems and aquatic resources of the Project site are described in detail in Section 2.3.2. Aquatic habitats on the Project site, associated off-site areas, and in the Project Vicinity include on-site streams, Belews Lake, Belews Creek, and the Dan River. Impacts on surface water resources as a result of building activities are described in Section 4.2.1. Building activities that can affect aquatic ecosystems include development of the features and structures associated with the cooling water systems on Belews Lake and the Dan River and on-site grading and land preparation. Indirect impacts, such as degradation of water quality from sedimentation and potential accidental spills, can reduce quality of aquatic habitats.

Additionally, accidental discharges of construction-related chemicals such as fuel, oil, or grease can occur during building activities. Compliance with federal, state, and local requirements minimizes potential impacts of building activities on aquatic ecosystems. A site-specific SWPPP as part of the NPDES permit compliance manages stormwater and minimizes pollutant loading within receiving water bodies. In addition, compliance with the terms of applicable Section 404 permits, and coordination with the USACE are required.

4.3.2.1 Aquatic Habitats and Biota

4.3.2.1.1 On-Site Streams

On-site streams are characterized as primarily first order streams and are described in Section 2.3.2. Building activities include site preparation, which includes clearing, site grading, and installation of stormwater management systems, as described in Section 3.3.2. Building activities directly impact approximately 16,875 linear ft. (5144 linear m) of on-site streams. Direct impacts on aquatic biota result in mortality associated with the placement of fill material within aquatic habitats. However, as indicated in Section 2.3.2.2, due to the intermittent availability of surface water, most on-site streams lack unique biological communities and provide minimal habitat for aquatic biota. Additionally, as described in Section 4.2.1, the remaining approximately 1256 linear ft. (323 linear m) of streams outside of the NDA and above the confluence of each of the streams with Belews Lake are indirectly impacted by flow alteration and increased sedimentation and turbidity from building activities.

As described in Section 4.2.1.1, impacts on streams are subject to USACE regulatory authority pursuant to Sections 401 and 404 of the CWA. As appropriate, permitting applications for streams are submitted in accordance with NCDEQ and USACE guidelines and mitigative requirements will be followed. Any required mitigation by USACE would comply with 33 CFR Part 332 “Compensatory Mitigation for Losses of Aquatic Resources.”

Erosion and sedimentation occur as part of the building process. To minimize impacts from the building process on aquatic ecosystems, BMPs are used to control erosion and limit the amount of soil and sediment entering surface waters. BMPs specific to the extent and type of construction are implemented prior to building activities and maintained throughout building activities to protect aquatic ecosystems. These controls may include mulching, geotextiles, sod

stabilization, flow diversion, buffer strips, and establishment of temporary or permanent vegetation. Sediment control measures established at the edges of the NDA can include silt fences, wattles, vegetative buffer strips, and sediment basins. To minimize stream disturbance, personnel and equipment only enter riparian areas when essential to complete work. Land disturbance in riparian areas is, to the extent practicable, limited to what can be stabilized quickly. A SWPPP prescribes methods for collection, mitigation, and control of stormwater runoff from building activities in accordance with state and federal regulations and permit requirements. Stormwater retention ponds are used to decrease sedimentation, and erosion impacts on on-site streams and Belews Lake.

Potential impacts related to accidental spills of petroleum products or industrial chemicals necessary for building activities may result in adverse effects on aquatic ecosystems. As described in Section 4.8, potential impacts are mitigated by designating storage areas for fuel and lubricants on the Project site that are equipped with appropriate spill containment measures in accordance with SPCC plans.

In summary, up to approximately 16,875 linear ft. (5144 linear m) of on-site streams are directly impacted by building activities, and approximately 1256 linear ft. (323 linear m) are impacted indirectly. The impacted streams are primarily first order, relatively small streams which are mostly intermittent in nature and do not demonstrate high-quality habitat. Impacts to on-site aquatic habitats including streams and wetlands are mitigated in accordance with Sections 404 and 401 of the federal CWA and Section 404 permitted by the NCDEQ and the USACE, respectively (see Section 4.2.1). Per Section 4.3.1.2, unavoidable impacts to on-site aquatic habitat, streams and wetlands will be mitigated in accordance with 33 CFR Part 332. Therefore, impacts on aquatic ecosystems within on-site streams are minor.

4.3.2.1.2 Belews Lake

Building activities that affect the aquatic community in Belews Lake include installation of the intake and discharge structures and associated pipelines. Section 3.2.2 describes the cooling system that includes intake and discharges. As described in Section 3.3.2, building activities related to the intake structure include excavation and lakebed dredging to prepare the Project site for building activities and temporary installation of cofferdams so that work can be performed in a dry environment. Two optional locations are included for the intake structure. Discharge options include one common discharge structure for all advanced reactors or a distinct discharge structure for each advanced reactor development area (Figure 3.1-1). Piping for each discharge structure extends from the shoreline to the submerged discharge structure.

In the immediate vicinity of the intake and discharge, increases in turbidity and sediment deposition may occur during development of these structures. Dredging is expected to occur in a 20-ft. (6-m) x 20-ft. (6-m) area to a depth of 3 ft. (0.9 m) for the installation of scour protection. From the site elevation to the shoreline, a 45-degree angled borehole is required to place the piping directly into Belews Lake. Dredging may be required at the outlet of the discharge piping to install scouring protection. It is estimated that, if required, approximately 1200 ft^3 (111 [m^3]) of soil and sediment can be dredged and disposed of within either an approved on-site or off-site landfill. The dredged material would be replaced with crushed rock. As described in Section 4.2.3.1, the intake structure or structures are expected to be within a 5000-ft^2 (464.5-m^2) area on the shoreline. As described in Section 3.3.2, cofferdams may be temporarily installed to perform work in a dewatered environment as the principal BMP to contain and control sedimentation. As Section 4.2.4.1.2 describes, a sediment monitoring program monitors potential constituents of concern that may remobilize from sediment disturbed during dredging.

Program results will determine whether additional BMPs or engineering controls are required to maintain water quality and aquatic habitat.

These temporary and localized impacts affect relatively small areas of aquatic habitats within Belews Lake, and effects are minimized through the use of BMPs, such as silt curtains or wattles. Mobile aquatic species, such as fish, avoid the building area, thereby reducing mortality. By comparison, less mobile or sessile benthic organisms (e.g., macroinvertebrates, mollusks, aquatic plants) are directly impacted. Benthic aquatic biota of Belews Lake are not rare and recolonize following the completion of building activities. Localized, indirect, adverse effects on aquatic organisms from sedimentation are also possible adjacent to direct disturbance areas. Additionally, potential impacts on aquatic organisms may occur as a result of spills of fuel, lubricants, solvents, or other liquids. As described in Section 4.2.3.1, such impacts are minimized because of BMPs that prevent and control spills in accordance with the SWPPP and SPCC plan.

Disturbances of habitats related to the building of the intake structure and discharge pipeline are temporary. The size of the area impacted by building activities is relatively small in relation to the area of Belews Lake. Additionally, the loss of aquatic habitat and resultant effects on aquatic biota is minor, relative to available aquatic habitats within Belews Lake.

Potential indirect impacts on the aquatic ecosystems of Belews Lake may also result from upland building activities. Building activities on the Project site may increase erosion, resulting in downstream sedimentation that may impact adjacent areas in Belews Lake. Sedimentation may result in reductions in quality habitat and smothering of sessile species in the localized vicinity of the impact. BMPs are used during building activities to minimize sedimentation in Project site water bodies. An approximate 100-ft. (30.5-m) buffer near water bodies minimizes potential sedimentation in Belews Lake.

Overall, the impacts on aquatic habitats and associated biota within Belews Lake as a result of building activities are localized and temporary. Impacts on aquatic habitats are limited to the location of the intake and discharge structures and associated pipelines within the lake and are minimized by implementation of BMPs to prevent and control spills in accordance with the SWPPP and SPCC plan. Therefore, impacts from building activities on aquatic habitats and biota within Belews Lake are minor.

4.3.2.1.3 Dan River

The only anticipated building activity on the Dan River is within the associated off-site area that includes the wastewater pipeline located at Outfall 006. While the wastewater pipeline is located within an approximate 100-ft. (30.5-m) wide corridor, building-related disturbances within the Dan River are more localized. As described in Section 3.2.2, the discharge structure within the Dan River consists of a pipeline buried within the river bottom. In-river excavation is conducted to install the discharge pipeline. This building activity occurs after the appropriate NCDEQ (Section 401) and USACE Wilmington District (Section 404) permits for waters of the U.S. are submitted and approved based upon final design. In addition, NCDEQ and USACE guidelines and mitigative requirements will be followed. Use of BMPs and adherence to permit conditions minimize impacts on aquatic communities within the Dan River. Temporary loss of aquatic habitats occurs in the footprint of building activities. Avoidance of the building area by mobile species decreases mortality and nonlethal adverse impacts on those individuals. Any required mitigation by the USACE will comply with 33 CFR Part 332 “Compensatory Mitigation for Losses of Aquatic Resources”, which adheres to the “no net loss” principle and the associated Final

Rule. This rule emphasizes a watershed approach in the selection of mitigation locations, generally ensuring that impacts are mitigated within the same watershed area. Habitat for more immobile organisms (benthic macroinvertebrates and mollusks) is temporarily lost but reestablished over time. Coordination with NCWRC will occur regarding the results of mussel surveys and the potential for mussel relocation prior to in-stream building activities.

Potential indirect impacts on Dan River habitat may occur through erosion, sedimentation, and accidental spills or chemical releases during the building period. Implementing BMPs to prevent and control spills in accordance with the SWPPP and SPCC plans minimizes potential impacts. Therefore, impacts from building activities on the aquatic ecosystems of the Dan River are minor.

4.3.2.2 Important Aquatic Species and Habitats

4.3.2.2.1 Important Aquatic Species

Important aquatic species that may be present in the Project site and associated off-site areas are described in Section 2.3.2.3. Impacts of building activities occur primarily in on-site streams and within Belews Lake. No federally listed or state-listed freshwater mollusk species or fish species have been documented in Belews Lake or in on-site streams. Therefore, no direct impacts on federally or state-listed species are expected to occur in Belews Lake as a result of building activities.

Within the Dan River, building activities directly impact 100 ft. (30.5 m) of the shoreline along the right descending bank at the location of the wastewater pipeline. Federal- and state-listed aquatic species present in the Dan River are described in Section 2.3.2.3. As building activities within the Dan River are localized to the immediate location of the wastewater pipeline, impacts are localized and temporary. Localized, indirect, adverse effects on aquatic organisms from sedimentation are also possible adjacent to direct disturbance areas. Additionally, potential impacts on aquatic organisms may occur as a result of spills of fuel, lubricants, solvents, or other liquids. As described in Section 4.2.3.1 such impacts are minimized because of BMPs that prevent and control spills in accordance with the SWPPP and SPCC plan. Avoidance of building activities by mobile species, coupled with the use of BMPs that Section 4.3.2.1.3 describes, minimizes potential adverse impacts. As described in Section 2.3.2.3, the state-endangered Roanoke Logperch (*Percina rex*) has been observed at the location of the wastewater pipeline. Duke Energy will consult with USFWS and NCWRC regarding avoidance, minimization, and appropriate conservation measures to limit potential effects on proposed critical habitats within the Dan River.

Sedimentation may result in reductions in quality habitat and smothering of sessile species in the localized vicinity of the impact. State-endangered and federally proposed threatened freshwater mussel Green Floater (*Lasmigona subviridis*) and federally endangered James Spinymussel (*Parvaspina collina*) are present in the Dan River. As Section 2.3.2.2 describes the location of the wastewater pipeline in the Dan River provides poor habitat for the Green Floater, and no live individuals of either species were observed in the immediate vicinity of the wastewater pipeline.

Within Belews Lake, building activities are limited to installation of the intake structure and discharge structure(s). As discussed in Section 2.3, recreationally valuable fish have been documented within Belews Lake. Each of these fish species is highly mobile and expected to avoid the areas where excavation and other building activities are performed. These activities

create short-term disturbances and noise that cause fish to avoid the immediate area. However, these activities are temporary and localized, and fish can readily avoid the source of disturbance. The use of BMPs, such as turbidity curtains, minimize impacts on aquatic habitats within Belews Lake, thereby reducing impacts on recreationally important aquatic species in Belews Lake during building activities.

Invasive aquatic species are documented to be present within Belews Lake (Section 2.3). The use of BMPs during building activities prevents the spread of aquatic invasive species, decreasing their impact on native species. Protective measures, such as shoreline stabilization and buffer zones are protective of native vegetation species and can assist in decreasing the spread of invasive vegetation. Localized disturbances are also minimized through the use of BMPs that decrease the colonization of non-native species.

Direct impacts on important aquatic species are localized and temporary. Indirect impacts on the important aquatic species are minimized through the use of BMPs during building activities, and coordination with NCWRC will occur regarding the results of mussel surveys and the potential for mussel relocation prior to instream building activities. Therefore, the impacts of building activities on important aquatic species are minor.

4.3.2.2.2 Important Aquatic Habitats

Important aquatic habitats on the Project site, associated off-site areas, and in the Project Vicinity are described in Section 2.3.2.4. Proposed critical habitat for state-endangered species and federally proposed threatened freshwater mussel Green Floater is present in the Dan River. As Section 2.3.2.2 describes the location of the wastewater pipeline in the Dan River provides poor habitat for the Green Floater, and no live individuals were observed in the immediate vicinity. Localized, short-term, indirect impacts on Dan River proposed critical habitat may occur through erosion, sedimentation, and incidental spills or chemical releases during construction of the discharge outlet in the Dan River.

As described in Section 4.2.3.1, surface water impacts are regulated by NCDEQ and the USACE. Ground-disturbing activities that have the potential to affect surface water quality will be permitted by applicable federal, state, and local regulations and guided by an approved SWPPP. The SWPPP will also contain a plan for the building activities. To minimize the impacts of building activities on surface water quality, BMPs are used to control erosion and limit the amount of soil and sediment entering surface waters. These controls may include silt fencing, mulching, geotextiles, sod stabilization, flow diversion, buffer strips, and establishment of temporary or permanent vegetation as outlined in the NC Erosion and Sediment Control Planning and Design Manual (NCDNR, 2013).

To control the discharge of oil spills and limit their effects on surface water, Duke Energy will implement an SPCC plan pursuant to 40 CFR Part 112 at the Project site. An SPCC plan includes BMP actions such as proper vehicle and equipment maintenance, containment for fuel or oil storage tanks, and the maintenance of spill response equipment and materials.

Duke Energy will consult with USFWS and NCWRC regarding avoidance, minimization, and appropriate conservation measures to limit potential effects on proposed critical habitats within the Dan River. Therefore, the impacts of building activities on important aquatic habitats are minor.

4.3.2.3 Transmission Corridors

As discussed in Section 1.1.5, additional transmission lines extending outside the Project site boundary is not required. Transmission improvements within the existing site boundary include a second 230-kilovolt switchyard and other transmission line improvements. Because these improvements are located within the overall Project site NDA, analysis of impacts on habitats and species within transmission corridors are captured within the preceding sections of Section 4.3.2.

4.3.2.4 Summary of Impacts on Aquatic Ecosystems

Building activities result in direct impacts on approximately 16,875 linear ft. (5144 linear m) of streams within the NDA and 100 linear ft. (30.5 m) within the associated off-site wastewater pipeline. An additional 1256 linear ft. (323 linear m) of streams on the Project site are indirectly impacted by building activities. The impacted streams are primarily first order, relatively small streams which are mostly intermittent in nature and do not demonstrate high-quality habitat. In Belews Lake, impacts on aquatic habitats are minor based on the lack of high quality or unique habitats in the locations in which building activities are to occur in Belews Lake. Impacts on most streams or other aquatic ecosystems are mitigated in accordance with permitting requirements. Impacts within Belews Lake and the Dan River are temporary and localized to the intake and discharge structures on the Project site.

There are no direct impacts on important aquatic habitats (e.g., natural areas, managed areas, or other designated areas) from construction and preconstruction activities within the NDA. Indirect impacts on aquatic communities from sedimentation, erosion, and incidental releases as a result of building activities are minimized under permitting and SWPPP requirements and through the use of BMPs. In addition, Duke Energy will consult with USFWS and the state of NC regarding avoidance, minimization, and appropriate conservation measures to limit potential effects on proposed critical habitats within the Dan River. The overall impacts of building activities on aquatic resources are therefore SMALL.

Table 4.3-1
Habitat Types Disturbed by Building Activities on the Project Site

Habitat Types	Area within Vicinity (6-mi.) (ac.)	On-Site Area				Associated Off-site Area (Wastewater Pipeline)			
		Total Habitat (ac.)	Approximate Habitat Affected (NDA) (ac.)	Affected Habitat as a Percent (%) of Total On-Site Habitat	Affected Habitat as a Percent (%) of Total Project Vicinity Area	Total Habitat (ac.)	Approximate Habitat Affected (ac.)	Affected Habitat as a Percent (%) of Total Associated Off-Site Habitat	Affected Habitat as a Percent (%) of Total Project Vicinity Area

	PFO	1.19	0.98	0.21
	Total	2.68	2.45	0.23

Note:
(a) Note that PFO wetlands are considered Woody Wetlands, and PEM are considered Emergent Herbaceous Wetlands. Wetland V is partially PFO and partially PEM and is therefore a split designation. It was designated as Woody Wetlands for the purpose of land cover analysis (Section 4.3.1.1 and Table 4.3-1).

Key: ac. = acre; PEM = palustrine (freshwater) emergent; PFO = palustrine (freshwater) forested

4.4 SOCIOECONOMIC IMPACTS

This section describes the potential socioeconomic impacts associated with building activities for the Project site. As described in Section 2.4, the region of influence (ROI) for the socioeconomic analysis is defined as the areas where the building and operations workforce and their families reside, spend their income, and use their benefits thereby affecting the economic conditions of the region. Because of expected commuter patterns, the distribution of residential communities in the area, and the likely socioeconomic impacts, the ROI is composed of the four counties nearest to the site—Rockingham, Stokes, Forsyth, and Guilford counties. These counties serve as the basis for the assessment of social and economic impacts from the Project.

The discussion is divided into five sections. Section 4.4.1 describes the physical impacts of building activities on the community. Section 4.4.2 provides a description of demographic impacts. Section 4.4.3 describes the economic impacts, including the impacts on the local and state economy and tax revenues. Section 4.4.4 describes impacts on infrastructure and community services and Section 4.4.1.5 provides a summary of physical impacts.

4.4.1 PHYSICAL IMPACTS

This section provides an analysis of physical impacts due to construction of the Project that may affect people, buildings, and roads in nearby communities. People living near or working at or near construction sites may be subject to the physical impacts of building activities. These include potential impacts associated with noise and vibration, odors, dust and air pollution, transportation, and aesthetics. The magnitude of these potential impacts is typically related to the specific building activities that occur at a given site, the nature and effectiveness of implemented environmental controls, and the proximity of the site to populated areas. This section addresses how these potential impacts may affect people, buildings, transportation routes, and the aesthetics of the area surrounding the Project site. Duke Energy is committed to meeting applicable environmental requirements and following construction BMPs to minimize physical impacts.

4.4.1.1 Noise and Vibration

Building activities at the Project site have the potential to result in elevated noise and vibrations beyond ambient levels. The potential impacts of noise and vibration from building activities on sensitive receptors including residences and surrounding recreational facilities and parklands are provided in Section 4.8.2. Therefore, this section assesses the physical impacts to buildings and structures associated with vibration from building activities.

Building activities, including the operation of heavy machinery, construction vehicles, and blasting, can create ground vibration. Ground vibration and ground noise can disturb people who live or work nearby. If the vibration amplitudes are high enough, physical, and cosmetic damage to structures may occur, as well as interference with the functioning of sensitive machinery. The length of time and strength of vibration varies with the equipment used. For example, the vibration from blasting has a high amplitude and a short duration, whereas vibration from grading or highway traffic have a lower amplitude but longer in duration, like a continuous gentle rumble (Caltrans, 2020). Typical levels of ground-borne vibration and the associated human and structural response are shown on Figure 4.4-1. As noted in Section 2.8.2, the nearest noise-sensitive receptor is located approximately 44 ft. (13.4 m) south of the

Project site at its closest point.

According to the Federal Transit Administration, the threshold of human perception to vibration is approximately 65 vibration decibels (VdB) at 50 feet (ft.) (15 m) from the source, and annoyance begins at a vibration level of 70 VdB. Cosmetic damage to structures, also at 50 ft. (15 m) from the source, can occur at 100 VdB for one-time activities such as blasting operations (FTA, 2018). As noted in Section 3.3.2, rock excavation activities within the power block areas (shown on Figure 3.3-1) most likely require controlled rock blasting. However, there are no residences or privately owned structures located within 50 ft. (15 m) of the power block areas that may be subject to vibration-related effects from blasting. For example, as stated in Section 2.8.2, the residence nearest to any power block area that may be subject to blasting is west of Craig Road near the southern gate entrance to BCSS, approximately 1456 ft. (444 m) from the southern power block area. Therefore, blasting results in minor vibration-related impacts on nearby residences.

Typical sources of vibration include machinery and vehicles needed to support clearing and grubbing, mass earthwork activities, substructure and equipment erection work, and marine construction work. As illustrated on Figure 4.4-1, bulldozers and other heavy-tracked construction equipment may generate vibration levels of approximately 95 VdB at locations 50 ft. (15 m) from the source. Heavy equipment use near any one specific location along the southern Project site boundary is relatively short-term and intermittent (not continuous). As vibration levels of 95 VdB are below the threshold for risk of minor cosmetic damage to fragile buildings (Figure 4.4-1), the vibratory effects of heavy construction equipment (other than blasting) near the closest residence at the southern Project site boundary are also minor.

Based on the above analysis, vibration effects to off-site residences and structures from building-related blasting and equipment use are minor.

4.4.1.2 Odors, Dust, and Air Pollution

Building activities generate temporary air emissions of both gaseous and particulate pollutants. Potential sources of emissions during building include emissions from the use of construction vehicles and engine-driven equipment (e.g., generators and compressors), emissions from motor vehicles used for material and equipment deliveries to the Project site, and from the daily commute of workers. Section 4.7.1.2 provides the analysis of building-phase impacts from heavy equipment emissions. Fugitive dust and fine particulate matter are generated during earthmoving activities, concrete batch plant operation, and movement of vehicular traffic over recently disturbed or cleared areas or unpaved roads. Painting, coating, and similar operations produce emissions of volatile organic compounds. However, such emissions are localized and do not affect off-site receptors. Localized odors from such materials dissipate and are not detectable by off-site receptors.

Because air emissions from on-site building activities are generally released from near ground-level sources, impacts are potentially greatest at the nearest off-site receptors. As stated in Section 4.7.1.2, the nearest sensitive receptors include recreators on Belews Lake, residences just south of the Project site boundary, and residences to the east of the North Plant Complex, across Belews Lake. To minimize temporary air and dust emissions, the following measures may be implemented during building activities at the Project site, as appropriate:

- Scheduling building activities to minimize vehicle idling time.

- Phasing activities and equipment use.
- Ensuring heavy equipment is in good condition, is properly maintained, and complies with applicable regulations.
- Ensuring all machinery is maintained and operated in accordance with the manufacturer's specifications.
- Maintaining low vehicle speeds on dirt roads and exposed areas to minimize dust generation.
- Implementing dust control measures by watering roadways and exposed areas.
- Minimizing the extent of soil storage piles that may be the source of fugitive dust.

Additionally, building activities are subject to air permits under state and federal laws that address the impact of air emissions on sensitive receptors. These permits are further discussed in Section 4.7.

Physical impacts of air emissions from building activities are minor because emissions are controlled using minimization measures and by maintaining established regulatory limits.

4.4.1.3 Transportation

This section discusses the physical impacts on off-site roadways resulting from increased traffic during building activities. The primary access roads to the Project site are identified in Table 2.4-13 and Figure 2.4-4. Traffic-related impacts are discussed in Section 4.4.4.1.

Project-related traffic, including project deliveries and construction, refueling, and maintenance workers, is expected to access the Project site via Craig Road during the building and operation phases. Consequently, the increased Project-related traffic accelerates the deterioration of Craig Road relative to other roads within the surrounding transportation network that provide access to Craig Road. Roadway repairs and improvements on Craig Road and other roadways in the Project Vicinity inadvertently affected by Project-related vehicles, may be necessary to reduce safety risks and restore pavement conditions. Any damage to public roads, markings, or signs caused by building activities is repaired to preexisting conditions or better in accordance with state and local requirements. Therefore, physical impacts from building activities on the transportation network in the Project Vicinity are minor.

4.4.1.4 Aesthetics

Visual and aesthetic effects result from the introduction of structures and facilities that are not consistent with the existing landscape or visual resources. The visual resources immediately surrounding the Project site includes Belews Lake, forested lands, the BCSS, and the rural/low-density residential lands to the south and east (Section 2.4.2.6). The BCSS is a large-scale industrial site with structures that are visible within the Project Vicinity. Visibility of existing BCSS structures from off-site receptors varies with terrain, the presence of existing forest lands and distance from BCSS. Potential receptors that may be affected by changes in the viewshed include recreators on Belews Lake, users of parklands (Belews Lake Park), residents along the southern Project site boundary and along the shoreline of Belews Lake opposite the Project site boundary, and motorists along adjacent roadways.

Aesthetic impacts of building activities result when landscapes or viewsheds are altered. Such impacts vary with receptor location, proximity, or presence of the BCSS within the viewshed, buffer characteristics, and permanence of effect. For example, in areas in which the BCSS is currently visible, the presence of the BCSS facility minimizes the aesthetic impacts associated with building activities, and the development of new structures represents a visual feature consistent with the existing developed viewshed of the BCSS facility. By comparison, modification of existing landscapes that lack the presence of developed structures or view of the existing BCSS industrial setting, is subject to potentially greater visual intrusions and aesthetic effects.

Building activities that may affect visual resources and overall aesthetics include general tree clearing, land surface grading, the use of heavy lift cranes (Section 3.3.3) and the building of vertical structures. Project site building activities are likely most visible to motorists along Pine Hall Road and Craig Road, surrounding residents, and recreators on Belews Lake. Building activities, such as the transport of large materials or components to the Project site, are also visible to residents and recreators within the Project Vicinity. Lighting may be used during building at night and for security purposes, which is visible from receptors in the surrounding area.

The aesthetic effects of building activities on residents near the southern boundary, specifically those along Craig Road and in neighborhoods along Windswept Drive and Crossing Ridge Drive, are noticeable and long-term given proximity to the NDA. By comparison, receptors on Belews Lake and the developed areas along the shoreline opposite the Project site experience aesthetic effects that are variable, based on distance from the Project site, visibility of BCSS, the condition and characteristics of the intervening vegetated buffer, the presence of other land masses and terrain. For receptors in close proximity to the Project site, aesthetic effects are considered to be noticeable, whereas those at greater distances effects are minor. Comparatively, motorists on surrounding roadways, including those on Craig Road and Pine Hall Road, may at times also have an unobstructed view of the Project site. For such receptors aesthetic effects are intermittent based upon the variability of terrain, visibility of BCSS, and the short duration of their exposure to altered viewsheds.

As noted in Section 4.4.1.3, all Project-related traffic, including project deliveries and construction, refueling, and maintenance workers, is expected to access the Project site via Craig Road during the building and operation phases. As a result, the increase in vehicular traffic due to building activities causes aesthetic impacts for sensitive receptors along this road. Traffic from the construction workforce primarily occurs during shift start and shift end. Increased traffic from on-site trucking of building materials is intermittent through normal working hours.

Potential effects of building activities are mitigated by the presence of natural existing buffers. A vegetated buffer along the edge of the Project site (Figure 3.3-1) further screens sensitive receptors from views of the Project site. This buffer zone is predominantly forested and is approximately 100 ft. (30.5 m) wide. As described in Section 2.1, forested land dominates land cover in the Project Vicinity (Table 2.1-2). The surrounding rolling hills and steep, forested slopes naturally screen the visibility of the Project site. Additionally, light shielding will be implemented to the extent practicable.

Therefore, based on the variable factors that may contribute to aesthetic effects and the existence of buffers and other mitigative measures during building activities, the overall aesthetic impacts are therefore variable and noticeable, but not destabilizing. Aesthetic impacts

to recreation are further discussed in Section 4.4.4.2.

4.4.1.5 Summary of Physical Impacts

Physical impacts of building-related noise and vibration on off-site structures is minimal because of the distance separating the nearest structure (residence) from the areas in which vibration-related activities occur. The nearest residence may be disrupted from the use of heavy machinery and vehicles; however, the use of this mobile equipment is intermittent. Emissions from building-related activities are controlled using minimization measures and by maintaining established regulatory limits; therefore, impacts associated with air emissions are minor. Any damage to public roads, markings, or signs caused by building activities are repaired to preexisting conditions or better, in accordance with state and local requirements. Therefore, physical impacts to transportation infrastructure are minor. Impacts to aesthetics from building activities are noticeable but not destabilizing because building activities may impact viewsheds for nearby residents and recreators of Belews Lake through the introduction of new structures, use of equipment, and increased traffic in the Project Vicinity. Therefore, physical impacts of building activities are SMALL for most factors, but MODERATE for aesthetics.

4.4.2 DEMOGRAPHIC IMPACTS

The following evaluation assesses potential impacts associated with building-related activities and the size of the construction workforce on the ROI population. The evaluation is focused on impacts within the ROI identified in Section 2.4 as the area where the workforce and their families reside, spend their income, and use their benefits thereby affecting the economic conditions of the region. The ROI for the Project is defined as encompassing Forsyth, Guilford, Rockingham, and Stokes counties. The analysis is based on the maximum number of workers required for the Project during the building phase. The analysis also applies the distribution of the existing workforce of BCSS as a predictive indicator of the distribution of the workforce and their families during the building phase. Actual workforce distribution and associated impacts on demography is variable based on the selected places of residency (temporary or permanent) of the workforce employees during the building phase.

4.4.2.1 Workforce Distribution

As described in Section 3.2, Duke Energy is considering various reactor technologies and has developed a PPE that encompasses several advanced reactor parameters that bound the attributes used for evaluating the environmental impacts of the Project (see Section 3.1.2). The most conservative scenario includes building up to six advanced reactors to be brought online sequentially. Assuming up to two units are constructed at a time, there is a peak employment period during which the last two units are being constructed while four units operate. Thus, based on the conservative scenario developed in the PPE, peak employment occurs when there is an overlap of both building and operations and consists of the maximum construction workforce plus the operations workforce for four advanced reactor units. The analysis of impacts to population is based on the peak employment that is determined for the building phase and operational phase as follows:

- Building Phase workforce for two advanced reactor units: 2096 workers.
- Operations Phase workforce for four advanced reactor units: 580 workers.

As a result, the total peak workforce (building plus operations) is 2676 workers.

Refueling and major maintenance is also required for approximately 22 to 32 days every maintenance cycle. Refueling and major maintenance of the operating units may also occur while the final units are under construction, contributing to the local employment. However, because refueling and major maintenance activities are infrequent and short-term, workers are assumed to relocate to the area temporarily without their families and use temporary housing such as hotels, motels, or short-term rentals. Therefore, these employees do not notably affect local demographics or community services and are not included in the peak employment calculation.

The direct impact to population during the building phase is contingent upon how many of the 2676 employees are sourced from within the ROI. For example, if all construction and operation workers reside in the ROI, there is no change in the ROI's total population resulting from the Project. Conversely, should workers relocate to the ROI from areas outside of Forsyth, Guilford, Rockingham, or Stokes counties, there are potential demographic impacts to the ROI in conjunction with the in-migration of the supporting workforce and their families.

4.4.2.2 Impacts on Demography

A construction workforce consists of two components: field craft labor and field non-manual labor. Field craft labor is the largest component of the workforce (typically 70 percent in conventional nuclear plant construction) and comprises civil, electrical, mechanical, piping, and instrumentation personnel. Field non-manual staff makes up the balance of the workforce (approximately 30 percent) and comprises field management, field supervision, field engineers, quality assurance/quality control, safety, and administrative staff. Approximately 70 percent, or 1467 of the 2096 construction workers needed during peak employment, are field craft laborers. Construction-sector occupational employment data for the metropolitan and nonmetropolitan areas that include the ROI counties, Greensboro-High Point and Winston-Salem, are published annually by the U.S. Bureau of Labor Statistics (BLS) (BLS, 2022a, 2022b). Based on the BLS data, approximately 50 percent of the field craft labor positions could be filled from the ROI's available labor force. Thus, approximately 50 percent, or an estimated 734 field craft laborers, come from outside the ROI to support building activities. The remaining 30 percent of the 2096 workers, or 629 workers, are field non-manual laborers who are assumed to be sourced from outside the ROI due to the specialized nature of these administrative and supervisory roles. Additionally, due to the total duration of consecutive building activities (Table 3.3-1), it is assumed that in-migrating construction workers seek long-term housing in the ROI and bring their families.

This analysis assumes that peak employment occurs during the building phase in which four units are operating while two additional units remain in the building phase. Operation of four units requires a workforce of 580 employees. Due to the specialized nature of many of the operational positions, it is conservatively assumed that all operations employees are sourced from outside the ROI. Based on this analysis, a total of 1943 workers (734 field craft laborers, 629 non-manual laborers, and 580 occupational workers) are sourced from outside the ROI and in-migrate to support the Project.

The residential distribution of the in-migrating workforce is assumed to be the same as the residential distribution of the current workforce for the BCSS. Twenty-five percent of the existing BCSS workforce commutes to the facility from outside the ROI. Consistent with these commuting patterns, 25 percent, or 486 of the 1943 in-migrating workforce reside in counties outside the ROI and commute to the Project site. Accordingly, the remaining 1457 in-migrating workers would relocate to the ROI and are assumed to bring a family. The average household

size in NC is 2.48 (USCB, 2022a). Therefore, an in-migrating workforce of 1457 and their families increases the ROI's population by approximately 3614 people. The distribution of this new population within the ROI is estimated based on the residential distribution of the BCSS workforce and is shown in Table 4.4-1. The estimated population increases have the greatest impact in Rockingham and Stokes counties, where new residents increase the population by approximately 1.5 percent and 2.6 percent, respectively (based on 2030 projections). Forsyth and Guilford counties each experience population increases of approximately 0.1 percent, while the ROI experiences a population increase of approximately 0.3 percent.

4.4.2.3 Summary of Demographic Impacts

The population increases associated with the in-migration of workers and their families account for less than 1 percent of the ROI's projected total population in 2030 (Table 4.4-1). Therefore, impacts to demographics associated with building activities are SMALL.

4.4.3 ECONOMIC IMPACTS TO THE COMMUNITY

This section describes the projected economic and tax revenue impacts of constructing the Project on the ROI. As described in Section 3.2, Duke Energy is considering various reactor technologies and has developed a PPE to evaluate the potential for building impacts from multiple advanced reactors. Economic impacts of large capital projects within a project setting are generally considered to be positive (beneficial) and are based on the amount of capital costs expended. Furthermore, because economic impacts are generally positive, the bounding economic condition is the configuration or option that results in the lower economic benefit. For this project, multiple advanced reactors are considered for development over three Plant Complexes. Therefore, the development of a single Plant Complex (two reactor units) represents a conservative economic scenario. As such, a single Plant Complex deployment is the bounding condition for this analysis as this would result in lower capital costs and a lower economic benefit as compared to building multiple Plant Complexes. The deployment of additional units would have a substantially greater impact on the ROI and Project Region.

Economic impacts of building activities are expressed both within the ROI and the Project Region. Counties within the ROI are the most affected because they are near the building activities and receive the largest influx of in-migrating workers. Other counties in the Project Region also experience economic impacts, but these impacts are widespread and dispersed across the larger geographic area.

4.4.3.1 Economy

4.4.3.1.1 Economic Input-Output Model

Economic effects from building are linked to both direct and indirect expenditures. Direct expenditures include costs for materials, equipment, and labor. Indirect effects arise from the spending and purchases of goods and services by the workforce. Through the multiplier effect, each dollar spent by workers and businesses circulates through the economy, creating more jobs, income, and economic activity in the ROI and Project Region. Regional input-output multipliers are economic tools that provide a way to estimate the total impact that an initial change in economic activity has on an economy.

The economic multiplier model used in this analysis is the Regional Input-Output Modeling System (RIMS) II developed by the U.S. Department of Commerce, Bureau of Economic

Analysis (BEA), Economics and Statistics Division. The model calculates economic multipliers for various industries and earnings within a specific region (BEA, 2024). The BEA RIMS II multipliers obtained for the ROI are used to evaluate impacts on employment and economic output based on total employment and total expenditure for a single Plant Complex.

4.4.3.1.2 Economic Model Predictions

The RIMS II direct effect employment multiplier for construction jobs is 1.69. Thus, for every newly created construction job, an estimated additional 0.69 jobs are created in the ROI. The change in indirect employment in the ROI during the building phase is estimated by applying the RIMS II direct effect employment multiplier to the total workforce during the building phase. Based on the workforce needed for a single Plant Complex (2096 workers), building the Project results in the creation of approximately 1437 indirect jobs within the ROI. Most indirect jobs are service-related, and those jobs are filled by the existing workforce in the ROI. Some of these indirect jobs could benefit unemployed or underemployed workers in the ROI. Overall, based on BLS labor force data, the combined approximately 3533 jobs (direct and indirect employment) represent 0.7 percent of the total labor force in the ROI.

The RIMS II multipliers are also used to estimate the economic impact resulting from building expenditures. The RIMS II multiplier for construction industry output is 1.83. Thus, for every dollar spent on building, an estimated $0.83 is added to the economy of the ROI. Total building expenditures for the single Plant Complex are estimated to be approximately $5 billion. Applying the RIMS II multiplier for construction industry output to building expenditures results in a total economic output of approximately $9.3 billion across local industries. This includes goods and services produced in the ROI during the building phase and indirect effects related to worker spending. However, as nuclear power plants are highly specialized in nature, certain building materials and equipment may be obtained from outside the Project Region. For such materials, there would be no economic benefit from the purchase of those goods in the ROI or Project Region. However, building of the Project requires generic construction materials and supplies (concrete, piping, and electrical components) which can be procured locally, if available. The purchase of those materials and supplies has a beneficial economic effect on the ROI. Because details regarding the breakdown of geographic origin of purchased materials and equipment are not available, this analysis assumes that all materials are obtained within the ROI. Therefore, the estimated economic output is higher than is likely to be realized in the ROI and Project Region.

In addition to expenditures by the building workforce, the in-migrating families of the workforce are also expected to spend payroll on goods and services within the ROI. While this spending cannot be precisely quantified, the expenditures associated with the increase of the additional in-migrating population (workers and their families) into the ROI during the building phase result in a beneficial impact on the local economy.

Building activities on the Project site introduce billions of dollars into the economy and indirectly create jobs that help reduce unemployment and provide opportunities for service-related industries. The economic impacts during building are conservatively analyzed based on a single Plant Complex (two advanced reactor units). However, Duke Energy is evaluating reactor technologies that could lead to deploying multiple reactor units across three Plant Complexes, which would result in substantially greater economic effects within the ROI and Project Region. While specialized nuclear materials are likely to be sourced from outside the Project Region, portions of the generic building material expenditures can be obtained in the ROI. These expenditures are primarily realized within the ROI, making the economic impact of construction

beneficial and noticeable.

4.4.3.2 Taxes

Building-related activities, purchases, and labor force expenditures generate tax revenues from individual income taxes, franchise taxes, tax on electricity, sales and use taxes, and property taxes.

4.4.3.2.1 Individual Income Tax

As noted in Section 2.4.2.3, the individual income tax assessed in NC is 4.75 percent for tax year 2023 and is gradually lowering to 3.99 percent by tax year 2026.

As shown on Table 2.4-9, in 2022, more than 500,000 individuals were employed in the ROI; therefore, the addition of the in-migrating workforce (for one Plant Complex) of 1363 is a minor increase in the total employed population in the ROI. According to BLS data, the mean salary of a construction laborer in NC is $40,830 per year (BLS, 2023a). Based on the 2026 tax rate, the additional in-migrating workers for one Plant Complex, at an estimated salary of $40,830 per year according to Section 4.4.3.2.4, are anticipated to generate approximately $2.2 million in income tax revenues for the state of NC (BLS, 2023a). This estimated increase in income tax revenue represents 0.01 percent of total income tax revenue of the state of NC in fiscal year 2023. The in-migrating workforce subsequently generates a minor increase in income tax revenue compared to the revenue from the existing employed population in the ROI. Therefore, there is a minor but beneficial increase in individual income tax revenue within the state of NC and the ROI associated with indirect jobs as a result of building activities.

4.4.3.2.2 Corporate Income Tax and Franchise Tax

For tax year 2023, the state of NC imposed a 2.5 percent income tax on corporations; however, by 2030, this tax will be reduced to zero percent (Section 2.4.2.3). During the building phase, no corporate income taxes are assessed as no revenue is generated from the Project site during this time.

As stated in Section 4.4.3, building activities have a multiplier effect on spending within the ROI that may result in new business developments. Therefore, there may be a minor increase in franchise taxes due to the indirect spending during the building phase. Additionally, existing businesses are likely to experience a minor increase in revenue from increased spending within the ROI, resulting in increased franchise taxes. Because Duke Energy does not pay franchise tax during building activities, the increase in franchise taxes paid by other businesses in the ROI are limited and minor.

4.4.3.2.3 Sale of Electricity

The state of NC imposes a 7 percent tax from the sale of electricity (Section 2.4.2.3). Building activities at the Project site are not anticipated to change the current state of Duke Energy's power assets, and it is anticipated that the sale of electricity remains unchanged. Therefore, no impacts to the sale of electricity tax revenues are anticipated.

4.4.3.2.4 Sales and Use Taxes

Taxable goods and services purchased in NC are subject to the state sales tax at a rate of 4.25

percent and an additional 2.0 to 2.75 percent from local taxing jurisdictions (Section 2.4.2.3). According to BLS data, the mean salary of a construction laborer in NC is $40,830 per year (BLS, 2023a). These workers are likely to spend most of their salaries on housing, goods, and services. Expenditures by the in-migrating workers and their families on items subject to sales and use taxes leads to increases in sales tax revenues in the ROI. Due to the small size of the in-migrating workforce for the deployment of one Plant Complex (two reactor units), the additional expenditures resulting from this population increase have a beneficial but minor impact on sales and use tax revenues in the ROI.

Sales tax revenues may also result from sales taxes collected from the purchase of building-related materials, equipment, and services. The distribution of these taxes depends on businesses located throughout the Project Region. However, estimates of regional expenditures expected during the duration of the building phase are unavailable.

4.4.3.2.5 Property Tax

As described in Section 2.4.2.3, Duke Energy paid Stokes County $6.8 million in property taxes in 2024. At this time, Duke Energy has not entered into or negotiated any special property tax abatements or agreements with Stokes County (Section 2.4.2.3) for the building phase.

If in-migrating workers purchase existing homes in the ROI, as opposed to renting, they continue to pay property taxes on those homes. Because there is sufficient housing available in the ROI (Section 4.4.4.3), it is not anticipated that in-migrating workers would build new housing. Therefore, there is no discernible change in property tax revenues in the ROI.

4.4.3.3 Summary of Economic Impacts

Building activities associated with the Project introduce millions of dollars into the economy and creates both direct and indirect jobs. These positive economic impacts are primarily realized within the ROI. Minor tax revenue impacts on local jurisdictions are accrued through increases in individual income tax, sale of electricity tax, and sales and use taxes. Therefore, the economic impacts are MODERATE and beneficial.

4.4.4 COMMUNITY INFRASTRUCTURE IMPACTS

This section provides the estimated impacts on infrastructure and community services, including transportation, recreation, housing, and public services. As described in Section 4.4.2, this analysis applies the distribution of the existing workforce of BCSS as a predictive indicator of the distribution of the workforce and their families during building activities. Actual workforce distribution and associated impacts on community infrastructure are variable based on the selected places of residency (temporary or permanent) of the workforce employees during the building period.

4.4.4.1 Transportation

This section evaluates the impacts on infrastructure from traffic generated by building activities. Section 4.8.3 discusses accident-related consequences of additional traffic from building activities.

4.4.4.1.1 Traffic

Impacts of the construction workforce on traffic are generally dependent on five factors:

- Number of workers during the building phase.
- Distribution of the workforce within the ROI and related commuting patterns.
- Number of truck deliveries to the Project site.
- Projected population growth rate in the ROI.
- Capacity of the potentially affected roadways.

As stated in Section 4.4.2, there is a peak employment period during which two advanced reactor units are being constructed while four advanced reactor units are operating. The assessment of impacts on traffic is based on this bounding condition. The potential traffic effects of the commuting workforce are determined by predicted commuting patterns which take into account the distribution of the workforce and roadway type. Traffic effects during other phases of the building process are reduced from those of the bounding condition.

The building-phase workforce (2096 workers) (Section 4.4.2) work during the daytime, arriving at 7:00 am and departing at 5:00 pm. During the peak employment period, the total number of workers accessing the Project site also includes an operational workforce of 450. These operational workers are divided into two 12-hour shifts. The day shift begins between 5:00 am and 7:00 am and ends between 5:00 pm and 7:00 pm. During the morning shift 400 operations workers enter for the day shift when 50 operations workers leave after the night shift. Between 5:00 pm and 7:00 pm, 400 workers leave after the day shift and 50 workers arrive for the night shift. As noted in Section 4.4.1.3, Project-related traffic is assumed to access the Project site via Craig Road (Figure 4.4-2).

A common practice for construction workers is to carpool or use employer-provided shared transportation to the construction site. However, this traffic analysis conservatively assumes one worker per vehicle because shared transportation information cannot be determined. This equates to a total of 2546 vehicles that enter and leave the construction site at the same times during peak employment. Additionally, it is conservatively assumed that 90 construction truck deliveries are made daily to the Project site. To reduce congestion, deliveries are not scheduled to arrive or depart at the same time as the construction workforce. Delivery traffic is evenly distributed throughout the work hours of the day and avoids peak traffic hours.

As shown on Table 2.4-3, the population in the ROI is projected to grow at a rate of approximately 0.7 percent annually throughout the building phase. Therefore, any increase in traffic due to population growth is minimal and is not further considered in this analysis.

As described in Section 2.4.2.2.3, the average annual daily traffic (AADT) is the average daily volume of motorized vehicle traffic on a highway or roadway segment. The estimated traffic generated by building activities is based on the assumptions listed above regarding peak employment and on the NC Department of Transportation AADT values shown in Table 2.4-13. Traffic operations for existing conditions and conditions during the building phase were analyzed using the Highway Capacity Software (HCS), which uses methodology from the Highway Capacity Manual Seventh Edition (NASEM, 2022).

Level of service (LOS) is a qualitative measure of operational conditions at a roadway segment or intersection. LOS is given a letter designation ranging from A to F (free flow to heavily congested). As described in Section 2.4.2.2.3, the primary roadways in the Project Vicinity currently operate at an acceptable LOS C or better except for U.S. 158 (east of NC Highway 68) and U.S.158 (between Belews Creek Road and NC Highway 68) which are operating at a LOS D. Roadways described in Section 2.4.2.2.3 and evaluated in this section are the roadways in the Project Vicinity that workforce commuters and other Project-related traffic utilize to access the Project site.

Peak traffic on primary roadways to the Project site in the evening, or "PM peak hour", was analyzed for impacts to LOS during peak employment as PM peak traffic is generally heavier than morning traffic, or "AM peak hour" traffic. This is due to additional activities like school pickups, errands, extracurricular activities, and social events that may occur during the afternoon. LOS during the building phase is shown on Figure 4.4-2 and presented in Table 4.4-2.

LOS along Pine Hall Road (south of NC Highway 65), Belews Creek Road (west of NC Highway 65), Fisherman Road, Hawkins Farm Road, Martin Luther King Jr. Road, and U.S. 220 (south of U.S. 158) does not change during the building phase. The LOS on U.S. 311 (south of NC Highway 65) changes from an A to B during the building phase. LOS on U.S. 311 (north of NC Highway 65), and Pine Hall Road (north of NC Highway 65) changes from A to C during the building phase. Under LOS C conditions, speeds are noticeably reduced on two-way highways. The LOS on U.S. 158 (south of Belews Creek Road), U.S. 220 (north of NC Highway 68), NC Highway 68 (south of U.S. 158), and NC Highway 65 (between Pine Hall North and U.S. 311) changes from C and B to D during the building phase. Under LOS D conditions, vehicles become more closely spaced, with volumes near capacity, on two-way highways.

In comparison, congestion and unstable operating conditions during the building phase cause LOS on other roadways to degrade to a failing LOS (LOS E/F). For example, the LOS on NC Highway 68 (north of U.S. 158), U.S. 158 (between Belews Creek Road and NC Highway 68), and U.S. 158 (east of NC Highway 68) changes from C/D to E/F; whereas the LOS on the remaining roads analyzed (NC Highway 65 [between Belews Creek Road and Pine Hall South], Belews Creek Road [between Craig Road, and NC Highway 65], Belews Creek Road [east of Craig Road], Craig Road, and NC Highway 65 [between Pine Hall South and Pine Hall North]) all experience a degradation of LOS from A/B to E/F during peak employment.

Because of the focused traffic at the intersections providing primary access to the Project site, four intersection locations were also reviewed to further analyze traffic impacts during the building phase. These intersections include Belews Creek Road at Craig Road, NC Highway 65 at Belews Creek Road (to the south), NC Highway 65 at Pine Hall Road (to the south), and NC Highway 65 at Pine Hall Road (to the north). Table 4.4-3 summarizes the results of the analysis for these unsignalized intersections during both existing conditions and during the building phase in the PM peak hour. Increased traffic at these intersections results in a decrease in LOS from LOS C or D to LOS F for at least one of the traffic movements at each intersection. This results in unstable traffic conditions characterized by low speeds, volumes exceeding capacity, and long delays with stop-and-go traffic.

The overall impacts on traffic due to the construction workforce are minor within the broader transportation network. However, impacts on local roads and intersections providing primary access to the Project site are potentially destabilizing (LOS changes from A to C, LOS A/B to

E/F, and LOS C/D to F). Traffic impacts along Craig Road are the most evident as it is expected that Project-related traffic accesses the Project site from the south via Craig Road. The most noticeable traffic impacts occur during the beginning and end of the shift and occur for less than two hours a day. These impacts are most evident to local residents closest to the Project site that access Craig Road. Impacts to roadway capacity are minor during other times of the day.

Duke Energy has identified several planned traffic management measures to minimize congestion and unstable traffic conditions including the following:

- Posting signs near construction entrances and exits to make the public aware of areas with high construction traffic.
- Development of a traffic control mitigation plan.
- Using staggered shift start and end times.
- Using carpooling.
- Enforcing the scheduling of deliveries to avoid peak traffic periods.

With the incorporation of traffic management measures during daily short durations of increased traffic in the immediate area near the Project site, impacts to traffic are noticeable, but not destabilizing.

4.4.4.1.2 Railroads

Some items such as heavy lift crane modules and large components are delivered by rail. Deliveries made by rail enter the Project site via an existing Norfolk Southern spur that branches off to connect to the BCSS as shown on Figure 2.4-4. The use of this rail spur does not impact other transportation systems used by the local communities, and the impact on railroads are minor.

4.4.4.1.3 Waterways

As described in Section 2.4.2.2.7, the waterways located within the Project Vicinity are not used for transportation-related purposes. Therefore, there are no building-related activities on the waterways that affect the transportation system.

4.4.4.1.4 Public Transportation

Public transportation services in the ROI are identified in Section 2.4.2.2.9; however, there are no transit services that provide direct access to the Project site. Therefore, there is no impact on public transportation.

4.4.4.2 Recreation

Recreational resources within the Project Vicinity are potentially affected by building activities at the Project site. Impacts may include (1) disruption of recreational experience from building activities including the cooling water intake and discharge structures within Belews Lake and the Dan River, (2) impaired recreational experience associated with the views of the building activities, (3) increased user demand associated with the projected increase in population as a

result of the in-migrating workforce and their families, and (4) possible access delays associated with increased traffic on local roadways.

Building activities change the recreational experience of hunters and recreators on Belews Lake. While specific restrictions on recreational activities have not been determined at this stage, it is expected that hunting on the Project site will be discontinued. Additionally, fishing tournaments that occur on Belews Lake and require the use of docks, landings, and launch ramps that are owned by Duke Energy may be affected during building activities.

As stated in Section 3.3.4, building the cooling water intake and discharge structures requires working within Belews Lake and the Dan River. This work may impact recreators; however, these activities only occur within a small portion of the lake and river during the overall building phase. Once construction of the cooling water intake and discharge structures is complete, it will no longer hinder recreators. However, if building activities associated with installation of intake or discharge structures impede the use of Belews Lake or associated facilities, including marinas, Duke Energy will coordinate with the NCWRC, as appropriate. Recreators on the Dan River as described in Section 2.4.2.6.2 may also be affected by building activities. For example, the discharge of the wastewater to the Dan River (see Section 3.2.3) may either use the existing discharge structure or be released from a new structure. Building a new structure may temporarily restrict recreational use in proximity to the structure installation area. Such effects, however, are temporary and minor.

Recreation users of Belews Lake may experience visual intrusions during building activities due to the presence of large equipment and construction lighting. Although these building activities alter the undeveloped nature of the Project site, the BCSS and associated infrastructure currently exist within the viewshed of recreators on Belews Lake. However, Duke Energy will maintain the existing natural buffer and implement light shielding, to the extent practicable, to screen views of the Project site. See Section 4.8.2 for noise-related impacts during building on recreators. As stated in Section 2.4.2.6.2, Belews Lake Park is currently in development south of the Project site. Phase one of the multiple construction phase schedule has been completed, and the park is open to visitors. Visitors may experience delays accessing the park's main entrance because of increased traffic on Craig Road due to building activities. These access delays are likely to occur primarily during the start and end of construction shifts.

Recreational areas within the Project Vicinity are also impacted by the increase in population associated with the in-migrating workers and their families. Workers who relocate to the ROI are expected to use recreational areas and outdoor activities at the same rates as the existing permanent population of the ROI. As noted in Section 4.4.2, the in-migrating workforce and their families increase population in the ROI by approximately 0.3 percent. Although the in-migrating population increases usage of recreational areas within the Project Vicinity, the increase is small compared to the existing population and is not anticipated to impede or disrupt current usage of recreational areas.

During the building phase, recreators may experience increased noise levels and aesthetic impacts from building at the Project site. The increased noise levels and aesthetic impacts may be noticeable to individual recreators on Belews Lake in areas adjacent to and north of the Project site; however, it does not reflect an impact that is more broadly evident within the larger reaches of Belews Lake and does not destabilize the overall recreational experience. Building activities are most noticeable to recreators on the lake while the intake and discharge structures are being built. Due to the small increase in in-migrating population, use of recreational facilities in the ROI is anticipated to be similar to existing conditions. Users of the Belews Lake Park may

experience delays associated with workforce and construction traffic on Craig Road; however, effects are more pronounced during work shift changes. Because recreators of Belews Lake are mobile, and the construction time frame is limited, impacts to recreation from building activities are minor.

Overall effects of building activities on recreational activities and resources, including those related to potentially impaired recreational experience associated with the views of the building activities, increased user demand associated with the projected increase in population as a result of the in-migrating workforce and their families, and possible access delays associated with increased traffic on local roadways are minor and short-term.

4.4.4.3 Housing

Section 2.4.2.7 describes the existing housing stock in the ROI. The number of vacant housing units in the ROI in 2022 is shown in Table 2.4-18. As described in Section 4.4.2.2, during peak employment, 1457 workers are housed within the ROI.

The in-migrating workforce demand on current available vacant housing, which is defined as housing units listed as for rent and for sale, is shown on Table 4.4-4. With an in-migration workforce of 1457, approximately 9.8 percent of the available vacant housing in the ROI is used to accommodate in-migrating households. Based on the assumed distribution of the in-migrating workforce within the ROI counties, Forsyth and Guilford counties have ample housing supply, while available vacant housing in Stokes County is deficient with demand exceeding supply. In Rockingham County, approximately 80 percent of available vacant housing is used to accommodate the in-migrating population. Adequate housing is available within the ROI, specifically in Forsyth, Guilford, and Rockingham counties, to accommodate the in-migrating population.

Workers on short-term outage and maintenance assignments may use temporary housing in the form of hotels, seasonal homes (for long-term rentals), and recreational vehicle (RV) parks and campgrounds. As described in Section 2.4.2.7, within Greensboro (Guilford County) and Winston-Salem (Forsyth County), there are 163 hotels, 25 bed and breakfasts, and 28 camping and RV sites. Additionally, within the ROI, there were 3908 seasonal, recreational, or occasional use housing units available in 2022 (Table 2.4-18).

Overall, sufficient housing is available within the ROI to accommodate both in-migrating and temporary short-term workers. Therefore, impacts on housing are minor.

4.4.4.4 Public Services

This section discusses the impacts on the existing water supply, wastewater treatment, police, fire protection, healthcare services, and education in the ROI during building. The impact on public services is primarily driven by the population increase associated with the Project, specifically, in-migrating construction workers and their families. As shown in Table 4.4-1, the estimated population increase associated with construction of the Project is 3614.

4.4.4.4.1 Water Supply and Wastewater Treatment

Table 2.4-21 details the current municipal water suppliers within the ROI and their capacities and utilization rates. All of the counties within the ROI have excess water capacity. The impact to local water supply systems from in-migrating workers and their families is estimated by

calculating the amount of water that is used by the total population increase. The average person in the U.S. uses about 82 gallons of water per day (USEPA, 2023a). The in-migrating workforce and their families account for an approximately 3614-person increase in the ROI, which increases the used capacity by less than 1 percent (Table 4.4-5). Therefore, the impact of the in-migrating workforce and their families on water supply systems is minor.

Current wastewater systems in the ROI and their treatment capacities are detailed in Table 2.4-22. All of the counties within the ROI have excess wastewater treatment capacity. The impact to wastewater treatment systems is calculated by assuming that 100 percent of the water used by the in-migrating population (82 gallons of water per person per day) is disposed of through existing wastewater treatment facilities. While the increase in population from the in-migrating workforce and their families increases use of wastewater treatment facilities within counties of the ROI, as identified in Table 4.4-6, each of the counties has sufficient excess capacity to accommodate the increased demand. Therefore, the relatively small increase in use from the in-migrating workforce and their families has a minor impact on wastewater systems.

4.4.4.4.2 Police and Fire Protection Services

Police services within the ROI are summarized in Table 2.4-23 which shows that the number of police officers per resident (i.e., 1 officer per 445 residents) falls slightly below the nationwide ratio of 2.4 officers per 1000 residents (1 officer per 417 residents) (Section 2.4.2.8). As discussed in Section 4.4.2, approximately 3614 people are migrating into the ROI during the building phase. Table 4.4-7 details the distribution of the in-migrating population and its associated impact on police services within the ROI. The in-migrating population increases the demand on police services by increasing the number of persons per police officer. However, the overall increase in population in the ROI is minimal (0.3 percent increase) (Table 4.4-1), resulting in a change in police services from 445-residents-per-officer to 447-residents-per-officer. Although the service level continues to exceed the nationwide ratio, the net increase in police service needs in the ROI is minor.

Table 2.4-24 details the existing fire protection services within the ROI which shows that the number of firefighters per resident in Forsyth and Guilford counties (i.e., 1 firefighter per 340 and 368 residents, respectively) exceeds the nationwide ratio of one firefighter for every 318 residents (Section 2.4.2.8.) Table 4.4-8 details the distribution of the in-migrating population and its associated impact on fire protection services within the ROI. The in-migrating population increases the demand for fire protection services by increasing the number of persons per firefighter. However, as detailed in Table 4.4-1, the overall increase in population of 3614 people is minimal (0.3 percent increase in population). The increase in population changes the service level in the ROI from the existing condition of 300 residents per firefighter to 301 residents per firefighter. Although the service level in Forsyth and Guilford counties continues to exceed the nationwide ratio, the remaining two counties in the ROI and the ROI overall remain below the nationwide ratio. As such, the limited increase in fire protection service needs is minor.

4.4.4.4.3 Medical Services

Hospitals in the ROI are shown on Table 2.4-25. As discussed in Section 4.4.2, approximately 3614 people are migrating into the ROI during the building phase. Table 4.4-9 details the distribution of the in-migrating population and its associated impact on the availability of hospital beds in the ROI. The in-migrating population increases the demand for hospital beds. However, the population increase is minimal (0.3 percent) and the associated increase in demand for hospital beds is minimal, increasing from 298 residents per hospital bed to 299 residents per

hospital bed. Therefore, the slight increase in number of residents per hospital bed in the ROI is minor.

Physicians and dentists located in the ROI are detailed in Table 2.4-27. Table 4.4-10 details the distribution of the in-migrating population and its associated impact on the availability of physicians and dentists in the ROI. The in-migrating population affects physicians and dental services by increasing the number of patients each provider must care for. However, as detailed in Table 4.4-1, the in-migrating population increases total population in the ROI by 0.3 percent, changing the number of patients per provider from 1169 residents per physician to 1173 residents per physician and 1702 residents per dentist to 1708 resident per dentist. Therefore, the limited increase in number of patients per physician and dentists in the ROI is minor.

4.4.4.4.4 Education

Schools and existing student enrollment are discussed in Section 2.4.2.9. According to 2022 U.S. Census Bureau (USCB) American Community Survey data, 19 percent of the population in NC is between 5 to 19 years old (i.e., school age). Using this percentage and applying it to the total in-migrating population of 3614 persons, approximately 688 persons are of school age. The increase in student enrollment within the ROI is detailed in Table 4.4-11. Assuming that all in-migrating school aged children attend public school, the increase in student enrollment within the ROI ranges from 92 (Guilford County) to 266 (Rockingham County). However, the increase due to the in-migrating school aged children does not change the student -to- teacher ratios within each of the ROI counties or within the ROI (Table 4.4-11). Additionally, the student-to-teacher ratios within the ROI counties and the ROI as a whole remain below the thresholds outlined in Section 2.4.2.9. Therefore, impacts of the in-migrating population on education services are minor.

4.4.4.5 Summary of Community Infrastructure Impacts

Building-related impacts on all infrastructure and community services are SMALL within the ROI, with the exception of traffic impacts. Impacts to transportation due to workforce traffic are SMALL within the broader transportation network, but MODERATE on two-lane segments and intersections that provide access to the Project site due to the short duration of daily peak traffic and implementation of planned traffic management measures to reduce congestion and unstable conditions.

Table 4.4-1
Population Increases in ROI Associated with the Peak Workforce

	Percentage of Existing BCSS Workforce by Place of Residence	Distribution of Workers Needed from Outside ROI	Total Number of New Residents	Baseline Population (2030 Projections)[a]	Percent Increase in Population
Within ROI	75.0%	1457[b]	3614[b]	1,132,724	0.3%
Forsyth County	11.0%	214	530	416,948	0.1%
Guilford County	10.0%	194	482	577,037	0.1%
Rockingham County	29.0%	563	1397	91,571	1.5%
Stokes County	25.0%	486	1205	47,168	2.6%
Outside ROI	25.0%	486[c]	N/A	NA	N/A
Total	**100.0%**	**1943**	**–**	**–**	**–**

Notes:

(a) Source: NCOSBM, 2023

(b) Expected to relocate to the ROI; estimates are rounded to the nearest whole number, accounting for potential discrepancies between the ROI total and the sum of the four ROI counties.

(c) Expected to commute from counties outside the ROI; workers and families continue to reside outside of the ROI and do not impact the ROI population.

4.6 HISTORIC AND CULTURAL RESOURCES

The purpose of this section is to evaluate potential impacts of building the Project on historic or cultural resources within the Area of Potential Effects (APE). As described in Section 2.6, the APE is based on the potential for direct and indirect effects and was determined to be the approximately 1080 ac. (437.06 hectares [ha]) contiguous area where Project impacts may occur, and a wastewater discharge pipeline corridor to the Dan River (Figure 2.6-1).

Building impacts, as well as operational impacts of the Project, determine whether the Project results in an adverse effect on historic properties, as defined in 36 CFR 800.5.

As a federal project requesting a permit from a federal agency, this Project is subject to review and consultation under Section 106 of the National Historic Preservation Act (16 U.S. Code [USC] § 470 et seq.) and its implementing regulations (36 CFR Part 800). Additionally, this Project is subject to the Native American Graves Protection and Repatriation Act (25 USC. 3001 et seq.), the Archaeological Resources Protection Act (16 USC 470aa-mm), the American Indian Religious Freedom Act (42 USC 1996), and the Archaeological and Historic Preservation Act (16 USC 469).

4.6.1 HISTORIC ARCHITECTURE RESOURCES

As noted in Section 2.6.3.1, the NC State Historic Preservation Office (NCSHPO) determined that the Project would not have an effect on historic structures in the Project Vicinity. Therefore, there are no impacts to historic structures from building.

4.6.2 ARCHAEOLOGICAL RESOURCES

Archaeological sites eligible for listing on the National Register of Historic Places (NRHP) may be affected by building the Project. Effects to archaeological sites within the APE and any required mitigation are dependent on the eligibility of each site for listing on the NRHP. Duke Energy conducted a Phase II investigation to assess the significance and eligibility for inclusion of archaeological sites in the APE for eligibility on the NRHP. As described in Section 2.6 and listed in Table 2.6-2, five sites within the APE were recommended as ineligible for listing on the NRHP and received NCSHPO concurrence. The remaining four sites remain in consultation with NCSHPO. Duke Energy has committed to avoidance or mitigation of these sites if they are deemed eligible. If any site is deemed eligible and avoidance is not possible, archaeological mitigation including Phase III data recovery will be required to resolve adverse effects. The results of all data recovery investigations are summarized as a technical report that is reviewed and approved by the NCSHPO.

The results of all data recovery investigations are summarized as a technical report that is reviewed and approved by the NCSHPO.

Ground-disturbing activities during the building phase include land clearing, grading, excavating, road work and facility construction and may have the potential to discover previously unknown archaeological resources or human remains. The Catawba Indian Nation, the only federally recognized tribe with interest in the Project area, requested to be notified if Native American artifacts or human remains are discovered. Consistent with Duke Energy Cultural Resources Procedures, if an inadvertent discovery of a cultural resource (e.g., graves or grave sites, archaeological sites, historical artifacts, etc.) is made during the building phase, then appropriate mitigative measures to address potential effects to these previously unknown

cultural resources will be developed in consultation with the tribes, NCSHPO, and NC Office of State Archaeology (NCOSA). Such measures may include the following:

- Ground-disturbing work will stop within a 50-ft. (15 m) radius of the discovery.
- Should previously unknown archaeological resources be discovered, sites will be protected and stabilized to prevent any further disturbance.
- Consultation will be initiated with the NCSHPO and federally recognized Native American tribes that attach religious and cultural significance to the property affected by the undertaking.
- A discovery plan will be developed and implemented to make an informed NRHP eligibility determination.

In the event of discovery of human remains during building activities, Duke Energy will implement the following measures:

- Ensure that the treatment of any human remains complies with all state and federal laws concerning archaeological sites and treatment of human remains.
- Immediately cease all ground-disturbing activities within a 10-ft. (3 m) radius of the burial.
- Notify the appropriate county coroner and the NCSHPO within 24 hours.

In summary, there were nine sites within the NDA that required further study. The NCSHPO concurred with five sites as being ineligible. The remaining four sites remain in consultation with the NCSHPO. Duke Energy has committed to avoidance or mitigation of any eligible archaeological site. As such, impacts of building activities are SMALL. However, if site avoidance is not possible, Duke Energy will conduct Phase III data recovery investigations in consultation with the NCSHPO. If eligible archaeological sites are not avoidable, impacts of building activities are MODERATE. Additionally, because of the potential for affecting undiscovered resources, mitigative measures developed in consultation with NCSHPO and NCOSA are proposed for addressing unavoidable archaeological sites and previously undiscovered resources.

4.6.3 CEMETERIES

The previously surveyed Branson Cemetery, shown as site [[ ]]^{CRI} on Figure 2.6-3, was visually inspected as part of the Phase I archaeological survey for the Project. The cemetery was determined ineligible for inclusion to the NRHP. However, cemeteries are protected under NC General Statutes Chapter 14-148 and 14-149 and are afforded consideration under Chapter 65. Therefore, the cemetery was recommended for avoidance. Duke Energy has undertaken work to conduct archival research with respect to the cemetery, including its history and associated records. The proposed development plan identified in Figure 3.1-1 assumes that the area within the NDA is permanently disturbed. Branson Cemetery is located within the NDA near the center of the Project site. Therefore, it is determined that avoidance of the Branson Cemetery is not possible. Accordingly, the provisions regarding exhumation and repatriation provided by NC General Statute Chapter 65-106 Removal of Graves will be followed as appropriate. Duke Energy plans to remove all graves in Branson Cemetery and relocate them to

a new burial ground in accordance with an approved cemetery relocation plan that includes delineation of the cemetery boundaries, generation of cemetery maps, and completion of historical and genealogical research. The plan will be developed in consultation with NCSHPO and in accordance with NC General Statute 65-106**.**

4.6.4 SUMMARY OF IMPACTS ON HISTORIC AND CULTURAL RESOURCES

Impacts to any NRHP-eligible archaeological site is minimized through avoidance and mitigated where site avoidance is not possible. Avoidance of the Branson Cemetery is not possible; however, Duke Energy will relocate all graves in accordance with an approved cemetery relocation plan. Therefore, impacts on historic and cultural resources are SMALL to MODERATE.

4.7 AIR RESOURCES

Section 2.7 discusses the meteorological characteristics and air quality at and around the Project site, while Section 4.7 contains a summary of potential cumulative environmental impacts to these resources that are associated with construction activities. The primary impacts on local meteorology and air quality of constructing a new nuclear power plant at the Project site would be from dust generated by land-clearing and building activities, emissions from heavy equipment and machinery, concrete batch plant operations, and emissions from vehicles used to transport workers and deliver materials to and from the site. Air-quality impacts directly associated with these building activities are described below in Section 4.7.1. Air-quality impacts associated with workforce transportation emissions are addressed in Section 4.7.2.

4.7.1 PRECONSTRUCTION AND CONSTRUCTION ACTIVITIES

Preconstruction and construction activities (sometimes referred to jointly as building activities) at the Project site would result in temporary impacts on local air quality. Potential air emission activities include:

- Land clearing and material processing, handling, and removal
- Material placement (e.g., subsurface preparation and concrete pouring and paving)
- Driving piles and erecting structures
- Machinery operation and maintenance
- Truck deliveries of supplies and materials
- Soil transport and temporary stockpiling
- Workforce commute (discussed in Section 4.7.2).

According to NUREG-1555, Section 4.4.1, “Physical impacts to a community from construction of a nuclear plant are not markedly different from any other large heavy construction project.”

4.7.1.1 Air Quality

The Clean Air Act (CAA) regulates air emissions from stationary and mobile sources. It authorizes the U.S. Environmental Protection Agency (USEPA) to establish National Ambient Air Quality Standards (NAAQS) to protect public health and public welfare and to regulate emissions of hazardous air pollutants. Compliance with the applicable regulatory limits defined by the NAAQS (40 CFR Part 50) and National Emission Standards for Hazardous Air Pollutants (40 CFR Part 61) involves implementation of emissions-specific strategies and measures. The Project site is located in the Northern Piedmont Intrastate Air Quality Control Region as set out in 40 CFR 81.150. Additionally, building activities are subject to air permits under state and federal laws that address the impact of air emissions on sensitive receptors.

NAAQS are established by the USEPA in Title 40 CFR Part 50 (Sections 50.4 - 50.13 and 50.15 - 50.18) for defined criteria pollutants which are sulfur dioxide, carbon monoxide (CO), nitrogen dioxide, particulate matter with a diameter less than 10 microns (PM_{10}), particulate matter with a diameter less than 2.5 microns ($PM_{2.5}$), lead, and ozone.

In addition, the USEPA has classified areas of the U.S. where the NAAQS are met (attainment areas), locations that sufficient data are not available for setting a classification (unclassifiable or undesignated), and locations that do not meet the NAAQS (nonattainment areas). These areas are designated on a pollutant-by-pollutant basis. NC reached full attainment with all NAAQS across all counties in 2015 (NCDEQ, 2024a, USEPA, 2024b). The pollutant needed to be redesignated to meet attainment was ozone and on July 28, 2015, the USEPA redesignated the NC portion of the Charlotte-Rock Hill, NC-SC, nonattainment area for the 2008 8-hour ozone NAAQS, effective August 27, 2015 (FR, 2016).

As discussed in Section 2.7, wind speeds at the Project site during 2024-2025 were light with an average 10-m speed of 4.3 mph and a prevailing wind direction from the WSW. Regional mean wind speeds recorded at Piedmont Triad International Airport (KGSO) for the 39-year period from 1983-2022 were moderate with an average annual mean speed of 7.1 mph and a prevailing wind direction from the SW. The wind data for KGSO and the Project site show a consistent pattern of wind directions predominant from the SW, with moderate seasonal variation. Based on the combination of uniformly light to moderate wind speeds and surrounding terrain, there will often be little transport of fugitive dust and other air pollutants away from the site. The impact on the air quality related to construction activities would be temporary and minimal.

4.7.1.2 Heavy Equipment Emissions

Equipment and vehicle emissions from preconstruction and construction activities would contain CO, oxides of nitrogen, volatile organic compounds, and oxides of sulfur to a lesser extent. Fugitive emissions of dust particles (including PM_{10} and $PM_{2.5}$) would be generated during windy periods, earth-moving, and movement of vehicular traffic over recently disturbed or cleared areas. Emissions of fugitive dust and construction equipment engine exhaust are generally limited in duration, infrequent, and localized to the Project area. Additionally, the emissions are intermittent, temporary, and transient (i.e., do not encompass the entire Project site at all times). Because emissions are localized to the Project site, there would be no impact to off-site sensitive receptors and recreation areas from dust and air pollution. As discussed above, the state of NC is in attainment for all criteria pollutants.

Preconstruction and construction activities associated with motor vehicle operation and engines produce temporary gaseous pollutant and particulate matter (PM) emissions. The numbers and types of equipment on-site during the preconstruction and construction phase have not yet been determined. Preliminary emissions estimates are provided in Table 4.7-1.

Authorizations for preconstruction, construction, and operation activities are discussed in Section 1.2. Air permits under NC and federal laws will address the impact of air emissions on sensitive receptors located in the vicinity of the Project site.

Emissions from preconstruction and construction are typically near ground level; therefore, air-quality impacts are greatest at the receptors nearest these activities. Figure 2.3-8 shows the location of the receptors. Emissions are expected to be minor and will be addressed under the NCDEQ and USEPA requirements.

Sensitive receptors, which are potentially affected by the Project, include recreators on Belews Lake, residences just south of the Project site boundary, and residences to the east of the Project site across Belews Lake. Additional sensitive receptors include visitors to the recreation areas within the Project Vicinity and residences and facilities located along access roads to the

Project site. Primary roadways in the Project Vicinity are shown on Figure 2.4-4. Because the surrounding topography consists of rolling hills and steep slopes with forested land, there is visual screening for the Project site from area roadways. The recreation areas within the Project Vicinity are shown on Figure 2.4-5.

There will be a concrete batch plant in operation at the Project site during construction (Section 3.3). PM emissions consisting primarily of cement and pozzolan dust, including some aggregate and sand dust emissions, is the primary pollutant of concern. In addition, there are emissions of some metals that are associated with this PM. The fugitive sources include the transfer of materials, truck loading, mixer loading, vehicle traffic, and wind erosion from storage piles (USEPA, 2011). Types of controls may include water sprays, enclosures, hoods, curtains, shrouds, and movable and telescoping chutes.

Emissions from the concrete batch plants are expected to be minor and will meet the requirements of the NCDEQ General Air Permit for Concrete Batch Plants.

Additionally, Duke Energy plans to implement an emissions mitigation plan. Section 4.4 of the ER lists air emissions mitigation measures that may be used, including the following:

- Phasing activities and equipment use
- Minimizing the idling time of vehicles
- Using properly maintained equipment in compliance with applicable regulations minimizing speeds on unpaved roads
- Watering roads and exposed areas
- Minimizing soil storage piles
- Locating stationary equipment (e.g., generators and compressors) away from sensitive receptors
- Minimizing dust-generating activities during high winds.

4.7.1.3 Greenhouse Gas Emissions

Preconstruction and construction activities, such as operation of on-road construction vehicles, commuter vehicles, nonroad construction equipment, and marine engines, would also result in greenhouse gas (GHG) emissions, principally carbon dioxide (CO_2). GHG emissions for preconstruction and construction equipment are derived from NRC Interim Staff Guidance COL/ESP-ISG-026, Interim Staff Guidance on Environmental Issues Associated with New Reactors (NRC, 2014). This guidance estimates GHG emissions of 39,000 MT CO_2 equivalent (CO_2e) for a reference 1000-megawatt electric (MWe) reactor with a 7-year preconstruction and construction duration (Table A-3. Nuclear Power Plant Lifetime GHG Footprint NRC, 2014). The estimates from the 1000 MW(e) reference reactor is expected to be conservative relative to the Project site, based on the duration of activities and the utilization of advanced reactors. This GHG emission mass in COL/ESP-ISG-026 translates to an emission rate of about 5570 MT CO_2e per unit (33,420 MT CO_2e for six units) annually, averaged over the 7-year period of preconstruction/construction, which amounts to about 0.004 percent per unit (0.0024 percent for six units) of the total estimated GHG emissions in NC (139.45 million metric tons (MMT) of gross) in 2020 (NCDEQ 2024b). This also equates to about 0.00009 percent per unit (0.00054 percent for six units) of the total U.S. annual emission rate of 6.3 billion MT CO_2e in 2022 (USEPA, 2024c). Based on the assessment of the relatively small construction equipment GHG

footprint compared to total NC and U.S. annual GHG emissions, the atmospheric impacts of GHGs from preconstruction and construction activities would be minimal and additional mitigation would not be warranted.

In general, emissions from preconstruction and construction activities, including GHG emissions, would vary based on the level and duration of a specific activity, but the overall impact is expected to be temporary and limited in magnitude. It is stated in Section 4.4.1.2 that emission-specific strategies and measures would be developed and implemented to ensure compliance with the applicable regulatory limits defined by the NAAQS (40 CFR Part 50). Additionally, a dust control program would likely be implemented by the Project site. Based on the applicant's stated intent to develop and implement strategies to reduce emissions to ensure compliance with federal, State, and local regulations, the impacts on air quality from Project site preconstruction and construction activities would not be noticeable and appropriate mitigation measures would be adopted.

4.7.2 TRAFFIC (EMISSIONS)

During building activities, additional commuter vehicles, trucks, and other construction vehicles would pass daily through Pine Hall Road or Craig Road, leading into the Project site (see Figure 2.4-4 for primary roadways). This traffic would include the passenger cars and light-duty trucks of the preconstruction and construction workforce and truck traffic for delivery of construction materials and heavy equipment used to support development (e.g., excavators, bulldozers, heavy-haul trucks, cranes). Increases in emission levels are expected to be temporary and would have a minimal impact on air quality from criteria pollutants.

The overall impact caused by increased traffic volume and congestion would be localized and temporary. The ER identifies mitigation measures that would be developed before building activities begin. These traffic mitigation measures would reduce the impact of increased traffic on air quality. Potential mitigation measures involve additional traffic ramps and changes to intersections to reduce congestion. Workers may carpool to the site to minimize the effect of added vehicle traffic.

Workforce transportation would also result in GHG emissions, principally CO_2. Assuming a 7-year period for preconstruction and construction activities and a typical workforce size, it is estimated that the total workforce GHG emission footprint for building a new 1000 MW(e) nuclear power plant at the Project site would be on the order of 43,000 MT CO_2e. The assumptions, factors, and other information used in any site-specific analysis will be described in sufficient detail to allow an independent evaluation and assessment of the resulting GHG emissions estimate per NRC COL/ESP-ISG-26 (Environmental Issues Associated with New Reactors Interim Staff Guidance).

Workforce transportation emissions from the Project site during the construction period amounts to about 0.09 percent of the total estimated GHG emissions from transportation in NC (50.35 MMT of gross CO_2e) in 2020 (NCDEQ, 2024b) and about 0.002 percent of the total estimated gross CO_2e U.S. transportation emissions (1810.4 MMT [USEPA, 2024a]).

Based on the relatively small preconstruction and construction workforce GHG footprint compared to the NC and U.S. annual GHG emissions, atmospheric impacts of GHGs from workforce transportation would not be noticeable, and additional mitigation would not be warranted. Based on the limited increase in local vehicle traffic and Duke Energy's stated intent to develop mitigation measures listed in the ER, the impact on the air quality related to

preconstruction and construction activities, including the effect of GHG emissions, would be temporary and not noticeable.

4.7.3 SUMMARY

An evaluation of potential impacts on air quality associated with criteria pollutants and GHG emissions during the Project site building activities is outlined above. It is determined that the impacts are minimal. On this basis, it can be concluded that the impacts on air quality from emissions of criteria pollutants and GHGs during Project site preconstruction and construction would be SMALL and that no further mitigation would be warranted beyond the mitigation strategies discussed for air emissions in Section 4.4.1.2.

4.8 NONRADIOLOGICAL HEALTH

Nonradiological health impacts on the public and workers from building activities at the Project site are described in this section. It includes the impacts on public and occupational health (Section 4.8.1), the impacts of noise and vibration (Section 4.8.2), and the impacts of transporting building materials and personnel to and from the Project site (Section 4.8.3). Nonradiological health impacts are summarized in Section 4.8.4.

4.8.1 PUBLIC AND OCCUPATIONAL HEALTH

Members of the public may be subject to health impacts from building activities at the Project site. Section 4.4.1 discusses health impacts to the public from building activities associated with noise and vibration, fugitive dust and odors, and air emissions from building equipment and vehicles. Section 4.4.1 notes that these impacts are minor due to the distance of the receptors from the Project site and the localized nature of the hazards.

Building activities involve risks to workers and on-site personnel from occupational accidents, injuries, and illnesses. These risks can result from exposure to airborne contaminants during close contact with solvents, exhaust, and other building-related chemicals; exposure to biological hazards, such as naturally occurring toxins in vegetation and insects; exposure to physical hazards, including slips, trips, and falls; heat or cold stress, burns, frostbite, noise; electric shock; and repetitive motion injuries. Section 2.8.1.1 describes that construction workers and on-site personnel receive training and use personal protective equipment to minimize the risk of potential harm (Duke Energy, 2023b). Regular health and safety monitoring is conducted during building activities as required.

Duke Energy facilities implement a range of control measures to minimize fugitive dust emissions. These measures include watering roads, covering truck loads, stabilizing material stockpiles, minimizing material handling, and limiting vehicle speeds. Worker health risks from engine exhaust are minimized by maintaining equipment in good mechanical condition. Fuel, oils, lubricants, and other fluids such as antifreeze are properly stored and handled to reduce risk to workers. Procedures for SPCC are used to prevent and mitigate adverse impacts to the public.

The BLS publishes statistics on incidence rates of occupational illnesses, injuries, and fatalities for all U.S. companies. As presented in Tables 2.8-1 and 2.8-2, in 2022 the construction industry incidence rate for nonfatal occupational injuries and illness was 2.4 per 100 full-time workers and the rate of fatal work injuries was 9.6 per 100,000 full-time equivalent workers (BLS, 2023b, c).

The incidence of nonfatal injuries and illnesses during the building phase has been calculated as the incidence rate times the number of workers. Using the construction workforce of 2096 (as provided in Section 4.4.2), recordable nonfatal injuries and illnesses during the building phase is estimated at 50 incidents. Based on the 2022 fatal occupational injury incidence rate from BLS and the construction workforce of 2096, fatal occupational injuries during construction would be less than one (0.2 incidents).

To protect workers and the public, mitigation measures outlined in the Duke Energy Environmental, Health, and Safety handbook are used to control fugitive dust emissions and minimize exposure to chemical spills and leaks. Chemical, biological, and physical occupational hazards are reduced by adhering to Occupational Safety and Health Administration, NC, and

Duke Energy safety standards and procedures. Safety training and the use of personal protective equipment further mitigate risks to workers.

Given the impacts associated with building activities that affect public health are minor, and the Project complies with all federal and state regulations, impacts on workers and the public from building activities are minor.

4.8.2 NOISE AND VIBRATION

Increased noise levels from building-related activities and traffic at the Project site may impact nearby sensitive receptors, which include residents and recreation users. Some activities that generate noise are also vibration-inducing activities; therefore, vibration impacts were analyzed in conjunction with the noise impacts.

4.8.2.1 Noise

Section 2.8.2 provides information and data related to background noise levels at the Project site. As Section 2.8.2.2 describes, there are no municipal, county, or state-level regulations that establish quantitative noise level limits applicable to the Project site. The USEPA guidelines recommend that outdoor noise levels do not exceed a day-night average community noise level of 55 dBA. However, this level is not a regulatory goal and is intentionally conservative to protect the most sensitive portion of the population with an additional margin of safety. The Department of Housing and Urban Development uses day-night average sound levels recommended by USEPA as guidelines for outdoors in residential areas. Noise levels are acceptable and allowable if the day-night average sound level outside a residence is less than or equal to 65 decibels. Therefore, this threshold provides the basis for impact determination in this analysis.

During building activities at the Project site, noise levels increase relative to background noise levels because of the operation of vehicles and machinery and building-related traffic. Building activities require the use of heavy equipment for clearing, excavating, grading, and building the facilities. Table 4.8-1 identifies building equipment that may be used during building activities and the attenuated noise levels for each piece of equipment at various distances.

Sound levels from operating most standard building equipment listed in Table 4.8-1 are 85 dBA or less at 50 ft. (15 m) from the source. An exception is the pile driver, which can reach up to 110 dBA at 50 ft. (15 m) from the source. Pile-driving activities are expected to occur periodically within the power block areas and may also occur as part of the intake and discharge structure installation. During building activities, temporary cofferdams may be used for shoreline or marine-based installations. Cofferdams are generally constructed of driven sheet piles, which are removed after the structure is built. Additionally, as described in Section 3.3.2 excavation for foundations including the power block and other support systems (see Figure 3.3-1), will likely require controlled rock blasting. Periodic blasting activities may produce noise levels that reach 126 dBA at 50 ft. (15 m) from the source (WSDOT, 2020). Noise from an isolated explosive blast event may be equivalent to a thunderclap at the source, or approximately 97 dBA at the nearest residence, and would be temporary and short-term.

Section 2.8.2 describes the nearest off-site noise-sensitive receptor to the Project site. This receptor is a residence located along Craig Road, approximately 44 ft. (13.4 m) south of the Project site boundary at its closest point. Notably, several other residents along Windswept Drive are also close to the Project site boundary but at greater distances than the nearest

residence along Craig Road. The loudest noise emissions during building activities that may affect this receptor are from building equipment that operates near the southern boundary of the Project site. Pile driving and rock blasting emit greater noise but would not occur at the southern boundary of the Project site.

Estimates of sound levels are calculated using straight-line noise attenuation which assumes sound travels in a straight line and attenuates based on distance. Based on straight-line attenuation, noise levels from the most standard operating equipment attenuate to 65 dBA or less at a distance of 500 ft. (152 m). However, for residents within this distance, noise levels remain at about the 65 dBA threshold. Environmental conditions that affect sound propagation such as vegetation, topography, and water are not factored into the calculation. Assuming straight-line noise attenuation, the loudest piece of equipment used during building (excluding pile driving and rock blasting, which would not occur at the southern boundary of the Project site) produces a sound level of 85 dBA measured at 50 ft. (15 m) from the source (Table 4.8-1). This equates to approximately 86 dBA at the nearest residence. Although the modeled 86 dBA at this receptor is notably greater than the average ambient noise levels for this area (Table 2.8-5), it represents a worst-case modeling assumption in which the loudest piece of equipment (excluding pile driving and rock blasting) is operated at the boundary of the NDA closest to the receptor. However, it is noted that portions of the Project site nearest to sensitive noise receptors are designated as laydown areas, and as such, they experience only occasional noise due to intermittent use and limited construction activity. In contrast, areas of the Project site located more than 500 ft. from the southern site boundary are subject to more frequent and elevated noise levels. These levels are expected to diminish to below 65 dBA at the site boundary. As a result, the overall impact of building-related noise on sensitive receptors is minimal.

Building equipment used for site preparation is not stationary but mobilizes across the Project site. As this equipment moves, the location of the noise source shifts, and the distance between the source and any given receptor increases, resulting in lower noise levels at that receptor over time. For example, as shown in Table 4.8-1, noise from equipment that attenuates to 85 dBA or less at 50 ft. (15 m) from the source attenuates to 67 dBA at 394 ft. (120 m) from the source. Most building activities occur well within the Project site boundary, and similar attenuation demonstrated in Table 4.8-1 indicates noise levels at residential receptors will remain below 65 dBA. As such, exposure to high noise levels for any particular receptor at or along the Project site boundary is variable and short-term during the building phase.

The nearest recreational area is Belews Lake, which is located immediately adjacent to the Project site boundary (Figure 2.4-5). Belews Lake is used for recreational boating and fishing. Residential areas are located along the shoreline of Belews Lake opposite the Project site. Most building activities at the Project site use typical equipment that produces noise levels of 85 dBA or less at 50 ft. (15 m) from the source (Table 4.8-1). These building activities do not occur directly at the Project site boundary along Belews Lake because of an approximate 100 ft. (30 m) vegetative buffer zone along the shoreline. Based on similar noise attenuation distances demonstrated in Table 4.8-1, the typical equipment used attenuates to 79 dBA at 98 ft. (30 m) near the site boundary. As described above, while this is greater than the 65-dBA threshold, it represents a conservative scenario in which the loudest piece of equipment is operated at the boundary of the NDA closest to the shoreline. As recreational areas of Belews Lake extend over large distances away from the Project site and shoreline residences are located across the lake (shown in Figure 3.1-2), noise levels from building activities attenuate to below 65 dBA for most lake users and residents. However, noise levels from the most standard operating equipment may be greater than 65 dBA only for recreators and residences within 500 ft. (152 m) of the

NDA. Additionally, building activities that involve pile driving or rock blasting may temporarily impact recreators. For example, pile driving during the installation of the intake and discharge structures near the Project site boundary generates noise exceeding 65 dBA on localized portions of Belews Lake. However, these building activities are short-term and temporary.

In addition to dispersed recreation occurring on Belews Lake, the closest developed recreational area is J. Dudley Watts Jr. Park (Belews Lake Park), which is approximately 1181 ft. (360 m) from the Project site boundary and approximately 3668 ft. (1118 m) from the southern power block. Assuming straight-line noise attenuation, the noise produced by the loudest piece of equipment (pile driver) operated at the closest power block area, attenuates to approximately 73 dBA at the park boundary. However, pile driving would be completed within a limited time frame, minimizing noise impacts to recreators in the park. Noise levels from other typical building equipment operated at the Project site boundary for much of the building period attenuate to approximately 58 dBA, which is less than the NRC threshold of 65 dBA.

The increase in traffic associated with workers commuting to the Project site and the delivery of construction materials also results in the generation of noise on roadways providing access to the Project site. Noise levels may increase on roadways based on vehicle, type, speed, and terrain. Noise would attenuate with distance to nearby residential receptors along the roadway network. These effects are more pronounced at residential receptors located close to Craig Road as it is expected that all Project-related traffic accesses the Project site from the south via this road. Noise impacts related to this increased traffic are most apparent during the morning and evening shift changes, when the volume of vehicles entering and exiting the site is at its peak. Such noise levels effects are short-term and temporary.

As stated, the maximum noise levels are higher than 65 dBA at each of the nearest sensitive receptors during building activities. However, as noise-producing equipment mobilizes across the Project site, the noise levels at any given point fluctuate, minimizing the overall noise impact by preventing prolonged exposure to high noise levels at the receptors closest to the Project site boundary. Noise is also minimized in areas where a vegetative buffer is retained along the perimeter of the Project site. Therefore, noise impacts from building activities are minor and further minimized through the use of common practices to mitigate noise, which include:

- Using noise-reduction devices on heavy equipment (e.g., mufflers).
- Limiting driving speeds, use of “Jake brakes,” and tail-gate slamming.
- Constructing earthen berms.
- Placing foliage or ground cover between the noise sources and receptors.

4.8.2.2 Vibration

Section 4.4.1.1 discusses vibration from the operation of heavy machinery, building-related vehicles, and blasting during building activities. As shown in Figure 4.4-1, residential annoyance begins at a level of 80 VdB at 50 ft. (15 m) from the source for infrequent events. The use of bulldozers and other heavy-tracked building equipment at 50 ft. (15 m) from the source may generate vibration levels of 95 VdB, which can be disruptive and may make concentrating on tasks such as reading a computer screen difficult. As noted in Section 4.8.2.1, the nearest residence is located along Craig Road, approximately 44 ft. (13 m) south of the Project site at its closest point; therefore, the nearest residents may be temporarily disrupted by vibration from building equipment. However, the use of mobile-heavy equipment near any one specific location

along the southern Project site boundary is relatively short-term and intermittent (not continuous). Thus, the impact of building-related vibration on public health is minor.

4.8.3 EFFECTS OF TRANSPORTATION OF CONSTRUCTION MATERIALS AND PERSONNEL TO AND FROM THE PROJECT SITE

This section analyzes how potential impacts related to increased traffic on roadways near the Project site during the building phase could increase the number of vehicle accidents involving injuries and fatalities. The analysis estimated new vehicle trips and additional traffic crashes including injuries and fatalities based on the peak employment period, which as described in Section 4.4.4.1, includes 2096 construction workers and 450 operations workers. In addition, as stated in Section 4.4.4.1, it is conservatively assumed that 90 construction truck deliveries per day are made to the construction site. Although building-related deliveries do not occur when workers arrive and depart the Project site, for this analysis, these deliveries are accounted for in the building-phase AADT along the roadways providing access to the Project site.

The crash rates (number of crashes per mi. per year) for the Project were estimated using the University of Florida Transportation Institute Highway Safety Software (HSS) (UTFI, 2025). The crash rates are estimated by considering the increase in AADT due to building-phase traffic on the primary roadways that provide access to the Project site. The predicted increase in traffic volume is used to estimate potential changes in crash rates consistent with the methodologies outlined in the Highway Safety Manual (AASHTO, 2024). Crash rates (predicted crashes per mi. per year) were developed for the existing condition (2024) to provide a baseline and the building phase for the roadway segments that commuters and delivery trucks use to access the Project site. In addition, predicted crash rates for the existing condition and building phase were developed at four intersections along these roadways: Belews Creek Road at Craig Road; Belews Creek Road at NC Highway 65; NC Highway 65 at Pine Hall Road (to the south); and NC Highway 65 at Pine Hall Road (to the north).

The HSS crash rate estimates predict average crash rates as a function of traffic volumes, roadway type (e.g., controlled-access), roadway characteristics (e.g., roadway geometry, number of lanes, lane width, shoulder type) and road segment length. The predicted crash rate associated with the increase in AADT during building for surrounding roadway segments identified in Figure 4.4-2 is shown in Table 4.8-2. These crash rates are variable. For example, the highest crash rates are predicted for U.S. 220, which is a high volume (AADT greater than 25,000), controlled-access freeway. By comparison crash rates are lowest on small local roads having a low AADT such as Craig Road, Fisherman Road, and Hawkins Farm Road. Crash rates for most roadway segments analyzed are predicted to be slightly higher for the building phase relative to the existing condition. The increase for Craig Road was greater than any other roadway segment (0.11 to 0.73). While notable, this increase is relatively minor. Overall, predicted crashes along the roadway network serving the Project site during the building phase are minor and do not destabilize traffic safety.

Table 4.8-3 presents predicted crashes at the four intersections that provide access to the Project site. The HSS estimates the number of predicted crashes based on factors including traffic volume, intersection geometry, and control. The number of predicted crashes at most intersections analyzed increase marginally during the building phase. The increase in predicted crashes (both injury and fatality) at the intersection of Belews Creek Road and Craig Road is slightly higher than as predicted at the other intersections analyzed. Overall, the effects of predicted increases in crash rates at intersections during the building phase on human health are minor.

The addition of vehicles associated with building-phase traffic results in a minor increase relative to the current traffic accident injury risk on the surrounding roadway network used by commuters to access the Project site. This minor increase is minimized through implementation of the traffic management measures identified in Section 4.4.4.1.

4.8.4 SUMMARY OF IMPACTS TO NONRADIOLOGICAL HEALTH

Impacts on nonradiological health and safety of workers and the public are minimized through compliance with all applicable state and federal regulations. Based on the most conservative application of analyses, noise levels at residences closest to the Project site are higher than the 65 dBA during building activities; however, because noise levels attenuate rapidly with distance, the sources of noise emission will also vary as equipment is mobilized across the Project site. Additionally, exposure to high noise levels for any particular receptor at or along the Project site boundary is short-term and temporary. As such, noise impacts are minor. The impact of building-related vibration on public health is minor. The addition of vehicles during the building phase on local roads accessing the Project site results in a minor increase in crashes. Based on these impact determinations, the nonradiological health impacts of building activities are SMALL.

Table 4.8-1
Noise Levels Expected for Operation of Representative Building Equipment

Source	Attenuated Noise Levels (dBA)			
	50 ft. [a] (15 m)	98 ft. [b] (30 m)	197 ft. [b] (60 m)	394 ft. [b] (120 m)
Backhoe	80	74	68	62

4.9 RADIOLOGICAL HEALTH

The purpose of this section is to estimate the annual radiation doses to construction workers at the Project site. As determined in the discussion below, construction workers are classified as members of the public and are not subject to radiation monitoring. Section 3.3.5 states that multiple units are anticipated to be sequentially constructed at the Project site.

As stated in Section 3.1, the Project site contains three separate disconnected advanced reactor areas classified as the Middle, North, and South Plant Complexes. These locations are shown in Figure 3.1-1.

The proposed construction schedule, contained in Table 3.3-1, shows that construction of the next unit or set of units would be complete one year after the previously completed unit(s) until the last scheduled unit has completed construction at the North Plant Complex at the Project site. Using this construction schedule, the construction worker analysis conservatively analyzes the dose to workers, with all but one unit constructed and operating. However, the analysis is performed at the Middle Plant Complex due to location conservatisms, despite the construction schedule indicating the final unit(s) constructed will be located at the North Plant Complex. Because the number of units vary based on the advanced reactor technology, and the advanced reactor technology has not been selected, the detailed construction worker dose analysis conservatively utilizes the bounding radionuclide release activity in Section 3.4.

Additionally, because construction workers will not be at a fixed location on the Project nor a constant distance from the operating units throughout the duration of their time on the Project site, the analysis bases the location (and therefore the assumed distance from an operating unit) of the workers with respect to the center of the assumed location of the last reactor building under construction.

4.9.1 DIRECT RADIATION EXPOSURES

4.9.1.1 Radiation Sources

Construction workers may be exposed to direct radiation sources from plant buildings and facilities of operating units (e.g., radioactive waste handling facilities, low-level waste storage facilities, condensate storage tanks) while subsequent units are under construction.

4.9.1.2 Calculated Dose Rates

Because an advanced reactor technology has not been selected, data available for larger operating pressurized-water reactors is considered in the construction worker dose analysis to provide a good indication (even compared to different technologies) that the potential direct radiation doses to construction workers next to operational reactors would be SMALL. Based on measurements previously used to estimate the construction worker dose for the construction of Vogtle Electric Generating Plant Units 3 and 4, and adjusting for changes in exposure time, distance, and power generation, the annual dose to an individual construction worker from direct shine of operating units is calculated to be 2.68E+01 mrem. This corresponds to an annual dose to the total construction workforce to be 5.63E+01 person-rem.

4.9.2 RADIATION EXPOSURES FROM GASEOUS EFFLUENTS

4.9.2.1 Radiation Sources

As stated in Section 3.4.2.5, radioactive gaseous effluents are released to the environment through a controlled and monitored release point (e.g., plant vent). Additionally, radioactive gases from plant system leakage to the building atmosphere will travel through ventilation systems, passing through filtration, and is released through monitored building ventilation system release points. The expected exposure pathways considered for construction workers include:

- External exposure to airborne radioactivity (Air Submersion)
- Inhalation of airborne radioactivity

Ground shine dose is assumed to be negligible in this evaluation. The annual dose due to ground shine from normal operation at the Project site boundary is significantly less than the air submersion plume dose from normal operation at the Project site boundary The construction worker is located within the Project site boundary and therefore closer to the release point, meaning that the construction worker ground shine dose is even smaller than the dose at the Project site boundary and the air submersion dose is larger.

The ingestion component that is due to eating and drinking food is not included in this section for determining dose due to exposures from gaseous effluents because it is assumed the food and drink ingested on the Project site will be sourced from beyond the Project site.

Additionally, as stated in Section 2.9, any gaseous effluents released from the McGuire Nuclear Station and the Shearon Harris Nuclear Power Plant is expected to be negligible. Therefore, gaseous effluents from McGuire Nuclear Station and Shearon Harris Nuclear Power Plant are not included in the analysis as a contributable radiation source.

4.9.2.2 Calculated Dose Rates

The methodology for estimating the annual dose to the construction workforce at the Project site uses a bounding atmospheric relative concentration value (i.e., atmospheric dispersion factor [χ/Q]) for the Plant Complexes containing operating reactors, bounding release activities, appropriate dose conversion factors, estimated total number of construction workers, and the estimated number of hours construction workers are expected to be on-site.

A χ/Q representing similar or bounding distance and wind direction for Plant Complexes containing operating reactors is utilized from the analysis performed to provide χ/Q values in Section 2.7. The χ/Q is determined using the XOQDOQ computer code, which implements RG 1.111 methodology.

The bounding χ/Q for Plant Complexes containing operating units are determined in an analysis using the constant mean wind direction model from RG 1.111. The distance from the release point is assumed to be 100 m (328.0 ft.) from the unit under construction based on analysis in which the construction worker is assumed to be in the middle of the Middle Plant Complex and the units (the operating unit and the unit under construction) evenly spaced from the other unit on the Middle Plant Complex and the eastern or western edges of the power block on the Middle Plant Complex boundary, respectively. Additionally, construction workers are conservatively assumed to be standing at the center of the gaseous effluent plume. The

bounding χ/Q for the Plant Complexes containing operating units is 1.10E-03 seconds per cubic meters (s/m^3).

Construction workers are assumed to be present at the Project site for 2400 hours per year (i.e., 40 hours per week for 50 weeks, with an overtime factor of 1.2), and the maximum number of workers during any period while construction of the subsequent unit is 2096. The analysis conservatively utilizes the projected bounding release activities from a single reactor, located in Table 3.4-7. The release activities in Table 3.4-7 are multiplied by the respective number of units operating at each Plant Complex (e.g., two operating units at both the South and North Plant Complexes and one operating unit at the Middle Plant Complex).

The dose received by construction workers due to inhalation are scaled using ICRP Publication 68 and is calculated to be 1.48E-02 rem annually. This corresponds to an annual dose to the total construction workforce to be 3.11E+01 person-rem.

The dose received by construction workers due to air submersion are scaled using ICRP Publication 144 and is calculated to be 3.93E-02 rem annually. This corresponds to an annual dose to the total construction workforce to be 8.24E+01 person-rem.

4.9.3 RADIATION EXPOSURES FROM LIQUID EFFLUENTS

4.9.3.1 Radiation Sources

As stated in Section 3.4.2.1, small quantities of radioactive effluents may be released to the environment at designated release points, typically in the cooling water discharge stream. While it is expected that the Project site cooling water discharge stream releases radioactive liquid effluent into the Dan River, it is not expected that construction workers will ingest any food, be submerged in liquid sources, or be located near the shoreline exposed to radioactive liquid effluent release pathways from operating units. Additionally, construction workers are not expected to ingest any drinking water exposed to radioactive liquid effluent pathways as the construction site has access to potable water lines that can be tied into for construction purposes. Therefore, construction workers are not expected to be exposed to radioactive liquid effluent pathways.

4.9.3.2 Calculated Dose Rates

Construction workers are not expected to be exposed to radioactive liquid effluent pathways, therefore no dose is received from any radioactive liquid effluent pathways from the Project site. Doses from liquid effluent pathways to members of the public, including construction workers when not on the job, are evaluated in Section 5.9 and are included in the dose contribution assumed to be received by the construction workers as members of the general public in Section 4.9.4.

4.9.4 TOTAL DOSE TO CONSTRUCTION WORKERS

As noted in Sections 4.9.1 through 4.9.3, the exposure pathways calculated for the Project site construction workers are from both direct shine and gaseous effluents of operating units during subsequent construction This includes external exposure to workers in the form of air submersion and inhalation. The sum of the doses to construction workers calculated in Sections 4.9.1 through 4.9.3 is the Total Effective Dose Equivalent (TEDE) of the estimated individual and collective construction worker dose results. These results are presented in Table 4.9-1 for

the individual construction worker and Table 4.9-2 for the collective construction workforce. The TEDE to an individual construction worker is determined to be 8.11E-02 rem to the individual and 1.70E+02 person-rem to the collective workforce of 2096 persons.

The dose limits for individual members of the public are found in 10 CFR 20.1301 and 10 CFR 20.1302. Table 4.9-3 lists the dose limits from 10 CFR 20.1301 and 10 CFR 20.1302 and compares against the values determined for the construction worker dose analysis. Based on the analysis presented in this section, the dose to construction workers is within the limits from 10 CFR 20.1301 and 10 CFR 20.1302, As such, construction workers are classified as members of the public and do not require additional monitoring. Therefore, impacts to construction workers from radiation exposure would be SMALL.

Table 4.9-1
Total Annual Construction Worker Doses

Exposure Type	Exposure (rem)
Dose Equivalent from Direct Shine	2.68E-02
Dose Equivalent from Gaseous Effluents	5.41E-02
Total Effective Dose Equivalent (TEDE)	8.10E-02

Table 4.9-2
Collective Construction Worker Doses

Parameter	Value
Total Individual Construction Worker TEDE (rem)	8.10E-02
Assumed Worker Population (persons)	2096
Total Collective TEDE (person-rem)	1.70E+02

Table 4.9-3
Comparison of Construction Worker Dose to Dose Limits

Exposure Type	Exposure	10 CFR 20.1301 and 10 CFR 20.1302 Limits	Percent of Limit
Annual Construction Worker TEDE (mrem/yr)	81.0	1.00E+02	81.0%
Dose from External Sources to Construction Worker in 1 Hour (mrem/hr)	9.25E-03	2	0.462%

4.10 NONRADIOACTIVE WASTE MANAGEMENT

Potential environmental impacts may result from the generation, handling, and disposal of nonradioactive waste during building activities at the Project site. Types of nonradioactive wastes generated, handled, and disposed of include cleared vegetation, building material debris, spoils, stormwater runoff, municipal and sanitary waste, dust, other air emissions, used oils and lubricants from heavy equipment maintenance, and other hazardous chemicals. The following sections present an assessment of potential impacts resulting from these types of wastes.

4.10.1 IMPACTS TO LAND

Impacts to land include waste generated by building and equipment maintenance activities, workforce activities, and storage and disposal of cleared vegetation, soil, rock, and other debris. Building activities generate vegetation and other earthworks waste, general waste, metal waste, and equipment waste within the Project Vicinity and Project site. As stated in Section 3.4.3.3.1, Duke Energy's Environmental Programs maintain policies and procedures to ensure waste is properly managed to ensure safe handling and to minimize environmental impacts. All nonradioactive waste will be segregated based on waste type and its potential hazards and stored in appropriate containers. Waste segregation will occur at the point of generation, and waste will be labeled accordingly to facilitate proper disposal. Impacts to land use from building activities are presented in Section 4.1.

As stated in Section 3.4.3, Duke Energy's existing waste management programs, which comply with federal, state, and local regulations, are followed to manage wastes generated during operation. It is expected that impacts to land from nonradioactive wastes generated during building would be minimal and that no further mitigation would be warranted.

4.10.1.1 Vegetation and Other Earthworks Waste

Clearing, grubbing, and grading activities at the Project site generate waste materials, such as vegetation, soil, and rock debris. This material is stockpiled in a remote location on-site and transported off-site as needed. Stockpiles on-site are covered with soil and have vegetative cover. Excavated material not suitable for fill is disposed of in accordance with federal, state, and local regulatory requirements.

4.10.1.2 General Waste

Building waste includes paper, wood, shipping materials, and miscellaneous material that are recycled or properly disposed of in regulatory-permitted and Duke Energy-approved landfills. Inert debris from existing operations is taken to Winston-Salem landfill for disposal. Winston-Salem/Forsyth County Utilities operates a state-permitted, active, municipal solid waste landfill on Hanes Mill Road. This is a composite-lined landfill permitted to accept municipal solid waste from Davie, Forsyth, Stokes, Surry, and Yadkin counties. Additionally, Hanes Mill Road Solid Waste Facility accepts construction debris (CWS, 2024a). The Hanes Mill Road Landfill reported an approximate 27.3 years remaining in the Landfill Capacity Report for Fiscal Year 2022-2023 (NCDEQ, 2024c). The City of Winston-Salem also operates the Old Salisbury Road Landfill for waste materials generated for construction and demolition activities. There is sufficient land at the Old Salisbury Road Landfill to meet construction and demolition waste disposal needs until approximately the year 2030 (CWS, 2024b). Other regional landfills may also be considered to support the waste disposal needs during the building phase.

Common waste includes aerosol cans, antifreeze, lighting, batteries, asbestos, and grease. Duke Energy manages these items in accordance with federal and state waste regulations. The waste is shipped to an approved site and, depending on the waste stream, may be processed by a Duke Energy-approved disposal or recycling facility. NC characterizes suspended or recalled pesticides, mercury-containing devices, lamps, and batteries as universal waste. Universal wastes are a subset of hazardous waste that can be managed under reduced requirements.

4.10.1.3 Metal Waste

Building activities generate metal waste from multiple sources. These sources include, but are not limited to, steel from structural installation, pipe of different alloys (e.g., carbon steel, stainless steel), rigid steel conduit, instrument tubing, steel support materials (e.g., framing, angle iron, tube steel), metal hardware and miscellaneous fasteners, metal shipping material, and building materials, such as purlins and siding. Materials are recycled to the fullest extent possible to reduce the impact on local municipal solid waste landfills and facilities. As stated in Section 3.4.3.3.1, Duke Energy Environmental Programs uses administrative policies and procedures to ensure all employees and contractors properly manage waste. .

4.10.1.4 Equipment Waste

Equipment waste is generated from on-site building-related vehicles and equipment. Routine maintenance is performed at an on-site mechanic shop. Volumes of equipment wastes at the Project site are comparable to other construction projects of similar size. Used oils and grease are stored at a designated location in accordance with applicable regulatory requirements. Used hazardous materials are transported to a licensed disposal facility for recycling and disposal. On-site fueling occurs at a centralized location and locally at the equipment location. Drip pans and other containment systems are utilized to retain any spillage. This waste is disposed of in accordance with permitting conditions and regulatory requirements. As stated in Section 3.4.3.3.1, Duke Energy's existing waste management programs, which comply with federal, state, and local regulations, are followed to manage wastes generated during building.

4.10.1.5 Impacts to Land Summary

Solid waste generation is minimized through the proposed practices mentioned herein and in accordance with Duke Energy waste procedures. In the Project Vicinity, adequate landfill capacity is available to meet the projected demand for waste disposal needs during the building phase. Duke Energy's required pollution prevention activities (e.g., SPCC plans) limit the impacts of wastes. Additionally, management of solid wastes complies with all applicable federal, state, and local requirements and standards. Therefore, the impacts on land from nonradioactive solid wastes generated during building activities are SMALL, and mitigation is not warranted.

4.10.2 IMPACTS TO WATER

Impacts to water from nonradioactive wastes associated with building activities include impacts from construction of the cooling water intake structure and discharge structures, erosion from disturbed areas and associated sedimentation within receiving waters, and potential effects associated with inadvertent spills within the Project site and Project Vicinity. Impacts to water from building activities are presented in Section 4.2.

4.10.2.1 Impacts to Water from Nonradioactive Wastes

Waste affects water primarily from sanitary wastewater treatment, stormwater runoff, vehicle maintenance activities, and accidental spills. Potential impacts related to accidental spills of petroleum products or industrial chemicals necessary for building activities may result in adverse effects on surface water quality. Pursuant to Title 40 of the CFR Part 112, an SPCC plan, which includes the use of BMPs to minimize the occurrence of spills and limit their effects on surface water, has been implemented at the Project site. BMPs include actions such as maintaining vehicles and equipment, containment for fuel or oil storage tanks, and maintaining spill response equipment and materials. As described in Section 3.3.2, designated storage areas for fuel and lubricants on the Project site are equipped with appropriate spill containment measures in accordance with the SPCC plan.

Installing erosion and sediment control devices is necessary to comply with NCDEQ's NPDES Construction Stormwater Permit, as described in Section 3.3.2. These controls include silt fencing, filter socks, stabilized construction entrances potentially with wheel wash systems, sediment basins, floating turbidity barriers, or similar systems used for managing stormwater during construction activities. Additional measures include containment and spill response kits and systems for construction materials such as oils, paints, and chemicals. These practices minimize potential water pollution impacts at the Project site and in the Project Vicinity.

Release points and methods are determined by site-specific characteristics to ensure that water quality standards are upheld during potential dewatering events.

Portable sanitary facilities on-site are used as needed during the peak building period until a permanent connection to the sanitary waste treatment facility is functional. All waste collected from these temporary facilities is disposed off-site by a licensed sanitary waste disposal contractor.

4.10.2.2 Impacts to Water Summary

The impacts of nonradioactive waste on water are minimized through the use of BMPs, which reduce pollutant loading and decrease downstream impacts on water quality. The potential for spills of petroleum or industrial chemicals are managed through the use of SPCC plans. Therefore, the impacts of nonradioactive waste during building activities to water are SMALL.

4.10.3 IMPACTS TO AIR

This section evaluates information on building activities that generate dust or emissions and the related potential impacts to air quality. Plans to mitigate potential associated impacts are also included in this section. Section 2.7 discusses the meteorological characteristics and air quality at and around the Project site. Impacts on air resources during building and operation are further discussed in Sections 4.7 and 5.7, respectively.

4.10.3.1 Air-Quality Impacts

Potential air-quality impacts substantially derived from building activities and inclusive of the development of the associate off-site pipeline corridor include the following:

- Land clearing and material processing, handling, and removal, including the construction of access roads.

- Material replacement (e.g., subsurface preparation and concrete pouring and paving).
- Driving piles and erecting structures.
- Machinery operation and maintenance.
- Truck deliveries of supplies and materials.
- Soil transport and temporary stockpiling.

Emissions of fugitive dust and construction equipment engine exhaust are generally limited in duration and localized to the Project site, as discussed in Section 4.7.1.2. Because emissions are localized, there are negligible impacts to off-site sensitive receptors and recreation areas from dust and air pollution.

Section 4.7.1.3 discusses the potential GHG emissions from construction and preconstruction activities. Building activities, such as operation of on-road construction vehicles, commuter vehicles, and non-vehicle construction equipment, result in GHS emissions, principally carbon dioxide. The atmospheric impacts of GHGs from construction and preconstruction activities are not noticeable and additional mitigation is not warranted.

Table 4.10-1 lists potential major equipment used during building. Initial equipment is primarily related to excavation, along with forklifts and cranes for offloading material. As the Project progresses, cranes, aerial work platforms, truck trailers, forklifts, and grading equipment are used. Preliminary emission estimates are provided in Section 4.7.

To alleviate impacts on air quality, various mitigation measures lower emissions during preconstruction and construction. Section 4.4 lists air emissions mitigation measures that may be used, including the following:

- Phasing activities and equipment use.
- Minimizing the idling time of vehicles.
- Using properly maintained equipment in compliance with applicable regulations minimizing speeds on unpaved roads.
- Watering roads and exposed areas.
- Minimizing soil storage piles.
- Locating stationary equipment (e.g., generators and compressors) away from sensitive receptors.
- Minimizing dust-generating activities during high winds.

As stated in Section 4.4.1.2, emission-specific strategies and measures ensure compliance with the applicable regulatory limits defined by the National Primary and Secondary Ambient Air Quality Standards (40 CFR Part 50). Duke Energy implements a dust control program and develops strategies to reduce emissions to ensure compliance with federal, state, and local regulations. Emissions of fugitive dust and construction equipment engine exhaust are limited in duration and localized to the Project area and necessary mitigation is implemented as needed. Therefore, the impacts on air quality from building activities are expected to be SMALL and localized to the Project site.

Table 4.10-1
Major Equipment Used During Building Activities

Major Equipment Classes
Class 02 Trucks - Light Duty
Class 03 Trucks - Heavy Duty
Class 04 Trailers
Class 05 Rebar Shop
Class 06 Personnel Carriers
Class 11 Earthmoving
Class 12 Pipelaying and Trenching Equipment
Class 13 Compaction
Class 14 Cranes
Class 15 Forklift
Class 16 Concrete and Aggregate
Class 17 Air Compressors
Class 18 Crane Accessories
Class 22 Rigging Equipment
Class 23 Gantry Equipment
Class 25 Cable Laying and Pulling Equipment
Class 28 Containers
Class 29 Site Services
Class 51 Winches and Tuggers
Class 52 Welding Equipment
Class 53 Generation Equipment
Class 54 Manlifts and Scissor lifts
Class 55, 56 Small Capital Equipment

4.11 MEASURES AND CONTROLS TO LIMIT ADVERSE IMPACTS DURING CONSTRUCTION

This section summarizes potential adverse environmental impacts from construction and preconstruction activities (collectively referred to as “building activities”) discussed in previous sections of this chapter, and the associated measures and controls to limit those impacts.

Construction activities subject to NRC authorization are those that have a reasonable nexus to radiological health and safety or common defense and security (NRC, 2007). Examples of construction activities defined in Title 10 of the CFR Part 50, specifically 50.10(a)(1) include the following: pile driving, subsurface preparation, placement of backfill, concrete, soil stabilization activities or permanent retaining walls within an excavation; installation of foundations; or in-place assembly, erection, fabrication, or testing of specified structures, systems, or components. This application does not include a Limited Work Authorization permit request - accordingly, Project activities are limited to preconstruction activities.

Preconstruction activities include those described in 10 CFR 50.10(a)(2), such as site preparation (e.g., clearing, grading, and installation of erosion control, and other environmental mitigation measures), erection of fences, excavation, erection of support buildings or facilities, building service facilities (e.g., roads, parking lots, rail lines, transmission lines, sanitary-treatment system, potable water system), and procurement or fabrication of components occurring at a location other than the final, in-place location at the site.

4.11.1 ADVERSE ENVIRONMENTAL IMPACTS

Duke Energy actively avoids and minimizes adverse environmental impacts wherever evident during building activities at the Project site. However, some adverse environmental impacts are unavoidable and result from building activities.

Impacts of building activities are analyzed in the previous sections of Chapter 4. A discrete significance level (i.e., SMALL, MODERATE, or LARGE) of potential impact to each resource is assigned consistent with the criteria established by the NRC in 10 CFR Part 51, Subpart A, Appendix B, Table B-1, footnote 3. This footnote defines the significance levels based on the potential for environmental effects and their ability to be mitigated or avoided and include the following:

- SMALL – Environmental effects are not detectable or are so minor that they will neither destabilize nor noticeably alter any important attribute of the resource. For the purposes of assessing radiological impacts, the NRC has concluded that those impacts that do not exceed permissible levels in the NRC’s regulations are considered small.
- MODERATE – Environmental effects are sufficient to alter noticeably, but not to destabilize, important attributes of the resources.
- LARGE – Environmental effects are clearly noticeable and are sufficient to destabilize important attributes of the resource.

Table 4.11-1 summarizes the potential impacts attributable to building the Project and describes their designated significance levels. If there is no impact to a resource from building activities, a “no impact” descriptor is used.

4.11.2 MEASURES AND CONTROLS TO LIMIT ADVERSE IMPACTS

Table 4.11-1 lists potential adverse building impacts that require mitigation, along with the corresponding measures and controls to minimize these environmental impacts. The listed measures and controls have been designed to be clear, specific, and reasonable; achieve a practical level of mitigation; and involve methods and techniques that are appropriate, achievable, and can be verified through subsequent field reviews and inspections.

Examples of general measures to minimize impacts on the environment include:

- Using BMPs for construction activities.
- Implementing plans to manage stormwater and to prevent and appropriately address accidental spills.

In addition to the general measures discussed above, the following specific factors limit potential adverse environmental impacts related to building activities at the Project site:

- Compliance with federal, state, and local laws, ordinances, and regulations intended to prevent or minimize adverse environmental effects (e.g., solid waste management, erosion and sediment control, air emissions, noise control, stormwater management, discharge prevention and response, and hazardous waste management).
- Compliance with applicable requirements, permits, and licenses required for building the Project (e.g., land disturbance permit and other applicable building-related permits) as listed in Section 1.4.
- Implementation of environmental compliance activities during construction for the new plant, including solid waste management, hazardous waste management, and discharge prevention and response.
- Incorporation of environmental requirements into construction contracts.
- Identification of environmental resources and potential effects during development of this ER.
- Development of relevant mitigation measures.

Review and revision of mitigation measures and controls, as appropriate, based on final design, in accordance with appropriate environmental regulations and permits.

Table 4.11-1
Summary of Measures and Controls to Limit Adverse Impacts During Construction
(Sheet 1 of 13)

Environmental Resources (Section Reference)	Summary Impact Finding	Impact Description or Activity	Mitigating Measures and Controls
4.1 Land Use Impacts			
On-site Impacts	MODERATE	1. Conversion of land (primarily forested land) to an industrial use. 2. Disturbance of approximately 906 acres (ac.) (367 hectares [ha]). 3. Ground-disturbing activities, including clearing, grubbing, excavation, and grading. 4. Generation of general waste, metal waste, and equipment waste. 5. Stockpiling of soils on-site. 6. Planned uses in compliance with current zoning in Stokes and Forsyth counties. 7. Conversion of prime farmland. 8. Discontinuation of hunting on the Project site. 9. Temporary disruption of public access to Duke Energy-owned docks, landings, and launch ramps on Belews Lake during building activities.	1. No mitigation measures or controls identified. 2,3. Grade each Plant Complex area to balance earthwork cut and fill quantities to the greatest extent practical. 4. Dispose of all building material in accordance with federal, state, and local regulatory requirements. 5. BMPs for erosion and sedimentation control are developed and installed prior to building activities and are maintained throughout construction. 6. Obtain appropriate county approvals for zoning as per Table 1.4-2. 7. No required mitigation measures or controls identified in consultation with the U.S. Department of Agriculture Natural Resources Conservation Service. 8. No mitigation measures or controls identified. 9. Access will be restored after building activities are complete.
Off-site Impacts	SMALL	1. Ground-disturbing activities, including clearing, grubbing, grading, trenching, and backfilling. 2. No change in corridor use.	1. BMPs for erosion and sedimentation control will be developed and installed prior to building activities and are maintained throughout construction. 2. No mitigation measures or controls needed.

Table 4.11-1
Summary of Measures and Controls to Limit Adverse Impacts During Construction
(Sheet 2 of 13)

Environmental Resources (Section Reference)	Summary Impact Finding	Impact Description or Activity	Mitigating Measures and Controls
4.2 Water-Related Impacts			
4.2.1 Hydrologic Alterations			
Surface Water	SMALL	1. Direct effects of up to approximately 16,875 linear feet (ft.) (5144 linear meters [m]) of streams and 100 linear ft. (30.5 m) within the associated off-site wastewater pipeline. Indirect effects to 1256 linear ft. (323 linear m) of streams.	1. Implement avoidance, minimization, and mitigation measures in accordance with Section 401 and 404 permitting by NCDEQ and U.S. Army Corps of Engineers (USACE), respectively. 1. Implement BMPs to stabilize soils, control sedimentation and stormwater flows, and remove construction debris to minimize indirect impacts to streams outside the NDA.
		2. Effects to local stormwater drainage patterns from building activities within the NDA.	2. Implement a stormwater management system that complies with regulatory requirements for site design. 2. Comply with NCDEQ permit for land disturbance and stormwater management. Implement BMPs and USACE 404 permit at completion of building activities. 2-4. Use temporary features to facilitate building and/or protect water quality during construction. These features will comply with relevant regulations, agency approvals, and typical standards for construction-related to erosion control and sedimentation.
		3. Localized and short-term increases in turbidity and sediment deposition and alteration of the Belews Lake shoreline and bottom associated with building intake and discharge structures.	3,4. Use erosion control measures (such as rip rap) placed in proximity to the building area.

Table 4.11-1
Summary of Measures and Controls to Limit Adverse Impacts During Construction
(Sheet 3 of 13)

Environmental Resources (Section Reference)	Summary Impact Finding	Impact Description or Activity	Mitigating Measures and Controls
		4. Localized sediment disturbance and alteration of the Dan River associated with building outfall in discharge wastewater pipeline corridor.	4. Obtain and comply with site-specific terms of USACE permit for placement of fill.
		5. Alteration of floodplains from installation of wastewater pipeline.	5. Use BMPs to minimize impacts from use of heavy equipment in the floodplain and revegetate or rehabilitate the floodplain after installation of the wastewater pipeline.
Groundwater	SMALL	1. Localized changes in groundwater levels from dewatering during excavation.	1. No mitigation measures or controls needed.
		2. Reduced infiltration and groundwater recharge in the immediate area of new impervious surfaces.	2. No mitigation measures or controls needed.
4.2.2 Water-Use Impacts			
Surface Water	SMALL	1. Use of surface water for concrete mixing, dust suppression, and other building-related activities.	1. Specific measures and controls are not needed.
Groundwater	SMALL	1. No planned use of groundwater during building activities.	1. No mitigation measures or controls needed.

Table 4.11-1
Summary of Measures and Controls to Limit Adverse Impacts During Construction
(Sheet 4 of 13)

Environmental Resources (Section Reference)	Summary Impact Finding	Impact Description or Activity	Mitigating Measures and Controls
4.2.3 Water Quality Impacts			
Surface Water	SMALL	1. Erosion and sedimentation associated with impacts to and alteration of on-site streams and stormwater from building activities.	1-3. Use BMPs in addition to NCDEQ 401 permit and controls to protect affected water bodies.
		2. Erosion and sedimentation associated with impacts to and alteration of Belews Lake from building activities.	1-3. Use BMPs to minimize erosion and sedimentation and establish and implement a SWPPP.
		3. Erosion and sedimentation associated with impacts to and alteration of Dan River from building activities.	1-3. Comply with NCDEQ NPDES general construction permit requirements to discharge stormwater associated with building activities and implement and SWPPP.
		4. Release of constituents from potential minor spills of hazardous materials (e.g., fuels, oils) into receiving water resources.	4. Establish and implement an SPCC plan for construction practices. 4. Use best construction practices to maintain equipment and prevent spills and leaks.
Groundwater	SMALL	1. Release of groundwater to the surface from dewatering during excavation.	1. Comply with NCDEQ NPDES permit to discharge water from groundwater dewatering associated with building activities.
		2. Inadvertent spills of fluids may affect groundwater resources.	2. Establish and implement an SPCC plan for construction practices.

Table 4.11-1
Summary of Measures and Controls to Limit Adverse Impacts During Construction
(Sheet 5 of 13)

Environmental Resources (Section Reference)	Summary Impact Finding	Impact Description or Activity	Mitigating Measures and Controls
4.3 Ecological Impacts			
4.3.1 Terrestrial Ecosystems and Wetlands	MODERATE	1. Direct impacts to terrestrial flora and fauna and habitat loss due to building activities including land clearing, grading, excavation, and filling; displacement of wildlife and loss of less mobile fauna.	1. Use erosion controls and follow BMPs to control erosion from disturbed land and reduce impacts to nearby waters.
		2. Opportunities for invasive species to become established during building activities.	2. Conduct periodic monitoring and control measures.
		3. Potential impacts to bird nests and migratory birds during building activities.	3. Minimize or avoid tree clearing during nesting season from April to July or use Duke Energy compliance recommendations.
		4. Potential impacts from bird collisions with structures and nocturnal pollinator disruption due to artificial lighting during building activities.	4. Minimize the amount of nighttime light, using downshielding, avoiding landscape lighting features, and using only low-pressure sodium, high-pressure sodium, or light-emitting diode light sources.
		5. Direct impacts to 2.45 ac. (0.99 ha) of wetlands within the Project site and 0.26 ac. (0.11 ha) within the associated off-site wastewater pipeline area.	5. Comply with NCDEQ and USACE 404 permit mitigation measures to achieve no net loss objectives.
		6. Indirect impacts to wetlands outside of the NDA associated with hydrologic alterations, erosion and sedimentation, encroachment of invasive species and habitat function.	6. Implement BMPs, such as erosion and sedimentation controls that limit the transport of sediment to wetlands via stormwater, comply with 33 CFR Part 332 “Compensatory Mitigation for Losses of Aquatic Resources,” which promotes the national goal of “no net loss” of wetland acreage and functions.

Table 4.11-1
Summary of Measures and Controls to Limit Adverse Impacts During Construction
(Sheet 6 of 13)

Environmental Resources (Section Reference)	Summary Impact Finding	Impact Description or Activity	Mitigating Measures and Controls
		7. Direct impacts to tricolored bat and foraging and roosting habitat due to clearing during building activities.	7. Implement tree-clearing restrictions or consult with USFWS and conduct surveys. Conduct culvert surveys.
		8. Impacts to monarch butterfly foraging habitat on the Project site.	8. Consult with USFWS regarding potential effects to the monarch butterfly if this species becomes federally listed.
		9. Potential impacts to bald eagle during active nesting season.	9. Avoid disturbance within 660 ft. of bald eagle nest during nesting season. Coordinate with the USFWS prior to construction and implement applicable conservation measures.

Table 4.11-1
Summary of Measures and Controls to Limit Adverse Impacts During Construction
(Sheet 7 of 13)

Environmental Resources (Section Reference)	Summary Impact Finding	Impact Description or Activity	Mitigating Measures and Controls
4.3.2 Aquatic Ecosystems	SMALL	1. Direct impacts on aquatic biota in Project site streams as well as indirect impacts by flow alteration and increased sedimentation and turbidity from building activities.	1. Comply with NCDEQ and USACE 404 permit guidelines. Use BMPs to control erosion and limit the amount of soil and sediment entering surface waters. Develop and implement a SWPPP for collection, mitigation, and control of stormwater runoff in accordance with state and federal regulations and permit requirements.
		2. Potential impacts aquatic biota and habitats related to accidental spills of petroleum products or industrial chemicals.	2. Designate storage areas for fuel and lubricants on the Project site that are equipped with appropriate spill containment measures in accordance with SPCC plans.
		3. Impacts to aquatic habitats and biota, including those to native species and habitats in vicinity of Belews Lake due to dredging, increases in turbidity and sediment deposition during installation of intake and discharge structures and associated pipelines.	3. Use BMPs such as cofferdams, silt curtains, wattles, or turbidity curtains to contain and control sedimentation. Maintain approximate 100-ft. (30.5-m) vegetated buffer around Belews Lake. Shoreline stabilization and buffer zones are protective of native aquatic species and habitats.
		4. Impacts to Dan River habitat due to physical habitat alteration, direct effects to or avoidance of aquatic biota.	4. See 2. and 3. above.
		5. Potential alterations to proposed critical habitat for Green Floater within the Dan River.	5. Consult with USFWS and NCWRC regarding avoidance, minimization, and appropriate conservation measures.

Table 4.11-1
Summary of Measures and Controls to Limit Adverse Impacts During Construction
(Sheet 8 of 13)

Environmental Resources (Section Reference)	Summary Impact Finding	Impact Description or Activity	Mitigating Measures and Controls
4.4 Socioeconomic Impacts			
4.4.1 Physical Impacts (includes noise, odors, dust, air pollution, physical transportation impacts, and visual intrusions)	SMALL to MODERATE	1. Vibration effects to off-site residences and structures from building-related blasting and equipment use are below the threshold for risk of minor cosmetic damage to fragile buildings. 2. Increase in emissions of on-site gaseous and particulate pollutants from construction vehicles and equipment, delivery vehicles, and personal vehicles. 3. Increase in emissions of fugitive dust and fine PM from earthmoving activities, concrete batch plant operation, and vehicular traffic on recently disturbed areas or unpaved roads. 4. Deterioration of public roads used during building activities. 5. Visual and aesthetic effects during building activities, including effects from lighting for nighttime building and security.	1. No mitigation measures or controls needed. 2. Comply with Clean Air Act National Ambient Air Quality Standards and regulatory limits. 2. Use BMPs and properly maintain construction equipment and vehicles to control emissions. 3. Use BMPs to minimize dust generation and implement dust control measures by watering roadways and exposed areas. 4. Repair damage to public roads, markings, or signs caused by building activities to preexisting conditions or better in accordance with state and local requirements. 5. Maintain natural existing buffers to screen views of the Project site, including an approximately 100 ft. (30.5 m) wide vegetated buffer zone along the edge of the Project site. 5. Implement light shielding to the extent practicable.
4.4.2 Demographic Impacts	SMALL	1. Potential effects related to in-migration of workers and their families.	1. No mitigation measures or controls identified.
4.4.3 Economic Impacts to the Community	MODERATE (Beneficial)	1. No adverse impacts.	1. No mitigation measures or controls needed.

Table 4.11-1
Summary of Measures and Controls to Limit Adverse Impacts During Construction
(Sheet 9 of 13)

Environmental Resources (Section Reference)	Summary Impact Finding	Impact Description or Activity	Mitigating Measures and Controls
4.4.4 Community Infrastructure (includes transportation, recreation, housing, and public services)	SMALL to MODERATE	1. Increased traffic in the vicinity of the Project site due to transport of workforce and materials, including potentially destabilizing impacts on two-lane segments and intersections providing primary access to the Project site.	1,4. Implement traffic management measures, including a traffic control mitigation plan.
		2. Disruption of recreational experience from building activities, including visual intrusions.	2. Coordinate with the NCWRC, as appropriate, if construction of the cooling water intake and discharge structures impede use of Belews Lake or associated facilities, including marinas. 2. Maintain natural existing buffers to screen views of the Project site. 2. Implement light shielding to the extent practicable.
		3. Increased user demand for recreational resources from in-migrating workforce and their families.	3. No mitigation measures or controls needed.
		4. Possible access delays or disruptions because of increased traffic on local roadways and building activities.	4. Access disruptions are mitigated by traffic management measures and a traffic control mitigation plan and restored when building activities are completed.
		5. Discontinuation of hunting on the Project site.	5. No mitigation measures or controls identified.
		6. Sufficient housing is available within the ROI to accommodate in-migrating and temporary workers.	6,7. No mitigation measures or controls needed.
		7. Increase in demand for public services from in-migrating individuals and their families.	
4.5 Not Used[(a)]	N/A	N/A	N/A

Table 4.11-1
Summary of Measures and Controls to Limit Adverse Impacts During Construction
(Sheet 10 of 13)

Environmental Resources (Section Reference)	Summary Impact Finding	Impact Description or Activity	Mitigating Measures and Controls
4.6 Historic Properties	SMALL to MODERATE	1. No impacts to historic structures from building.	1. No mitigation measures or controls needed.
		2. Impacts to any site eligible for listing on the NRHP if avoidance is not possible.	2. Implement avoidance measures for any NRHP-eligible archaeological site as required. 2. If required, develop Phase III data recovery investigations in coordination with NCSHPO for any NRHP-eligible archaeological site that cannot be avoided. 2. Implement procedures for addressing inadvertent cultural resource discoveries per Duke Energy Cultural Resources Procedure.
		3. Potential for effects to undiscovered resources.	3. Consult with the NCSHPO, NCOSA, and Catawba Indian Nation and implement mitigative measures as appropriate, if previously unknown archaeological resources or human remains are discovered during any building activities. Human remains would be treated in accordance with all state and federal laws.
		4. Relocation of Branson Cemetery	4. Conduct archival research on the cemetery, including its history and associated records. 4. Follow provisions regarding exhumation and repatriation provided by North Carolina General Statute Chapter 65-106 as appropriate. 4. Develop cemetery relocation plan in consultation with NCSHPO that includes delineation of the cemetery boundaries, generation of cemetery maps, and completion of historical and genealogical research.

Table 4.11-1
Summary of Measures and Controls to Limit Adverse Impacts During Construction
(Sheet 11 of 13)

Environmental Resources (Section Reference)	Summary Impact Finding	Impact Description or Activity	Mitigating Measures and Controls
4.7 Air Resources	SMALL	1. Potential for air emissions from preconstruction and construction activities associated with heavy equipment to impact sensitive receptors located in the vicinity of the Project site. 2. Potential for PM emissions from the concrete batch plant in operation. 3. Potential for GHG emissions from preconstruction and construction equipment and on-road vehicles. 4. Varying emissions from preconstruction and construction activities based on level and duration of activity. 5. Emissions from additional commuter vehicles, trucks and other construction vehicles.	1. Adhere to the NCDEQ and USEPA requirements. 2. Implement control methods including water sprays, enclosures, hoods, curtains, shrouds, and movable and telescoping chutes. 3. Develop and implement emission-specific strategies and measures to ensure compliance with the applicable regulatory limits defined by the NAAQS (40 CFR Part 50). 4. Implement dust control program. 5. Implement mitigation measures including additional traffic ramps and changes to intersections to reduce congestion. Encourage workers carpool to minimize the effect of added traffic.
4.8 Nonradiological Health	SMALL	1. Potential for exposure of workers and the public to chemical hazards or physical nonradiological hazards.	1. Implement the SPCC plan; conduct equipment maintenance and stabilize roads and soil stockpiles to minimize fugitive dust. 1. Adhere to NRC, U.S. Occupational Safety and Health Administration, state, and Duke Energy safety standards and provisions for worker safety. 1. Implement worker safety training and require use of personal protective equipment.

Table 4.11-1
Summary of Measures and Controls to Limit Adverse Impacts During Construction
(Sheet 12 of 13)

Environmental Resources (Section Reference)	Summary Impact Finding	Impact Description or Activity	Mitigating Measures and Controls
		2. Modeled, worst-case variable and short-term noise levels above 65 dBA at nearby sensitive residential and recreational receptors 3. Short-term and intermittent disruptive vibration levels 4. Potential for minor increase in accident rate with increased construction traffic.	2. Use common practices to mitigate noise, including noise-reduction devices on heavy equipment and limiting driving speeds. 3. No mitigation measures or controls needed. 4. Implement traffic management measures including a traffic control mitigation plan.
4.9 Radiological Health	SMALL	1. Exposure to construction workers is within established regulatory limits.	1. No specific mitigation measures or controls identified.
4.10 Nonradioactive Waste Management			
4.10.1 Impacts to Land	SMALL	1. Increased generation, storage, and disposal of waste during building activities.	1. Implement policies and procedures under Duke Energy's Environmental Programs to properly manage waste to ensure safe handling and minimize environmental impacts. 1. Properly dispose of waste in accordance with federal, state, and local regulatory requirements. 1. Recycle metal waste and other materials to the fullest extent possible to reduce impacts on local municipal solid waste landfills and facilities. 1. Implement BMPs to minimize waste generation from on-site construction vehicles.

Table 4.11-1
Summary of Measures and Controls to Limit Adverse Impacts During Construction
(Sheet 13 of 13)

Environmental Resources (Section Reference)	Summary Impact Finding	Impact Description or Activity	Mitigating Measures and Controls
4.10.2 Impacts to Water	SMALL	1. Potential for accidental spills into water resources.	1. Implement an SPCC plan and associated BMPs to minimize the occurrence of spills and limit their effects on surface water. 1. Adhere to the NCDEQ NPDES Construction Stormwater Permit requirements to minimize impacts from stormwater runoff into receiving waterbodies. 1. Maintain portable sanitary facilities on-site and properly dispose of sanitary waste until a permanent connection to the sanitary waste treatment facility is functional.
4.10.3 Impacts to Air	SMALL	1. Air emissions from building activities including gaseous pollutants and PM.	1. Building-related emissions are typically limited to the vicinity. 1. Implement air emissions mitigation measures to ensure compliance with applicable regulatory limits defined by the National Primary and Secondary Ambient Air Quality Standards (40 CFR Part 50) and state and local regulations.

Notes:

(a) Deleted (Executive Order, 2025a, 2025b)

Key: ac. = acre; BMP = best management practice; CFR = Code of Federal Regulations; dBA = A-weighted decibels; ft. = feet; ha = hectare; m = meter; NCOSA = North Carolina Office of State Archaeology; NCSHPO = North Carolina State Historic Preservation Office; NCDEQ = North Carolina Department of Environmental Quality; NCWRC = North Carolina Wildlife Resources Commission; NDA = net disturbance area; NPDES = National Pollutant Discharge Elimination System; NRC = Nuclear Regulatory Commission; NRHP = National Register of Historic Places; ROI = region of influence; SPCC = Spill Prevention, Control, and Countermeasures; SWPPP = stormwater pollution prevention plan; USACE = U.S. Army Corps of Engineers; USFWS = U.S. Fish and Wildlife Service

GLOSSARY

Term	Definition
°C	degree Celsius
°F	degree Fahrenheit
7Q10	7-day Duration, 10-year Return Period
AADT	average annual daily traffic
ac.	acre
ac-ft	acre-feet
AERMOD	American Meteorological Society/USEPA Regulatory Model
AGL	above ground level
ALARA	as low as is reasonably achievable
APLIC	Avian Power Line Interaction Committee
BCSS	Belews Creek Steam Station
BDBE	beyond design basis event
BLS	U.S. Bureau of Labor Statistics
BMP	best management practice
BTA	best technology available
Btu	British thermal unit
Btu/hr	British thermal unit per hour
BWR	boiling-water reactor

Term	Definition
CCW	condenser cooling water
cfm	cubic feet per minute
CFR	Code of Federal Regulations
cfs	cubic feet per second
cm	centimeter
CO	carbon monoxide
CO_2	carbon dioxide
CO_2eq	carbon dioxide equivalent
CORMIX	Cornell Mixing Zone Expert System
CTM	critical thermal maxima
CWA	Clean Water Act
CWIS	cooling water intake structure
CWS	circulating water system
dBA	A-weighted scale decibel
DBA	Design Basis Accident
Delta-T	vertical temperature difference
DOE	U.S. Department of Energy
D/Q	Ground Deposition Factor

Term	Definition
EAB	exclusion area boundary
EAB/LPZ	exclusion area boundary/low population zone
EMF	electromagnetic field
EPRI	Electric Power Research Institute
ER	Environmental Report
ESP	Early Site Permit
ESPA	Early Site Permit Application
ESRP	environmental standard review plan
FGD	flue gas desulfurization
ft.	feet
ft/s	feet per second
g	gram
g/s	grams per second
GA	general arrangement
GHG	greenhouse gases
gpd	gallons per day
gpm	gallons per minute
GVH	GE Vernova Hitachi Nuclear Energy

Term	Definition
ha	hectare
HAA	haloacetic acid
HCS	Highway Capacity Software
hr.	hour
HSS	Highway Safety Software
HTGR	High-Temperature Gas-Cooled Reactor
ICRP	International Commission on Radiological Protection
IEEE	Institute of Electrical and Electronic Engineers
ILBA	Instrument Line Break Accident
ISC	industrial source complex
ISFSI	independent spent fuel storage installation
kg	kilogram
kg/ha/mo	kilograms per hectare per month
$kg/km^2/mo$	kilograms per square kilometer per month
kg/s	kilograms per second
km	kilometer
kV	kilovolt
lb/ac/mo	pounds per acre per month

Term	Definition
LLW	low-level waste
LMDCT	linear mechanical draft cooling tower
LOS	level of service
LPGS	Liquid Pathway Generic Study
LPZ	low population zone
LWR	light-water reactor
m	meter
MACCS	MELCOR Accident Consequences Code System
m^3/d	cubic meters per day
m^3/s	cubic meters per second
MEI	Maximally Exposed Individual
MEL	Maximally Exposed Location
mg	milligram
mg/L	milligrams per liter
mi.	mile
MJ/m^2	megajoules per square meter
mgd	million gallons per day
mrad	millirad

Term	Definition
mrad/day	millirad/day
mrem	millirem
mSv	millisievert
MRI	Midwest Research Institute
MW	megawatt
MW/Btu	megawatt per British thermal unit
MWe	megawatts electric
MWIS	Makeup Water Intake Structure
MWt	megawatts thermal
NAAQS	National Ambient Air Quality Standards
NaCl	salt (sodium chloride)
NC	North Carolina
NCAC	North Carolina Administrative Code
NCDEQ	North Carolina Department of Environmental Quality
NCDEQ-DAQ	North Carolina Department of Environmental Quality Department of Air Quality
NCEI	National Centers for Environmental Information
NCSHPO	North Carolina State Historic Preservation Office
NDA	net disturbance area

Term	Definition
NEI	Nuclear Energy Institute
NESC	National Electrical Safety Code
NOAA – ESRL	National Oceanic and Atmospheric Administration – Earth Systems Research Laboratory
NO_x	nitrogen oxides
NPDES	National Pollutant Discharge Elimination System
NRC	U.S. Nuclear Regulatory Commission
NRHP	National Register of Historic Places
NUREG	NRC Technical Report designation
O_3	ozone
ODCM	Off-site Dose Calculation Manual
OSHA	Occupational Safety and Health Administration
PFAS	perfluoroalkyl and polyfluoroalkyl substances
PM	particulate matter
$PM_{2.5}$	particulate matter with a diameter of 2.5 micrometers or less
PM_{10}	particulate matter with a diameter of 10 micrometers or less
PPE	plant parameter envelope
ppm	parts per million
PRA	probabilistic risk assessment

Term	Definition
Project	All nuclear site development proposed by the applicant including transmission lines, access roads, utility corridors supporting the facility, etc.
Project Region	The area encompassed within a 50-mi. (80-km) radius of the Belews Creek, NC site bounding limit unless otherwise specified for a particular resource.
Project site	Belews Creek, NC site
Project Vicinity	The area encompassed within a 6-mi. (10-km) radius of the Plant site center point unless otherwise specified for a particular resource.
PWR	pressurized-water reactor
QA	Quality Assurance
QC	Quality Control
RCRA	Resource Conservation and Recovery Act
rem	roentgen equivalent man
REMP	radiological environmental monitoring program
RFFA	reasonably foreseeable future action
RG	Regulatory Guide
RIS	representative important species
ROI	region of influence
ROW	right-of-way
SACTI	seasonal and annual cooling tower impact

Term	Definition
SACTI2	seasonal and annual cooling tower impact, version 2
SAV	submerged aquatic vegetation
SCRAM	Support Center for Regulatory Atmospheric Modeling
SD	small depressurization
SMR	small modular reactor
SNL	Sandia National Laboratories
SO_x	sulfur oxide
SPCC	spill prevention, control, and countermeasures
SQG	small quantity generator
SSAR	Site Safety Analysis Report
Sv	Sievert
SWPPP	stormwater pollution prevention plan
TDS	total dissolved solids
TEDE	Total Effective Dose Equivalent
TLD	Thermoluminescent Dosimeter
TRISO	TRi-structural ISOtropic
TTHM	Trihalomethane
U.S.	United States

Term	Definition
USACE	U.S. Army Corps of Engineers
USC	U.S. Code
USEPA	U.S. Environmental Protection Agency
VOC	volatile organic compounds
WER	water effect ratio
WQS	water quality standard
yr.	year
µm	microns
χ/Q	atmospheric dispersion factor

Chapter 5 ENVIRONMENTAL IMPACTS FROM OPERATION OF THE PROPOSED PLANT

5.1 LAND USE IMPACTS

This section assesses impacts to land use and land cover at the Belews Creek, North Carolina (NC) site (Project site), Project Vicinity (6 miles [mi.] [10 kilometers {km}]) and associated off-site areas during operations. Section 5.1.1 discusses impacts to land use on the Project site and Section 5.1.2 discusses land use impacts at associated off-site areas in the Project Vicinity. Adverse impacts to land use at the Project site and associated off-site areas occur primarily during building activities.

5.1.1 ON-SITE IMPACTS

Land use impacts from building activities are described in Section 4.1. As stated in Section 4.1.1, the net disturbance area (NDA) is approximately 906 acres (ac.) (367 hectares [ha]) and encompasses the area that is disturbed during the operational life of the Project. Building support areas are intended to be permanently disturbed and serve operational needs. These needs may include parking or additional structures. In addition, the proposed transmission lines and switchyard areas are located within the NDA. No additional land will be acquired to support operations. Construction and maintenance activities on the Project site that require ground disturbance during operations are conducted in accordance with site-specific procedures and any required federal, state, or local authorizations.

As noted in Section 3.4.2.2, development of an independent spent fuel storage installation (ISFSI) is being considered at the Project site, within the NDA, to store spent fuel. The size and location of the ISFSI is currently undetermined, although it will meet the requirements set forth in 10 Code of Federal Regulations (CFR) Part 72.

As indicated in Section 4.1.1, operation of the Project is consistent with applicable land use planning and zoning in Stokes and Forsyth counties. Additionally, because no further land conversion is expected during operations, there are no additional impacts to prime or unique farmland or floodplains. Potential impacts from operations to water resources are discussed in Section 5.2. As discussed in Section 5.3.1.2, any potential wetland impacts during operation are primarily related to landscape maintenance and are minimized by implementation of appropriate best management practices (BMPs).

Section 4.4.2 states that hunting activities on the Project site will cease during the building phase and remain prohibited throughout operations. However, as stated in Section 2.4.2.6.2, there are several other hunting opportunities available within the Project Vicinity. As shown on Figure 2.4-5, recreational facilities on Belews Lake, such as the Pine Hall public boat ramp, Piney Bluff Boat Launch, and commercial marinas, are situated at a considerable distance from the Project site or across Belews Lake. Therefore, operations do not impact access to these facilities.

Operating the mechanical draft cooling towers has the potential to affect nearby land through fogging, icing, and salt drift. However, the findings from the Seasonal and Annual Cooling Tower Impact (SACTI) analysis, as described in Section 5.7.1.2, indicate that these concerns are minimal. The SACTI analysis predicts no occurrences of fogging or plume rime icing, low rates

of salt deposition, limited visual impacts, and insignificant levels of plume water deposition. Thus, impacts on land use within the Project site and Project Vicinity are minor.

Operation of the Project does not require additional land acquisition, is consistent with applicable zoning and land use, does not impact use of surrounding recreational facilities, and does not impact land within the Project Vicinity. Therefore, impacts during operations on land use are minor.

5.1.2 OFF-SITE IMPACTS

As stated in Section 2.1.2, no new off-site transmission line corridors are needed for the Project, and operation of existing transmission line corridors does not change. Therefore, there are no corresponding off-site transmission-related land use changes during operations.

As described in Section 4.1.2, building activities occur within the approximately 40-ac. (16-ha) associated off-site wastewater pipeline corridor. No additional land is required to support operations, and the corridor would continue to be managed as it is currently. Indirect impacts associated with corridor maintenance to the wetland in the associated off-site area are minimized by implementation of appropriate BMPs as indicted in Section 5.3.1.2. Therefore, impacts on land use on the associated off-site area from operations are minor.

5.1.3 SUMMARY OF LAND USE IMPACTS

Overall, the impacts to land use during operations are minor and would neither destabilize nor noticeably alter any important attribute of land use on the site or in the vicinity. Similarly, impacts to land use from operation of the off-site wastewater pipeline are minimal as all operations are contained within the existing corridor. Therefore, land use impacts during operations on-site and off-site are SMALL.

5.2 WATER RESOURCES

This section identifies impacts to surface water and groundwater resources from Project operations. Water resources at the existing Project site are described in detail in Section 2.2. As described in Section 3.4, Project operations require water for cooling and other operational uses. The sources of this water are Belews Lake and the Dan River.

Analyses of potential impacts to surface water resources are complex in consideration of past and existing operations of the existing Belews Creek Steam Station (BCSS), the operational characteristics of the Project, and the planned closure of BCSS. Belews Lake was constructed to support power generation and began filling in June 1970. Belews Lake reached full pond level in May 1973 and the first BCSS unit was placed into commercial operation in 1974.

As described in Section 3.3.5, the building and operational schedule has not yet been established. However, building of all advanced reactor units at the Project site follows a phased approach over several years. In conjunction with this phased approach, Duke Energy Carolinas, LLC (Duke Energy) will also derate the operations of BCSS during the phased implementation period in a manner that replaces and balances overall generation capacity between both the Project and BCSS. This transitional period is known as the “phased implementation period.” Thus, there will not be a time when no generation is present on the lake prior to advanced reactor commissioning. Therefore, the past 50 years of BCSS operation and its effects on Belews Lake and the surrounding environment represent the existing baseline condition as described in Section 2.2.

As is described in Section 1.2.1, the proposed action is the issuance of an Early Site Permit (ESP) by the U.S. Nuclear Regulatory Commission (NRC) under the provisions of 10 CFR Part 52 for the Project site. The issuance of the ESP does not authorize construction or operation of any facility but establishes the Project site’s suitability for future licensing decisions, contingent on the selection of the specific advanced reactors. Because the decision to close BCSS is a separate action from the Belews Creek, NC site ESP Application Project, BCSS closure is a reasonably foreseeable future action (RFFA) as described in Section 7.1. As described in Section 7.1.2, the BCSS closure results in consequences that include changes in the baseline environmental conditions relative to those described in Chapter 2. The phased approach for implementation of the Project in conjunction with the BCSS closure results in gradual changes in environmental conditions over the phased implementation period. The analysis of operational effects on surface water resources described in this section are based on the affected environment described in Chapter 2. Where appropriate, supplemental analyses are also provided that summarize the existing permitted operational condition of BCSS and effects of BCSS closure that are expected to continue during Project operations.

Project operation impacts, including changes induced from BCSS closure as described in Section 7.1.2.1, to the condition of surface water resources are considered in the following subsections, as appropriate:

- Surface water hydrologic alterations (Section 5.2.1.1)
- Surface water use (Section 5.2.2.1)
- Surface water quality (Section 5.2.3.1)

5.2.1 HYDROLOGIC ALTERATIONS

This subsection presents an analysis of the water use impacts of Project operation in consideration of the phased implementation period and baseline conditions described in Section 5.2. The analysis of operational effects on surface water and groundwater hydrology resources described in this section are based on the affected environment described in Chapter 2. Where appropriate, supplemental analyses are also provided that summarize the BCSS Continuous Maximum Generation Condition as well as the characteristics of the lake based on a condition in which BCSS has ceased operations.

Specific effects of BCSS closure relevant to surface water and groundwater hydrology include the following (with description of how effects relate to the Project):

- Belews Lake water levels are no longer influenced by BCSS consumptive uses (similar effects continue with Project operations).
- Water circulation in Belews Lake is no longer influenced by BCSS Condenser Cooling Water (CCW) intake and discharge flow (effects not prevalent in Project operations).

5.2.1.1 Surface Water

Operational activities may impact surface waters within the Project site, Belews Lake, and the Dan River. These surface waters are directly connected with discharges from Project operation activities and water withdrawn from the Dan River and Belews Lake. Operations-related effects associated with stormwater runoff within the Project site are also evaluated.

5.2.1.1.1 Project Site

As described in Section 4.2.1, the NDA is the entire permanently disturbed area within the Project site (Figure 4.2-1). As described in Section 3.1.5 the approximate 906-ac. (367-ha) NDA encompasses the South, Middle, and North Plant Complex areas. An approximate 100-foot (ft.) (30.5-meter [m]) vegetative buffer zone is retained as part of the operations as an undisturbed area along most of the shoreline of Belews Lake.

In conjunction with Project site building activities, an engineered stormwater collection system is developed to manage stormwater that includes a combination of swales, retention and detention basins, pipes, and culverts. Sediment and erosion control measures are designed to minimize discharge of sediments and site runoff to Belews Lake. Sedimentation basins installed during the building phase may be converted to detention or retention facilities for the permanent stormwater management system during the operational period. Other building phase stormwater facilities may be temporary or converted to permanent stormwater management facilities. Section 3.4.3.3.3.2 describes the stormwater system and BMPs to channel stormwater as required. Localized hydrologic alterations including flow patterns and sedimentation occur within Belews Lake where stormwater is integrated into Belews Lake.

Duke Energy maintains an existing general stormwater permit authorization for the BCSS condition, NCS000573, which complies with both NC water quality standards (WQSs) and federal permitting requirements. Duke Energy plans to either submit a modification request for this permit or terminate this permit and request a new National Pollutant Discharge Elimination System (NPDES) Permit from the North Carolina Department of Environmental Quality

(NCDEQ) for discharge of stormwater associated with industrial activity subject to the requirements of 15A North Carolina Administrative Code (NCAC) 02H.0126 (NCDEQ, 2017).

A small portion of the Project site is located in Forsyth County. Forsyth County is a tipped county which means it is subject to the post-construction portion of the municipal separate storm sewer system requirements of 15A NCAC 02H.1017. The requirements only apply to industrial stormwater discharged into surface waters without the watershed water supply classifications of I through IV (Table 2.2-22) (NCDEQ, 2017). The additional monitoring and BMP requirements from 15A NCAC 02H.1017 are incorporated into future permitting and stormwater management operational programs as applicable.

5.2.1.1.2 Belews Lake

This subsection assesses Project-related effects on surface water hydrology of Belews Lake. During the phased implementation period, the effects of reduced BCSS operations coupled with partial Project operations (a portion of the advanced reactor units) are expected to result in hydrologic effects that differ from those of the base condition described in Section 2.2.1.1. and further discussed in Section 5.2.1.1.2.1. The use of mechanical draft cooling towers in conjunction with Project operations results in increased consumptive water uses (and related hydrologic alterations) (Section 3.2.2 and Section 3.2.3).

Full Project consumptive uses for the advanced reactors exceed those that may be expected during the phased implementation period in which any combination of both BCSS and advanced reactors may be operating in a manner that replaces and balances overall generation capacity. As evident in Table 5.2-1, the total consumptive water use (consumptive withdrawals and forced evaporation) for Belews Lake during full Project operations exceeds that of BCSS operations. For the BCSS operations, the total consumptive use includes the forced evaporation in addition to the consumptive use for flue gas desulphurization (FGD) unit operations, and other in-plant uses.

In conjunction with the phased implementation period, consumptive uses associated with BCSS operations decline as they are correlated with generation capacity. Concurrent consumptive uses associated with Project operations increase as additional advanced reactor units are brought online. However, at no time does the sum of consumptive uses from BCSS operations coupled with Project operations exceed the full Project operational consumptive use (see Table 5.2-1). This consumptive use increase during full Project operations represents the bounded condition and results in increased Belews Lake drawdown levels during drought periods as described below.

Therefore, the impacts of operations captured in Section 5.2.1.1.2.2 are based only on full Project operational water use, which represents a bounded condition for the assessment of impacts associated with hydrologic alterations.

Hydrologic Model Development

The comprehensive hydrologic model was developed to effectively characterize the hydrology of Belews Lake and serve as a tool for predictive analysis of potential project effects. The model is a spreadsheet analysis of Belews Lake mass balance using a monthly time step. The model solves the water balance equation for each month based on the inflows, lake level, and outflows

and provides output regarding Belews Lake levels /storage. Elements of the model inputs/outputs include the following:

Inflows

- Runoff to Belews Lake
- Precipitation
- MWIS pumping from the Dan River

Outflows

- Belews spillway release
- Spillway gate leakage
- Natural lake evaporation
- Forced evaporation
- Consumptive withdrawal
- Seepage through dam
- Net seepage loss to groundwater

The model also provides a characterization of Dan River hydrology and diversion, an analysis of Belews Lake historic water budget, and a predictive analysis of Belews Lake water levels under various MWIS pumping conditions. For the historic condition (1997-2024), the model solves for the Belews Lake watershed runoff based on end-of-month lake level (and associated storage volume). Model scenarios include the BCSS historical conditions, the BCSS Continuous Maximum Generation Condition, and the Project operations condition.

For the future conditions, a longer period of model simulation was incorporated to capture more historic drought periods by using a surrogate Belews Creek watershed runoff record. The USGS Reedy Fork near Oak Ridge streamflow station record extending back to 1956 was substituted for the estimated Belews Lake watershed runoff record from the Historic Condition model, resulting in a 68-year future condition simulation period (1956-2024). The Reedy Fork near Oak Ridge streamflow record was selected from numerous regional USGS streamflow station records. It was used based on its similarity to the estimated Belews Lake watershed runoff on a unit drainage area basis (i.e., cfs/sq mi). The Reedy Fork near Oak Ridge station is also located only approximately 7 mi (11.3 km) from the center of the Belews Lake watershed. The model runoff rate transferred to the Belews Lake runoff was also modified by a scaling factor to make the long-term runoff equivalent to the estimated Belews Lake watershed long-term average runoff from 1997 to 2024.

The Belews Lake elevation – surface area – storage volume relationship in the model is defined by a set of equations for the initial lake condition (no sedimentation) and for selected assumed sedimentation storage loss assumptions in subsequent years.

Analyses of regional streamflow characteristics is an essential step in development of the model. Information characterizing regional streamflow serves three purposes. First, it facilitates selection of a net seepage loss rate that is considered most likely in combination with the Belews Lake watershed back-calculated runoff rate. Second, it allows selection of one or more regional streams as surrogate streams having a lengthy flow record encompassing multiple significant drought periods. The longer surrogate streamflow record is then substituted for the back-calculated Belews Lake watershed historic runoff data to predict Belews Lake storage levels under modeled future conditions. The third use of the regional streamflow information is to identify regional streamflow data useful in extending the short Dan River flow record at the Dan River at Pine Hall gage for use in the modeled future condition water balance model to estimate the ability of the Dan River to augment Belews Lake storage while meeting existing NPDES permit limitations for the MWIS operation.

5.2.1.1.2.1 Permitted Uses of Belews Lake Under BCSS Operations

Water levels within Belews Lake are managed by Duke Energy in conjunction with Project operations. Descriptions of the hydrology and other physical characteristics are included in Section 2.2.1.1.3.1 and Section 2.2.1.1.3.2, respectively. As described in Section 2.2.1.1.3, the Belews Lake surface area at full lake level is approximately 3862 ac. (1562.9 ha).

As described above, a comprehensive hydrologic model evaluates relevant inputs and outputs (i.e., direct precipitation onto the lake surface, stream inflow, consumptive losses from water use, natural evaporation, forced evaporation, seepage losses, and supplemental pumping from the Dan River) using average monthly data to evaluate long-term hydrologic characteristics of Belews Lake and the Dan River. Table 5.2-1 presents the parameters considered for the hydrologic model for each model scenario.

As is summarized in Section 2.2.1.1.3.1.2, the hydrologic model was calibrated using Belews Lake hydrologic conditions for the 27-year historical period from 1997 to 2024 based on historical operations of BCSS (i.e., the historical conditions). The historical condition model calculated the Belews Lake watershed runoff for the study period based on various observed and estimated data for other water balance parameters as an initial step before applying the calibrated model to the other hypothetical conditions (i.e., model scenarios). The 27-year historical conditions model established an estimate of the Belews Lake watershed runoff rates. The estimated runoff rates were subsequently used to select a surrogate U.S. Geological Survey long-term regional streamflow station with similar runoff rates to construct a long-term Belews Lake hydrologic model to predict lake water levels and discharges for modeled future conditions. For this assessment of Project operational effects, a 68-year long simulation period based on data from 1956 through 2024 was used to evaluate all model scenarios—other than the 27-year historical conditions model.

Figure 2.2-9 provides a characterization of the varying Belews Lake water levels over the historical modeling period. The end-of-month water levels plotted are measured water levels. This figure also depicts the primary inflow component (i.e., watershed runoff) and outflow component (i.e., spillway releases). BCSS consumptive uses over the historic period illustrated in Figure 2.2-9 result in noticeable water-level fluctuations within Belews Lake during periods of increased drought severity. Table 5.2-2 summarizes the range of water-level reductions from full pond level of 725.0 feet (ft.) (220.97 m) under the BCSS historical period for mild (e.g., 2-year drought recurrence), moderate (e.g., 10-year drought recurrence), and extreme (e.g., 100-year drought recurrence) drought conditions. The minimum observed water level that occurred during the conditions of the drought in 2002 and 2003 was 7.4 ft. (2.26 m) below full pond level. The extended critical drought period under the historical BCSS operational period was observed to be 23 months. For the historical BCSS conditions, the total consumptive use (including forced evaporation) for the 1997 to 2024 period was approximately 27 cfs (0.76 m^3/s), the spillway release was approximately 28.9 cfs (0.82 m^3/s), and the Dan River diversion using the temporary pumping systems averaged approximately 1.5 cfs (0.042 m^3/s).

While the BCSS capacity factor has lessened in recent years, BCSS operates with a NCDEQ NPDES permit that supports full operational capacity of the BCSS plant. The NPDES permit allows for up to 100 cfs (2.83 m^3/s) of pumping by the makeup water intake structure (MWIS). However, a model pumping rate of 80 cfs [2.27 m^3/s] was used as a bounding value to evaluate the effect on lake levels. Under this modeled operational condition of supplemental pumping of

water by the MWIS (the BCSS Continuous Maximum Generation Condition), BCSS consumptive uses result in noticeable water-level fluctuations within Belews Lake during periods of increased drought severity as illustrated in Figure 5.2-1.

Table 5.2-2 summarizes the range of water-level reductions from full pond level of 725.0 feet (ft.) (220.97 m) under the BCSS Continuous Maximum Generation Condition for mild (e.g., 2-year drought recurrence), moderate (e.g., 10-year drought recurrence), and extreme (e.g., 100-year drought recurrence) drought conditions. The minimum predicted level that is consistent with the conditions of the drought that occurred in 2002 and 2003 was 8.2 ft. (2.50 m) below full pond level. The extended critical drought period under the BCSS Continuous Maximum Generation Condition is estimated to be 22 months. For the BCSS Continuous Maximum Generation Condition, the total consumptive use (including forced evaporation) is approximately 43.3 cfs (1.23 m^3/s), the spillway release is approximately 19.4 cfs (0.55 m^3/s), and the MWIS diversion rate is approximately 7.8 cfs (0.21 m^3/s).

The predictive analysis based on the BCSS Continuous Maximum Generation Condition is similar to that observed for the BCSS historic condition due to the contributing effect of supplemental MWIS pumping from the Dan River to augment the lake levels.

5.2.1.1.2.2 Belews Lake Hydrology Under Project Operations

5.2.1.1.2.2.1 Project Water Uses

Belews Lake is the cooling water source for the Project during operations. As described in Section 3.4.1.1, water interfaces as part of the plant cooling water system include the MWIS located at the confluence of the Dan River and Belews Creek which discharges to Belews Lake near the spillway (Figure 2.2-3), an intake structure in Belews Lake common to all units, and cooling water system discharge(s) to Belews Lake. Two locations are being considered for the Belews Lake intake structure as illustrated in Figure 4.2-1. Section 3.2.2.4.3 describes two cooling tower blowdown discharge options to Belews Lake: either a single combined discharge structure or three separate cooling tower blowdown discharge structures, one for each Plant Complex (Figures 3.1-1 and 4.2-1). Table 3.4-1 identifies the consumptive use from cooling tower evaporation and cooling tower blowdown rates. The MWIS provides supplemental pumping from the Dan River to augment water levels within Belews Lake (see Section 5.2.1.1.3.2). Operating limitations of the MWIS are outlined in the existing NPDES permit as described in Section 3.4.1.1.2.

Cooling tower makeup water is pumped from Belews Lake via the intake structure as indicated on Figure 2.2-13. The inlet to the intake is connected to the shoreline pumping station by a buried conduit (Figure 3.2-1). Water depths in the vicinity of the cooling tower blowdown structures for each discharge are identified in Figure 2.2-14. The offshore inlet and discharge locations are in deep water, within the hypolimnion below the thermocline that may be present at the lowest simulated drought lake level (Table 5.2-4).

Circulation refers to the pattern and magnitude of currents internal to Belews Lake, including natural currents driven by runoff inflows and wind-driven currents, and man-made currents due to discharges and withdrawals. Neither current measurements nor a hydrodynamic model are available to quantify circulation. However, conceptual circulation patterns can be reliably identified based on the locations and magnitudes of inflows and outflows.

Pumping water by the intake structure results in alterations of flow patterns in the vicinity of the offshore intake structure. Additionally, the Project discharges are located such that the positively buoyant effluents mix rapidly with the colder hypolimnion water. The effects of these alterations are localized and minor during typical lake conditions. When runoff inflows are elevated, those inflows dominate the circulation with lake currents all following the natural downstream flow pattern to the spillway. As described in Section 2.2.1.1.3.2.2, under periods of low and normal watershed runoff to Belews Lake, the BCSS CCW system creates a counterclockwise flow circulation pattern with recirculated CCW flowing southwest through the lower West Belews Creek embayment to the BCSS intake

Under the Project condition with no BCSS cooling discharge, circulation in Belews Lake is influenced by the locations of the intake and the discharges, as well as the MWIS discharge location near the spillway. During low watershed runoff conditions, circulation in Belews Lake is influenced by the locations of the intake and the discharges, as well as the MWIS discharge location near the spillway.

However, the magnitude of flow changes by each of these influences is minor in comparison to the existing flows that result from BCSS operations. For example, the maximum BCSS circulating water flow is approximately 2300 cfs, whereas the influencing flows of Project features (see Figure 3.2-4) are substantially lower: maximum intake flow: approx. 90.5 cfs, maximum discharge flow: approx. 14 cfs, maximum MWIS flow into Belews Lake: up to 100 cfs. As such, the resulting dry weather average flow velocities through the Belews Creek arm of the reservoir are negligible as compared to circulation in conjunction with BCSS operations

5.2.1.1.2.2.2 Belews Lake Water Levels

During Project operations, Belews Lake provides water for cooling tower operations and is the source for the water processing plant (Figure 3.2-4). Table 5.2-1 compares the Project conditions to the other modeled scenarios. For the Project Condition, the consumptive use for the Project is approximately 60.7 cfs (1.72 m^3/s), the spillway release is approximately 12.5 cfs (0.34 m^3/s), and the MWIS diversion rate is approximately 18.2 cfs (0.52 m^3/s). Other hydrologic components of the Belews Lake water balance are relatively unchanged. The Project Condition average MWIS diversion rate from the Dan River is 10.4 cfs (0.29 m^3/s) larger than the BCSS Continuous Maximum Generation Condition diversion but well within the existing, permitted limitations.

Operational use of water from Belews Lake for the Project results in fluctuations of water levels. Figure 5.2-2 depicts the modeled water levels of Belews Lake for the Project Condition based on the same rate of MWIS supplemental pumping as that for the BCSS Continuous Maximum Generation Condition. Table 5.2-2 summarizes the range of water-level reductions from full pond level of 725.0 ft. (220.97 m) under Project operations for mild (e.g., 2-year drought recurrence), moderate (e.g., 10-year drought recurrence), and extreme (e.g., 100-year drought recurrence) drought conditions. The minimum observed water level that is consistent with the conditions of the drought that occurred in 2002 and 2003 was 13.1 ft. (2.26 m) below full pond level of 725 ft. (220.98 m). The estimated extended critical drought period under the Project operational period was approximately 31 months.

As described in Section 5.2.1.1.2.2.1, supplemental water is pumped from the Dan River via the MWIS to Belews Lake to maintain lake levels in accordance with normal operations and existing

NPDES permit conditions. Duke Energy's NPDES permit for the MWIS allows for a maximum pumping capacity of up to 100 cfs (2.83 m^3/s) from the Dan River to Belews Lake; however, analyzing a pumping rate of 80 cfs (2.27 m^3/s) provides a more conservative bounding condition to assess hydrologic alterations to Belews Lake from Project operations while providing margin to the 100 cfs (2.83 m^3/s) permitted limits, further minimizing impacts on the Dan River.

Figure 5.2-2 depicts the modeled water levels of Belews Lake under Project operations. This predicted pattern of change in water levels within Belews Lake is similar to the predicted pattern of water levels under existing operations of the BCSS at full capacity under the same NPDES permitted MWIS pumping scenario (i.e., 80.0 cfs [2.27 m^3/s]) (Figure 5.2-1). Because the rate of consumptive water use under Project operations (i.e., approximately 61.0 cfs [1.73 m^3/s] including forced evaporation) is greater than that of the BCSS Continuous Maximum Generation Condition (i.e., approximately 43.0 cfs [1.22 m^3/s] including forced evaporation), Project water use during operations results in lower minimum Belews Lake levels compared to the predicted BCSS Continuous Maximum Generation Condition (Table 5.2-1).

The Belews Lake water levels for the three conditions (BCSS historic, BCSS Continuous Maximum Generation Condition, and Project Condition) for the period 1996 – 2025 are plotted together on Figure 5.2-3. Overall, the Belews Lake water levels are variable and have a predicted potential lower minimum level during Project Condition relative to other modeled scenarios as a result of increased consumptive use. Under each scenario, alterations of Belews Lake water levels are noticeable during periods of increased drought severity but are not considered to be destabilizing. The modeled future predictive analysis based on Project operation indicates lake water-level fluctuations similar to those predicted for BCSS Continuous Maximum Generation Condition. However, the water-level drawdowns under Project operations are more pronounced relative to the BCSS Continuous Maximum Generation Condition and increased by 0.6 ft and 3.0 ft, for the 2-year and 100-year drought return periods, respectively.

The increased operation of the MWIS minimizes the reduction in lake levels from the increased consumptive use. The predicted Belews Lake level fluctuations during Project operations are similar to the BCSS Continuous Maximum Generation Condition but result in somewhat greater drawdowns and an extended critical drought duration relative to the BCSS Continuous Maximum Generation Condition. Overall, however, lake hydrologic function and water levels are generally maintained by the operation of the MWIS, which minimizes the reduction in lake levels from the increased consumptive use. Therefore, impacts on water levels from Project operations are noticeable during periods of increased drought severity, but are not considered to be destabilizing.

5.2.1.1.2.3 Effects of Sediment Transport from the Dan River

As described in Section 2.2.1.1.3, Belews Lake continues to accumulate sediment transported into the lake from the watershed tributaries and shoreline erosion. Conditions contributing to the rate of sediment influx to the lake from these sources are unaffected by the Project operations. Watershed contribution is subject to potential increase if watershed development occurs that may result in increased streamflow rates that result in channel adjustments and increase in erosion. The other source of sediment influx to the lake is the MWIS in conjunction with Project operations.

In conjunction with supplemental pumping from the Dan River, MWIS operations result in the entrainment of sediment and pumping into Belews Lake. The sediment concentration in the pumped diversion flow is dependent upon the sediment concentration in the river. The Dan River suspended sediment concentration increases with river flow. The sediment load discharged to the lake varies only slightly with variable MWIS pumping capacity. The sediment load to the lake at any given time is dependent on the river suspended sediment concentration and the pumping rate. The estimated average annual sediment load via the MWIS is approximately 500 to 550 tons (454 to 499 kilograms [kg]) per year, or approximately 0.42 to 0.47 acre-feet (ac-ft) (518 to 579 cubic meters [m^3]) per year if the average sediment deposit density is 60 pounds per cubic foot (961 kg per m^3). This average annual sedimentation rate is approximately 1.4 percent of the assumed sedimentation rate based on a watershed contribution of 0.52 ac-ft per square mile per year (640.0 $m^3/km^2/yr$) (Section 2.2.1.1.3.2.3.2). Therefore, the impacts of sediment entrainment from the Dan River on Belews Lake are negligible.

5.2.1.1.3 Dan River

5.2.1.1.3.1 Makeup Water Intake Structure Operation

As part of Project operations, diversion pumping via the MWIS will be permitted in accordance with an NPDES permit issued by the NCDEQ. Because of the phased implementation of Project operations with BCSS closure, the effects of this action are consistent with the BCSS Continuous Maximum Generation Condition. The existing permit will be modified for the inclusion of operation of advanced nuclear reactors and is expected to maintain the existing, conservative conditions regarding pumping rates, seasonal restrictions, and amount of bypass flow required in the Dan River as are currently authorized for operation of the BCSS as described in Section 3.4.1.1.2. Relevant conditions similar to those that are in place for existing BCSS operations are considered to be effective for Project operations and are effective for maintaining sufficient water to support aquatic habitat and river discharge characteristics. Specifically, NCDEQ has created a target flow recommendation for this site in the Dan River of 110 cfs (3.11 m^3/s) (NCDEQ, 2025a). This flow value was developed in consultation with the U.S. Fish and Wildlife Service, North Carolina Wildlife Resources Commission, U.S. Army Corps of Engineers (USACE), NCDEQ, and Duke Energy.

Under Project operations, the installed pumping capacity of the MWIS is increased to allow for pumping of up to the amount allowed by the NPDES permit. Diversion at the maximum allowable flow (100 cfs [2.83 m^3/s]) from the Dan River via the MWIS was selected as a bounding value for the purpose of assessing impacts on downstream water users. While MWIS operations include diversion pumping at a wide range of river flow conditions, low flow levels critical to water uses and supply on the Dan River were considered in this analysis.

At higher river flows, pumping by the MWIS has no significant impact of downstream river flows. For example, for a river flow of 1000 cfs (28.3 m^3/s), the minimum downstream flow is 900 cfs (25.4 m^3/s), which is 90 percent of the natural flow. This value is well above natural low flow conditions and has no identified significant adverse impacts. The long-term average is provided in Table 2.2-3. The geomorphic bankfull discharge, the flow identified as most representative of the flow controlling the physical channel conditions through sediment transport, is estimated to be in the range of 5000 cfs to 8000 cfs (142 m^3/s to 227 m^3/s) based on regional hydraulic geometry relationships (Harman, 2024; Page et al., 2024).

The MWIS operation impact on the Dan River annual minimum average monthly flow probabilities under BCSS Continuous Maximum Generation Condition and Project Condition are illustrated on Figure 5.2-4 and in Table 5.2-3. Based upon the statistical characterization of flow in Figure 5.2-4, it is observed that there is not a notable difference from the natural flow condition of water availability downstream of the MWIS for monthly average river flows greater than 350 cfs (9.91 m^3/s) or less than 110 cfs (3.11 m^3/s). Consequently, for Project operations there is a lesser effect on the annual minimum monthly low flow greater than approximately 350 cfs (9.91 m^3/s) and no impact on flows below 110 cfs (3.1 m^3/s), as no pumping is allowed when river flow is 110 cfs (3.11 m^3/s) or lower.

Accordingly, the range of flows of potential concern for impacts by operation of the MWIS are between 110 cfs (3.11 m^3/s) and approximately 350 cfs (9.91 m^3/s). Low flow conditions occurring during the months of July through November (months 7 to 11) are most subject to effects of pumping (Figure 5.2-4). For example, the effects of MWIS pumping are identified in Figure 5.2-4 under moderately low flow conditions when the Dan River discharge is between approximately 350 cfs (9.91 m^3/s) and the NCDEQ NPDES permit target minimum flow of 110 cfs (3.11 m^3/s). This target minimum flow is 30 cfs (0.85 m^3/s) higher than the summer 7-day duration, 10-year return period (7Q10) 80 cfs (2.27 m^3/s) flow (NCDEQ, 2025b). Table 5.2-3 summarizes the monthly average low flows on the Dan River downstream of the MWIS under BCSS Continuous Maximum Generation Condition, Project Conditions, and natural flow conditions. Notably, the 110 cfs (3.11 m^3/s) flow rate is close to the 25-year low flow identified in Table 5.2-3. Greater effects are evident under conditions corresponding to a return period range of 5 to 10 years, in which the flow in the Dan River is reduced by approximately 30 cfs (0.85 m^3/s). In contrast, the effect on the 2-year return period (or more frequent conditions) is an approximate 25 cfs (0.71 m) reduction. For return periods greater than approximately 25 years there is even less, or zero, effect on downstream water availability. That occurs because in that low flow range the diversion rate is controlled by regulatory limits and not the pumping capacity.

Overall, MWIS pumping results in hydrologic alterations on the Dan River that affect river discharge downstream of the MWIS. However, such alterations do not noticeably alter the general hydrologic functions of the Dan River related to water availability, geomorphic processes, and sediment transport function. Operation of the Project conforms with the existing NPDES permit requirements effective for the BCSS and is not anticipated to further impact water levels on the Dan River. Therefore, impacts of MWIS pumping on the hydrology of the Dan River are minor.

5.2.1.1.3.2 Discharge to Dan River

Figure 3.2-4 shows the projected normal and maximum operational flow rates to and from the various water systems, the source water for each system, and the receiving body of water for liquid discharges. Table 3.4-1 summarizes the projected normal and maximum operational flow rates to the Dan River that include liquid discharges which may consist of intermittent cooling tower blowdown, miscellaneous power plant systems (water processing plant, fire protection system, sanitary waste, etc.), and the liquid radioactive waste.

As described in Section 5.2.3.1.2.2, Project nonradioactive discharges are routed through the existing Outfall 006. Liquid radioactive wastes are routed through a new discharge in a corridor adjacent to existing Outfall 006 and are diluted with cooling tower blowdown discharge. Discharges to the Dan River result in localized changes in flow patterns, currents, and total flow.

The approximate maximum discharge to the Dan River is approximately 25 percent of the Dan River Summer 7Q10 80 cfs (2.27 m^3/s) flow, approximately 3 percent of the average 665 cfs (1.48 m^3/s) flow, and approximately 0.4 percent of the geomorphic bankfull flow of approximately 5000 cfs (141.58 m^3/s).

A fraction of the discharge, after mixing with the river flow, may be pumped to Belews Lake during periods when the MWIS is simultaneously operating. Potential effects of normal operations related to the discharge of low-level liquid radiological waste streams are evaluated in Section 5.9. Duke Energy will evaluate administrative and engineering controls regarding discharge and MWIS operations to minimize the potential for transport of radionuclides from the Dan River to Belews Lake. Additionally, as summarized in Section 5.9.6, a radiological monitoring program inclusive of the Dan River and Belews Lake will also be implemented in conjunction with Project operations.

Discharge flow rates are regulated in conjunction with NCDEQ NPDES permitting requirements. As such, overall effects from hydrologic alterations are controlled and minor.

5.2.1.1.4 Transmission Corridors

As discussed in Sections 1.1.5 and 3.2.4, additional transmission lines that extend outside of the existing Project site boundary are not required. Transmission lines are not anticipated to affect hydrological conditions.

5.2.1.1.5 Summary of Hydrologic Alterations to Surface Waters

Hydrologic alterations in Belews Lake and the Dan River result from operation of the intake and discharge structures within Belews Lake, increased consumptive water use within Belews Lake, MWIS operation which transfers water from the Dan River into Belews Lake, and wastewater discharges into the Dan River.

The effects of Project operations on flow and circulation patterns within Belews Lake as a result of intake, discharge, and MWIS are localized and minor. Additionally, the potential impacts of sediment transport into Belews Lake from the MWIS operation are negligible. Belews Lake water levels are noticeably altered as the result of increased consumptive use from Project operations.

Discharge into the Dan River results in localized changes in flow patterns, currents, and total flow and discharge flow rates are regulated in conjunction with NCDEQ NPDES permitting requirements and are expected to be similar to the existing Outfall 006 wastewater discharge. Therefore, the hydrological impacts of discharge are minor. Pumping by the MWIS results in minor hydrologic alterations on the Dan River during higher flow conditions. Pumping by the MWIS is not allowed when natural discharge is less than 110 cfs (3.11 m^3/s).

Overall, Project operations result in increased predicted water-level variations as a result of increased consumptive use. MWIS operation mitigates the reduction in lake levels from the increased consumptive use. The predicted pattern of water levels during Project operations is similar to the BCSS Continuous Maximum Generation Condition, but results in somewhat greater drawdowns and an extended critical drought duration relative to the BCSS Continuous Maximum Generation Condition. Overall, however, lake hydrologic function and features are

generally maintained by operation of the MWIS that mitigates the reduction in lake levels from the increased consumptive use.

The overall impacts on hydrologic alterations to surface waters are SMALL for all Project operations except for the effects associated with consumptive use including that on Belews Lake and the MWIS operations on the Dan River. Under conditions in which water levels are stabilized and consumptive losses are offset by MWIS pumping, impacts on Belews Lake hydrology are SMALL. During periods of increased drought intensity, the impacts on Belews Lake hydrology are MODERATE.

5.2.1.2 Groundwater

There are few hydrologic alterations that affect groundwater availability during operations. No groundwater use or dewatering occurs during operation that may affect local aquifers. However, as mentioned in Section 4.2.1.2, building activities result in the development of permanent use areas within the NDA. While specific details of site layout within the NDA have not yet been fully designed, it is expected that the permanent use areas consist of land uses that are impervious to groundwater infiltration. As described in Section 3.1.5 approximately 906 ac. (367 ha) is designated for permanent disturbances such as the power blocks, cooling towers, laydown areas, and switchyards. Impervious surfaces from the development of these areas results in reduced infiltration and groundwater recharge in the immediate area of these structures. Other lands within the NDA are expected to allow for varying degrees of groundwater infiltration and recharge. Surface water that does not infiltrate to groundwater is managed as stormwater runoff and ultimately discharged to Belews Lake. In locations where groundwater recharge is affected, corresponding effects (reductions) in groundwater levels may occur. Overall impacts on groundwater levels are expected to be minor. Therefore, impacts of hydrologic alteration on groundwater from operations are SMALL.

5.2.2 WATER USE IMPACTS

This subsection presents an analysis of the water use impacts from Project operation. Section 5.2 describes the phased approach and Section 2.2 describes the baseline conditions to which Project impacts are compared.

The analysis of operational effects on surface water resources described in this section are based on the affected environment described in Chapter 2. Where appropriate, supplemental bounding analyses are also provided that summarize the BCSS Continuous Maximum Generation Condition as well as the characteristics of Belews Lake based on a condition in which BCSS has ceased operations.

Specific effects of BCSS closure relevant to water use include the following (with description of how effects relate to Project):

- Reduced consumptive water use by BCSS to support FGD operations, forced evaporation, and other water uses (similar effects continue with Project operations).
- Authorized pumping operations associated with the MWIS on the Dan River are transferred to Project operations (effects transition to Project operations).

5.2.2.1 Surface Water

Withdrawal of surface water conducted to support Project operations, which includes water to support the cooling water system and other plant systems, is described in Section 3.4. The anticipated normal and maximum operational flow rates are provided in Table 3.4-1 and illustrated in Figure 3.2-4. For this analysis, impacts to water use associated with operational activities are assessed and quantified by water source.

5.2.2.1.1 Belews Lake

Water use of Belews Lake includes Duke Energy use for thermoelectric power generation and public use for recreational purposes. Thermoelectric power generation includes the use of water for cooling. Details regarding water use for the cooling system associated with Project operation are discussed further below in Section 5.2.2.1.1.1. Details regarding water use for recreation are discussed further in Sections 5.2.2.1.1.2 and 5.4.4.2.

5.2.2.1.1.1 Cooling System

Belews Lake is the principal source of consumptive and nonconsumptive water use for the Project as shown in Figure 3.2-4 and Table 3.4-1. As stated in Section 2.2.2.1.3.2, Belews Lake is designed and built specifically for thermoelectric power generation and does not supply any other water users besides Duke Energy.

As described in Section 5.2.1.1.2.2.2, operational use of cooling water from Belews Lake for the Project results in drawdown of water levels. However, as described in Section 5.2.1.1.2.1, BCSS operates with an NCDEQ NPDES permit that supports the full operational capacity of the BCSS plant. Because of the phased implementation of Project operations with BCSS closure, the capacity for MWIS pumping in accordance with the NPDES permit is extended during the Project operations phase. As described in Section 5.2.1.1.2.1, the MWIS has a permitted limit of 100 cfs (2.83 m^3/s), but a model pumping rate of 80 cfs (2.27 m^3/s) was used as a bounding value to evaluate the effect on lake levels.

Section 5.2.1.1.2.2 describes the supplemental water pumping from the Dan River via the MWIS to Belews Lake to maintain lake levels in accordance with normal operations and existing NPDES permit conditions. Duke Energy's NPDES permit for the MWIS allows for a maximum pumping capacity of 100 cfs (2.83 m^3/s) from the Dan River to Belews Lake; however, a pumping rate of 80 cfs (2.27 m^3/s) provides a more conservative bounding condition to assess hydrologic alterations to Belews Lake from Project operations as it provides a margin to the 100 cfs (2.83 m^3/s) permitted limits, further limiting the impacts on the Dan River. The MWIS is operated in accordance with the conditions of the NPDES permit and the MWIS operating plan to manage Belews Lake levels.

Figure 5.2-2 depicts the modeled water levels of Belews Lake based on supplemental pumping of the MWIS under Project conditions. Section 5.2.1.1.2.2.2 describes the effects of Project operations on the Belews Lake water levels. A comparison of Project operations and the BCSS Continuous Maximum Generation Condition is provided in Tables 5.2-1 and 5.2-2.

Overall, Belews Lake water use as supplemented by MWIS operation is increased compared to the BCSS Continuous Maximum Generation Condition. While hydrologic alterations are noticeable during periods of increased drought severity as described in Section 5.2.1.1.5, the

alterations do not affect the availability of water in Belews Lake to support Project operations. As is described in Section 3.2.2.4.1 and illustrated in Figure 3.2-1, the water intake to the facility is at an adequate depth to not affect full rated power generation capabilities of the facilities during analyzed drought conditions. As such, consumptive use in conjunction with Project operations does not impact water availability and does not preclude the capacity for Belews Lake to continue to provide a reliable source for cooling water in support of thermoelectric power generation (Section 2.2.2.1.4.1). Impacts on water use are therefore minor.

5.2.2.1.1.2 Recreation

The impact to recreational use of Belews Lake from operation of the Project is described in Section 5.4.4.2. Changes in water levels have related effects on recreational use that include those related to boater and pedestrian access to the lake, reduced accessibility to the upper arms of Belews Lake, potential for boater safety hazards, alterations to aesthetic viewsheds, affects to the aquatic ecosystem including recreational and sport fishing, and effects of noise from operating cooling towers. Overall effects of Project operations on recreation are evaluated in Section 5.4.4.2.

5.2.2.1.2 Dan River

As described in Section 2.2.2.1.2.1 the Dan River is used by several downstream communities as a water supply system. These communities include the Town of Madison, NC, City of Eden, NC, and Danville, Virginia (see Table 2.2-20 and Figure 2.2-31). Additionally, the Dan River is a recreational resource that provides opportunities for paddling, canoeing, tubing, fishing, and kayaking (Section 2.4.2.6.2). Potential direct and indirect water use impacts associated with Project operations include those related to the operation of the MWIS and the wastewater pipeline as discussed in the following subsections.

Estimates of Dan River flow available downstream of the MWIS to downstream water users during facility operation are based on existing Dan River flow data from Section 2.2.1.1.2, water use associated with the MWIS and applicable permit limitations regarding Dan River flow.

5.2.2.1.2.1 Effects of MWIS Operation on Dan River Water Users

Section 3.4.1.1.2 describes the existing and permitted MWIS pumping capacity. Even with fluctuations in withdrawal rates resulting from pump performance variability, water withdrawal at the MWIS is less than the maximum withdrawal limit of 100 cfs (2.83 m^3/s), or 64.63 million gallons per day (mgd) (244,658 cubic meters per day [m^3/d]), allowed by the NPDES permit for withdrawals from the Dan River. For this analysis a pumping rate of 100 cfs (2.83 m^3/s) is used as a bounding condition by which to assess hydrologic alterations and water use within the Dan River.

The MWIS operational impact on the Dan River flow operations are discussed in Section 5.2.1.1.3.1. The MWIS operational impact on the Dan River natural and after-diversion annual minimum monthly average flow probabilities are illustrated on Figure 5.2-4 and in Table 5.2-3.

The nearest downstream surface water user on the Dan River is the Town of Madison. The Madison Water Treatment Plant intake is located approximately 8 river miles downstream of the Pine Hall Station (USGS Station No. 02069000) and has a capacity to withdraw 2.3 cfs (0.065 m^3/s) from the Dan River, corresponding to 2.1 percent of the 110 cfs (3.11 m^3/s) Dan River flow

at which MWIS pumping is not allowed.. As provided in Table 2.2-1, the drainage basin area at the Pine Hall Stream Station is 501 mi^2 (1297 km^2) whereas the drainage basin area at the Madison Water Treatment Plant intake is approximately 594 mi^2 (1538 km^2). As such, flow contributions provided by the added drainage basin area between the Pine Hall Stream Station and the Dan River confluence with the Mayo River is minor and downstream water users within this reach predominantly rely on flows influenced by MWIS operation. Ultimately, the Town of Madison's capacity, in addition to other downstream water users, to obtain water is not diminished provided they have implemented water supply systems capable of withdrawing water during minimum 7Q10 low flow conditions in compliance with 15A NCAC 18C.0403 (NCDEQ, 2019). Project operation has no impact on water levels downstream of the MWIS under minimum low flow conditions.

Although MWIS operation reduces the water available to downstream water users, this reduction does not compromise the overall availability or reliability of surface water to users downstream of the Project. Therefore, the overall impacts of MWIS operation on downstream water use by communities is minor.

5.2.2.1.2.2 Recreation

The impact of Project operations on recreational use of the Dan River is described in Section 5.4.4.2. The existing Outfall 006 and the new Dan River outfall within the wastewater pipeline corridor, along with the existing MWIS structure locally affect the area. Additionally, the MWIS operation may reduce water availability for recreators impacting recreation within the Dan River. However, as described in Section 5.2.1.1.3.1, MWIS operation does not affect naturally occurring low flow conditions on the Dan River because pumping is not allowed under conditions in which the natural river discharge is below 110 cfs (3.11 m^3/s). Water levels and availability of the Dan River results in minor effects to Dan River recreation under either low flow conditions or during MWIS use. Although MWIS operation reduces the water available to downstream water users, this reduction does not compromise the overall availability or reliability of surface water to users downstream of the Project. Overall effects of Project operations on recreation are evaluated in Section 5.4.4.

5.2.2.1.3 Municipal Water Impacts in the Project Vicinity

Duke Energy obtains municipal water from Winston-Salem/Forsyth County for Project operation. Winston-Salem/Forsyth County has an existing maximum treatment capacity of 91 mgd (approximately 344 million liters per day) and withdraws water from the Yadkin River and Salem Lake (Winston-Salem, 2023). Table 3.4-1 shows the expected maximum and average withdrawal rates for Project operations. Municipal water use associated with the operation of the Project is a minute percentage of existing municipal potable water capacity and does not destabilize the ability of the municipality to meet the needs of other users. Therefore, the impact on municipal water users is minor.

5.2.2.1.4 Water Use Impacts Summary

Belews Lake consumptive water use, as supplemented by MWIS operation, results in increased water uses as described in Section 5.2.1. However, consumptive uses do not affect the availability of water in Belews Lake to support Project operations. As such, consumptive use in conjunction with Project operations does not adversely affect the availability of water for Project

intake systems. Impacts on water use of Belews Lake are therefore, SMALL. Although MWIS operation reduces the water available to downstream water users, this reduction does not compromise the overall availability or reliability of surface water to users downstream of the Project. Impacts of MWIS operation on downstream water use by communities are SMALL.

Therefore, overall impacts of Project operations on surface water use are SMALL.

5.2.2.2 Groundwater

No groundwater from on-site or off-site sources is used during operation of the Project. Furthermore, no permanent dewatering system is planned for use during operations. Therefore, impacts of groundwater use from operations are SMALL.

5.2.3 WATER QUALITY IMPACTS

This subsection presents an analysis of the water quality impacts of Project operation as compared to the phased approach and baseline conditions described in Section 5.2. These include the impact of operational water use on water quality that could affect the use of water by other users.

The analysis of operational effects on surface water resources described in this section are based on the affected environment described in Chapter 2. Where appropriate, supplemental analyses are also provided that summarize a condition in which BCSS has ceased operations.

Specific effects of BCSS closure relevant to water quality include the following (with description of how effects relate to the Project):

- Water quality that is no longer influenced by the effects of wastewater discharges from fossil fuel power generation. This includes the elimination of inputs from the emergency spillway of the South Coal Pile Basin, treated FGD wet scrubber wastewater, once-through non-contact chiller water, industrial stormwater, and once-through condenser cooling water and intake screen backwash. These effects are generally absent during Project operations.
- Lake water temperatures that reflect characteristics of a lake lacking substantive thermal input from power generation. These effects are generally absent during Project operations.

5.2.3.1 Surface Water

5.2.3.1.1 On-site Streams

The remaining streams on the Project site not impacted by building activities, discussed in Section 4.2.3.1.1, are potentially impacted during operation by industrial stormwater runoff.

As described in Section 5.2.1.1.1, Duke Energy maintains an existing NPDES stormwater permit which is updated as needed to adequately address the potential operational industrial stormwater impact to remaining on-site streams. Duke Energy maintains a stormwater pollution prevention plan (SWPPP) in conjunction with the individual NPDES Industrial Stormwater General Permit to control pollutants in stormwater discharges associated with industrial activity

and implement and manage appropriate BMPs during operations. Existing site storm drainage outfalls may be modified and new outfalls built to route stormwater to either the on-site streams or Belews Lake. Duke Energy maintains an operational spill prevention, control, and countermeasure (SPCC) plan which prevents spilled oil from being released into receiving waters.

Compliance with NCDEQ permit requirements, NPDES permits, and stormwater BMPs maintain water quality in the on-site streams during Project operations. The impact from industrial stormwater and operational activities is therefore minor.

5.2.3.1.2 Belews Lake

As illustrated in Figure 2.2-16, July 2002 surface temperature observations in Belews Lake demonstrate elevated summer water temperatures in the West Belews Creek arm and other areas of Belews Lake as the result of BCSS operations.

As described in Section 5.3.2.1.2.1.1, existing elevated summer temperatures within Belews Lake may be stressful to aquatic biota, whereas elevated winter temperatures may extend the growth season. As a result of BCSS closure, lake-wide temperatures begin to cool upon the beginning of the phased implementation period and are notably cooler following the phased in period. Loss of substantive thermal inputs from power generation result in overall benefits regarding water quality and conditions of reduced stress on aquatic biota during the summer but may potentially reduce or alter the spawning season due to lower winter temperatures for some species.

Thermal stratification profiles in Mayo Reservoir, a lake similar to Belews Lake but with minimal anthropogenic heat load, were reviewed to provide a potential prediction of the stratification dynamics of Belews Lake in the absence of the contributing heat load from BCSS (Table 5.2-4). The observed profiles for Belews Lake and for Mayo Reservoir reflect a generally similar trend in temperature, but with relatively consistent differences as shown in Figure 5.2-5 and Figure 5.2-6 in which temperatures in Mayo Reservoir are generally cooler than those of Belews Lake.

5.2.3.1.2.1 Cooling Tower Blowdown

5.2.3.1.2.1.1 Phased Implementation Period

As described in Section 5.2.1.1.2, Duke Energy considered the hydrologic characteristics of the phased implementation period and determined that because full Project operations are associated with maximum consumptive use, it represents a bounded condition for the assessment of impacts associated with hydrologic alterations and water use. Therefore, hydrologic modeling analyses were based on Project conditions only, as they represent a bounded impact relative to the phased implementation period.

Likewise, for the analysis of potential impacts on the water quality of Belews Lake, Duke Energy considered attributes of cooling water discharged from BCSS operations and the effects of cooling tower blowdown from Project Operations within Belews Lake.

Under existing conditions, the BCSS CCW outfall discharges to West Belews Creek arm where thermal effluents dissipate widely. Thermal effluent within the CCW flow is then conveyed via the CCW canal to the main Belews Creek arm of the lake. Belews Lake is strongly stratified in

summer months (see Figure 2.2-18), which limits the interaction between surface water (epilimnion) and deeper water (hypolimnion). Therefore, the effluents conveyed by the CCW canal are effectively a surface discharge that enters the Belews Creek arm epilimnion with little or no mixing occurring within the hypolimnion. Consequently, the hypolimnion temperatures of the Belews Creek arm are not substantially influenced by BCSS discharges.

In conjunction with the phased implementation period, BCSS operations are reduced (relative to the BCSS Continuous Maximum Generation Condition) and offset by Project operations. Duke Energy plans to balance overall generation at Belews Lake between BCSS and the Project, meaning that as new advanced reactors are brought online, a corresponding amount of BCSS generation is taken offline. As a result, the thermal load to Belews Lake is substantially reduced. This reduced thermal load correspondingly reduces environmental impacts relative to the existing condition described in Chapter 2. Subsections 2.2.3.1.2 and 2.2.3.1.5.1 describe the existing thermal conditions within Belews Lake under existing BCSS operations that represent a condition that bounds thermal effects during the phased implementation period.

In contrast to existing BCSS operations, Project cooling tower blowdown discharges are conveyed at depth to the hypolimnion of the Belews Creek arm of Belews Lake via gravity pipe conveyance(s). Mixing of the cooling tower blowdown to achieve the regulatory temperature excess criterion of 2.8 degrees Celsius (°C) (5.04 degrees Fahrenheit [°F]) is completed entirely within the hypolimnion and is not mixed with the epilimnion. Additionally, during the phased implementation period, the introduction and use of advanced reactor units are phased into operation in a manner that balances the net generation as BCSS is derated. Therefore, Project-related thermal inputs are correspondingly limited and reduced relative to the full BCSS Continuous Maximum Generation Condition and are further described in Section 5.2.3.1.2.1.2.2. The BCSS once-through cooling-water-per-kilowatt heat load to Belews Lake is substantially greater than the per-kilowatt power generation from the advanced reactors because of the use of the cooling towers. Therefore, as each advanced reactor unit is placed into operation during the phased implementation period, the heat load to Belews Lake is correspondingly reduced by derating BCSS operations. Therefore, based on the heat loads and plume characteristics, only the Project full generation condition discharges were modeled.

In summary, no specific thermal model analyses of the phased implementation period discharges to Belews Lake are necessary, and was therefore not completed, because the effects of the bounded thermal condition as described in Chapter 2 had previously been evaluated. Specifically:

- The full operational BCSS discharge to Belews Lake (as represented in Chapter 2 under existing conditions) defines the bounding condition for temperature characteristics of Belews Lake. BCSS plant operations result in a substantially larger thermal load (flow rate and temperature excess) as compared to the full Project.
- BCSS thermal CCW effluents are discharged to the West Belews Creek arm where they dissipate. Thermal effluent within the CCW flow enters the Belews Creek arm where thermal effluents are substantially confined to the epilimnion.
- The phased implementation period consists of notably lower thermal effluents from BCSS and relatively minor Project-related thermal discharges that are substantially unmixed.

- Project operations have a lower per-kilowatt power generation heat contribution compared to the existing BCSS. Therefore, the thermal load during the phased implementation period is reduced as the Project operations come online and BCSS is derated.
- Both the phased implementation period and Project operations have a lower thermal load generated compared to full BCSS operations. Therefore, thermal impacts to Belews Lake are bounded by the existing condition (Chapter 2).
- Full Project operations result in maximum cooling tower blowdown flows and thermal loading that are significantly lower than existing BCSS operations.
- Project cooling tower blowdown effluents are mixed within the hypolimnion and do not substantially affect or mix with the epilimnion.

5.2.3.1.2.1.2 Full Project Operations

As discussed in Section 3.4.1.1.4 conceptual cooling tower discharge designs being considered for Belews Lake include a base discharge design consisting of separate individual discharges for each of the three Plant Complexes. The blowdown for each of the three Plant Complexes discharge via gravity to Belews Lake. An alternative design includes combining the blowdown from each of the three Plant Complexes into a combined discharge located northeast of the most northern Plant Complex as shown on Figure 3.1-1. While blowdown is predominately returned to Belews Lake, blowdown flow may be diverted to the Dan River in a discharge outfall located within the existing corridor adjacent to Outfall 006 as described in Section 5.2.3.1.4.1.

The average and maximum flow rates for the discharges to Belews Lake are described in Table 3.4-1, and the anticipated water treatment chemicals are provided in Table 3.2-1. Table 3.4-3 presents the concentrations of anticipated blowdown constituents. As described in NUREG-1437, Rev. 1, *Generic Environmental Impact Statement for License Renewal of Nuclear Plants*, surface water quality impacts may occur from the concentration and discharge of chemicals added to the recirculating cooling water to prevent corrosion and biofouling. Table 5.2-5 compares the expected cooling tower blowdown concentrations with applicable U.S. Environmental Protection Agency (USEPA) water quality criteria for human health and aquatic life, and NC water quality criteria for domestic water and surface water, fish, and aquatic life. It includes the most restrictive water quality criteria values for the applicable designated uses.

A supplemental Cornell Mixing Zone Expert System (CORMIX) water quality analysis evaluated the impact of selected cooling tower blowdown constituents that are discharged to Belews Lake. CORMIX is a widely used model developed with support from the USEPA beginning in the 1970s. The model is currently available as proprietary software from MixZon. CORMIX is an expert system model for analyzing discharge plumes. The model performs steady-state hydraulic analyses and can model both near-field and far-field plume regions. The expert system first determines a flow classification for each portion of the plume being analyzed. It then selects the appropriate mixing algorithm for each segment. The CORMIX model was used to analyze the near-field discharges of the cooling tower blowdown discharged to Belews Lake. As described in Subsection 5.2.3.1.2, the thermal stratification profiles in Mayo Reservoir were reviewed to provide a prediction of the stratification dynamics of Belews Lake in the absence of the contributing heat load from BCSS. All CORMIX modeling analyses were conducted only for Project conditions at Belews Lake.

5.2.3.1.2.1.2.1 Analysis of Cooling Tower Blowdown Constituents

Table 5.2-5 identified six constituents in the cooling tower blowdown that exceed NCDEQ regulatory criteria (chronic or acute): copper, cadmium, lead, selenium, total dissolved solids (TDS), and zinc. Copper and cadmium were the two selected water quality constituents for near-field mixing evaluation based on the discharge concentrations being above NCDEQ regulatory criteria (chronic or acute values) among the parameters in Table 5.2-5. Temperature was also selected as a constituent and is discussed further in Section 5.2.3.1.4. CORMIX mixing results are presented in Table 5.2-6 for both the individual discharge scenario and combined discharge scenario. Based on the analysis, a regulatory mixing zone is required during operation for both the combined discharge and individual discharge scenarios to satisfy regulatory requirements.

The term mixing zone in the following discussions refers to a general area within which mixing occurs that is similar to typical regulatory mixing zones defined by federal and state guidance and regulatory documents. It is different than a regulatory mixing zone which is established through the NPDES permitting process with certain length, width, and cross-sectional area limitations. No regulatory mixing zone has been identified through the CORMIX analyses performed for proposed permitting.

Section 3.2.2.4.3 describes two discharge options for cooling tower blowdown to Belews Lake. Based on the CORMIX mixing analysis, there are effectively no substantive differences in near-field mixing predictions for the individual discharges. Should operations discharge to a combined outfall, the only difference in CORMIX model near-field mixing predictions to the individual discharge scenario is that the combined effluent is influenced by the additional discharge momentum due to the combined flow. The larger jet requires slightly more distance than the smaller jets for a given downstream dilution to be attained as shown in Table 5.2-6 and Figure 5.2-7.

Wastewater discharges from the Project are regulated by the NCDEQ through an existing NPDES permit as described in Table 1.4-2. An NPDES permit includes discharge limits established to protect receiving waters and monitoring to ensure compliance with those limits. Chemical concentrations for discharges comply with the terms and conditions of the NPDES permit with the use of a regulatory mixing zone.

Section 3.4.3.1 describes the established Water Chemistry Program that covers cooling tower operations for the existing nuclear fleet to ensure NPDES compliance. The program utilizes several administrative procedures to ensure regulatory compliance and describes the implementation for treatments, maintenance, and testing best suited for the site-specific design and environment.

A summary of the curvilinear distance and vertical plume rise for constituents which exceeded water quality criteria and were evaluated with CORMIX are found in Table 5.2-6. Table 5.2-6 demonstrates that constituents which may exceed WQSs are rapidly diluted within a mixing zone defined based on typical regulatory mixing zones dimensions. The other cooling tower blowdown constituents satisfy existing NPDES discharge limits and are managed under the established Water Chemistry Program, to ensure continued compliance. Therefore, cooling tower blowdown operations have limited water quality impacts and the impact from cooling tower blowdown chemical constituents to Belews Lake is minor.

5.2.3.1.2.1.2.2 Thermal Impacts

As described in Section 5.2.3.1.2.1 and Figure 3.2-4, cooling tower blowdown is routed to Belews Lake and has a peak temperature of 95ºF (35ºC). Discharged wastewater is permitted under the NCDEQ NPDES program and is subject to the NCDEQ temperature narrative standard requirements of 15A NCAC 02B.0211 (18), which states: “Temperature: not to exceed 2.8°C (5.04°F) above the natural water temperature and in no case to exceed 32°C (89.6°F) for lower piedmont and coastal plain waters.” Belews Lake was permitted and constructed as a cooling impoundment and was created solely for the purpose of serving as part of the BCSS cooling water system (HDR, 2022). Under the existing BCSS NPDES permit, the point of thermal compliance for Belews Lake is located on Belews Creek at the dam spillway.

Because of the phased implementation of Project operations with BCSS closure, thermal discharges from BCSS operations are discontinued. As described in Section 7.1.2.1.2, surface water temperatures are reduced (cooler). The CCW discharge would cease, and heated effluent would no longer disperse within the West Belews Creek arm or be conveyed via the CCW canal to the Belews Creek arm as illustrated in Figures 2.2-16 and 2.2-17 (summer and winter temperatures, respectively). General cooling would occur within each reach of Belews Lake until temperatures equilibrate within the lake. Spatial variability in temperature conditions within Belews Lake that are evident under BCSS operations would normalize such that each area of the lake would reflect conditions that are not influenced by the thermal discharges from BCSS. Water temperatures within the West Belews Creek arm of Belews Lake would resemble those observed in the other areas of Belews Lake. As summarized in Section 7.2.2.3, because of the effects of BCSS closure and the minimal effects of plant operations, the cumulative effects on surface water quality in Belews Lake are LARGE and beneficial.

As described in Section 5.2.3.1.2.1, a CORMIX water quality mixing analysis evaluated the near-field (i.e., the lake volume close to the discharge structures) impact of discharging cooling tower blowdown into Belews Lake. The evaluation included estimated projections for wastewater discharge during summer and winter drought conditions as well as normal summer operating conditions.

The CORMIX analyses identified the dimensions of a mixing zone, where applicable, at each discharge to meet regulatory standards. Table 5.2-7 provides a summary of the curvilinear distance and vertical plume rise required to reduce the temperature excess to 2.8°C (5.04°F) above ambient condition. The CORMIX near-field modeling indicates that either of the two basic cooling tower blowdown discharge options, a single combined discharge for all Plant Complexes (i.e., Combined Discharge) or three separate discharges (i.e., South, Middle, and North Discharge), satisfactorily mix the cooling tower blowdown in the near field as well as minimize the chance of direct recirculation with the cooling tower makeup intake location. Therefore, CORMIX predictions indicate the thermal plume disperses rapidly and effects are localized. Therefore, the effects of thermal discharges on Belews Lake are minor.

The impact of thermal discharge on recreation is discussed in Section 5.4.4.2.1.

5.2.3.1.2.2 Nonradioactive Liquid Discharge

As shown in Figure 3.2-4 and described in Section 3.4.1.1, while Belews Lake receives non-radioactive cooling tower blowdown discharges, it does not receive nonradioactive liquid waste

discharges from Project operations. As described in Section 3.4.3.3.3, nonradioactive liquid waste discharges (e.g., turbine building sumps, groundwater sumps, and water treatment discharges) are routed to the consolidated sump, where they undergo treatment before discharging to the Dan River. Liquid effluent discharges are managed in accordance with the Project site-issued NPDES permit.

5.2.3.1.2.3 Supplemental Pumping from the Dan River

As described in Section 5.2.1.1.3.1, pumping from the Dan River into Belews Lake via the MWIS is conducted during operations to supplement lake levels. The periodic addition of Dan River water via the MWIS has the potential to introduce additional trace metals and other contaminants to Belews Lake.

Duke Energy evaluated the impact on Belews Lake from temporary MWIS pumping over three separate periods from December 2002 through March 2009. Section 2.2.3.1.3.3 describes the previous evaluations of the potential effects of supplemental pumping from the Dan River on Belews Lake water quality which determined the impact was temporary and localized to the makeup water discharge location (Figure 2.2-3). The 2008 temporary pumping report noted a long-term, slight upward trend in lake-wide specific conductance thought to be linked to evaporative concentration caused by the preceding drought and not the temporary pumping contribution (Finley, 2008).

As part of the permitting requirements described in Section 2.2.4.1.1, Duke Energy has produced periodic Dan River monitoring reports once per permit cycle to address the potential effects of selenium, arsenic and mercury (NCDEQ, 2025a). The original monitoring plan also suggested cadmium, copper and zinc be included in the analysis (NCDEQ, 1983). The most recent report for a monitoring period between 2019 and 2022 found that all fish collected were below the USEPA's screening value for arsenic, mercury, and selenium (Duke Energy, 2023). As part of the preapplication monitoring of water quality within the Dan River, as summarized in Section 2.2.3, Duke Energy measured arsenic, selenium, cadmium, copper, zinc, and mercury. Each of these target metals were below the NCDEQ aquatic freshwater standard. Based on periodic fish tissue monitoring and data from the preapplication monitoring program within the Dan River, it is not expected that constituent accumulation would occur within Belews Lake as a result of increased MWIS operations.

Section 5.2.1.1.3.1 describes the MWIS NPDES permitting requirements during Project operation which limit the volume and time period in which water may be transferred into Belews Lake. Duke Energy is required to perform routine semi-annual lake monitoring to assess limnological conditions in Belews Lake as a result of pumping which minimizes the potential for unknown, long-term potential impacts (NCDEQ, 2025a). Nonradiological chemical constituents within the Dan River are not appreciably different from Belews Lake, and the Dan River does not have any measured metal accumulation impacts. Historical monitoring demonstrates MWIS operation has only a localized, temporary impact on Belews Lake water quality; therefore, the impact from supplemental pumping is expected to be minor. Potential impacts are mitigated via NPDES permit requirements and limnological monitoring.

Potential sedimentation impacts to Belews Lake as a result of MWIS operation are described in Section 5.2.1.1.2.2.2.

5.2.3.1.3 Summary of Surface Water Quality Impacts on Belews Lake

Direct effects of operation on water quality within Belews Lake include the addition of cooling tower blowdown wastewater constituents, reduced thermal load and supplemental pumping from the Dan River. The additional wastewater discharges are not expected to accumulate and will meet NPDES permitting limits and requirements within a regulatory mixing zone, which will be established during the permitting process. Section 5.2.4.1.2 describes monitoring programs to ensure regulatory compliance. Therefore, the overall impacts on surface water quality are considered SMALL. However, as summarized in Section 7.2.2.3, because of the effects of BCSS closure in substantially eliminating thermal contributions to Belews Lake and the minimal effects of plant operations, the cumulative effects on surface water quality in Belews Lake are LARGE and beneficial.

5.2.3.1.4 Dan River

As described in Section 3.4.1.1 and shown on Figure 3.2-4 water quality within Dan River may be impacted by wastewater discharge consisting of cooling tower blowdown, treated liquid radwaste, water processing plant wastewater, MWIS operation, and sanitary waste.

5.2.3.1.4.1 Cooling Tower Blowdown

As discussed in Section 5.2.3.1.2.1 and shown on Figure 3.2-4, the discharge design concept may route a portion of cooling tower blowdown to the Dan River in a corridor adjacent to existing Outfall 006 to support water quality strategies and provide dilution for treated liquid radiological waste.

As stated in Section 5.2.3.1.2.1, six cooling tower blowdown constituents exceed NCDEQ regulatory criteria. A CORMIX supplemental water quality analysis evaluated the impact of cooling tower blowdown discharge into the Dan River. Copper, cadmium, and TDS were selected as the water quality constituents mixing evaluation based on the discharge concentrations being above NCDEQ regulatory criteria (chronic or acute values) among the parameters in Table 5.2-5. Temperature was also selected as a constituent and is discussed further in Section 5.2.3.1.4.4. CORMIX mixing results are presented in Table 5.2-8 and Table 5.2-9 and determined a mixing zone is required to achieve water quality compliance.

As described in Section 3.4.1.1.4, cooling tower blowdown directed to the Dan River in a corridor adjacent to existing Outfall 006 occurs intermittently which limits potential impacts. Duke Energy maintains several Dan River monitoring programs to assess the impact of metals accumulation within the Dan River and ensure Project operational discharges do not destabilize existing water quality conditions as described in Section 5.2.3.1.2.3. Should impacts be measured, additional BMPs would be considered to mitigate impacts on Dan River water quality.

Duke Energy's wastewater discharges are regulated by the NCDEQ through an existing NPDES permit as described in Section 2.2.3.1.3.2. An NPDES permit includes discharge limits established to protect receiving waters and monitoring to ensure compliance with those limits. Chemical concentrations for discharges comply with the terms and conditions of the NPDES permit with the use of a regulatory mixing zone.

A summary of the direct distance for the select constituents which exceeded water quality criteria and were evaluated with CORMIX are found in Table 5.2-8. Table 5.2-8 demonstrates that constituents which may exceed WQSs are rapidly diluted within a mixing zone of similar size to typical riverine regulatory mixing zones. The other cooling tower blowdown constituents satisfy existing NPDES discharge limits and are managed under the established Water Chemistry Program, as described in Section 5.2.3.1.2.1, to ensure continued compliance. Additional engineering or administrative controls are evaluated, as needed, if further mitigation is required based on the results of the operational water monitoring program described in Section 5.2.4.1.2. Therefore, cooling tower blowdown operations have limited water quality impacts, and the impact from cooling tower blowdown chemical constituents to the Dan River is minor.

5.2.3.1.4.2 Nonradioactive Liquid Discharge

As described in Section 3.4.3.3.3, nonradioactive liquid waste discharges (e.g., turbine building sumps, groundwater sumps, and water treatment discharges) are routed to the consolidated sump, where they undergo treatment before discharging to the Dan River. Liquid effluent discharges are managed in accordance with the Project site-issued NPDES permit.

As discussed in Section 3.4.3.3.3 and illustrated in Figure 3.2-4, nonradioactive liquid waste from Project operations, including industrial stormwater, sanitary waste, and other conventional liquid discharge streams, is routed to the consolidated sump, where it undergoes treatment before discharging to the Dan River via Outfall 006.

Duke Energy's liquid effluent discharges are regulated via an existing NPDES permit as described in Section 5.2.3.1.2.1. The current permit does not include a Dan River regulatory mixing zone. Duke Energy's industrial stormwater discharges are also regulated via an existing NPDES permit. Existing site storm drainage outfalls may be modified, and outfalls built to route stormwater to the Dan River where applicable.

Effluent characteristics and concentrations are managed using appropriate engineering controls in a manner that complies with both state WQSs and federal permitting requirements. Water quality in the Dan River is maintained with the added discharge due to compliance with NCDEQ permit requirements and the impact is minor.

5.2.3.1.4.3 Liquid Radwaste Discharge

As described in Section 3.4.2.4 and Figure 3.2-4, liquid low-level radioactive waste is collected and treated in accordance with the requirements of 10 CFR Part 20 and the "as low as is reasonably achievable" (ALARA) principles of Title 10 CFR Part 50, Appendix I. The bounding annual release of radioactivity in liquid effluents from the proposed Project site is provided in Table 3.4-4, and the bounding average annual liquid effluent release of radioactivity from a single advanced reactor is shown in Table 3.4-5. The potential impact of liquid radwaste discharge is further discussed in Section 5.9. Duke Energy will evaluate administrative and engineering controls as needed regarding discharge and MWIS operations to minimize the potential for transport of radionuclides from the Dan River to Belews Lake. Additionally, as summarized in Section 5.9.6, a radiological monitoring program inclusive of the Dan River and Belews Lake will also be implemented in conjunction with Project operations.

5.2.3.1.4.4 Thermal Impacts

As described in Section 5.2.3.1.4.1 and Figure 3.2-4, a portion of cooling tower blowdown may be discharged to the Dan River in a corridor adjacent to existing Outfall 006. Cooling tower blowdown thermal characteristics and permitting limits are described in Section 5.2.3.1.2.4.

As described in Section 5.2.3.1.4.1, a CORMIX water quality analysis evaluated the impact of discharging cooling tower blowdown into the Dan River. The blowdown is used for dilution of liquid low-level radiological wastewater. The evaluation included estimated projections for wastewater discharge during Dan River summer and winter 7Q10 low-flow condition.

The analyses were based on the following:

- Winter and summer conditions, including 7Q10 river flows and a water temperature not more than 21°F (11.7 °C) (summer) and 28°F (15.6 °C) (winter) above ambient river values.
- Initial temperature excess based on monthly 0.4% probability exceedance wet bulb temperatures and resulting blowdown temperatures,
- Estimated monthly minimum river temperatures based on the monthly air temperature related to the cooling tower wet bulb temperature and 100% relative humidity that maximizes the initial temperature excess.
- Effluent discharge rate based on the bounding rate of 9450 gpm (20.1 cfs or 0.60 m^3/s) (including cooling tower blowdown dilution flow).
- Compliance with the regulatory thermal limitation (2.8°C [5.04°F]) and a potential regulatory mixing zone based on typical length, width, and cross-sectional area limitations of three times the channel width, 50% of the channel width, and 33% of the channel cross-sectional area, respectively.

The CORMIX analyses identified the dimensions of an assumed regulatory mixing zone, where applicable, to assess potential regulatory requirements. Table 5.2-9 provides a summary of the direct distance from the end of the pipe to the end of the mixing zone required to reduce the temperature excess to the regulatory criterion of 2.8°C (5.04°F) above ambient. The CORMIX modeling indicates that wastewater, including blowdown, discharged into the Dan River satisfactorily mixes with river flow. There is a fully-vertically mixed condition in the diffuser jet and plume due to the shallow river depths at low flows, including the winter 7Q10 flow. Therefore, the effects of thermal discharges on the Dan River are minor.

The impact of thermal discharge on recreation is discussed in Section 5.4.4.2.2.

5.2.3.1.4.5 Summary of Surface Water Quality Impacts on Dan River

Direct effects of operation on surface water quality within the Dan River include the addition of cooling tower blowdown wastewater constituents and thermal load and nonradioactive liquid discharges.

Dan River Project operational impacts to water quality are mitigated through engineering and administrative controls and monitoring programs as described in Section 5.2.4.1.2. The additional wastewater discharges are managed within NPDES permitting limits and requirements; therefore, overall impacts of surface water quality are SMALL.

5.2.3.2 Groundwater

Accidental spills of materials such as diesel fuel, hydraulic fluid, or lubricants are unlikely during operations. However, if they occur, impacts are minimized by appropriately designed containment systems and established procedures for cleanup in accordance with a SPCC plan, as described in Section 4.2.3.2. Although actions outlined in an SPCC plan are primarily intended to prevent spilled oil from being released into receiving waters, they also mitigate impacts to local groundwater because accidental spills are quickly attended to and not allowed to penetrate though the soil surface into groundwater. Because the engineering controls described above prevent or minimize the release of harmful effluents, and because concentrations of constituents in surface water are maintained at levels below permitted limits, any impacts to groundwater quality are SMALL.

5.2.4 WATER MONITORING

5.2.4.1 Surface Water Monitoring

This section describes the monitoring programs Duke Energy uses to provide for protection of waterbodies that may be affected during operation of advanced reactors and to obtain timely and accurate information so that actions can be taken to limit operational impacts. This section discusses the thermal and chemical monitoring programs, as applicable, for surface water and groundwater at the Project site and the Dan River. Methodologies and constituents included as part of the operational radiological monitoring program are described in Section 5.9. Operational monitoring programs are compared to baseline conditions to identify potential concerns and take appropriate actions toward limiting the impact on both surface water and groundwater resources. The proposed surface water monitoring program will be submitted at the construction permit or license application phase.

5.2.4.1.1 Preoperational Monitoring Program

The purpose of the preoperational monitoring program is to establish baseline surface water conditions at each of the proposed reactor locations at the North, Middle, and South Complex areas before operation.

Duke Energy monitors existing locations as described in Section 2.2.4.1.1 throughout the preoperational monitoring program. Additional monitoring locations may be included with respect to the surface water preoperational monitoring program following technology selection and final design. Details of the preoperational monitoring program are defined following technology selection and include thermal, chemical, and radiological monitoring as needed. As part of the program, a monitoring plan is developed to specify locations, sampling frequencies, sampling protocols, and quality assurance procedures for sampling and analysis. Samples are analyzed for standard water quality parameters (temperature, pH, conventional pollutants), metals, and selected radionuclides following the guidance of NUREG-1555, Initial, *Standard Review Plans for Environmental Reviews for Nuclear Power Plants* as described in Section 2.2.4.1.2.

5.2.4.1.2 Operational Monitoring Program

Duke Energy maintains NPDES wastewater permit NC0024406 and NPDES stormwater permit NCS000573. An operational monitoring program will be developed as part of its existing wastewater and stormwater NPDES permit applications to include the discharges described in Section 3.4.1.1 and Figure 3.2-4. There is currently no operational Project, so potential additional monitoring requirements for operation of advanced reactors are not included. Discharge of cooling water and other effluents during operations is subject to monitoring to ensure compliance with all federal, state, and local discharge requirements. Discharge of cooling water and other effluents during operations is subject to monitoring to ensure compliance with the NPDES permit.

Regular monitoring is required to ensure that liquid effluent discharges comply with the conditions of the NPDES permit for plant wastewater and stormwater. The specific requirements for hydrologic monitoring, water quality parameters, number of stations, station locations, frequency and method of measurement, and equipment type are specified in the NPDES program. Temperature and contaminant concentration limits will be established, along with modeling efforts needed to demonstrate compliance, and reflected in the NPDES permit.

It is anticipated that the surface water monitoring locations monitored during operation are the same locations used during the preoperational monitoring program. The operational monitoring program cannot be defined until a reactor design is selected but includes thermal, radiological, and chemical monitoring. As part of the program, a monitoring plan would be developed for specific locations, sampling frequencies, protocols, and procedures for sampling and analysis.

5.2.4.2 Groundwater

Duke Energy will prepare preoperational and operational monitoring programs for hydrological and water quality monitoring to establish a baseline for groundwater characteristics to identify impacts to the groundwater during plant operation. Methodologies and constituents included as part of the operational radiological monitoring program are described in Section 5.9. The preoperational and operational monitoring programs cannot be defined until a technology has been selected. These monitoring programs will be developed following the guidance of NUREG-1555. The proposed groundwater monitoring program will be submitted at the construction permit or license application phase.

5.2.4.2.1 Preoperational Monitoring Program

Duke Energy's preoperational monitoring program may consist of a subset of groundwater observation wells used in the preapplication monitoring program as described in Section 2.2.4.2, as well as additional wells depending on the future technology chosen. The purpose of the preoperational monitoring program is to establish baseline groundwater conditions at each of the proposed reactor locations at the North, Middle, and South complex areas before operation. Samples are analyzed for standard water quality parameters (i.e., temperature, pH, conventional pollutants) and metals following the guidance of NUREG-1555. Groundwater elevations will also be measured monthly from the monitoring wells chosen for this preoperational monitoring program. Parameters include selected radionuclides and other parameters, as appropriate and as described in Section 2.2.3.2.

5.2.4.2.2 Operational Monitoring Program

It is anticipated that the groundwater wells that are monitored during operation may be the same wells used during the preoperational monitoring program as well as additional wells depending on the future technology chosen. The operational monitoring program cannot be defined until a reactor design is selected but includes water level and chemical monitoring. As part of the program, a monitoring plan would be developed to specific locations, sampling frequencies, protocols, and procedures for sampling and analysis.

Table 5.2-1
Belews Lake Long-Term Water Balance Components

Parameter	Model Scenario		
	Historical (Actual)[a]	**BCSS Continuous Maximum Generation Condition (Permit)**[b,c]	**Project Condition**[c]
MWIS Pumping Rate (cfs)	(temp. pumps)	80[d]	80[d]
Watershed Runoff (cfs)	68.5	68.4	68.4
Direct Precipitation (cfs)	19.5	19.8	19.5
Dan R Diversion (cfs)[e]	1.5	7.8	18.2
Total Inflow (cfs)	**89.4**	**96.1**	**106.1**
Consumptive Withdrawal (cfs)	10.2	18.3	60.7
Forced Evaporation (cfs)	16.8	25.0	0.2
Subtotal Consumptive Use (cfs)	***27.0***	***43.3***	***60.9***
Natural Evaporation (cfs)	16.9	16.9	16.6
Spillway Release (cfs)	28.7	19.4	12.5
Gate Leakage & Dam Seepage (cfs)	7.8	7.8	7.7
Net Seepage Loss (cfs)	8.8	8.8	8.6
Storage Change (Initial - Final) (gallons)	0.0	-0.1	-0.1
Total Outflow (cfs)	**89.2**	**96.1**	**106.1**
Average Water Level (ft.)[f,g]	723.81 (1.19)	723.76 (1.24)	723.03 (1.97)
Minimum Water Level (ft.) (EOM)[f,g]	717.59 (7.41)	716.76 (8.24)	711.89 (13.11)
Water Level (1%) (ft.)[f,g,h]	718.98 (6.02)	718.67 (6.33)	714.67 (10.33)
Water Level (2%) (ft.)[f,g,h]	720.38 (4.62)	720.57 (4.43)	718.21 (6.79)
Water Level (5%) (ft.)[f,g,h]	721.27 (3.73)	721.18 (3.82)	719.52 (5.48)
Water Level (10%) (ft.)[f,g,h]	722.25 (2.75)	721.72 (3.28)	720.43 (4.57)
Water Level (50%) (ft.)[f,g,h]	724.32 (0.68)	724.07 (0.93)	723.01 (1.99)

Notes:
(a) Based on actual historical BCSS operations 1997 – 2024.
(b) Based on BCSS continuously operating at 100% capacity and permitted conditions.
(c) Based on simulated data from data obtained from 1956 through 2024.
(d) 80 cfs is the bounding condition for Belews Lake MWIS diversions.
(e) Dan River Diversion is the calculated average diversion rate.
(f) Lake level (lake level drawdown below 725.0 ft.).
(g) Parenthetical value is the drawdown (ft.) below the full lake level (725.0 ft.).
(h) Percentile value of the total dataset from 1956 through 2024.
Key: cfs = cubic feet per second; EOM = End of Month; ft. = feet; MWIS = Makeup Water Intake Structure; NA = Not Applicable; temp. = temporary

Table 5.2-2
Belews Lake Minimum Level Frequencies (Minimum Water Levels in ft. NAVD 88)
(Sheet 1 of 2)

	Historical (Actual)[a]		BCSS Continuous Maximum Generation Condition [b,c,d]		Project Condition[c,d]		
	Elevation	Drawdown[e] (ft.)	Elevation	Drawdown[e] (ft.)	Elevation	Drawdown[e] (ft.)	Change Relative to BCSS Continuous Maximum Generation Condition (ft.)
MWIS Pump Capacity (cfs):	(temp. pumps)		80[d]		80[d]		
2-Year[f]	723.26	1.7	722.19	2.8	721.56	3.4	-0.6
5-Year[f]	721.67	3.3	721.20	3.8	720.03	5.0	-1.2
10-Year[f]	720.47	4.5	720.45	4.5	718.87	6.1	-1.6

Minimum Observed / Predicted[h]	717.59	7.4	716.8	8.2	711.89	13.1	-4.9
Critical Drought Duration[i]	23 months		22 months		31 months		
End Date of Critical Drought	April 2003		January 2003		January 2013		

Table 5.2-2
Belews Lake Minimum Level Frequencies (Minimum Water Levels in ft. NAVD 88)
(Sheet 2 of 2)

Notes:
(a) Based on actual historical BCSS operations 1997 – June 2024.
(b) Based on BCSS continuously operating at 100% generation capacity and permitted conditions.
(c) Based on data from simulation period 1956 through 2024.
(d) MWIS rate of 80 cfs (2.26 m^3/s) is the bounding condition for Belews Lake MWIS diversions.
(e) Full Pond level is defined as an elevation of 725.0 ft. Drawdown is the difference between the full pond level of 725.0 ft and the predicted pond elevation.
(f) Drought Event Recurrence Condition.
(g) 100-year minimum lake level estimates are approximate, based on simple regression equation fit to annual minimum lake level versus Weibull plotting position.
(h) Data obtained from Table 5.2-1.
(i) Based on drought period lake drawdown below water level 724.0 ft; duration in months.

Key: "--" = Not applicable or evaluated; BCSS = Belews Creek Steam Station; cfs = cubic feet per second; ft = feet; m^3/s = cubic meters per second; MWIS = Makeup Water Intake Structure; NAVD 88= North American Vertical Datum of 1988;; temp. = temporary

Table 5.2-3
Average Monthly Low Flow Frequency Data – Dan River Below MWIS

Return Period	River Flow (cfs)		
	BCSS Continuous Maximum Generation Condition [a,c]	Flow Under Project Conditions[b,c]	Natural Flow[d]
2-Year	231	213	238
5-Year	156	146	171
10-Year	127	118	142
25-Year	109[e]	105[e]	112
50-Year	79[e]	79[e]	79
100-Year	32[e]	32[e]	32

Notes:

(a) Based on BCSS continuously operating at 100% generation capacity,80 pumping cfs, and permitted conditions.

(b) Based on Project 100 cfs pumping at permitted conditions.

(c) All active pumping cases follow the same permit conditions as described in Subsection 3.4.1.1.2.

(d) No BCSS or MWIS pumping.

(e) MWIS pumping would be reduced or halted during Project Operations to maintain entire natural flow when natural flow is less than 110 cfs.

Key: BCSS = Belews Creek Steam Station; cfs = cubic feet per second; MWIS = Makeup Water Intake Station

Table 5.2-4
Thermal Stratification Characteristics of Belews Lake and Mayo Reservoir

Characteristic	Units	Belews Lake	Mayo Reservoir	Difference
Epilimnion Depth	Feet	26-33	13-23	10-13

Table 5.2-5
Cooling Tower Blowdown Constituent Concentrations and Water Quality Criteria
(Sheet 3 of 3)

Notes:

(a) Values are sourced from the PPE Table 2 calculated based on existing water quality at sample location nearest to proposed intake location and assuming maximum normal operating 12 Cycles of Concentration.

(b) NCDEQ Surface Water Quality Standards Rules 15A NCAC 02B.0100 through 0300.

(c) Acute and chronic freshwater aquatic life standards for metals shall be based upon measurement of the dissolved fraction of the metal.

(d) Non-trout waters.

(e) Hardness of 26 mg/L has been used to determine the site-specific NC 2B Water Quality Standards for specific metals. 26 mg/L is taken from water quality data at nearest upstream sample location to proposed intake or Sample Location 410.

(f) The WER shall be assigned a value equal to one unless determined otherwise under Sub-Item (11(b)) of Subchapter 02B – Surface Water and Wetland Standards.

(g) WER·[{1.101672-[ln hardness](0.041838)} · e^{0.7977[ln hardness]-3.909}].

(h) WER·[{1.136672-[ln hardness](0.041838)} · e^{0.9789 [ln hardness]-3.443}].

(i) WER· [0.860 · e^{0.8190[ln hardness]+0.6848}].

(j) WER· [0.316 · e^{0.8190[ln hardness]+3.7256}].

(k) WER· [0.960 · e^{0.8545[ln hardness]-1.702}].

(l) WER· [0.960 · e^{0.9422[ln hardness]-1.700}].

(m) WER· [{1.46203-[ln hardness](0.145712)} · e^{1.273[ln hardness]-4.705}].

(n) WER· [{1.46203-[ln hardness](0.145712)} · e^{1.273[ln hardness]-1.460}].

(o) Manganese has been monitored by NCDEQ and has been shown to have elevated background level concentrations that are somewhat flow related and are caused by the geology of the region. NCDEQ removed manganese as a standard as there was no evidence of to conclude that discharges of manganese will impact any beneficial uses of North Carolina's waters (NCDENR, 2015).

(p) Mercury water quality standards shall be based upon measurement of the total recoverable metal.

(q) WER· [0.997 · e^{0.8460[ln hardness]+0.0584}].

(r) WER· [0.998 · e^{0.8460[ln hardness]+2.255}].

(s) Nickel is limited to either the calculated standard or 25 µg/l, whichever is less.

(t) Nitrate nitrogen limit.

(u) The standard for chronic selenium has the following components: fish egg/ovary tissue, fish whole body or muscle tissue, and water column (lentic and lotic). These components shall be used in the following order of preference provided data is available: 1. Fish egg/ovary tissue; 2. Fish whole body or muscle tissue; 3. Water column (NCDEQ, 2022).

(v) WER· [0.986 · e^{0.8473[ln hardness]+0.884}].

(w) WER· [0.978 · e^{0.8473[ln hardness]+0.884}].

(x) Value for total chromium. Speciation for bounding value in PPE not provided.

(y) WER · 11.

(z) WER · 16.

(aa) The Dan River is a class IV waterbody. Regulatory criteria for hardness dependent metals may vary from Belews Lake, but all other standards will be identical.

(bb) Hardness of 21 mg/L has been used to determine the site-specific NC 2B Water Quality Standards for specific metals for the Dan River. 21 mg/L is taken from water quality data at nearest upstream monitoring station A_2_710.0.

Key: mg/L = milligrams per liter; NCAC = North Carolina Administrative Code; NCDEQ = North Carolina Department of Environmental Quality; NE = Regulatory standard not established for this constituent; ng/L = nanograms per liter; PPE = plant parameter envelope; µg/L = micrograms per liter; SU = Standard Units; WER = Water Effect Ratio

Table 5.2-6
CORMIX Evaluation Distances to Obtain Water Quality Regulatory Compliance in Belews

Constituent	Concentration (µg/L)					Distance from End of Pipe to End of Mixing		
	Ambient[a]	Discharge	Excess	Acute WQS	Dilution Required	North Discharge[b,c]		Combi
						Trajectory[d] (m)	Vertical (m)	Trajectory[d]
Copper	1.17	14	12.8	3.78	4.92	2.96	0.76	10.27
Cadmium	0.1	1.2	1.1	0.85	1.47	0.89	0.16	3.20

Notes:

(a) Ambient condition within Belews Lake is the discharge concentration divided by 12 cycles of concentration.

(b) Based on the bounding summer drought conditions.

(c) North Discharge is representative of Middle and South Discharges and is the most conservative of the three outfalls.

(d) Curvilinear distance from end of pipe discharge to meet WQS.

Key: m = meters; NA = Not Applicable; TDS = Total Dissolved Solids; µg/L = micrograms per liter; WQS = Water Quality Standard

Table 5.2-7
CORMIX Evaluation Distances to Obtain Regulatory Compliance for Temperature in Belews Lake

Hydrologic Condition	Season	Distance from End of Pipe to Obtain 5.04º F Excess Temperature Criteria							
		South, Middle, North Discharges[a]				Combined Discharge			
		Trajectory[b,c]		Vertical		Trajectory[a,b]		Vertical	
		Meters	Feet	Meters	Feet	Meters	Feet	Meters	Feet
Drought	Summer	9.7	31.7	3.1	10.2	16.2	53.2	6.3	20.7
Drought	Winter	10.4	34.0	3.4	11.3	17.3	56.8	7.0	23.0
Normal	Summer	9.7	31.9	3.1	10.3	16.2	53.0	6.3	20.6
Normal	Winter	NE[d]	NE[d]	NE[d]	NE[d]	NE[d]	NE[d]	NE[d]	NE[d]

Notes:

(a) For the initial mixing in the near field with no boundary influences, the jet trajectories at the South, Middle, and North Discharges are essentially the same. The primary differences between the South, Middle, and North Discharges are their ambient bounded channel geometries.
(b) The NCDEQ temperature narrative standard requirements of 15A NCAC 02B.0211 (18) states, “Temperature: not to exceed 2.8°C (5.04°F) above the natural water temperature and in no case to exceed 32°C (89.6°F) for lower piedmont and coastal plain waters.”
(c) Curvilinear distance from end of pipe discharge to obtain 2.8 ºC (5.04 ºF) excess criteria. Discharges are located below the thermocline in the hypolimnion region of Belews Lake and the hypolimnion lake temperature range is found in Table 5.2-4.
(d) This condition and season were not evaluated as it has been determined a bounding case is a summer drought. The discharge pipe is located in the hypo limnological region which has a narrow temperature range (Table 5.2-4) with limited seasonal variation.

Key: ºC = degrees Celsius; °F = degree Fahrenheit; ft. = feet; NCDEQ = North Carolina Department of Environmental Quality; NE = Not Evaluated

Table 5.2-8
CORMIX Evaluation Distances to Obtain Water Quality Regulatory Compliance in the Dan River

Constituent	Units	Concentration (µg/L)			Direct Distance (m) from MPD to Meet WQS[b,c]			
		Ambient[a]	Discharge	Excess	Acute WQS	Dilution Required (unitless)	Summer[d]	Winter[e]
Copper	µg/L	0.00	14	14	3.09	4.5	41.77	21.43
Cadmium	µg/L	0.00	1.2	1.2	0.64	1.88	0.75	0.37
TDS	mg/L	61	940	879	500	2.0	0.93	0.46

Notes:
(a) Based on existing upstream water quality monitoring results.
(b) Direct distance accounts for the horizontal (x) parallel to the riverbank, vertical (z) rise, and horizontal (y) distance perpendicular to the bank.
(c) Vertical rise within the Dan River is negligible.
(d) Considers the summer 7Q10 scenario with a five-port multiport diffuser.
(e) Considers the winter 7Q10 scenario with a five-port multiport diffuser.
Key: 7Q10 = 7-day, 10-year river flow; m = meter; mg/L = milligrams per liter; µg/L = micrograms per liter; MPD = multiport diffuser; TDS = total dissolved solids; WQS =water quality standard;

Table 5.2-9
CORMIX Evaluation Distances to Obtain Regulatory Compliance for Temperature in the Dan River

Description	CORMIX Parameter	Summer 7Q10				Winter 7Q10			
		Value	Unit	Value	Unit	Value	Unit	Value	Unit
Dan River Characteristics	River Flow	2.27	m^3/s	80	cfs	4.53	m^3/s	160	cfs
	Chan Width	23.9	m	96	ft	32.9	m	108	ft
	Avg. Chan Depth	0.29	m	0.94	ft	0.4	m	1.3	ft
	Chan Area	8.36	m^2	90	ft^2	13.01	m^2	140	ft^2
CORMIX RMZ Data	RMZ Length[(b)]	88	m	289	ft	99	m	324	ft
	RMZ Width[(c)]	14.7	m	48	ft	16.5	m	54	ft
	RMZ Area[(d)]	2.77	m^2	30	ft^2	4.29	m^2	46	ft^2
Plume characteristics at RMZ[(g)]	Distance[(e,f)]	35.4	m	116	ft	52.4	m	172	ft
	Dilution	4.2	-	4.2	-	5.8	-	5.8	-
	Plume Width	8.9	m	29.2	ft	10.3	m	33.8	ft
	Plume Thickness	0.31	m	1.02	ft	0.42	m	1.38	ft

Notes:
(a) The NCDEQ temperature narrative standard requirements of 15A NCAC 02B.0211 (18) states, “Temperature: not to exceed 2.8 ºC (5.04 ºF) above the natural water temperature and in no case to exceed 32 ºC (89.6 ºF) for lower piedmont and coastal plain waters.”
(b) Assumed RMZ length is equal to three times the channel width.
(c) Assumed RMZ width is equal to half of the channel width.
(d) Assumed RMZ cross-sectional area is equal to one-third of the channel cross-sectional area.
(e) There is no plume rise in the vertical direction prior to obtaining regulatory compliance.
(f) Distance refers to the horizontal distance along the centerline of the plume.
(g) Plume characteristics based on maximum plume cross-sectional area.

Key: Avg. = Average; cfs = cubic feet per second; Chan = Channel; RMZ = regulatory mixing zone; m^3= cubic meters; m = meters; ft. = feet; ft^2 = square feet;

5.3 ECOLOGICAL RESOURCES

This section describes the potential effects on terrestrial, wetland, and aquatic ecological resources from Project operations. The terrestrial and aquatic ecosystems of the Project site are described in detail in Sections 2.3.1 and 2.3.2, respectively. These subsections include information about upland, wetland, and aquatic habitats, associated ecological communities, and important species they support. This section is divided into two subsections: Section 5.3.1 describes terrestrial and wetland impacts, and Section 5.3.2 describes impacts on aquatic resources.

5.3.1 TERRESTRIAL AND WETLAND IMPACTS

This subsection evaluates the potential effects of operation on the terrestrial and wetland ecological resources that occur on the Project site and associated off-site areas. As discussed in Section 2.3.1.2, wetlands are those areas that are inundated or saturated by surface water or groundwater at a frequency and duration sufficient to support a prevalence of vegetation typically adapted for life in saturated soil conditions. Types of wetlands include swamps, marshes, bogs, and similar areas. The wetland discussion in Section 5.3.1.2 includes all potential jurisdictional wetlands on the Project site.

5.3.1.1 Terrestrial Habitat

Due to the extensive size of the NDA, much of the Project site is developed. Thus, remaining terrestrial habitat is limited on the Project site. Impacts to terrestrial habitat primarily during operations consist of landscape maintenance activities such as pesticide/herbicide use, mowing, and disturbance by heavy equipment. Licensed herbicide/pesticide applicators will be used to handle and apply pesticides safely and effectively according to the label-recommended pesticide/herbicide usage and application method and rates. Application areas will include ground cover in corridors while limiting impacts on terrestrial habitat during landscape maintenance. Application will be in accordance with Duke Energy's general NPDES permit for pesticide application (general permit # NCG560000).

Impacts to terrestrial habitat from transmission line maintenance are minimized by appropriate BMPs used in transmission line corridors during corridor maintenance, as discussed above.

Disturbance associated with building activities creates conditions for invasive species to establish in different areas of the Project site and the associated off-site wastewater pipeline corridor (Section 4.3.1.1). Maintenance to reduce the spread of invasive species during operation includes monitoring disturbed lands to identify and control areas that are dominated by invasive plants and the implementation of appropriate control measures. Control methods may include using pesticides/herbicides, hand-pulling, or mechanical treatment as applicable to the species and situation.

As described in Section 3.4.2.2, an ISFSI facility is anticipated within the NDA and is, therefore, within the developed portion of the Project site. Details of the ISFSI including its layout, capacity, and operational characteristics will be determined during the construction permit or license application.

Operation of the mechanical draft cooling towers and associated heat dissipation systems can potentially impact plant communities through salt deposition; increased precipitation, humidity,

fogging, icing; and plume shading. As discussed in NUREG-1437, “Generic Environmental Impact Statement for License Renewal of Nuclear Plants,” these types of impacts can lead to structural damages and changes in plant communities. These small amounts of particulates from cooling towers are dispersed over a wide area, but most of the deposition occurs in relatively close proximity to the cooling towers. Generally, deposition rates at other existing operating nuclear plants have been below those that are known to result in measurable adverse impacts on plants. However, as discussed in NUREG-1555, tolerance levels of native plants, ornamentals, and crops to salt deposition from drift are not precisely known. The NRC recommends using an order-of-magnitude approach to evaluate salt (NaCl) drift deposition thresholds and its potential effects on vegetation. According to NUREG-1555, the following thresholds should be used in such assessments:

- 1 to 2 kilograms per hectare per month (kg/ha/mo) (100 to 200 kilograms per square kilometer per month [kg/km^2/mo]) equivalent to 571 to 1142 pounds per square mile per month [lb/mi^2/mo]: salt deposition generally not damaging to plants.
- Approaching or exceeding 10 kg/ha/mo (1000 kg/km^2/mo) equivalent to 5710 pounds per square mile per month (lb/mi^2/mo): threshold range for visible leaf damage from salt deposition on leaves in any month during the growing season.
- Hundreds or thousands of kg/ha/year (tens of thousands or hundreds of thousands of kg/km^2/year): could cause damage sufficient enough to suggest the need for changes of tower-basin salinities or a reevaluation of tower design, depending on the extent of the area impacted and the uniqueness of the terrestrial ecosystems expected to be exposed to drift deposition.
- The Seasonal and Annual Cooling Tower Impact Model, Version 2 (SACTI2) model analysis for the Project predicts that the greatest seasonal salt deposition from the cooling towers occurs during the summer at 984 feet (ft.) (300 meters [m]) east-northeast of the Project site center point. This summer deposition rate is 63.51 kg/km^2/mo (362.58 lb/mi^2/mo), which is well below the range that causes leaf damage in many species. During other seasons and on an annual basis, the maximum modeled deposition rates range from 41.57 kg/km^2/mo (237.37 lb/mi^2/mo) (annual basis) to 51.77 kg/km^2/mo (296 lb/mi^2/mo) (spring). These salt deposition rates are below the 1000 – 2000 kg/km^2/mo (5710 – 11,420 lb/mi^2/mo) range that could cause leaf damage in many species, as defined by NUREG-1555.

  The SACTI2 model analysis also indicates that cooling tower operation does not produce additional ground fogging or plume rime icing at any distance from the towers. Additional plume water deposition from cooling towers is insignificant compared to observed climatological precipitation rates. Some increase in relative humidity occurs close to the towers or in an elevated plume. However, based on insignificant levels of modeled plume water deposition, no predicted fogging, and no predicted plume rime icing, the predicted impacts on ground-level humidity from operation of all the cooling towers is minor.

Similar to the findings in NUREG-1437, results of SACTI2 modeling for the operation of cooling towers at the Project site indicate that salt deposition rates are well below the threshold range for damaging plants during the growing season or any season. Thus, the impacts of salt deposition to plants on the Project site is minor.

Overall, the impacts of Project operation on terrestrial habitat are minimized through the use of BMPs during landscape maintenance and transmission line maintenance. Therefore, impacts are minor.

5.3.1.2 Wetlands

As discussed in Section 4.3.1.2, building activities directly or indirectly impact all wetlands on the Project site and the associated off-site wetland. Impacts to remaining wetlands primarily consist of landscape maintenance activities in areas surrounding wetlands such as transmission lines. Impacts to wetlands are limited by use of BMPs, such as prohibiting herbicide usage around wetlands and avoiding mowing and other heavy equipment operation within wetlands. The establishment of invasive species because of building activities in wetlands is minimized by control methods as discussed in Section 5.3.1.1.

Inadvertent spills or stormwater runoff during plant operations have the potential to affect wetlands that may be downgradient of such releases. Measures to control potential effects of inadvertent spills include the implementation of a SPCC plan pursuant to 40 CFR Part 112 during operations at the Project site. A SPCC plan includes BMPs such as proper vehicle and equipment maintenance, containment for fuel or oil storage tanks, and the maintenance of spill response equipment and materials. With adherence to permit conditions and implementation of mitigation measures, including the use of an SPCC plan and BMPs, impacts of operations on wetlands from such releases are minor and are mitigated as described in Section 4.2.3.

In some Project settings, groundwater withdrawals from operations have the potential to affect the hydrology of nearby wetlands. As described in Section 5.2.2.1, there are no hydrologic alterations at the Project site that affect groundwater availability during operations. No groundwater use or dewatering occurs during operation that may affect local aquifers. Thus, no impacts occur to wetlands from groundwater usage or withdrawal that may indirectly alter wetland hydrology.

Heat dissipation systems such as mechanical draft cooling towers can potentially impact plant communities within wetlands. However, as discussed in Section 5.3.1.1, results of SACTI2 modeling for the operation of cooling towers at the Project site indicate that salt deposition rates are well below the threshold range for damaging plants during any season. Thus, the impact of salt deposition to plants within wetlands on the Project site is minor.

Overall, the impacts of Project operation on wetlands are minimized through adherence to applicable wetland permit conditions and regulations, including the use of a SPCC plan and BMPs.

5.3.1.3 Wildlife

Based on the extent of the NDA, much of the Project site is developed and wildlife communities are limited to peripheral habitats of the vegetated buffer area and other habitats. Wildlife remaining on the Project site may be impacted by operational noise, such as the operation of the mechanical draft cooling towers and vehicles. As discussed in Section 2.8.2.1.3, background noise at the Project site is the result of noise emissions from the existing BCSS, vehicles on roadways, boats and other recreational activities on Belews Lake, and natural noises. Wildlife within the vicinity of roads on the Project site are currently exposed to traffic from the existing BCSS, and traffic continues during Project operations. Noise levels associated

with operation of the Project are bounded by the noise emissions from the mechanical draft cooling towers (Section 5.8.2). As described in Section 5.8.2, cooling tower noise emissions are up to 58.1 A-weighted scale decibels (dBA) at a distance of 1000 ft. (305 m) from the source. As discussed in Section 4.3.1.3, the threshold noise level at which birds and small mammals are frightened or startled is 80 to 85 dBA. Based on straight-line noise attenuation, this noise threshold level is expected to occur at 80.35 ft. (24.49 m) from the cooling towers. Based on this noise level across the NDA, noise-sensitive wildlife are expected to avoid areas near the cooling towers characterized by elevated noise levels. Any wildlife occurring in proximity to active areas of the Project site avoid areas characterized by excessive noise levels and move to more suitable habitat nearby.

As described in Section 5.4.4.1.1, traffic level of service (LOS) along most of the roadways analyzed does not change during the operations phase. Traffic impacts occur during the beginning and end of work shift and occur for less than 2 hours a day. Any changes to traffic and traffic patterns during operations are not expected to impact wildlife as wildlife is expected to continue to avoid roads and move to suitable habitat areas.

As described in Section 2.3.1.8, the Project site is located within the Atlantic Flyway migration route. As discussed in Section 2.3.1.3.1, Belews Lake provides suitable habitat for migratory and water dependent birds. Waterfowl and other birds crossing the Project site may occasionally collide with tall structures such as the power block bounding structure, with a height of 176 ft. (53.6 m) above grade, as discussed in Section 3.1.5. Other tall structures on-site include transmission structures, with variable heights that normally range from 80 to 120 ft. (24 to 37 m) (Section 3.2). However, as described in Section 4.3.1.3, bird collisions with nuclear power plant structures occur at rates that are unlikely to affect local or migratory bird populations.

Impacts to wildlife from transmission line maintenance are minor due to the limited frequency of transmission corridor maintenance activities. Potential impacts to nesting birds from transmission line maintenance are also minimized through compliance with the Migratory Bird Treaty Act. Collisions of birds with transmission lines and electrocution of birds by transmission lines may occur during operations. Bird diverters and avian-safe insulator assemblies may be used to minimize effects on the local avian population, reduce the frequency of bird collisions and electrocution, and ensure reliable transmission system operation. Wildlife near transmission lines is also exposed to electromagnetic fields (EMFs). However, according to NUREG-1437, there is no evidence to date that wildlife is affected by EMFs. Therefore, impacts are considered minor.

Operational maintenance that may impact pollinators includes mowing, pesticide use, and other grounds maintenance in transmission corridors and other maintained areas. The greatest impacts on pollinators are in areas with a diverse composition of flowering plants, such as the transmission corridors. When possible, transmission line maintenance activities are scheduled to minimize harm to pollinators by limiting mowing to the fall or winter when flowers are not blooming. Artificial lighting on the Project site during operations also has the potential to disrupt patterns of pollinators. However, much of the Project site is developed during the operational period and does not support pollinator habitat. Additionally, as discussed in Section 4.3.1.3, mitigation measures to limit artificial light impact are incorporated into Project design.

Overall, impacts of operations on wildlife are minimal because wildlife presence is limited on the Project site due to the extent of permanently developed areas. For the limited wildlife on-site, species avoid areas of existing noise emissions. Impacts to birds are also minimized by adherence to the Migratory Bird Treaty Act and use of bird-safe transmission system measures such as those outlined by the Avian Power Line Interaction Committee (APLIC). Populations of wildlife within the Project Vicinity and Project Region are not affected by operations. Therefore, impacts to wildlife during operations are minor.

5.3.1.4 Important Terrestrial and Wetland Species and Habitats

5.3.1.4.1 Important Terrestrial and Wetland Species

Important terrestrial and wetland species that may be impacted by Project activities are discussed in Section 2.3.1.5 and summarized in Table 2.3-9. Species that are federally listed or proposed for listing include Schweinitz's sunflower (*Helianthus schweinitzii*), tricolored bat (*Perimyotis subflavus*), bog turtle (*Glyptemys muhlenbergii*), and monarch butterfly (*Danaus plexippus*). Schweinitz's sunflower has not been documented on the Project site, and operational impacts to this species and its associated plant community are limited due to BMPs for landscape maintenance and reducing the spread of invasive species.

Due to the extensive building activities and resulting development, suitable roosting or foraging habitat for tricolored bats is limited on the Project site during operations. However, bats may move through the Project site between areas of suitable habitat. Impacts on tricolored bats during operation on the Project site are limited due to reduced habitat suitability associated with converted land use and noise levels from cooling tower operation. Bats are also vulnerable to collisions from tall structures on the Project site. As discussed in NUREG-1437, bat collisions with human-made structures at nuclear power plants are not well documented but are likely rare based on the available information. Previous effects assessments from power plants in Ohio, New York, New Hampshire, Virginia, and Wisconsin documented few bat collisions or low potential for bat collisions at these sites.

Bog turtles have not been documented on the Project site, and operational impacts to this species are limited due to BMPs and regulations pertaining to maintenance around wetlands on the Project site.

During 2024 surveys, monarch butterflies were not documented on the Project site, and breeding habitat for this species was limited to rare occurrences during surveys in the southwest portion of the Project site and along the associated off-site wastewater pipeline corridor, as discussed in Section 2.3.1.5.1 and shown in Figure 4.3-4. However, after building activities and development, suitable foraging habitat exists on the Project site in the form of herbaceous areas such as the transmission line corridor. Potential operational effects on habitats that may be used as foraging areas by monarch butterfly and other pollinators are minimized by implementing BMPs such as conducting mowing in the fall or winter when foraging habitat (flowers) are not blooming, controlling invasive species, and following the label-recommended pesticide/herbicide usage to promote foraging habitat quality and extent.

Other important terrestrial species potentially occurring on the Project site include bald eagles (*Haliaeetus leucocephalus*; protected under the Bald and Golden Eagle Protection Act and state-listed); rusty blackbird (*Euphagus carolinus*; state-listed); coppery emerald (*Somatochlora*

georgiana; North Carolina Natural Heritage Program [NCNHP]-designated “significantly rare”); and marsh St. John’s-wort (*Triadenum tubulosum*; NCNHP-designated “significantly rare”). As discussed in Section 4.3.1.4.1, the active bald eagle nest and associated nesting buffer is outside of any on-site and off-site disturbance areas. Therefore, operation of the Project is not expected to directly impact the nest, and operational impacts to bald eagles are limited to behavioral effects associated with avoidance of developed high-activity areas and infrequent bird collisions with structures or powerlines. However, during operations, Duke Energy will update the site’s existing Bald Eagle Nest Management Plan, as appropriate. As discussed above in Section 5.3.1.3, bird collisions with tall structures and transmission lines do not affect local bird populations. Rusty blackbirds were not observed on the Project site, but their preferred hardwood forest habitat along the shoreline is represented by the vegetated buffer. However, no notable impacts occur on this species as Project operations do not affect the vegetated buffer. Therefore, operations have no impact on this species. Impact on stream habitat of the coppery emerald is minor and are discussed in Section 5.3.2.1.1. No notable Project operations impacts occur to marsh St. John’s-wort habitat around Belews Lake, as Project operations do not affect the vegetated buffer.

Important species of recreational value on the Project site include game species, non-game species, and furbearers. White-tailed deer (*Odocoileus virginianus)*, beaver (*Castor canadensis)*, gray fox (*Urocyon cinereoargenteus*), opossum (*Didelphis virginiana)*, raccoon (*Procyon lotor)*, fox squirrel (*Sciurus niger*), gray squirrel (*Sciurus carolinensis)*, striped skunk (*Mephitis mephitis)*, eastern cottontail rabbit (*Sylvilagus floridanus*), wood duck (*Aix sponsa)*, mallard (*Anas platyrhynchos)*, Canada goose (*Branta canadensis)*, wild turkey (*Meleagris gallopavo)*, and mourning dove (*Zenaida macroura)* are recreationally valuable as game species on the Project site, while coyotes (*Canis latrans)* and groundhogs (*Marmota monax*) are non-game species hunted in NC. Beaver, opossum, groundhog, striped skunk, coyote, gray fox, and raccoon are recreationally valuable as furbearers on the Project site. American bullfrogs (*Lithobates catesbeianus*) are non-game species that have not been documented on-site but are common in the Project Vicinity. These species are common in the area and within the Project Vicinity, and based on the extent of the NDA, habitat suitability for these species is limited within the Project site. Species occurring in proximity to active areas of the Project site can relocate to suitable habitat nearby.

Additionally, minimization measures and adhering to the Migratory Bird Treaty Act and guidelines from the APLIC limits collision impacts on birds.

Overall, impacts of Project operation on important species and habitats are minor due to the limited habitat that is suitable to important species during operations. Furthermore, Project operations do not affect populations of important species within the Project Vicinity and Project Region.

5.3.1.4.2 Important Terrestrial and Wetland Habitats

As discussed in Section 2.3.1.6, the only important habitats on the Project site are wetlands. As previously mentioned above in Section 5.3.1.2, wetlands on the Project site are extremely limited due to extensive building activities. Discussion of station operation effects to wetlands are discussed in Section 5.3.1.2 and impacts are minor.

5.3.1.5 Transmission Corridors

As discussed in Section 1.1.5, additional transmission lines that extend outside of the existing Project site boundary are not required. As described in Section 3.2.4.1, transmission improvements within the existing Project site include a new switchyard and other transmission line improvements. Because these improvements are located within the Project site boundary, discussion of operational impacts to habitats and species within transmission corridors is integrated into the preceding subsections of Section 5.3.1.

5.3.1.6 Summary of Impacts to Terrestrial and Wetland Ecology

Operational impacts on terrestrial ecology are foremost limited by the lack of habitat on-site as a result of development of the NDA. Most of the Project site is developed, and the resulting wildlife communities are limited to small areas on the Project site such as the vegetated buffer areas around Belews Lake. Impacts associated with landscape maintenance activities, potential for invasive species establishment, noise emissions, cooling tower salt deposition and potential for collisions with tall structures are minor and are mitigated using BMPs and general landscape maintenance activities. Control methods limit impact of invasive species on vegetation and native wildlife. Compliance with the Migratory Bird Treaty Act reduces impacts to birds during transmission or other maintenance activities. Impacts on important terrestrial species and habitats are also minor. Overall, impacts on terrestrial ecology and wetlands from operation are SMALL.

5.3.2 AQUATIC IMPACTS

This subsection describes the impacts of operation on aquatic communities within the Project site and the Project Vicinity. Operational impacts on Belews Lake are related to the operation of the plant intake and discharge structures, the cooling towers, and the sanitary and radwaste systems. A description of plant interfaces with water are described in Section 3.4.1.1. Impacts of operation on surface water are described in Section 5.2.

5.3.2.1 Aquatic Habitats and Biota

Aquatic habitats on the Project Site and in the Project Vicinity are described in Section 2.3.2. The aquatic ecosystems and aquatic resources of the Project site are described in detail in Section 2.3.2. Aquatic habitats on the Project site, associated off-site areas and in the Project Vicinity include on-site streams, Belews Lake, Belews Creek, and the Dan River. Impacts on surface water resources as a result of operation are described in Section 5.2.

5.3.2.1.1 On-Site Streams

Impacts of building activities on on-site streams are described in Section 4.2.1.1. On-site streams that remain after building activities are limited on the Project site. Stormwater runoff can result in sedimentation and reduction in water quality, which can result in reductions in available suitable aquatic habitats. Additionally, chemical spills or releases can result in reductions in water quality or mortality of aquatic biota in areas affected. Impacts to aquatic ecosystems on the Project site from accidental spills or stormwater runoff are minimized as described in Section 5.2.3.1.1. Stormwater discharges are regulated through an NPDES permit. Stormwater on the Project site is managed in accordance with a site-specific NPDES permit to minimize pollutants, and various BMPs are used to manage stormwater runoff. The operations-related stormwater

system at the Project site is designed to comply with relevant federal, state, and local stormwater regulations. The use of BMPs reduces potential negative impacts on aquatic biota present in on-site streams. An SPCC plan is in place to mitigate potential oil spills.

Based on adherence to regulatory requirements, including an NPDES permit for proper design and operation of stormwater management facilities, impacts of stormwater on the limited number of on-site streams and streams outside of the NDA are localized during operation and do not adversely affect aquatic biota of receiving waterbodies or Belews Lake. Vegetative buffer areas around Belews Lake reduce the amount of stormwater runoff and sedimentation in Belews Lake. Therefore, the impacts of operations on aquatic ecosystems on the Project site are minor.

5.3.2.1.2 Belews Lake

As is described in Section 5.2 and Section 7.1.1, the building and operational schedule for units at the Project site is conducted in a phased approach over several years. In conjunction with this phased approach, Duke Energy will also derate the operations of BCSS in a manner that replaces and balances overall generation capacity between both the Project and BCSS. The closure of BCSS is considered a RFFA (see Table 7.1-2). Accordingly, the BCSS closure results in gradual changes in the baseline environmental conditions relative to those described in Chapter 2.

Although the phased approach for implementation of the Project in conjunction with the BCSS closure results in gradual changes in environmental conditions over the phased implementation period, this analysis of Project operational effects on aquatic ecology considers the characteristics of the BCSS closure condition. Where appropriate, supplemental analyses are also provided that summarize the existing permitted operational condition of BCSS and effects of BCSS closure that are expected to persist during Project operations. These include the following:

- Belews Lake water levels are no longer influenced by BCSS consumptive uses (similar effects continue with Project operations).
- Water circulation in Belews Lake is no longer influenced by BCSS CCW intake and discharge flow (effects not prevalent in Project operations).
- Authorized pumping operations associated with the MWIS on the Dan River are transferred to Project operations (effects transition to Project operations).
- Lake water temperatures are no longer influenced by the BCSS and therefore reflect characteristics of a lake lacking substantive thermal input from power generation (effects not present during Project operations).

5.3.2.1.2.1 Relevant Effects of BCSS Closure on Aquatic Biota

5.3.2.1.2.1.1 Effects of Temperature Changes from BCSS Closure

As a result of BCSS closure (see Section 7.1.2.1.2), lake-wide temperatures begin to cool upon the beginning of the phased implementation period and are notably cooler following the phased in period. Impacts of BCSS closure on lake temperature would occur in conjunction with a

phased implementation period of Project operations. General cooling would occur within each reach of Belews Lake until temperatures normalize. Spatial variability in temperature conditions within Belews Lake that are evident under BCSS operations would normalize such that each area of the lake would reflect conditions that are not influenced by the thermal discharges from BCSS. Water temperatures within the West Belews Creek arm of Belews Lake would resemble those observed in the other areas, similar to those located near the sample location marked "SPILLWAY" in Figure 2.2-34, of Belews Lake. Across Belews Lake, the elimination of CCW discharges leads to reduced temperatures throughout the Lake.

Aquatic macrophyte growth within Belews Lake reflects the presence of established communities within the upper arms of West Belews Creek and Belews Creek. However, the distribution and density of aquatic macrophytes are predominantly associated with depth-related factors (Duke Energy, 2021). Aquatic macrophyte establishment and growth is complex and related to a range of factors that include substrate characteristics and stability, flow rates, temperature and other factors. There was no apparent trend in locations and density of vegetated points and zones of thermal influence (Duke Energy, 2021). Accordingly, BCSS closure and the widespread reduction in temperatures in Belews Lake are likely to have minimal effects on aquatic macrophyte communities.

Temperature-related effects of the closure of BCSS likely results in a taxonomic shift in the fish community, changes in relative abundance of species such as Gizzard Shad (*Dorosoma cepedianum*) and Threadfin Shad (*Dorosoma petenense*) (Section 7.1.2.2). Threadfin Shad in particular, is intolerant of colder temperatures, and is likely to exhibit a reduced population abundance with discontinuation of BCSS thermal effluents that may provide more favorable habitats to Threadfin Shad in winter months. Fish condition shifts are also likely to occur. Normalization of water temperatures and the subsequent loss of warmer winter temperatures in the West Belews Creek arm of Belews Lake will affect the timing of spawning and result in a shorter growth season. Some species may exhibit higher overall condition, as cooler temperatures may reduce the level of caloric intake required to meet the stressful energetic needs associated with habitats with elevated temperatures. With BCSS closure, the loss of winter thermal refugia may result in changes to winter movement patterns of selected fish species within the lake. Changes in the forage base (e.g., forage fish) may reduce diet availability for certain fishes, which may ultimately result in changes in piscivore fish size, population density, and trophic dynamics.

The combination of a truncated growing season and the potential reduction in cold-sensitive forage species such as Threadfin Shad may alter abundance and condition of sportfish through changes to forage for species such as Largemouth Bass, Alabama Bass, Black Crappie, White Crappie (*Pomoxis annularis*), catfishes, and perches (Percidae). The same sportfish species are still expected to persist in Belews Lake. However, the closure of BCSS is expected to have some effects to the composition and abundance of certain fish species within Belews Lake such that there would be greater similarity to the composition of Mayo Reservoir (see Section 5.2.3.1.2) in regard to condition and trophic dynamics.

Operations impacts based on the above-referenced changes to the characteristics of Belews Lake for aquatic ecology are considered in the following subsections, as appropriate.

5.3.2.1.2.2 Project-Related Impacts

Impacts of operation on the aquatic communities in Belews Lake result from the potential for impingement or entrainment at plant intake, water quality alterations associated with plant discharge, and potential changes in water levels within Belews Lake. Characteristics of aquatic ecosystems in Belews Lake are described in Section 2.3.2 but are expected to be altered in conjunction with BCSS closure as described above. No operational activities in Belews Lake result in changes to potential disease vectors for aquatic biota.

5.3.2.1.2.2.1 Cooling Water Intake Structure

Primary issues related to the Belews Lake cooling water intake structure (CWIS) operation are associated with the potential for aquatic organisms to be impinged on the intake screens or entrained within the circulating water system (CWS). Impingement occurs when organisms are trapped against the intake screens by the force of water passing through the intake structure. Impingement can result in death or injury due to exhaustion, asphyxiation (water velocity forces may prevent proper gill movement or organisms may be removed from the water for prolonged periods of time), descaling, and other physical injuries. Entrainment occurs when organisms within the intake water flow are drawn through the intake structure into the CWS. Organisms that become entrained normally are relatively small forms that float or swim freely in the water column, including plankton and early life stages of fish small enough to pass through the intake screen mesh. As entrained organisms pass through the cooling system, they are subject to mechanical, thermal, and toxic stresses that are often lethal (USEPA, 2001).

Operation of the intake structure(s) at the Project site is described in Section 3.2.2.4.1. Belews Lake was permitted and constructed as a cooling impoundment and was created solely for the purpose of serving as part of the BCSS cooling water system. The passive screens of the intake structure are designed with appropriate size, quantity, and depth to support continuous operation. Passive wedgewire screens are designed to have a low through-screen velocity (less than 0.5 feet per second [ft/s]), that meets impingement requirements of Section 316(b) of the Clean Water Act (CWA), and appropriate back flush debris removal systems to maintain clean surface areas. Section 316(b) of the federal CWA (33 USC Section 1326) requires the USEPA to issue regulations on the design and operation of cooling intake structures, in order to minimize adverse environmental impacts. Impingement studies conducted by the USEPA suggest a through-screen velocity of 0.5 (ft/s) is protective of fish survival (survival of 96 percent of the fish tested) (USEPA, 2001).

5.3.2.1.2.2.2 Cooling System Discharge Structure

As described in Section 3.2.2, the cooling system discharge options include one common discharge structure for all three Plant Complexes or three distinct discharge structures, one for each of the three Plant Complexes (Figure 3.1-1). Piping for each discharge structure extends from the shoreline to the submerged discharge structure. The discharge structure(s) are located within Belews Lake as indicated in Figure 4.2-1.

Cooling tower blowdown constituents and concentrations at the discharge point(s) are shown in Table 3.4-3. Additionally, as described in Section 3.2.2.4.3, effluents are managed to minimize release of these chemicals and concentrations to meet NPDES permit requirements, as applicable.

5.3.2.1.2.2.3 Biothermal Impacts of Discharge

The maximum blowdown temperature at the point of discharge to Belews Lake is 95°F (35°C). As described in Section 5.2.3, the CORMIX analysis modeled selected, conservative constituents that are present in cooling tower blowdown. As described in Section 5.2.3.1.2.1, the existing BCSS operating condition as described in Chapter 2 bounds thermal effects to Belews Lake during the phased implementation period. Therefore, thermal effects on aquatic biota were evaluated for the bounding operational condition during full Project operations.

The water quality criteria specify a water temperature not more than 2.8°C (5.04°F) above ambient. The only effluent constituents identified as requiring a mixing zone (i.e., discharge exceeding a regulatory standard) are copper, cadmium, and temperature, which is reduced to the 2.8°C (5.04°F) temperature excess criterion within a curvilinear distance of approximately 32 ft. (10 m) of the cooling tower blowdown at South, Middle, and North Complex Discharges and approximately 53 ft. (16.2 m) at the Combined Discharge for the bounding summer drought condition. The vertical rise of the discharge plume prior to attaining a 2.8°C (5.04°F) temperature excess is approximately 10 ft. (3.1 m) (under the individual discharge options for each Plant Complex at the South, Middle, and North Complex Discharges) and approximately 21 ft. (6.3 m) for the Combined Discharge option for the bounding summer drought condition. The 2.8°C (5.04°F) temperature excess is attained for each model case prior to interacting with the model pycnocline.

Established aquatic macrophyte beds generally occur within the West Belews Creek and Belews Creek arms in shallow water zones (Figure 2.3-11). Because discharge structures are established at depth (Figure 2.2-14), aquatic macrophytes are not subject to exposure to thermal effluents under most Project operational conditions as thermal discharges within Belews Lake are limited to the hypolimnion and are rapidly mixed. Additionally, thermal discharges do not extend to shoreline habitats where macrophytes are more predominant. Therefore, the effects of thermal effluents on aquatic macrophyte beds under such conditions are negligible.

Potential impacts to benthic biota including macroinvertebrates and mussels from thermal discharge is localized to the immediate area of the discharge. Riprap is integrated into discharge outlet design to minimize the effects of scour on sediments and associated benthic communities of Belews Lake. Additionally, the discharge is angled upward slightly to promote mixing and raising the thermal effluent in the water column, thereby limiting impacts to benthic areas. The rapid mixing of thermal effluent results in minimal thermal impacts to benthic macroinvertebrate and mussel communities. As thermal effluents are rapidly mixed and do not result in prolonged exposure of high-temperature effluents to bottom habitats, impacts to the benthic macroinvertebrate and mussel community within Belews Lake are localized and minor.

Critical thermal maxima (CTM) were used to assess acute impacts of thermal discharge on representative important species (RIS) of fish in Belews Lake. The CTM is the pre-mortality thermal maximum at which locomotory movements become disorganized and a fish loses the ability to escape from conditions that may ultimately lead to its death (Beitinger et al., 2000). CTM for those RIS present in Belews Lake are summarized in Table 5.3-1. The selected RIS are species that use a variety of habitats, including pelagic and benthic fish species. One of the species included in the assessment, Gizzard Shad, is considered a thermally sensitive species, and is particularly vulnerable to high temperatures. The estimated thermal dilution as a result of

Project discharges is demonstrated to be extremely localized to the area in the immediate vicinity of the discharges.

Acute temperatures along the longitudinal axis of the plume, as described above, are expected to be limited to areas within the immediate proximity of the discharges, and within the regulatory mixing zone boundary. As such, the CTM of each RIS beyond the mixing zone boundary are not exceeded under model conditions. Accordingly, avoidance behavior based on exceedance of CTM for RIS is not expected.

Thermal avoidance is a behavioral response of mobile species to move from stressful, high-temperature areas to areas with more tolerable temperatures (Mathur et al., 1983). This avoidance response can minimize acute impacts of thermal exposures. Zone of passage issues are most relevant in Project settings where elevated thermal discharges present a potential exclusion area that limits the movement of fishes between upstream and downstream areas. In Belews Lake, the location of the discharge is not bound by physical features, and ample habitat is available to support fish movement within the Belews Creek arm of Belews Lake and other reaches of the lake. Additionally, temperatures associated with the discharge are rapidly diluted, and effects are localized. Therefore, substantial areas of habitat would not be excluded, and a zone of passage would always be maintained for RIS.

Long-term impacts of exposure to elevated temperatures can result in chronic mortality in fishes and other aquatic biota. Although under extreme conditions, temperatures may exist in the immediate vicinity of the discharge that may have the potential to cause mortality under extended chronic exposure, such conditions are limited spatially and of relatively short duration and are not predicted to result in mortality. Additionally, due to the presence of an adequate zone of passage, behavioral avoidance of areas of extreme temperature will mitigate chronic exposure of fishes in Belews Lake. Because the discharges are located in the hypolimnetic zones that are not generally used for spawning, there are no important spawning areas located within the vicinity of the discharges. As such, the limited size of the thermal plume results in negligible impacts on spawning activities of fishes within Belews Lake. At early life stages, fish are highly sensitive to elevated temperatures. Optimal growth temperatures are species specific. Because the elevated temperatures of the thermal plume from the Project are localized to the immediate vicinity of the discharges, there are negligible chronic impacts of thermal stress on juvenile and embryonic fish growth.

Because both the selected discharge constituents and the thermal plume of the discharge(s) are demonstrated to rapidly disperse, and because thermal effluents within the mixing zone are below thermal criteria of aquatic biota, impacts to aquatic biota are localized and minor. Additionally, compliance with thermal discharge limits required under the operational NCDEQ NPDES permit will limit adverse impacts to aquatic biota.

5.3.2.1.2.2.4 Belews Lake Water Levels and Circulation

Operational use of cooling water from Belews Lake for the Project results in fluctuations of water levels (Section 5.2.1) and changes in water circulation patterns. BCSS closure also affects circulation patterns in Belews Lake. As described in Section 2.2.1.1.3, the BCSS CCW flow influences lake circulation patterns whereby water from the CCW discharge flows through the CCW canal and into the Belews Creek arm. As illustrated in Figure 2.2-3 general circulation patterns carry flow within the lake into the West Belews Creek arm and back to the BCSS

CWIS. However, under BCSS closure, the influence of CCW flow is eliminated, resulting in circulation patterns that are more influenced by tributary inflows, wind and releases from the spillway. As described in Section 5.2.1.1.2.3, supplemental water is pumped by the MWIS into Belews Lake in conjunction with Project operations. Figure 5.2-2 depicts the modeled water levels of Belews Lake based on supplemental pumping of the MWIS during Project operations. As summarized in Table 5.2-2, the drawdown from the full pond level under the Project operations is predicted to be approximately 3.4 ft. (1.04 m) under a mild drought condition (e.g., 2-year drought recurrence). Future moderate drought conditions (e.g., 10-year drought recurrence) may result in a drawdown of approximately 6.1 ft (1.86 m). However, during extreme future drought conditions (e.g., 100-year drought recurrence) drawdowns may reach approximately 10.0 ft. (3.05 m). These lake water-level fluctuations are similar to those predicted for BCSS Maximum Generation Condition, which includes MWIS supplemental pumping up to 100 cfs (2.83 m^3/s). However, under drought conditions, as compared to the BCSS Maximum Generation Condition (Section 5.2.1.1.2.3), the water-level drawdowns under Project operations are increased between approximately 0.6 ft (0.18 m) and 3.0 ft (0.91 m) (21 and 43 percent) for the 2-year and 100-year drought return periods, respectively. As such, Project effects on aquatic habitats and biota as described above are marginally increased relative to the BCSS Maximum Generation Condition in conjunction with the increased extent and duration of water-level reductions.

Seasonal fluctuations in surface water level during drought conditions may impact aquatic biota along nearshore areas of Belews Lake including littoral zones, aquatic habitats, aquatic macrophytes and related aquatic biota. Increased frequency and duration of water-level fluctuations is likely to result in changes to macrophyte growth within Belews Lake. Rapid water-level fluctuations can result in inundation of macrophyte beds, resulting in loss of macrophyte growth. Emergent macrophytes rely on stable water levels, and prolonged periods of low water levels or drought can result in drying of a substantive portion of lake littoral habitat (Havens et al., 2005). Water-level fluctuations can lead to changes in diversity of aquatic vegetation, with resulting pronounced negative implications for vegetation diversity (He et al., 2023). Such water-level fluctuations may also be expected to affect fish reproductive success during recurring drought conditions in which macrophyte beds used for spawning and nursery may be less available to fish.

Water-level fluctuations in shallow areas during drought conditions may decrease the overall presence of submerged aquatic vegetation (SAV) in nearshore areas. Oligotrophic lakes, such as Belews Lake, are generally characterized by low densities of SAV. Low water levels that last for a longer period within the growing season than those observed under BCSS operations may result in decreased growth of macrophytes in those shoreline areas that will no longer have surface water present for periods of the growing season. Water-level fluctuations have been demonstrated to influence the extent and abundance of SAV in lake and reservoir systems through influences on water clarity and light limitation (Shivers et al., 2018). Areas with high levels of water fluctuations see decreased SAV, with vegetation shifting to communities dominated by floating leaf plants (Shivers et al., 2018). Some SAV species, such as Hydrilla, are able to rapidly recolonize areas following periods of declines in spatial vegetative coverage (Shivers et al., 2018).

Increased fluctuation and duration in water levels during drought conditions will impact shallow, nearshore areas of Belews Lake, resulting in instability within the benthic macroinvertebrate

community in these species locations. Under operational conditions, intermittent periods of prolonged (e.g., weeks to months) drought will result in expanded areas in which benthic macroinvertebrate habitat is temporarily lost. Recolonization of benthic macroinvertebrate communities in these areas can be expected to occur when water levels stabilize. However, fluctuating water levels that occur on a more frequent basis, such as those for daily industrial or power generation needs, have been demonstrated to reduce macroinvertebrate recruitment by exposing and desiccating eggs laid in shallow water habitats, with some species being affected in as little as 2 hours (Miller et al., 2020). Additionally, in lakes with fluctuating water levels, the effects of the water fluctuations on macroinvertebrates can be significant, particularly for invertebrates with relatively long lifecycles (Aroviita and Hämäläinen, 2008). These more regular water-level fluctuations may have an impact on nearshore aquatic invertebrates.

There are no sensitive (i.e., federally- or state-listed) mussel species present in Belews Lake. Therefore, even with potential changes to habitat suitability as a result of drought condition water-level fluctuations, overall, the mussel communities are likely to remain consistent. Nearshore benthic areas that may be exposed during periods of low water will no longer be suitable habitat for the mussel species, thereby restricting the range of certain mussels to areas that are consistently submerged with water. Unlike benthic macroinvertebrate communities, however, recolonization by mussels in these nearshore areas is likely to be more limited, as these longer-lived species are more susceptible to water-level fluctuations over time.

Increased duration of water-level fluctuations during drought conditions may indirectly impact growth of adult fish. Changes to the macrophyte community may result in changes to habitat and access to foraging for adult fish, particularly during drought or periods of low water levels within Belews Lake. Overall decreases in fish condition may occur due to fluctuations and instability in the forage base (e.g., macrophyte beds) resulting from frequent fluctuations in water level. Water-level fluctuations may result in a loss of nursery and habitat areas. Macrophyte beds are important nursery habitats. SAV provides shelter and food resources for many fish species such as Bluegill (*Lepomis macrochirus*) and Largemouth Bass. Embryonic and larval growth occurs within late spring and summer. These months are critical for survival of larval fish.

Based on the predictive hydrologic model (Figure 5.2-2), the Project operation results in a system that is subject to water-level fluctuations that are similar to those experienced under BCSS Continuous Maximum Generation Condition. Under normal operational conditions, stabilized water levels result in suitable spawning habitat in the nearshore areas of Belews Lake. Under drought conditions, it is predicted that Belews Lake will be subject to increased frequency and severity of drawdown as compared to current BCSS Continuous Maximum Generation Condition (Figure 5.2-2). Many fishes that spawn within shallow littoral zones, including some centrarchids such as Largemouth Bass, will be impacted by drought condition water-level fluctuations. Largemouth Bass spawn at depths between 0.15 m (0.5 ft.) and 1.10 m (3.6 ft.) (Nack et al., 1993). Largemouth Bass build nests in areas which offer protection such as slopes, boulders, ledges, and submerged vegetation (Miller, 1971). Water-level fluctuations, such as those predicted under drought conditions by hydrological modeling, may result in loss of nearshore spawning habitat. Losing access to these areas could reduce Largemouth Bass and other Centrarchid numbers in Belews Lake. While hydrological modeling suggests that during a drought year lake elevation will not fall below full pond during months when Largemouth Bass spawn (typically mid-April through mid-June), there may be minor loss of spawning habitat for those species that are nest building or nest guarding, such as centrarchids.

5.3.2.1.2.3 Summary of Project Effects on Belews Lake

Direct impacts of operation on aquatic ecosystems in Belews Lake include impingement and entrainment associated with the CWIS, effects of cooling tower effluent constituents and thermal effluents, and effects of water-level fluctuations within Belews Lake. Belews Lake was constructed and permitted as a cooling impoundment and is classified as a closed cycle cooling system. Impingement and entrainment are minimized through design elements of the CWIS that comply with regulations adopted to implement Section 316(b) of the CWA that are considered protective of aquatic life.

Potential thermal impacts on all biotic categories, including habitat formers, benthic macroinvertebrates and mussels, fish, and related habitats within Belews Lake, from Project operation include the following:

- Negligible potential for localized acute adverse effects, such as thermal mortality, from recirculation of heated effluent. Potential effects are limited to the immediate area (less than 2 ft. [0.6 m]) around the discharge for RIS.
- Negligible potential for acute impacts of thermal excesses due to avoidance behavior of fish within Belews Lake.

Belews Lake water-level fluctuations during typical conditions are similar to those predicted for BCSS Continuous Maximum Generation Condition (Table 5.2-2). However, during drought conditions, potential impacts to aquatic species and habitats from hydrologic alterations such as increased water-level fluctuations within Belews Lake from Project operations include:

- Changes to the macrophyte communities, including nearshore emergent vegetation communities and SAV communities.
- Decreased habitat availability and potential desiccation of benthic macroinvertebrate and mussel communities in shallow littoral zones.
- Indirect adverse impacts to fish communities through alteration of near shore littoral zone habitats (e.g., spawning habitat, nursery areas, foraging habitat).
- Increased potential for proliferation of nuisance macrophytes, such as Hydrilla. However, the balance of fish communities is not expected to shift in such a way that would promote the expansion of nonindigenous fish beyond those already present in Belews Lake.
- Depending on the frequency of such drought conditions and related water-level fluctuation, corresponding effects may also be evident in the condition of recreationally important sport fish (i.e., smaller fish, changes in community structure, and other factors) that may be sought after by anglers.

Therefore, impacts on aquatic ecosystems within Belews Lake from operations, under normal operational conditions in which water levels are stabilized and consumptive losses are offset by MWIS pumping, are minor. However, aquatic ecology is impacted to a greater degree in Belews Lake as a result of water-level fluctuations that result in a noticeable effect on aquatic biota and associated habitats in littoral zones in conjunction with increased drought intensity.

5.3.2.1.3 Dan River

Impacts of operation on the Dan River are primarily related to the operations of the MWIS at the confluence of the Dan River and Belews Creek, and the wastewater pipeline discharge located near Dan River Outfall 006 (Figure 4.2-1). Aquatic ecosystems in the Dan River are described in Section 2.3.2.

5.3.2.1.3.1 Makeup Water Intake System

The MWIS located at the confluence of Belews Creek and the Dan River supplies makeup water to Belews Lake. The NPDES Permit NC0024406 is associated with current BCSS operations. The hydrologic impacts of pumping by the MWIS are described in Section 5.2.1. Impacts to surface water quality as a result of operation of the MWIS are described in Section 5.2.3. Regulatory stipulations required under the operational NPDES permit limit adverse impacts to aquatic ecology within the Dan River. The NPDES permit allows for operation of a four-pump MWIS with a capacity not to exceed 100 cfs (2.83 m^3/s). Operational conditions of the permit as described in Section 3.4.1.1.2 include:

- Pumping will not lower flow in the Dan River below 110 cfs (3.11 m^3/s) to maintain flow and habitat availability within the main channel.
- The intake structures on the Dan River and Belews Creek are positioned above the river bottom and are designed to have a velocity less than 0.5 ft/s (0.15 m/s) at the inlet of the velocity caps. The MWIS is equipped with a 2-millimeter (mm) fine mesh traveling screen to minimize fish entrainment and impingement.
- The withdrawal location is near the confluence of the spillway channel below Belews Lake Dam and the Dan River. This scoured bottom area does not provide suitable aquatic habitat for mollusks.
- Semi-annual lake monitoring to assess limnological conditions in Belews Lake is performed.
- To avoid fish spawning periods, no pumping occurs between April 1 and June 30.
- At least 80 percent of ambient flow of the Dan River is maintained at all times, meaning withdrawals will not exceed 20 percent of the river flow.
- Pumping may occur to a maximum water level in Belews Lake of 724.5 feet above mean sea level (220.8 meters above sea level).

As described in Section 7.1.1, closure of BCSS eliminates the need for supplemental pumping from the Dan River to compensate for consumptive uses from BCSS operations. However, authorized pumping operations associated with the MWIS are transferred to Project operations. Additionally, as described in Section 3.4.1.1.2, routine inspection and cleaning in and around the velocity cap inlet structures, including the removal of silt, sediment, and debris, ensures their effectiveness is maintained. Maintenance activities at the Dan River MWIS include material removal to reduce water debris load at the intake. Methods of material removal include slurry pumping, vacuum operations, air bursts, flush water, or mucking. Material removal is conducted in a preventive manner to maintain operational characteristics of the MWIS. The volume of material removed is variable, but generally small. Removal of materials results in localized loss of benthic habitat in the specific area of sediment removal. Mobile aquatic biota are expected to

avoid effects from maintenance activities, whereas direct effects occur to less mobile organisms. Losses of less mobile organisms are short-term and temporary as recolonization of impacted areas by benthic species occurs rapidly.

The MWIS is operated in compliance with regulations adopted to implement Section 316(b) of the CWA in regard to impingement and entrainment. A Section 316(b) demonstration conducted by Duke Energy in 2022 indicated compliance with impingement mortality best technology available (BTA) requirements under Section 316(b) of the CWA. Debris screens within the MWIS have a maximum through-screen velocity of less than 0.5 ft/s and are equipped with 2.0-mm fine mesh screens and an aquatic organism return system to minimize entrainment and impingement, and flow restrictions (HDR, 2022).

In conjunction with Project operations, Duke Energy will install the number of approved pumps within the MWIS to provide for a pumping capacity of up to 100 cfs (2.3 m^3/s) to provide sufficient makeup water to Belews Lake to supplement the cooling water system. Additional pumps are equipped with similar fish protection technologies as the existing debris screens. Operational pumping from the Dan River for makeup water also encompasses the same operational conditions set forth in the existing NPDES permit listed above to minimize fish entrainment and impingement, avoid fish spawning periods, and maintain ambient flow levels. Duke Energy also continues to perform semi-annual lake monitoring to assess limnological conditions in Belews Lake.

Pumping operation of MWIS also has the potential to affect aquatic biota due to reduced water availability in the Dan River and associated habitat alteration. However, under NPDES Permit NC0024406 the existing Duke Energy MWIS is permitted to withdraw up to 100 cfs for makeup water to Belews Lake. This permitted pumping limit is considered to be protective of aquatic biota and their habitat. Because Duke Energy limits pumping of the MWIS under Project operations to within permitted limits, no additional impacts on aquatic biota or their habitat occur under Project operations.

In summary, the existing MWIS on the Dan River is permitted for the intake of makeup water under the existing NPDES permit. The pumping capacity of the MWIS may be installed up to the maximum permitted pumping rate of 100 cfs. Impingement and entrainment are minimized through compliance with regulations adopted to implement Section 316(b) of the CWA. Further, compliance with NPDES operational conditions is protective of aquatic life and their habitat. Therefore, impacts of operation of the MWIS on the Dan River are minor.

5.3.2.1.3.2 Dan River Discharge

Effluents have the potential to affect aquatic biota through decreases in water quality that can cause chronic and/or acute mortality of species, particularly non-mobile species such as mussels. Nonradioactive liquid waste discharges (e.g., turbine building sumps, groundwater sumps, and water treatment discharges) are routed to the consolidated sump, where they undergo treatment before discharging to the Dan River Outfall 006 (Section 3.4.3.3.3.3). As described in Section 3.4.2.4, after treatment, liquid radiological waste is diluted to acceptable limits using cooling tower blowdown water. After mixing, the wastewater is directed to a new discharge located within the corridor adjacent to existing Outfall 006 described in Section 3.4.2.4 and shown on Figure 3.2-3. The common liquid radioactive waste line is located within the existing corridor, adjacent to the Outfall 006 piping. The discharge is controlled and

monitored to ensure compliance with environmental safety standards as described in Subsection 5.2.3.1.4.1. Liquid radioactive waste processing systems are designed to keep radiation exposures of plant personnel ALARA and ensure that discharges to the Dan River stay within the limits set by the NRC and other applicable regulations, including those integrated in an NPDES permit issued by NCDEQ. The NPDES permit establishes discharge limitations for quantity and quality parameters to protect surface waters and maintain aquatic biological communities. Additionally, the NPDES permit is expected to require ongoing assessment of aquatic biological communities downstream of permitted releases. Any uptake of constituents of the discharge at the MWIS downstream and into Belews Lake are evaluated and controlled through operational measures.

5.3.2.1.3.2.1 Biothermal Impacts of Discharge

A CORMIX analysis and description evaluating the thermal load is provided in Subsection 5.2.3.1.4.4. A biothermal analysis was conducted to assess impact of thermal discharge on aquatic communities in the Dan River. Table 5.2-9 describes the assumed mixing zone characteristics required to obtain regulatory compliance including the width, thickness, and area with respect to the Dan River. As described in Section 5.2.3.1.4.4, the width of the thermal plume is limited to approximately 37 percent of the channel width in the summer and 31 percent in the winter.

Potential impacts of discharge on benthic macroinvertebrates are related to elevated temperatures of the new discharge and the potential for benthic scour. More mobile species may be able to behaviorally avoid areas of excess high temperature by moving laterally or downstream. In areas of excess high temperatures near the new discharge, taxonomic composition of benthic macroinvertebrates may shift to more tolerant taxa. These temperature-related effects are expected to be localized based on rapid mixing demonstrated by the CORMIX analysis as described in Subsection 5.2.3.1.4.4. Thermal effluents, particularly in the immediate vicinity of the discharge, may also locally modify available habitat where benthic habitat is disturbed from building or installation of the new discharge structure. Benthic scour can also result in decreased habitat quality in areas in the immediate vicinity of the discharge diffuser. However, such effects are mitigated through the implementation of scour protection measures. As the impacts of thermal discharge on benthic communities are localized, overall impacts to macroinvertebrate communities in the Dan River are negligible.

In general, mussel habitat was limited at the survey locations upstream of the pump station at the confluence of Belews Creek, while at and below the pump station, mussel habitat was more widespread. Potential impacts of discharge on mussels are related to exposure to elevated temperatures of thermal discharge and the potential effects related to benthic scour. Freshwater mussels are particularly vulnerable to thermal stressors because they are relatively sedentary which limits their ability to seek refuge, and due to their relatively complex life histories (Fogelman et al., 2023). Elevated temperatures can result in stress, reduced growth, and potentially death. For example, Eastern Elliptio has a lethal thermal maxima of 42.7°C (108.9°F); (Fogelman et al., 2023). Benthic scour additionally can result in decreased habitat quality, as the velocity and frequency of discharge can negatively impact benthic habitat within the mixing zone. In 2024 sampling, only one mussel species Eastern Elliptio was observed in the area of the discharge. Thermal discharge may further locally reduce available mussel habitat. Potential thermal discharge impacts on habitat are localized and limited to the assumed mixing zone. Therefore, because suitable mussel habitat in proximity to the new discharge is

poor, and both temperature and scour effects are localized, impacts to mussels in the Dan River are minor.

An assessment of RIS present indicates that predicted temperatures are expected to be near, but not exceed the CTM for RIS with the lowest CTM, Black Crappie and White Sucker (CTM = 34.9°C), within the thermal plume at higher discharge velocities. For the other RIS, CTM temperatures are not exceeded, except for in potential extreme temperature events. Winter ambient temperatures, combined with temperature excesses from routine operation, may in some cases result in thermal shock of fishes within the thermal plume. However, as the extent of the thermal plume is approximately one-third of the width of the river, adequate area exists to avoid thermal impacts. Acute temperatures of the plume are expected to be limited to areas within the immediate proximity of the diffuser ports, and within the assumed mixing zone boundary. As such, the CTM of RIS beyond the mixing zone boundary are not exceeded under model conditions. Accordingly, acute thermal effects on fish beyond the mixing zone boundary are minor. There is minor potential for acute adverse effects on fish, but these effects are localized and limited to the immediate area around the discharge for RIS.

As the length of thermal exposure for larval and embryonic fish is primarily related to the length of time spent in the plume, exposure is reliant on plume length and river flow. At high flow, embryonic and larval fish are expected to pass through the thermal plume more quickly, thereby reducing exposure. Because of the relatively short length of the thermal plume and the flow within the Dan River, exposure of embryonic and larval fishes to elevated temperatures is expected to be for a relatively short duration, limiting chronic impacts.

For some species, such as White Sucker and Fantail Darter, summer temperatures at the edge of the assumed mixing zone (78.98°F) are expected to exceed the optimal growth temperature. However, this exceedance is limited to summer temperatures, and temperature dissipates with increasing distance downstream of the mixing zone. As the water temperature is less than the species-specific minimum acceptable weekly mean temperature for growth for the assessed RIS, no impacts to growth are expected at the edge of the mixing zone. Behavioral avoidance of areas by adult fish in the immediate vicinity of the discharge diffuser and mixing within downstream areas decrease effects to adult fish growth as a result of thermal exposure. As the thermal plume is localized, chronic effects on fishes of thermal discharge are minor.

Long-term impacts of exposure to elevated temperatures can result in chronic mortality in fishes and other aquatic biota. For mobile species, such as fishes, behavioral avoidance of the thermal plume will reduce impacts of chronic thermal exposure within the mixing zone. Chronic exposure to elevated temperatures above the species-specific minimum acceptable weekly mean temperature for growth results in cessation of growth and may result in elevated stress. For many species, the upper avoidance temperature, or the temperature at which fish behaviorally avoid the thermal stressor, may be greater than the minimum acceptable weekly mean temperature for growth. This may result in fish remaining in areas characterized by water temperatures that are greater than their minimum acceptable weekly mean temperature for growth. However, because the extent of the thermal plume is limited to the mixing zone and is less than 33 percent of the width of the Dan River, chronic exposure is unlikely to impact mobile species. Therefore, chronic impacts of thermal discharge in the Dan River are expected to be negligible for fishes.

Spawning generally occurs during late spring and early summer. Peak spawning occurs between April and June. The thermal plume is not expected to result in altered spawning conditions within the Dan River, as the minimum acceptable weekly mean temperature for growth for RIS are not exceeded beyond the mixing zone. As no important spawning areas are within the assumed mixing zone, impacts to spawning timing and aggregations are negligible. Impacts to nursery habitats, or areas which are important for juvenile fish growth, can result in chronic impacts to larval and juvenile fishes. However, no important nursery areas are located within the geographic area of the assumed mixing zone. Impacts on important nursery areas are therefore minor.

The portion of cross-sectional area or volume of flow of the receiving stream not included in the mixing zone is termed the zone of passage. The existence of a zone of passage for fish at the location of the discharge diffuser minimizes impacts of thermal discharge. The assumed mixing zone width is equal to half of the total channel width. The width of the thermal plume is limited to approximately 37 percent of the channel width in the summer and 31 percent in the winter. This results in a zone of passage that is approximately 2/3 of the width of the Dan River along the length of the thermal plume. This zone of passage allows the free passage of fish upstream or downstream without subjecting them to adverse conditions associated with the thermal plume.

Compliance with NPDES discharge limitations is protective of aquatic ecosystems in the Dan River. The selected discharge effluents and the thermal plume of the discharge are demonstrated to rapidly disperse, such that concentrations at the edge of the mixing zone are in accordance with expected NPDES permit limits. Additionally, thermal effluents are below thermal criteria of aquatic biota outside of the assumed mixing zone. Therefore, impacts to aquatic biota within the Dan River are localized and minor.

5.3.2.1.4 Summary of Effects on the Dan River

Direct effects of operation on aquatic ecosystems in Dan River include potential impingement and entrainment impacts associated with the MWIS, effects on aquatic biota and their habitats from water withdrawals from the MWIS, and effects of wastewater discharge effluents including radiological and nonradiological constituents and thermal effluents. Direct impacts to aquatic species are limited to the MWIS and the wastewater discharge in the Dan River. Impacts of impingement and entrainment at the MWIS are minimized through compliance with regulations adopted to implement Section 316(b) of the CWA. Potential thermal effects on biotic categories, including habitat formers, benthic macroinvertebrates, mussels, fish, and related habitats within the Dan River, from Project operation include the following:

- Minor effects to biotic categories including habitat formers, benthic macroinvertebrates, mollusks, and fish;

- Minor potential for acute adverse effects. Potential effects to fish are localized and limited to the immediate area around the discharge;

- Minor potential for acute impacts of thermal excesses due to avoidance behavior in fishes within the Dan River. The thermal plume is limited to, at most, 37 percent of the width of the river, resulting in the presence of an adequate zone of passage;

- Limited potential for impacts to adult fish growth, spawning, and embryonic and juvenile fish development;

- Minimal long-term (chronic) impacts on fish are expected;

- Minor impacts to aquatic invasive species, as elevated thermal excesses are localized and constitute a relatively low level of thermal excess beyond the assumed mixing zone;

- No important spawning habitat or nursery areas are located within the assumed mixing zone; therefore, no impacts to important spawning habitat are predicted as a result of thermal discharge; and

- Benthic scour is expected to be localized in the vicinity of the diffuser. However, effects are minimized by incorporation of appropriate scour protection (i.e., riprap protection downstream of the discharge diffuser) in conceptual diffuser design.

Impacts of the MWIS and discharge operation are minimized through compliance with NPDES permit requirement. Therefore, anticipated impacts of operation on aquatic species within the Dan River are minor.

5.3.2.2 Important Aquatic Species and Habitats

5.3.2.2.1 Important Aquatic Species

Important aquatic species that may be present in the Project site are described in Section 2.3.2.3. Impacts of building activities on important aquatic species are described in Section 4.3.2.2. Impacts of operation on aquatic systems occur primarily in Belews Lake and in the Dan River. No federally listed or state-listed freshwater mollusk species or fish species have been documented in Belews Lake or in on-site streams. Therefore, no impacts to federally or state-listed species occur in Belews Lake as a result of operation.

Within the Dan River, operational impacts are limited to the operation of the MWIS at the confluence of the Dan River and Belews Creek, and the wastewater pipeline discharge to the Dan River.

Federal- and state-listed aquatic species present in the Dan River are described in Section 2.3.2.3. In the Dan River, the MWIS is managed under restrictions that are protective of aquatic ecosystems in the immediate area as described above. One live individual green floater (*Lasmigona subviridis*) mussel was identified at the location of the MWIS within the Dan River in a 2024 survey (Duke Energy, 2024). Previous surveys have indicated the presence of green floater upstream and downstream of the MWIS in 2014. However, the risk of impacts of impingement and entrainment of these species is minimized based upon existing BTA integrated in the operation of the MWIS (HDR, 2022). As described in Section 5.2.1.1.3.1 operational pumping from the Dan River also encompasses the same restrictions as the existing NPDES permit listed above in order to minimize fish entrainment and impingement, avoid fish spawning periods, and maintain ambient flow levels. Such measures provide protection for listed important species. As Section 5.2.1.1.3.2 describes, effluents associated with the wastewater discharge at Dan River are managed in compliance with NPDES requirements to ensure protection of aquatic ecosystems of the Dan River, thereby minimizing impacts on

important aquatic species. One individual state-listed Roanoke Logperch (*Percina rex*) was observed in the Dan River near the wastewater discharge during mussel surveys in 2004.

Potential impacts of operations on recreationally important species within Belews Lake and other important aquatic species within the Dan River are minor.

In summary, impacts to federal- and state-listed aquatic species in the Dan River are minimized through compliance with NPDES permitting of the Dan River discharge, and through compliance with regulations adopted to implement Section 316(b) of the CWA for the MWIS. Impacts to recreationally important species in Belews Lake are limited. Therefore, impacts on important aquatic species are minor.

5.3.2.2.2 Important Aquatic Habitats

Important aquatic habitats on the Project site, associated off-site areas, and in the Project Vicinity are described in Section 2.3.2.4. Proposed critical habitat for state-endangered species and federally proposed threatened freshwater mussel (green floater) is present in the Dan River. As is described in Section 2.3.2.2.3.2, the location of the wastewater pipeline in the Dan River has been determined to consist of poor habitat for the green floater, and no live individuals were observed in the immediate vicinity. In a 2024 mussel survey in Dan River, no green floater individuals were observed near the wastewater discharge in the Dan River. Seven individual green floater were observed downstream within the Dan River.

Maintenance activities at the MWIS, including material removals, impact benthic habitat in the Dan River. In a 2024 survey, one live green floater was observed in the area around the MWIS. Therefore, any activities related to maintenance and material removals at the MWIS are done after consultation with the U.S. Fish and Wildlife Service, the NCDEQ, and USACE regarding avoidance, minimization, and appropriate conservation measures to limit potential effects on proposed critical habitat in the Dan River. Ground-disturbing activities, such as sediment removal or disturbance in the area of the intake structure, which have the potential to affect surface water quality are permitted by applicable federal, state, and local regulations and are regulated by the USACE.

Effluents from the wastewater discharge to the Dan River may result in alterations to water quality which may impact the suitability of the Dan River green floater critical habitat. At the location of the discharge diffuser, mussel habitat is limited. Impacts to mussel habitat is described in Subsection 5.3.2.1.2.2.3. Therefore, impacts of thermal discharge on Critical Habitats are minor.

Impacts of operation activities on proposed critical habitat for green floater are limited to material removal impacts at the MWIS and potential impacts of effluents at the wastewater discharge. Through compliance with state and federal regulations regarding material removal and effluent chemical concentrations, impacts on water quality and habitats within the Dan River are limited; therefore, impacts of operation on important aquatic habitats are minor.

5.3.2.3 Transmission Corridors

As discussed in Section 1.1.5, additional transmission lines that extend outside of the existing Project site boundary are not required.

5.3.2.4 Summary of Impacts to Aquatic Species and Habitats

Direct impacts of operation on aquatic ecosystems in Belews Lake include impingement and entrainment associated with the CWIS, effects of cooling tower effluent constituents and thermal effluents, and effects of water-level fluctuations within Belews Lake. Operational impacts to aquatic ecosystems include impacts related to on-site stormwater runoff and incidental spills. Impacts on-site are managed through stormwater management systems and, therefore, are minor. In Belews Lake, impacts are associated with the intake and discharge structures operations, and changes in water levels. Impacts of the discharge(s) are expected to dissipate rapidly, limiting impacts on aquatic ecosystems. Impacts of intake operation are minimized through compliance with regulations adopted to implement CWA Section 316(b).

Potential thermal impacts on all biotic categories, including habitat formers, benthic macroinvertebrates and mussels, fish, and related habitats within Belews Lake are localized and negligible. Compliance with thermal discharge limits required under the operational NCDEQ NPDES permit will limit adverse impacts to aquatic biota.

In conjunction with closure of BCSS, the aquatic ecological community will reflect a lake lacking significant thermal input from power generation, including recreationally important sport fish. Impacts to recreationally important species in Belews Lake are limited.

Impacts on aquatic species and habitats within Belews Lake from operations, under normal operational conditions in which water levels are stabilized and consumptive losses are offset by MWIS pumping are minor. Potential impacts to aquatic species and habitats from hydrologic alterations associated with increased water-level fluctuation under drought conditions within Belews Lake relate to effects on aquatic macrophyte communities, benthic macroinvertebrates and mussels, effects on fish communities through alteration of habitats (e.g., spawning habitat, nursery areas, foraging habitat), and increased potential for proliferation of nuisance macrophytes. The balance of fish communities is not expected to shift in such a way that would promote the expansion of nonindigenous fish beyond those already present in Belews Lake.

In the Dan River, operational impacts are associated with operation of the MWIS at the confluence of Belews Creek and the Dan River, and with the wastewater discharge. Impacts of MWIS operation on impingement and entrainment in the Dan River are regulated through intake flow requirements under the existing NPDES permit and are minimized through the use of technologies and design features. Discharge effluents released to the Dan River are regulated through an NPDES permit obtained in support of operations. Impacts of thermal discharge are expected to be minor for all aquatic biota. Impacts to important species and their habitats are minor.

Overall impacts of Project operations on aquatic species and habitats are SMALL, but MODERATE under drought conditions. Supplemental pumping from the MWIS in accordance with the limits established in the NCDEQ NPDES permit mitigates the reduction in lake levels and associated effects on near shore aquatic habitats and minimizes potential effects related to water-level fluctuations.

Table 5.3-1
Critical Thermal Maxima for Representative Important Species within Belews Lake

Common Name	Scientific Name	Indigenous	Trophic Guild	Thermally Sensitive Species	Acclimation Temperature (°C)	Critical Thermal Maximum (°C)	Critical Thermal Maximum (°F)	Source
Common Carp	*Cyprinus carpio*		OM		25.0	35.7	96.3	Hokanson, 1977
Bluegill	*Lepomis macrochirus*	X	IN		26.0	36.4	97.5	Beitinger et al., 2000
Largemouth Bass	*Micropterus nigric*ans	X	TC		20	36.7	98.1	Beitinger et al., 2000
Channel Catfish	*Ictalurus punctatus*	X	OM		20	35.5	95.9	Beitinger et al., 2000
Black Crappie	*Pomoxis nigromaculatus*	X	TC		23.8	34.9	94.8	Reutter and Herdendorf, 1974
Yellow Perch	*Perca flavescens*	X	IN		25	33.4	92.1	Hokanson, 1977

5.4 SOCIOECONOMICS

This section describes the potential socioeconomic impacts associated with operation of the Project at the Project site. As described in Section 2.4, the region of influence (ROI) for the socioeconomic analysis is defined by the areas where the workforces and their families for the building and operations phases reside, spend their income, and use their benefits. Because of expected commuter patterns, the distribution of residential communities in the area, and the likely socioeconomic impacts, the ROI is composed of the four counties nearest to the site: Rockingham, Stokes, Forsyth, and Guilford counties. These counties serve as the basis for the assessment of social and economic impacts from the Project.

Section 5.4.1 presents a summary of the physical impacts of the Project. Section 5.4.2 provides a description of the demographic impacts. Section 5.4.3 describes the economic impacts, including impacts on the local economy and tax revenues. Section 5.4.4 describes the impacts on infrastructure and community services.

5.4.1 PHYSICAL IMPACTS

This subsection provides an analysis of physical impacts due to operation of the Project that may affect people, buildings, and roads in the nearby communities. Potential impacts include the effects of noise and vibration, odors, dust and air pollution, thermal emissions, roadway deterioration and aesthetics. Duke Energy is committed to meeting all federal, state, and local environmental regulations applicable to these potential effects to reduce the potential for adverse impacts to relevant sensitive receptors.

5.4.1.1 Noise

The principal sources of noise from nuclear power plant operations are cooling towers, transformers, and loudspeakers. Other occasional noise sources may include auxiliary equipment (such as pumps to supply cooling water and diesel generators) and corona discharge from the high-voltage transmission lines. The primary source of continuous noise associated with the operation of the Project is the mechanical draft cooling towers.

As described in Section 5.8.2, during operations, overall impacts from noise are minor as residents and recreators nearest the Project site experience cooling tower noise below the 65 dBA threshold considered acceptable and allowable outside a residence by the USEPA (Section 4.8.2.1). Other residences further from the Project site and across Belews Lake also experience noise from operation of the cooling towers below 65 dBA, which is further attenuated by the distance from the towers and the vegetative buffer. Although residents experience noise at higher levels than the existing average ambient condition, the resulting noise levels remain well below 65 dBA. Additionally, due to the exclusion area boundary (EAB) proposed for each of the three Plant Complexes, recreational users of Belews Lake are not permitted in areas of the lake where noise levels are above 65 dBA. Additional analysis of potential effects of noise emissions from these noise sources on nonradiological health are evaluated in Section 5.8.2.

5.4.1.2 Odors, Dust, and Air Pollution

Operation-related air quality impacts are addressed in Section 5.7.2. Principal sources of air emissions from operations include mechanical draft cooling towers, auxiliary boilers, emergency equipment, and emergency power supply system diesel generators, and gas turbines.

Additional operation-related traffic may also result in nominal, localized increases in fugitive dust and exhaust emissions from worker and delivery vehicles that travel to and from the Project site. Operations-related exhaust emissions could also result in odors.

As described in Section 5.7.2, operating equipment releases air pollutants which include substances like nitrogen oxides (NO_x), carbon monoxide (CO), sulfur oxides (SO_x), hydrocarbons in the form of volatile organic compounds (VOCs), and particulate matter (PM). However, standby and auxiliary equipment are operated on an intermittent basis rather than continuously. As indicated in Section 4.4.1, dust and odors resulting from emissions are localized and dissipate rapidly. Dust emissions are minimized by relevant management measures, as appropriate.

The Project site is located in an attainment area for all National Ambient Air Quality Standards (NAAQS) criteria pollutants. As noted in Section 5.7.2, Project-related emissions do not result in exceedances of the NAAQS. Therefore, air quality impacts from operation onto nearby residences, recreation areas, and facilities are minor.

5.4.1.3 Thermal Emissions

As described in Section 3.4.1, the cooling system includes mechanical draft cooling towers, which remove excess heat by evaporating water. Physical impacts to structures from operational activities are related to cooling tower drift and deposition of salts. Detailed analyses of the transfer and dissipation of heat from the cooling tower as a visible vapor plume and the associated deposition of salt from the vapor plume water droplets are discussed in Section 5.7.1. As documented in the SACTI2 analysis (Section 5.7.1.2.2.3), the maximum modeled plume drift is located near the central and north-central parts of the Project site and as shown in Figure 5.7-9, does not reach off-site structures.

5.4.1.4 Transportation

This subsection discusses the physical impacts on off-site roadways resulting from increased traffic during operations. As described in Section 2.4.2.2.7, the waterways located within the Project Vicinity are not used for transportation-related purposes. As described in Section 3.3.2, rail unloading areas with heavy haul roads will be developed leading from the unloading areas to the construction storage and staging areas. The primary access roads to the Project site are identified in Table 2.4-13 and in Figure 2.4-4. Traffic-related impacts are discussed in Section 5.4.4.1.

As noted in Section 4.4.1.3, Craig Road provides ingress and egress to the Project site during the operations phase. Consequently, the Project-related increased traffic during the building phase accelerates the deterioration of Craig Road and other roadways providing access to the Project site. However, during operations, Project-related traffic volumes are substantially reduced from those observed during the building phase (see Section 5.4.4.1). Therefore, the physical impacts to roads are correspondingly reduced, and the operations-related impacts are minor.

5.4.1.5 Aesthetics

Visual and aesthetic effects occur as a result of viewshed alterations that may relate to alteration of natural or developed landscapes, increased or decreased visibility of structures, or

the addition of visible nonstructural features that are not consistent with the existing viewshed. The existing visual resources near the Project site are described in Section 2.4.2.6.1. Based on the bounding values in the plant parameter envelope described in Table 3.1-1, the principal visual features of the Project site are the power block structures (up to 176 ft. [53.6 m] tall), cooling towers (up to 75 ft. [23 m] tall), and the switchyard and its associated powerlines. These principal visual features are illustrated in Section 3.1, Figures 3.1-4 through 3.1-7 which present representative renderings of the plant from various angles. Additionally, vapor plumes associated with operation of the cooling towers are also a prominent visual feature of the Project site.

Sensitive visual receptors that may be affected by changes in the viewshed are described in Section 2.4.2.6.1 and include recreators on Belews Lake, users of parklands (Belews Lake Park), residents along the southern Project site boundary, property owners across Belews Lake opposite the Project site boundary, and motorists along roadways in the Project Vicinity (6 mi. [10 km]).

Cooling tower plumes have both height and length characteristics that are influenced by weather conditions. As described in Section 5.7.1.2.1, the SACTI2 model simulates the visible plume from cooling towers under different meteorological conditions and frequencies. As summarized in Table 5.7-14, modeled plumes are longest in the winter and shortest in the summer, which is generally consistent with the annual temperature cycle. Similarly, plumes have a greater height in the winter and a lower height during summer. The longest plumes extend to 2.7 km (1.7 mi.) which would occur approximately 2 percent of the time on an annual basis while a 100 m (325 ft.) plume occurs 100 percent of the time during operations. As shown in Table 5.7-15, the modeled plume heights are typically 30 m (98.4 ft.) or less.

To evaluate the potential impact of operations on the visual environment, consideration was given to both attributes of the principal visual feature (height, size) of the Project site and its frequency as a feature in the viewshed. Structures potentially visible from receptors represent features that are permanent and therefore, have a greater effect on visual intrusion. By comparison, the degree of visibility of cooling tower plumes depends on the season, weather conditions (e.g., clear skies, storms, fog), location and perspective of the observer, amount of intervening tree cover, and time of day. Therefore, plumes may be visible and intermittent during an average year and not a constant feature in the viewshed. Therefore, persistent visual intrusions are recognized as having a greater effect on aesthetics than the infrequent occasions when plumes may be visible. Persistent visual intrusions are represented by the permanent alteration of the site, which occurs during the building phase with the clearing of vegetation. These intrusions are further defined by the introduction of the principal visual features at each of the three Plant Complexes.

As described in Section 7.1, plant closure is a RFFA in which BCSS operations are discontinued. As such, the existing stacks of BCSS are evaluated as long-term, persistent structures in the viewshed, whereas the plume from the BCSS stacks are absent in the long term as operations of BCSS are discontinued.

As shown in Figures 3.1-4 through 3.1-7, the principal structures on the Project site are prominent in relation to the surrounding landscape. These structures are mostly visible to recreators at Belews Lake and residents and businesses along the shoreline across the lake. Vegetation clearing within the Project site, the new structures within the Plant Complex areas,

and the associated plumes add an industrial aspect to a mostly natural landscape, noticeably altering the existing viewshed. For sensitive visual receptors near the Project site, aesthetic effects are noticeable. However, due to the vegetative buffer along the shoreline, and the presence of the existing BCSS facility, impacts to recreators on Belews Lake are not destabilizing. Impacts are minor on those receptors at greater distances. Therefore, the visual intrusion due to operation ranges from minor to noticeable, but not destabilizing, depending on the location of the observer and the atmospheric conditions.

5.4.1.6 Summary of Physical Impacts

The physical impacts from noise, odors, dust, and air pollution, thermal emissions, and transportation from operations-related activities are SMALL. Additionally, new plant structures and related cooling tower plumes at the Project site noticeably affect the aesthetic qualities of the natural landscape for nearby residents and recreators on Belews Lake. Thus, physical impacts on aesthetic quality from operations are MODERATE.

5.4.2 DEMOGRAPHIC IMPACTS

The following evaluation assesses potential impacts associated with the operations workforce on the ROI population. The evaluation is focused on impacts within the ROI identified in Section 2.4 and is based on the maximum number of workers required when all advanced reactor units are operating.

As described in Section 3.3.5, the Project is expected to operate at full capacity by the late 2030s. Therefore, the projected 2040 population serves as the baseline for assessing demographic impacts during operation. This evaluation also assumes that due to the anticipated duration of building activities (see Section 1.3.2), approximately 50 percent of the population from the building phase (see Section 4.4.2) retain their permanent residence in the ROI upon completion of building activities. As a result, 512 construction workers and their families remain in the ROI. An additional 170 people that in-migrated during the building phase reside in counties outside the ROI and do not commute to the ROI for operations-related activity. The population remaining in the ROI from the building phase and their families are assumed to follow the same residential distribution as detailed in Section 4.4.2.

Duke Energy anticipates the total operations staff to be approximately 818 full-time employees once all units are operational. It is conservatively assumed that all approximately 818 operations workers are sourced from outside the ROI. In addition, as stated in Section 5.4.4.4.1, an additional 350 temporary outage workers are needed during refueling and major maintenance activities. However, because these activities are infrequent and short-term, temporary outage workers needed from outside the ROI are assumed to relocate to the area temporarily without their families. In-migrating outage workers primarily use temporary housing such as hotels, motels, or short-term rentals, and do not have a notable impact on local demographics or community services. Thus, the following analysis focuses on the full-time operations staff (818 employees) plus 50 percent of the population from the building phase that retain a permanent residence in the ROI (512 employees).

The residential distribution of the in-migrating operations workforce is assumed to be the same as the residential distribution of the existing BCSS workforce. Consistent with these commuting patterns, 25 percent, or 204 of the 818 full-time operations staff reside in counties outside the

ROI and commute to the Project site. Accordingly, the remaining 614 operations workers relocate to the ROI and are assumed to bring a family. The average household size in North Carolina is approximately 2.48 (USCB, 2022). Therefore, the in-migrating operations workforce of 614 people and their families, along with the remaining population from the building phase and their families, increases the ROI's population by approximately 2790. The distribution of this new population within the ROI is shown in Table 5.4-1. The estimated population increases have the greatest effects in Rockingham and Stokes counties, where new residents increase the population by approximately 1.2 percent and 2.0 percent, respectively, based on 2040 projections. Forsyth and Guilford counties each experience population increases of approximately 0.1 percent, while the population in the ROI increases by approximately 0.2 percent.

The population increases associated with the in-migration of operations workforce, together with the construction workforce that remain within the ROI, and their families account for less than 1 percent of the ROI's projected total population in 2040 (Table 5.4-1). Therefore, impacts to demographics within the ROI associated with operation are SMALL.

5.4.3 ECONOMIC IMPACTS TO THE COMMUNITY

This subsection describes the projected economic and tax revenue impacts of operations on the ROI. Economic impacts of operational activities occur both within the ROI as well as the Project Region (50-mi. [80 km] radius of the Project site). As described in Section 4.4.3, counties within the ROI are the most affected due to proximity to the Project site. Other counties in the Project Region also experience economic impacts, but these impacts are widespread and dispersed across the Project Region.

This subsection describes the economic and tax impacts in the ROI during operations. As described in Section 4.4.3, because economic impacts are generally positive, the bounding economic condition is the configuration or option that results in the lower economic benefit. For this Project, multiple advanced reactors are considered for development over three Plant Complexes. Therefore, the development of a single Plant Complex (two reactor units) represents a conservative economic scenario. As such, a single Plant Complex deployment is the bounding condition for this analysis as this would result in lower capital costs and a lower economic benefit as compared to the operation of multiple Plant Complexes.

5.4.3.1 Economy

5.4.3.1.1 Economic Input-Output Model

Economic effects over the course of the 40-year operational life of the Project are linked to both direct and indirect expenditures and operations-related employment. Direct expenditures include payment of wages and salaries to the operating workforce, purchase of goods and services, and capital expenditures. Indirect effects are related to spending and purchases of goods and services by the operations workforce. As described in Section 4.4.3, the multiplier effect creates more jobs, income, and economic activity in the ROI and Project Region. Regional input-output multipliers are economic tools for estimating the broader economic impact of initial changes in economic activity across various sectors.

The economic multiplier used in this analysis is from the Regional Input-Output Modeling System (RIMS) II developed by the U.S. Department of Commerce, Bureau of Economic

Analysis (BEA), Economics and Statistics Division. This model calculates multipliers for various industries and earnings within a specific region (BEA, 2024). The BEA RIMS II multipliers obtained for the ROI are used to model impacts to employment and economic output based on total employment and total operation-related expenditures (payroll).

5.4.3.1.2 Economic Model Predictions

The RIMS II direct effect employment multiplier in the electric power generation industry is 3.76. As such, for every direct job created, an estimated 2.76 indirect jobs are generated in the ROI. The change in indirect employment in the ROI during the operations phase is estimated by applying the RIMS II direct effect employment multiplier to the total operations workforce. Based on the operations workforce needed for a single Plant Complex (339 workers), approximately 935 indirect jobs are created within the ROI. Most indirect jobs are service-related, and those jobs are conservatively assumed to be filled by the existing workforce in the ROI. Some of these jobs could benefit unemployed or underemployed workers in the ROI. Overall, based on 2022 data, the combined approximately 1274 jobs (direct and indirect employment) represent 0.2 percent of the total labor force within the ROI.

The RIMS II multipliers are also used to estimate the economic impact resulting from operations-related payroll expenses. The RIMS II direct effect earnings multiplier for the electric power generation industry is 2.05. Meaning that for every dollar spent on operations payroll, an estimated $1.05 is added to the economy within the ROI. For a single Plant Complex (two reactor units) payroll is estimated to be approximately $30.5 million annually. Using the RIMS II direct effect earnings multiplier and the annual operations-related payroll results in a total economic output of approximately $62.4 million across local industries annually. During the operations phase, the construction-related workforce that remains within the ROI is expected to earn salaries comparable to those received during the building phase, resulting in additional spending within the ROI.

Capital expenditures and purchases of goods and services during operations have a multiplier effect that results in an increase in business activity, particularly in the retail and service industries. However, at this stage, the extent of the capital expenditures and purchase of goods and services occurring within the ROI or the Project Region is unknown. As described in Section 4.4.3.1.2, nuclear power plants are highly specialized in nature and operations-related expenditures are likely to be sourced from retailers outside the Project Region. However, generic operations-related goods and services can be purchased in the ROI and are likely to have a minor but beneficial impact on the economy.

Project operation introduces millions of dollars into the economy annually and indirectly creates employment opportunities. The economic impacts during operations are conservatively analyzed for a single Plant Complex (two reactor units). As Section 4.4.3 states, Duke Energy is analyzing a range of reactor technologies, including multiple reactor units across three Plant Complexes, which would result in substantially greater beneficial economic effects within the ROI and Project Region. Operations-related payroll expenditures are primarily realized within the ROI, making the economic impact of operations beneficial and noticeable.

5.4.3.2 Taxes

Primary tax revenues associated with operations at the Project site arise from individual income tax, corporate income tax and franchise tax, sale of electricity tax, sales and use tax, and property taxes which are beneficial to both the state and the Project Region.

5.4.3.2.1 Individual Income Tax

The in-migrating operations workforce, together with the construction workforce that remains within the ROI, increases the workforce total associated with the Project to 1126 (see Table 5.4-1). As shown on Table 2.4-9, in 2022, more than 500,000 individuals were employed in the ROI. Therefore, the addition of 1126 workers represents a minor increase in the total employed population in the ROI.

Construction workers that remain within the ROI after the building phase concludes are expected to make similar salaries when they transition to new employment within the ROI. Based on the projected 2026 North Carolina income tax rate described in Section 2.4.2.3 and a salary of $40,830 per year, the construction workers that remain in the ROI generate approximately $0.8 million in income tax revenue for the State of North Carolina (BLS, 2023a). Income tax revenue generated from operations workers for one Plant Complex based on an estimated average annual salary of $90,000 per year is approximately $1.2 million for the State of North Carolina. This combined estimated increase in income tax revenue represents 0.01 percent of the total tax revenues for the State of North Carolina in fiscal year 2023. Additionally, employment created through the multiplier effect described in Section 5.4.3.1.2 results in state income tax generation within the ROI. Therefore, there is a minor but beneficial increase in individual income tax revenue within the ROI and for the State of North Carolina associated with operations-related employment.

5.4.3.2.2 Corporate Income Tax and Franchise Tax

As stated in Section 2.4.2.3, for tax year 2023, the State of North Carolina imposed a 2.5 percent income tax on corporations. However, by 2030, this tax is reduced to zero percent. Therefore, operation of the Project has no impact on corporate income and franchise tax.

5.4.3.2.3 Sale of Electricity

The State of North Carolina imposes a 7 percent tax on the sale of electricity (Section 2.4.2.3). Operations of the Project is not anticipated to change Duke Energy's power assets. BCSS is slated to be retired by the mid-2030s (Section 1.2.2). Therefore, the tax revenues from the sale of electricity remain unchanged, and no impacts to electricity tax revenues are expected.

5.4.3.2.4 Sales and Use Taxes

Sales and use taxes are generated by purchases supporting operations at the Project site. While the exact amount of local operational expenditures is unknown, over the 40 year operational life of the plant, a beneficial and minor impact occurs throughout the ROI and Project Region.

Total sales and use taxes collected in the ROI increase because of (1) the in-migrating operations workforce and their families and (2) the operations workforce that resides outside the

ROI but travels into the ROI. While the state collects 4.25 percent state sales and use tax, local jurisdictions levy and collect additional sales and use taxes, ranging from 2.0 to 2.75 percent (see Section 2.4.2.3). The average operations worker salary is approximately $90,000 per year, which is saved or spent on goods and services. Over the Project's 40-year licensing period, sales and use tax revenues are generated from the expenditures of the operations workforce, the remaining construction workforce, and their families. However, due to the small population increase (see Section 5.4.2), the resulting annual revenue return is beneficial and minor.

5.4.3.2.5 Property Tax

Property tax revenues are generated through property taxes on the Project site based on assessed valuation and through property taxes paid by the operations workforce. The construction of a single Plant Complex increases the appraised value of the Project site. As identified in Section 2.4.2.3, Duke Energy paid Stokes County $6.8 million in property taxes for 2024. Improvements made to the Project site are expected to increase its appraised value. These improvements suggest a potential increase in future property tax obligations. However, the exact amount of these obligations is currently unknown.

Members of the in-migrating workforce and the remaining construction workers pay property taxes within the ROI county in which they reside. Based on the residential patterns illustrated in Table 5.4-1, a majority of the operations workers are expected to reside in Rockingham County. While many of these in-migrating workers buy existing homes and pay property tax rates, some workers may choose to build their own homes and thus generate a minor increase in property tax revenues within the ROI.

Therefore, the impact on property taxes from the operational facility, the in-migrating workforce, and the construction workers that remain within the ROI is beneficial and noticeable.

5.4.3.3 Summary of Economic Impacts on the Community

Operational activity introduces millions of dollars into the economy and creates jobs. These positive economic impacts are primarily realized within the ROI. Minor tax revenue impacts on local jurisdictions are accrued through increases in revenue generated from individual income taxes, sales and use taxes, and property taxes. Therefore, the economic and tax impacts are SMALL and beneficial.

5.4.4 COMMUNITY INFRASTRUCTURE IMPACTS

This subsection provides the estimated impacts on infrastructure and community services, including traffic, recreation, and public services.

5.4.4.1 Transportation

This subsection evaluates the traffic impacts generated by operations activities. Section 5.8.3 discusses the accident-related consequences of additional traffic from operations activities.

5.4.4.1.1 Roadway Traffic

Impacts to traffic as a result of operations are generally dependent on five factors:

1. Number of operations workers and their vehicles on the roads.
2. Distribution of the workforce within the ROI and related commuting patterns.
3. Number of truck deliveries to the Project site.
4. Projected population growth rate in the ROI.
5. Capacity of the potentially affected roadways.

As identified in Section 4.4.1.1, the total number of workers accessing the Project site during operations on any day is 450. Conservatively, approximately 90 truck deliveries are made daily to the Project site. Operations workers are divided into two 12-hour shifts. The day shift begins between 5:00 a.m. and 7:00 a.m. and ends between 5:00 p.m. and 7:00 p.m. A total of 400 operations workers enter for the day shift when 50 operations workers leave after the night shift. This analysis conservatively assumes one worker per vehicle because shared transportation information cannot be determined. As noted in Section 4.4.1.3, Project-related traffic, including Project deliveries and refueling and maintenance workers, is expected to access the Project site via Craig Road during operations. Delivery traffic is evenly distributed throughout the work hours of the day and avoids peak traffic hours.

During refueling and maintenance operations, a 350-person temporary outage workforce travels to the Project site during scheduled outages. Using the same shift breakdown as described for the operations workers, temporary outage workers are divided into two shifts: in the morning, 300 enter for the day shift while 50 leave from the previous night shift; in the evening, 50 enter the Project site for the night shift as 300 leave from the day shift. Together, the total number of vehicles accessing the Project site during operations and scheduled outages (800) is less than the total number of construction and operations workers accessing the site during the building phase (2546) (Section 4.4.4.1.1). Therefore, it is expected that impacts on LOS, on surrounding roadway segments and intersections analyzed are less impactful than at peak employment during the building phase. Additionally, potential effects on traffic during the building phase may be minimized by implementing traffic management measures (Section 4.4.1.1), which may also be effective during periodic outage operations, to address impacts during the building phase. As a result, the temporary traffic impact from the outage workforce is considered minimal and is not analyzed further.

As shown on Table 2.4-3, the population in the ROI is projected to grow at a rate of approximately 0.7 percent annually throughout the operations phase. Therefore, any increase in traffic due to population growth is minimal and is not further considered in this analysis.

As described in Section 2.4.2.2.3, the average annual daily traffic (AADT) is calculated by dividing the total volume of motorized vehicle traffic on a highway or roadway segment over the course of the year by 365. Following the same analysis approach described in Section 4.4, the estimated traffic generated by operations activities is based on the assumptions listed above regarding peak employment and on the North Carolina Department of Transportation AADT values shown in Table 2.4-13. Traffic operations for existing conditions and conditions during operations were analyzed using the Highway Capacity Software (HCS), which uses methodology from the seventh edition of the Highway Capacity Manual (NASEM, 2022).

Also noted in Section 2.4.2.2.3, LOS is a qualitative measure of operational conditions at a roadway segment or intersection. LOS is given a letter designation ranging from A to F (free

flow to heavily congested). The primary roadways in the Project Vicinity currently operate at an acceptable LOS C or better, except for U.S. 158 (east of NC Highway 68) and U.S. 158 (between Belews Creek Road and NC Highway 68), which operate at a LOS D. Roadways described in Section 2.4.2.2.3 and evaluated in this subsection are the roadways in the Project Vicinity that operations workers and other Project-related traffic use to access the Project site.

Peak traffic on primary roadways to the Project site in the evening, or the "p.m. peak hour," was analyzed for impacts to LOS during peak employment because p.m. peak-hour traffic is generally heavier than morning traffic, or the "AM peak-hour" traffic, due to additional activities like school pickups, errands, extracurricular activities, and social events. LOS during operations is shown on Figure 5.4-1 and presented in Table 5.4-2.

LOS along most of the roadways analyzed does not change during the operations phase. Changes in LOS from an A to a B during operations are anticipated on U.S. 311 (north and south of NC Highway 65), and Belews Creek Road (between Craig Road and NC Highway 65). LOS on NC Highway 65 (between Belews Creek Road and Pine Hall South), Belews Creek Road (east of Craig Road), and NC Highway 65 (north and south of Pine Hall Road) changes from A and B to C during the operations phase. Under LOS C conditions, speeds along these roadway segments are noticeably reduced during peak hours.

The LOS on NC Highway 68 (north of U.S. 158) changes from a C to D during operations. Under LOS D conditions, vehicles become more closely spaced, with volumes near capacity, on two-way highways. The LOS on U.S. 158 (between Belews Creek Road and NC Highway 68) experiences a degradation from LOS D to E during peak hours. Under LOS E volumes are at or near capacity.

Because of the focused traffic at intersections providing primary access to the Project site, four intersection locations were also reviewed to further analyze traffic impacts during operations. Table 5.4-3 summarizes the results of the analysis for these unsignalized intersections during both existing conditions and operations in the p.m. peak hour. Increased traffic at these intersections results in a decrease in LOS from LOS C or D to LOS E or F for at least one of the traffic movements at each intersection. This results in unstable traffic conditions characterized by low speeds, volumes exceeding capacity, and long delays with stop-and-go traffic.

Overall impacts at two of the intersections providing access to the Project site are noticeable and potentially destabilizing (LOS C/D to F). These impacts are most evident to local residents closest to the Project site that rely on Craig Road to access Belews Creek Road. The most noticeable traffic impacts occur during the beginning and end of the shift and occur for less than 2 hours per day. Impacts to roadway capacity are minor during other times of the day. Duke Energy has identified several planned traffic management measures to minimize congestion and unstable traffic conditions during building phase, as described in Section 4.4.4.1.1, that will alleviate congestion and unstable conditions during operations. With the incorporation of traffic management measures during daily short durations of increased traffic in the immediate area near the Project site, impacts to traffic are noticeable, but not destabilizing.

5.4.4.1.2 Railroads

As described in Section 4.4.4.1.2, deliveries made by rail enter the Project site via an existing Norfolk Southern spur that connects to the BCSS. The use of this rail spur for operational

deliveries does not impact other transportation systems used by the local communities, and the impact on railroads are minor.

5.4.4.1.3 Waterways

As described in Section 2.4.2.2.7, the waterways located within the Project Vicinity are not used for transportation-related purposes. Therefore, there are no operations-related activities on waterways that affect water-based transportation.

5.4.4.1.4 Public Transportation

Public transportation services in the ROI are identified in Section 2.4.2.2.9. However, there are no transit services that provide direct access to the Project site. Therefore, there is no impact on public transportation.

5.4.4.2 Recreation

Recreational resources within the Project Vicinity are potentially affected by operations at the Project site. Impacts may include disruption of recreational experience due to operational use of water, increased user demand associated with the projected increase in population as a result of the in-migrating workforce and their families, and impaired recreational experience associated with operational noise and visual intrusion.

5.4.4.2.1 Operational Water Effects on Recreation

As described in Section 5.2 and Section 7.1.1, the building and operational schedule for units at the Project site is conducted in a phased schedule over several years. In conjunction with this phased approach, Duke Energy will also derate the operations of BCSS in a manner that replaces and balances overall generation capacity between both the Project and BCSS. The closure of BCSS is considered a RFFA (see Table 7.1-2). Accordingly, the BCSS closure results in gradual changes in the environmental conditions relative to those described in Chapter 2.

As is described in Section 5.2.1.1.2.2.2, operational use of water from Belews Lake for the Project results in water-level fluctuations. Figure 5.2-2 depicts the modeled water levels of Belews Lake for the Project operations condition based on supplemental pumping of the MWIS. Specific changes in the affected environment relevant to recreation include the following:

- The future predictive analysis based on Project operation reflects a condition of water levels that fluctuate in a manner that is similar to that predicted for BCSS under full operation. However, the water-level drawdowns under Project operations are more pronounced relative to the BCSS Continuous Maximum Generation Condition and increased by 0.6 ft and 3.0 ft for the 2-year and 100-year drought return periods, respectively.
- Aquatic ecological communities that reflect a lake lacking significant thermal input from power generation including recreationally important sport fish (Section 5.3.2).
- Depending on the frequency of drought conditions and related water-level fluctuation, corresponding effects may also be evident in the condition of recreationally important sport fish (i.e., smaller fish, changes in community structure, and other factors) that may be sought after by anglers (Section 5.3.2).

- Restricted access to several small coves that fall within the EAB as described in Section 5.4.1.1.

Operations impacts based on the above-referenced changes for recreation are considered in the following subsections, as appropriate.

5.4.4.2.1.1 Belews Lake

As described in Section 5.2.1, operational use of cooling water from Belews Lake for advanced reactor technologies results in fluctuations of water levels. Additionally, as a result of BCSS closure, water quality (notably, temperature) within Belews Lake is normalized to that characteristic of other regional lakes that lack thermal inputs from power generation. As described in Section 5.2.3, thermal profiles in Mayo Reservoir, a lake similar to Belews Lake but with minimal anthropogenic heat load, were reviewed to provide a potential predictive future condition of Belews Lake without the contributing heat load from BCSS. Temperature-related changes that potentially affect recreation are attributable to BCSS closure rather than the proposed action. As such, these effects are assessed in Section 7.1 as part of the cumulative effects analysis.

Under conditions in which water levels are stabilized and consumptive losses are offset by MWIS pumping, impacts on Belews Lake recreation are minor. However, impacts on Belews Lake recreation are more noticeable in conjunction with the effects of increased drought intensity for the following:

- Altered recreational access and use due to limitations of boat ramps and boat docks under low water conditions. As identified in Figure 2.4-5, potentially affected access areas include the Pine Hall public boat ramp, Carolina and Humphrey's Ridge marinas, the Piney Bluff boat launch, and individual boat docks within the residential areas of Belews Lake. An accessible fishing dock is also planned for Belews Lake Park. Potential effects to each of these resources may occur depending upon the extent and frequency of each specific drawdown period as described in Section 5.2.1.1.2.2.2 and illustrated in Table 5.2-2, and the specific characteristics of each feature (length and depth of boat ramps, dock design details, etc.).
- Reduced water depth in arms and tributary inlets of Belews Lake that restrict or limit boating access to public boat ramps and approximately 63 permitted private docks and structures (Section 2.4.2.6.2). Several locations within Belews Lake are potentially affected by reduced water levels. Duke Energy will work with the North Carolina Water Resources Commission to extend public boat ramps during these conditions as necessary. Key locations where boat access is potentially impacted by reduced water levels include:
  - Cove near Oak Level Church Road
  - Belews Creek Road underpass on the Belews Creek Arm
  - East Belews Creek Arm at Belews Creek Road
  - East Belews Creek Arm at Reidsville Road
  - Several locations within Belews Creek Arm between Belews Creek Road and Reidsville Road.

Accessibility to the arms of Belews Lake via these key connection areas varies with water-level conditions. Under most conditions accessibility may be possible but more constrained due to water depth limitations. As illustrated in Figure 5.2-3, under moderate and extreme drought conditions, access from Belews Lake to the upper arms of Belews Lake may not be possible due to low water conditions.

- Drought related effects may also indirectly affect fishing including the ability to use boat ramps, as described above, and access all areas of the lake. This may reduce accessibility for fishing and angling activities in Belews Lake. As such, the frequency of fishing tournaments at Belews Lake and the related benefits to local businesses that depend on such recreators may also be affected.
- Pedestrian shoreline access to the water may be limited in certain areas depending on the extent of mud flats or other exposed shoreline areas, particularly during periods of low water levels.
- Increased incidence of boater safety hazards may be present in areas of reduced water levels. Lower water levels may affect boater safety in conjunction with greater frequency of boater contact with exposed or submerged stumps, rocks, and other underwater obstructions.
- The fluctuation of water levels has the effect of creating unvegetated reservoir “rings” and mud flats along the perimeter of the lake. Increased depth of drawdown has the potential to expand the exposed mud flats and shoreline relative to the BCSS full operational condition. Such effects have the potential to diminish the visual appeal of these areas thereby affecting a wide range of activities that rely on scenic quality.
- Changes in water levels and temperature characteristics of Belews Lake described in Sections 5.2.1 and 5.2.3, may also affect fishing. Belews Lake water-level fluctuations during typical conditions are similar to those predicted for BCSS under full operation. However, potential impacts to aquatic species and habitats from hydrologic alterations such as increased water-level fluctuations during drought conditions within Belews Lake from Project operations may include changes to the macrophyte communities, including loss of nearshore emergent vegetation communities and SAV communities. Indirect negative impacts to fish communities may occur through alteration of habitats (e.g., spawning habitat, nursery areas, foraging habitat) and increased potential for proliferation of nuisance macrophytes, such as Hydrilla. Increased frequency and duration of water-level fluctuations during drought conditions have the potential to affect impacts to adult fish growth, spawning, and embryonic and juvenile fish development in conjunction with habitat alteration. However, the balance of fish communities is not expected to shift in such a way that would promote the expansion of nonindigenous fish beyond those already present in Belews Lake. Depending on the frequency of drought conditions and related water-level fluctuation, corresponding effects may also be evident in the condition of recreationally important sport fish (i.e., smaller fish, changes in community structure, and other factors) that may be sought after by anglers.
- As discussed in Section 7.1.2, thermal loading to Belews Lake is significantly reduced in conjunction with the closure of BCSS. The CCW discharge would cease, and heated effluent would no longer disperse within the West Belews Creek arm or be conveyed via the CCW canal to the Belews Creek arm. Loss of warmer winter temperatures in the West Belews Creek arm of Belews Lake will result in a shorter growth season and may result in decreased fish condition through the loss of winter thermal refugia. However, in

conjunction with BCSS closure, normalization of water temperatures across Belews Lake including cooler temperatures within the West Belews Creek arm of Belews Lake in winter, would result in a shorter growing season. However, improved (cooler) summer high water temperatures may also result in reduced stress on the aquatic ecosystem within Belews Lake that may also improve overall fish condition. Accordingly, reductions of elevated temperatures may result in benefits of overall higher fish condition and decreased fish stress in the summer. The loss of thermal discharges from the closure of BCSS will affect recreational sportfishing in Belews Lake. Belews Lake is a popular destination for fishing. Largemouth Bass, Black Crappie, and Alabama Bass are the primarily targeted species for fishing. However, Belews Lake is also fished for catfish, Bluegill, and other sunfish. Due to its warm temperatures resulting from the BCSS discharge, Belews Lake is one of the state's more productive lakes for fishing in the winter. With the establishment of cooler water within Belews Lake under BCSS closure, Belews Lake fish will no longer be attracted to thermal discharges, thereby changing winter movement patterns, which may result in reduction in the degree of winter sportfishing success. The combination of a truncated growing season and the potential reduction in thermally sensitive forage species such as Threadfin Shad may alter abundance and condition of sportfish such as Largemouth Bass, Alabama Bass, Black Crappie, White Crappie (*Pomoxis annularis*), catfishes, and perches (Percidae) that prey upon shad species in the short term; however, the same sportfish species are still expected to persist in Belews Lake.

Potential effects of operations on recreation as noted above result in fluctuating water levels that affect Belews Lake and its recreational characteristics. However, recreational use and quality within Belews Lake and its associated shoreline are subject to Duke Energy policy. Because Duke Energy owns all the land within and immediately adjacent to Belews Lake, adjoining property owners own water view, not waterfront property. Duke Energy grants shoreline access leases to adjacent property owners for permission to access the lake across Duke Energy property and, in limited cases, to maintain existing private piers. Duke Energy's primary goal as it relates to shoreline management is to provide for public and private access to Duke Energy lands while appropriately managing natural, cultural, and recreational resources and protecting the primary function of Belews Lake—supporting electricity production (Duke Energy, 2020).

In summary, overall effects of Project operation on recreation within Belews Lake are primarily dependent upon the water use and related water-level fluctuations. Such effects are intensified by periodic droughts that further depress water levels for short periods. Given the size of Belews Lake and its capacity to continue to provide water-based recreation, impacts are noticeable but not destabilizing.

5.4.4.2.1.2 Dan River

As described in Section 2.4.2.6.2, 90 mi. (145 km) of the Dan River is part of a state paddle trail. During operations, water is withdrawn from the Dan River for makeup to Belews Lake that may alter water levels on the Dan River and potentially impact recreators along the state paddle trail. As stated in Section 3.4.1.1.2, the existing BCSS NPDES Permit NC0024406 and design of the MWIS allow for a pumping capacity of 100 cfs (2.83 m^3/s). Naturally occurring fluctuations of river flow result in an existing condition in which water levels fluctuate seasonally and annually (see Section 2.2.1). Operation of the Project conforms with the existing NPDES permit requirements effective for the BCSS and is not anticipated to further impact water levels on the

Dan River. Additionally, the effects of pumping on bypass flow and associated uses on the Dan River are determined to be minor as described in Section 5.2.1.

Discharge to the Dan River from a new outfall within a corridor adjacent to the existing Outfall 006 results in intermittent flows and hydrologic alterations associated with periodic releases of wastewater effluents in conjunction with blowdown from the cooling tower. Discharges from existing Outfall 006 consist of conventional waste from advanced reactors upon closure of BCSS. The Project discharge structure is designed to be a low-profile structure to limit obstruction to river flow and promote mixing. Because the structure has a low-profile design the effects of the structure on paddlers or recreators on the Dan River are minor. Periodic releases of water from the Project discharge are in accordance with NPDES permit requirements and result in localized flow and current alterations in the vicinity of the release points, but do not result in overall adverse alterations of Dan River flow (Section 5.2.1). Cautionary signage is posted to minimize impacts on recreators. Therefore, due to adherence to NPDES permitted conditions and effective design of the discharge that does not result in an impediment to recreators, impacts to recreators on the Dan River from operations are minor.

5.4.4.2.2 Impacts on Recreational Resources in the Project Vicinity

The Project Vicinity offers various recreational opportunities that are described in Section 2.4.2.6.2 and include Belews Lake and the Dan River. Belews Lake supports aquatic recreation and fishing, while the Dan River provides options for paddling, canoeing, tubing, fishing, and kayaking. Opportunities for camping, bicycling, hunting, and hiking are available throughout the Project Vicinity. The population increase attributable to the operations workers and the remaining building phase workers and their families places additional demand on recreational areas within the Project Vicinity. However, the extent of this impact depends on the capacity of existing facilities. As noted in Section 5.4.2, the overall population increase during the operational phase is minor and this population is expected to use recreational areas and facilities at a rate similar to that of the existing population. Because many of the recreational opportunities in the area are outdoor activities that extend over large areas, recreational venues can effectively accommodate an increased number of users. Consequently, the impacts on recreational resources by the operations workforce and their families is minor.

As described in Section 5.8.2, during operations, overall impacts from noise are minor as residents and recreators nearest the Project site experience cooling tower noise below the 65 dBA threshold considered acceptable and allowable outside a residence by the USEPA (Section 4.8.2.1). Due to the EAB proposed for each of the three Plant Complexes, recreational users of Belews Lake are not permitted in areas of the lake where noise levels are above 65 dBA. Additionally, Duke Energy plans to install buoys or other suitable barriers to demarcate the EABs and provide notification to recreational users of the lake that crossing the boundary is prohibited. In addition to dispersed recreation occurring on Belews Lake, J. Dudley Watts Jr. Park (Belews Lake Park) is the closest developed recreational area located within the Project Vicinity (Section 4.8.2.1). As discussed in Section 5.8.2, the noise produced by the nearest cooling towers at the park boundary is lower than the 65 dBA threshold. Thus, impacts to recreators at Belews Lake Park from noise during plant operation are minor.

As discussed in Section 5.4.1.5, the principal structures on the Project site are prominent in relation to the surrounding landscape and are mostly visible to recreators at Belews Lake and residents and businesses along the shoreline across the lake. Vegetation clearing within the

Project site, the new structures within the Plant Complex areas, and the associated plumes add an industrial aspect to a mostly natural landscape, noticeably altering the existing viewshed. For recreators on Belews Lake, aesthetic effects are noticeable. However, due to the vegetative buffer along the shoreline, and the presence of the existing BCSS facility, impacts are not destabilizing. Impacts are minor on recreators at greater distances. Therefore, the visual intrusion due to operation ranges from minor to noticeable, but not destabilizing, depending on the location of the observer and the atmospheric conditions.

5.4.4.2.3 Summary of Impacts to Recreation

Recreational resources in the Project Vicinity may be affected by operations activities at the Project site. Impacts may include (1) effects associated with water-level changes in Belews Lake; (2) effects of pumping and discharge operations on the Dan River; (3) increased user demand because of the in-migrating workforce and their families as well as the additional population from the building phase that retain a permanent residence in the ROI; (4), noise associated with operation of the cooling towers; and (5) aesthetic changes to the Project site as viewed from recreators on Belews Lake. Under conditions in which water levels are stabilized and consumptive losses are offset by MWIS pumping, impacts on Belews Lake recreation are minor. However, impacts on Belews Lake recreation are noticeable in conjunction with the effects of increased drought intensity and alteration of the existing viewshed. As described above, the overall effects of operations on recreation are noticeable but not destabilizing.

5.4.4.3 Housing

As described in Section 5.4.2, during operation, a total of 1126 Project-related personnel (in-migrating operations workers and construction workers that remain within the ROI) reside within the ROI as shown on Table 5.4-1. Table 5.4-4 identifies the demand placed on available vacant housing, defined as housing units listed as for rent and for sale, by the increased population. Approximately 7.6 percent of the available vacant housing in the ROI is expected to be occupied by this increased population. Based on the distribution of the population across the ROI, Forsyth and Guilford counties have ample housing supply to meet demand. While housing availability in Stokes and Rockingham counties is more constrained, housing units are available to meet demand in these counties.

Workers on short-term outage and maintenance assignments may use temporary housing in the form of hotels, seasonal homes (for long-term rentals), and recreational vehicle parks and campgrounds. As discussed in Section 2.4.2.7 and Section 4.4.4.3, there is abundant temporary housing available within the ROI to accommodate these workers.

Overall, sufficient housing is available within the ROI to accommodate both operations-related workers and temporary short-term workers. Therefore, impacts on housing are minor.

5.4.4.4 Public Services

This subsection discusses the impacts on the existing water supply, wastewater treatment, police, fire protection, healthcare services, and education in the ROI. The impact on public services is primarily driven by the population increase associated with the Project, specifically, in-migrating operations workers, construction workers who remain within the ROI, and their families. As shown in Table 5.4-1, the estimated population increase associated with the Project is 2790.

5.4.4.4.1 Water Supply and Wastewater Treatment

Table 2.4-21 outlines the municipal water suppliers within the ROI with their capacities and utilization rates, indicating that all ROI counties have surplus water capacity. As stated in Section 4.4.4.4.1, the average water usage in the United States is 82 gallons per person per day. Given the projected population increase during operations, water usage increases by 0.2 mgd (909 m^3/d) in the ROI. Table 5.4-5 presents the impact of this increased demand on public water supply systems. Overall, this change results in a capacity reduction of less than 1 percent across the ROI. Therefore, the impact on water supply is minor.

Table 2.4-22 details wastewater systems in the ROI, including their treatment capacity and utilization rates, indicating that these facilities are operating below capacity. The impact on wastewater treatment systems from operations is assessed assuming that 100 percent of the water used by the increased population (82 gallons per person per day) is processed through existing wastewater treatment facilities. Table 5.4-6 presents the impact of increased demand on these facilities. During operations, population growth generates 94.1 mgd (427,787 m^3/d) of wastewater in the ROI. The largest impact to wastewater treatment capacity is in Stokes County where the additional wastewater represents a 13 percent increase over baseline levels. Despite this increase, Stokes County wastewater treatment facilities maintain excess capacity of 71 percent. Across the remaining counties and the broader ROI, wastewater generated by operations-related population growth accounts for less than 1 percent of the available capacity within existing treatment systems. Therefore, the increased demand on wastewater treatment capacity from the in-migrating operations workers and construction workers who remain within the ROI, and their families is minor.

5.4.4.4.2 Police and Fire Protection Services

The ratio of police officers to residents for the counties in the ROI are presented in Table 2.4-23. The number of police officers per resident in the ROI falls below the nationwide average ratio of 2.4 officers per 1000 residents (1 officer per 417 residents) (Section 2.4.2.8). Table 5.4-7 details the distribution of the population increase associated with the Project and the impact on police services within the ROI. Although the population increase raises the ratio of officers to residents across the ROI, the overall percent change of the ratio is minimal. While the service level remains below the national average, the net increase in police service demand within the ROI is relatively minor.

Table 2.4-24 details the existing fire protection services within the ROI. The number of firefighters per resident in Forsyth and Guilford counties falls below the nationwide average ratio of one firefighter for every 318 residents, while the ratio of firefighters to residents in remaining counties and the ROI exceeds the nationwide ratio (Section 2.4.2.8.). Table 5.4-8 details the distribution of the population increase associated with the Project and the impact on fire protection services within the ROI. The change in percentage of the ratio of firefighters to residents in the ROI is minimal and the increased population does not notably alter the ratio of firefighters to residents within the counties in the ROI. Therefore, the increased demand for fire protection service needs is minor.

5.4.4.4.3 Medical Services

Available hospitals in the ROI are shown in Table 2.4-25. Table 5.4-9 presents the effect of the Project-related population increase on the availability of hospital beds within the ROI. Although the increased population places a demand on hospital services, the overall population increase is minimal. As a result, the change in hospital bed demand is negligible, with the ratio shifting slightly from one hospital bed per 298 residents to one hospital bed per 299 residents. This minor change indicates that the increase in population has a minimal effect on medical facilities within the ROI.

Physicians and dentists located in the ROI are detailed in Table 2.4-27. Table 5.4-10 presents the effect of the Project-related population increase on the availability of these healthcare providers. The increased population affects physicians and dental services by increasing the number of patients each provider must serve. However, as detailed in Table 5.4-10, the in-migrating population represents a minimal increase in the total population in the ROI, resulting in a minimal change in provider workload. The number of residents per physician increases from 1169 to 1172, and the number of residents per dentist increases from 1702 to 1707. This limited increase indicates that the impact on healthcare service availability is minor.

5.4.4.4.4 Education

Schools and student populations in the ROI are discussed in Section 2.4.2.9. According to the 2022 U.S. Census Bureau American Community Survey, approximately 19 percent of the population of North Carolina is between the ages of 5 and 19 (i.e., school age) (Section 4.4.4.4). Applying the statewide percentage, approximately 531 of the 2790 operation-related population are school aged. This represents a less than 1 percent increase in overall school enrollment within the ROI as shown in Table 5.4-11. However, the student-to-teacher ratios within the ROI counties and the ROI as a whole remain unchanged and continue to fall below the thresholds outlined in Section 2.4.2.9. Therefore, the impact of the increased population on education services is minor.

5.4.4.5 Summary of Community Infrastructure Impacts

Operation-related impacts on all infrastructure and community services are SMALL within the ROI, with the exception of impacts to traffic and recreation. Impacts to transportation due to operations traffic are SMALL within the broader transportation network, but MODERATE on two-lane segments and intersections that provide access to the Project site. Additionally, overall impacts on recreation are SMALL to MODERATE. Under conditions in which water levels lin Belews Lake are stabilized and consumptive losses are offset by MWIS pumping, impacts on Belews Lake recreation are SMALL. However, impacts on Belews Lake recreation are MODERATE in conjunction with the effects of increased drought intensity and visual intrusion.

Table 5.4-1
Population Increase in ROI During Operations

	Percentage of Existing BCSS Workforce by Place of Residence	Workforce from Building Phase Remaining	Operations Workforce	Total New Residents[a]	Baseline Population (2040 Projections)[b]	Percent Increase in Population
ROI	75.0%	512[c]	614[c]	2790[c]	1,219,453	0.2%
Forsyth County	11.0%	75	90	409	453,437	0.1%
Guilford County	10.0%	68	82	372	626,975	0.1%
Rockingham County	29.0%	198	237	1079	91,570	1.2%
Stokes County	25.0%	171	205	930	47,471	2.0%
Outside ROI	25.0%	170[d]	204[e]	N/A	N/A	N/A
Total	100.0%	682	818	–	–	–

Note:

(a) Values derived from sum of remaining building phase workforce and operations phase workforce multiplied by the average household size in North Carolina of 2.48.

(b) Source: NCOSBM, 2023; estimates are rounded to the nearest whole number.

(c) Expected to maintain a permanent residence in the ROI throughout the operational life of the facilities.

(d) The remaining construction workforce and their families would continue to reside outside the ROI and would not impact ROI population.

(e) Expected to commute from counties outside the ROI; workers and families would continue to reside outside of the ROI and would not impact the ROI population.

Deleted (Removed based on Executive Order, 2025).

5.6 HISTORIC AND CULTURAL RESOURCES

Potential impacts from Project operations at the Project site on historic and cultural resources are assessed in this section. Section 2.6 presents the cultural context of the Project site and describes the archaeological sites identified as eligible for listing on the National Register of Historic Places (NRHP). Section 106 of the National Historic Preservation Act of 1966, as amended (NHPA) (54 USC 300101 et seq.), requires that federal agencies consider the effects of the agency's undertaking on historic properties included in, or eligible for, the NRHP. The NRC will consider the information presented herein and make a recommendation regarding the issuance of an ESP. Therefore, the Project is subject to review and consultation under Section 106 of the National Historic Preservation Act (16 USC 470 et seq.) and its implementing regulations (36 CFR 800.8).

5.6.1 HISTORIC ARCHITECTURE RESOURCES

As noted in Section 2.6.3.1, the North Carolina State Historic Preservation Office (NCSHPO) determined that the Project as proposed would not have an effect on historic structures in the Project Vicinity. Therefore, there are no impacts to historic structures from operations.

5.6.2 ARCHAEOLOGICAL RESOURCES

The advanced reactor units and supporting facilities are located on the Project site within the NDA identified in Figure 3.3-1. The 906-ac. (367-ha) NDA is located within the 1080-ac. (436-ha) area of potential affect established for the Project and described in Section 2.6.

The operation of the advanced reactor units and supporting facilities occurs in areas that are disturbed during the building phase. Following construction, it is unlikely that archaeological resources in disturbed areas are intact.

No operations phase ground-disturbing activities are identified beyond the NDA. Nonetheless, if ground-disturbing activities are undertaken beyond the NDA during operations, the potential exists for affecting undiscovered resources within the Project site. As described in Section 4.6.2, mitigative measures developed in consultation with NCSHPO and the North Carolina Office of State Archaeology are proposed for addressing the previously undiscovered resources, and internal procedures will be followed for such discoveries. Therefore, impacts to archaeological sites during operations are expected to be minimal to none and are therefore considered SMALL.

5.6.3 CEMETERIES

Site 31SK269, the Branson Cemetery, is present on the Project site, and, as described in Section 2.6.3.1, it was determined to be ineligible for the NRHP. However, cemeteries are protected under North Carolina General Statutes Chapter 14-148 and 14-149 and are afforded consideration under Chapter 65. As described in Section 4.6, avoidance of the cemetery is not possible based on the extent of the NDA. Duke Energy has undertaken work to conduct archival research with respect to the cemetery, including its history and associated records. Accordingly, the provisions regarding exhumation and repatriation provided by North Carolina General Statute Chapter 65-106 will be followed as appropriate. All cemetery relocation activities will be undertaken in advance of, or during, the building phase. As such no cemetery will be present on the Project site during operation. Therefore, there are no impacts to cemeteries during operations.

5.7 AIR RESOURCES

The primary impacts of operating a new nuclear power plant at the Project site on air resources are from releases to the environment of heat and moisture from linear mechanical draft cooling towers (LMDCTs), operation of auxiliary equipment (e.g., generators and auxiliary boilers), and mobile emissions (e.g., vehicles driven by workers).

Section 5.7.1 discusses potential impacts from the mechanical draft cooling towers. Potential air quality impacts from criteria pollutant and greenhouse gas (GHG) effluent releases are discussed in Section 5.7.2. Section 5.7.3 discusses potential air quality impacts associated with transmission lines during plant operation.

5.7.1 COOLING SYSTEM IMPACTS

5.7.1.1 Mechanical Draft Cooling Towers

Duke Energy proposes to construct up to three nuclear power Plant Complexes on the Project site. Each complex may contain multiple advanced reactors. A specific reactor design has not been selected by Duke Energy. Details of the required cooling systems have also not been finalized. For modeling purposes back-to-back cell LMDCTs are used.

LMDCTs remove excess heat by evaporating water. Upon exiting a cooling tower, a plume of water vapor mixes with the surrounding air which generally leads to condensation and formation of a visible plume, which may have aesthetic impacts. Associated meteorological impacts of the plume may include ground-level fogging/icing, plume shadowing, drift particulate deposition from dissolved solids in the cooling water, and ground-level temperature and humidity increases. Plumes from the cooling towers may also contribute to regional pollutant increases.

Although the final design has not been selected, the normal operating drift loss for cooling towers is estimated based on 0.001 percent of the cooling water flow in the plant parameter envelope (PPE). This drift loss is consistent with current mechanical draft cooling tower designs.

5.7.1.2 Cooling Tower Impact Modeling

The NRC has identified several plume-related codes as acceptable methodologies. A model endorsed by NUREG-1555, Environmental Standard Review Plan (ESRP) Section 5.3.3.1, is described by Carhart et al., (1992). In NUREG-1555, the NRC suggests using the Carhart and Policastro, (1991) reference that shows their model predicts plume rise within a factor of 2 approximately 75 percent of the time and visible plume length within a factor of 2.5 approximately 70 percent of the time. The model was incorporated in the Electric Power Research Institute's (EPRI) Seasonal/Annual Cooling Tower Impact Prediction Code (SACTI) in 1991, and later modified in 2015 (EPRI, 2015).

EPRI, 2015 discusses improvements incorporated in SACTI2. Among the improvements is SACTI2's ability to model multiple natural- or mechanical draft cooling towers in any geometric orientation and to merge multiple plumes to show combined impacts across the modeled domain. SACTI2's multiple plume algorithm has been validated with field and laboratory data.

The current version of the SACTI plume modeling code (EPRI, 2015), hereinafter referred to as SACTI2, is used to develop the model for the evaluation of potential plumes from LMDCTs at the Project site. SACTI2 defines seasons based on the dates for astronomical seasons (see Table 4-2 in EPRI, 2015).

SACTI2 is used for assessing near-field impacts of cooling towers out to approximately 10 km (6.2 mi.) (EPRI, 2015). Key assumptions incorporated in the core SACTI2 model are listed below (see, Section 1.1 of EPRI, 2015).

- Impacts are only computed at ground level.
- Receptor height is zero (i.e., the terrain is locally flat).
- All cooling tower cell exit ports are assumed to be at the same height.
- "Flagpole" receptors, or elevated terrain receptors such as those used in the USEPA American Meteorological Society/EPA Regulatory Model (AERMOD) air dispersion model, or the Industrial Source Complex (ISC) model are not used in SACTI2. The terrain is assumed to be flat in SACTI2 as noted above.

Modern LMDCTs may employ hybrid (wet/dry) configurations which use dry air to abate the effluent plume so that the effluent plume is less visible or completely invisible compared to wet cooling. The current version of SACTI2 does not simulate emissions from towers employing plume abatement (EPRI, 2015).

The SACTI2 plume prediction code is run on a desktop computer via an executable at the disk operating system prompt (console mode). The program creates a series of output tables in text format that are processed with standard plotting programs, spreadsheets, and text editors.

Per NUREG-1555 Section 5.3.3.2, Terrestrial Ecosystems, an order-of-magnitude approach is used to analyze potential impacts from modeled salt drift deposition:

- Deposition of salt (NaCl) drift at rates of 1 to 2 kg/ha/mo (100 – 200 kg/km^2/mo) equivalent to 571 to 1142 pounds per square mile per month (lb/mi^2/mo), is generally not damaging to vegetation.
- Deposition rates approaching or exceeding 10 to 20 kg/ha/mo (1000 – 2000 kg/km^2/mo) equivalent to 5710 to 11,420 lb/mi^2/mo in any month during the growing season could cause leaf damage in many species.
- Deposition rates of hundreds or thousands of kg/ha/yr could cause damage sufficient to suggest the need for changes of tower-basin salinities or a reevaluation of tower design, depending on the amount of land impacted and the uniqueness of the terrestrial ecosystems expected to be exposed to drift deposition.

In addition to potential impacts from salt deposition on terrestrial ecosystems, excessive salt deposition may cause operational issues for exposed electrical equipment. Mineral deposition may not only cause incidents of insulator failure, but also accelerates corrosion on metal surfaces (equipment and structures) increasing rust and decreasing the metal's integrity.

The Institute of Electrical and Electronic Engineers (IEEE) *Electric Power Engineering Handbook* (IEEE, 2001) provides mineral deposition ranges for salt on electrical components above which increased incidents of insulator failure and flashover may occur. Salt deposition severity ranges in milligrams per square centimeter (mg/cm^2) from IEEE, 2001 and their

corresponding ranges in units used in NUREG-1555 Section 5.3.3.2 (kg/km^2/mo) are provided in Table 5.7-1.

IEEE, 2001 does not specify an accumulation time for deposition, whereas SACTI2 provides monthly deposition rates. For purposes of comparing the results from SACTI2, the deposition rates specified by IEEE, 2001 are taken to persist for an entire month. Effectively this assumes that no precipitation occurs which may wash off some deposited salts. At sites with relatively frequent rainfall such as the Project site, this is a conservative assumption.

Per NUREG-1555, an order-of-magnitude approach is used to analyze potential impacts from fogging or icing:

- Fogging or icing of vegetation on the order of a few hours per year is generally not severe.
- Fogging or icing of vegetation on the order of tens of hours per year may cause detectable damage to vegetation.
- Fogging or icing of vegetation on the order of hundreds of hours per year could be severe enough to suggest the need for design changes, depending upon the amount of land impacted and the uniqueness of the terrestrial ecosystems.

5.7.1.2.1 Model Inputs

Model inputs for SACTI2 are described in the following subsections.

5.7.1.2.1.1 Meteorological Data

SACTI2 requires one year of input surface meteorological data. The source of the surface data can be an airport or other facility with data available in the National Centers for Environmental Information (NCEI) Integrated Surface Database format, or data from an on-site tower in NRC format. However, RG 1.23, Rev. 1 specifies use of a minimum of one year (12 consecutive months) of on-site meteorological data. An on-site meteorological tower was installed at the Project site in late January 2024. The on-site tower is described in Section 2.7.4. The location of the tower is shown in Figure 5.7-1.

Input meteorological data from the first year of operation of the on-site tower covers the period February 7, 2024 through February 6, 2025. During this period, the joint data availability of 92.98 percent was captured for 10 m (32.8 ft.) and 60 m (196.9 ft.) wind speed/direction, vertical temperature difference (Delta-T) between 10 m (32.8 ft.) and 60 m (196.9 ft.), dewpoint and relative humidity at the 10 m-level (32.8 ft-level) used in SACTI2. This joint data availability exceeds the annual 90 percent data availability requirements in RG 1.23, Rev. 1 and USEPA, 2000. Based on input meteorological data completeness, the on-site data are suitable for use in SACTI2.

Figure 5.7-2 shows an annual wind rose at the 10 m (32.8 ft.) above ground level (AGL) reference level from the on-site tower. The annual wind rose shows a multi-modal wind direction distribution with winds most frequently blowing from the southwest through south sectors, west-northwest, or east. Southwest is consistent with the general southwest-northeast orientation of the terrain features in the region around the Project site as shown in Figure 5.7-1.

Corresponding wind roses based on astronomical seasons are shown in Figure 5.7-3 through Figure 5.7-6. The seasonal wind roses show that northwest winds are more frequent in spring,

fall, and winter. East winds are more frequent in spring. Southwest winds are typical all year. Northeast winds are relatively infrequent at the Project site, with the exception of summer, despite the regional tendencies. Southeast winds are least frequent, which is consistent with regional conditions.

SACTI2 also requires input morning and afternoon mixing heights. Section 3.2 of EPRI, 2015 provides two methods for determining mixing heights. One of these methods uses daily radiosonde observations from National Oceanic and Atmospheric Administration – Earth Systems Research Laboratory (NOAA – ESRL). This data set is no longer available as of late 2024 (see page 3-23 of USEPA, 2024a). However, Appendix B of EPRI, 2015 provides an alternative method when daily radiosonde observations of morning and afternoon mixing heights are not available. This method uses a customized utility "SeasonalZi" that is packaged with the SACTI2 code in EPRI, 2015. This utility re-formats user-supplied seasonal average mixing heights into a format compatible with SACTI2. The procedure for running "SeasonalZi" and its input is described in Appendix B of EPRI, 2015. Mixing heights for Greensboro, NC, were obtained from the USEPA Support Center for Regulatory Atmospheric Modeling (SCRAM) (USEPA, 2024b). The USEPA data are more current than the traditional reference from Holzworth (1972) that is often used as a source of seasonal mixing height data.

Seasonal and annual estimates of mixing heights for the Project site are presented in Table 5.7-2. Mixing heights vary during the day, with the lowest average mixing heights (approximately 379 m [1243 feet {ft.}]) generally recorded during the morning hours in the fall and the highest readings (approximately 1609 m [5278 ft.]) recorded during the afternoon in the summer for the 7-year period of record (1984-1987 and 1989-1991) of the SCRAM dataset.

SACTI2 also requires input of monthly cloudiness indices and monthly average total global radiation. These parameters are available from Knapp et al., 1980 for Greensboro, NC. These parameters are presented in Table 5.7-3 and Table 5.7-4, respectively.

SACTI2 requires input of approximate roughness length when using surface meteorological data from a site-specific tower. The Project site is in a forested region. From values for forested areas presented in Table 3.5 of USEPA, 2024a, a roughness length of 1 m (3.28 ft.) is used.

5.7.1.2.1.2 Cooling Tower Parameters

The final cooling tower design has not been determined, but certain site-specific input is required by SACTI2. Therefore, the bounding design uses a total of six LMDCTs. Each LMDCT consists of 18 cells (two banks containing nine cells in each bank) for a total of 108 cooling tower cells (6 LMDCTs x 18 cells per tower = 108 cells). However, there is a limit to the number of cells that can be processed in SACTI2 due to limitations on the field width in certain input/output files. The field width is limited to two digits, which corresponds to a maximum of 99 cells. Thus, SACTI2 was run with 96 cells (corresponding to six towers, each with 16 cells), with the cell exit diameter adjusted upward from 10.4 m (34.1 ft.) to 11.0 m (36.1 ft.) to maintain the same mass airflow rate per cooling tower. The dimensions of the towers were not changed.

The locations of the LMDCTs are provided in Figure 5.7-7. Modeled bounding cooling tower design parameters from the PPE are provided in Table 5.7-5.

Unlike air quality models that are used in industrial source air permitting, such as AERMOD or the ISC models, which typically use geographical coordinate systems, SACTI2 uses a local coordinate system for modeling impacts of all LMDCTs in the model domain. In practice the

center of this coordinate system is set at a convenient point near all the LMDCTs being modeled (see examples in EPRI, 2015). The representative locations of the LMDCTs are extracted from site general arrangement (GA) drawings. The locations of the six cooling towers modeled in SACTI2 are plotted in Figure 5.7-7.

The locations of all cooling towers and cells are located relative to the site center point in SACTI2. All cooling towers are oriented with their long axes set to 35 degrees east of true north as shown in the site GA diagram developed for the bounding plant configuration, or in an approximate southwest-northeast orientation.

The source of water for the cooling towers is Belews Lake. Based on water quality measurements at the cooling water intake, a bounding value of TDS concentration of 940 parts per million (ppm) is used from the PPE. As cooling water evaporates from the towers or is lost via drift, the concentration of minerals in the water increases, which can lead to scaling and corrosive conditions. To control TDS levels, a portion of the circulating water is blown down through a planned discharge. A bounding value of 12 cycles of concentration is used.

In lieu of design-specific droplet size information, a drift droplet size distribution from Reisman and Frisbie, 2002 is input into SACTI2 to model drift deposition. This distribution is provided in Table 5.7-6. Table 5.7-6 shows that approximately 89 percent of the mass of the droplet size distribution consists of droplets with diameters ranging from 60 microns (µm) to 180 µm with a peak diameter of approximately 90 µm. This is consistent with a droplet size distribution from cooling tower tests conducted by the Midwest Research Institute () published in MRI, 1991 and cited in USEPA, 1995. The peak of the droplet size distribution in MRI, 1991 includes droplets with diameters ranging from approximately 40 µm to 100 µm.

5.7.1.2.2 Modeled Impacts

5.7.1.2.2.1 Ground Fogging

Ground fog events are defined to occur when a modeled plume contacts the ground and/or the plume is below the height of the cooling towers. The maximum modeled number of hours with fogging per season and on an annual basis for all the LMDCTs are provided in Table 5.7-7. No hours of fogging are predicted. These results are generally consistent with modeling results reported in the ESPA for a SMR project at the Clinch River Nuclear site near Oak Ridge, Tennessee. The Clinch River Nuclear site reported no additional hours of fogging in its SACTI2 modeling of LMDCTs (NRC, 2019a).

5.7.1.2.2.2 Plume Rime Icing

Rime icing occurs when the ambient air temperature is below freezing during a plume ground fogging event. Rime icing occurs when supercooled water droplets freeze on contact with structures.

The maximum modeled number of hours with rime icing per season and on an annual basis are provided in Table 5.7-8. No hours of icing are predicted. Given the relatively warm climate of the Project site, this result is reasonable. This result is also consistent with modeling results reported in the ESPA for an SMR project at the Clinch River Nuclear site near Oak Ridge, Tennessee. The Clinch River Nuclear site reported no hours of icing in its SACTI2 modeling of LMDCTs at their site (NRC, 2019a). The Clinch River Nuclear site and the Project site are both

located in a humid subtropical climate with warm summers (see page 8 of Espenshade and Morrison, 1978) and therefore should have similar plume rime icing frequencies.

5.7.1.2.2.3 Plume Drift Deposition

The maximum modeled seasonal and annual salt deposition rates from operation of all LMDCTs are summarized in Table 5.7-9. The highest seasonal deposition rate (summer — 63.51 kg/km^2/mo [0.64 kg/ha/mo]) is located 300 m (984 ft.) east-northeast of the site center point. The maximum modeled seasonal salt deposition rate is in the very light range as classified in Table 5.7-1. The maximum modeled seasonal salt deposition rate is well below the 1000 – 2000 kg/km^2/mo range that could cause leaf damage in many species as noted in NUREG-1555. Conservatively applying the threshold from NUREG-1555, locations within Duke Energy property along Craig Road may be slightly impacted by plume deposition.

The maximum modeled seasonal deposition rates from all LMDCTs (summer) are plotted in Figure 5.7-8, along with the approximate locations of the cooling towers. The salt deposition pattern in Figure 5.7-8 shows the highest deposition rates located near the central and north-central parts of the site. The deposition pattern is consistent with the annual and seasonal wind roses in Figure 5.7-2 and Figures 5.7-3 through 5.7-6, respectively. In general, deposition often occurs within a smaller horizontal extent than the other impacts, primarily because larger water droplets carrying dissolved salts settle out of the air quickly due to gravity.

During the other seasons and on an annual basis, the maximum modeled deposition rates shown in Table 5.7-9 range from 41.57 kg/km^2/mo (0.42 kg/ha/mo) (annual basis) to 51.77 kg/km^2/mo (0.52 kg/ha/mo) (spring), which are all in the very light range as classified in Table 5.7-1. These deposition rates are below the 1000 – 2000 kg/km^2/mo (10-20 kg/ha/mo) range that could cause leaf damage in many species. The locations of the maximum modeled salt deposition on a seasonal and annual basis are on-site.

To inform the future design of the switchyards and other electrical systems, a plot of the annual salt deposition rates is provided in Figure 5.7-9. The modeled deposition rates in Figure 5.7-9 include contributions from all four seasons. Figure 5.7-9 shows that the highest annual deposition rates are located near the central and north-central parts of the site — similar to results shown in Figure 5.7-8 for summer. Figure 5.7-9 also shows an area of very light deposition ranging from 3 – 12 kg/km^2/mo (0.03 – 0.12 kg/ha/mo) located approximately 500 – 1000 m (1640 – 3280 ft.) southeast of the site center point. This is due to winds from the northwest that are more frequent in spring, fall, and summer as discussed in Section 5.7.1.2.1.1. The maximum annual deposition rates are well below the range that could cause leaf damage.

Significant levels of chloride runoff can contribute to water quality degradation which can affect aquatic life. However, since the predicted deposition rates are relatively low and precipitation is relatively high and frequent at the Project site, deposited salts will be diluted quickly and therefore do not greatly impact Belews Lake and the surrounding area. However, SACTI2 does not predict the dilutive effects of precipitation on deposited solids. Overall, salt drift deposition is not expected to be a significant concern.

5.7.1.2.3 Visible Plumes

5.7.1.2.3.1 Plume Shadowing

Visible cooling tower plumes are those elevated plumes that occur and have sufficient optical density to appear opaque to an observer. The maximum modeled number of hours with plume shadowing on seasonal and annual bases are summarized in Table 5.7-10. The modeled annual hours with plume shadowing (with a maximum of 380.9 hours per year) are plotted in Figure 5.7-10. Figure 5.7-10 shows that modeled visual impacts are most pronounced near the center of the Project site. The overall shape of the area with the highest plume shadowing is consistent with the multi-modal wind direction distribution depicted in the annual wind rose in Figure 5.7-2. Locations along the onsite private plant road accessed via Craig Road may be most impacted by plume shadowing. Plume shadowing is the most frequent in central parts of the site near the LMDCTs. Maximum plume shadowing effects are expected to occur within the site boundary.

On a seasonal basis Table 5.7-10 shows that impacts are the highest in the winter (137.0 hours), and lowest in the summer and fall which is generally consistent with the annual temperature cycle. In all seasons and on an annual basis, the location of the highest number of hours with plume shadowing are predicted near central parts of the site.

5.7.1.2.3.2 Solar Radiation Losses

Incoming solar radiation consists of direct solar radiation from the solar disk and diffuse radiation. Direct solar radiation is also referred to as beam radiation. Total solar radiation is the sum of beam and diffuse radiation components.

Visible cooling tower plumes may have sufficient optical density to reduce incoming solar radiation, resulting in solar radiation losses at the surface. SACTI2 computes total solar radiation losses (in megajoules per square meter [MJ/m^2]), fractional total solar radiation losses (in percent), and fractional beam radiation losses (in percent).

The maximum modeled annual and seasonal total solar radiation losses are summarized in Table 5.7-11. The modeled annual losses arising from operation of all the LMDCTs (with a maximum modeled loss of 233 MJ/m^2 [20,517 BTU/ft^2]) are plotted in Figure 5.7-11. Figure 5.7-11 shows that the overall shape of the area with the largest solar radiation losses is consistent with the multi-modal annual wind direction distribution depicted in the annual wind rose in Figure 5.7-2. The highest modeled solar radiation losses are located near the center point which is consistent with the location of the highest modeled plume shadowing frequencies in Table 5.7-10 and Figure 5.7-10.

The maximum modeled fractional total solar radiation losses are summarized in Table 5.7-12. Table 5.7-12 shows that the maximum modeled annual solar radiation losses arising from operation of all the LMDCTs is 4.5 percent. The modeled annual fractional total solar radiation losses are plotted in Figure 5.7-12. The highest modeled annual fractional solar radiation losses are located near the center point and are consistent with the location of the highest modeled plume shadowing in Table 5.7-10 and Figure 5.7-10.

The maximum modeled fractional beam radiation losses are summarized in Table 5.7-13. The maximum modeled annual fractional beam radiation losses associated with operation of the LMDCTs is 7.9 percent. The modeled annual fractional beam losses are plotted in Figure 5.7-

13. The highest modeled fractional solar radiation losses are located near the center point and are consistent with the location of the highest modeled plume shadowing frequencies in Table 5.7-10 and Figure 5.7-10.

5.7.1.2.3.3 Plume Length

SACTI2 provides summaries of seasonal and annual visible plume length. Table 5.7-14 shows the percentage of the time that plumes exceed a specified length. Table 5.7-14 shows that modeled plumes are longest in the winter and shortest in the summer. This is consistent with the annual air temperature cycle at the Project site and annual trends in the modeled hours with plume shadowing described in Section 5.7.1.2.3.1. The longest plumes extended to 2.7 km (1.7 mi.).

5.7.1.2.3.4 Plume Height

SACTI2 provides summaries of the modeled seasonal and annual visible plume height. Table 5.7-15 shows the percentage of time that plumes exceed a specified height. Table 5.7-15 shows modeled plume heights are typically 30 m (98.4 ft.) or less.

5.7.1.2.3.5 Plume Radius

SACTI2 provides summaries of the modeled seasonal and annual visible plume radius. Table 5.7-16 shows the percentage of time that plumes exceed a specified maximum radius. Table 5.7-16 shows that the modeled plume radius is typically 15 m (49.2 ft.) or less.

5.7.1.2.4 Additional Precipitation and Humidity

SACTI2 provides annual average water deposition rates for distances to a maximum of 10 km (6.2 mi.). The maximum plume water deposition rates are summarized in Table 5.7-17. The highest annual plume water deposition rate is 34,700 kg/km^2/mo (347 kg/ha/mo) which occurs 100 m (330 ft.) east-northeast of the Project site center point. This rate, which is equivalent to approximately 0.0014 inches (in.) (0.0036 cm) of deposited water per month, is insignificant when compared to the corresponding average monthly precipitation measured at the on-site meteorological tower (3.17 in. [8.05] precipitation per month) between February 7, 2024 and February 6, 2025. This rate is also an insignificant amount when compared to the average monthly normal precipitation recorded at the Piedmont Triad International Airport (3.66 in. [9.30] per month from NCEI, 2022). Thus, additional water deposition from all the LMDCTs at the Project site is expected to be insignificant.

No calculations for predicted relative humidity levels are provided by the SACTI2 model. Some increase in relative humidity may occur close to the LMDCTs or in an elevated plume. However, based on insignificant levels of modeled plume water deposition and no predicted fogging, the impacts on ground-level humidity from operation of all the LMDCTs is expected to be minimal.

5.7.1.2.5 Summary of Modeled Impacts of the Cooling Towers

Given no predicted fogging, no predicted plume rime icing, low predicted salt deposition rates, limited visual impacts, and insignificant plume water deposition rates, the predicted impacts from operation of all LMDCTs at the Project site are SMALL.

5.7.2 AIR QUALITY IMPACTS

Air emission sources associated with a new nuclear power plant would be managed in accordance with federal, state, and local air quality control laws and regulations. A new plant at the Project site would comply with all regulatory requirements of the Clean Air Act, and the NCDEQ Department of Air Quality (DAQ) requirements to minimize impacts on state and regional air quality.

The Project site is located in Stokes and Forsyth counties, NC, and is bordered by Rockingham County to the east and Guilford County to the southeast. The Project site is located in an attainment area for all NAAQS criteria pollutants (NCDEQ, 2024). Therefore, the proposed Project is not subject to a Nonattainment New Source Review.

After the final Project design is selected, air dispersion modeling, if required by NCDEQ, will be conducted to demonstrate that Project emissions do not result in exceedances of the NAAQS.

5.7.2.1 Air Pollutant Sources

5.7.2.1.1 Criteria Pollutants

The principal sources of criteria air pollutants at a new nuclear power plant at the Project site are mechanical draft cooling towers, auxiliary boilers, standby equipment, and emergency power supply system diesel generators and/or gas turbines.

Auxiliary boilers are used for heating buildings, primarily during the winter months, and for process steam during site startups. The diesel generators/gas turbines and engine-driven emergency equipment are used intermittently and for brief durations. Emissions from the equipment include NO_x, CO, SO_x, hydrocarbons in the form of VOCs, and PM.

A specific reactor technology and supporting equipment have not been selected. Bounding annual emission rates from the PPE for the cooling towers are provided in Table 5.7-18. Bounding annual emissions rates for the auxiliary boilers and diesel generators are provided in Tables 5.7-19 and 5.7-20, respectively. Annual estimated criteria pollutant emissions from the assumed supporting equipment are summarized in Table 5.7-21. These values were obtained from the PPE table and assumed worst case emissions scenarios from all potential technology vendors and are based on 8760 operating hours per year per cooling towers, 864 hours per year for each auxiliary boiler at 36 days per year, and 4 hours per month for each standby and / or ancillary diesel generators.

Additional operations-related traffic may also result in vehicular air emissions. Nominal localized increases in emissions occur due to the increased numbers of cars, trucks, and delivery vehicles that travel to and from the Project site. Most of the increased traffic is associated with employees driving to and from work. Once the workers are at the Project site, the volume of traffic and its associated emissions are expected to decrease. Mitigation measures that may be considered during operations include staggering work shifts, requiring delivery vehicles to shut down engines while off-loading, restricting idling times of on-site vehicles, using electric and hybrid vehicles, and supporting and promoting van/carpooling and other commuter programs.

Impacts from operations-related traffic are transient and can be mitigated. Operation of the advanced reactors increases gaseous and particulate emissions to the air, primarily from

cooling towers, auxiliary boilers, standby equipment, and standby power supply system diesel generators and/or gas turbines. The diesel generators/gas turbines and engine-driven emergency equipment are used intermittently and for brief durations. Air emission sources would be managed in accordance with federal, state, and local air quality control laws and regulations. Air dispersion modeling, if required by NCDEQ-DAQ, will be conducted to demonstrate that Project-related emissions of criteria pollutants do not result in exceedances of the NAAQS and the North Carolina Air Toxics Regulation. Accordingly, air quality impacts from emissions from the Project site are SMALL.

5.7.2.2 Greenhouse Gas Emissions

As discussed in Section 2.7, the impact of GHG emissions from the Project site on air quality is compared to GHG emissions at the state and national levels. At the state level, annual GHG emissions in North Carolina are 115.6 million metric tons total carbon dioxide (CO_2) (EIA, 2024). At the national level, net GHG emissions in the United States in 2022 totaled 6,343.2 million metric tons carbon dioxide equivalent (CO_2eq) after accounting for sequestration from the land sector (USEPA, 2024c). The GHG emissions footprint of a generic 1000-megawatt-electric (MWe) reactor provides a conservative estimate of impacts. The lifetime GHG emissions footprint of a generic 1000 MWe reactor is 10.5 million metric tons CO_2eq. (Table A-3. Nuclear Power Plant Lifetime GHG Footprint in NUREG-1437). Lifetime GHG emissions from a generic reactor are an estimated 9.1 percent of the annual GHG emissions in North Carolina (10.5 million to 115.6 million metric tons) and 0.17 percent of the annual 2022 carbon equivalent emissions in the U.S. (10.5 million to 6343.5 million metric tons). Given the relatively small lifetime GHG emission footprint of a generic reactor, impacts of GHG emissions from the Project site are SMALL.

5.7.3 TRANSMISSION LINE IMPACTS

Small amounts of ozone (O_3) and substantially smaller amounts of oxides of nitrogen (NO_X) are produced by transmission lines during corona, a phenomenon that occurs when air ionizes near isolated irregularities on the conductor surface such as abrasions, dust particles, raindrops, and insects.

The NRC NUREG 1437, Volume 1 (2013) quantified the impacts of existing transmission lines on air quality resulting from corona. Specifically, the amount of O_3 generated from even the largest lines in operation (765 kilovolts [kV]) is insignificant. Further, monitoring of O_3 levels for two years near a Bonneville Power Administration 1200-kV prototype line revealed no increase in ambient O_3 concentrations caused by the line. NUREG 1437, concluded that O_3 concentrations generated by transmission lines are too low to cause any significant effects to air quality. Additionally, the small amounts of NO_X produced are similarly insignificant.

Depending upon the generation technology selected, the potential for a new 230-kV switchyard may be constructed at the Project site. Construction of a new switchyard involves new 230-kV transmission lines and relocation of existing 230-kV transmission lines within the Project site.

The capacities of existing transmission lines and any additions at the Project site are well within the range of transmission line capacities evaluated in NUREG-1437. Therefore, the air quality impacts of existing transmission lines and additions at the Project site are SMALL.

Table 5.7-1
Salt Deposition Ranges for Impacts on Exposed Electrical Equipment

	Salt Deposition	
Category	**mg/cm^2 (from IEEE, 2001)**	**kg/km^2/mo (from NUREG-1555; Subsection 5.3.3.2)**
Very light	0 – 0.03	0 – 300
Light	0.03 – 0.06	300 – 600
Moderate	0.06 – 0.1	600 – 1000
Heavy	> 0.1	> 1000

Key: kg/km^2/mo = kilograms per square kilometer per month; mg/cm^2 = milligrams per square centimeter

Table 5.7-5
Bounding Mechanical Draft Cooling Tower Parameters and Related Model Inputs from the Plant Parameter Envelope

Description	Value and Units	Comments
Number of banks of cooling towers	6	6 LMDCTs from PPE
Number of cells	108	6 LMDCTs; each LMDCT has 18 cells (2 x 9); 2 x 9 x 6 = 108 cells (modeled in SACTI2 as 6 LMDCTs each with 16 cells (2 x 8) as explained in ER Section 5.7.1.2.1.2)
LMDCT orientation (long axis), degrees east of true north	35° (southwest – northeast alignment of long axis of towers)	Based on bounding technology in PPE
Cell height (m)	15.3 m	Tower height = 50 ft. (15.2 m) (based on lower bound of heights in PPE of 50 – 75 ft.)
Fan diameter (m)	10.4 m	Fan diameter = 34.0 ft. (10.4 m)
Total heat dissipation (rejection) rate (MW)	3869 MW	Based on rate of 1.32×10^{10} Btu/hr from PPE for all six towers (1.32×10^{10} Btu/hr x 2.9307×10^{-7} MW/Btu = 3869 MW, or 645 MW/tower)
Total mass airflow rate (kg/s)	84,327 kg/s	Based on air delivery per fan of 1,377,637 cfm and an air density of 1.2 kg/m^3
Length of LMDCT housing (m)	148.2 m	Length = 486 ft.
Width of LMDCT housing (m)	32.9 m	Width = 108 ft.
Locations of the centers of the LMDCT housings	Tower center locations shown in Figure 5.7-7.	Based on bounding technology in PPE
Total drift emission rate for all cells (g/s)	974.2 g/s	Based on drift rate = 0.001% of circulating water flow rate. Circulating water flow rate = 110% x 233,950 gpm
Salt concentration (g salt/g solution)	0.00094	940 ppm, per PPE. Value based on existing water quality at sample location nearest to proposed intake location and assuming maximum normal operating 12 cycles of concentration.

Key:

Note:

(a) 8760 hours of operation for cooling towers, 864 hours per year for auxiliary boilers, and 4 hours per month for diesel generators.

Key: CO = carbon monoxide; lb/yr = pounds per year; N/A = not applicable; NO_x = Nitrogen oxides; $PM_{2.5}$ = particulate matter – 2.5 micrometers or less in diameter; PM_{10} = particulate matter – 10 micrometers or less in diameter; SO_x = sulfur oxides; VOC = volatile organic compounds

5.8 NONRADIOLOGICAL HEALTH

This section addresses the health impacts associated with the Project's operational activities at the Project site. Nonradiological health impacts on the public during operations are evaluated for several factors, including the cooling system, noise from operations, EMFs, and transportation activities related to operations and outage workers. Potential impacts on workers during operations are also discussed. Radiological health impacts during operations are addressed in Section 5.9.

5.8.1 ETIOLOGICAL AGENTS AND EMERGING CONTAMINANTS

5.8.1.1 Etiological Agents

The cooling system associated with the Project is described in Section 3.2.2. This system draws source water for cooling from Belews Lake, circulates it through mechanical draft cooling towers, and discharges the resulting cooling tower blowdown back to Belews Lake. Intermittent use of cooling tower blowdown is also conveyed to the Dan River for dilution of effluent constituents prior to discharge. The potential for exposure exists for recreators using Belews Lake, the Dan River, and for workers conducting maintenance on the mechanical draft cooling towers. The Project water source is described in Section 2.2.1.1.3, and water quality of Belews Lake and the Dan River are characterized in Section 2.2.3. The water source is neither reclaimed nor impaired water. Nonradioactive waste streams during operations are described in Section 3.4.3. As described in Section 3.2.2 the normal blowdown rate is based on eight cycles of concentration, and the maximum blowdown rate is based on six cycles of concentration. Temperature increases associated with cooling tower blowdown are the only identified operational feature that is considered to potentially affect human health.

As discussed in Section 2.8.1.2, etiological agents associated with nuclear power plant operations can be found in cooling ponds or towers or thermal discharges. According to NUREG-1555, etiologic agents, including organisms formerly referred to as thermophilic microorganisms, can increase in frequency of occurrence and population size due to heat in aquatic systems. Etiologic agents can also resist moderately high temperatures long enough to be released into a cooler water body where they can reproduce. When such microorganisms are etiologic agents capable of causing human disease (pathogens), they can pose a risk to workers and the public from exposure. Potential pathways for exposure include thermal cooling system discharge or workers performing cooling tower maintenance. Microorganisms of concern include enteric pathogens (such as *Salmonella* spp. and *Pseudomonas aeruginosa*), bacteria (including *Legionella* spp. and *Vibrio* spp.), free-living amoeba (such as *Naegleria fowleri* and *Acanthamoeba* spp.), thermophilic fungi, blue-green algae, and dinoflagellates (*Karenia brevis*).

As indicated in Section 2.8.1.2, the BCSS discharged thermal effluents into the Belews Creek arm of Belews Lake from May to October 2017, raising water temperatures to as high as approximately 100°F (38°C), a range that permits the growth of *Legionella* spp. Thermophilic fungi are fungi species that can grow in temperatures above 68°F (20°C), with a maximum growth temperature at or above 122°F (50°C). Although the presence of blue-green algae was confirmed in Belews Lake in 2012, the toxins associated with blue-green algae were not confirmed. Additionally, no known records exist of the presence of dinoflagellates in Belews Lake. As such, while elevated temperature conditions within selected areas of Belews Lake have occasionally been documented, no established populations or outbreaks of etiological agents have been documented within Belews Lake.

Section 5.2.3.1.2.4 describes the potential effects of the hydrothermal discharge from the cooling system on water temperatures in Belews Lake. The maximum temperature of the cooling water discharge from the cooling tower is 95°F (35°C) which is released to the cooler hypolimnetic waters of Belews Lake. Modeling of the discharges indicates that thermal mixing occurs rapidly and does not achieve the elevated temperatures that are favorable to the growth of thermophilic organisms (etiological agents). As described in Section 7.1, BCSS plant closure is a RFFA in which operations of BCSS are discontinued. In conjunction with the phased approach for implementation of the proposed action, the continued operation of BCSS action results in a phased decline in the thermal discharges to Belews Lake over the Project building period. As such, overall lake temperatures are reduced as operation of BCSS is discontinued. In conjunction with full Project operations, Belews Lake is expected to be notably cooler within surface areas as water temperatures in Belews Lake during operations lack the thermal influence from the operation of BCSS and are several degrees cooler at the surface (see Section 5.2.3). As such, they do not support conditions favorable to the establishment and growth of etiological agents. Therefore, potential effects associated with the development of etiological agents as a result of operation of advanced reactors at the Project site within Belews Lake are minor.

5.8.1.2 Emerging Contaminants

As discussed in Section 2.8.1.2,emerging contaminants of concern in drinking water include perfluoroalkyl and polyfluoroalkyl substances (PFAS), trihalomethanes (TTHMs), and Haloacetic acids (HAAs).

Operations from the Project entail the release of chemical constituents to the Dan River as part of wastewater. However, as described in Section 3.4.3, PFAS and TTHMs and HAAs are not constituents identified as part of the wastewater discharge stream. As such, there are no contributing effects of plant operation on concentrations of emerging contaminants in the Dan River.

As described in Section 3.4.3.2, sanitary wastewater is routed to the existing BCSS domestic wastewater treatment plant for treatment prior to discharge. The NPDES permit establishes discharge limitations for quantity and quality parameters to protect surface waters, and the Project complies with these requirements. Therefore, impacts are minor. Water quality impacts from the Project discharge are further addressed in Section 5.2.

5.8.2 NOISE IMPACTS

Section 2.8.2 provides information and data related to background noise levels at the Project site. As described in Section 2.8.2.2, there are no municipal, county, or state-level regulations that establish quantitative noise level limits applicable to the Project site.

The principal sources of noise from nuclear power plant operations include cooling towers, and intermittent noise from transformers and loudspeakers. Other occasional noise sources may include the operation of auxiliary equipment (such as pumps to supply cooling water) and corona discharge associated with high-voltage transmission lines. The primary source of continuous noise is associated with the operation of the mechanical draft cooling towers. Based on the bounding condition in the PPE (Table 3.1-1), cooling towers produce noise levels of up to 55.1 dBA per cooling tower array at a distance of 1000 ft. (305 m) from the source. There are up to two cooling tower arrays per Plant Complex. Because of the logarithmic nature of the dBA scale, adding two identical sources of noise (doubling the signal) increases the total noise level

by 3 dBA. Thus, the operation of two cooling towers generates noise levels up to 58.1 dBA at a distance of 1000 ft. (305 m).

As discussed in Section 4.8.2.1, noise levels are acceptable and allowable if the day-night average sound level outside a residence is less than or equal to 65 dBA. NUREG-1437, Rev. 2, indicates that noise levels below 65 dBA are considered acceptable outside a residence. It also notes that cooling towers emit noise of a broadband nature, which is largely indistinguishable from, and less obtrusive than, noise of a specific tonal nature (such as transformer or loudspeaker noise). Applying straight-line noise attenuation, noise levels from the cooling towers attenuate to 65 dBA at a distance of 450 ft. (137 m). The nearest noise-sensitive receptor is a residence located along Craig Road, located approximately 1197 ft. (365 m) south of the cooling tower area in the South Plant Complex. At this residence, noise levels from the cooling towers attenuate to 56.5 dBA. Other sensitive receptors including residents along Windswept Drive near the South Plant Complex and those across Belews Lake northeast of the Project site (Figure 3.1-2), are farther away from the cooling tower areas than the nearest residence along Craig Road and noise will further attenuate at these locations because of distance and the vegetative buffer along the perimeter of the Project Site. While noise levels from operations are below the 65 dBA threshold at the surrounding sensitive receptors, they represent an increase over the existing average ambient community noise levels described in Section 2.8.2.1.4 which range from 49 and 53 dBA L_{dn}. Considering that noise levels from cooling towers attenuate below the 65 dBA threshold at nearby residences, noise impacts are minor.

The nearest recreational area is Belews Lake, which is located immediately adjacent to the Project site boundary (Figure 2.4-5). The lake supports recreational boating and fishing, and lake users may experience cooling tower noise. However, based on straight-line noise attenuation described above, cooling tower noise attenuates to 65 dBA at 450 ft. (137 m) from the towers. EABs are proposed for each of the three Plant Complexes and extend into Belews Lake beyond the 450 ft. radius (137 m) where in most areas noise levels from the cooling towers attenuate to 65 dBA or less. Duke Energy plans to install buoys or other suitable barriers to demarcate the EABs and provide notification to recreational users of the lake that crossing the boundary is prohibited. As a result, recreators are restricted from entering areas on the lake that are within a 450 ft. (137 m) radius from the cooling towers and within the EAB.

In addition to dispersed recreation occurring on Belews Lake, J. Dudley Watts Jr. Park (Belews Lake Park) is the closest developed recreational area located within the Project Vicinity (Section 4.8.2.1). Assuming straight-line noise attenuation, the noise produced by the nearest cooling towers attenuates to approximately 47.17 dBA at the park boundary, which is less than the acceptable and allowable threshold of 65 dBA. Thus, impacts to recreators at Belews Lake Park from noise during plant operation are minor.

During operations, the nearest residence to the Project site experiences cooling tower noise at 56.5 dBA which is below the 65 dBA threshold. Other residences near the Project site and across Belews Lake also experience noise from operation of the cooling towers below the 65 dBA threshold which is further attenuated with distance from the towers and the vegetative buffer. Although residents experience noise at higher levels than the existing average ambient condition, the resulting noise levels remain well below the 65 dBA threshold. Recreational users of Belews Lake are not permitted in areas of the lake where noise levels are above the 65 dBA threshold. Therefore, the overall impacts from noise during operations are minor.

5.8.3 ELECTRIC SHOCK IMPACTS

The interconnection of the existing Belews Creek 230-kV line to the Project site is presented in Section 3.2.4. A new 230-kV switchyard will connect each unit to the new switchyard via individual bus lines. Four individual bus lines will then connect the new switchyard to the existing Belews Creek 230-kV switchyard. All new structures will be designed and constructed to comply with all National Electrical Safety Code (NESC) provisions as well as Duke Energy safety standards.

The NRC indicates that the greatest electrical shock hazard from a transmission line is direct contact with the conductors. Tower designs preclude direct public access to the conductors. However, electrical shocks can occur without physical contact. Secondary shock can occur when humans contact either capacitively charged bodies (such as a vehicle parked near a transmission line) or magnetically linked metallic structures (such as fences near transmission lines), and these shocks could be painful. The intensity of the shock would depend on the EMF strength, the size of the object, and the degree of insulation between the object, the person, and the ground.

The NESC has a provision that describes how to establish minimum vertical clearances to the ground for electric lines with voltages exceeding 98 kV. The clearance must limit the induced current due to electrostatic effects to 5 milliamperes if the largest anticipated vehicle or equipment is short-circuited to ground (IEEE, 2006).

As described in Section 3.2.4.2, the transmission lines are designed to conform with NESC requirements, which include standards related to line clearance to limit shocks from induced currents. Because the on-site transmission lines comply with the NESC standards, impacts to the public and operations personnel associated with potential electrical shock are minor.

5.8.4 CHRONIC EFFECTS OF ELECTROMAGNETIC FIELDS

As discussed in Section 2.8.4, the scientific evidence regarding the chronic health effects from EMFs, including the potential effects associated with exposure of electrical fields that are associated with electric power usage, does not conclusively link EMF exposure to adverse health impacts. In addition, as noted in NUREG-1437, Table B-1, chronic effects of EMFs are of uncertain impact. Thus, impacts to the public attributable to EMF exposure from transmission system operations are minor.

5.8.5 OCCUPATIONAL HEALTH

Occupational health risks for nuclear power plant workers engaged in operational maintenance, testing, or plant modifications generally include those associated with exposure to toxic nonradioactive materials or other industrial safety and health hazards such as falls, confined space, and equipment energization hazards (OSHA and NRC, 2013). Public and occupational health impacts may result from exposure to noise, hazardous materials, emissions, EMFs, and infectious diseases.

The U.S. Bureau of Labor Statistics (BLS) publishes statistics on incidence rates of occupational illnesses, injuries, and fatalities for all U.S. companies. As presented in Section 2.8.1.1, in 2022 the utilities industry incidence rate for nonfatal occupational injuries and illness was 1.7 per 100 full-time workers and the rate of fatal work injuries was 3.4 per 100,000 full-time equivalent workers (BLS, 2023b, 2023c).

The incidence of nonfatal injuries and illnesses during the operations phase has been calculated as the incidence rate times the number of workers. Using the daily operations workforce of 450 (as provided in Section 5.4.2), recordable nonfatal injuries and illnesses during the operations phase is estimated at an annual average of approximately eight incidents. Based on the 2022 fatal occupational injury incidence rate from BLS and the daily operations workforce of 450, fatal occupational injuries during operations would be less than one (0.02 incidents) per year.

Occupational injury and fatality risks are minimized through Duke Energy's robust safety culture, use of established internal safety guides and procedures, and strict adherence to NRC requirements and Occupational Safety and Health Administration (OSHA) safety standards (29 CFR Part 1910) practices and procedures during operations.

Therefore, based on this analysis, it is anticipated that the operation of the Project will result in no more potential occupational injuries and fatalities than other similarly sized power plants.

5.8.6 HUMAN HEALTH IMPACTS FROM TRANSPORTATION

This subsection analyzes how potential impacts related to increased traffic on roadways near the Project site during operations could increase the number of vehicle accidents involving injuries and fatalities. The analysis estimated new vehicle trips and additional traffic crashes including injuries and fatalities based on the number of operations workers (450), truck deliveries per day (90), and outage workers (350) as described in Section 5.4.4.1.1. Although operations-related deliveries do not occur when operations workers arrive and depart the Project site, these deliveries are accounted for in the operations activities AADT along the roadways providing access to the Project site.

As described in Section 4.8.3, the crash rates (number of crashes per mile per year) for the Project were estimated using the University of Florida Transportation Institute Highway Safety Software (HSS) (UFTI, 2025). The crash rates are estimated by considering the increase in AADT due to operations phase traffic on the primary roadways that provide access to the Project site. The predicted increase in traffic volume is used to estimate potential changes in crash rates consistent with the methodologies outlined in the Highway Safety Manual (AASHTO, 2024). Crash rates (predicted crashes per mile per year) were developed for the existing condition (2024) to provide a baseline and the operations for the roadway segments that commuters and delivery trucks use to access the Project site. In addition, predicted crash rates for the existing condition and operations were developed at four intersections along these roadways: Belews Creek Road at Craig Road, Belews Creek Road at NC Highway 65, NC Highway 65 at Pine Hall Road (to the south), and NC Highway 65 at Pine Hall Road (to the north).

The HSS crash rate estimates predict average crash rates as a function of traffic volumes, roadway type (e.g., controlled-access), roadway characteristics (e.g., roadway geometry, number of lanes, lane width, shoulder type) and road segment length. The predicted crash rate (injuries and fatalities) associated with the increase in AADT during operations for surrounding roadway segments (identified in Figure 4.4-2) is shown in Table 5.8-1. Crash rates are variable. For example, the highest crash rates are predicted for United States (U.S.) Highway 220, which is a high volume controlled-access freeway (AADT greater than 25,000). By comparison crash rates are lowest on small local roads having a low AADT such as Craig Road, Fisherman Road, Hawkins Farm Road, and Pine Hall Road. Crash rates for most roadway segments analyzed are predicted to be slightly higher during operations relative to the existing condition. The increase in crash rates for Craig Road was greater than any other roadway segment (0.11 crashes per

vehicle mile traveled to 0.26 crashes per vehicle mile traveled). While notable, this increase is relatively minor. Overall, predicted crashes along the roadway network serving the Project site during operations are minor and do not destabilize traffic safety.

Table 5.8-2 presents the number of predicted crashes (resulting in injuries and fatalities) at the four intersections that provide access to the Project site per year. The HSS estimates the number of predicted crashes based on factors including traffic volume, intersection geometry, and control. The number of predicted crashes at the four intersections analyzed increases marginally during operations. The increase in predicted crashes (both injury and fatality) at the intersection of Belews Creek Road and Craig Road is slightly higher than predicted at the other intersections analyzed. Overall, the effects of predicted increases in crash rates at intersections during operations on human health are minor.

The addition of vehicles associated with operations traffic results in a minor increase in traffic accident injury risk on the surrounding roadway network relative to the base condition. This minor increase is minimized through implementation of the traffic management mitigation measures identified in Section 4.4.4.1 that are implemented to accommodate the higher building phase traffic volumes.

5.8.7 SUMMARY

During operations, water temperatures in Belews Lake do not support conditions favorable to etiological agent establishment and growth. Therefore, potential effects associated with the development of etiological agents within Belews Lake resulting from operation of advanced reactors at the Project site are minor. Sanitary wastewater discharged to the Dan River complies with NPDES permit requirements. Additionally, there are no contributing effects of plant operation on concentrations of emerging contaminants in the Dan River. Because the on-site transmission lines comply with the NESC and Duke Energy safety standards, impacts associated with potential electrical shock and impacts to the public attributable to EMF exposure from transmission system operations are minor. Operations result in cooling tower noise emissions that vary with distance, however overall effects of noise are minor. The additional vehicles associated with operational traffic results in a minor increase in the risk of traffic accidents (both injury and fatality) on the surrounding roadway network relative to the base condition. Therefore, impacts on nonradiological health are SMALL.

Table 5.8-1
Predicted Operations Phase Crash Rates on Roadways in the Project Vicinity

	Roadway Segments	Segment Length (mi)	AADT		Predicted Crash Rate (crashes / mile / year)	
			Existing Condition	Operations	Existing Condition	Operations
1	U.S. 158 (S of Belews Creek Rd)	5.00	7400	7459	0.91	0.92

5.9 RADIOLOGICAL HEALTH DURING NORMAL OPERATION AND RADIOACTIVE WASTE MANAGEMENT

This section describes the radiological impacts of normal plant operation from the Project site to members of the public, plant workers, and biota. Section 5.9.1 describes the exposure pathways by which radiation and radiological effluents could be transmitted from the Project site to members of the public and biota occupying areas near the Project site. Section 5.9.2 estimates individual and collective doses to members of the public. Section 5.9.3 evaluates the impact of these doses by comparing them to regulatory limits. Section 5.9.4 discusses occupational doses. Section 5.9.5 evaluates the impact to non-human biota. Section 5.9.6 discusses the Radiological Environmental Monitoring Program (REMP). Section 5.9.7 contains information regarding solid waste management and on-site spent fuel storage.

As stated in Section 3.1, the Project site is expected to be comprised of three individual site areas (the north, middle, and south site areas) where nuclear power plants may be sited and are referred to as the North Plant Complex, Middle Plant Complex, and South Plant Complex. These locations are shown in Figure 3.1-7.

5.9.1 EXPOSURE PATHWAYS

During normal operation of the plants considered for the Project site, radiological effluents are expected to be discharged to the environment. Exposure to the radiological effluents from normal operation is dependent on the radiological exposure pathway. A radiological exposure pathway is the vehicle by which a receptor may become exposed to radiological releases from nuclear facilities. The major pathways of concern are those that could yield the highest radiological doses for a given receptor. These pathways are determined from the type and amount of radioactivity transported, the transport mechanism, and the consumption or usage factors of the receptor. Environmental transport mechanisms for gaseous effluents consider the historical meteorological characteristics of the area that are defined by windspeed and wind direction. Additional factors such as location of homes, use of cattle for milk, and gardens for vegetable consumption are considered when evaluating exposure pathways.

Radioactive effluent pathways to humans and non-human biota consist of a combination of liquid and gaseous effluents and exposure from direct radiation. Radioactive liquid effluent pathways include drinking water, ingestion of fish and invertebrates, direct radiation from exposure during shoreline activities (i.e., boating, swimming, and recreational shoreline use), and ingestion of vegetables; meat; and milk irrigated by the Dan River. Radioactive gaseous effluent pathways considered include direct radiation from immersion in the gaseous plume, inhalation of iodines and particulates, ingestion of iodines and particulates through the milk cow; milk goat; meat animal; vegetation pathways, and deposition on plants and soil. Additionally, exposure to direct radiation is considered from the project site due to normal operating conditions.

The exposure pathways considered for the Project site are analyzed and estimated for the maximally exposed individual (MEI), nearby off-site receptor locations (Table 5.9-1), and the general population surrounding the Project site. The MEI is the member of the public who is positioned to receive the maximum possible calculated dose. The doses estimated for the Project site are based on NRC Regulatory Guide (RG) 1.109, Rev. 1, “Calculation of Annual Doses to Man from Routine Releases of Reactor Effluents for the Purpose of Evaluating Compliance with 10 CFR Part 50, Appendix I” and NRC RG 1.111, “Methods for Estimating Atmospheric Transport and Dispersion of Gaseous Effluents in Routine Releases from Light-

Water-Cooled Reactors." These estimated doses are used to confirm that anticipated releases, associated with normal operation of the plants (being considered for the Project site), will result in doses that are within the dose limits to the public described in 10 CFR Part 50, Appendix I; 10 CFR Part 20; and 40 CFR Part 190, the U.S. Environmental Protection Agency (USEPA) limits on dose to the public.

The projected population within 50 miles (mi.) (80 kilometer [km]) of the Project site for the year 2079 is provided in Table 5.9-2. Additionally, since the Project site has not selected an advanced reactor technology, the activity released for the plant is based on a total bounding approach, as discussed in Section 3.4.2.

5.9.1.1 Liquid Pathways

As stated in Section 3.4.2.1, small quantities of radioactive liquid effluents are expected to be discharged to the environment at designated release points, typically in the conventional water discharges and liquid radwaste. The Project site will release small quantities of treated and diluted radioactive liquid effluent into the Dan River. As such, the liquid effluent pathways associated with the Dan River are analyzed to estimate the dose from liquid releases during normal operation.

The LADTAP II module of the NRCDose computer code implements the methodology discussed in RG 1.109, Rev. 1 to estimate doses from liquid effluents from the Project site (NRC, 1986). The code estimates the dose to the MEI and to the average individual through the following pathways:

- Internal exposure from ingestion of aquatic foods.
- Internal exposure from ingestion of drinking water.
- Internal exposure from ingestion of milk and meat from livestock consuming pasture feed from farms irrigated by contaminated water.
- Internal exposure from ingestion of vegetables and fruits from farms irrigated by contaminated water.
- External exposure to shoreline sediments.
- External exposure from boating and swimming.

The reactor effluent discharge flow rate of 7.35 cubic feet per second (cfs) (0.208 cubic meters per second [m^3/s]) and a mean flow rate for the Dan River of 498.4 cfs (14.11 m^3/s) is utilized for the analysis. Additionally, transit time from liquid discharge to the Dan River is assumed to be zero. This is conservative since the Dan River is greater than 2.24 mi. (3.61 km) from the Project site, and thus some decay will occur before it is discharged into the river.

The shoreline, swimming, and boating usage is determined by multiplying the 50-mile population for the year 2079 (Table 5.9-2) by the average shoreline usage rate. The fish consumption is similarly determined by multiplying the 50-mile population for the year 2079 (Table 5.9-2) by the average adult fish consumption; however, the only identified location of fish supply within 50-miles of the project site produces 250,000 pounds of tilapia per year. Therefore, the average adult fish consumption is reduced by 50 percent to account for the

fraction of consumption attributed to the Dan River.

The drinking water usage rate is determined using the survey conducted in 2024, which shows that the Dan River is used as drinking water for two locations (i.e., city of Eden and town of Madison in North Carolina). The 2025 population for both locations (i.e., 17,455) was used and scaled appropriately to 2079, using the same scale factors (i.e., 1.39) used for the projected 2079 50-mile population.

The milk production, meat production, and produce production that utilized irrigation from the Dan River, downstream of the radioactive liquid effluent discharge location, is determined using the survey conducted in 2024 and consumption rates from the GASPAR II Technical Manual (NRC,1987). Using the survey, the sum of the fraction of irrigated cropland is determined to be 0.0153. Additionally, the ratio of total cropland from counties using irrigation to the total cropland within 50 miles is identified to be 0.585. For the analysis, the national irrigation usage rate in 2024 of 38.1 liters/m^2/month is utilized. Using this information and the consumption rates in Table 5.9-6, the production rates for milk, meat and produce that use Dan River water for irrigation are determined.

Table 5.9-3 contains an overview of the liquid pathway parameters used by LADTAP II. Table 5.9-4 contains the fish and invertebrate consumption rates and aquatic recreation usage rates used for the MEI and average individual. The most conservative consumption factor (infant, child, teen, or adult) from RG 1.109, Rev. 1 is used to determine the dose to the average individual and MEI. Additionally, these consumption factors are multiplied by the projected population (Table 5.9-2) within 50 mi. (80 km) of the Project site. The bounding liquid release activity utilized for the Project site and for each reactor is provided in Tables 3.4-4 and 3.4-5, respectively.

A pump station located roughly three miles downstream from the discharge location can pump river water into Belews Lake in accordance with permitted limitations related to river flow and season. However, any dose contributions from pathways associated with the Belews Lake would be negligible due to the distance from the discharge location, additional dilution from the Dan River and Belews Lake, and the assumption that liquid radioactive effluent is released in batch releases and could be discharged when the pump is not operating.

5.9.1.2 Gaseous Pathways

As stated in Section 3.4.2.2, radioactive gaseous effluents are released to the environment through a controlled and monitored release point (e.g., plant vent). Additionally, radioactive gases from plant system leakage to the building atmosphere will travel through ventilation systems, passing through filtration, and be released through monitored building ventilation system release points.

Section 2.7.3 contains discussion regarding the atmospheric dispersion (χ/Q) and ground deposition (D/Q) factors for the Project site. The χ/Q factors in Section 2.7.3 are determined using the XOQDOQ computer code, which implements RG 1.111, Rev. 1 methodology (NRC, 1982). Table 5.9-7 contains the χ/Q and D/Q values for the maximally exposed location (MEL) and off-site receptors that are utilized for the evaluation.

The GASPAR II module of the NRCDose computer code implements the methodology discussed in RG 1.109, Rev. 1 to estimate doses from gaseous effluents from the Project site (NRC, 1987). The code calculates the radiation exposure to people through the following

potential pathways:

- External exposure to airborne radioactivity
- External exposure to deposited activity on the ground
- Inhalation of airborne radioactivity
- Ingestion of contaminated agricultural products

Table 5.9-5 contains an overview of the gaseous pathway parameters used by GASPAR II. The fraction of the year that leafy vegetables are grown, and milk and meat animals are on pasture is based on-site-specific conditions. North Carolina experiences all four seasons; Therefore, it is not expected that vegetables are grown all year and milk and meat animals are on pasture all year.

Figure 2.2 in the GASPAR II technical manual (NRC,1987) is used to determine the length of the growing season. In the case of the Project site, the growing/pasture season is 8 months. The GASPAR II technical manual states to add one month for goats for nine total months and to subtract 3 months for leafy greens for 5 months.

The fraction of the maximum individual's vegetable intake that is from their own garden is expected to be lower than the default GASPAR II value. The land survey conducted in December of 2024 identified the nearest vegetable garden as a soybean farm. Furthermore, the survey found that the crop production within 2 miles of the Project site is comprised of corn, sorghum, soybeans, tobacco, winter wheat, triticale, and hay. The crop production within 2 miles also appears to be operations that would require the crops to be processed and shipped outside of the project area. As such, it is not reasonable to assume that 76 percent (i.e., the value from Table E-15 of RG 1.109) of vegetables consumed are from an individual's garden. Therefore, it is reasonable, and still conservative to assume that an individual consumes roughly a third of their vegetable intake (i.e., 0.35) for 42 percent (i.e., 5 months) of the year from their own garden.

Table 5.9-6 contains the food consumption rates for the average individual and the MEI within 50 mi. (80 km) of the Project site. The table is based on the most conservative consumption factor (infant, child, teen, or adult) from the GASPAR II technical manual (NRC,1987), which is used to determine the dose to the average individual and the MEI. Additionally, these consumption factors are multiplied by the projected population (Table 5.9-2) within 50 mi. (80 km) of the Project site. Because milk and meat animals are not identified to be within 5 mi. (8 km) of the Project site, dose contributions from milk and meat animals do not contribute to the MEI dose.

Additionally, since Duke Energy has not yet selected a technology for the Project site, the activity assumed to be released from the site is based on an enveloping approach to bound the technologies considered in this application. The bounding gaseous release activity per reactor utilized for the Project site and for each reactor is provided in Tables 3.4-6 and 3.4-7, respectively.

5.9.1.3 Direct Radiation

As noted in NRC Technical Report (NUREG)-2226 (NRC, 2019b), direct radiation from sources

within a light-water reactor (LWR) is due primarily to nitrogen-16. Because the primary coolant of an LWR is contained in a heavily shielded area, dose rates in the vicinity of LWRs are generally undetectable and less than 1 mrem/yr at the unrestricted area boundary. Some plants (mostly boiling-water reactors [BWRs]) do not have completely shielded secondary systems and may contribute some measurable off-site doses. Additionally, since the dose rates discussed in NUREG-2226 and NUREG-1437 relate more to units that are larger than the advanced reactors considered in the analysis, the dose is expected to be less for the technologies considered for the Project site. Therefore, a dose rate for direct radiation of 1 mrem/yr at the unrestricted area boundary is utilized. However, since 40 CFR Part 190 applies to the MEI, which is located at the nearest resident, and since the nearest resident is located farther from the unrestricted area boundary, any contributions to the MEI from direct radiation are expected to be negligible.

5.9.2 RADIATION DOSES TO MEMBERS OF THE PUBLIC

This subsection provides an evaluation of the calculated doses to the MEI and calculated doses at other sensitive receptor locations (Table 5.9-1). This section also evaluates the collective population dose from liquid and gaseous effluents released from the Project site using the methodologies and parameters specified in Section 5.9.1.

5.9.2.1 Liquid Pathway Doses

Table 5.9-8 provides the resultant doses from LADTAP II to the MEI at each pathway location determined. Table 5.9-9 provides the collective population doses from liquid effluents to individuals living within a 50 mi. (80 km) radius of the Project site. For the collective population doses, the projected population data to the year 2079 is used (Table 5.9-2).

5.9.2.2 Gaseous Pathways Doses

Table 5.9-10 provides the resultant doses from GASPAR II to the MEI at each pathway location. Table 5.9-11 provides the collective population doses from gaseous effluents to individuals living within a 50 mi. (80 km) radius of the Project site. Similar to 5.9.2.1, the collective population doses are determined using the projected population data to the year 2079 (Table 5.9-2).

5.9.3 IMPACTS TO MEMBERS OF THE PUBLIC

As noted in Sections 5.9.1.1 through 5.9.1.2, the exposure pathways analyzed for the Project site are from liquid and gaseous effluents. The exposure pathways are analyzed using methodologies and parameters specified in Sections 5.9.1.1 and 5.9.1.2.

Table 5.9-12 compares 10 CFR Part 50, Appendix I, dose limits for liquid and gaseous effluents to the MEI doses for a single unit. The MEI doses calculated from liquid and gaseous effluents for the Project site are compared to 40 CFR Part 190, as shown in Table 5.9-13.

The collective population dose resulting from natural background radiation to individuals within a 50 mi (80 km) radius of the Project site of 9.48E+05 person-rem/yr Total Effective Dose Equivalent (TEDE) is presented in Table 5.9-14. The natural background radiation dose is based on a dose rate of 310 mrem/yr (3.1 mSv/yr), as presented in Section 2.9 and the total 2079 projected population within a 50-mile radius (Table 5.9-2). Comparing this value to the sum of the calculated population doses in Tables 5.9-9 and 5.9-11 demonstrate that the calculated person-rem/yr exposure from the plant is less than the estimated person-rem/yr

exposure from natural background radiation.

Considering the results discussed above, impacts to members of the public from normal operation of the Project site are SMALL.

5.9.4 OCCUPATIONAL DOSES TO WORKERS

The annual occupational dose to operational workers, including workers involved with major maintenance and outage activities, will be provided in the construction permit or license application. This dose will be maintained ALARA in compliance with 10 CFR 20.1101.

5.9.5 DOSES TO NON-HUMAN BIOTA

Radiation exposure pathways to non-human biota are examined. This assessment uses surrogate species that provide representative information on the various dose pathways potentially affecting broader classes of living organisms. Surrogates are typically used for judging doses to biota since important attributes are well defined and accepted. This assessment uses pathway models adopted from RG 1.109.

5.9.5.1 Liquid Effluents

Surrogate biota doses from liquid effluents are determined using the LADTAP II computer code. Table 5.9-15 presents the maximum liquid effluent dose to biota. Surrogate aquatic biota includes algae, invertebrates, and fish. Liquid effluent pathways that can irradiate biota include:

- Ingestion of water.
- Ingestion of aquatic food including fish, invertebrates, and aquatic plants.
- External exposure from water immersion and shoreline sediments.

5.9.5.2 Gaseous Effluents

Surrogate biota doses from gaseous effluents are determined using the site boundary doses from Table 5.9-10 and are presented in Table 5.9-16. This results in the dose to the maximally exposed animal. Surrogate terrestrial biotas include muskrat, racoon, heron, and duck. Pathways of irradiation include:

- External exposure to immersion in gaseous effluent plumes.
- Surface exposure from deposition of iodine and particulates from gaseous effluents.
- Inhalation of gaseous effluents.
- Ingestion of terrestrial vegetation and organisms.

Since GASPAR II does not determine biota dose, the following methodology is utilized to determine the maximum biota dose from gaseous effluents. Because doses from immersion in plume and ground deposition are largely independent of organism size, and it is conservative because the internal dose for humans is based on a much longer retention period than would be expected for biota, the doses for humans can also be applied to the surrogate terrestrial

animals. The human ground plane doses are increased by a factor of two for animals to account for their close proximity to the ground. This assumption is based on the approach for biota used in NUREG/CR-4013, LADTAP II Technical Reference and User Guide. Inhalation and vegetation ingestion doses are approximated by human doses as well. The total body inhalation dose and total body vegetation ingestion dose, rather than organ specific dose, are used since the biota doses are assessed on a total body basis. Based on these assumptions, all non-human biota have the same exposure.

5.9.5.3 Biota Doses

Table 5.9-17 presents the calculated maximum biota doses from liquid and gaseous effluents and direct radiation. The total maximum biota dose of 148 mrem/yr does not meet the 40 CFR Part 190 limit of 25 mrem/yr.

Although the 40 CFR Part 190 whole-body dose limit of 25 mrem/yr is exceeded, the dose is conservatively based on 100 percent occupancy at the maximum gaseous and maximum liquid effluent locations. However, the geological position for both maximum gaseous and liquid effluent locations are not the same. As such, it is not reasonable to expect that biota would receive the maximum dose from both pathways. Furthermore, use of exposure guidelines, such as 40 CFR Part 190, which apply to members of the public, in unrestricted areas, is considered very conservative when evaluating calculated doses to biota.

When actions taken to protect humans from radiation and radioactive materials are not adequate to protect biota in accordance with 4.j(2)(b) of the Department of Energy (DOE) Order 458.1 (DOE, 2011), an alternative approach may be used to demonstrate that the dose rates to representative biota populations do not exceed the dose rate criteria in Table 2.2 of DOE-STD-1153-2002 (DOE, 2022). The dose rate criteria in Table 2.2 of DOE-STD-1153-2002 are 1 rad/day for aquatic biota and 0.1 rad/day for terrestrial biota. As indicated in Table 5.9-17, all biota analyzed for the Project site are within the dose limits of 1 rad/day (1000 mrad/day) for aquatic biota and 0.1 rad/day (100 mrad/day) for terrestrial biota.

5.9.6 RADIOLOGICAL MONITORING

The REMP for the Project site is designed to adequately characterize the radiological environment of the biosphere in the vicinity of the Project site. The REMP provides data on measurable levels of radiation and radioactive materials in the site environs and baseline data from surveillance of principal pathways of exposure to the public.

The primary objective of the REMP is to monitor for potential radiological exposures to operations and construction workers, the public, and the surrounding environment prior to and during construction and active facility operations.

The REMP includes:

- Number and location of sample collection points and measuring devices, and the pathway sampled or measured.
- Sample collection frequency.
- Type and frequency of analysis.

Sampling locations have been selected based on their relative location to the Project site and prevailing wind direction. Sampling locations are selected in accordance with the requirements of Table 6.2-2 of NUREG-1555.

5.9.6.1 Belews Creek, NC Site Radiological Environmental Monitoring Program

The REMP is implemented in accordance with 10 CFR 20.1501 and Criterion 64 of 10 CFR Part 50, Appendix A. The program is developed using the following guidance published by the NRC:

- RG 1.21, Rev. 3, *Measuring, Evaluating, and Reporting Radioactive Material in Liquid and Gaseous Effluents and Solid Waste*.
- RG 4.1, Rev. 2, *Radiological Environmental Monitoring for Nuclear Power Plants*.
- RG 4.13, Rev. 2, *Environmental Dosimetry – Performance Specifications, Testing, and Data Analysis*.
- RG 4.15, Rev. 2, *Quality Assurance for Radiological Monitoring Programs (Inception Through Normal Operations to License Termination) – Effluent Streams and the Environment*.
- RG 1.109, Rev. 1, *Calculation of Annual Doses to Man from Routine Releases of Reactor Effluents for the Purpose of Evaluating Compliance with 10 CFR Part 50, Appendix I*.
- NUREG-1301, *Off-site Dose Calculation Manual Guidance: Standard Radiological Effluent Controls for Pressurized Water Reactors*.
- NUREG-1302, *Off-site Dose Calculation Manual Guidance: Standard Radiological Effluent Controls for Boiling Water Reactors*.

The REMP has the following objectives:

- Survey the radiological conditions in the vicinity of the Project site before initial reactor operation to establish the baseline radiological conditions in the local environment.
- Measure radiological conditions in the local environment during operational lifetime of the Project site.
- Evaluate the measurements to determine the effects on proposed operations relative to the local radiological environment.
- Collect data needed to refine environmental radiation transport models used in off-site dose calculations.
- Verify that radioactive material containment systems are functioning to minimize environmental releases to levels ALARA.
- Demonstrate compliance with regulations by reporting measurement results, summaries, and trends regarding radiation and radioactive materials in the local

environment.

Implicit in these objectives are the requirements to analyze trends and assess radiation exposure rates and radioactivity concentrations in the environment that may contribute to radiation exposure to plant personnel and the general public. The program consists of two phases: preoperational and operational.

- Preoperational radiological environmental monitoring: The preoperational REMP is used to adequately characterize the radiological conditions in the vicinity of the reactor site before initial facility operation. The preoperational REMP measures background levels and their variations along the anticipated critical pathways in the area surrounding the Project site; trains personnel; and evaluates procedures, equipment, and techniques. The preoperational monitoring program, which is implemented two years before initial facility operation, monitors the radiological environment around the Project site. The duration of the preoperational program for specific media is presented in Table 5.9-18.

- Operational radiological environmental monitoring: The operational REMP monitors the radiological environment around the Project site once the facility becomes operational and evaluates any differences observed between the preoperational REMP and operational REMP. The operational REMP documents the effectiveness of procedures and processes that restrict or control releases of radioactive materials to the environment.

The sampling media and analysis type for both the preoperational and operational REMP phases are essentially the same. Sampling media for both the preoperational and the operational REMP are identified in Table 5.9-18. Sampling locations (Table 5.9-19) are chosen based on the Project site design parameters (e.g., land use, expected pathways, census data, etc.).

The REMP monitors the environment by sampling air, water, soil, and food products (aquatic, meat, milk, and produce), as well as measuring radiation directly. According to Table 3.12-1 of NUREG-1301/1302, milk samples should be taken from three locations within 3 mi. (5 km) of the Project site that are likely to have the highest dose potential. If there are no milking locations within 3 mi. (5 km), then one sample should be taken between 3 and 5 mi. (5 and 8 km) of the Project site. Additionally, one sample should be taken from a control location 9 to 19 mi. (15 to 30 km) from the Project site. Since no milk-producing animals (cows or goats) are identified within 5 mi. (8 km) of the Project site, no milk samples will be collected and analyzed.

5.9.6.2 Pathways Monitored

Radiological exposure pathways are ways by which people might become exposed to radioactive material. The major pathways of concern are those that could cause the highest calculated radiological dose. The projected pathways are determined from the type and amount of radioactive material that might be released, the environmental transport mechanism, and the use of the environment. Environmental transport mechanisms include, but are not limited to, local hydrology (water) and meteorology (weather).

The release of radioactive gaseous effluents can affect the public via pathways such as external whole-body exposure, deposition on plants and soils, and human inhalation/ingestion. The release of radioactive constituents in liquid effluents can affect the public via pathways such as drinking water, fish consumption, direct exposure from shoreline sediments, and submersion

dose while swimming.

The following radiological exposure pathways are monitored for the Project site:

- Direct (dosimeters)
- Airborne (iodine and particulates)
- Ingestion (vegetation, fish, and invertebrates)
- Waterborne (surface water and river sediment)

5.9.6.3 Indicator and Control Locations

The REMP includes sampling indicator and control locations for the identified exposure pathways. A description of Project site monitoring, sampling and control locations to be used to monitor the exposure pathways is provided in Table 5.9-19 and approximate locations are shown in Figures 5.9-1 and 5.9-2. Indicator locations near and around the Project site are used to show any increase or buildup of radioactivity that might occur from operation of the Project site. Control locations are farther away from the site 9 to 19 mi. (15 to 30 km) and are used to indicate the background radiation levels. Indicator results are compared with control and preoperational results to assess any impact that the Project site might have on the surrounding environment.

Pathways are monitored at sampling indicator and control locations. REMP indicator locations chosen for the Project site are based on meteorological factors, preoperational monitoring requirements, and results of the land use surveys. A number of locations have been selected as controls per guidance from NUREG-1301/1302.

Samples from these control locations provide a basis for measuring background fluctuations in radioactivity at indicator locations caused by natural phenomena and fallout. By comparing radioactive material concentrations at indicator locations to these control locations, increases resulting from commercial operation are distinguishable.

Monitoring locations consist of an inner ring of thermoluminescent dosimeters (TLDs) in each 22.5-degree direction sector in the vicinity of the site boundary, with a TLD for each compass direction (T-1 through T-16), and an outer ring of TLDs ranging from 4 to 5 miles from the center of the Project site (T-17 through T-32). Monitoring is also provided at eight special interest locations identified in Table 5.9-19 (T-33 through T-40). Particulate and airborne iodine are monitored close to the Site Boundary in the direction sectors that have the highest calculated annual average ground-level deposition, in the vicinity of a community with the highest annual average ground-level D/Q, and at a control location. Waterborne and ingestion pathways are monitored as outlined in NUREG-1301/1302.

Table 5.9-20 summarizes the sampling frequency and analysis method of each sample type. The Off-site Dose Calculation Manual (ODCM) provides a detailed description of the monitoring program including the general types of sample collection and measuring equipment and lower limit of detection for each analysis. Sample media and sample size are defined in environmental monitoring and laboratory standard operating procedures.

5.9.6.4 Reporting Requirements

An Annual Radiological Environmental Operating report will be submitted to the NRC. The report includes summaries, interpretations, and an analysis of the radiological environmental surveillance activities for the report period. These reports include a comparison with preoperational studies with operational controls (as appropriate), previous environmental surveillance reports, and an assessment of the observed impacts of plant operation on the environment.

A land use census will be conducted annually to ensure that changes at and beyond the site boundary are identified and that modifications to the REMP are made, if required. This census satisfies the requirements of Section IV.B.3 of 10 CFR Part 50, Appendix I, Numerical Guides for Design Objectives and Limiting Conditions for Operation to Meet the Criterion “As Low as is Reasonably Achievable” for Radioactive Material in Light-Water-Cooled Nuclear Power Reactor Effluents. Land use census results are included in the Annual Radiological Environmental Operating Report

5.9.6.5 Quality Assurance Program

The standards for quality assurance (QA) related to the REMP program are established in RG 4.15, “Quality Assurance for Radiological Monitoring Programs.” The purpose of the QA program is “to ensure the quality of the results of measurements of radioactive materials in the effluents from, and environment outside of, facilities that process, use, or store radioactive materials during all phases of the facility’s life cycle.”

QA is made up of all those planned and systematic actions that are necessary to provide adequate confidence in the assessment of monitoring results. Quality control (QC) is made up of those QA actions that provide a means to measure and control the characteristics of measurement equipment and processes to meet established standards; QA includes QC.

QA is necessary to ensure that all radiological and nonradiological (flowrate, run time, etc.) measurements that support the radiological monitoring program are reasonably valid and of a defined quality. These programs are needed (1) to identify deficiencies in the sampling and measurement processes and report them to those responsible for these operations so that licensees may take corrective action and (2) to obtain some measure of confidence in the results of the monitoring programs to assure the regulatory agencies and the public that the results are valid. All steps of the monitoring process should involve QA (for example, sampling, shipment of samples, receipt of samples in the laboratory, preparation of samples, radiological measurements, data reduction, data evaluation, and reporting of the measurement and monitoring results).

Examples of the activities of the QA program typically include the following:

- Perform duplicate analysis of the samples to check laboratory precision.
- Perform regular review of sample collection and records.
- Perform regular review of laboratory procedures and methods.
- Count quality indicator and control samples routinely.

- Review analytical results provided by the laboratory monthly to validate that the required minimum sensitivities have been achieved, and the correct analyses have been performed.

- Ensure known concentrations of radioactivity are used by laboratory in test samples to ensure consistent quality results on an ongoing basis.

- Ensure laboratory participation in intercomparison programs.

- Track deviations/non-conformances, including associated corrective measures using the corrective action program.

The REMP uses QA programs and processes to accomplish the following tasks:

- Ensure personnel are trained and qualified to perform radiological monitoring.

- Ensure laboratory processes are documented (that is, maintenance, storage, and use of radioactivity reference standards), and calibration and checks of radiation radioactivity measurement systems and sample tracking and control are performed.

- Ensure the processes and procedures of the REMP are documented.

- Ensure periodic audits of analysis laboratory functions and their facilities are conducted.

5.9.7 SOLID WASTE MANAGEMENT AND ON-SITE SPENT FUEL STORAGE

Section 3.4 discusses the plans for minimizing the production and processing of low-level waste (LLW) on-site. Additionally, Section 3.4 contains discussion on the amount of LLW to be stored on-site and spent fuel stored in an ISFSI.

Table 5.9-1
Off-Site Receptor Locations

Off-Site Receptor No.	Receptor Description	Distance from Site Boundary to Receptor (m)	Sector	Distance from North Plant Complex (m)	Distance from Middle Plant Complex (m)	Distance from South Plant Complex (m)

Table 5.9-5
Gaseous Pathway Parameters

Value	Description
0.42	Fraction of the year that leafy vegetables are grown.
0.67	Fraction of the year that milk cows are on pasture.
0.35	Fraction of the maximum individual's vegetable intake that is from his own garden.
1.0	Fraction of milk-cow feed intake that is from pasture while on pasture.
8.0	Average absolute humidity over the growing season (g/m^3).
0.75	Fraction of the year that goats are on pasture.
1.0	Fraction of goat-feed intake that is from pasture while on pasture.
0.67	Fraction of the year that beef cattle are on pasture.
1.0	Fraction of beef-cattle feed intake that is from pasture while the cattle are on pasture.

Key: g/m^3 = grams per cubic meter

Table 5.9-6
Food Consumption Rates

Consumer	Vegetables (kg/yr)	Leafy Vegetables (kg/yr)	Milk (L/yr)	Meat (kg/yr)
Average Adult	190	30	110	95
Average Teen	240	20	200	59
Average Child	200	10	170	37
Maximum Adult	520	**64**	310	**110**
Maximum Teen	**630**	42	**400**	65
Maximum Child	520	26	330	41
Maximum Infant	0	0	330	0

Note: Maximum values are bold.

Key: kg/year = kilograms per year; L/yr = liters per year

Radiological Environmental Monitoring Program Sampling Frequency
(Sheet 2 of 2)

Exposure Pathway and/or Sample	Number of Representative Samples and Sample Locations	Sample and Collection Frequency	Type and Frequency of Analysis
Sediment from Shoreline	One Location	Semiannually	Gamma isotopic analyses semiannually
Radiation by Ingestion			
Fish and Invertebrates	Two Locations	Sample in season, or semiannually if they are not seasonal	Gamma isotopic analysis on edible portions
Food Products	Five Locations	At time of harvest Monthly during growing season	Gamma isotopic analysis on edible portion. I-131 analysis on green leafy vegetables

5.10 NONRADIOACTIVE WASTE MANAGEMENT

This section describes the impacts on the environment that could result from the generation, handling, and disposal of nonradioactive waste and mixed waste during operations at the Project site. As stated in Section 3.4.3, types of nonradioactive waste that are generated, handled, and disposed of during operational activities include cooling water that may contain water treatment chemicals or biocides, waste from floor and equipment drains, water treatment residuals, sanitary effluents, stormwater runoff, gaseous effluents, used oils, universal waste, and hazardous waste. Regulations for generating, managing, handling, storing, treating, and disposing of these wastes are contained within certain provisions of 10 CFR (NRC regulations), 40 CFR (USEPA regulations), NC Administrative Code, and NC General Statutes.

5.10.1 IMPACTS TO LAND

Operating the Project site will generate solid and hazardous waste not contaminated with radionuclides, as well as potential mixed waste, all of which could impact land.

5.10.1.1 Solid Waste Management and Disposal

As stated in Section 3.4.3.3.1, Duke Energy Environmental Programs uses administrative policies and procedures to ensure all employees and contractors properly manage waste.

The waste is segregated based on waste type and its potential hazards and is stored in appropriate containers. Waste segregation occurs at the point of generation and is labeled accordingly to facilitate proper disposal. An approved waste vendor list is also used to ensure waste is recycled or disposed of through an approved facility.

Solid waste generated on-site includes trash, paper, wood, sewage residuals, water treatment wastes, and laboratory wastes. Solid waste, defined as nonhazardous waste by 40 CFR Part 261 are collected and disposed of in a local landfill. Winston-Salem/Forsyth County Utilities operates a state-permitted, active municipal solid waste landfill on Hanes Mill Road, which has approximately 27 years remaining in permitted volume. Other regional landfills may also be considered to support the waste disposal needs during the operations period. Section 3.4.3.2 states that sanitary wastes are discharged to internal Outfall 009 which ultimately discharges into the Dan River. Under the proposed Project, sanitary NPDES effluent limits for internal Outfall 009 will remain in effect as specified in the existing permit. The Project site will continue to operate in compliance with the existing permit.

As stated in Section 3.4.3, Duke Energy's existing waste management programs, which comply with federal, state, and local regulations, are followed to manage wastes generated during operation. Therefore, impacts to land from nonradioactive waste generated, handled, stored, and disposed of during operations are SMALL.

5.10.1.2 Hazardous Waste Management and Disposal

The USEPA defines hazardous waste in the Resource Conservation and Recovery Act (RCRA), specifically in 40 CFR Part 261. The Project site complies with RCRA requirements as a Small Quantity Generator (SQG) of hazardous waste, as detailed in Section 3.4.3.3.2. Common hazardous waste generated at the Project site includes waste paints, lab packs, and solvents. These wastes are typically stored in designated on-site areas before being shipped off-site for treatment and disposal. Hazardous waste, according to the USEPA, may be listed as known

hazardous waste or exhibit one or more of the following characteristics: ignitability, corrosivity, reactivity, or toxicity.

The quantities of hazardous waste generated at individual plants vary but are typically small compared to those produced at most other industrial facilities. Numerous RCRA-authorized treatment and disposal facilities exist across the United States and are able to handle the hazardous waste generated from operations.

Operations at the Project site are expected to generate waste in quantities similar to those outlined in the Environmental Impact Statement for an ESP at the Clinch River Nuclear site (NUREG-2226), classifying the site as a SQG of hazardous waste. SQGs generate more than 100 kg (220 lb.), but less than 1000 kg (2205 lb.) of hazardous waste per month. Major requirements for SQGs include:

- SQGs may accumulate hazardous waste on-site for 180 days without a permit (or 270 days if shipping a distance greater than 200 mi. [322 km]).
- The quantity of hazardous waste on-site must never exceed 6000 kg (13,227 lb.).
- SQGs must comply with the hazardous waste manifest requirements of 40 CFR Part 262, subpart B and the pre-transport requirements at 40 CFR 262.30 through 262.33.
- SQGs must manage hazardous waste in tanks or containers subject to the requirements of 40 CFR 262.16(b)(2) and (3).
- SQGs must comply with the preparedness and prevention requirements of 40 CFR 262.16(b)(8) and (9), and the land disposal requirements at 40 CFR Part 268.
- There must always be at least one employee available to respond to an emergency. This employee is the emergency coordinator responsible for coordinating all emergency response measures. SQGs are not required to have detailed, written contingency plans (USEPA, 2025).

As noted in Section 3.4.3.3.2, the existing BCSS holds this classification, and hazardous waste generated from ongoing operations are disposed of through licensed vendors.

All activities related to the management of hazardous wastes—storage, treatment, transport, and disposal—are conducted pursuant to federal, state, and local regulations as described in Section 3.4.3. Therefore, impacts to land from nonradioactive waste generated, handled, stored, and disposed of during operations are SMALL.

5.10.1.3 Mixed Waste Management and Disposal

Mixed waste contains both radioactive and hazardous wastes and is generally accumulated in designated areas on-site and then shipped off-site for treatment and disposal. This waste is regulated by both the USEPA and by the NRC under the Atomic Energy Act.

The management of mixed waste must adhere to NRC requirements for general radiation protection in 10 CFR Part 20, emission control requirements for low-level mixed waste in 10 CFR Part 61, and relevant provisions of the RCRA for managing hazardous waste in 40 CFR Parts 260 through 268.

5.10.1.3.1 Generating Mixed Waste

The NRC identified several common mixed wastes generated at nuclear power plants in NUREG-1437, Rev. 1, *Final Generic Environmental Impact Statement for License Renewal of Nuclear Plants*. These include organics (e.g., liquid scintillation fluids, waste oils, halogenated organics), metals (e.g., lead, mercury, chromium, and cadmium), solvents, paints, and cutting fluids. NUREG-1437, while specific to license renewals, determined the impacts from mixed waste to be SMALL.

Although the quantities generated during operations are generally small, the dual regulation complicates the management and disposal of mixed wastes compared to other types. While there is potential to generate mixed waste at the Project site, Duke Energy uses site-specific Nuclear Operating Fleet Administrative Procedures to minimize this potential. Additionally, advanced technologies under consideration are designed to segregate waste and reduce mixed waste streams.

5.10.1.3.2 Mixed Waste Storage and Disposal

Duke Energy operates 11 nuclear units at six sites in NC and South Carolina (Duke Energy, 2025). These sites use nuclear-specific operating procedures to ensure safe and compliant handling of mixed waste. These procedures are designed to minimize the generation of mixed waste and ensure that any mixed waste generated is properly stored, managed, and disposed of in accordance with NRC, USEPA, and state-specific regulations.

5.10.1.3.3 Impacts of Mixed Waste

Based on Duke Energy's established practices, plans to manage mixed waste consistent with the current operating nuclear fleet, and consistent with the NRC findings described in NUREG-2226, the environmental impacts from mixed waste generated at the Project site are expected to be SMALL.

5.10.1.4 Summary of Impacts to Land

Duke Energy maintains administrative policies and procedures to ensure waste streams are properly managed and disposed of in accordance with federal and state guidelines. The Project site produces SQG quantities of hazardous waste as described in Section 3.4.3.3.2. Although the reactor technology has not been selected, Duke Energy manages all solid, hazardous, and mixed waste generated from the site in accordance with federal and state regulations. Therefore, impacts to land from waste management and disposal are SMALL.

5.10.2 IMPACTS TO WATER

Nonradioactive liquid waste from plant operation includes sanitary wastewater, cooling tower blowdown, stormwater discharges, and other conventional liquid discharge streams (i.e., turbine building sumps, groundwater sumps, water treatment discharges).

5.10.2.1 Sanitary Wastes

Management of sanitary waste during operation is described in Section 3.4. Wastewater discharges to support the Plant Complexes are routed to the BCSS sanitary wastewater treatment system and are managed using appropriate engineering controls in compliance with the NPDES permit number NC0024406 associated with BCSS operations for combined industrial and domestic wastewater discharges. The NPDES permit establishes discharge limitations for quantity and quality parameters to protect surface waters. Maximum effluent flow rates from the sanitary system are described in Section 3.4.3.2. Sanitary wastewater is treated on-site and discharged to the Dan River via Outfall 006. Because sanitary wastes are discharged in accordance with an NPDES permit, the impacts of these wastes are SMALL.

5.10.2.2 Stormwater

Stormwater is managed in accordance with a site-specific NPDES permit, as described in Section 3.4.3.3.3.2. The NPDES permit provides for implementation of BMPs to control and mitigate stormwater quantity and impacts to surface water quality. The stormwater system is designed to comply with relevant federal, state, and local stormwater regulations. Because the stormwater system on the Project site is managed under a NPDES permit and impacts are minimized through BMPs, impacts of stormwater are SMALL.

5.10.2.3 Liquid Effluents

Discharges associated with liquid effluents are described in Section 3.4.3.3.3. Cooling tower blowdown is routed to Belews Lake or the Dan River based on operational needs. Discharges to Belews Lake are released through either a combined discharge structure or a separate discharge structure for each Plant Complex. Nonradiological discharges are released to the Dan River at the existing Outfall 006 location. NPDES Permit NC0024406 is associated with current BCSS operations. The normal and maximum cooling tower blowdown to Belews Lake are described in Section 3.4. A portion of the cooling tower blowdown is diverted as dilution flow to be combined with the other liquid wastewater including liquid radiological wastes. As stated in Section 3.4, the NPDES permit authorizes an average discharge of 9 mgd (34,069 m^3/day) to the Dan River and includes pollutant discharge limits and routine monitoring.

As described in Section 3.4.3.1, the Project site uses biocides and other chemicals to treat cooling and process waters to avoid scaling or fouling. Operational effluents are processed to minimize the release of these treatments but may still contain some low-level chemicals or biocides. Chemical concentrations are managed to adhere to NPDES permit requirements. Specific chemicals and biocides to be used depend upon the characteristics of the water to be treated and the design requirements of the selected reactor technology. The projected constituents and their concentrations in the Belews Creek nonradioactive liquid waste discharges are provided in Table 3.4-3 in Section 3.4. Because the concentration of all potential chemical releases is managed under the NPDES permit, impacts are SMALL.

Other nonradiological liquid waste discharges (i.e., turbine building sumps, groundwater sumps, and water treatment discharges) are routed to the consolidated sump, treated, and discharged to the Dan River Outfall 006, as described in Section 3.4. As stated in Section 3.4, NPDES Permit No. NC0024406 is associated with current BCSS operations and authorizes discharges to the Dan River and includes pollutant discharge limits and requirements for routine monitoring. These waste discharges are managed under the existing NPDES permit, and therefore impacts are SMALL.

5.10.2.4 Summary of Impacts to Water

Operational discharges to water, including sanitary wastes, stormwater, and liquid effluents, are managed in accordance with federal, state, and local laws and regulations. The impacts of sanitary wastes and liquid effluents are managed through engineering controls in accordance with a NPDES permit. All stormwater discharges are managed through a separate NPDES stormwater permit and controlled and minimized using BMPs. Therefore, environmental impacts to water from nonradioactive waste discharges are SMALL.

5.10.3 IMPACTS TO AIR

This Section evaluates the impacts to air quality from nonradioactive waste streams associated with operating activities at the Project site.

5.10.3.1 Air Emissions

The Project site is located in an attainment area, as discussed in Section 5.7.2. Operating the site will increase gaseous emissions to the air from equipment associated with plant auxiliary systems such as diesel generators and auxiliary boilers. This equipment will operate infrequently during startup, shutdown, or testing, and the related emissions will be intermittent. Cooling towers will frequently run, except during scheduled or maintenance outages, and will result in PM emissions. Emissions from the cooling towers are discussed in Section 5.7.1. Results from cooling tower impact modeling in Section 5.7.1 show no predicted fogging, no predicted plume rime icing, low predicted salt deposition rates, limited visual impacts, and insignificant plume water deposition rates; therefore, the predicted impacts from operational activities at the Project site are SMALL. Additionally, emissions from the diesel generators and auxiliary boilers are discussed in Section 5.7.2.

As discussed in Section 3.4.3.3.2, the Project site operates as a SQG and manages and disposes of hazardous waste in accordance with the RCRA to minimize the potential for air emissions from this waste. Additionally, nonradioactive gaseous effluents generated at the Project site are described in Section 3.4.3.3.4.

5.10.3.1.1 Summary of Impacts to Air

Air emission sources associated with operating the Project site are managed in accordance with federal, state, and local air quality control regulations. Based on the estimated amount of potential air emissions, the intermittent nature of the potential emissions, and the requirement to adhere to prevention of significant deterioration requirements, impacts to air quality are anticipated to be SMALL.

5.11 ENVIRONMENTAL IMPACTS OF POSTULATED ACCIDENTS

5.11.1 DESIGN BASIS ACCIDENTS

5.11.1.1 Accident Selection

As discussed in Section 1.2.1, Duke Energy is considering several nuclear technologies for potential construction and operation on the Project site. A specific technology has not yet been selected. Accordingly, as discussed in Section 3.0, Duke Energy is employing a PPE approach in the ESPA. The advanced reactor technologies considered in development of the PPE for this ESPA include enhanced design and passive safety features expected to improve overall reactor safety compared to current operating reactors. These technologies include:

- GVH BWRX-300 – An advanced BWR design with passive safety features that uses standard LWR fuel and generates 870 megawatts thermal (MWt).
- NuScale VOYGR – An advanced, integral pressurized-water reactor (PWR) design with passive design features that uses standard LWR fuel with a shorter fuel assembly length with up to 12 reactors generating 250 MWt each, with the containment of each reactor submerged in the Reactor Building pool.
- Holtec SMR-300 – An advanced PWR design that includes passive safety features, uses standard LWR fuel, and generates approximately 1000 MWt.
- WEC AP300 – An advanced PWR design that includes passive safety features, uses standard LWR fuel, and generates 990 MWt.
- TerraPower Natrium – An advanced, metal fueled, pool-type sodium fast reactor with passive design features that generates 840 MWt and uses sodium-bonded metallic fuel with high chromium martensitic steel cladding, that operates at near atmospheric pressures and includes a molten salt energy storage system.
- X-energy Xe-100 – An advanced high-temperature gas-cooled (helium) reactor (HTGR) that includes passive safety features. Each reactor generates 200 MWt. The X-energy Xe-100 uses TRi-structural ISOtropic (TRISO) particle fuel. The reactor and steam generator are located inside the containment structure.

As discussed in NRC Regulatory Guide (RG) 4.2, Rev. 3 Section 5.11.1, *Design Basis Accidents*, the evaluation of design basis accidents in the Environmental Report (ER) is intended to provide a realistic assessment of the environmental consequences of postulated design basis accidents. Whereas the Design Basis Accident (DBA) analyses in the Final Safety Analysis Report or in the case an ESPA, the Site Safety Analysis Report (SSAR), are developed to provide adequate assurance that radiological impacts to the public do not exceed regulated dose limits as the measure to demonstrate adequate safety to the public, the conservatisms inherent to these analyses do not provide a realistic assessment of the actual consequences of such accidents. Thus, NRC RG 4.2 states that within the ER, the applicant should evaluate DBAs using site-specific data and realistic meteorology (i.e., 50th percentile atmospheric dispersion factors) to estimate doses at off-site locations. Accordingly, this subsection provides an assessment of the DBA dose consequences for the EAB and the Low Population Zone (LPZ) using 50th percentile atmospheric dispersion factors to provide a more realistic assessment of the dose consequences for the limiting DBA. For the Project site, the EAB and LPZ are

established at the same boundary as shown in SSAR Figure 2.1-5.

As discussed above, Duke Energy is considering several potential technologies for the Project site and is thus employing a PPE approach for this ESPA. As discussed in the SSAR, Chapter 15, in accordance with that approach, Duke Energy has selected a source term expected to yield the highest post-accident doses at the EAB/LPZ as the surrogate for the purpose of evaluating the Project site against the site radiological consequence evaluation factors set forth in 10 CFR 52.17(a)(1)(ix) and 10 CFR 50.34(a)(1)(ii)(D).

The surrogate accident source term selected for analysis is for a postulated instrument line break accident (ILBA) associated with one of the light water reactors identified above (GVH BWRX-300). The accident assumes a non-isolable circumferential break of a primary cooling system instrument line located outside of primary containment, resulting in release of the activity to the environment with no credit for holdup or filtration of the effluent.

Using the surrogate source term, doses have been calculated using 50th percentile atmospheric dispersion factors at the EAB/LPZ for the two-hour period producing the highest dose following initiation of the accident, and for the 30-day period following initiation of the accident. The 50th percentile atmospheric dispersion factors are presented in Section 2.7.3. The accident is modeled assuming an instantaneous release to maximize doses at the EAB/LPZ. The doses calculated using the surrogate source term are expected to be the largest accident doses of the technologies under consideration in this ESPA at the site EAB/LPZ over any two-hour period and the 30-day period following initiation of the accident.

5.11.1.2 Source Term

The surrogate accident source term (integral activity released to the environment as a function of time) used in evaluating the EAB/LPZ doses is provided in Table 5.11-1. As discussed above, the surrogate accident source term is based on a GVH BWRX-300 primary cooling system ILBA and modeled as an instantaneous release. Refer to SSAR Chapter 15, Section 15.2 for further details concerning the development of the DBA source term.

5.11.1.3 Evaluation Methodology and Conclusions

Doses for the surrogate accident at the limiting EAB/LPZ boundary are shown in Table 5.11-2. The two-hour EAB short-term atmospheric dispersion factor is conservatively applied to the LPZ dose determination because the EAB and the LPZ boundary are the same, the release is an instantaneous release, and the zero to two-hour EAB short-term atmospheric dispersion factor is larger than the zero-to-eight-hour LPZ short-term atmospheric dispersion factor, and thus conservative.

Key inputs to determination of the doses in Table 5.11-2 include:

- Use of short-term 50th percentile accident atmospheric dispersion factors (χ/Qs) for the Project site in accordance with the guidance in NRC RG 4.2, Rev. 3. Table 2.7-47 identifies the limiting χ/Q value used in calculating the zero to two-hour and the 30-day accident doses at the EAB/LPZ.

- Use of the surrogate accident source term to calculate doses at the EAB/LPZ.

The Project site short-term dispersion factors were calculated using conservative assumptions:

- Radiological releases are assumed to occur at ground level instantaneously with no credit for dilution or holdup.

- No building wake effects were credited.

- Effluent release points are assumed to occur at the perimeter of each of the technology composite footprints depicted as power block areas in Figure 2.1-5. This adds additional conservatism as the actual releases in most cases occur at the perimeter of the reactor building, located well inside of the perimeter of each vendor's technology plot footprint.

- It is assumed that the LPZ dose is equal to the 0-2 hour EAB dose for the instantaneous release since the EAB and the LPZ are the same boundary. This is conservative as the 0-8 hour LPZ χ/Q is smaller than the 0-2 hour EAB χ/Q factor, which would result in a smaller dose at the LPZ. Since an instantaneous release is assumed, it is acceptable to utilize the 0-2 hour EAB χ/Q as the 0-8 hour LPZ χ/Q.

The resulting accident doses are expressed as TEDE, consistent with 10 CFR 50.34(a)(1)(ii)(D). As shown in Table 5.11-2, the accident doses of the selected technologies are significantly below the 25 roentgen equivalent man (rem) (0.25 sieverts [Sv]) TEDE limits specified in 10 CFR 50.34(a)(1)(ii)(D) at the EAB/LPZ for the Project site. Therefore, impacts to the public from radiation exposure due to postulated accidents are expected to be SMALL.

5.11.2 SEVERE ACCIDENTS

This section evaluates the potential environmental impacts of severe accidents at the Project site. The environmental impacts from postulated severe accidents are calculated using site-specific data to demonstrate acceptability.

Duke Energy requested that each of the potential advanced reactor vendors provide information from the probabilistic risk assessment (PRA) for its design to allow the assessment of potential severe accident consequences. However, final PRA information was not available for any vendors at the time of preparation of this ESPA. While information regarding severe accident release categories, source terms, and release frequencies was provided to Duke Energy from some vendors, information was not received from all vendors. Therefore, Duke Energy assessed the potential severe accident consequences of two vendors that provided sufficient information and presented the vendor with the most conservative results for the majority of the evaluated consequence metrics.

This section uses PRA information for severe accidents, along with site-specific characteristics, to estimate the impacts of severe accidents. The results identify the environmental impacts from potential severe accidents.

5.11.2.1 Methodology

The MELCOR Accident Consequences Code System (MACCS) computer code (Version 4.2, with the WinMACCS graphical user interface) is developed to model the environmental consequences of the severe accidents. MACCS is developed specifically for the NRC to evaluate severe accidents at nuclear power plants (SNL, 2021). The MACCS analysis uses three accident source terms (shown in Table 5.11-3). The accidents include a steam generator tube rupture accident, a depressurization accident, and a seismic accident. The associated

accident frequencies are shown in Table 5.11-4.

5.11.2.2 MACCS Code

The MACCS computer code is used to evaluate the environmental consequences of the severe accidents. The radiation exposure pathways modeled include external exposure from the passing plume, external exposure from material deposited on the ground, inhalation of material in the passing plume or re-suspended from the ground, and ingestion of contaminated food and surface water. The MACCS code primarily addresses radiation dose from the air pathway, but also calculates dose from surface runoff and deposition on surface water. The code also evaluates the extent of contamination. The analysis uses site-specific meteorology and population data and also includes the ingestion pathway over the entire life cycle of the accident.

To assess human health impacts, the assessment includes the collective dose, risk of early fatalities, and the risk of latent cancer fatalities from a severe accident for the population within a 50-mile (mi.) (80-kilometer (km)) radius. Economic costs are also determined, including the costs associated with short-term relocation of people, decontamination of property and equipment, and interdiction of food supplies.

Five files provide input to a MACCS analysis: ATMOS, EARLY, CHRONC, a meteorological file, and a site characteristics file. ATMOS provides data to calculate the amount of material released to the atmosphere that is dispersed and deposited. The calculation uses a Gaussian plume model. Important reactor specific inputs in this file include the released activity and duration of the accidents. EARLY provides inputs to calculations regarding exposure in the time period immediately following the release. CHRONC provides data for calculating long-term impacts and economic costs and includes region-specific data on agriculture and economic factors. These files access and use input from a meteorological file and a site characteristics file. The meteorological file provides meteorological monitoring data (hourly data that includes wind speed and direction, stability class, and rainfall) representative of the site for one year. The Project site had an on-site meteorological tower installed in early 2024. The tower was installed at the approximate grade elevation of the finished reactors. Meteorological data from the tower during February 6, 2024 – February 6, 2025, is used to create the MACCS meteorological data input file. The site characteristics file generated by SecPop 4.3.0 provides site-specific population data, land usage, watershed index, and economic data for the region. For this analysis, the transient population projected to 2079 in addition to the resident population projected to 2079 is used.

The MACCS calculation results and the release frequency are used to determine risk. Risk is the product of the release frequency of an accident multiplied by the consequences of the accident. The consequence can be radiation dose, fatalities, economic cost, or farmland that needs to be decontaminated. Dose risk is the product of the collective dose times the accident frequency. The same process is applied to estimating the risk of fatalities (fatalities per reactor per year), the economic cost-risk (dollars per reactor per year), and the risk of farmland requiring decontamination (hectares per reactor per year).

5.11.2.3 Consequences to Population Groups

This Section evaluates impacts of severe accidents from air, surface water, and groundwater pathways. The MACCS code is used to evaluate the doses from the air pathway and from water ingestion with site-specific data. MACCS does not model other surface water and groundwater

dose pathways. These are analyzed qualitatively based on a comparison of doses from the atmospheric (air) pathway for the Project site to those of the existing fleet of United States nuclear reactors.

5.11.2.3.1 Air Pathways

The three accidents are analyzed in MACCS to estimate population dose, number of early and latent fatalities, cost, and farmland requiring decontamination. The analysis assumed that no emergency evacuation of the 50-mi. (80-km) population occurred after the start of the accident. The total dose risk to the 50-mi. (80-km) population, risk of fatalities, economic cost, and farmland decontamination is provided in Table 5.11-7.

5.11.2.3.2 Surface Water Pathways

People are exposed to radiation when airborne radioactivity is deposited onto the ground and washed into surface water or directly deposited into the surface water. The exposure pathway can be from drinking the water, submersion in the water, activities taking place near the shoreline, or ingestion of fish. For the surface water pathway, MACCS only calculates the dose from ingestion of water. The water ingestion dose risk to the 50-mi. (80-km) population is provided in Table 5.11-7.

Surface waters located near the Project site are discussed in Section 2.2.2.1 and include streams, rivers, and reservoirs that were constructed for flood control, water supply, and power generation. In NUREG-1437, Rev. 0, the NRC evaluates doses from the aquatic food pathway (fishing) for the current nuclear fleet of reactors. For sites discharging to small rivers, the NRC evaluation estimates the uninterdicted population exposure including the aquatic food pathway dose risk as 0.4 person-rem (4E-03 person-Sv) per reactor year. For sites near large water bodies, values range from 270 person-rem (2.7 person-Sv) per reactor year (Hope Creek on Delaware Bay) to 5500 person-rem (55 person-Sv) per reactor year (Calvert Cliffs on Chesapeake Bay). The NRC evaluation concludes that with interdiction, the risk associated with the aquatic food pathway is found to be small relative to the atmospheric pathway for most sites. Therefore, the dose risk from other surface water pathways is expected to be less than the Project site atmospheric pathway dose risk.

5.11.2.3.3 Groundwater Pathways

People can also receive a dose from groundwater pathways. Radioactivity released during a severe accident can enter groundwater or can move through an aquifer that eventually discharges to surface water.

NUREG-1437 Rev. 0 also evaluates the groundwater pathway dose, based on the analysis in NUREG-0440, the Liquid Pathway Generic Study (LPGS) (NRC, 1978). NUREG-0440 analyzes a core meltdown that contaminated groundwater that subsequently contaminated surface water. However, NUREG-0440 does not analyze direct drinking of groundwater because of the limited number of potable groundwater wells and limited accessibility. The LPGS results provide conservative, uninterdicted population dose estimates for six generic plant-site categories: small rivers, large rivers, the Great Lakes, oceans, estuaries, and “dry” sites (located a considerable distance from surface water or where groundwater flow is away from surface water). These dose estimates are one or more orders of magnitude less than those attributed to the atmospheric pathway. Because the LPGS values are much less than the atmospheric pathway, it is reasonable to conclude that the atmospheric pathway dominates the groundwater pathway.

Therefore, the dose risk from the Project site groundwater pathway is expected to be less than the dose risk from the Project site atmospheric pathway.

5.11.2.4 Health Risks

The MACCS analysis evaluates the early and latent fatality risks and compares the risks to the NRC Safety Goals. The risk to an average individual in the vicinity of a nuclear power plant of experiencing a prompt fatality resulting from a severe reactor accident should not exceed one-tenth of one percent (0.1%) of the sum of "prompt fatality risks" resulting from other accidents to which members of the U.S. population are generally exposed. As noted in the Safety Goals Policy Statement (FR, 1986), "vicinity" is defined as the area within one mi. (1.61 km) of the plant-site boundary. "Prompt Fatality Risks" are defined as the sum of risks which the average individual residing in the vicinity of the plant is exposed to as a result of normal daily activities (driving, household, chores, occupational activities, etc.). For this evaluation, the sum of prompt fatality risks is taken as the U.S. accidental death risk value of 57.6 deaths per 100,000 people per year (CDC, 2023).

The risk to the population in the area near a nuclear power plant of latent cancer fatalities that might result from nuclear power plant operation should not exceed one-tenth of one percent (0.1%) of the sum of the cancer fatality risks resulting from all other causes. As noted in the Safety Goal Policy Statement (FR, 1986), "near" is defined as within 10 mi. (16.1 km) of the plant. The cancer fatality risk is taken as an average of 148.0 deaths per 100,000 people per year for 2017 to 2020 (CDC, 2023).

5.11.2.5 Conclusions

The MACCS analysis calculates the estimated number of people within 50 mi. (80-km) of the Project site who receive acute or lifetime doses exceeding a threshold. The estimated number of people exceeding the dose limits of 25 rem (0.25 Sv) and 200 rem (2 Sv) is zero (Table 5.11-5).

As previously described, dose risk is a product of dose and frequency. Normal operation has a frequency of one. For comparison, the total population dose within 50 mi. (80-km) of the Project site from normal operation is provided in Table 5.11-6. The total whole-body effective dose risk to the 50-mile (80-km) population of 7.83E+00 person-rem (7.83E-02 person-Sv) per plant year from severe accidents (calculated by summing the dose risks from all accident scenarios) is lower than the dose risk of 2.54E+02 person-rem (2.54 person-Sv) per plant year for Project site normal operation. The total dose risk to the 50-mile (80-km) population is less than the dose risks from five of the reactors listed in Table 5.11-8 and is less than the maximum, mean, and median dose risks for current generation reactors that have undergone license renewal (Table 5.11-9).

The early and latent cancer fatality risks from a severe accident are provided in Table 5.11-7 and 5.11-8. The prompt cancer fatality risk of zero is below the NRC Safety Goal of 5.76E-07 per plant year and the latent cancer fatality risk of 1.22E-09 per plant year is below the NRC Safety Goal of 1.48E-06 per plant year.

The total calculated dose risk to the 50-mi. (80-km) population is less than the maximum, mean, and median dose risks for current generation reactors, the early and latent cancer fatality risks meet the NRC Safety Goals, and the estimated number of people within 50 mi. (80-km) exceeding the dose limits of 25 rem (0.25 Sv) and 200 rem (2 Sv) is zero. Therefore, the

environmental impacts of severe accidents are expected to be SMALL.

5.11.3 SEVERE ACCIDENT MITIGATION ALTERNATIVES

This section is not required for an ESPA.

Note:

(a) Risks were calculated using the MACCS code and presented in NUREG-1150.

(b) Risks were calculated with MACCS code using Project site-specific inputs. Values are the 99.5 percentile estimates with the exception of the average individual prompt and latent fatalities. The per plant year and person-rem per plant year units used in the Project site values from Table 5.11-7 are assumed to be equivalent to the per reactor year and person-rem per reactor year units used for the other reactor facilities in this table.

(c) Discussed in the NRC Safety Goal Policy Statement (51 FR 30028). Values are 0.1 percent of the risks discussed in 5.11.2.7.

(d) Per the NRC Safety Goal Policy Statement (51 FR 30028), mean estimates are used for implementing the policy. Average individual prompt and latent fatality risks are calculated for 0-1 mi. and 0-10 mi. ranges, respectively.

(e) Risks were calculated using the MACCS code and presented in NUREG-1437.

Key: rem = roentgen equivalent man

Table 5.11-9
Comparison of 50-mile Population Doses of the Project Site to Current Plants

	Severe Accident Frequency (per reactor year)	50-mi Population Dose Risk (person-rem per reactor year)
Current Reactor Maximum[(a)]	2.4E-04	6.9E+01
Current Reactor Mean[(a)]	3.1E-05	1.5E+01
Current Reactor Median[(a)]	2.5E-05	1.3E+01
Current Reactor Minimum[(a)]	1.9E-06	5.5E-01
Project site[(b)]	1.23E-04	7.83E+00

Note:

(a) Based on MACCS calculations for over 70 current plants at over 40 sites (NUREG-2168).

(b) The 99.5 percentile dose risk was calculated with MACCS code using site-specific input. The per plant year and person-rem per plant year units used in the Project site values from Table 5.11-7 are assumed to be equivalent to the per reactor year and person-rem per reactor year units used for the other values in this table.

Key: rem = roentgen equivalent man

5.12 MEASURE AND CONTROLS TO LIMIT ADVERSE IMPACTS DURING OPERATION

5.12.1 ADVERSE ENVIRONMENTAL IMPACTS

Sections 5.1 through 5.11 identify adverse impacts resulting from the operation of the Project and the measures and controls to avoid, minimize, or mitigate those impacts. Table 5.12-1 summarizes the impact finding for each resource category, a description of the impacts or activities that result in impacts, and the mitigation measures and controls that are identified in previous sections.

The assignment of significance levels as SMALL, MODERATE, or LARGE assumes that for each impact, corresponding feasible and adequate measures and controls (or equivalents) are implemented. If a significance determination of SMALL is made without the implementation of measures and controls, then no additional measures and controls are identified in Table 5.12-1. If there is no impact to a resource from operation of the Project, a “no impact” descriptor indicates such and no mitigative measures are needed. Each “Impact Description or Activity” attribute is assigned a number, and each “Mitigating Measures and Controls” attribute is assigned a number corresponding to the respective “Impact Description or Activity.”

Based on a review of the operational impacts described in this chapter, generally feasible and adequate measures and controls for reducing adverse impacts at the Project site include:

- Implementing terms of agreements or conservation measures that are developed in conjunction with applicable consultations with federal and state agencies as indicated in Table 1.4-1.
- Complying with applicable requirements of permits or licenses required for plant operations at the Project site as summarized in Table 1.4-2.
- Complying with applicable federal, state, and local laws, ordinances, and regulations intended to prevent or minimize adverse environmental impacts (e.g., solid waste management, erosion and sediment control, air emissions, noise control, stormwater management, discharge prevention and response, and hazardous material management).

The feasible and adequate measures and controls described in Table 5.10-1 are based on statutes and regulatory requirements or are generally accepted practices within the utility industry. General feasible and adequate measures and controls for reducing adverse impacts at the Project site include:

- Implementing an environmental safety and health plan for the Project site that governs operations. This includes Safety Data Sheets for applicable hazardous materials at the Project site. Operational employees are trained in the appropriate safety measures and use of hazardous materials.
- Treating, storing, and disposing of hazardous waste in accordance with the RCRA and other applicable federal, state, and local laws and regulations and Duke Energy procedures. Operational employees are trained in the appropriate handling and disposal of hazardous waste.
- Performing operational activities in accordance with applicable local, state, and federal ordinances, laws, and regulations and Duke Energy procedures intended to prevent or

minimize adverse environmental effects of operational activities on air, water, land, plants, animals, workers, and the public.

- Performing operational activities in compliance with applicable Duke Energy corporate environmental, safety, and operational procedures, which place controls on how activities are performed.

Table 5.12-1
Summary of Measures and Controls to Limit Adverse Operational Impacts
(Sheet 1 of 13)

Environmental Resources (Section Reference)	Summary Impact Finding	Impact Description or Activity	Mitigating Measures and Controls
5.1 Land Use Impacts			
5.1.1 On-site Impacts	SMALL	1. No adverse impacts.[(a)]	1. No mitigation measures or controls are needed.
5.1.2 Off-site Impacts	SMALL	1. No adverse impacts.[(a)]	1. No mitigation measures or controls are needed.
5.2 Water-Related Impacts			
5.2.1 Hydrologic Alterations			
Surface Water	SMALL (MODERATE under drought conditions)	1. Hydrologic alterations, including flow patterns and sedimentation, where stormwater is discharged to Belews Lake.	1. Manage stormwater and minimize discharge of sediment and site runoff to Belews Lake through an engineered stormwater collection system and sediment and erosion control measures. 1. Comply with the requirements of the NCDEQ NPDES permit for discharge of stormwater associated with industrial activity. 1. Comply with the monitoring and BMP requirements from 15A NCAC 02H.1017 and incorporate these into future permitting and stormwater management operational programs as applicable.
		2. Variable lake water levels and a lower predicted minimum level during operations compared to modeled BCSS operational scenarios as a result of increased consumptive use. Lake water-level drawdowns are noticeable during periods of increased drought severity but are not considered to be destabilizing.	2,3. Regulate supplemental pumping from the Dan River in conjunction with NCDEQ NPDES permitting requirements consistent with existing BCSS permitted conditions.

Table 5.12-1
Summary of Measures and Controls to Limit Adverse Operational Impacts
(Sheet 2 of 13)

Environmental Resources (Section Reference)	Summary Impact Finding	Impact Description or Activity	Mitigating Measures and Controls
		3. Extended critical drought duration compared to the BCSS full generation scenario.	
		4. Localized and minor effects on flow and circulation patterns in Belews Lake as a result of intake, discharge, and MWIS operations.	4. Regulate discharge flows in conjunction with NCDEQ NPDES permitting requirements.
		5. Negligible sedimentation impacts on Belews Lake from sediment entrainment from the Dan River during MWIS operations.	5. No mitigation measures or controls are needed.
		6. Localized changes in flow patterns, currents, and total flow in the Dan River due to discharge adjacent to existing Outfall 006.	6. Install cautionary signage to mark outfall and intake locations in the Dan River for watercraft awareness.
		7. Minor hydrologic alterations in the Dan River from MWIS operations that affect river discharge downstream.	7. Regulate supplemental pumping from the Dan River in conjunction with NCDEQ NPDES permitting requirements consistent with existing BCSS permitted condition.
Groundwater	SMALL	1. Reduced infiltration and groundwater recharge in immediate area of new structures and impervious surfaces.	1. No mitigation measures or controls are identified.

Table 5.12-1
Summary of Measures and Controls to Limit Adverse Operational Impacts
(Sheet 3 of 13)

Environmental Resources (Section Reference)	Summary Impact Finding	Impact Description or Activity	Mitigating Measures and Controls
5.2.2 Water Use Impacts			
Surface Water	SMALL	1. Belews Lake water use as supplemented by MWIS operation is increased compared to the BCSS Continuous Maximum Generation Condition. While water use is noticeable during periods of increased drought severity this water use does not preclude the capacity for Belews Lake to continue to provide a reliable source for cooling water in support of thermoelectric power generation; therefore, impacts on water use are minor. 2. Minor impacts to water availability and reliability for downstream water users along the Dan River.	1. No mitigation measures or controls are needed. 2. Comply with NPDES permit limits for water withdrawals from the Dan River.
Groundwater	SMALL	1. No adverse impacts.[(a)]	1. No mitigation measures or controls are needed.

Table 5.12-1
Summary of Measures and Controls to Limit Adverse Operational Impacts
(Sheet 4 of 13)

Environmental Resources (Section Reference)	Summary Impact Finding	Impact Description or Activity	Mitigating Measures and Controls
5.2.3 Water Quality Impacts			
Surface Water	SMALL	1. Minor impacts to water quality in on-site streams from industrial stormwater. 2. Minor water quality impacts on Belews Lake from cooling tower blowdown, including temperature changes and chemical constituents. 3. Localized, temporary impact on Belews Lake water quality from MWIS operation. 4. Minor water quality impacts in the Dan River from cooling tower blowdown and wastewater discharge, including temperature changes, nonradioactive liquid discharges, and radwaste.	1. Manage stormwater through an engineered stormwater collection system and sediment and erosion control measures. 1. Comply with NPDES permit requirements, maintain an operational SWPPP and SPCC, and implement stormwater BMPs. 1-4. Conduct thermal and chemical monitoring programs, as applicable, for surface water at the Project site and Dan River. 2,3,4. Mitigate by rapid mixing and adherence to NPDES permitting requirements in Belews Lake and by administrative and engineering controls as needed to meet NPDES requirements, monitoring programs, dilution effects, and mixing within the pipeline prior to mixing within the Dan River.
Groundwater	SMALL	1. Potential for accidental spills.	1. Minimize by containment systems and established procedures in SPCC plan pursuant to 40 CFR Part 112 to minimize the release of constituents associated with accidental spills.

Table 5.12-1
Summary of Measures and Controls to Limit Adverse Operational Impacts
(Sheet 5 of 13)

Environmental Resources (Section Reference)	Summary Impact Finding	Impact Description or Activity	Mitigating Measures and Controls
5.3 Ecological Impacts			
5.3.1 Terrestrial and Wetland Impacts	SMALL	1. Impacts to plant communities and wetlands primarily consist of landscape maintenance activities such as pesticide/herbicide use and mowing, within the Project site and the associated off-site wastewater pipeline corridor.	1. Use BMPs including following the label-recommended pesticide/herbicide usage and application method and rates, only using licensed herbicide/pesticide applicators, maintaining ground cover in corridors, prohibiting herbicide usage around wetlands, and avoiding mowing and other heavy equipment operation within wetlands.
		2. Potential establishment and spread of invasive plant species.	2. Monitor disturbed lands to identify and control areas that are dominated by invasive species. Control methods may include using pesticides/herbicides, hand-pulling, or mechanical treatment as applicable.
		3. Impacts to wetlands from inadvertent spills or stormwater runoff.	3. Implement an SPCC plan pursuant to 40 CFR Part 112 to minimize the release of constituents associated with accidental spills on wetlands.
		4. Impacts to wildlife from operational noise. Noise-sensitive wildlife are expected to avoid areas within the NDA and other habitats characterized by elevated noise levels.	4-5. No mitigation measures identified.
		5. Occasional bird collisions with tall structures. Bird collisions with nuclear power plant structures occur at rates that are unlikely to affect local or migratory bird populations.	
		6. Minor impacts to wildlife from transmission line maintenance due to the limited frequency of maintenance activities. Bird collisions with transmission lines may occur during operations.	6. Comply with the Migratory Bird Treaty Act. May use bird diverters and avian-safe insulator assemblies to reduce the frequency of bird collisions and ensure reliable transmission system operation.

Table 5.12-1
Summary of Measures and Controls to Limit Adverse Operational Impacts
(Sheet 6 of 13)

Environmental Resources (Section Reference)	Summary Impact Finding	Impact Description or Activity	Mitigating Measures and Controls
		7. Minor impacts to wildlife from EMFs.	7. No mitigation measures or controls are needed.
		8. Impacts to pollinators from mowing and pesticide use, and artificial lighting.	8. Schedule transmission line activities to minimize harm to pollinators, when possible, by limiting mowing to the fall or winter when flowers are not blooming. Incorporate mitigation measures to limit artificial light impact.
		9. Limited impacts on tricolored bat (*Perimyotis subflavus*) from reduced habitat suitability, noise levels from cooling tower operations, and low risk of collision with tall structures.	9. No mitigation measures or controls are identified.
		10. Potential effects on habitats that may be used as foraging habitats by monarch butterfly (*Danaus plexippus*) and other pollinators.	10. Conduct mowing in the fall or winter when foraging habitat (flowers) are not blooming, controlling invasive species, and following the label-recommended pesticide/herbicide usage.
		11. Limited impacts to bald eagle (*Haliaeetus leucocephalus*) from behavioral effects associated with avoidance of developed high-activity areas and infrequent collisions with structures or powerlines.	11. Update the Project site's existing Bald Eagle Nest Management Plan as appropriate.
5.3.2 Aquatic Impacts	SMALL (MODERATE under drought conditions)	1. Potential impacts to aquatic ecosystems in on-site streams from stormwater runoff or accidental spills.	1. Comply with requirements of the site-specific NPDES permit for stormwater discharges and relevant federal, state, and local stormwater regulations. Implement stormwater BMPs. 1. Implement an SPCC plan pursuant to 40 CFR Part 112 to minimize the release of constituents associated with accidental spills.

Table 5.12-1
Summary of Measures and Controls to Limit Adverse Operational Impacts
(Sheet 7 of 13)

Environmental Resources (Section Reference)	Summary Impact Finding	Impact Description or Activity	Mitigating Measures and Controls
		2. Impingement and entrainment of organisms by the intake structure on Belews Lake.	2. Intake structure is designed to meet the impingement and entrainment requirements in regulations adopted to implement Section 316(b) of the CWA.
		3. Impacts to aquatic biota and associated habitats along nearshore areas of Belews Lake from seasonal fluctuations in surface water levels and changes in water circulation patterns. Effects of lake water-level drawdowns are increased under modeled extreme drought conditions.	3. Increased supplemental pumping from the MWIS in accordance with the limits established in the NCDEQ NPDES permit mitigates the reduction in lake levels and near shore aquatic habitats and minimizes potential effects related to water-level fluctuations.
		4. Minor, localized impacts to aquatic biota within Belews Lake from thermal discharges.	4. Comply with thermal discharge limits required under the operational NCDEQ NPDES permit to limit adverse impacts to aquatic biota.
		5. Direct impacts to aquatic species are limited to the MWIS and the wastewater discharge in the Dan River.	5. Impacts of the MWIS and discharge operation are minimized through compliance with NPDES permit requirement and through the use of technologies and design features.
		5. Localized loss of benthic habitat and loss of less mobile organisms during maintenance activities at the Dan River MWIS.	5. No mitigation measures or controls are needed.
		6. Impingement and entrainment of organisms and potential effects to aquatic habitat from operation of the MWIS at the confluence of Belews Creek and the Dan River.	6. Operate the intake structure in compliance with regulations adopted to implement Section 316(b) of the CWA in regard to impingement and entrainment.

Table 5.12-1
Summary of Measures and Controls to Limit Adverse Operational Impacts
(Sheet 8 of 13)

Environmental Resources (Section Reference)	Summary Impact Finding	Impact Description or Activity	Mitigating Measures and Controls
		7. Minor water quality impacts on aquatic biota in Belews Lake and the Dan River associated with operational effluents.	7. Comply with regulatory stipulations required under the operational NPDES permit to limit adverse impacts to aquatic ecology. 7. Design liquid waste processing systems and apply administrative and engineering controls and monitoring to manage concentrations of constituents within effluents in compliance with the site-specific NCDEQ NPDES permit.
		8. Impacts to proposed critical habitat for green floater from maintenance activities at the MWIS that affect benthic habitat.	8. Consult with the U.S. Fish and Wildlife Service, State of North Carolina, and U.S. Army Corps of Engineers and implement appropriate avoidance, minimization, and conservation measures to limit potential effects on proposed critical habitat for any activities related to maintenance or material removals at the MWIS.
5.4 Socioeconomic Impacts			
5.4.1 Physical Impacts (includes noise, odors, dust, air pollution, physical transportation impacts, and visual intrusions)	SMALL to MODERATE (AESTHETICS)	1. Minor effects from increase in noise level from cooling tower operation. 2. Air emissions including dust during operations do not exceed the NAAQS for criteria pollutants. 3. Vapor plume from the cooling towers does not reach off-site structures. 4. Minimal operations-related impacts on road conditions from physical deterioration due to reduced traffic volumes compared those during the building phase.	1 No mitigation measures or controls are identified. 2. Air emission sources are managed in accordance with federal, state, and local air quality control laws and regulations. 3. No mitigation measures or controls are identified. 4. No mitigation measures or controls are needed.

Table 5.12-1
Summary of Measures and Controls to Limit Adverse Operational Impacts
(Sheet 9 of 13)

Environmental Resources (Section Reference)	Summary Impact Finding	Impact Description or Activity	Mitigating Measures and Controls
		5. Minor to noticeable, but not destabilizing, visual intrusions of structures and cooling tower plumes depending on the location of the observer and atmospheric conditions.	5. Maintain an approximate 100-ft. (30.5-m) vegetative buffer along most of the shoreline of Belews Lake.
5.4.2 Demographic Impacts	SMALL	1. No adverse impacts.[(a)]	1. No mitigation measures or controls are needed.
5.4.3 Economic Impacts to the Community	SMALL (beneficial)	1. No adverse impacts.[(a)]	1. No mitigation measures or controls are needed.
5.4.4 4 Community Infrastructure Impacts (includes transportation, recreation, housing, and public services)	SMALL to MODERATE (RECREATION under drought conditions, AESTHETICS, and TRANSPORTATION)	1. Impacts to level of service along roadways and selected intersections providing access to the Project site. 2. Impacts to recreation on Belews Lake from fluctuating water levels, noise, and visual intrusions. 3. Effects of the discharge structure on paddlers or recreators on the Dan River. 4. Limited effects on recreation in the Dan River during MWIS operations.	1. Implement relevant traffic management measures from building phase. 2. Regulate supplemental pumping from the Dan River in conjunction with NCDEQ NPDES permitting requirements consistent with existing BCSS permitted condition. 2. Work with the North Carolina Water Resources Commission to extend public boat ramps during low water conditions as necessary. 3. Post cautionary signage to minimize impacts on recreators. 3. Design discharge structure to be low profile to limit effects on recreators. 4. Regulate supplemental pumping from the Dan River in conjunction with NCDEQ NPDES permitting requirements consistent with existing BCSS permitted condition.

Table 5.12-1
Summary of Measures and Controls to Limit Adverse Operational Impacts
(Sheet 10 of 13)

Environmental Resources (Section Reference)	Summary Impact Finding	Impact Description or Activity	Mitigating Measures and Controls
		5. Minor increase in demand for housing, recreational facilities, and public services (water supply, wastewater treatment, police, fire protection, healthcare services, and education) within the region of influence.	5. No mitigation measures or controls are needed.
5.5 Not Used	N/A	N/A	N/A
5.6 Historic and Cultural Resources	SMALL	1. Potential effects to undiscovered archaeological resources within the Project site if ground-disturbing activities occur outside of the net disturbance area.	1. Comply with mitigative measures developed in consultation with the North Carolina State Historic Preservation Office and North Carolina Office of State Archaeology.
5.7 Air Resources	SMALL	1. Particulate emissions and plumes from LMDCT cooling towers. 2. Emissions from operation of auxiliary equipment (e.g., generators and auxiliary boilers), and mobile emissions from operations-related traffic (e.g., vehicles driven by workers). 3. Nominal localized increases in vehicular emissions. 4. Small lifetime greenhouse gas (GHG) emissions footprint compared to annual GHG emissions in North Carolina.	1. No mitigation measures or controls are identified. 2. Conduct dispersion modeling, if required, to demonstrate that emissions do not result in exceedances of the NAAQS. 3. Stagger work shifts, require delivery vehicles to shut down engines while off-loading, restrict idling times of on-site vehicles, use electric and hybrid vehicles, and support and promote van/carpooling and other commuter programs. 4. No mitigation measures or controls are needed.

Table 5.12-1
Summary of Measures and Controls to Limit Adverse Operational Impacts
(Sheet 11 of 13)

Environmental Resources (Section Reference)	Summary Impact Finding	Impact Description or Activity	Mitigating Measures and Controls
		5. Small emissions of ozone and substantially smaller amounts of nitrogen oxides produced by transmission lines during corona discharges.	5. No mitigation measures or controls are needed.
5.8 Nonradiological Health	SMALL	1. Low potential for impacts from etiological agents. 2. Minor water quality impacts from operational and sanitary wastewater discharges. 4. Minor risk of electric shock from electrical infrastructure at the Project site. 5. Occupational health risks for nuclear power plant workers. 6. Minor human health effects from predicted increases in vehicle crash rates at intersections providing access to the Project site.	1. No mitigation measures or controls are identified. 2. Comply with discharge limitations established in the site-specific NPDES permit. 4. Comply with the National Electrical Safety Code standards for transmission lines. 5. Adhere to Duke Energy's robust safety culture, established internal safety guides and procedures, and NRC requirements and Occupational Safety and Health Administration safety standards. 6. Implement traffic management mitigation measures identified in Section 4.4.4.1.
5.9 Radiological Health			
5.9.1 Exposure Pathways	SMALL	1. Releases to the environment from gaseous and liquid effluents are within regulatory limits. 2. Exposure from direct radiation is negligible.	1,2. No specific mitigative measures or controls are identified.
5.9.3 Impacts to Members of the Public	SMALL	1. Exposure to the public from the release of gaseous and liquid effluents are within design objective of 10 CFR Part 50 Appendix I and within the regulatory limits of 40 CFR Part 190.	1. Implement off-site monitoring in accordance with the radiological environmental monitoring program is conducted to evaluate off-site exposure.
5.9.4 Occupational Doses to Workers	SMALL	1. Exposure to the occupational workforce is within regulatory limits.	1. Develop monitoring programs for the occupational workforce to maintain ALARA in compliance with 10 CFR 20.1101.

Table 5.12-1
Summary of Measures and Controls to Limit Adverse Operational Impacts
(Sheet 12 of 13)

Environmental Resources (Section Reference)	Summary Impact Finding	Impact Description or Activity	Mitigating Measures and Controls
5.9.5 Impacts to Biota Other than Members of the Public	SMALL	1. Exposure to terrestrial and aquatic ecosystems from the release of gaseous and liquid effluents are within the 25 millirem per year whole-body limit prescribed by 40 CFR Part 190 and less than 100 mrad/day (threshold cited in NUREG-1555 per scientific literature).	1. Implement off-site monitoring in accordance with the radiological environmental monitoring program is conducted to evaluate off-site exposure.
5.10 Nonradioactive Waste Management			
5.10.1 Impacts to Land	SMALL	1. Disposal of solid, hazardous, and mixed waste.	1. Manage wastes in accordance with all applicable federal, state, and local requirements and standards and Duke Energy Environmental Programs' policies and procedures and dispose of wastes within landfills having sufficient capacity.
5.10.2 Impacts to Water	SMALL	1. Discharge of sanitary wastewater to the Dan River. 2. Discharge of nonradioactive liquid effluent waste streams to Belews Lake or the Dan River. 3. Discharge of stormwater runoff.	1,2. Control and monitor discharges associated with all liquid discharges (sanitary waste and nonradioactive liquid effluents) in accordance with NPDES permit requirements. 3. Manage stormwater discharges in accordance with NPDES stormwater permit requirements and minimize discharges using BMPs.
5.10.3 Impacts to Air	SMALL	1. Gaseous emissions into the air from equipment associated with auxiliary systems such as diesel generators and auxiliary boilers. 2. Particulate matter emissions from cooling towers. 3. Air emissions from hazardous wastes.	1,2. No mitigation measures beyond mitigation measures discussed in Section 5.7 and adhering to federal, state, and local air quality control regulations. 3. Manage and dispose of hazardous waste in accordance with the Resource Conservation and Recovery Act to minimize air emissions.

Table 5.12-1
Summary of Measures and Controls to Limit Adverse Operational Impacts
(Sheet 13 of 13)

Environmental Resources (Section Reference)	Summary Impact Finding	Impact Description or Activity	Mitigating Measures and Controls
5.11 Environmental Impacts of Postulated Accidents	SMALL	1. The calculated dose consequences of design basis accidents at the Project site were found to be within regulatory limits. 2. The calculated probability-weighted dose risk of severe accidents at the Project site were found to be less than the maximum, median, and mean dose risk for current operating reactors and the individual prompt and latent cancer fatality risks are below the NRC safety goals.	1. Radioactive releases and doses comply with regulatory limits.

Note:

(a) A “no impact” descriptor indicates there is no impact to a resource from operation of the Project, and no mitigative measures are needed.

(b) Deleted (Executive Order, 2025).

Key: ALARA = as low as is reasonably achievable; BCSS = Belews Creek Steam Station; BMP = best management practice; CFR = Code of Federal Regulations; cfs = cubic feet per second; CWA = Clean Water Act; EMF = electromagnetic field; ft. = feet; LMDCT = linear mechanical draft cooling tower; m = meter; m^3/s = cubic meters per second; mrad/day = millirad/day; MWIS = makeup water intake structure; NAAQS = National Ambient Air Quality Standards; NC = North Carolina; NCAC = North Carolina Administrative Code; NCDEQ = North Carolina Department of Environmental Quality; NDA = net disturbance area; NPDES = National Pollutant Discharge Elimination System; NRC = U.S. Nuclear Regulatory Commission; PM = particulate matter; SPCC = Spill Prevention and Control Countermeasures; SWPPP = stormwater pollution prevention plan

Chapter 6 Fuel Cycle, Transportation, and Decommissioning Impacts

6.1 FUEL-CYCLE IMPACTS AND WASTE MANAGEMENT

This section discusses the effects on the environment from the uranium fuel cycle (UFC) associated with the technologies under consideration for the Duke Energy Belews Creek, North Carolina (NC) site (Project site). The UFC is defined as the total of those operations and processes associated with the provision, utilization, and ultimate disposition of fuel for nuclear power reactors.

The United States (U.S.) Nuclear Regulatory Commission (NRC) evaluated the environmental impacts associated with operating UFC facilities other than reactors in two documents: WASH-1248, *Fuel Fabrication Environmental Impacts* and NUREG 0116, *Environmental Survey of the Reprocessing and Waste Management Portions of the LWR [light water reactor] Fuel Cycle*. The types of facilities and their environmental impacts considered in these two documents include:

- Uranium recovery facilities:
    - Uranium mining – facilities in which the uranium ore is mined.
    - Uranium milling – facilities in which the uranium ore is refined to produce uranium concentrates in the form of triuranium octaoxide (U_3O_8).
- Uranium conversion – facilities in which the uranium concentrates are converted to uranium hexafluoride (UF_6).
- Enrichment – facilities in which the isotopic ratio of the uranium-235 (U-235) isotope in natural uranium is increased to meet the requirements of LWRs.
- Fuel fabrication – facilities in which the enriched UF_6 is converted to uranium dioxide (UO_2) and made into sintered UO_2 pellets. The pellets are subsequently encapsulated in fuel rods, and the rods are assembled into fuel assemblies ready to be inserted into the reactors.
- Reprocessing – facilities that disassemble the spent fuel assemblies, chop up the fuel rods into small sections, chemically dissolve the spent fuel out of sectioned fuel rod pieces, and chemically separate the uranium in spent fuel from the plutonium for reuse and from other radionuclides (primarily fission products and actinides).
- Storage and disposal of radiological wastes – facilities in which the radioactive wastes generated at all fuel cycle facilities, including the reactors, are buried. Spent nuclear fuel (SNF) that is removed from the reactors and not reprocessed was also assumed to be disposed of at a geologic repository.

Title 10 of the Code of Federal Regulations (CFR) 51.51(a) requires that:

> "Every environmental report prepared for the construction permit stage or early site permit stage or combined license stage of a light-water-cooled nuclear power reactor, and submitted on or after September 4, 1979, shall take Table S–3, Table of Uranium Fuel Cycle Environmental Data, as the basis for evaluating the contribution of the environmental effects

> of uranium mining and milling, the production of uranium hexafluoride, isotopic enrichment, fuel fabrication, reprocessing of irradiated fuel, transportation of radioactive materials and management of low-level wastes and high-level wastes related to uranium fuel cycle activities to the environmental costs of licensing the nuclear power reactor. Table S–3 shall be included in the environmental report and may be supplemented by a discussion of the environmental significance of the data set forth in the table as weighed in the analysis for the proposed facility."

10 CFR 51.51 and Table S-3 are specific to applications for light-water cooled nuclear power reactors. However, as required in 10 CFR 51.50(b)(3) and 51.50(c), for other than light-water-cooled nuclear power reactors (i.e., non-LWRs), an Environmental Report (ER) for an Early Site Permit (ESP) or a Combined License shall contain the basis for evaluating the contribution of the environmental effects of fuel cycle activities for the nuclear power reactor.

Four of the six technologies under consideration for the Project site are small modular reactors (SMRs) that are based on traditional LWR technology and that use conventional fuel (i.e., UO_2 fuel pellets with an enrichment of less than 5 percent): the GE Vernova Hitachi Nuclear Energy (GVH) BWRX-300, the NuScale VOYGR, the Holtec SMR-300, and the Westinghouse AP300. Therefore, environmental impacts from the UFC for these reactors can be appropriately estimated using Table S-3 as described in 10 CFR 51.51.

To estimate environmental impacts of the UFC using Table S-3, environmental impacts from Table S-3 (which are estimated for a reference 1000 megawatts electric [MWe] LWR with a capacity factor of 80 percent) must be scaled to the proposed plant using the effective electric output, which is the product of the net electric output of the plant and the capacity factor.

Because each SMR listed above has a different power output, different technologies would utilize differing numbers of units on the site and produce a different total output. For this analysis, the bounding value of 2250 MWe maximum gross output is used as the total site output (2100 MWe net output). The maximum capacity factor among the advanced reactors listed above is the Westinghouse AP300, with a capacity factor of 97 percent or higher, and 97 percent has been used as the bounding value for this analysis. Table 6.1-1 shows these values and the associated scaling factor used to complete the comparison with Table S-3.

Table 6.1-2 shows environmental impacts of the reference reactor from Table S-3 and environmental impacts estimated for the Project site LWRs, using the bounding values for power output and capacity factor described above. Section 6.1.1 presents a detailed discussion of environmental impacts from the UFC for LWRs at the Project site.

The fifth technology under consideration for the Project site is X-energy's Xe-100. This advanced reactor is a gas-cooled reactor using TRi-structural ISOtropic (TRISO) fuel, which also uses high-assay, low-enriched uranium (HALEU) metallic fuel. Because this is not an LWR using traditional UO_2 fuel, this reactor is considered separately in Section 6.1.2.

The sixth technology under consideration for the Project site is the TerraPower Natrium reactor. This is a sodium-cooled reactor using HALEU metallic fuel. Because this is not an LWR using traditional UO_2 fuel, this reactor is considered separately in Section 6.1.3.

The United States does not currently reprocess spent fuel, therefore, only the no-recycle option is described here. The data provided in Table S-3, however, are bounding of the maximum recycle option impact for each element of the fuel cycle. Thus, the analysis of the environmental

impacts of the uranium fuel cycle based on Table S-3 presented here is not related to selection of a specific recycling option. As described in Section 6.1.2, reprocessing is not considered for TRISO fuel.

6.1.1 COMPARISON TO TABLE S-3 FOR LWR TECHNOLOGIES

In general, environmental impacts from the UFC for LWRs have decreased since Table S-3 was developed, for the following reasons:

- In situ recovery uranium mining is increasingly common; unlike methods in general use when Table S-3 was developed, this method does not produce mine tailings and releases less radon gas.
- U.S. uranium enrichment technology is transitioning from gaseous diffusion to gas centrifugation. The latter process uses only a small fraction of the electrical energy per separation unit compared to gaseous diffusion.
- Current LWRs use nuclear fuel more efficiently because of higher fuel burnup. Less uranium fuel per year of reactor operation is required than in the past to generate the same amount of electricity. This increase in fuel use efficiency means that lower environmental impacts from fuel production activities are attributable to a given amount of electricity generation. In addition, LWRs are discharging fewer spent fuel assemblies per reactor-year, so the waste storage/repository impact is lessened.
- Closure of U.S. coal plants means that electrical generation sources used by UFC facilities produce less gaseous effluent.

For all these reasons, Table S-3 is a conservative estimate of environmental impacts from the UFC. In NUREG-1437, Rev. 0, *Generic Environmental Impact Statement for License Renewal of Nuclear Plants*, issued in 1996, the NRC provided a detailed analysis and concluded that the assumptions and methodologies used in preparing Table S-3 were conservative enough that the impacts described by the use of Table S-3 would still be bounding. In NUREG-1437, Rev. 1, issued in 2013, and Rev. 2, issued in 2024, the NRC confirmed that this conclusion still holds. Because the extensive discussion found in NUREG-1437, Rev. 0, is not repeated in the newer revisions, the subsections below reference information and analyses from Rev. 0 of NUREG-1437. These analyses and the resulting conclusions are all confirmed in the newer revisions of the document. Therefore, the information in Table S-3 remains adequate for use in the bounding approach used in this analysis.

6.1.1.1 Land Use

The total annual land requirement for the UFC supporting an LWR plant at the Project site is presented in Table 6.1-2. This includes values for both permanently and temporarily committed land. NUREG-1555, Initial, *Standard Review Plans for Environmental Reviews for Nuclear Power Plants: Environmental Standard Review Plan* states that a “temporary” land commitment is a commitment for the life of the specific UFC plant (for example, a mill, enrichment plant, or succeeding plants). Following completion of decommissioning, such land can be released for unrestricted use. “Permanent” commitments represent land that may not be released for use after plant shutdown or decommissioning. This is because decommissioning activities on the pertinent land cannot remove sufficient radioactive material to meet the limits in 10 CFR Part 20, Subpart E, for release of land for unrestricted use. The division of temporarily committed land

into undisturbed and disturbed land is presented in Table 6.1-2. Based on values for coal plants presented in NUREG-1437, Rev. 0, a coal-fired power plant using strip-mined coal with the same power output capacity as the Project site requires the disturbance of approximately 450 acres (ac.) (182 hectares [ha]) per year for fuel alone, a larger value than the combined temporary and permanent land use shown for the Project site LWRs in Table 6.1-2. The values shown in Table 6.1-2 demonstrate that impact on land use from the UFC to support the Project site for the LWR technologies is SMALL.

6.1.1.2 Water Use

The primary water requirement of the UFC is waste heat removal from power stations supplying electrical energy to the enrichment stage of the UFC. Values for water uses required for the Project site LWRs are presented in Table 6.1-2.

In Table S-3, water requirements for the UFC supporting a 1000-MWe reference reactor are compared to the annual requirements for an LWR. The amount of water withdrawn from surface and groundwater and discharged to air by UFC activities represents only 2 percent of the annual discharges to air of an LWR with cooling towers. The UFC discharges are spread among facilities involved in the various stages of the fuel cycle; thus, the water discharge to air from any one of these facilities is less than 2 percent of LWR annual discharges. The environmental impacts of water withdrawal, use, and discharge from LWRs with cooling towers are found to have only small, or in special, but unusual, circumstances, moderate environmental impacts. Given that the water discharged to the air from fuel cycle facilities for a reference reactor year is only a small fraction of the discharge from an LWR, the environmental consequences are even smaller.

The amount of water withdrawn from surface and groundwater and discharged to water bodies and to the ground to support the reference reactor represents only 4 percent of the annual discharges to water bodies and the ground of an LWR with once-through cooling. The fuel cycle discharges are spread among UFC facilities; thus, the water discharges from any one of these facilities is less than 4 percent of LWR annual discharges. The environmental impacts of water withdrawal and discharge from LWRs with once-through cooling are found to be small. Given that the water discharged to water bodies and to the ground from UFC facilities for a reference reactor year is only a small fraction of the discharge from an LWR, the environmental consequences are even smaller.

The expected thermal effluent values for the Project site for the LWR technologies are presented in Table 6.1-2. On a thermal-effluent basis, annual discharges from the UFC for a 1000 MWe reference reactor are about 4 percent of those from a 1000-MWe LWR using once-through cooling. In NUREG-1437, Rev. 0, the NRC concluded that even given maximum consumptive water use, thermal effluents would be negligible for the reference reactor, and that environmental impacts associated with the combinations of thermal loadings and water consumption described for the UFC of the reference 1000-MWe reactor were acceptable relative to water use and thermal discharges. Therefore, the Project site LWRs have SMALL environmental impacts associated with water use for the UFC.

6.1.1.3 Fossil Fuel Impacts

Electrical energy and process heat are required during various phases of the UFC process. The electrical energy is usually produced by combustion of fossil fuels at power plants. Electrical energy needs for the UFC associated with the Project site LWRs are presented in Table 6.1-2.

While fossil fuels (coal and natural gas) are consumed to produce electrical energy and process heat during the various phases of the UFC, the use of fossil fuels in the UFC enables the production of electricity with nuclear fuel, resulting in a net savings in the requirements for fossil fuels in order to produce electricity. Electrical energy needs associated with the UFC represents about 5 percent of the annual electrical power production of the reference reactor. Process heat is primarily generated by the combustion of natural gas. This gas consumption, if used to generate electricity rather than in the UFC, would produce less than 0.4 percent of the electrical output from the reference reactor.

The NRC provided guidance in Attachment 1 of COL/ESP-ISG-026, Interim Staff Guidance (ISG) on Environmental Issues Associated with New Reactors, for estimating the impacts of greenhouse gas (GHG) emissions from the UFC for a proposed plant. In Appendix A of ISG-026, Attachment 1, fossil fuel use information presented in Table S-3 was used to estimate that the GHG footprint of the fuel cycle to support the reference reactor for a 40-year operational period is on the order of 10,100,000 metric tons of carbon dioxide equivalent (MT CO_2e). This estimate can be scaled to the proposed Project site LWRs using the same scaling factor used throughout the Table S-3 analysis, resulting in an estimate of 27,270,000 MT CO_2e produced over the 40-year life of the plant, or 681,750 MT CO_2e annually. This is approximately 0.47% of NC's annual GHG (USEPA, 2023) and 0.011% of total U.S. annual GHG emissions (USEPA, 2024).

The largest source of CO_2 emissions associated with nuclear power is from electric power generation to support the UFC, and the largest use of electricity in the UFC is the enrichment process. As described above, the switch from gaseous diffusion to the more efficient gas centrifugation, as well as the widespread replacement of coal-based power with natural gas, means that the values for electricity use and air emissions in Table S-3 continue to be appropriate bounding values.

The fossil fuel effects, including GHG emissions, from the consumption of electrical energy for UFC operations are SMALL relative to the net power production of the proposed plant.

6.1.1.4 Chemical Effluents

The quantities of chemical effluents from UFC processes needed to support the Project site LWRs are presented in Table 6.1-2.

The gaseous effluents sulfur oxides (SO_x), nitrogen oxides (NO_x), hydrocarbons, carbon monoxide (CO), and particulates listed in Table S-3 are the consequence of the coal-fired electrical energy used in the UFC. The volume of effluent associated with the UFC of the reference reactor is equivalent to that of a small (45-MWe) coal-fired plant; thus, the contribution to the degradation of air quality is small. The generation of electricity with nuclear rather than coal-fired power, as enabled by the use of fossil fuels in the UFC, results in a net improvement in air quality. For these reasons, the impact of these effluents is considered SMALL.

Table S–3 states that the fuel cycle for the reference 1000-MWe LWR requires 323,000 megawatt hours (MWh) of electricity. The fuel cycle for Project site LWRs would therefore require 872,100 MWh of electricity, or 0.021 percent of the 4.2 billion MWh of electricity generated in the United States in 2023 (EIA 2024). Therefore, the gaseous and particulate chemical emissions would add about 0.021 percent to the national gaseous and particulate chemical effluents for electricity generation, a small additional atmospheric loading in comparison with these total emissions.

Liquid chemical effluents produced in UFC processes are related to fuel enrichment and fabrication and may be released to receiving waters. These effluents are usually present in such small concentrations that only small amounts of dilution water are required to reach levels of concentration that are within established standards. Table 6.1-2 presents the amount of dilution water required for specific constituents. Additionally, any liquid discharges into the navigable waters of the United States from plants associated with UFC operations are subject to requirements and limitations set in a National Pollutant Discharge Elimination System (NPDES) permit issued by an appropriate federal, state, regional, local, or affected Native American tribal regulatory agency. The impacts of these liquid chemical effluents from the UFC are SMALL and, therefore, mitigation is not required.

Tailings solutions and solids are generated during the milling process. These materials are not released in quantities sufficient to have a significant effect on the environment.

The impacts of chemical effluents are SMALL.

6.1.1.5 Radiological Effluents

The estimates of radioactive effluent releases to the environment are presented in Table 6.1-2. These are from waste management activities and certain other phases of the UFC process. In NUREG-1437, Rev. 0, the NRC presented an analysis of the effects of radiological effluents from the UFC for the reference reactor, including the effects of radon-222 and technetium-99. which are not addressed in Table S-3. The NRC concluded that the effects of radiological effluents from the UFC for the reference reactor are small. Because the dose to members of the public is a very small fraction of the regulatory limit and an even smaller fraction of natural background exposure, the effects of radiological effluents from the UFC for Project site LWRs, based on the scaling factor applied to the reference reactor UFC effluents as presented in Table 6.1-2, can also be considered SMALL.

6.1.1.6 Radiological Wastes

Quantities of buried radioactive waste material (low level waste [LLW], high level waste [HLW], and transuranic [TRU] wastes), associated with the UFC for the Project site LWRs are specified in Table 6.1-2.

The NRC notes in the reference reactor data presented in Table S-3 that no significant radioactive release to the environment is expected from LLW disposed of at land burial facilities. Land disposal facilities are licensed and regulated by the NRC according to requirements set forth in 10 CFR Part 61. Experience from the operation of these facilities shows that the additional environmental impacts are not significant compared to the impacts described in Table S–3.

The NRC notes in Table S-3 that TRU and HLW wastes are expected to be buried at a repository, and that no release to the environment is expected to be associated with such disposal. The gaseous and volatile radionuclides contained in the spent fuel would have been released and monitored before disposal. The NRC is one of three federal agencies under the Atomic Energy Act with a role in the disposal of spent nuclear fuel and other HLW. Responsibility among the three agencies is described as follows:

- The U.S. Department of Energy (DOE) is responsible for developing permanent disposal capacity for spent fuel and other high-level radioactive waste.

- The U.S. Environmental Protection Agency (USEPA) is responsible for developing environmental standards to evaluate the safety of a geologic repository.

- The NRC is responsible for developing regulations to implement the USEPA safety standards and for licensing the repository.

Because a repository has not yet been licensed, there are no current regulatory limits for off-site releases of radionuclides. If it is assumed that limits for the future repository are developed along the lines of the 1995 National Academy of Sciences report, Technical Bases for Yucca Mountain Standards, and that in accordance with the 2010 update of the NRC's Waste Confidence Decision, 10 CFR 51.23, *Environmental impacts of continued storage of spent nuclear fuel beyond the licensed life for operation of a reactor*, a repository can, and likely will, be developed at some site that will comply with such limits; peak doses to virtually all individuals will be 100 millirem per year (mrem/yr) or less. NUREG-2157, *Generic Environmental Impact Statement for Continued Storage of Spent Nuclear Fuel*, presented an NRC analysis of the environmental impacts of at-reactor storage, away-from-reactor storage, and cumulative impacts of cumulative storage. Most impacts were found to be SMALL and SMALL to MODERATE. The analyses of NUREG-2157 were codified in 10 CFR 51.23.

The NRC regulations for geologic disposal of HLW in 10 CFR Part 60 limit the releases of radioactive material to the accessible environment. In addition to satisfying an overall performance objective to be established by USEPA, the basic requirements are that containment of HLW within the waste packages will be substantially complete for a period determined by the NRC but for a period that shall not be less than 300 nor more than 1000 years after permanent closure of the geologic repository, and that the annual releases from the engineered barrier system thereafter should not exceed one part in 100,000 of the total inventory of each radionuclide calculated to be present 1000 years following permanent closure of the repository. For HLW, 10 CFR 60.111 requires compliance with 10 CFR Part 20 and with USEPA general environmental standards in 40 CFR Part 191.

Based on the discussion presented above, the environmental impact of radioactive waste disposal from the UFC for the Project site LWRs is expected to be SMALL.

6.1.1.7 Occupational Dose

The annual occupational dose attributable to all phases of the UFC for the Project site LWRs is presented in Table 6.1-2. Occupational doses would be maintained to meet the dose limit in 10 CFR Part 20, which is 5 rem/yr. On this basis, it is concluded that environmental impacts from this occupational dose are anticipated to be SMALL.

6.1.1.8 Transportation Dose

The transportation dose to workers and the public is presented in Table 6.1-2 for the Project site LWRs. For comparison, the estimated collective dose from natural background radiation to the population within 80 kilometers (km) (50 miles [mi.]) of the Project site is 6508 person-Sv/yr (650,840 person-rem/yr). This is based on a 2020 population of 2,032,605 and an average individual dose of 320 mrem/yr in NC (Mauro and Briggs, 2005). On this basis, the environmental impacts of transportation are anticipated to be SMALL.

6.1.1.9 Conclusions for the LWRs

Based on the discussion in the above subsections and using Table S-3 as stipulated in 10 CFR 51.51, the environmental effects from the UFC for any of the SMR technologies based on LWRs being considered for use at the Project site would be SMALL.

6.1.2 COMPARISON TO TABLE S-3 FOR THE XE-100 TECHNOLOGY

The Xe-100 is a gas-cooled reactor that uses TRISO fuel pebbles. TRISO fuel is composed of fuel particles or seeds less than 1 millimeter (mm) (0.04 inches [in.]) in diameter. Each has a kernel (approximately 0.5 mm [0.02 in.]) of uranium oxycarbide (or UO_2), and the uranium is likely to be enriched up to 20 percent by weight of U-235. This kernel is surrounded by layers of carbon and silicon carbide, giving a containment for fission products that is expected to be stable up to very high temperatures (up to 1800 degrees Celsius [3272 degrees Fahrenheit]). These particles are arranged in billiard ball-sized pebbles of graphite encased in silicon carbide, each with about 19,000 fuel particles and 0.25 ounces (7 grams) of uranium.

The DOE report *Non-LWR Fuel Cycle Environmental Data* (PNNL-29367) estimated the environmental impacts of the UFC for several non-LWR technologies, including a helium-cooled pebble bed modular reactor using TRISO fuel (Napier, 2020).

As described in PNNL-29367, because TRISO is a uranium based fuel, its UFC relies on uranium recovery facilities and processes similar to those used in developing Table S-3 and described in Section 6.1 above. Similarly, the decrease in environmental impacts since the development of Table S-3 described in Section 6.1.1 is applicable to the discussion of the TRISO fuel cycle, because uranium used in TRISO fuel is mined, converted, and enriched at the same facilities (Napier, 2020). Each of the six types of facilities described in the introduction to Section 6.1 is considered below in more detail.

NUREG-1910, *Generic Environmental Impact Statement for In-Situ Leach Uranium Milling Facilities* addresses common environmental issues associated with the building, operating, and decommissioning of this type of facility, as well as groundwater restoration. In situ recovery has removed many of the causes of harmful uranium recovery impacts because this process does not directly remove the uranium ore from a site, transport the uranium ore to a large milling facility, and process large volumes of uranium ore that produce tailing piles and leachate ponds and the associated release of radon gas. Thus, the in situ recovery process avoids many of the environmental impacts of these past uranium recovery processing steps. Therefore, the environmental impacts for in situ recovery are expected to be less than those listed in Table S-3 for uranium recovery facilities. Thus, Table S-3 can be considered to be bounding for environmental impacts related to uranium recovery for the UFC supporting the Xe-100, even though this technology was not considered during development of Table S-3.

Uranium conversion in the United States occurs at a single facility. Since the development of Table S-3, improvements in efficiency at both the conversion facility and operating nuclear plants, the passage of more stringent environmental regulations, and the conversion of coal-fired power generation stations to less environmentally impactful alternatives have reduced the overall environmental impacts of uranium conversion compared to those assessed for Table S-3. Therefore, it is appropriate to consider Table S-3 bounding for the UFC supporting the Xe-100 with regard to uranium conversion, even though this technology was not considered during development of Table S-3.

A similar argument applies for enrichment. The separative work unit, or SWU, is the standard measure of the effort required to separate isotopes of uranium (U-235 and uranium-238 [U-238]) during an enrichment process and is independent of the enrichment process (either gaseous or centrifuge). To obtain 2200 pounds (lb.) (1000 kilograms [kg]) of uranium enriched 4 percent by weight from natural uranium, assuming the tails are 0.25 percent U-235 by weight, requires 5832 SWU. To obtain the same amount of 20 percent enriched uranium (the maximum for TRISO fuel), requires 41,579 SWU (UXC, 2024). The gaseous-diffusion process consumes about 2500 kilowatt hours (kWh) per SWU, while modern gas centrifuge plants require only about 50 kWh per SWU (WNA, 2022).

Based on standard technology at the time of development, Table S-3 assumed the use of a gaseous diffusion plant to obtain 4 percent by weight enriched uranium. Based on the above, this facility would require approximately 14,600,000 kWh of power to obtain 2200 lb. (1000 kg) of 4 percent enriched uranium. Using centrifuge enrichment, a modern plant would require 2,100,000 kWh to obtain 2200 lb. (1000 kg) of 20 percent by weight enriched uranium. The additional power required to enrich fuel past the limit assumed in Table S-3 is offset by the more efficient power use of modern enrichment technology. Thus, Table S-3 can be considered bounding for TRISO fuel with regard to enrichment, even though this technology was not considered during development of Table S-3.

The processes used to fabricate TRISO fuel are not the same as those used in existing NRC-licensed fuel fabrication facilities. To demonstrate that fuel fabrication environmental impacts for TRISO fuel can be bounded by Table S-3, it must be shown that impacts are bounded by the model fuel fabrication plant described in Appendix E of WASH-1248 (AEC, 1974). This model plant operates 300 days per year with a plant lifetime of 20 years and has a capacity of 3 metric tons uranium (MTU) per day. It produces the annual fuel requirements for up to 26 model LWRs. The model plant used a wet process method of UF_6 to UO_2 conversion, which involves the use of ammonium hydroxide to form an intermediate ammonium diuranate compound prior to final conversion to UO_2. Electricity to supply the plant is largely from coal power plants, with some natural gas used for process heat.

Table 6.1-3 was developed to compare the TRISO fuel fabrication process with the values provided in Appendix E of WASH-1248 (AEC, 1974), using information provided in the application made to the NRC for the TRISO-X fuel fabrication facility in Oak Ridge, Tennessee (TRISO-X, 2022). The proposed TRISO-X fuel fabrication facility produces 16 MTU of fuel per year. An Xe-100 plant producing 2250 MWe requires approximately 11.3 MTU of fuel per year. The comparison provided in this table indicates that Table S-3 can be considered bounding for the UFC supporting the Xe-100 with regard to fuel fabrication. Furthermore, as described above, greater efficiency at operating nuclear plants and less reliance on coal-fired electrical generation has the effect of decreasing environmental impacts from the fuel fabrication portion of the UFC and increasing the conservatism of the Table S-3 estimates.

Because TRISO is so structurally sound, reprocessing is currently unlikely. An open fuel cycle is anticipated. Used TRISO fuel is assumed to be stored on-site in an NRC-licensed facility until ultimate disposal. Therefore, there are no reprocessing environmental impacts to consider, and Table S-3 can be considered bounding for impacts of reprocessing.

WASH-1248 (AEC, 1974) stated that the total volume of low-level radioactive waste generated during UFC operations is variable and difficult to estimate, but provided an analysis that suggests that even the most conservative estimates still only represent a fraction of the annual LLW shipped from all U.S. sources to the four Agreement State-licensed LLW disposal facilities.

Low-level waste generated at operating nuclear reactors includes items that have become contaminated with radioactive material or have become radioactive through exposure to neutron radiation. This waste typically consists of contaminated protective shoe covers and clothing, wiping rags, mops, filters, reactor water treatment residues, equipment and tools, luminous dials, medical tubes, swabs, injection needles, syringes, and laboratory animal carcasses and tissues. Advanced nuclear reactors like the Xe-100 are expected to generate LLW in the same ways as currently operating LWRs. Thus, the environmental impacts of LLW described in Table S-3 are applicable to the Xe-100. Moreover, the WASH-1248 (AEC, 1974) analysis was based on lower burnup levels than those currently allowed for LWRs and anticipated for the Xe-100 using TRISO fuel. Higher burnup means that uranium fuel is used more efficiently, which results in lower cumulative environmental impacts.

Overall, much of the impact analysis related to storage, shipping, and disposal of high-level radioactive waste and spent fuel is not related to reactor or fuel type. This is because storage, transportation, and disposal are each stringently regulated with regard to packaging, physical protection, and dose impacts to workers and members of the public. In general, regulations for waste and spent fuel inventories, as well as their associated certified spent fuel shipping and storage containers, are expected to be broad enough to address new types of fuel associated with advanced reactor designs, including TRISO fuel. The LWR evaluations in NUREG-2157, *Generic Environmental Impact Statement for Continued Storage of Spent Nuclear Fuel,* are expected to be applicable to advanced reactor fuels. In addition, the following regulatory requirements of 10 CFR Part 40, *Domestic Licensing of Source Material*, 10 CFR Part 50, *Domestic Licensing of Production and Utilization Facilities*, 10 CFR Part 70, *Domestic Licensing of Special Nuclear Material*, 10 CFR Part 71, *Packaging and Transportation of Radioactive Material*, 10 CFR Part 72, *Licensing Requirements for the Independent Storage of Spent Fuel, High-Level Radioactive Waste, and Reactor-related Greater Than Class C Waste*, and 10 CFR Part 73, *Physical Protection of Plants and Materials* must be satisfied for any fuel type or technology.

The above discussion indicates that although the Xe-100 and TRISO fuel are not LWRs and thus were not considered in the development of Table S-3, it is still appropriate to consider Table S-3 impacts as bounding for this reactor and fuel type. Therefore, the following subsections present a detailed comparison of environmental impacts from the UFC for an Xe-100 plant at the Project site generating 2250 MWe. Xe-100 units have a capacity factor of greater than 95 percent. These power output and capacity factor values are used to scale the Project site with the Xe-100 technology to the reference reactor, as shown in Table 6.1-1.

6.1.2.1 Land Use

The total annual land requirement for the UFC supporting the Project site for the Xe-100 plant is presented in Table 6.1-2. This includes values for both permanently and temporarily committed land (both undisturbed and disturbed), as described in Section 6.1.1.1. As a comparison, based on values for coal plants presented in NUREG-1437, Rev. 0, a coal-fired power plant using strip-mined coal with the same power output capacity as the bounding value for the Project site requires the disturbance of approximately 450 ac. (182 ha) per year for fuel alone. The impact on land use from the UFC to support the Project site for the Xe-100 plant is SMALL.

6.1.2.2 Water Use

Values for the various water uses required for the Xe-100 plant at the Project site and the expected thermal effluent from this plant are presented in Table 6.1-2. Section 6.1.1.2 discusses

UFC water requirements and thermal effluent and provides some comparisons to the annual water requirements and thermal effluent for an LWR. An Xe-100 plant at the Project site has SMALL environmental impacts associated with water use for the UFC.

6.1.2.3 Fossil Fuel Impacts

Electrical energy needs for the UFC associated with an Xe-100 plant at the Project site are presented in Table 6.1-2. Using the guidance in ISG-026, Attachment 1, as described in Section 6.1.1.3, the reference reactor GHG estimate can be scaled to the proposed Xe-100 plant at the Project site using the same scaling factor used throughout the Table S-3 analysis, resulting in an estimate of 27,270,000 MT CO_2e produced over the 40-year life of the plant, or 681,750 MT CO_2e annually. This is approximately 0.47% of NC's annual GHG (USEPA, 2023) and 0.011% of total U.S. annual GHG emissions (USEPA, 2024). Section 6.1.1.4 further describes the use of fossil fuels in the UFC and provides some comparisons between electrical energy needs of the UFC and reference reactor power production. The fossil fuel effects, including GHG emissions, from the consumption of electrical energy for UFC operations are SMALL relative to the net power production of the proposed plant.

6.1.2.4 Chemical Effluents

The quantities of chemical effluents from UFC processes needed to support an Xe-100 plant at the Project site are presented in Table 6.1-2.

Section 6.1.1.5 describes gaseous and particulate effluents from the UFC and compares this to effluent from a coal-fired power plant. Table S–3 states that the fuel cycle for the reference 1000-MWe LWR requires 323,000 MWh of electricity. The fuel cycle for an Xe-100 plant at the Project site would therefore require 872,100 MWh of electricity, or 0.021 percent of the 4.2 billion MWh of electricity generated in the United States in 2023 (EIA 2024). Therefore, the gaseous and particulate chemical emissions would add about 0.021 percent to the national gaseous and particulate chemical effluents for electricity generation, a small additional atmospheric loading in comparison with these total emissions.

Table 6.1-2 presents the amount of dilution water required for specific constituents of liquid effluents. The limited impacts of liquid chemical effluents produced in UFC processes are described in Section 6.1.1.5.

Tailings solutions and solids generated during the milling process are described in Section 6.1.1.5.

The impacts of chemical effluents are SMALL.

6.1.2.5 Radiological Effluents

The estimates of radioactive effluent releases to the environment are presented in Table 6.1-2. These are from waste management activities and certain other phases of the UFC process. In NUREG-1437, Rev. 0, the NRC presented an analysis of the effects of radiological effluents from the UFC for the reference reactor, including the effects of radon-222 and technetium-99, which are not addressed in Table S-3. The NRC concluded that the effects of radiological effluents from the UFC for the reference reactor are small. Because the dose to members of the public is a very small fraction of the regulatory limit and an even smaller fraction of natural background exposure, the effects of radiological effluents from the UFC supporting an Xe-100

plant at the Project site, based on the scaling factor applied to the reference reactor effluents as presented in Table 6.1-2, can also be considered SMALL.

6.1.2.6 Radiological Wastes

Quantities of buried radioactive waste material (LLW, HLW, and TRU wastes), associated with the UFC for an Xe-100 plant at the Project site are specified in Table 6.1-2. Section 6.1.1.6 provides a discussion of radiological wastes from the UFC, including low-level waste, high-level waste, and spent fuel. Based on this discussion and the information in Table 6.1-2, the environmental impact of radioactive waste disposal from the UFC for an Xe-100 at the Project site is expected to be SMALL.

6.1.2.7 Occupational Dose

The annual occupational dose attributable to all phases of the UFC for an Xe-100 plant at the Project site is presented in Table 6.1-2. Occupational doses would be maintained to meet the dose limits in 10 CFR Part 20, which is 5 rem/yr. On this basis, it is concluded that environmental impacts from this occupational dose are anticipated to be SMALL.

6.1.2.8 Transportation Dose

The transportation dose to workers and the public is presented in Table 6.1-2 for an Xe-100 plant at the Project site. Section 6.1.1.8 provides a comparison of this dose to the dose to the NC population from natural background radiation. On this basis, the environmental impacts of transportation are anticipated to be SMALL.

6.1.2.9 Conclusions for the Xe-100

Based on the discussion in the above subsections and using Table S-3 as stipulated in 10 CFR 51.51, the environmental effects from the UFC for an Xe-100 plant at the Project site would be SMALL.

6.1.3 COMPARISON TO TABLE S-3 FOR NATRIUM

The Natrium reactor is a sodium-cooled fast reactor using HALEU metallic fuel. Its initial core will include 162 fuel assemblies containing enriched uranium-235 as fuel. The fuel employs a metal fuel system instead of oxides. The enrichment level of the fuel is less than 20 weight percent, and the burnup is in the range exhibited by Generation III+ LWR designs and Power Reactor Innovative Small Module (greater than 33,000 megawatt-days/MTU).

Because Natrium, like the Xe-100, uses a uranium-based fuel, its UFC relies on uranium recovery facilities and processes similar to those used in developing Table S-3 and described in Section 6.1. The decreases in environmental impacts since the development of Table S-3 described in Section 6.1.1 and considered applicable to the TRISO fuel cycle, as described in Section 6.1.2, are also generally applicable to the Natrium fuel cycle. Each of the six types of facilities described in the introduction to Section 6.1 is considered below. Where the previous discussion is valid for Natrium and HALEU fuel, the section above is referenced; where Natrium or HALEU-specific information is available, this is presented.

The discussion of uranium recovery (mining and milling) in Section 6.1.2 is applicable to Natrium fuel. Table S-3 can be considered bounding based on the technology advancements

that have generally reduced environmental impacts for this stage of the fuel cycle.

The discussion of uranium conversion in Section 6.1.2 is applicable to Natrium fuel. Table S-3 can be considered bounding based on the overall reduced environmental impact of uranium conversion facilities in the United States.

A similar argument applies for enrichment. To obtain 2200 lb. (1000 kg) of uranium enriched 4 percent by weight from natural uranium, assuming the tails are 0.25 percent U-235 by weight, requires 5832 SWU. To obtain the same amount of 20 percent enriched uranium requires 41,579 SWU (UXC, 2024). Enrichment for the Natrium fuel is identified as 19.75 percent but is conservatively analyzed as 20 percent enriched uranium for this argument. The gaseous-diffusion process consumes about 2500 kWh per SWU, while modern gas centrifuge plants require only about 50 kWh per SWU (WNA, 2022). As such, a similar conclusion to Section 6.1.2 can be applied and Table S-3 can be considered bounding for Natrium fuel with regard to enrichment, even though gas centrifuge technology was not considered during development of Table S-3.

As noted in the Kemmerer Unit 1 ER (TerraPower, 2024), the proposed Natrium fuel fabrication facility (NFFF) at the Global Nuclear Fuels – America, LLC's (GNF-A) facility, located at Wilmington, NC, is expected to support fuel fabrication for Kemmerer Unit 1 with an estimated throughput of 18 MTU per year. A single Natrium unit requires roughly 3.8 MTU for every fuel reload (i.e., every 24 months) or 1.9 MTU every year; therefore, it is reasonable to assume that the proposed NFFF would be able to support fuel demands for the Project site if the Natrium technology is selected. According to a GNF-A NFFF schedule update on July 11, 2023, the license amendment request is expected to be submitted in the third quarter of 2025 for NRC review (GNF, 2023). The Kemmerer Unit 1 ER states that the Environmental Assessment (EA) for the proposed NFFF demonstrated that the addition of the NFFF would provide fabrication of fuel less than 20 weight percent U-235 and would not change the scope or nature of the activity at the existing GNF-A facility at Wilmington, NC, and that the environmental impacts would be the same as those from the existing facility (TerraPower, 2024).

Because the NFFF is not expected to change the scope or nature of the GNF-A facility, the values from WASH-1248 (AEC, 1974) are scaled to represent values for the NFFF, without considering deconversion and metallization. A scale factor is determined by identifying the amount of fuel required by the Project site producing 2250 MWe per year. As mentioned above, a single Natrium reactor requires 1.9 MTU of fuel each year. In order for the Project site to reach the desired output, 6.88 (i.e., 2250 MWe/327 MWe) Natrium units would need to be constructed. Multiplying the amount of fuel required for a single Natrium reactor by the number of units needed to reach the desired power output results in a yearly fuel requirement of 13.1 MTU (i.e., 6.88 Natrium Reactors x 1.9 MTU per Natrium Reactor). Using the lifetime average annual fuel requirement for a model LWR from WASH-1248 of 35 MTU, a scale factor of 0.37 (13.1 MTU/35 MTU) is determined. As such, to compare the environmental impacts associated with the NFFF, not including deconversion or metallization, the values in Appendix E of WASH-1238 would be multiplied by 0.37, resulting in a reduction of environmental impacts by more than 60 percent.

While the proposed NFFF is expected to be bounded by the analysis performed in WASH-1248 (AEC, 1974), the processes at the current GNF-A facility do not include deconversion or metallization as steps in the uranium fuel cycle. These steps are part of the Natrium fuel cycle because the Natrium reactor utilizes metallic fuel. Therefore, it is necessary to demonstrate that the environmental impacts from Appendix E of WASH-1248 bound the environmental impacts from the proposed NFFF, including the impacts associated with deconversion and metallization.

DOE/EA-2087 (DOE, 2019) discusses the environmental impacts associated with deconversion and metallization for a 5000-kg throughput facility. The document states that a federal agency can prepare an EA at any time for a proposed action. If potential significant environmental impacts are identified, an environmental impact statement can always be pursued. Conversely, if no significant environmental impacts are identified, the EA is the appropriate level of documentation and no further evaluation is necessary. Because an EA was completed for the deconversion and metallization action, environmental impacts not discussed with the EA are expected to be minimal.

DOE/EA-2087 (DOE, 2019) stated that the only anticipated source of greenhouse gas emissions in the proposed action analyzed in the document would be from a diesel backup generator. Emissions from the transport of nuclear material would also be included. 100% renewable diesel fuel would be used, resulting in '0' metric tons carbon dioxide equivalent (MT CO2e) of anthropogenic GHG emissions. If 100% renewable diesel is not available, the total anthropogenic GHG emissions are estimated to be less than 0.5 MT CO2e, assuming heavy-duty vehicle burning 100% diesel and taking 20 one-way trips at 20 miles per trip. As such, fossil fuel impacts associated with deconversion, and metallization are considered negligible.

Environmental impacts from chemical effluents associated with deconversion and metallization are briefly discussed in DOE/EA-2087 (DOE, 2019), but ultimately are identified as being minimal. Therefore, impacts from chemical effluents associated with deconversion and metallization is considered negligible.

Environment impacts from radiological effluents associated with deconversion and metallization are discussed in DOE/EA-2087 (DOE, 2019). Site boundary and offsite receptors are identified for the INL site. These receptors are analyzed with the radionuclide inventory that is potentially emitted from the processing facility. Additionally, groundwater exposure pathways and surface soil exposure pathways are evaluated within the EA and the impacts were determined to be SMALL. While the meteorological data and offsite receptors for the NFFF are expected to be different than those at the INL site, any fuel fabrication facility would need to be compliant with regulatory limits or provide additional mitigation to be within regulatory limits. Therefore, impacts from radiological effluents associated with deconversion and metallization would need to be considered for the license amendment of the fabrication facility and would be expected to be SMALL.

DOE/EA-2087 (DOE, 2019) states that the environmental impacts from radioactive waste associated with deconversion and metallization are generally less than 20 cubic meters (700 cubic feet) of LLW and 1 cubic meter (35 cubic feet) of transuranic waste. Comparing to the bounding waste value transported from the Project site of 38,988 cubic feet per year (see Table 6.2-1), the impacts associated with radioactive waste associated with deconversion and metallization are expected to be SMALL.

Lastly, environmental impacts associated with transportation associated with deconversion and metallization in DOE/EA-2087 (DOE, 2019) are identified as SMALL, which includes the impacts of transportation accidents. Per 10 CFR 51.52, Table S-4 classifies radiological effects from transportation accidents as SMALL. As such, it is expected that transportation impacts associated with deconversion, and metallization is expected to be SMALL.

While the DOE/EA-2087 (DOE, 2019) discusses a facility with a throughput limit of 5 MTU annually, the NFFF would have a throughput roughly 3.6 times (i.e., 18 MTU/5MTU) that analyzed in DOE/EA-2087. However, accounting for the increase in production for deconversion

and metallization by a factor of 3.6, using the discussion above, the environmental impacts would still be considered SMALL. Furthermore, it is not expected that the environmental impacts associated with deconversion and metallization would outweigh the 60 percent reduction in impact identified for the proposed fabrication facility as discussed above. Thus, the environmental impacts contained in Appendix E of WASH-1248 (AEC, 1974) are expected to bound the NFFF, and, therefore, Table S-3 can be considered bounding for impacts associated with the fuel fabrication process.

There are no current plants to reprocess Natrium fuel, nor is progress on reprocessing in the United States anticipated in the foreseeable future (TerraPower, 2024). Therefore, it is anticipated that fuel cycle impacts of reprocessing Natrium fuel are bounded by those in Table S-3.

The discussion of high-level waste and LLW from the UFC in Section 6.1.2 is applicable to the Natrium fuel cycle. The ER for Kemmerer Unit 1 states that scaling environmental impacts to Table S-3 based on the annual fuel requirement is acceptable for this environmental impact (TerraPower, 2024).

The above discussion indicates that although the Natrium is not a LWR and thus was not considered in the development of Table S-3, it is still appropriate to consider Table S-3 impacts as bounding for this reactor and fuel type. Therefore, the following subsections present a detailed comparison of environmental impacts from the UFC for the Project site generating 2250 MWe using Natrium technology. The Natrium has a capacity factor of 92.5 percent or greater. The power output and capacity factor are used to scale the Project site with the Natrium technology to the reference reactor, as shown in Table 6.1-1.

6.1.3.1 Land Use

The total annual land requirement for the UFC supporting the Project site for the Natrium plant is presented in Table 6.1-2. This includes values for both permanently and temporarily committed land (both undisturbed and disturbed), as described in Section 6.1.1.1. As a comparison, based on values for coal plants presented in NUREG-1437, Rev. 0, a coal-fired power plant using strip-mined coal with the same power output capacity as the bounding value for the Project site requires the disturbance of approximately 450 ac. (182 ha) per year for fuel alone. The impact on land use from the UFC to support the Project site for the Natrium Plant is SMALL.

6.1.3.2 Water Use

Values for the various water uses required for the Natrium plant at the Project site and the expected thermal effluent from this plant are presented in Table 6.1-2. Section 6.1.1.2 discusses UFC water requirements and thermal effluent and provides some comparisons to the annual water requirements and thermal effluent for an LWR. A Natrium plant at the Project site has SMALL environmental impacts associated with water use for the UFC.

6.1.3.3 Fossil Fuel Impacts

Electrical energy needs for the UFC associated with a Natrium Plant at the Project site are presented in Table 6.1-2. Using the guidance in ISG-026, Attachment 1, as described in Section 6.1.1.3, the reference reactor GHG estimate can be scaled to the proposed Natrium plant at the Project site using the same scaling factor used throughout the Table S-3 analysis, resulting in

an estimate of 26,260,000 MT CO_2e produced over the 40-year life of the plant or 656,500 MT CO_2e annually. This is approximately 0.46% of NC's annual GHG (USEPA, 2023) and 0.010% of total U.S. annual GHG emissions (USEPA, 2024). Section 6.1.1.4 further describes the use of fossil fuels in the UFC and provides some comparison between electrical energy needs of the UFC and reference reactor power production. The fossil fuel effects, including GHG emissions, from the consumption of electrical energy for UFC operations are SMALL relative to the net power production of the proposed plant.

6.1.3.4 Chemical Effluents

The quantities of chemical effluents from UFC processes needed to support a Natrium plant at the Project site are presented in Table 6.1-2.

Section 6.1.1.5 describes gaseous and particulate effluents from the UFC and compares this to effluent from a coal-fired power plant. Table S-3 states that the fuel cycle for the reference 1000-MWe LWR requires 323,000 MWh of electricity. The fuel cycle for a Natrium Plant at the Project site would therefore require 839,800 MWh of electricity, or 0.020 percent of the 4.2 billion MWh of electricity generated in the United States in 2023 (EIA 2024). Therefore, the gaseous and particulate chemical emissions would add about 0.020 percent to the national gaseous and particulate chemical effluents for electricity generation, a small additional atmospheric loading in comparison with these total emissions.

Table 6.1-2 presents the amount of dilution water required for specific constituents of liquid effluents. The limit impacts of liquid chemical effluents produced in UFC processes are described in Section 6.1.1.5.

Tailings solutions and solids generated during the milling process are described in Section 6.1.1.5.

The impacts of chemical effluents are SMALL.

6.1.3.5 Radiological Effluents

The estimates of radioactive effluent releases to the environment are presented in Table 6.1-2. These are from waste management activities and certain other phases of the UFC process. In NUREG-1437, Rev. 0, the NRC presented an analysis of the effects of radiological effluents from the UFC for the reference reactor, including the effects of radon-222 and technetium-99, which are not addressed in Table S-3. The NRC concluded that the effects of radiological effluents from the UFC for the reference reactor are small. Because the dose to members of the public is a very small fraction of the regulatory limit and an even smaller fraction of natural background exposure, the effects of radiological effluents from the UFC supporting a Natrium plant at the Project site, based on the scaling factor applied to the reference reactor effluents as presented in Table 6.1-2, can also be considered SMALL.

6.1.3.6 Radiological Wastes

Quantities of buried radioactive waste material (LLW, HLW, and TRU wastes), associated with the UFC for a Natrium plant at the Project site are specified in Table 6.1-2. Section 6.1.1.6 provides a discussion of radiological wastes from the UFC, including low-level waste, high-level waste, and spent fuel. Based on this discussion and the information in Table 6.1-2, the environmental impact of radioactive waste disposal from the UFC for a Natrium at the Project

site is expected to be SMALL.

6.1.3.7 Occupational Dose

The annual occupational dose attributable to all phases of the UFC for a Natrium plant at the Project site is presented in Table 6.1-2. Occupational doses would be maintained to meet the dose limits in 10 CFR Part 20, which is 5 rem/yr. On this basis, it is concluded that environmental impacts from this occupational dose are anticipated to be SMALL.

6.1.3.8 Transportation Dose

The transportation dose to workers and the public is presented in Table 6.1-2 for a Natrium Plant at the Project site. Section 6.1.1.8 provides a comparison of this dose to the dose to the NC population from natural background radiation. On this basis, the environmental impacts of transportation are anticipated to be SMALL.

6.1.3.9 Conclusions for the Natrium

Based on the discussion in the above subsections and using Table S-3 as stipulated in 10 CFR 51.51, the environmental effects from the UFC for a Natrium plant at the Project site would be SMALL.

6.1.4 CONCLUSIONS

Although the technology and reactor vendor have not yet been selected for the Project site, the above discussion demonstrates that a comparison to Table S-3, as described in 10 CFR 51.51, is appropriate for all reactors under consideration. Furthermore, the above discussion demonstrates that the UFC supporting a plant with a maximum net power output of 2250 MWe at the Project site has SMALL environmental impacts, regardless of the technology selected.

Table 6.1-1
Scaling Factor – Reference Plant, LWRs, Xe-100, and Natrium Plant

Parameter	10 CFR 51.51 Reference Plant (1000 MWe LWR) Reactor	Project site[a]		
		LWRs	Xe-100	Natrium
Net Electric Output	1000 MWe	2250 MWe[b]	2250 MWe[b]	2250 MWe[b]
Capacity Factor	80 percent	97 percent	95 percent	92.5 percent
Effective Electric Output	800 MWe	2183 MWe	2138 MWe	2081 MWe
Ratio of Effective Electric Output Values to the Reference Plant	1	2.7	2.7	2.6

Notes:

(a) Values are presented for the LWRs, the Xe-100, and the Natrium.
(b) Bounding value for site.

Key: CFR = Code of Federal Regulations; LWR = light water reactor; MWe = megawatt electric

Table 6.1-3
WASH-1248 Fuel Fabrication Environmental Impacts Compared to TRISO Fuel Fabrication Impacts
(Sheet 1 of 3)

Environmental Impact	WASH-1248 Value for the Model Plant	TRISO Value for Fuel Fabricated to Support a Plant Generating 2250 MWe	Comments
Site Size (ac.)	100	110 (TRISO-X fuel fabrication facility area)	The model plant uses less than 5 percent of the land area committed by the rest of the fuel cycle. WASH-1248 notes that actual fuel fabricators surveyed occupied sites ranging from a few acres up to a few thousand acres and that even for a 1000 ac. site, the temporarily committed land for an annual fuel requirement would be less than 5% of that committed by the rest of the fuel cycle. Based on this information, the land use impacts for the TRISO-X fuel fabrication facility are bounded by those described in WASH-1248.
Annual Water Consumption (gallons)	5,200,000[(a)]	81,148,125[(b)(c)]	The model plant uses about 0.05 percent of the water used by the model LWR evaluated by WASH-1248. While the TRISO-X facility requires a larger volume of water to support annual fuel production for a given plant, the amount of water used to support fuel fabrication for the 2250-MWe Xe-100 plant is still less than 0.8 percent of the water used by the model LWR evaluated in WASH-1248.
Power Required Whole facility Annual fuel requirement	 6 MWe 1700 MWh[(a)]	 not available	The model plant uses about 0.5 percent of the electricity of the enrichment plant evaluated by WASH-1248. The power requirement for the TRISO fuel fabrication plant is not available at this time. However, the model plant is assumed to use power generated from coal. The TRISO fuel fabrication plant is located in Oak Ridge, Tennessee. In Tennessee, nearly half of the electric power generated is from nuclear plants and only approximately 20 percent from coal. Therefore, the environmental impacts of power generation to support the facility are lower than those for the model plant because of the lower impact of the plants generating electricity.

Table 6.1-3
WASH-1248 Fuel Fabrication Environmental Impacts Compared to TRISO Fuel Fabrication Impacts
(Sheet 2 of 3)

Environmental Impact	WASH-1248 Value for the Model Plant	TRISO Value for Fuel Fabricated to Support a Plant Generating 2250 MWe	Comments
Annual Natural Gas Usage for Process Heat (cubic feet)	3,600,000	not available	The model plant uses about 4 percent of the natural gas consumed by the total nuclear fuel cycle. The natural gas usage for process heat for the TRISO fuel fabrication facility is not available at this time. While natural gas consumed for process heat represents an environmental impact of the fuel fabrication process, this use allows the production of electricity with nuclear fuel, which results in a substantial reduction in the overall requirements for coal and natural gas as fuels to produce electricity. Thus, the use of fossil fuels in the UFC, including for fuel fabrication, still represents a net savings in the use of resources compared to the case where the electrical output of the nuclear plant is supplied by a coal- or natural gas-fired plant. Table 6.1-2 presents the electrical energy needed by the UFC for a 2250-MWe Xe-100 plant and shows that the impacts associated with this energy use are small compared to plant electrical output.
Liquid Waste Stream Volume (gallons per day)	25,000	70,625[(b)]	At the model plant, this is combined with about 425,000 gpd of process cooling water in the holding ponds prior to release off-site. The TRISO-X facility discharges only to the Oak Ridge Municipal Sewer. While the TRISO-X facility liquid waste stream has a greater volume for the annual fuel requirement to support a given plant, the total facility release is only 0.3 percent of City of Oak Ridge Treatment capacity.
Annual Solid Waste Volume (MT) Whole facility Annual fuel requirement	 680 26	 919 672[(b)]	For the model plant, this consists of calcium fluoride precipitate from the liquid waste stream for retaining on site (11 cubic yards [8.4 cubic meters]) [(e)]

WASH-1248 Fuel Fabrication Environmental Impacts Compared to TRISO Fuel Fabrication Impacts
(Sheet 3 of 3)

Environmental Impact	WASH-1248 Value for the Model Plant	TRISO Value for Fuel Fabricated to Support a Plant Generating 2250 MWe	Comments
Annual Gaseous Airborne Activity Released (curies) Whole facility Annual fuel requirement	 0.005 0.000192[a]	 0.0000452 0.000032[b]	For the model plant, this release is less than 0.1 percent of the applicable 10 CFR Part 20. The TRISO-X facility has a lower release than the model plant.
Annual Liquid Activity Released (mCi)	40	0	For the model plant, this release is less than 10 percent of 10 CFR Part 20 limits for release to an unrestricted area. The TRISO-X fuel fabrication facility does not release radioactive liquid effluent.
Annual Solid Activity for Disposal (mCi)	25[a]	624[d]	Activity shipped per annual fuel requirement[e]

Notes:

(a) 10 CFR 51.51 Table S-3, states that there are 26 annual fuel requirements produced by the model LWR fuel fabrication facility (the fuel fabrication facility produces the annual fuel requirements for 26 1000-MWe reference reactors). This assumption was used to scale whole-facility values to determine the amount attributable to the annual fuel requirement to support one reference reactor.

(b) A process similar to that described in footnote (a) was used for the TRISO-X facility, assuming that the proposed 2250-MWe plant at the Project site would use 11.3 MTU of the total annual facility production of 16 MTU.

(c) Appendix E of WASH-1248 (AEC, 1974) assumed that the model fuel fabrication plant operated 300 days per year. It has also been assumed that the TRISO-X fuel fabrication facility operates for 300 days. This assumption was used in calculating annual water consumption.

(d) This value was calculated using the ratio of activity to volume from WASH-1248, where 26 MT waste attributable to the annual fuel requirement of the reference reactor was associated with 25 mCi, and the 672 MT solid waste associated with the annual fuel requirement for the 2250-MWe Xe-100 plant.

(e) The solid waste volume and the solid radioactive waste activity for disposal generated for the annual fuel requirement of an Xe-100 plant at the Project site exceeds the values determined for the annual fuel requirement of the model LWR plant analyzed in WASH-1248. However, Table 2.1-5 of the TRISO-X Fuel Fabrication Facility ER shows that the extent of impact from waste management is SMALL (TRISO-X, 2022). Section 4.2, of the TRISO-X Fuel Fabrication Facility ER states that shipments of radiological waste meet the surface dose rate limit of 10 CFR 71.47(a) and 49 CFR 173.441(a) and the group of containers meet the 1 m (3.3 ft) dose rate limits of 49 CFR 173.441(d). Additionally, environmental impacts from transporting radioactive materials are identified as SMALL (TRISO-X, 2022).”

Key: MT = metric tons | mCi = millicuries

6.2 TRANSPORTATION OF FUEL AND WASTES

This section discusses the impacts to the environment of normal conditions of transport and postulated transportation accidents involving shipment of radioactive materials including unirradiated fuel, irradiated fuel, and radioactive waste to and from the Project site.

The NRC performed a generic analysis of the environmental effects of the transportation of fresh fuel to and irradiated fuel / radioactive waste from LWRs in the WASH-1238, Environmental Survey of Transportation of Radioactive Materials To and From Nuclear Power Plants (AEC, 1972), and in Supplement 1 to WASH-1238, NUREG-75/038, and found the impact to be small. These documents provided the basis for Table S-4 in 10 CFR 51.52, Environmental effects of transportation of fuel and waste, which summarizes the environmental impacts of transportation of fuel and waste to and from one 3,000 to 5,000 megawatts thermal (MWt) (1,000 to 1,500 MWe) LWR. Impacts are provided for normal conditions of transport and accidents in transport for a reference 1,100 MWe LWR.

Per 10 CFR 51.52, every ER prepared for the construction permit stage or ESP stage or combined license stage of a LWR, and submitted after February 4, 1975, shall contain a statement concerning transportation of fuel and radioactive wastes to and from the reactor. That statement shall indicate that the reactor and this transportation either meet all of the conditions in 10 CFR 51.52(a) or all the conditions of 10 CFR 51.52(b).

As shown in Table 6.2-1, conditions 2 and 3 of 10 CFR 51.52(a) are not met by the technologies considered. More specifically, fuel enrichment for the different technologies shows a minimum enrichment of 4.95 percent, up to 19.75 percent. Furthermore, all the technologies exceed the average level of irradiation to the irradiated fuel of 33,000 megawatt-day per metric ton uranium (MWd/MTU). Therefore, as stated in 10 CFR 51.52(b), a full description and a detailed transportation analysis are required as part of the ER.

6.2.1 COMPONENTS OF A FULL DESCRIPTION AND DETAILED ANALYSIS

As discussed in Section 6.2, the Project site does not meet all of the conditions in 10 CFR 51.52(a), therefore, to be in accordance with 10 CFR 51.52, a full description and a detailed transportation analysis of the environmental effects of transportation of fuel and radioactive waste to and from the Project site, including values for the environmental impact under normal conditions of transport and environmental risk from accidents in transport, is required as part of the ER.

Guidance from Regulatory Guide (RG) 4.2 states that the detailed analysis of transportation impacts should include the following:

- Transportation of unirradiated fuel, including the radiological impacts associated with the normal conditions of transport and the nonradiological impacts associated with transportation accidents.

- Transportation of irradiated fuel, including the radiological impacts associated with the normal conditions of transport and the radiological and nonradiological impacts associated with transportation accidents.

- Transportation of radioactive waste, including the radiological impacts associated with

the normal conditions of transport and the nonradiological impacts associated with transportation accidents.

While radiological impacts associated with transportation accidents involving unirradiated fuel and radioactive waste are not designated in RG 4.2, the impacts are discussed in Section 6.2.1.2 for the Project site.

The detailed transportation analysis utilizes guidance from RG 4.2 and NUREG-1555. As such, the WebTRAGIS and NRC-RADTRAN computer codes are used to determine the impacts of transporting radioactive materials to and from the Project site.

WebTRAGIS is used to determine the distance traveled by truck for each route analyzed in the detailed transportation analysis. For fabricated fuel and radioactive waste, the Highway Route-Controlled Quantities (HRCQ) option is utilized. The irradiated fuel route utilizes the HRCQ-Nevada National Security Site (NNSS) option. The significant output from WebTRAGIS, other than the route itself, is the population densities potentially exposed along the route based on 2010 U.S. Census data (USCB, 2010). WebTRAGIS uses 2010 U.S. Census data because that is the data set that is the population dataset that is maintained in the WebTRAGIS population database. Both the route information and population densities are used as input to NRC-RADTRAN.

NRC-RADTRAN is used to calculate population doses from a single truck shipment given the routes defined by WebTRAGIS. Other parameters utilized for each shipment (during normal conditions of transport and an accident), such as packaging, dose rate from shipment, and characteristics of the truck are used as input for the NRC-RADTRAN analysis.

Annual doses to transportation workers and the general public, and the annual transportation population accident risk to the general public are calculated based on the number of annual shipments, discussed in Section 6.2.2, for each shipment type (i.e., unirradiated fuel, irradiated fuel, and radioactive waste), and the associated results for a single truck shipment from the NRC-RADTRAN output.

6.2.1.1 Radiological Impacts of Normal Conditions of Transport

NRC-RADTRAN is used to calculate the crew and population doses associated with transport of radioactive material during normal conditions to and from the Project site from a single shipment given the routes defined by WebTRAGIS. As mentioned in Section 6.2.1, three types of nuclear shipments are identified to be shipped to and from the Project site: Shipment of fabricated fuel from a fabrication facility, shipment of low-level radwaste from the project site to a disposal site, and shipment of irradiated fuel from the project site to a proposed geological repository. Information used as input into NRC-RADTRAN regarding the dose rate, characteristics of the truck, population density, and other shipment details are contained in Table 6.2-2.

Since the population count from WebTRAGIS uses 2010 Census data (USCB, 2010), the doses need to be adjusted to account for the increase in population for when the plant is expected to receive the first fuel shipment for Unit 1, which is estimated to be in 2033. As such, to account for the total population increase between 2010 and 2033, a scaling factor of 1.185 is applied to the population dose to account for the increase in population. The scaling factor is based on the increase in population from the year 2010 to 2020 of 7.4% and the average increase in population from the year 2000 to 2020 of roughly 0.855% each year. The scale factor is determined by adding the increase in population from the year 2010 to 2020 of 7.4% to the

product of the yearly average population increase of 0.855% by 13 years (i.e., 2033 – 2020 = 13) to result in 1.185 (i.e., 1.074 + [0.00855 x 13]).

Transportation of Unirradiated Fuel During Normal Conditions

WebTRAGIS is used to determine the route from the fuel fabrication facility, which is assumed to be the Framatome fuel fabrication facility in Richland, WA to the Project site. Shipment of fabricated fuel from the Framatome fuel fabrication facility is acceptable because it is the furthest identified licensed fuel fabrication facility to be used from the list of technologies considered for the Project site. Table 6.2-3 shows the shipment route link data utilized from WebTRAGIS. Table 6.2-7 presents the dose from a single shipment and annual dose to the workers and general public associated with shipment of fabricated fuel.

Transportation of Radwaste During Normal Conditions

WebTRAGIS is used to determine the route from the Project site to two potential radwaste disposal facilities, which are assumed to be the Waste Control Specialists (WCS) facility near Andrews, TX and the EnergySolutions disposal facility in Clive UT. Shipment of radwaste to both the WCS facility and EnergySolutions disposal facility is acceptable because both locations accept radwaste from all regions of the United States, pending prior permission (required for WCS). Tables 6.2-4 and 6.2-5 shows the shipment route link data utilized from WebTRAGIS for the WCS and EnergySolutions routes, respectively. Tables 6.2-8 and 6.2-9 presents the dose from a single shipment and annual dose to the workers and general public associated with shipment of radwaste to Andrews, TX and Clive, UT, respectively.

Transportation of Irradiated Fuel During Normal Conditions

WebTRAGIS is used to determine the route from the Project site to a proposed geological repository, which is assumed to be the Yucca Mountain site in Nye County, NV. Shipment of irradiated fuel to the Yucca Mountain site is acceptable because Yucca Mountain is identified as a possible repository for irradiated fuel. Table 6.2-6 shows the shipment route link data utilized from WebTRAGIS. Table 6.2-10 presents the dose from a single shipment and annual dose to the workers and general public associated with shipment of irradiated fuel.

The DOE Resource Handbook on DOE Transportation Risk Assessment suggests an irradiated fuel truck dose rate of 14 millirem per hour (mrem/hr) at 1 meter from the shipment. However, the NRC developed a probabilistic distribution of dose rates based on fuel cooling times that indicates that approximately three-fourths of the spent fuel to be transported will have dose rates less than half of the regulatory limit. Based on the analysis performed by the NRC, the dose rate was reduced to 5 mrem/hr, which is approximately 50 percent confidence interval of the dose rate distribution estimated for future spent fuel shipments.

Conclusion of Normal Conditions of Transport Analysis

Table 6.2-11 presents a summary of the transportation dose to workers and the general public from the Project site.

General public doses in Table 6.2-11 meet the 3 person-rem dose criterion for transportation of fabricated fuel, however, the doses for transportation of radwaste and irradiated fuel exceed the Table S-4 dose criterion. General public doses due to radwaste shipments are determined for the GVH BWRX-300 reactor, which has the largest waste volume of the 6 reactor types

evaluated. The large waste volume along with the large distances to the radwaste facilities result in larger doses to the general public.

While it is briefly noted above, the large distance for each route is a contributor for the dose exceeding the limits contained in Table S-4 of 10 CFR 51.52, a more in-depth discussion is contained in this paragraph. The limits contained in Table S-4 were established using significantly shorter distances than those used in the normal conditions of transport calculation. More specifically, the largest distance traveled for a shipment in WASH-1238 was roughly 1000 mi., which included shipments of fabricated fuel and spent fuel. As can be seen in Tables 6.2-3 through 6.2-6, the distances analyzed in the normal conditions of transport calculation range from 1500 to 2800 mi. Additionally, the doses determined in the normal conditions of transport calculation are further inflated compared to the limits contained in Table S-4 of 10 CFR 51.52 because the population has increased, which is a significant variable in determining the total population dose.

The largest total population dose from transporting material from the Project site of 13.4 person-rem includes shipping radwaste to Clive, UT. This value is lower than the value of 1754 person-rem, determined by the International Commission on Radiological Protection (ICRP) and National Council on Radiation Protection and Measurements (NCRP), that would suggest a result in zero excess health effects. Furthermore, the bounding maximum in-transit dose to a member of the public, determined by NRC-RADTRAN, of 9.66E-05 mrem per radioactive waste shipment can be multiplied by the number of shipments per year to determine the annual maximum individual in-transit dose of 9.70E-02 mrem/yr (i.e., [9.66E-06 mrem/fabricated fuel shipment x 11 fabricated fuel shipments] + [9.66E-05 mrem/radioactive waste shipment x 234 radioactive waste shipments] + [1.35E-03 mrem/irradiated fuel shipment x 55 irradiated fuel shipments]) and compared against the estimated average radiation dose from natural background radiation of 310 mrem/yr, determined in Section 2.9, which results in the annual maximum individual in-transit dose being several orders of magnitude lower than the estimated average radiation dose from natural background radiation. Therefore, while the doses exceed the limits provided in Table S-4, the environmental impact associated with normal conditions of transport of radioactive materials from the Project site is still considered SMALL.

6.2.1.2 Radiological Impacts – Accident Conditions of Transport

NRC-RADTRAN is used to calculate the crew and population risk associated with an accident while transporting radioactive material to and from the Project site from a single shipment given the routes defined by WebTRAGIS. As mentioned in Section 6.2.1, three types of nuclear shipments are identified to be shipped to and from the Project site: Shipment of fabricated fuel from a fabrication facility, shipment of low-level radwaste from the project site to a disposal site, and shipment of irradiated fuel from the project site to a proposed geological repository. Information used as input into NRC-RADTRAN regarding the dose rate, characteristics of the truck, population density, and other shipment details are contained in Table 6.2-12.

Similar to 6.2.1.1, since the population count from WebTRAGIS uses 2010 Census data, the doses need to be adjusted to account for the increase in population for when the plant is expected to receive the first fuel shipment for Unit 1, which is estimated to be in 2033. As such, to account for the total population increase between 2010 and 2033, a scaling factor of 1.185 is applied to the population dose to account for the increase in population (See Section 6.2.1.1).

Accident rates are the probability of an accident per kilometer of travel. The transportation accident analysis utilizes accident rates based on 2006 data instead of the accident rates

provided in NUREG-2266. This is because the accident rates utilized in the transportation accident are larger (i.e., more conservative) than the accident rates provided in NUREG-2266 (which are limited to truck involved accidents). The highway accident rates for each state are shown in Table 6.2-13.

The conditional probability fractions for LWRs are taken from Table 7.31 of NUREG/CR-6672. The conditional probability fractions utilized for the X-energy Xe-100 and TerraPower Natrium are from PNNL-29365 (PNNL, 2020). The conditional probability fractions for each accident scenario has an associated release fraction for each group of radionuclides in the package. Release fractions are typically lower for accident scenarios that are more likely to happen. Similarly, accident scenarios that have a lower probability to happen typically have larger release fractions.

The release fraction for each reactor type is included in the NRC-RADTRAN analysis. The release fraction for LWR technology is taken for each respective reactor type from NUREG-2266, Table B-12 and B-13. Since the Xe-100 and Natrium are non-LWR technologies, the release fractions in NUREG-2266 are not applicable to be used. However, appropriate release fractions are determined in PNNL-29365, where Group 5 applies to the Xe-100 and Group 1 applies to the Natrium reactor. Additionally, all release categories utilize a deposition velocity of 0.1 meters per second (m/s), except for gases, which utilize a deposition velocity of 0 m/s. The release fractions and deposition velocities associated with each reactor technology are shown in Tables 6.2-16 through 6.2-19.

Accident While Transporting Unirradiated Fuel

As stated in WASH-1238 (AEC, 1972), the radiological impact to the environment from an accident while transporting unirradiated fuel is negligible. Therefore, any risk contributed from an accident of unirradiated fuel would not contribute to the risk from an accident while transporting radwaste or irradiated fuel.

Accident While Transporting Radwaste

The WebTRAGIS routes utilized for normal conditions of transport of radwaste are utilized for the transportation accident analysis. Additionally, the radionuclide inventory is a parameter used in the NRC-RADTRAN analysis. The radionuclide inventory for solid radwaste is adjusted based on Table 3.4-8 of this ER. It should be noted that not all radionuclides from Table 3.4-8 of this ER are used in the detailed analysis. The radionuclides utilized from Table 3.4-8 are presented in Table 6.2-15. These radionuclides were utilized because they are contained in the radionuclide library contained in NRC-RADTRAN.

Accident While Transporting Irradiated Fuel

The WebTRAGIS route utilized for normal conditions of transport of irradiated fuel is utilized for the transportation accident analysis. Additionally, the radionuclide inventory associated with irradiated fuel shipments is taken from Table A-1 of NUREG-2266 (NRC, 2024) and is presented in Table 6.2-14 on a 0.5 MTU fuel assembly basis.

Conclusion of Transportation Accident Analysis

Table 6.2-20 presents a summary of the transportation risk to the general public from the Project site due to an accident while transporting radioactive material. While a detailed

transportation analysis is required as part of the ER since all the reactor technologies in the Plant Parameter Envelope (PPE) exceed the burnup criterion in 10 CFR 51.52(a), no numerical value is listed in Table S-4 of 10 CFR 51.52 for comparison of environmental risks. However, the bounding risk from a single route can be used to compare against values that affect health and the population dose associated with background radiation. The bounding risk from a single route is associated with transportation of irradiated fuel from a pressurized-water reactor (PWR), which is shown as 3.04E-03 person-rem. Similar to 6.2.1.1, this value is lower than the value of 1754 person-rem, determined by the ICRP and NCRP, that results in zero excess health effects. Additionally, the total estimated collective annual population dose from natural background radiation along the route is estimated to be 7.00E+06 person-rem using the estimated average radiation dose from natural background radiation of 310 mrem/yr, determined in Section 2.9 of this ER. Although the total estimated collective population background dose is associated with only one route, the background dose from one route is larger than the total annual transportation population risk associated with shipment of radioactive material for each reactor technology. Therefore, the environmental risk associated with transportation accidents in this evaluation is considered SMALL.

6.2.1.3 Non-Radiological Impacts of Transport

Non-radiological impacts associated with postulated transportation accidents are calculated for:

- Injuries and fatalities during transportation of unirradiated fuel
- Injuries and fatalities during transportation of irradiated fuel
- Injuries and fatalities during transportation of radwaste

The non-radiological impacts from postulated transportation accidents are evaluated using the WebTRAGIS code to define appropriate routing and population density along the route, and NRC-RADTRAN to calculate the non-radiological impacts (e.g., injuries and fatalities).

The injury and fatality rates (i.e., injuries/accident and fatalities/accident) are determined by using the accidents per km, injuries per km, and fatalities per km from NUREG-2266 and are presented in Table 6.2-21. More specifically, the injuries per km or fatalities per km are divided by the accidents per km. The accident rates from NUREG-2266, presented in Table 6.2-21, are used for the non-radiological analysis.

The non-radiological impacts are based on round-trip distances because the return of the empty truck is included in the evaluation. Therefore, the frequency (fatalities/shipment and injuries/shipment) are multiplied by double the number of shipments identified in Section 6.2.2 for each transportation route.

Accident While Transporting Unirradiated Fuel

The routing parameters that are used to analyze non-radiological impacts of transporting unirradiated fuel are the same as those used to analyze the radiological impacts associated with transporting unirradiated fuel. Additionally, the accident rates and injury/fatality rates from Table 6.2-21 are utilized in the analysis. The number of unirradiated fuel shipments each year is identified in Section 6.2.2.1.

Accident While Transporting Radwaste

The routing parameters that are used to analyze non-radiological impacts of transporting radwaste are the same as those used to analyze the radiological impacts associated with transporting radwaste. Additionally, the accident rates and injury/fatality rates from Table 6.2-21 are utilized in the analysis. The number of radwaste shipments each year is identified in Section 6.2.2.3.

Accident While Transporting Irradiated Fuel

The routing parameters that are used to analyze non-radiological impacts of transporting irradiated fuel are the same as those used to analyze the radiological impacts associated with transporting irradiated fuel. Additionally, the accident rates and injury/fatality rates from Table 6.2-21 are utilized in the analysis. The number of irradiated fuel shipments each year is identified in Section 6.2.2.2.

Conclusion of Transportation Accident Analysis

Table 6.2-22 uses the NRC-RADTRAN injury and fatality results per shipment to determine the injuries and fatalities per 10 years and 100 years, respectively, from the Project site due to an accident while transporting radioactive material. A detailed transportation analysis is required as part of the ER since all the reactor technologies in the Plant Parameter Envelope (PPE) exceed the burnup criterion in 10 CFR 51.52(a). A numerical value of 1 fatal injury in 100 reactor years and 1 nonfatal injury in 10 reactor years is listed in Table S-4 of 10 CFR 51.52 for comparison of environmental risks for non-radiological impacts. The estimated number of fatal injuries is 2.54E-02 per reactor year (2.54 in 100 years) for the Project site, which is more than the fatal numerical value listed in Table S-4. The estimated number of non-fatal injuries is 3.13E-01 per reactor year (3.13 in 10 reactor years), which is more than the non-fatal numerical value listed in Table S-4.

The values contained in Table S-4 were established using significantly shorter distances than those used in the analysis for non-radiological impacts associated with an accident while transporting radioactive material. More specifically, the largest distance traveled for a shipment in WASH-1238 was roughly 1000 mi., which included shipments of fuel and radwaste. As can be seen in Tables 6.2-3 through 6.2-6, the distances analyzed for the non-radiological transport analysis range from 1500 to 2800 mi. Furthermore, the injury and fatality frequencies include a return trip, which increases the total distance traveled by a factor of two. While the increase in distance directly contributes to the increase in injury and fatality frequencies, less than one fatality and non-fatal injury is estimated per year. Therefore, the non-radiological environmental risks associated with transportation accidents in this evaluation is considered SMALL.

6.2.2 ESTIMATING THE NUMBER OF SHIPMENTS AND NORMALIZATION OF SHIPMENTS

As mentioned in Section 6.2.1, NRC-RADTRAN is used to calculate population doses from a single truck shipment given the routes defined by WebTRAGIS. However, to fully determine the annual population dose for each route defined by WebTRAGIS, the estimated annual number of shipments for each route type needs to be determined and normalized to a 1100 MWe LWR using guidance from RG 4.2. The following subsections discuss the methods used to determine the estimated number of shipments for each route analyzed in this section.

6.2.2.1 Number of Shipments of Unirradiated Fuel

RG 4.2 is used to estimate and normalize the number of shipments for fabricated fuel. Parameters given in Table 6.2-1 for the six reactor types, discussed in the PPE, are used with the equations given in RG 4.2.

Since the equation requires the number of initial core shipments and the average annual shipment per year over 39 years, and the PPE provides the number of fuel assemblies, the methodology in WASH-1238 (AEC, 1972) is utilized to determine the number of shipments required for initial core load and reloading using the number of fuel assemblies. WASH-1238 states that two fuel assemblies consist of one package and a truckload minimally fits six packages.

Using this information, the BWRX-300 reactor is used to determine the number of unnormalized fabricated fuel shipments since that reactor results in the maximum number of shipments, which is determined to be 21 unnormalized shipments per year. The reactor power level and capacity factor given for the BWRX-300 for the Project site are used with the normalization equation given in RG 4.2, which results in 11 normalized shipments per year.

6.2.2.2 Number of Shipments of Irradiated Fuel

RG 4.2 is used to estimate and normalize the number of shipments for irradiated fuel. RG 4.2 states that a transportation cask capacity of 0.5 MTU per shipment should be used to estimate the number of unnormalized shipments. The Westinghouse AP300 contains the largest amount of MTU per fuel reload from the technologies considered. Following the guidance from RG 4.2 of 0.5 MTU per shipment, 114 unnormalized shipments of irradiated fuel are estimated each year. The reactor power level and capacity factor given for the AP300 for the Project site are used with the normalization equation given in RG 4.2, which results in 55 normalized shipments per year.

However, the guidance in RG 4.2 regarding a transportation cask capacity of 0.5 MTU per shipment is based on shipping casks designed to transport shorter-cooled fuel (i.e., 90 days out of the reactor). Since there are no active irradiated fuel disposal repositories, irradiated fuel is expected to be cooled longer than 90 days before shipped from the site. The cask capacity in the Environmental Impact Statement (EIS) for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada assumes 1.8 MTU. The NRC believes this is a reasonable projection for future spent fuel truck shipping capacities; therefore, use of 1.8 MTU per shipment is utilized for the normal conditions of transport analysis in this ER. Using the larger cask capacity from the EIS of 1.8 MTU the number of irradiated fuel shipments is reduced to 32 shipments per year, which is normalized to 16 shipments of irradiated fuel per year.

6.2.2.3 Number of Shipments of Radwaste

RG 4.2 is used to estimate and normalize the number of shipments for radwaste. RG 4.2 states that a shipment capacity of 2.34 cubic meters (m^3) per shipment should be used to estimate the number of unnormalized shipments. As can be seen in Table 6.2-1, the BWRX-300 generates the largest waste volume per year. Utilizing the guidance from RG 4.2, 472 unnormalized radwaste shipments are estimated each year. The reactor power level and capacity factor given for the BWRX-300 for the Project site is used with the normalization equation given in RG 4.2, which results in 234 normalized shipments per year.

Table 6.2-1
PPE Reactor Parameters

Reactor Technology (Type)	Power Level (MWe)	Capacity Factor	Number of Units/Reactor Type	Initial Fuel Loading # of Assemblies	Cycle Duration (Reload Frequency)	# Reload Assemblies	Annual Radioactive Waste Volume (ft^3/yr)	Fuel Enrichment	Maximum Average Assembly Burnup (MWD/MTU)
BWRX-300 (BWR)	1890	94	6	1440	12 to 24 months	192 (12 months) 432 (24 months)	38,988	5%	65,000
AP300 (PWR)	1896	> 97	6	726	36 months	360	9162	< 5%	43,000
VOYGR (PWR)	924	≥ 95	12	444	18 months	156	8460	≤ 4.95%	62,000
Xe-100 (HTGR)	1252	95	14	–	Online	–	16,660	15.5%	169,450
SMR-300 (PWR)	2310	>95	6	–	18 months	–	22,219	< 5%	51,000
Natrium (Sodium)	654	92.5	2	–[(a)]	24 months	–	4140	Less than or equal to 19.75%	160,000

Note:
(a) Section 6.2.2.1 of the Kemmerer Power Station Unit 1 Environmental Report (TerraPower, 2024) states that an annual average of 1.4 shipments of fabricated fuel is expected to be shipped for one TerraPower Natrium unit; therefore, the number of unnormalized fabricated fuel shipments per year for two TerraPower Natrium units is estimated at roughly 3 shipments per year.

Key: BWR = boiling-water reactor; HTGR = High-Temperature Gas-Cooled Reactor; ft^3/yr = cubic feet per year; MWD/MTU = megawatt-day per metric ton uranium; MWe = megawatts electric; PWR = pressurized-water reactor

Virginia	4.54E-07	1.73E-07	3.81E-01	1.05E-08	2.31E-02
Washington	2.48E-07	4.68E-08	1.89E-01	8.44E-09	3.40E-02
Wyoming	3.55E-07	8.23E-08	2.32E-01	5.67E-09	1.60E-02

Notes:

(a) The accident, injury, and fatality rates per km are taken from NUREG-2266 (NRC, 2024).

(b) The injury and fatality rates per accident are determined by dividing the injury and fatality rates per km from columns three and five by the accident rate in column two.

Table 6.2-22
Project Site Annual Transportation Non-Radiological Accident Impacts Summary

Injury Analysis				
Shipment Type	**Injuries per Shipment**	**Shipments per Year**	**Injuries per Year[a]**	**Injuries per 10 Years[b]**
Fabricated Fuel (Richland, WA)	5.32E-04	11	1.17E-02	1.17E-01
Irradiated Fuel (Nye County, NV)	5.31E-04	55	5.84E-02	5.84E-01
Radwaste (Clive, UT)	4.60E-04	234	2.15E-01	2.15E+00
Radwaste (Andrews, TX)	5.20E-04	234	2.43E-01	2.43E+00
Total[d]	–	300	3.13E-01	3.13E+00
Fatality Analysis				
Shipment Type	**Fatalities per Shipment**	**Shipments per Year**	**Fatalities per Year[a]**	**Fatalities per 100 Years[c]**
Fabricated Fuel (Richland, WA)	4.92E-05	11	1.08E-03	1.08E-01
Irradiated Fuel (Nye County, NV)	4.94E-05	55	5.43E-03	5.43E-01
Radwaste (Clive, UT)	4.04E-05	234	1.89E-02	1.89E+00
Radwaste (Andrews, TX)	3.31E-05	234	1.55E-02	1.55E+00
Total[d]	–	300	2.54E-02	2.54E+00

Notes:

(a) The injuries/fatalities per year are determined as a product of the injuries/fatalities per shipment and double the number of shipments per year.

(b) The injuries per 10 years is determined by multiplying the injuries per year by a factor of 10.

(c) The fatalities per 100 years is determined by multiplying the fatalities per year by a factor of 100.

(d) The totals row for both the injury and fatality analysis sums the fabricated fuel value, irradiated fuel value, and the larger radwaste value between the Clive, UT route and the Andrews, TX route.

6.3 DECOMMISSIONING

This section reviews the environmental impacts of decommissioning the Project site. The NRC defines decommissioning in 10 CFR 50.2, which involves safely removing the facility from service and reducing residual radioactivity to levels that allow for either unrestricted property release or release under restricted conditions along with the termination of the operating license.

Upon license termination, both the NRC and the licensee must follow 10 CFR 50.82, for decommissioning actions, ensuring that the radiological criteria for license termination, as specified in 10 CFR Part 20, Subpart E, are satisfied.

NRC regulation 10 CFR 50.82 prohibits decommissioning activities that result in significant environmental impacts not previously reviewed. Licensees can refer to the NUREG-0586, *Generic Environmental Impact Statement (GEIS) on Decommissioning of Nuclear Facilities*, Supplement 1 (GEIS-DECOM), for guidance. Published in 2002, the GEIS-DECOM incorporates technological advances, operational experience, and regulatory changes since the original 1988 version. It outlines decommissioning activities and establishes an envelope of potential environmental impacts associated with the process. Because detailed decommissioning plans are only required after a decision to cease operations, this section focuses on the general environmental impacts of decommissioning.

6.3.1 DECOMMISSIONING APPROACH

Environmental impacts from three decommissioning options are evaluated in the GEIS-DECOM and include:

- Immediate Dismantling (DECON): The equipment, structures, and portions of the facility and site that contain radioactive contaminants are removed or decontaminated to a level that permits termination of the license shortly after cessation of operations. DECON comprises four distinct periods of effort: (1) pre-shutdown planning/engineering, (2) facility deactivation and transition (no activities are conducted during this period that will affect the safe operation of the spent fuel pool), (3) decontamination and dismantlement with concurrent operations in the spent-fuel pool until the pool inventory is zero, and (4) license termination.

- Safe Storage (SAFSTOR): The facility is placed in a safe, stable condition and maintained in that state until it is subsequently decontaminated and dismantled to levels that permit license termination. During SAFSTOR, a facility is left intact, but the fuel is removed from the reactor vessel and radioactive liquids are drained from systems and components and then processed. Radioactive decay occurs during the SAFSTOR period, thus reducing the quantity of contaminated and radioactive material that must be disposed of during the decontamination and dismantlement of the facility at the end of the storage period.

- Entombment (ENTOMB): This alternative involves encasing radioactive systems, structures, and components (SSC) in a structurally long-lived substance, such as concrete. The entombed structure is appropriately maintained, and continued surveillance is carried out until the radioactivity decays to a level that permits termination of the license.

NRC regulations do not require ESP or combined license applicants to select one of these decommissioning alternatives or prepare specific decommissioning plans. Applicants must prepare these plans after a decision to cease operations is made, as outlined in 10 CFR 50.82.

6.3.1.1 Scope of Decommissioning Activities

Environmental impacts during decommissioning arise from the removal of SSC, the management of radioactive materials, and the potential for land contamination. Activities and impacts the NRC considered to be within the scope of the GEIS-DECOM include:

- Activities performed in preparation of removing the facility from service such as, removal of fuel from the reactor and organizational changes, beginning when the licensee certifies that the facility has permanently ceased operations.
- Activities performed in support and the resulting impacts of radiological decommissioning, including decontamination and dismantlement of radioactive SSC and any activities required to support the decontamination and dismantlement process.
- Activities performed in support of dismantlement of nonradiological SSCs required for the operation of the reactor, such as the cooling towers and backup generator buildings.
- Activities performed up to license termination and their resulting impacts as provided in the definition of decommissioning such as removal of radioactive waste.
- Nonradiological impacts occurring after license termination from activities conducted during decommissioning.
- Activities related to release of the facility such as any necessary site boundary modifications or ongoing surveillance.
- Human health impacts from radiological and nonradiological decommissioning activities.
- Activities related to preparing the facility for entombment, if selected as part of the decommissioning strategy.

Decommissioning activities will comply with the provisions of 10 CFR 50.82 and are considered during the reactor technology decision process for the site, which are anticipated to be within the bounding parameters established in the GEIS-DECOM.

6.3.2 ENVIRONMENTAL IMPACTS OF DECOMMISSIONING

The NRC's evaluation of the environmental impacts of decommissioning presented in the GEIS-DECOM, considered 22 nuclear units with thermal power ratings ranging from 23 MWt to 3411 MWt per unit, which were shut down between 1963 and 1997. The technologies analyzed included LWRs, two high-temperature gas-cooled reactors, and a fast breeder reactor. Three of these units were permanently shut-down facilities.

The GEIS-DECOM concludes that decommissioning a nuclear facility generally has a positive environmental impact. Environmental effects on air quality, water quality, and ecosystems are expected to be smaller during decommissioning than during construction and operation. Based on the assessed environmental issues, most impacts are generic and SMALL (defined in 6.3.2.1) for all nuclear plants, regardless of the decommissioning activity.

However, if decommissioning activities occur beyond the operational area, these are considered

site-specific impacts that require further analysis. These site-specific impacts can include off-site land use to support decommissioning activities, such as land used for waste burial or storage. Impacts on aquatic and terrestrial resources outside of the facility's operational area may result from runoff or additional land clearing, and impacts to cultural, historic, or archeological resources beyond the operational area such as needing additional corridors.

The primary environmental impact, regardless of the chosen decommissioning option, is the use of land for off-site waste burial. On-site disposal is not considered when using the DECON approach, as the focus is on removing contamination and waste. Additionally, the decommissioning process can create both positive and negative socioeconomic effects on the local community. These include increased demands on infrastructure such as housing, transportation, services, and economic contributions from workers employed to carry out the decommissioning tasks.

Impacts from decommissioning are expected to be smaller than those during construction and will be bounded by the GEIS-DECOM.

6.3.2.1 Levels of Significance and Applicability of Environmental Impacts

The GEIS-DECOM provides a measure of significance and severity of potential environmental impacts and the applicability of these impacts to a variety of nuclear plants both permanently shut down and operating. The significance of the environmental impact is described as either SMALL, MODERATE, or LARGE. The definitions of significance are as follows:

- SMALL – Environmental impacts are not detectable or are so minor that they will neither destabilize nor noticeably alter any important attribute of the resource. For the purposes of assessing radiological impacts in NUREG-0586, the NRC concluded that radiological impacts are considered small if the impacts do not exceed permissible levels in the NRC's regulations.
- MODERATE – Environmental effects are sufficient to alter noticeably, but not to destabilize, important attributes of the resource.
- LARGE – Environmental effects are clearly noticeable and are sufficient to destabilize important attributes of the resource.

The applicability of these impacts to a nuclear plant decommissioning activities is categorized as either generic or site-specific. Environmental issues categorized as generic can be applied to all nuclear plants, while the site-specific category requires further evaluation as part of the decommissioning plan submitted in accordance with 10 CFR 50.82.

Environmental issues were assessed and most of the impacts were determined to be generic and SMALL, because the impacts are limited to operational areas. Threatened and endangered species was identified as an area that requires site-specific analysis. Four issues were determined to be conditionally site-specific relating to land use, aquatic ecology, terrestrial ecology, and historic and cultural resources primarily involving off-site areas to support decommissioning activities.

The GEIS-DECOM concluded that decommissioning activities closely resemble construction activities, meaning their associated impacts are similar to those described in Chapter 4 of this ER. Based on the findings in ER Chapter 4, the environmental impacts from decommissioning activities are anticipated to be SMALL to MODERATE. These impacts will be evaluated in more

detail pursuant to the requirements specified in 10 CFR 50.82 prior to ceasing operations.

6.3.2.2 Air Quality Impacts from Greenhouse Gases

The GEIS-DECOM does not specifically address the GHG footprint of decommissioning activities. However, it does conclude that the decommissioning workforce is expected to be smaller than the operational workforce and that the decontamination and demolition activities could take up to ten years to complete. Given this information, the NRC prepared Attachment 1 of COL/ESP-ISG-026, which provides a generic GHG footprint.

Using a reference 1000-MWe reactor, the NRC staff estimated the GHG footprint for various nuclear plant activities, including decommissioning. Based on the GEIS-DECOM and evaluation of air quality impacts from GHG in COL/ESP-ISG-026, the NRC concludes that if regulatory requirements on decommissioning activities are met, the decommissioning activities will result in a SMALL impact.

Construction activities at the Project site are described in Section 4.7 and GHG emissions are detailed in Section 4.7.1.3. Based on the advanced technologies being considered for the site, the GHG estimates from the 1000-MWe reference reactor in COL/ESP-ISG-026 are considered conservative given SMRs have a modular design, smaller footprint, fewer components to dismantle, and a lower power output per reactor. Decommissioning activities at the Project site are anticipated to fall within the bounds of the GEIS-DECOM and GHG emissions will be bounded by COL/ESP-ISG-026.

6.3.3 FINANCIAL ASSURANCE FOR DECOMMISSIONING

The ESP process outlined in 10 CFR 52.17 requires site-specific factors such as environmental considerations and site-safety characteristics rather than financial details related to construction, operation, and decommissioning of the site. As such, the NRC regulation 10 CFR 50.75, which requires financial resources for reasonable assurance to perform decommissioning, does not apply to ESP applications. The following information provides general information relevant to SMR and advanced reactor decommissioning costs.

Currently, the NRC regulations do not provide specific decommissioning cost estimates formulas for SMR designs. They do allow the use of a site-specific estimate instead of the amount calculated through a generic formula for large pressurized-water and boiling-water reactors, as long as the site-specific estimate is equal to or greater than the amount of the generic formula.

With respect for funding assurance of advanced nuclear technologies, the NRC has identified some differences between advanced SMR technologies and previously licensed reactors in SECY-11-0181, such as:

- Reduced size and quantity of components and equipment to be disposed.
- Reduced area to be decontaminated (depending on the number of modules).
- Possible difficulty with accessibility for decontamination because of the small size of the components.
- Possible difficulties related to the decommissioning of modules while other modules are in operation.

Additionally, in 2004 the DOE funded a compilation of five studies that included a comparative analysis of decommissioning and funding requirements between existing reactors and advanced reactors. Four advanced reactor designs were evaluated using the prompt decommissioning alternative, DECON, which is undertaken shortly after the facility ceases operation (DOE, 2004).

The decommissioning cost estimates for advanced reactors consider typical site features, such as the steam supply systems, power generation, support services, buildings, and ancillary facilities. These estimates are based on necessary assumptions like regulations, project risks, and low-level radioactive waste disposal practices. The main costs come from labor and managing radioactive waste (DOE, 2004). The 2004 DOE, study concluded that with similar operating and management assumptions, decommissioning costs for advanced reactors are comparable to those for existing reactors, with some savings due to smaller plant inventories.

Under current regulations, to obtain permission to use a site-specific estimate less than the mandatory minimum in 10 CFR 50.75, an applicant would have to request and technically justify an exemption from the regulation. Requirements for financial assurance detailed in 10 CFR 50.33(k)(1) will be provided as part of the construction permit or license application.

6.3.4 SUMMARY

Duke Energy compared the activities analyzed in the GEIS-DECOM (NUREG-0586) on the environmental impacts of decommissioning the existing fleet of domestic nuclear power reactors with those used by DOE to estimate decommissioning costs for advanced reactor designs and determined that the scope of activities is generally the same.

GLOSSARY

Term	Definition
°C	degree Celsius
°F	degree Fahrenheit
ac.	acre
APE	area of potential effect
BCSS	Belews Creek Steam Station
BMP	best management practice
CAA	Clean Air Act
CAM	Chatham Advanced Manufacturing
CCW	condenser cooling water
CFR	Code of Federal Regulations
cfs	cubic feet per second
CO_2-eq	carbon dioxide equivalent
CWA	Clean Water Act
dBA	A-weighted decibel
DBA	Design Basis Accident
EAB	exclusion area boundary
EMF	electromagnetic field
ESF	Educational State Forest

Term	Definition
FERC	Federal Energy Regulatory Commission
FGD	flue gas desulphurization
ft.	feet
GAI	geographic area of interest
GHG	greenhouse gas
GTCC	Guilford Technical Community College
ha	hectare
HALEU	high-assay, low-enriched uranium
km	kilometer
LPZ	low population zone
LWR	light-water reactor
m	meter
m^3/s	cubic meters per second
MACCS	MELCOR Accident Consequences Code System
mi.	mile
MMT	million metric tons
MVP	Mountain Valley Pipeline
MWe	megawatts electric

Term	Definition
MWIS	makeup water intake structure
NC	North Carolina
NCDEQ	North Carolina Department of Environmental Quality
NCTPC	North Carolina Transmission Planning Cooperative
NDA	net disturbance area
NPDES	National Pollution Discharge Elimination System
NRC	U.S. Nuclear Regulatory Commission
NRHP	National Register of Historic Places
NUREG	NRC Technical Report designation
OSHA	U.S. Occupational Health and Safety Administration
Piedmont	Piedmont physiographic province
PLC	Piedmont Land Conservancy
PRA	probabilistic risk assessment
Project	All nuclear site development proposed by the applicant including transmission lines, access roads, utility corridors supporting the facility, etc.
Project Region	The area encompassed within a 50-mile (80-km) radius of the Belews Creek, NC site bounding limit unless otherwise specified for a particular resource
Project site	Belews Creek, NC site

Term	Definition
Project Vicinity	The area encompassed within a 6-mile (10-km) radius of the Project Site Center Point unless otherwise specified for a particular resource
rem	roentgen equivalent man
rev.	revision
RFFA	reasonably foreseeable future action
RNG	renewable natural gas
ROI	Region of Influence
SMR	small modular reactor
SPCC	spill prevention, control, and countermeasure
Sv	sievert
SWPPP	stormwater pollution prevention plan
TEDE	total effective dose equivalent
TRISO	TRi-structural ISOtropic
UFC	uranium fuel cycle
USACE	U.S. Army Corps of Engineers
USEPA	U.S. Environmental Protection Agency
VADCR	Virginia Department of Conservation and Recreation
WTP	Water Treatment Plant

Chapter 7 Cumulative Impacts

Cumulative impacts of the proposed action and all other past, present, and reasonably foreseeable future actions (RFFAs) in the geographic areas of interest (GAIs) for various impacted resources are described in this chapter. After a brief introduction to cumulative impact analysis, the chapter contains the following sections:

- Past, Present, and Reasonably Foreseeable Future Actions – Section 7.1
- Resource Impact Assessment – Section 7.2
- Impact Assessment Conclusions – Section 7.3

The U.S. Nuclear Regulatory Commission (NRC), under Title 10 of the Code of Federal Regulations (CFR) Part 51 (10 CFR 51), implements the National Environmental Policy Act of 1969, as amended (42 U.S. Code § 4321 et seq.). The regulations in 10 CFR 51.71(d) require the NRC to evaluate the cumulative impacts of proposals under its review.

Cumulative impacts are the impacts on the environment that result from the incremental impact of an action when added to other past, present, and RFFAs regardless of what agency (federal or nonfederal) or person undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions that take place over time.

The cumulative impact analysis focuses on the environmental resources of concern and the geographic areas where site-specific activities—both direct and indirect—could potentially alter (degrade) the quality of regional resources. For each resource area, the GAI refers to the specific impact areas over which past, present, and RFFAs could contribute to cumulative impacts. As indicated by Regulatory Guide 4.2, Rev. 3, the GAIs for each environmental resource must be suited both to the resource and the individual action under consideration.

Therefore, the GAI may be different for each resource. Table 7.1-1 identifies the GAI for each resource considered in the cumulative effects analysis.

The cumulative impact analysis evaluates the combined effects of the proposed action (i.e., the Project) with the past, present, and RFFAs within the GAI of each resource. It specifically considers the incremental effects of building and operation activities contained in Chapters 4 and 5. The analysis incorporates the effects of past and present actions into the baseline environmental conditions described in Chapter 2. It also accounts for the potential effects of RFFAs listed in Table 7.1-2 within the specified GAI of each resource, as described in Section 7.2.

The assessment of cumulative effects to each of the identified environmental resources are provided in Section 7.2. Table 7.2-1 provides a summary of the cumulative impact on each resource.

7.1 PAST, PRESENT, AND REASONABLY FORESEEABLE FUTURE ACTIONS

Table 7.1-2 identifies relevant past, present, and RFFAs within the 50-mile (mi.) (80-kilometer [km]) Project Region. It highlights past and present actions that may have significantly affected the existing environment as described in Chapter 2. RFFAs include future actions likely to occur and are capable of contributing to cumulative impacts.

To support the cumulative impacts analysis, a search was conducted to identify other relevant projects in the Project Region. This search included information from regional economic development agencies, state and federal agencies, county and municipal governments, and additional sources. Sources used to identify past, present, and RFFAs are referenced in the status column of Table 7.1-2.

The analysis considers actions to be reasonably foreseeable when supported by published permit applications, secured funding, or reasonable extensions of current trends. It excludes actions deemed speculative, conceptual, or lacking concrete evidence of progression.

7.1.1 EFFECTS OF BELEWS CREEK STEAM STATION CLOSURE

Among the RFFAs identified in Table 7.1-2, the closure of Belews Creek Steam Station (BCSS) is noted to have particular relevance to the assessment of cumulative effects in conjunction with the Project. As described in Section 1.2, the proposed federal action is the NRC issuance of an Early Site Permit under 10 CFR Part 52.

As described in Section 1.3.2, the building and operational schedule has not been established. However, as described in Section 3.3.5, a Conceptual Preconstruction and Construction Activities Schedule has been developed to support analyses. Building of the advanced reactors at the Belews Creek, NC site (Project site) is anticipated to proceed in a phased manner over several years. In conjunction with this phased approach, Duke Energy Carolinas, LLC (Duke Energy) will also derate the operations of BCSS in a manner that replaces and balances overall generation capacity between the Project and BCSS. This transitional period is known as the “phased implementation period.”

The closure of BCSS is considered an RFFA (see Table 7.1-2). Deconstruction of BCSS is also considered reasonably foreseeable (see Table 7.1-2), but this action would not be undertaken during the phased implementation of the Project. Phased implementation of the Project, in conjunction with BCSS closure, results in gradual changes in the environmental conditions relative to the selected resources described in Chapter 2 of this Environmental Report. The effects of BCSS closure result in conditions in which the relevant GAIs are not influenced by BCSS operations. These effects are characterized in this subsection. Furthermore, because such effects of BCSS closure have near-term temporal and spatial effects relative to the Project, such effects are used in the assessment of Project impacts in Chapter 5 as appropriate.

Key considerations regarding the BCSS closure that affect the characteristics of the affected environment include:

- Belews Lake water levels are no longer influenced by BCSS consumptive uses (similar effects continue with Project operations) (see Section 5.2.1).
- Water circulation in Belews Lake is no longer influenced by BCSS condenser cooling water (CCW) intake and discharge flow. (Effects not prevalent in Project operations) (see Section 5.2.1).
- Reduced water use by BCSS to support flue gas desulphurization (FGD) operations, forced evaporation, and other water uses. (Similar effects continue with Project operations) (see Section 5.2.2).

- Authorized pumping operations associated with the makeup water intake structure (MWIS) on the Dan River are transferred to Project operations (Effects transition to Project operations) (see Section 5.2.2).
- Water quality that reflects characteristics lacking the effects of wastewater discharge inputs from fossil fuel power generation including discharge from the emergency spillway of the South Coal Pile Basin, treated flue gas desulfurization wet scrubber wastewater, ash basin dewatering discharge, once-through non-contact chiller water, industrial stormwater, and once-through cooling water and intake screen backwash (Effects generally not present during Project operations) (see Section 5.2.3).
- Lake water temperatures that reflect characteristics of a lake lacking substantive thermal input from power generation (Effects not present during Project operations) (see Section 5.2.3).
- Elimination of air emissions from BCSS.
- Cessation of operational noise from BCSS.

Accordingly, Duke Energy considered the effects of BCSS closure on all relevant environmental resources to assess the contribution of BCSS closure on cumulative effects. The following subsections summarize the anticipated effects of the BCSS action on relevant environmental resources for the purposes of this cumulative effects analysis.

7.1.2 RESOURCE ANALYSIS

The effects of BCSS closure on groundwater, terrestrial ecology, demographics, traffic, employment, nonradiological health, and nonradioactive waste management were also reviewed. However, these resources are not included in the analysis below because they are not adversely affected, or the effects are negligible. Therefore, only the resources below are considered in greater detail to provide a characterization of the relevant substantive effects of BCSS closure relative to the effects of the Project.

7.1.2.1 Surface Water Resources

Effects of BCSS closure on relevant surface water resources are described in this subsection. Effects of Project operations for surface water are examined in Sections 5.2.1 and 5.2.3.

7.1.2.1.1 Belews Lake Water Levels and Circulation

BCSS closure results in a condition in which Belews Lake is not subject to water-level fluctuations from BCSS operational water use, including forced evaporation and consumptive use. Forced evaporation is a type of consumptive use calculated separately in the hydrologic model due to its influence on water levels at Belews Lake. Under BCSS closure, Duke Energy continues to maintain and operate the Belews Lake dam and spillway. Water levels are controlled by the spillway in response to lake water levels resulting from direct precipitation and runoff along with losses to groundwater; however, as described in Section 5.2, this condition is largely theoretical and is not expected to persist because at no point will there be a time frame when no generation is present on the lake prior to advanced reactor commissioning. Although Belews Lake water levels are no longer influenced by BCSS consumptive uses, similar effects continue with Project operations.

BCSS closure also affects circulation patterns in Belews Lake. As described in Section 2.2.1.1.3, the BCSS CCW flow influences lake circulation patterns whereby water from the CCW discharge flows through the CCW canal and into the Belews Creek arm. As illustrated in Figure 2.2-3 general circulation patterns carry flow within the lake into the West Belews Creek arm and back to the BCSS cooling water intake structure. However, under BCSS closure, the influence of CCW flow is eliminated, resulting in circulation patterns that are more influenced by tributary inflows, and releases from the spillway.

7.1.2.1.2 Belews Lake Water Quality

Thermal loading to Belews Lake is significantly reduced in conjunction with the closure of BCSS. The CCW discharge would cease, and heated effluent would no longer disperse within the West Belews Creek arm or be conveyed via the CCW canal to the Belews Creek arm as illustrated in Figures 2.2-16 and 2.2-17 (summer and winter temperatures, respectively). As described in Section 5.2.3.1.2, temperatures within Belews Lake are affected and undergo a process in which temperatures are reduced and general cooling occurs within each reach of Belews Lake until temperatures stabilize to a condition influenced mainly by seasonal patterns in a manner similar to Mayo Reservoir, a similar regional lake with minimal anthropogenic heat load. Water temperatures within the West Belews Creek arm of Belews Lake would resemble those observed in the other areas of Belews Lake not influenced by BCSS thermal inputs.

Across Belews Lake, the elimination of CCW discharges leads to decreased temperatures through the Lake. Based on the closure of BCSS, temperatures in West Belews Creek arm during winter are expected to be like those currently observed in the Belews Creek arm, with a decrease in the mean winter temperature of approximately 16 degrees Celsius (°C) (30 degrees Fahrenheit [°F]).

7.1.2.1.3 Dan River Flow

As described in Section 7.1.1, closure of BCSS eliminates the need for supplemental pumping from the Dan River to compensate for consumptive uses from BCSS operations. However, authorized pumping operations associated with the MWIS are transferred to Project operations., It is anticipated that Project operations will utilize the MWIS to provide supplemental water to Belews Lake. Under Project operations, pumping by the MWIS is conducted using the same conditions of the existing North Carolina Department of Environmental Quality (NCDEQ) National Pollution Discharge Elimination System (NPDES) permit as described in Section 3.4.1.1.2. Although supplemental pumping from the Dan River is no longer influenced by BCSS uses, the MWIS pumping in conjunction with Project operations results in similar effects to the Dan River flow as those authorized by the existing NPDES permit. Discharges from the Project will be added to the existing NPDES permit.

7.1.2.1.4 Dan River Water Quality

BCSS closure eliminates the need for most wastewater discharge inputs from fossil fuel power generation currently discharged from Outfall 006 to the Dan River, including discharge from the emergency spillway of the South Coal Pile Basin, treated flue gas desulfurization wet scrubber wastewater, ash basin dewatering discharge, once-through non-contact chiller water, industrial stormwater, and once-through cooling water and intake screen backwash.

As described in Section 3.4.3.3.3.3, Project operations will utilize the existing Outfall 006 for nonradioactive wastewater streams (e.g., turbine building sumps, groundwater sumps, water treatment discharges). These nonradioactive waste streams are directed through a series of sumps and then routed to either the existing "Lined Retention Basin" system for further treatment or directly to current NPDES Outfall 006. While nonradioactive discharges via Outfall 006 are no longer influenced by BCSS uses, some minor BCSS effects from groundwater remediation and landfill leachate continue during Project operations.

7.1.2.2 Aquatic Ecology

7.1.2.2.1 Belews Lake Aquatic Ecology

Previous studies conducted by Duke Energy used Mayo Reservoir as a reference lake because it has similar characteristics to Belews Lake; however, it lacks the thermal influence that Belews Lake has because of operation of BCSS. Mayo Reservoir has similar productivity and nutrient loads to Belews Lake and has a similar long retention time for water. Additionally, in 2018, the North Carolina Division of Water Resources found the Mayo Reservoir to have a relatively balanced and stable fish community (Duke Energy, 2021).

With the closure of BCSS, elevated summer temperatures evident in Figure 2.2-16 are eliminated resulting in reduced stress on aquatic biota. No notable changes in overall composition of planktonic, benthic macroinvertebrate, or freshwater mussel communities in Belews Lake are expected to occur in conjunction with BCSS closure.

Aquatic macrophyte growth within Belews Lake reflects the presence of established communities within the upper arms of West Belews Creek and Belews Creek. Aquatic macrophyte establishment and growth is complex and related to a range of factors that include depth, substrate characteristics and stability, flow rates, temperature and other factors. There was no apparent trend in locations and density of vegetated points and zones of thermal influence. Accordingly, BCSS closure and the significant reduction in temperatures in Belews Lake are likely to have minimal effects on aquatic macrophyte communities.

The closure of BCSS may result in a taxonomic shift in the fish community, likely resulting in a community that is more closely aligned with that observed in Mayo Reservoir. Taxonomic shifts may be directly related to decreased temperatures. Threadfin Shad in particular, is intolerant of colder temperatures, and is likely to exhibit a reduced population abundance with discontinuation of BCSS thermal effluents that may provide more favorable habitats to Threadfin Shad in winter months. Fish condition shifts are also likely to occur. Changes to cooler water temperatures and the subsequent loss of warmer winter temperatures in the West Belews Creek arm of Belews Lake will affect the timing of spawning and result in a shorter growth season. Some species may exhibit higher overall condition, as cooler temperatures may reduce the level of caloric intake required to meet the stressful energetic needs associated with habitats with elevated temperatures. With BCSS closure, the loss of winter thermal refugia may result in changes to winter movement patterns of selected fish species within the lake. Changes in the forage base (e.g., forage fish) may reduce diet availability for certain fishes, which may ultimately result in changes in piscivore fish size, population density, and trophic dynamics.

7.1.2.2.2 Sport Fish Abundance and Condition

As described in Section 5.4.4.2.1.1, improved (cooler) summer high-water temperatures may also result in reduced stress on the aquatic ecosystem within Belews Lake that may also

improve overall fish condition. Accordingly, reductions of elevated temperatures may result in benefits of overall higher fish condition and decreased fish stress in the summer. The loss of thermal discharges from the closure of BCSS will affect recreational sportfishing in Belews Lake. Belews Lake is a popular destination for fishing. Largemouth Bass, Black Crappie, and Alabama Bass are the primarily targeted species for fishing. However, Belews Lake is also fished for catfish, Bluegill, and other sunfish. Due to its warm temperatures resulting from the BCSS discharge, Belews Lake is one of the state's more productive lakes for fishing in the winter. With the establishment of cooler water within Belews Lake under BCSS closure, Belews Lake fish will no longer be attracted to thermal discharges, thereby changing winter movement patterns, which may result in reduction in the degree of winter sportfishing success. The combination of a truncated growing season and the potential reduction in thermally-sensitive forage species such as Threadfin Shad may alter abundance and condition of sportfish such as Largemouth Bass, Alabama Bass, Black Crappie, White Crappie (*Pomoxis annularis*), catfishes, and perches (Percidae) that prey upon shad species in the short term; however, the same sportfish species are still expected to persist in Belews Lake.

7.1.2.2.3 Dan River Aquatic Ecology

As described in Section 7.1.1, closure of BCSS eliminates the need for supplemental pumping from the Dan River to compensate uses from BCSS operations. However, authorized pumping operations associated with the MWIS are transferred to Project operations. It is anticipated that Project operations will utilize the MWIS to provide supplemental water to Belews Lake. Under Project operations, pumping by the MWIS is conducted using the same conditions of the existing NCDEQ NPDES permit as described in Section 3.4.1.1.2. Although supplemental pumping from the Dan River is no longer influenced by BCSS uses, the MWIS pumping in conjunction with Project operations incorporates restrictions that are protective to aquatic biota of the Dan River.

While supplemental pumping from the Dan River is no longer influenced by BCSS uses, similar effects related to potential impingement and entrainment of aquatic biota continue with Project operations. However, the permitted and installed design of the MWIS includes fish protection technologies that are compliant with Clean Water Act Section 316(b) requirements that minimize effects and aquatic biota within the Dan River.

7.1.2.3 Socioeconomics

7.1.2.3.1 Physical Impacts

Although the closure of BCSS will eliminate noise emissions associated with plant operations, similar noise emissions continue with advanced reactor operations. As described in Section 5.8.2, during operations, residents and recreators nearest the Project site experience cooling tower noise below the 65 A-weighted decibel (dBA) threshold is considered acceptable and allowable outside a residence by the U.S. Environmental Protection Agency (USEPA) (Section 4.8.2.1). Other residences further from the Project site and across Belews Lake also experience noise from operation of the cooling towers below 65 dBA, which is further attenuated by the distance from the towers and the vegetative buffer.

As described in Section 2.4.2.6, the BCSS is an industrial facility that is visible in the surrounding viewshed. Major visual features, such as stacks and transmission lines will remain

in place under BCSS closure. Ultimately stacks will be removed as part of deconstruction while transmission lines will remain for life of the Project. However, the steam plume from the stacks will no longer be visible within the viewshed. While the removal of the visible steam plume from BCSS reduces the vertical visual prominence of the facility, the remaining infrastructure continues to define the viewshed in the short term. As a result, the overall visual presence of the site is diminished but not eliminated, and the facility remains a noticeable feature in the landscape. While BCSS closure and deconstruction eliminate certain visual intrusions, other visual intrusions continue with Project operations.

7.1.2.3.2 Recreation

In conjunction with BCSS closure, water quality conditions (notably, temperature) within Belews Lake stabilize to a condition influenced mainly by seasonal patterns. As is described in Section 5.2.3, thermal profiles in Mayo Lake, a lake like Belews Lake but with minimal anthropogenic heat load, were reviewed to provide a potential predictive future condition of Belews Lake without the contributing heat load from BCSS. Profiles from Mayo Lake as compared to Belews Lake indicate typical thermal stratification within Mayo Lake during summer months is consistent with that observed for Belews Lake. However, based upon temperature characteristics of Mayo Lake, mean surface temperatures of Belews Lake after closure of BCSS may be approximately 3 to 5°C (5 to 9°F) cooler than current conditions.

Potential recreational effects of both water-level changes and changes in water temperature within Belews Lake after closure of BCSS may include the following:

- Belews Lake water levels are no longer influenced by BCSS consumptive water uses (see Section 5.2.1).
- Aquatic ecological communities that reflect a lake lacking significant thermal input from power generation including recreationally important sport fish (Section 5.3.2).
- Depending on the frequency of drought conditions and related water-level fluctuation, corresponding effects may also be evident in the condition of recreationally important sport fish (i.e., smaller fish, changes in community structure, and other factors) that may be sought after by anglers (Section 5.3.2).
- The number of fishing tournaments held at Belews Lake (as described in Section 2.4.2.6.2) and the related benefits to local businesses that depend on such recreators may also be correspondingly reduced.
- Restricted access to several small coves that fall within the exclusion area boundary (EAB) as described in Section 5.4.1.1.

7.1.2.4 Air Quality

Closure of the BCSS would result in reduced air emissions over the Project Region. As described in Section 5.7.2.1, the criteria air pollutants at the new nuclear plant would occur from mechanical draft cooling towers, auxiliary boilers, standby equipment, and emergency power supply system diesel generators and/or gas turbines, which would result in reduced emissions from the sources currently at the BCSS. Table 7.1-3 compares the emissions from the BCSS during the year 2024, while operating at less than 30 percent capacity factor, to the estimated new annual nuclear plant emissions. Percent decreases in criteria pollutant emissions exceed 97.7 percent.

Closure of the BCSS would also result in reduced greenhouse gas (GHG) emissions over the Project Region. As described in Section 5.7.2.2, the GHG emissions footprint of a generic 1000-megawatt-electric (MWe) reactor provides a conservative estimate of impacts. The lifetime GHG emissions footprint of a generic 1000- MWe reactor is 10,500,000 metric tons carbon dioxide equivalent (CO_2-eq). For comparison, in 2022 and 2023 and while operating at less than 50 percent capacity factor, the BCSS emitted 5,922,637 and 5,584,208 metric tons CO_{2}-eq, respectively, per USEPA Flight data. In 2022 and 2023 combined (the two most recent years of USEPA flight data), the BCSS has emitted more CO_{2}-eq than the estimated lifetime emissions of the new nuclear facility.

As described in Section 4.7, overall emission impacts from preconstruction and construction activities would be temporary and minimal in magnitude for both criteria pollutants and GHGs.

Table 7.1-1
Geographic Area of Interest by Resource

Resource	Project Geographic Area of Interest
Land Use	Project site and 6-mi. (10-km) Project Vicinity.
Water Resources (Hydrology, Water Use and Quality)	
Surface Water	Project site, Belews Creek (includes Belews Lake), Dan River, and Town Fork Creek in Project Vicinity.
Groundwater	Project site and Belews Lake. GAI based on potential for direct and indirect effects on groundwater.
Ecology	
Terrestrial Ecology	Project site and Project Vicinity.
Aquatic Ecology	Project site, Belews Lake, Dan River, and Town Fork Creek. GAI based on watershed connectivity.
Socioeconomics	
Physical Impacts	Project site and Project Vicinity. GAI based on area of direct and indirect effects.
Demographics	Region of Influence (ROI) (Forsyth, Guilford, Rockingham, Stokes Counties). GAI based on effects associated with workforce population.
Economic Impacts	ROI. GAI based on direct and indirect project expenditures associated with the workforce.
Community Infrastructure Impacts	ROI. GAI based on effects associated with workforce population.
Historic and Cultural Resources	Area of Potential Effect (APE) as described in Chapter 2, the Project site, and a wastewater pipeline corridor to the Dan River.
Air Quality	Region of Influence (ROI) (Forsyth, Guilford, Rockingham, and Stokes counties). All counties in North Carolina are in attainment.
Greenhouse Gas	Global.
Nonradiological Health	The Project site and surrounding area (etiological agents, noise, EMFs and electric shock) for occupational health, and ROI (for public and transportation-related impacts).
Radiological Health	The 50-mi. (80-km) Project Region.
Nonradioactive Waste Management	The 50-mi. (80-km) Project Region. GAI is dependent on type of waste generated and available disposal locations. Identified land-based waste disposal facilities include those within the Project Region.
Postulated Accidents	The 50-mi. (80-km) Project Region.
Fuel Cycle, Transportation, and Decommissioning	Nationwide or global for fuel cycle and transportation. Much of the uranium fuel cycle impact occurs at facilities scattered throughout the United States, or in the case of foreign-purchased uranium, in other countries. The 50-mi. (80-km) Project Region for decommissioning.

Key: APE = Area of Potential Effect; EMF = electromagnetic fields; GAI = Geographic Area of Interest; km = kilometer; mi. = mile; ROI = Region of Influence

Table 7.1-2
Past, Present, and Reasonably Foreseeable Future Actions Considered in the Cumulative Impact Analysis
(Sheet 1 of 8)

Project Name	Description	Approximate Distance from the Project Site	Status
NATURAL GAS AND COAL-FIRED ELECTRIC POWER PLANTS			
Belews Creek Steam Station (BCSS) Operation	2220 megawatt (MW) dual unit coal and natural gas-fired electric generating facility.	Adjacent	Past, present, and reasonably foreseeable. Operation began in 1974. Natural gas added in 2020 and 2021. (Duke Energy, 2020a)
BCSS Closure	Phased closure of the BCSS.	Adjacent	Reasonably foreseeable. Per Duke Energy retirement planned for mid-2030s.
BCCS Deconstruction	Deconstruction of the BCSS	Adjacent	Reasonably foreseeable, subsequent to BCSS closure. Timeline has not been defined.
BCSS Ash Basin Closure and Landfill Construction	Excavation of approximately 12 million tons of ash and relocation to lined on-site landfill, adjacent to Pine Hall Road and approximately 125 ft. (38 m) in height.	Adjacent	Past, present, and reasonably foreseeable. Placement of material in the new landfill began in 2023 and is expected to take approximately 11 years. (Duke Energy, 2020b; WFDD, 2023)
WAGABOX® Renewable Natural Gas (RNG) Plant	Construct and operate a RNG plant at Rockingham County Landfill.	14 mi. (22 km) ENE	Reasonably foreseeable. Construction is expected to be finished in 2026. (Rockingham County, 2024)
NATURAL GAS PIPELINES			
Enbridge – T-15 Reliability Project	Construct a 45 mi. (72 km) natural gas pipeline (along previously existing rights of way) from Eden to Roxboro, NC. Also includes construction of a new compressor station.	24 mi. (39 km) ENE	Reasonably foreseeable. Permitting expected by mid-2025. Construction is expected to begin in 2025, with the majority of construction planned for 2026. In service by late 2027 – early 2028. (Enbridge, 2025)
Transco, LLC – Southeast Supply Enhancement Project	Construct and operate two natural gas pipeline loops totaling approximately 55 mi. (89 km) and replace existing facilities to provide additional capacity.	7 mi. (11 km) E and 24 mi. (39 km) NE, respectively	Reasonably foreseeable. Targeted construction start date by mid-2026. Targeted in-service date by end of 2027. (FERC, 2024; Williams, 2024)

Table 7.1-2
Past, Present, and Reasonably Foreseeable Future Actions Considered in the Cumulative Impact Analysis
(Sheet 2 of 8)

Project Name	Description	Approximate Distance from the Project Site	Status
Mountain Valley Pipeline (MVP) – Southgate Project	Construct and operate an approximately 75 mi. (121 km) natural gas pipeline and associated aboveground facilities interconnecting with MVP's mainline system.	23 mi. (37 km) NE	Reasonably foreseeable. The Federal Energy Regulatory Commission (FERC) granted MVP a three-year extension to construct and make available for service by June 18, 2026. (FERC, 2023)
ELECTRIC-SOLAR POWER PLANTS			
Baxter Creek Solar Center	Construct a new solar photovoltaic facility with a generative capacity of roughly 30 MW owned by Duke Energy Carolinas, LLC.	45 mi. NW	Reasonably foreseeable. Per Duke Energy, operation is scheduled to begin in June 2026.
Bear Branch Solar Project	Construct and operate a new solar photovoltaic facility on roughly 320 ac. (130 ha) near Walnut Cove.	6 mi. (10 km) NNW	Reasonably foreseeable. Anticipated commercial operation date is third quarter of 2026. (Gem Wiki, 2025; Capital Power, 2025)
TRANSMISSION LINES/SUBSTATIONS			
NCTPC 2023-2033 Collaborative Transmission Plan	Various transmission projects that include reconductoring, upgrading, replacing, and adding new transmission lines to enhance system reliability and resiliency, support the addition of new generation resources, and potentially enable increased economic electricity transpires across the transmission network.	Throughout the 50-mi. (80 km) Project Region.	Past, present, and reasonably foreseeable. Various projects scheduled for commission between 2023 and 2033. (NCTPC, 2024a; NCTPC, 2024b)

Table 7.1-2
Past, Present, and Reasonably Foreseeable Future Actions Considered in the Cumulative Impact Analysis
(Sheet 3 of 8)

Project Name	Description	Approximate Distance from the Project Site	Status
PARKS AND RECREATION			
Future Mayo River State Park in Virginia	State Park on 637 ac. (258 ha) at the confluence of the North and South Mayo Rivers. Managed by the VADCR.	19 mi. (31 km) N	Past, present, and reasonably foreseeable. All parcels were acquired in 2021. The VADCR expects to adopt the Master Plan to guide long-range development objectives by Summer 2026. (VADCR, 2024)
Belews Lake Park	Phase I includes Construction of a 215-ac. (87 ha) park featuring picnic areas, natural trails, comfort stations, and fishing dock. Phase II will expand these facilities.	2 mi. (3 km) S	Present and reasonably foreseeable. Construction of Phase 1 completed in February 2025. Funding for construction of Phase 2 is included in the 2024 North Carolina Parks and Recreation Trust Fund. (FCPR, 2025; NCGOV, 2024)
Future Bashavia Creek Preserve	Planned 127-ac. (51 ha) nature preserve owned and managed by the Piedmont Land Conservancy (PLC) to protect wildlife and provide low-impact recreational opportunities to the public.	21 mi. (34 km) WSW	Present and reasonably foreseeable. PLC is currently in the process of creating a master plan to guide future development within the Preserve. Expected to open to the public in 2025-2026 (PLC, 2024)
Dan River State Trail	Designate approximately 90 mi. (145 km) of the Dan River as a State Blueway with multiple public access points.	Throughout the 6-mi. (10 km) Project Vicinity	Past, present, and reasonably foreseeable. Approximately 59 mi. (95 km) of the planned 90-mi. (145 km) Blueway has been designated for use as of August 1, 2024. (NCDPR, 2025)
Mountains-to-Sea State Trail	Planned Statewide trail that traverses approximately 1400 mi. (2253 km) across the width of North Carolina. Connect multiple existing trails to form one continuous path.	Throughout the 50-mi. (80 km) Project Region.	Past, present, and reasonably foreseeable. Approximately 684 mi. (1101 km) of the planned 1400-mile (2253 km) trail has been designated for use as of August 1, 2024. (NCDPR, 2025)
Windsor Chavis Nocho Community Complex	Construct a 65,000 sq. ft. (ft^2) (6,039 m^2) indoor/outdoor community recreation center in Greensboro.	22 mi. (35 km) SE	Present and reasonably foreseeable. Construction is expected to begin in 2025 and conclude by 2027. (City of Greensboro, 2025a)

Table 7.1-2
Past, Present, and Reasonably Foreseeable Future Actions Considered in the Cumulative Impact Analysis
(Sheet 4 of 8)

Project Name	Description	Approximate Distance from the Project Site	Status
Horizons Park Multi-modal Trails	Construct multi-modal trail system. Includes addition of parking areas and amenities at Horizon's Park. Construction activities will include erosion control, grading, surveying, tree removal, trail construction, retaining wall construction, asphalt parking lot construction, site amenities installation, and seeding/landscaping/grading.	10 mi. (16 km) WSW	Reasonably foreseeable. Invitation to Bid, submitted by Forsyth County Parks and Recreation, closed on December 11, 2024. (City of Winston-Salem, 2024)
TRANSPORTATION PROJECTS			
Future I-685	Designate a new approximately 86-mi. (138 km) interstate route from I-85 in Greensboro to I-95 near Dunn. Approximately 56 mi. (89 km) of the route will follow existing U.S. HWY 421.	22 mi. (35 km) SE	Present and reasonably foreseeable. The corridor was designated by congress as part of the Infrastructure Investment and Jobs Act and is currently in the planning and design stage. (NCDOT, 2022)
Winston-Salem Northern Beltway	Construct an approximate 35-mi. (56-km) multi-lane freeway loop around northern Winston-Salem to alleviate traffic congestion and improve safety along heavily traveled routes in Forsyth County.	10 mi. (16 km) WSW	Past, present, and reasonably foreseeable. Portions of the Eastern and Western Loop will be completed by 2030. (NCDOT, 2024)
Big Mill Farm/Hopkins Road Improvements	Improve Hopkins Road from West Mountain Street (NC 66) to Big Mill Farm Road and improve and extend Big Mill Farm Road from U.S. 421 to Harmon Creek Road with a new interchange at U.S. 421.	10 mi. (16 km) SSW	Reasonably foreseeable. Construction is expected to begin in early 2025. (NCDOT, 2023a)

Table 7.1-2
Past, Present, and Reasonably Foreseeable Future Actions Considered in the Cumulative Impact Analysis
(Sheet 5 of 8)

Project Name	Description	Approximate Distance from the Project Site	Status
U.S. 158 (Reidsville Road) Improvements	Widen approximately 19 mi. (30 km) of the existing two-lane, two-way roadway to a multi-lane, median-divided roadway from U.S. 421 in Winston-Salem to U.S. 220 in Guilford County to relieve increased traffic congestion.	5 mi. (8 km) SSW	Present and reasonably foreseeable. Construction of the first phase is in progress as of 2024. (NCDOT, 2018; NCDOT, 2023b)
Johnson Street and Sandy Ridge Road Widening	Widen approximately 4 mi. (6 km) of Johnson Street and Sandy Ridge Road in Guilford County to help reduce congestion and traffic delays. Includes construction of bike lanes and a multiuse path.	13 mi. (21 km) SSE	Past, present, and reasonably foreseeable. Construction in progress as of December 2023 with estimated completion by Fall 2027. (NCDOT, 2023c)
U.S. 220 Widening (Greensboro)	Widen U.S. 220 in Greensboro to six lanes from Westridge Road to the I-840 ramps to address congestion and improved mobility. Work would also involve installing a median and sidewalks.	14 mi. (23 km) SE	Reasonably foreseeable. Planning and development are underway. (NCDOT, 2025)
NC 65 (Belews Creek Road) and NC 68 Intersection Improvements	Improve six intersections along the NC 65, NC 65/NC 68, and NC 68 corridor between U.S. 158 in Stokesdale and I-73 in Rockingham County to reduce the incidence and severity of crashes.	8 mi. (13 km) ESE	Past, present, and reasonably foreseeable. Right-of-Way Acquisition complete. Construction is expected to begin in May 2026. (NCDOT, 2023d)
Carolinian Piedmont Passenger & Freight Improvements	Improve the capacity of North Carolina Railroad Company's NC-Line to meet the growing demands of both freight and passenger rail traffic. The project would add over 5 miles of sidings, reconstruct up to 69 mi. (111 km) of track, eliminate one grade crossing, and improve track geometry at key locations including Hillsborough, Burlington, and Greensboro.	Throughout the 6-mi (10 km) Project Vicinity	Present and reasonably foreseeable. Construction is expected to begin in 2025, following design and environmental permitting. (FRA, 2024; NCRR, 2024)

Table 7.1-2
Past, Present, and Reasonably Foreseeable Future Actions Considered in the Cumulative Impact Analysis
(Sheet 6 of 8)

Project Name	Description	Approximate Distance from the Project Site	Status
Walnut Cove Greenway	Add two walking/biking trails to provide safe and effective transportation between the Walnut Tree neighborhood and downtown Walnut Cove.	4 mi. (6 km) W	Reasonably foreseeable. Funding for the Project is included in the 2023 U.S. Department of Transportation Reconnecting Communities and Neighborhoods Grant Program. (PTRC, 2022; USDOT, 2023)
Piedmont Greenway	Develop a shared-use path extending 19 mi. (31 km) from Salem Lake to Summerfield.	9 mi. (14 km) SSE	Reasonably foreseeable. The Master Plan is finalized and feasibility studies have been completed for certain sections. (PLC, 2021)
OTHER ACTIONS/PROJECTS			
Madison River Park Restoration	Replace the Lindsey Bridge Dam with a series of small rapids to facilitate upstream migration of a federally endangered fish species and to provide public recreation opportunities. Phase II will involve additional facility expansions after the bridge on Lindsey Bridge Road is replaced.	8 mi. (13 km) NNE	Past, present, and reasonably foreseeable. Phase I opened to the public on May 1, 2021. Underbrush has been cleared and surveys have been performed for Phase II. (DRBA, 2023; Madison River Park, 2025)
Dan River Educational State Forest (ESF) – Shoebuckle Tract	Develop infrastructure for an ESF that prioritizes public recreation and outdoor education on approximately 848 ac. (343 ha) on the Dan River in Stokes County, North Carolina.	8 mi. (13 km) NNE	Present and reasonably foreseeable. PLC acquired the land in 2023. The future goal is to acquire funding to build infrastructure and staff positions. (PLC, 2023)
Marshall Aerospace Maintenance and Engineering Facility	Construction and operation of a 192,000 ft^2 (17,837 m^2) aircraft maintenance facility at Piedmont Triad International Airport in Greensboro, North Carolina.	13 mi. (21 km) SSE	Present and reasonably foreseeable. Construction ongoing. Fully operational by early 2025. (Marshall Group, 2024)
Guilford Technical Community College (GTCC) Aviation Training Center	Construct a new 100,000 ft^2 (9290 m^2) aviation training facility at GTCC's Donald W. Cameron Campus.	13 mi. (16 km) SSE	Reasonably foreseeable. Phase 1 construction expected to begin mid-2025. The initial phase is expected to open in January 2027. (GTCC, 2024; North Carolina Construction News, 2024)

Table 7.1-2
Past, Present, and Reasonably Foreseeable Future Actions Considered in the Cumulative Impact Analysis
(Sheet 7 of 8)

Project Name	Description	Approximate Distance from the Project Site	Status
SBA Home Manufacturing Facility	Convert an existing 500,000 ft^2 (46,451 m^2) facility to manufacture furniture at the Davie Industrial Center.	39 mi. (63 km) SW	Present and reasonably foreseeable. Production is expected to begin in October 2025. (DCEDC, 2024)
Morinaga Hi-Chew Facility Expansion	Expand existing operations by constructing a roughly 100,000 ft^2 (9290 m^2) production space adjacent to the existing plant in Mebane, NC.	47 mi. (76 km) ESE	Reasonably foreseeable. Construction is expected to be complete by 2027. (Orange County, 2024)
Microporous Project Stellar Phase I	Construct a coated lithium-ion battery separator plant on approximately 212 ac. (85 ha) at the Southern Virginia Megasite.	35 mi. (56 km) NE	Present and reasonably foreseeable. Groundbreaking in November 2024. Construction is anticipated to last for approximately 12 months for building installation, and 24 months for equipment installation. (Alston Construction, 2024; NETL, 2024)
Project Ice – Innovative Construction Group	Construct and operate a housing component manufacturing facility on approximately 46 ac. (19 ha) at the Chatham Advanced Manufacturing (CAM) Site.	47 mi. (76 km) SE	Reasonably foreseeable. Fully operational by 2029. (CCEDC, 2024; EDPNC, 2024)
John Palmour Manufacturing Center for Silicon Carbide	Operation and future expansion of a silicon carbide semiconductor manufacturing plant on approximately 445 ac. (180 ha) at the CAM Site.	47 mi. (76 km) SE	Past, present, and reasonably foreseeable. The first unit began production in June 2024. Additional capacity will be added, as needed, by 2030. (Wolfspeed, 2022; Wolfspeed, 2025)
Toyota Battery Manufacturing North Carolina	Construct and operate a battery manufacturing facility for hybrid and electric-powered vehicles on approximately 1850 ac. (749 ha) at the Greensboro-Randolph Megasite.	35 mi. (56 km) SE	Past, present, and reasonably foreseeable. Operation began in April 2025. Final construction of all facilities to be completed by 2030. (City of Greensboro, 2023; Toyota, 2024; Toyota Global, 2025)

Project Name	Description	Approximate Distance from the Project Site	Status
WATER AND WASTEWATER IMPROVEMENT PROJECTS			
Mitchell WTP Improvements Project	Install a Granular Activated Carbon contractor system for the existing Mitchell WTP to ensure compliance with U.S. Environmental Protection Agency National Primary Drinking Water Regulation Maximum Concentration Levels.	19 mi. (31 km) SE	Present and reasonably foreseeable. WTP upgrades are anticipated to be completed by 2029. (City of Greensboro, 2025b)
Town of Oak Ridge Water Tower	Construct a 250,000 gal (946 m^3) elevated water storage tank on Town property to support further development of the municipal water system in Oak Ridge.	8 mi. (13 km) SSE	Present and reasonably foreseeable. Groundbreaking ceremony held January 23, 2025. Water tower construction expected to be completed by January 2026. (Town of Oak Ridge, 2025)
Wolfspeed Watermain Extension Project	Construct a watermain extending from Asheboro to the CAM site to provide water for Wolfspeed's John Palmour Manufacturing Center.	41 mi. (66 km) SSE	Reasonably foreseeable. Construction is expected to begin in early 2025. Completed by 2026. (Asheboro City Government, 2024)

7.2 RESOURCE IMPACT ASSESSMENT

As described above, the time frame for the cumulative impact analysis incorporates the combined effects from building and operation of the Project in combination with past, present, and RFFAs as impacts may accumulate or develop over time. The baseline assessment presented in the affected environment for each resource (as discussed in Chapter 2) accounts for past and present actions. Direct and indirect impact analyses (Chapter 4 and 5) address the incremental impacts of building and operation. These combined impacts may be individually minor but may collectively result in significant impacts from actions taking place over a period of time. An impact that may be SMALL by itself could result in a MODERATE or LARGE cumulative impact when considered in combination with the impacts of other actions on the affected resource. Table 7.2-1 summarizes the cumulative impact on each resource. The potential for cumulative effects to each of the identified environmental resources of concern are analyzed below.

7.2.1 LAND USE

The description of the affected environment in Section 2.1.1 serves as a baseline for the cumulative impacts assessment for land use. Within the Project Region, predominant land uses include undeveloped forested land and hay/pasture. Large tracts of forested land are located within the northern portion of the Project Region. Developed land is concentrated in major cities in the south-central portion of the Project Region. Land use within the Project Vicinity comprises undeveloped forested land, followed by hay/pasture. Evergreen forest is primarily located around Belews Lake with undisturbed pockets of mixed forest, deciduous forest, and hay/pasture dispersed throughout the Project Vicinity. Developed land classified as low intensity or open space is located sparsely throughout the Project Vicinity, whereas most of the high intensity and medium intensity developed lands are found within the BCSS, Walnut Cove, and Stokesdale areas. As summarized in Table 2.1-2, the Project Vicinity encompasses approximately 99,000 acres (ac.) (40,063 hectares [ha]). All developed lands account for approximately 12.4 percent of the Project Vicinity, and lands converted to agricultural uses (cultivated, hay/pasture) account for approximately 20.4 percent of the Project Vicinity (Table 2.1-2).

As Sections 4.1 and 5.1 describe the impacts on land use from building and operation of the Project are characterized as MODERATE (building activities) and SMALL (operation). Impacts to land use at the Project site and in the Project Vicinity occur primarily during building. Land use impacts from building activities associated with the Project result from effects to undeveloped lands within the Project site that are located adjacent to the BCSS. During operation, the Project does not result in additional land use conversion. Additionally, operation does not conflict with established land use controls.

Table 7.1-1 identifies the GAIs for land use to be the Project site and Project Vicinity. Table 7.1-2 identifies past, present, and RFFAs that have the potential to result in impacts to land use. However, many of these identified projects are located outside of the GAI and have limited or no relevance to land uses within the GAI. For example, RFFAs such as the Enbridge – T-15 Reliability Project, the Southeast Supply Enhancement Project, the Mountain Valley Pipeline, the Baxter Creek Solar Center, the Winston-Salem Northern Beltway, and other similar actions have the potential for adverse effects to land uses, but these projects are substantially outside of the GAI. Several RFFAs are linear projects (transmission, roadway and rail improvements, greenway developments) that are identified within the Project Vicinity, including:

- U.S. 158 (Reidsville Road) Improvements
- North Carolina Transmission Planning Cooperative (NCTPC) 2023-2033 Collaborative Transmission Plan
- Carolinian Piedmont Passenger & Freight Improvements
- Walnut Cove Greenway
- Mountain to Sea State Trail

The above actions are generally expected to consist of improvements to lands that are either within or along existing established corridors and do not result in substantial land use alterations within the GAI. Therefore, these new or updated actions do result in noticeable conversion of land that is not previously disturbed or categorized as developed. NCTPC transmission improvements may be required for various transmission projects that include reconductoring, upgrading, replacing, and adding new transmission lines to enhance system reliability and resiliency. These potential actions require final decision-making resulting from future interconnect studies that Duke Energy will conduct to determine the type and location of the uprates and reconductoring activities. It is expected that uprate and reconductoring activities and other RFFAs that are transportation improvements would predominantly be conducted within or along established corridors. Therefore, impacts associated with these activities on land use are expected to be minor.

The following actions identified in Table 7.1-2 are considered to have greater potential to substantially contribute to cumulative impacts on land use:

- BCSS Deconstruction
- BCSS Ash Basin Closure and Landfill Construction
- J. Dudley Watts Jr. Belews Lake Park (Belews Lake Park)
- Bear Branch Solar Project

BCSS deconstruction may entail decommissioning and removal of all previously developed features and infrastructure associated with the fossil plant. Similarly, the BCSS Ash Basin Closure and Landfill Construction Project will entail long-term maintenance in conjunction with closure. Therefore, no other substantive land use changes would occur with this action. However, the BCSS site and the landfill areas are likely to remain in industrial use and may be subject to future development. Therefore, no alterations of the designated land use or zoning of the BCSS site are expected.

Belews Lake Park is a designated recreational area located south of the Project site that is undergoing development. As Table 7.1-2 indicates, Phase I includes construction of a 215-ac. (87-ha) park featuring picnic areas, natural trails, comfort stations, and a fishing dock. Phase II will include additional development of these facilities. Therefore, the reasonably foreseeable future development of the park furthers the recreational services of the area and maintains overall designated land uses.

The Bear Branch Solar Project is an energy generation development on approximately 320 ac. (130 ha) located 6 miles (mi.) (3.2 kilometers [km]) north-northwest of the Project site that is anticipated to begin commercial operation in 2026. The project is located on previously cleared, vacant land and lacks forested land cover. The project entails conversion of herbaceous and

shrub land cover to developed uses. Therefore, the conversion of undeveloped non-forested lands to developed uses is a minor land cover conversion relative to the Project Vicinity (see Table 2.1-2).

As described above, corridor improvement projects, such as the U.S. 158 (Reidsville Road) improvement and the Carolinian Piedmont Passenger and Freight improvement, are expected to consist of land alterations that are either within or along existing established corridors. Therefore, they do not result in substantial land use alterations within the GAI.

In summary, the cumulative impact of building and operating activities from the Project on land use, added to the effects associated with past, present, and RFFAs within the GAI on land use is noticeable but not destabilizing and therefore MODERATE. Because of extensive past and present modification of land use within the GAI, and the Project site's proximity to the adjacent existing industrial BCSS site, the impact of building of the Project is a noticeable, but not a destabilizing contributor to the cumulative impact on land use. The impact of operation of the Project is a minor contributor to the cumulative impact on land use.

7.2.2 WATER

As described in Table 7.1-1, the GAI established for surface water includes the Project site, Belews Creek (includes Belews Lake), Dan River, and Town Fork Creek in the Project Vicinity. The GAI established for groundwater includes the Project site and Belews Lake. The GAI is based on potential for direct and indirect effects on groundwater.

7.2.2.1 Hydrology

7.2.2.1.1 Surface Water Hydrology

The description of the affected environment in Section 2.2.1.1 of this document serves as a baseline for the cumulative impacts assessment for surface water hydrology. As further described below, the Project may have limited effects on Belews Lake, the Dan River, Belews Creek downstream of the Belews Lake spillway, and smaller tributary streams on the Project site. The Dan River is a free-flowing unchanneled river system that is relatively narrow with mid-channel depths that range from less than 1 foot (ft.) (0.3 meters [m]) to approximately 3 ft. (0.9 m). Potential flow diversions are associated with the MWIS located on the Dan River at the confluence with Belews Creek that provides makeup water to Belews Lake. Belews Lake is a man-made reservoir with primary arms of the reservoir formed by Belews Creek and West Belews Creek. Belews Lake drains to the Dan River downstream of the dam spillway via Belews Creek. Project site streams include intermittent and perennial streams that connect to Belews Lake, the Dan River, or downstream surface waters. Stream characteristics are somewhat variable but are generally narrow and have evidence of an ordinary high-water mark, clear natural shelving, sediment sorting, changes in the character of the soil, a natural bank line, and moderately continuous bed and bank.

Impacts to surface water hydrology associated with the building and operation of the Project is described in Sections 4.2.1 and 5.2.1, respectively. Impacts to Belews Lake during building activities are limited to the locations of the intake, discharge, and associated lakebed piping structures. Stormwater runoff patterns across the net disturbance area (NDA) are altered resulting in changes in stormwater runoff rates across the Project site. Implementation of design measures and best management practices (BMPs) coupled with adherence to federal, state, and local permit conditions related to Sections 401 and 404 of the Clean Water Act (CWA)

reduce direct and indirect impacts from building activities on stormwater runoff rates to Belews Lake and the Dan River. For impacts that cannot be reduced, Duke Energy implements specific compensatory mitigation measures in accordance with 33 CFR Part 332. The overall impacts of hydrologic alterations to surface waters during building activities are mitigated and are therefore SMALL.

During operations, sedimentation basins installed during the building phase are converted to detention or retention facilities for the permanent stormwater management system during the operational period, minimizing discharge of sediments and site runoff to Belews Lake. The effects of Project operations on flow patterns within Belews Lake as a result of intake, discharge, and MWIS are localized and minor. Additionally, the potential impacts of sediment transport into Belews Lake from the MWIS operation are negligible. Overall, Project operations result in predicted Belews Lake water-level variations that result from increased consumptive use. Under conditions in which water levels are stabilized and consumptive losses are offset by MWIS pumping, impacts on Belews Lake hydrology are SMALL. However, impacts on Belews Lake hydrology are MODERATE in conjunction with the effects of increased drought intensity.

Project discharges into the Dan River in a corridor adjacent to existing Outfall 006 results in localized changes in flow patterns, currents, and total flow. Discharge flow rates are regulated in conjunction with NCDEQ NPDES permitting requirements. Therefore, the hydrological impacts of discharge are minor. Pumping by the MWIS results in minor hydrologic alterations on the Dan River during higher flow conditions but does not affect Dan River flow when natural discharge is less than 110 cfs (3.1 m^3/s). Hydrological impacts of MWIS operation on the Dan River are SMALL. As described in Table 7.1-1, the GAI established for surface water hydrology includes the Project site, Belews Creek (includes Belews Lake), Dan River, and Town Fork Creek in the Project Vicinity. Many of the past, present, and RFFA projects listed in Table 7.1-2 have the potential to result in some effects to surface water hydrology. However, most projects are located outside of the GAI, are relatively minor in scope, and have limited or no connectivity to surface water hydrology affected by the Project. Several RFFAs are within the GAI but are not expected to greatly impact surface water hydrology including:

- U.S. 158 (Reidsville Road) Improvements
- Carolinian Piedmont Passenger & Freight Improvements
- NCTPC 2023-2033 Collaborative Transmission Plan
- Bear Branch Solar Project
- BCSS Ash Basin Closure and Landfill Construction

These projects represent the continued or new operation of industrial infrastructure such as roads, railways, transmission projects, solar facilities, or other industrial uses. While these projects do not have direct impacts on surface water hydrology within the GAI, indirect impacts, such as degradation of water quality from sedimentation and potential accidental spills, could occur to streams flowing into the Dan River, Belews Lake, or Town Fork Creek. Compliance with federal, state, and local requirements minimizes these potential indirect impacts on surface water hydrology. Compliance with the terms of applicable Section 404 permits (including minimization and mitigation) and using BMPs further reduces impacts.

As described in Section 2.2.1.1.3, Belews Lake is a man-made reservoir formed in 1970 following construction of an earthen embankment dam across Belews Creek. The lake was constructed primarily to serve as a CCW source for the BCSS. Three named streams flow into

Belews Lake: Belews Creek, West Belews Creek, and East Belews Creek. The impoundment of Belews Lake resulted in persistent noticeable hydrologic effects related to watershed runoff and residence time, water currents and circulation, water retention and depth characteristics within Belews Lake, sedimentation and sediment transport.

The BCSS closure identified in Table 7.1-2 may also contribute to substantial cumulative impacts on surface water hydrology through direct impacts to waters within the GAI.

As described in Section 7.1.2, BCSS closure has several potential effects on surface water hydrology that include reduced water use by BCSS to support FGD operations, forced evaporation, and other water uses. Pumping operations associated with the MWIS on the Dan River and discharge flow from Outfall 006 are transferred to Project operations. The cumulative effects of BCSS closure in conjunction with the Project are generally offsetting as the phased implementation of the Project in conjunction with BCSS closure has the effect of impacting surface water hydrology in a similar manner with respect to the effects on Belews Lake and the Dan River. The Project is also subject to federal and state permitting. Therefore, effects are reduced by mitigation in accordance with the U.S. Army Corps of Engineers (USACE) and NCDEQ, and Section 7 of the Endangered Species Act, as appropriate.

In summary, because of extensive past and present modification of Belews Creek and its tributaries, as a result of the impoundment of Belews Lake, the cumulative impact of building and operating the Project on surface water hydrology, added to the effects associated with past, present, and RFFAs within the GAI on surface water hydrology is MODERATE. The impact of building the Project is a minor contributor to the cumulative impact on surface water hydrology due to the mitigation of impacts to low-quality streams on-site, impacts to Belews Lake, and stormwater runoff changes. However, the impact of operation of the Project is a noticeable contributor to the cumulative impact on surface water hydrology in conjunction with the effects of increased drought intensity.

7.2.2.1.2 Groundwater Hydrology

Section 2.2.1.2 of this document serves as a baseline for the cumulative impacts assessment for groundwater hydrology. The Project site is situated in the Piedmont physiographic province (Piedmont), which is characterized by gently rolling, well-rounded hills and long, low ridges. The Project Region receives groundwater recharge through infiltration of precipitation. Local groundwater is influenced by many perennial and ephemeral streams, creeks, and lakes within the Project Vicinity.

Permanent and temporary impacts to groundwater hydrology associated with the future building and operation of the Project is described in Sections 4.2.1.2 and 5.2.1.2, respectively. Alterations to groundwater hydrology during building include those associated with dewatering. However, once building activities are completed, dewatering is no longer needed, and the water table is returned to static baseline conditions. Groundwater flow patterns may be affected during building and grading activities; however, effects are localized and are not noticeably altering. Structure foundation development does not result in long-term impacts on groundwater levels, availability, or flow patterns. Additionally, loss of pervious surfaces associated with permanent use areas results in localized alterations in groundwater patterns associated with reduced groundwater infiltration from some areas of the Project site during operations. No groundwater use or dewatering occurs during operation that may affect local aquifers. As described in Sections 4.2.1.2 and 5.2.1.2, the impacts on groundwater hydrology from building and operation of the Project are SMALL.

As described in Table 7.1-1, the GAI established for groundwater hydrology is based on aquifers evident on the Project site and Belews Lake. Several of the past, present, and RFFA projects listed in Table 7.1-2 have the potential to result in some effects to groundwater hydrology. However, none are located within the GAI and would not have the potential to substantially contribute to cumulative impacts on groundwater hydrology.

Groundwater hydrology in the GAI is influenced by surface water bodies and seasonal precipitation patterns. The effects of other past and ongoing projects on groundwater are localized and cumulative effects to groundwater hydrology are minor.

In summary, the cumulative impact of building and operating the Project on groundwater hydrology, added to the effects associated with past, present, and RFFAs within the GAI on groundwater hydrology, is minor, and therefore, SMALL. Because the Project's groundwater alterations are limited to the building phase and result in localized effects from dewatering and reduced infiltration due to site grading and the construction of new impervious surfaces, the impact of building and operating the Project is not a significant contributor to the cumulative impact on groundwater hydrology.

7.2.2.2 Water Use

7.2.2.2.1 Surface Water Use

The description of the affected environment in Section 2.2.2.1 serves as a baseline for the cumulative impacts assessment for surface water use. Regional surface water use includes public water supply, industrial, thermoelectric power, mining, livestock, aquaculture, and irrigation. Consumptive water use in the Project Region consists of that used in thermoelectric power generation and irrigation. Recreation is prevalent in the Project Region including opportunities for fishing, paddling, canoeing, tubing, and kayaking in the Dan River. There are no public water supply facilities that withdraw water from surface water resources within the Project Vicinity. Vicinity recreational water use include the Dan River State Trail and Belews Lake. Belews Lake is used for various kinds of recreation including fishing, boating and other aquatic forms of recreation. Belews Lake is not used for consumptive water uses such as municipal water supply, irrigation, or thermoelectric power generation associated with entities outside of Duke Energy. On the Project site, BCSS draws water from Belews Lake via an intake structure located in a natural cove on the western arm of Belews Lake. Heated effluent discharges into West Belews Creek. A man-made canal crosses the site peninsula to convey cooling water from the discharge area to the eastern portion of Belews Lake.

As Sections 4.2.2.1 and 5.2.2.1 describe the impacts on surface water use from building and operation of the project are characterized as SMALL. Water is required for dust suppression and withdrawn from Belews Lake during building activities, but the effects are negligible. No building phase water use is obtained from the Dan River. The effects of potable water usage during building activities are minor since the potable water supply has excess capacity. Proposed facility operations require water use of Belews Lake. Consumptive use in conjunction with Project operations does not adversely affect the availability of water for Project intake systems and does not affect the overall purpose of Belews Lake in providing water to support thermoelectric power generation. Given the minimum flow requirements established in the NPDES permit, which is expected to carry over to the Project, water availability and reliability downstream of the MWIS are not destabilizing to downstream water users. Additionally, adherence to the NPDES permit along with a low-profile MWIS structure result in minor impacts

that do not noticeably impact the recreational use of the Dan River. Therefore, the overall impacts of Project operations on surface water use are considered SMALL.

As described in Table 7.1-1, the GAI established for surface water use includes the Project site, Belews Creek (includes Belews Lake), Dan River, and Town Fork Creek in the Project Vicinity. Table 7.1-2 identifies past, present, and RFFAs that have the potential to result in impacts to surface water use. All actions listed in Table 7.1-2 are expected to be permitted in accordance with state and federal regulations that ensure the protection of surface water use. Similarly, most are expected to represent a substantial potential to contribute to additional stressors on surface water use within the GAI. The Dan River State Trail project, where more of the Dan River is designated as a State Blueway, is discussed further in Section 7.2.4.

The BCSS closure identified in Table 7.1-2 may contribute to substantial cumulative impacts on surface water use through direct impacts to waters within the GAI, including beneficial impacts.

As described in Section 7.1.2, BCSS closure has several potential effects on surface water use that include reduced water use by BCSS to support FGD operations, forced evaporation, and other water uses; transfer of pumping operations associated with the MWIS on the Dan River; and elimination of most discharge flow to the Dan River from Outfall 006. The cumulative effects of BCSS closure in conjunction with the Project are generally offsetting in which the phased implementation of the Project in conjunction with BCSS closure has the effect of impacting surface water use in a similar manner with respect to the effects on Belews Lake and the Dan River. The Project is also subject to federal and state permitting. Therefore, effects are reduced by mitigation in accordance with USACE and NCDEQ, and Section 7 of the Endangered Species Act, as appropriate.

In summary, the cumulative impact of building and operating activities from the Project on surface water use, added to the effects associated with past, present, and RFFAs within the GAI on surface water use is SMALL. The impact of building and operation of the Project have a minor effect on water use.

7.2.2.2.2 Groundwater Use

Section 2.2.2.2 of this document serves as a baseline for the cumulative impacts assessment for groundwater use. Regional and Project Vicinity groundwater use is primarily for public water supply. Other than water withdrawals associated with the Duke Energy groundwater corrective action plan remediation system located approximately 2.2 mi. (3.5 km) northwest of the Project site, no groundwater withdrawals currently exist at the operating BCSS. Impacts to groundwater use from building and operating the Project is described in Sections 4.2.2.2 and 5.2.2.2. While dewatering may be required during building, groundwater is not used as a source of water for building activities or operation. As such, the impacts from groundwater use are SMALL.

As described in Table 7.1-1, the GAI established for groundwater use is based on aquifers evident on the Project site and Belews Lake. All actions listed in Table 7.1-2 are expected to be permitted or authorized in accordance with state and federal regulations concerning groundwater use. Several of the past, present, and RFFA projects listed in Table 7.1-2 have the potential to result in some effects to groundwater use. However, none are located within the GAI and would have the potential to substantially contribute to cumulative impacts on groundwater use.

In summary, the cumulative impact of building and operating activities from the Project on groundwater use, added to the effects associated with past, present, and RFFAs within the GAI on groundwater use, is minor, and therefore, SMALL. Because no groundwater is used by the Project during building or operation, the impact of building and operation of the Project is negligible and not a significant contributor to the cumulative impact on groundwater use.

7.2.2.3 Water Quality

7.2.2.3.1 Surface Water Quality

Section 2.2.3.1 of this document serves as a baseline for the cumulative impacts assessment for surface water quality. As described in Section 2.2.3.1, Project site streams are characterized by narrow channels with moderate gradients. Temperatures in the on-site streams did not exceed any NCDEQ water quality standards. The upper portion of the West Belews Creek arm of Belews Lake currently receives heated effluent from the BCSS. Belews Lake and a major portion of the discharge arm near BCSS maintain temperatures adequate to support biological communities under adverse lake-level and weather conditions. Water quality sampling results indicate that the seasonal water quality and chemistry of Belews Lake provides a suitable physicochemical environment for sustaining a balanced and indigenous biological community. Measured temperatures in the Dan River did not exceed any NCDEQ water quality standards. Water quality impacts from pumping Dan River water into Belews Lake to augment the water level were found to be localized to the immediate pump outlets in the lake and are insignificant compared to effects, such as stormwater runoff. Town Fork Creek within the Project Vicinity is meeting quality standards and is not impaired.

Impacts to surface water quality associated with building and operation of the Project is described in Sections 4.2.3.1 and 5.2.3.1. Direct physical alteration of surface waters from building activities resulting in the filling of streams in conjunction with site grading, results in adverse impacts to surface water quality. Activities such as erosion and sedimentation, accidental spills, or releases of stormwater can result in indirect impacts on surface water quality. Surface water impacts during building activities are regulated by NCDEQ and the USACE. BMPs are used to control erosion and limit the amount of soil and sediment entering surface waters. A spill prevention, control, and countermeasure (SPCC) plan will be implemented to control the discharge of oil spills and limit their effects on surface water. A site-specific stormwater pollution prevention plan (SWPPP) mitigates the impact of building activities on off-site stream water quality caused by the permanent impact to streams within the NDA. Permitting requirements including the implementation of appropriate BMPs and control measures minimizes impacts such that impacts to the water quality of Belews Lake are localized and temporary.

Excavation in the Dan River is conducted to install the discharge pipeline and results in localized sediment disturbance and water quality alterations related to turbidity and suspended solids. Riprap is placed in conjunction with the discharge to minimize scour and erosion of the riverbed. Disturbance of riparian vegetation by construction equipment operations within the wastewater pipeline corridor can also indirectly reduce the water quality of the Dan River due to erosion, associated sedimentation, and potential accidental releases from spills. As a result of mitigative measures and engineering controls (e.g., BMPs, SWPPP, and SPCC) regulated by NCDEQ and USACE that are implemented during building activities, impacts to surface water quality are controlled, localized, and temporary. Therefore, the impacts on surface water quality are SMALL.

Impact from operations to on-site streams is limited due to the removal of the majority of on-site streams during building activities. The remaining streams on the Project site not impacted by building activities are potentially impacted during operation by industrial stormwater runoff, which is minimized by an existing NPDES stormwater permit and SPCC plan. Direct effects of operation on water quality within Belews Lake include the addition of cooling tower blowdown wastewater constituents and thermal load and supplemental pumping from the Dan River. The additional wastewater discharges are not expected to accumulate and will meet NPDES permitting limits and requirements with a regulatory mixing zone. As described in Section 5.2.4.1.2, Duke Energy maintains monitoring programs to ensure regulatory compliance. Therefore, the overall impacts of surface water quality during operations are considered SMALL.

As described in Table 7.1-1, the GAI established for surface water quality includes the Project site, Belews Creek (includes Belews Lake), Dan River, and Town Fork Creek in the Project Vicinity. Many of the past, present, and RFFA projects listed in Table 7.1-2 have the potential to result in some effects on surface water quality. However, most projects are located outside of the GAI and have limited or no connectivity to surface water quality affected by the Project. Therefore, the effects of such projects on cumulative effects to surface water quality are expected to be minor. Several RFFAs are within the GAI but are not expected to greatly impact surface water quality including:

- U.S. 158 (Reidsville Road) Improvements
- Carolinian Piedmont Passenger & Freight Improvements
- NCTPC 2023-2033 Collaborative Transmission Plan
- Bear Branch Solar Project
- BCSS Ash Basin Closure and Landfill Construction

These projects represent the continued or new operation of industrial infrastructure such as roads, railways, transmission projects, solar facilities, or other industrial uses. While these projects do not have direct impacts on surface water quality, indirect impacts, such as degradation of water quality from sedimentation and potential accidental spills, could occur with streams flowing into the Dan River, Belews Lake, or Town Fork Creek. Compliance with federal, state, and local requirements minimizes these potential indirect impacts on surface water quality. Compliance with the terms of applicable Section 404 permits (including minimization and mitigation) and using BMPs further reduces impacts.

The BCSS closure identified in Table 7.1-2 may contribute to substantial cumulative impacts on surface water hydrology through direct impacts to waters within the GAI.

As described in Section 7.1, BCSS closure has several potential effects on surface water quality including the cessation of thermal inputs from BCSS. As described in Section 7.1.2.1.2, thermal loading to Belews Lake is significantly reduced in conjunction with the closure of BCSS. Therefore, water temperatures within Belews Lake are primarily affected and undergo a process by which temperatures are greatly reduced resulting in reduced stress to aquatic biota within the lake. General cooling would occur within each reach of Belews Lake until temperatures stabilize to a condition influenced mainly by seasonal patterns and would result in significant beneficial improvement in overall water quality within Belews Lake. BCSS closure would also result in the substantial elimination of discharges of BCSS constituents to the Dan River from Outfall 006. This action is also subject to federal and state permitting. Therefore, effects are reduced by appropriate mitigation in accordance with USACE and NCDEQ, and Section 7 of the

Endangered Species Act, as appropriate. Impacts associated with this activity on water quality are minor.

In summary, the cumulative impact of building and operating activities from the Project on surface water quality, added to the effects associated with past, present, and RFFAs within the GAI on surface water quality, is noticeable and stabilizing, primarily due to the beneficial effects of BCSS closure. Overall impacts, therefore, are LARGE and beneficial. Because of adherence to regulations and permits by the NCDEQ and USACE, use of BMPs, and implementation of SPCC plan and SWPPP, the impact of building and operation of the Project is minor and not a significant contributor to the cumulative impact on surface water quality.

7.2.2.3.2 Groundwater Quality

Section 2.2.3.2 of this document serves as a baseline for the cumulative impacts assessment for groundwater quality. As described in 2.2.3.2, groundwater quality from the Piedmont and Blue Ridge aquifers is generally suitable for drinking. Some pre-site development exceedances of pH, metals, and coliforms were detected in groundwater wells. As described in Section 2.2.3.2.3.2, constituents such as aluminum, arsenic, iron, and manganese commonly have elevated naturally occurring groundwater concentrations in the Piedmont. Other than water withdrawals associated with the Duke Energy groundwater corrective action plan remediation system, no groundwater withdrawals currently exist at the operating BCSS.

Impacts to groundwater quality associated with building and operation of the Project are described in Sections 4.2.3.2 and 5.2.3.2. Dewatering of the power block areas usually occurs within a limited area during the duration of the building of the below-grade nuclear island structures and foundations. Drainage sumps at the bottom of the excavation area pump water that may enter the excavation area into an on-site permanent stormwater basin prior to its permitted release to Dan River. Water quality effects of such releases on surface water are discussed in Section 4.2.3.1. An SPCC plan will be prepared and implemented at the Project site, which would include the use of BMPs to minimize the occurrence of spills and limit their effects on groundwater. Because engineering controls prevent or minimize the release of harmful effluents, and effluent concentrations are maintained at levels below permitted limits that are established to be protective of water quality, impacts to groundwater quality from building and operation are SMALL.

As described in Table 7.1-1, the GAI established for groundwater quality is based on aquifers evident on the Project site. All actions listed in Table 7.1-2 are expected to be permitted or authorized in accordance with state and federal laws and regulations concerning groundwater quality. Several of the past, present, and RFFA projects listed in Table 7.1-2 have the potential to result in some effects on groundwater quality. However, none are located within the GAI and would have the potential to substantially contribute to cumulative impacts on groundwater use.

In summary, the cumulative impact of building and operation of the Project on groundwater quality, added to the effects associated with past, present, and RFFAs within the GAI on groundwater quality, is minor, and therefore, SMALL. Because engineering controls as described above prevent or minimize the release of harmful effluents and effluent concentrations are maintained at levels below permitted limits that are established to be protective of water quality, the impact of building and operation of the Project is negligible and not a significant contributor to the cumulative impact on groundwater quality.

7.2.3 ECOLOGY

7.2.3.1 Terrestrial Ecosystems

Section 2.3.1 provides a description of the affected environment and serves as a baseline for the cumulative impact assessment for terrestrial ecosystems, including wetlands. The Project site and Project Vicinity are located within the Piedmont Ecoregion which has changed over the last 200 years - shifting from forest to farm, then back to forest, and now reflects a greater abundance of developed land cover types from growing urbanization. The most prevalent land cover in the Project Vicinity is deciduous forest, followed by hay/pasture, evergreen forest, and mixed forest. Many terrestrial plant communities and associated habitats within the Project site are composed of previously disturbed communities consisting of developed lands or marginal evergreen, herbaceous, and scrub shrub habitat. Wildlife habitat value and associated wildlife communities are considered limited in these areas. However, deciduous forest and associated stream valley habitats and wetlands provide higher-quality wildlife habitat and breeding and nesting areas for wildlife.

Impacts from building activities and operations of the Project are described in Sections 4.3.1 and 5.3.1 respectively. Impacts on plant communities and habitats from building activities are noticeable based on the size of the area affected. Although much of the impacts on-site are on low-quality habitats, higher-quality habitats on-site are also impacted. Wildlife composition within the Project site is altered to naturalized communities, and impacts on wildlife are limited because of mitigation measures, BMPs, and the short duration of building activities. The only important terrestrial habitat on-site are wetlands, and these impacts are mitigated by BMPs and federal or state mitigation requirements. Impacts on important species are also limited because of the low probability of occurrence, the presence of extensive habitat characterized by low-quality plant communities, and the abundance of similar suitable habitat within the Project Vicinity. In addition, implementation of appropriate conservation measures minimizes impacts on important terrestrial species. As described in Section 4.3.1, impacts to terrestrial ecology and wetlands from building activities are MODERATE.

Impacts from operations on the Project site are limited by the lack of on-site habitat due to development of the Project site during the preceding building activities phase. Impacts associated with landscape maintenance activities, potential for invasive species establishment, noise emissions, cooling tower salt deposition, and potential for collisions with tall structures are minor and mitigated by using BMPs, invasive species control methods, compliance with the Migratory Bird Treaty Act, and use of bird-safe transmission system measures. As described in Section 5.3.1 the impact on terrestrial ecosystems and wetlands from operation of the Project is SMALL.

As identified in Table 7.1-1, the GAI for terrestrial ecosystems is the Project site and Project Vicinity. Table 7.1-2 identifies past, present, and RFFAs that have the potential to result in impacts to terrestrial ecosystems. However, many of these identified projects are either relatively minor in scope or located outside of the GAI and have limited or no connected action to terrestrial ecosystems, including wetlands, within the GAI. For example, RFFAs such as the Enbridge – T-15 Reliability Project or the Future Bashavia Creek Preserve have the potential for adverse or beneficial effects associated with habitat alteration or preservation respectively. But such projects are substantially outside of the GAI, and therefore, are not expected to contribute to cumulative effects to terrestrial ecosystems and wetlands within the GAI.

The following RFFAs are linear roadway and rail improvement projects that are identified within the GAI but are not expected to greatly impact terrestrial resources within the Project Vicinity:

- U.S. 158 (Reidsville Road) Improvements
- Carolinian Piedmont Passenger and Freight Improvements

These road and railway projects represent the continued and future operation of existing industrial infrastructure and are expected to alter habitat that is either within or along existing established corridors within the GAI. These established, developed corridors along roads and railways are considered low-quality habitat and thus, additional development within them would not result in a substantial loss to terrestrial ecosystems. Any potential effects of these actions are subject to federal and state permitting. Effects are reduced by appropriate mitigation in accordance with USACE, NCDEQ, Section 7 of the Endangered Species Act, and the Migratory Bird Treaty Act, as appropriate. Therefore, impacts associated with these activities on terrestrial ecosystems are expected to be minor.

The following actions identified in Table 7.1-2 within the GAI have the potential to substantially contribute to cumulative impacts on terrestrial ecosystems:

- NCTPC 2023-2033 Collaborative Transmission Plan
- Bear Branch Solar Project

New industrial developments such as transmission and solar projects are expected to commit additional land to industrial uses. The NCTPC Transmission Plan may involve adding new transmission lines which could involve the conversion of habitat to more developed or maintained land. Although specific details of potential impacts to terrestrial ecosystems and wetlands are not known for the NCTPC transmission project, any potential effects of these actions are subject to federal and state permitting. Therefore, effects are reduced by appropriate mitigation in accordance with USACE and NCDEQ, Section 7 of the Endangered Species Act, and the Migratory Bird Treaty Act, as appropriate.

Bear Branch Solar Project is an energy generation development on approximately 320 ac. (130 ha) located 6 mi. (3.2 km) north-northwest of the Project site, within the Project Vicinity. The project is located on previously cleared, vacant land and lacks forested habitat. The project entails conversion of herbaceous and scrub shrub habitat to developed uses. With approximately 2917 ac. (1180 ha) of herbaceous habitat and 2387 ac. (966 ha) of scrub shrub habitat in the Project Vicinity (Table 4.3-1), the loss of herbaceous and shrub habitat to this solar project is a minor habitat conversion. However, this RFFA could prevent larger wildlife from using this area as a habitat corridor for traveling between areas of higher habitat. Smaller animals could move through the solar project under or through the fences, so not all wildlife movement would be restricted.

In summary, the cumulative impact of building and operating activities from the Project on terrestrial ecology and wetlands, added to the effects associated with past, present, and RFFAs within the GAI on terrestrial ecology and wetlands, is noticeable but not destabilizing and therefore MODERATE. The impact of building activities on terrestrial ecosystems and wetlands results in degradation of quality habitat that is persistent. Because of extensive forest habitat loss on the Project site and associated impacts with wildlife, the impact of the building and operation of the Project would be a noticeable contributor to the MODERATE cumulative impact on terrestrial ecology.

7.2.3.2 Aquatic Ecosystems

The description of the affected environment in Section 2.3.2 serves as a baseline for the cumulative impacts assessment for aquatic ecosystems. On-site streams contain species representative of relatively low water and habitat quality. Belews Lake contains species that are indicators of moderate to good water quality with reproductive, self-sustaining fish populations. Dan River contains habitat suitable for mussels and sensitive fish species that may include good water quality, suitable foraging, low pollutant loads, and a variety of substrate/habitat types.

Impacts to aquatic ecosystems associated with the Project are described in Sections 4.3.2 and 5.3.2, respectively. Building activities result in impacts to several on-site streams. However, given their small size, intermittent nature, and indicators of lower water and habitat quality, on-site streams are of poor quality. Impacts on aquatic habitat in Belews Lake during building activities is minor based on lack of high quality or unique habitats in the areas of impact. Within Belews Lake, impacts are temporary and localized to the specific location of intake and discharge structures. Indirect impacts to aquatic communities are minimized under permitting and SWPPP requirements and with BMPs. Unavoidable impacts to on-site aquatic habitats are mitigated in conjunction with regulatory requirements in conjunction with CWA Section 401 and Section 404 permitting by NCDEQ and USACE, respectively (see Section 4.2.1). Given the small size of stream features supporting common and widespread aquatic biota, and the commitment to implement appropriate compensatory mitigation, overall impacts are minor. Duke Energy will consult with U.S. Fish and Wildlife Service and the North Carolina Wildlife Resources Commission regarding avoidance and mitigation measures to limit potential effects on proposed critical habitats within the Dan River. As described in Sections 4.3.2, the impacts on aquatic ecology from building and operation of the Project are SMALL.

Operational impacts to aquatic ecosystems include impacts related to on-site stormwater runoff and incidental spills that are managed through stormwater management systems. In Belews Lake, operational impacts are associated with the location of the intake and discharge structures, and with changes in water levels. Impacts of the discharge(s) are expected to dissipate rapidly, limiting impacts on aquatic ecosystems. Impacts of intake operation are minimized through compliance with CWA Section 316(b) requirements. In the Dan River, operational impacts are associated with operation of the MWIS at the confluence of Belews Creek and the Dan River, and with the wastewater discharge. Impacts of MWIS operation on impingement and entrainment in the Dan River are regulated through intake flow requirements under the existing BCSS NPDES permit NC0024406 and are minimized by technologies and design features, therefore impacts on important species and their habitats are minor.

Additionally, as described in Section 5.3.2, consumptive uses of Belews Lake in support of Project operations, result in water-level fluctuations. Depending upon the extent and duration of droughts, aquatic communities may be adversely affected by water-level fluctuations that result in the desiccation of aquatic substrates and impacts on benthic organisms, aquatic macrophytes, and valuable spawning and nursery areas for fish. Under conditions in which water levels are stabilized and consumptive losses are generally offset by MWIS pumping, impacts on Belews Lake aquatic ecology are SMALL. However, impacts on Belews Lake aquatic ecology are impacted to a greater degree as a result of noticeable and prolonged water-level fluctuations in conjunction with increased drought intensity. Under such conditions, effects on aquatic biota of Belews Lake are MODERATE.

As described in Section 5.3.2, the impacts on aquatic ecology from building and operation of the Project are SMALL for most conditions but are MODERATE within Belews Lake under periods of increased drought intensity.

As described in Table 7.1-1, the GAI established for aquatic ecology is based on watershed connectivity and includes the Project site, Belews Lake, Dan River, and Town Fork Creek. Table 7.1-2 identifies past, present, and RFFAs considered in assessing cumulative impacts to aquatic ecosystems. Many of these identified projects are either relatively minor in scope or are not within the GAI. Several RFFAs are within the GAI but are not expected to greatly impact aquatic ecosystems, including:

- U.S. 158 (Reidsville Road) Improvements
- Carolinian Piedmont Passenger & Freight Improvements
- NCTPC 2023-2033 Collaborative Transmission Plan
- Bear Branch Solar Project
- BCSS Ash Basin Closure and Landfill Construction

These projects represent the continued or new operation of industrial infrastructure such as roads, railways, transmission projects, solar facilities, or other industrial uses. While these projects do not have direct impacts on aquatic resources described in the GAI, indirect impacts, such as degradation of water quality from sedimentation and potential accidental spills, could occur to streams flowing into the Dan River, Belews Lake, or Town Fork Creek. Compliance with federal, state, and local requirements minimizes these potential indirect impacts on aquatic ecosystems. Compliance with the terms of applicable Section 404 permits (including minimization and mitigation) and using BMPs further reduces impacts.

As described in Section 2.2.1.1.3, Belews Lake is a man-made reservoir formed in 1970 following construction of an earthen embankment dam across Belews Creek. The lake was constructed primarily to serve as a CCW source for the BCSS. Three named streams flow into Belews Lake: Belews Creek, West Belews Creek, and East Belews Creek. As described in Section 2.3.2.2.2, the impoundment of Belews Lake resulted in effects related to the development of an aquatic ecological community that is characteristically different from that of Belews Creek and its tributaries. Recent monitoring on Belews Lake reflected the presence of a balanced and indigenous aquatic biological community. The presence of macrophytes was limited to shallower areas of the reservoir. Benthic macroinvertebrate communities were dominated by pollution-tolerant species; however, the presence of pollution intolerant mayflies in spring and summer were indicators of moderate to good water quality. The fish community was characterized by multiple trophic guilds, with a size-structure that indicated reproductive, self-sustaining populations. While the aquatic communities of Belews Lake represent a valuable aquatic ecological community that is an important recreational resource, the effects on the aquatic community are persistent and noticeable.

The BCSS closure, identified in Table 7.1-2 may also contribute to substantial cumulative impacts on aquatic ecosystems through direct impacts to waters within the GAI.

As described in Section 7.1.2, BCSS closure has several potential effects on aquatic ecology that result from the elimination of thermal discharges to Belews Lake that provide for improved water quality, and reduced stress on aquatic biota within Belews Lake. It is anticipated that Project operations will be authorized under a modification of the existing BCSS NCDEQ NPDES

permit NC0024406 to manage intake flow requirements, minimize effects on Dan River aquatic biota, and minimize impingement and entrainment by the MWIS. Thus, permitted supplemental pumping from the Dan River is no longer influenced by BCSS uses, but similar effects continue with Project operations.

Within Belews Lake, cumulative effects of BCSS closure in conjunction with the Project are mixed in which periods of water-level fluctuations caused by increased drought intensity may lead to increased instability in aquatic macrophyte communities, with resulting adverse effects on vegetation diversity. Water-level fluctuations under drought conditions are expected to lead to decreased habitat availability and potential desiccation to benthic macroinvertebrates and mussels. Such water-level fluctuations may also be expected to affect fish reproductive success during recurring drought conditions in which macrophyte beds are used for spawning and nursery may be less available to fish. Further, there is increased potential for proliferation of nuisance macrophytes, such as Hydrilla under these conditions. However, the balance of fish communities is not expected to shift in such a way that would promote the expansion of nonindigenous fish beyond those already present in Belews Lake.

Additionally, closure of BCSS results in significant benefits that result in cooler water temperatures within Belews Lake that persist throughout the licensing period. Effects of Project thermal discharges on whole lake temperatures within Belews Lake are localized and negligible. Therefore, aquatic communities are expected to reflect a taxonomic shift in the fish community, likely to result in a community that is more closely aligned with that observed in Mayo Reservoir. Fish condition shifts are also likely to occur. Changes to cooler water temperatures and the subsequent loss of warmer winter temperatures in the West Belews Creek arm of Belews Lake will affect the timing of spawning and result in a shorter growth season. Some species may exhibit higher overall condition, as cooler temperatures may reduce the level of caloric intake required to meet the stressful energetic needs associated with habitats with elevated temperatures. Changes to the forage base may result in changes in trophic and population dynamics across the lake. Within the Dan River, the cumulative effects of BCSS closure in conjunction with the Project are generally offset due to the phased implementation of the Project, and because the BCSS closure impacts aquatic resources through the same level of MWIS pumping.

In summary, the cumulative impact of building and operating activities from the Project on aquatic ecology, added to effects associated with past, present, and RFFAs within the GAI on aquatic ecology is MODERATE. This conclusion accounts for the cumulative effects of past impoundment of Belews Creek and its resultant effects on the aquatic ecosystem within Belews Creek and its tributaries. The incremental contribution of building and operation of the Project is a minor contributor to the cumulative impact on aquatic ecosystems under normal conditions and noticeable in conjunction with the effects of increased drought intensity.

7.2.4 SOCIOECONOMICS

As described in Section 2.4, socioeconomic impacts primarily affect the four counties (Guilford, Forsyth, Rockingham and Stokes Counties) that make up the region of influence (ROI) where expected shifts in workforce demographics are expected to influence socioeconomic conditions. Therefore, the ROI is the GAI for assessing cumulative socioeconomic impacts unless otherwise specified. Table 7.1-2 details recent past, present, and RFFAs within the GAI.

7.2.4.1 Physical Impacts

Section 4.4.1 describes physical impacts from building activities, including those associated with noise and vibration, odors, dust and air pollution, transportation, and visual impacts. The impact of noise and vibration on nearby structures is minimal due to the distance between the areas on the Project site where vibration-inducing activities take place and the closest residence. Air emissions are effectively managed through mitigation measures and adherence to regulatory limits, resulting in only minor air quality impacts. Physical impacts on transportation infrastructure are minor. Any damage to public roads, pavement markings, or signage caused by building activities are repaired to preexisting conditions or better, in accordance with state and local requirements. Aesthetic impacts associated with building activities are noticeable but not destabilizing. These impacts are primarily related to the introduction of new structures, use of construction equipment, and increased traffic in the Project Vicinity. Therefore, physical impacts of building activities are SMALL for most factors, but MODERATE for aesthetics.

As stated in Section 5.4.1 physical impacts from operation including odors, dust, and air pollution, thermal emissions, noise, and transportation-related impacts are SMALL. However, the addition of new cooling towers, associated steam plumes, and reactor facilities at the Project site noticeably alters the visual environment for nearby residents and recreators on Belews Lake. Thus, physical impacts on aesthetics from operations are MODERATE.

Because most physical impacts from construction and operation diminish rapidly with distance, the GAI for physical impacts is generally limited to the Project site. However, for impacts with a broader reach, such as transportation-related effects, noise, and aesthetics, the GAI extends into the surrounding Project Vicinity.

Many of the past, present, and RFFA projects listed in Table 7.1-2 have the potential to result in some physical effects to the surrounding environment. However, most projects are located outside of the GAI and have limited or no connectivity to resources potentially affected by physical impacts from the Project. Additionally, several of the projects are past, present, and ongoing actions that have been captured in the affected environment and building and operations-related impacts analysis and therefore do not represent an additional cumulative impact. These include:

- BCSS operation
- BCSS Ash Basin Closure and Landfill Construction
- NCTPC 2023-2033 Collaborative Transmission Plan
- Dan River State Trail
- Mountains-to-Sea State Trail
- Carolinian Piedmont Passenger & Freight Improvements
- Walnut Cove Greenway

Among the RFFAs, the following are considered to have the potential to substantially contribute to cumulative impacts on the physical environment:

- BCSS closure
- BCSS Deconstruction

- Bear Branch Solar Project
- Belews Lake Park
- U.S. 158 (Reidsville Road) improvements

Future actions including the BCSS closure and deconstruction, solar projects, Belews Lake Park, and U.S. 158 (Reidsville Road) Improvements, could contribute to physical impacts associated with air emissions, noise, impacts to structures, and visual impacts. Like the Project, these impacts — particularly air emissions, noise, and structural impacts — are expected to be localized, diminishing rapidly with distance from each Project site. Visual impacts of these RFFAs depend on existing topography, proximity to sensitive receptors, and operations-related activities. The solar projects are expected to have a lasting impact on the visual landscape. In contrast, construction at Belews Lake Park and along U.S. 158 are anticipated to cause temporary visual impacts during construction, with minimal impact once operational.

As described in Section 7.1.2.3, following closure of the BCSS, the disappearance of the steam plume reduces the facility's visual prominence. However, the remaining infrastructure continues to define the viewshed. As a result, the overall visual presence of the site is diminished but not eliminated, and the facility remains a notable feature in the landscape.

Deconstruction activities associated with the BCSS may result in minor, short-term increases in air emissions, noise levels, and traffic within the Project Vicinity. These impacts are expected to be limited in scale and duration, occurring only during the defined deconstruction period. Temporary visual changes, such as the presence of equipment and structural dismantling, may also be noticeable. Although the exact timeline for deconstruction has not been established, any associated impacts would be confined to that period and may overlap with ongoing Project operations.

The cumulative physical impacts of building activities and operations of the Project, together with past, present, and RFFAs within the GAI on the physical environment is SMALL for all categories except aesthetics, which is MODERATE. The Project is a noticeable contributor to the cumulative impact on aesthetics-related to physical impacts within the GAI. In contrast, its contributions to other physical impacts are minor and do not alter the overall SMALL cumulative impact to those resources.

7.2.4.2 Demographic Impacts

The description of the affected environment in Section 2.4.1 serves as the baseline for assessing cumulative demographic impacts. As detailed in Sections 4.4.2 and 5.4.2, population increases resulting from the in-migration of workers and their families are estimated to raise the population in the ROI by approximately 0.3 percent during the building phase and 0.2 percent during operations. Given the limited scale of these changes, the cumulative demographic impacts are SMALL.

The GAI for demography includes four counties: Forsyth, Guilford, Rockingham, and Stokes that comprise the ROI where socioeconomic impacts are expected based on the effects associated with the workforce population. Many of the past, present, and RFFA projects listed in Table 7.1-2 are located outside of the GAI and do not influence demographic conditions within the ROI.

Several RFFAs within the GAI are primarily construction projects (pipelines, solar projects, transmission, roadway and rail improvements, greenway developments, water treatment plant

improvements, water tower construction) and do not require a substantial operational workforce that would result in notable demographic changes in the GAI. Additionally, projects involving park and recreational facility improvements primarily attract transient populations, rather than permanent residents, and therefore do not result in a notable change in existing demographic patterns.

Among the RFFAs the following actions listed in Table 7.1-2 are considered to have the potential to contribute to cumulative impacts on demography:

- BCSS closure
- BCSS Deconstruction
- WAGABOX Renewable Natural Gas (RNG) Plant
- Windsor Chavis Nocho Community Complex
- Marshall Aerospace Maintenance and Engineering Facility
- Guilford Technical Community College (GTCC) Aviation Training Center
- Toyota Battery Manufacturing North Carolina

Future actions, including the deconstruction of BCSS, and the construction and operation of energy facilities and other industrial and manufacturing projects, create jobs and are likely to bring in-migrating workers to the ROI. While changes in population are expected to be minor in areas near the Project and in other rural parts of the ROI, larger demographic shifts are more likely in urban centers such as Kernersville, Winston-Salem, and High Point, which tend to attract a greater share of in-migrating populations.

As discussed in Section 2.4.1, the population within the ROI is projected to grow at an average annual rate of approximately 0.8 percent, with the most significant growth occurring in Guilford and Forsyth Counties. Urban centers already possess the infrastructure (housing, schools, healthcare, and other services) needed to accommodate modest population increases without significant strain. BCSS closure results in a reduction of workforce. However, it is expected that most former BCSS workers will continue to reside within the ROI.

As shown in Table 2.4-3, population growth within the ROI is expected to continue, and the additional population associated with RFFAs is anticipated to align with or slightly accelerate these existing trends. Therefore, the cumulative demographic impacts of these RFFAs are considered minor.

The cumulative demographic impact of building and operating activities from the Project, when considered alongside the effects of past, present, and RFFAs (including projected population growth within population centers within the ROI) is SMALL. This is primarily due to the relatively large existing population in the ROI and the comparatively small size of the Project's workforce during building and operation. As a result, the Project is a minor contributor to the SMALL cumulative impact on demography.

7.2.4.3 Economic Impacts

The description of the affected environment is Section 2.4.2 serves as a baseline for assessing cumulative economic impacts. Section 4.4.3 details the impacts during the building phase, projecting that the Project will introduce millions of dollars into the economy and generate both

direct and indirect employment. These positive economic impacts are primarily realized within the ROI. Minor increases in local tax revenues are expected through individual income taxes, sale of electricity tax, and sales and use taxes. Therefore, impacts on the economy during the building phase are MODERATE and beneficial.

Section 5.4.3 addresses economic impacts during the operation of the Project. Similar to the building phase, operations are expected to contribute millions of dollars into the economy and create both direct and indirect jobs. However, the scale of economic activity during operations is smaller, and therefore, the overall impact during operations is SMALL and beneficial.

The GAI for economic impacts includes four counties that comprise the ROI where economic effects are expected based on the direct and indirect Project expenditures associated with the workforce. Many of the past, present, and RFFA projects listed in Table 7.1-2 are located outside of the GAI or are of a scale (such as local park improvements) that do not appreciably influence economic conditions within the ROI. Several of the RFFAs are linear projects across the GAI (transmission, roadway and rail improvements, greenway developments) that are identified within the Project Vicinity, including:

- Enbridge – T-15 Reliability Project
- Mountain Valley Pipeline (MVP) Southgate Project
- NCTPC 2023-2033 Collaborative Transmission Plan
- Dan River State Trail
- Mountains-to-Sea State Trail
- Transportation projects
- Greenway Improvements/developments
- Water and wastewater improvements

The above actions are generally expected to have a positive economic impact through workforce-related expenditures. However, because the effect is dispersed across a broad geographic area, the overall beneficial impact is minor.

Many of the past, present, and RFFA projects listed in Table 7.1-2 have the potential to result in economic effects that are primarily realized within the GAI. These include:

- BCSS closure
- BCSS Deconstruction
- WAGABOX RNG Plant
- Bear Branch Solar Project
- Windsor Chavis Nocho Community Complex
- Marshall Aerospace Maintenance and Engineering Facility
- GTCC Aviation Training Center
- Toyota Battery Manufacturing North Carolina

The construction and operation of these actions involve capital expenditures, create employment opportunities, and contribute to overall economic benefits. Although these actions are located within the ROI, project-specific spending and potential increases in local tax revenues are not anticipated to significantly influence the regional economy. BCSS closure results in a reduction of workforce. However, it is expected that most workers are otherwise employed within the ROI.

As noted in Section 7.1.1, the closure of the BCSS may result in loss of local employment opportunities, with approximately 150 current BCSS employees potentially facing temporary unemployment. However, as identified in Section 2.4.2, unemployment rates for all four of the counties in the ROI ranged from 5.2 percent to 6.5 percent. Given the size of the regional labor force, the relatively small number of affected workers, and the addition of in-migrating Project workers the adverse impact of these job losses is negligible.

The cumulative economic impact of the Project, in combination with other past, present, and RFFAs within the GAI, is considered MODERATE and beneficial. The Project is a noticeable contributor to this cumulative impact, particularly through job creation and increased local spending.

7.2.4.4 Community Infrastructure Impacts

The description of the affected environment in Section 2.4.2 serves as a baseline assessing cumulative impacts to infrastructure and community services. Sections 4.4.3 and 5.4.4 describes impacts to infrastructure and community services during the building phase as SMALL within the ROI, with the exception of traffic impacts. Impacts to transportation due to workforce traffic are SMALL within the broader transportation network, but MODERATE on two-lane segments and intersections that provide access to the Project site. Impacts on recreational resources during operations are described in Section 5.4.4.2 and are considered SMALL under conditions in which Belews Lake water levels are stabilized and consumptive losses are offset by MWIS pumping. Operational impacts to recreation are considered MODERATE in conjunction with the effects of increased drought intensity and visual intrusion from the new structures within the Plant Complex areas and the associated plumes.

The GAI for analyzing infrastructure and community service impacts is the ROI, where impacts to infrastructure and demands on community services are expected to increase due to changes associated with the workforce population. As described in Section 2.4.2.6 the ROI contains many opportunities for recreation including natural areas, community parks, golf courses, hiking trails, a campground, and opportunities for boating, fishing, hunting, and bicycling. Many of the past, present, and RFFA projects listed in Table 7.1-2 are located outside of the GAI and do not affect infrastructure or the demand on community services within the ROI.

Several RFFAs within the GAI are primarily construction projects (pipelines, solar projects, transmission, roadway and rail improvements, greenway developments, water treatment plant improvements, water tower construction) and do not require a substantial workforce that would result in notable impacts on the local transportation network or the demand for community services. Additionally, projects involving park and recreational facility improvements primarily attract transient populations, rather than permanent residents, and therefore do result in notable impacts to infrastructure or demand for community services.

Among the RFFAs the following actions listed in Table 7.1-2 are considered to have the potential to contribute to cumulative impacts on infrastructure and community services:

- BCSS Closure
- WAGABOX RNG Plant
- Bear Creek Solar Project
- Marshall Aerospace Maintenance and Engineering Facility
- GTCC Aviation Training Center
- Toyota Battery Manufacturing North Carolina

As described in Section 7.1.2, in conjunction with BCSS closure, potential recreational effects of both water-level changes and changes in water temperature within Belews Lake after closure of BCSS may include the following:

- Belews Lake water levels are no longer influenced by BCSS consumptive water uses (see Section 5.2.1).
- Aquatic ecological communities that reflect a lake lacking significant thermal input from power generation including recreationally important sport fish (Section 5.3.2).
- Depending on the frequency of drought conditions and related water-level fluctuation, corresponding effects may also be evident in the condition of recreationally important sport fish (i.e., smaller fish, changes in community structure, and other factors) that may be sought after by anglers (Section 5.3.2).
- The number of fishing tournaments held at Belews Lake (as described in Section 2.4.2.6.2) and the related benefits to local businesses that depend on such recreators may also be correspondingly reduced.
- Restricted access to several small coves that fall within the EAB as described in Section 5.4.1.1.

Other than the BCSS closure action, these future actions create jobs and are likely to bring in-migrating workers to the ROI. The scale of which varies from relatively minor (solar projects, RNG plant) to potentially large (Toyota Battery Manufacturing North Carolina). As discussed in Section 2.4.1, the population within the ROI is projected to grow at an average annual rate of approximately 0.8 percent, with the most significant growth occurring in Guilford and Forsyth Counties. Urban centers such as Kernersville, Winston-Salem, and High Point already possess the infrastructure, housing, schools, healthcare, and other services needed to accommodate these population increases without significant strain.

The cumulative effect of the Project on infrastructure and community services, when combined with past, present, and RFFAs within the GAI is considered SMALL based on the broader opportunities for recreation within the ROI. While the Project has noticeable effects on traffic and recreation at Belews Lake (as described in Section 5.4.4.2), the Project is a minor contributor to this overall cumulative impact.

7.2.5 NOT USED

Deleted (Executive Order, 2025a, 2025b)

7.2.6 HISTORIC AND CULTURAL PROPERTIES

The description of the affected environment in Section 2.6 of this document serves as a baseline for the cumulative impacts assessment for historic and cultural resources. The area of potential effects (APE) means “the geographic area or areas within which an undertaking may directly or indirectly cause alterations in the character or use of historic properties, if any such properties exist.” The determination of the APE is based on the potential for both direct and indirect effects. Direct effects are defined as those that result from activities that could damage or destroy the physical integrity of a cultural resource. Direct effects are typically associated with building activities. Indirect effects are those that do not directly destroy the physical integrity of a cultural resource but would adversely affect contributing elements of the cultural resource. For historic structures, this typically consists of visual effects to the viewshed of the cultural resource that may diminish its overall context. The APE includes a contiguous area on the Project site and a wastewater discharge pipeline corridor to the Dan River. Both are located on land owned by Duke Energy as indicated in Section 2.1.1.3. As described in Section 2.6, a Phase I cultural resource survey identified nine sites potentially eligible for listing on the National Register of Historic Places (NRHP). The Branson Cemetery is also located within the APE, but it is not eligible for NRHP listing. A subsequent Phase II cultural resource survey was conducted and recommended that four of the nine sites are eligible for NRHP listing.

As described in Sections 4.6, the impacts on historic and cultural resources from building the Project are characterized as SMALL to MODERATE. Duke Energy seeks to avoid all sites in conjunction with detailed site development and design activities following technology selection. As such, impacts of building activities are SMALL. However, if site avoidance is not possible, Duke Energy will conduct Phase III data recovery investigations in consultation with NCSHPO. If sites are not avoidable, impacts of building activities are MODERATE. As described in Section 5.6, the impacts on historic and cultural resources from operation are characterized as SMALL. Ground disturbing activities during building may also have the potential to discover previously unknown archaeological resources or human remains. If an inadvertent discovery of a cultural resource (e.g., graves or grave sites, archaeological sites, historical artifacts, etc.) is made during the building phase, then appropriate mitigative measures to address potential effects to these previously unknown cultural resources will be developed in consultation with the tribes, the North Carolina State Historic Preservation Office, and the North Carolina Office of State Archaeology. The Catawba Indian Nation, the only federally recognized tribe with interest in the project area, requested to be notified if Native American artifacts or human remains are discovered.

Based on consultation with and written confirmation from the North Carolina State Historic Preservation Office, an architectural viewshed survey was not required; therefore, an indirect APE beyond the archaeological APE was not established. No portions of the APE include federal, state, or tribal-owned lands. Therefore, as indicated in Table 7.1-1, the GAI for historic and cultural resources is the same as the APE.

RFFAs identified as part of this cumulative effects analysis are identified in Table 7.1-2. Each of the RFFAs are considered in the cumulative effects analysis for impacts to historic properties. Among the projects listed in Table 7.1-2, no new or updated actions within the GAI (i.e., the APE) have the potential to contribute to cumulative impacts on historic and cultural resources.

In summary, the cumulative impacts of building and operating activities on historic and cultural resources, added to the effects associated with past, present, and RFFAs within the GAI on historic and cultural resources is SMALL to MODERATE. Because no other RFFAs are

identified within the APE, the impact of building activities is a SMALL to MODERATE contributor to the cumulative impact on historic and cultural resources.

7.2.7 AIR QUALITY

Section 2.7 provides a description of the affected environment and a baseline for the cumulative impact assessment for air quality. The Project site is in Stokes and Forsyth Counties, North Carolina, and is bordered by Rockingham County to the east and Guilford County to the southeast. The Project site, in addition to all of Stokes, Forsyth, Rockingham, and Guilford Counties are in attainment for all of the National Ambient Air Quality Standard criteria pollutants (NCDEQ, 2024). In addition, these counties are part of the Northern Piedmont Intrastate Air Quality Control Region.

As described in Section 4.4.1.2, air emissions from building activities are minor. Emissions are controlled using minimization measures and by maintaining established regulatory limits. Fugitive dust and fine particulate matter are generated during earth-moving activities, concrete batch plant operation, and movement of vehicular traffic over recently disturbed or cleared areas or unpaved roads. Vehicles and engine-driven equipment (e.g., generators and compressors) generate combustion product emissions such as carbon monoxide, oxides of nitrogen, and to a lesser extent, sulfur dioxides. Painting, coating, and similar operations produce emissions of volatile organic compounds.

As described in Section 5.7, the number of vehicles on roadways associated with operations is smaller than during construction and the Project is a de minimis contributor to air emissions, as expected for a clean energy source. Air emission sources during operation at the Project site are managed in accordance with federal, state, and local air quality control laws and regulations. A new plant at the Project site will comply with all regulatory requirements of the Clean Air Act (CAA), and NCDEQ Division of Air Quality (DAQ) requirements to minimize impacts on state and regional air quality.

More detailed facility-wide assessments will be prepared during the facility's air permitting phases with the NCDEQ-DAQ after final design; therefore, impacts on air quality during operation are SMALL.

As described in Section 5.7.2.2, the impacts of GHG emissions from the Project site and workforce transportation relative to the impacts on GHG emissions in North Carolina and in the United States are also SMALL.

As described in Section 5.7.3, the impacts of existing transmission lines and additions at the Project site are SMALL.

As shown on Table 7.1-1, the GAI for criteria pollutants includes Stokes, Forsyth, Rockingham, and Guilford counties because air quality designations are made on a county-by-county basis.

Table 7.1-2 identifies past, present, and RFFA projects that have the potential to result in air quality impacts. Among the RFFAs, the following actions are within the GAI for air quality and are considered to have the potential to contribute to cumulative impacts on air quality:

- BCSS Closure
- BCSS Ash Basin Closure and Landfill Construction

- WAGABOX RNG Plant
- Natural Gas Pipeline Projects (Enbridge; Transco, LLC; MVP)
- Electric-solar power plant projects
- Transmission line projects
- Parks and recreation improvement projects
- Transportation projects
- Water and wastewater improvement projects

7.2.7.1 Criteria Pollutants

The air quality of the GAI, currently in attainment, has been impacted by past and ongoing industrial land uses. Existing operations such as the BCSS facility and WAGABOX construction are not expected to contribute to reduced air quality within the GAI and they are expected to continue their operations within the terms of their existing environmental permits. Additionally, building activities associated with transmission line, parks and recreation, electric-solar power plant, transportation, and water and wastewater projects, are expected to implement BMPs to minimize potential air quality impacts during construction. The impacts of their future operation will be limited and controlled in accordance with the applicable state and federal regulations such that they do not adversely affect attainment.

The BCSS closure identified in Table 7.1-2 may contribute to substantial cumulative impacts on air quality through direct impacts within the GAI.

As described in Section 7.1.2.4, the BCSS closure has effects on local and regional air quality that include over 97 percent reduced emissions of all criteria pollutants. The cumulative effects of the BCSS closure, in conjunction with the Project, result in smaller criteria pollutant emissions as shown in Table 7.1-3 and contribute to beneficial effects on the existing attainment status of regional air quality within the GAI.

The cumulative impact of building and operating activities from the Project on criteria pollutants, added to the effects associated with past, present, and RFFAs within the GAI is SMALL (beneficial). The impact of the building and operation of the Project site is not a significant contributor to the cumulative impact on air quality.

7.2.7.2 Greenhouse Gas Emissions

GHG emissions are relevant to global climate change, the GAI for GHG is appropriately worldwide.

As described in Section 5.7.2.2, in 2022, North Carolina emitted 116.6 million metric tons (MMT) of CO_2-eq (EIA, 2025). At the national level, net GHG emissions in the United States in 2022 totaled 6343.2 MMT CO_2-eq after accounting for sequestration from the land sector (USEPA, 2024a). These emission rates are existing and reflect the contributing effects of all past and existing projects that emit GHG within both North Carolina and the United States.

The GHG emissions footprint of a generic 1000-megawatt-electric (MWe) reactor provides a conservative estimate of impacts. The lifetime GHG emissions footprint of a generic 1000-MWe reactor is 10.5 MMT CO_2-eq. (Table A-3. Nuclear Power Plant Lifetime GHG Footprint NRC,

2014). Lifetime GHG emissions from a new power plant are an estimated 9 percent of annual 2022 GHG emission in the state of North Carolina (10.5 to 116.6 MMT) and 0.17 percent of the annual 2022 carbon equivalent emissions in the U.S. (10.5 to 6343.5 MMT). Given the relatively small lifetime GHG emission footprint of a generic reactor, impacts of GHG emissions from the Project site are SMALL. Annual GHG emissions in North Carolina from other RFFAs identified in Table 7.1-2 are not notable contributors at the state level.

Estimated annual GHG emissions from the Project and other RFFA projects are a fraction of national GHG emissions. Because GHG emissions and associated impacts require a global perspective, small incremental changes from individual projects must be evaluated collectively. This is beyond the scope of an individual project and is therefore addressed by the U.S. under the authority of the USEPA at the national scale. However, mitigation measures provide individual projects with the ability to minimize GHG emissions. Further, in 2010 the U.S. Environmental Protection Agency (USEPA) promulgated the Tailoring Rule to address GHG emissions under the CAA permitting programs. As initially promulgated, the Tailoring Rule specified that new sources, as well as existing sources with the potential to emit more than 100,000 tons per year CO_2-eq were subject to USEPA permitting requirements. Modifications of existing facilities that increase GHG emissions by at least 75,000 tons per year are also subject to permitting requirements. Subsequent revisions to the Tailoring Rule have not resulted in different GHG emission thresholds (USEPA, 2024b).

The BCSS closure identified in Table 7.1-2 may contribute to substantial cumulative impacts through direct impacts to GHGs within the GAI.

As described in Section 7.1.2.4, BCSS closure has potential beneficial effects on GHG emissions in the Project Region. Compared to BCSS GHG emissions data in 2022 and 2023 combined (the two most recent years of USEPA flight data), the BCSS has emitted more CO_2-eq than the estimated lifetime emissions of the new nuclear facility. The cumulative effects of the BCSS closure, in conjunction with the Project, result in smaller GHG emissions. However, because the GAI for GHG emissions is worldwide, the effects of reduced GHG emissions is minor.

Therefore, the cumulative impact of building and operating activities from the Project on GHG emissions, added to the effects associated with past, present, and RFFAs within the GAI is SMALL. The impact of the building and operation of the Project site is not a significant contributor to the cumulative impact on GHG emission levels.

7.2.8 NONRADIOLOGICAL HEALTH

The description of the affected environment in Section 2.8 serves as a baseline for the cumulative impacts assessment for nonradiological health. Section 2.8 describes public and occupational health related to occupational injuries, etiological agents, noise, and human health issues associated with transportation and electromagnetic fields (EMFs). The existing environment for public and occupational health is partially characterized by information related to the nearest industrial facility (BCSS), as well as statewide data on injuries and fatalities, exposure to etiological agents, traffic patterns, and crash frequencies. Several existing regulations help protect and minimize impacts to public and occupational health including those set by the Occupational Health and Safety Administration (OSHA), the NRC. Duke Energy maintains Environmental Health and Safety manuals outlining policies, responsibilities, and management systems. Additionally, ambient noise at the Project site is below the USEPA public health and welfare threshold of L_{dn} 55 dBA for outdoor residential areas.

As described in Section 4.8, potential public health risks associated with building activities include exposure to chemical hazards or other physical nonradiological hazards, such as air pollution from engine exhaust and fugitive dust, vibration, and noise. Other potential health hazards include transportation-related impacts associated with an increase in crashes related to the additional vehicular traffic from construction and operations workers and the transport of supplies traveling to and from the Project site. Nonradiological health impacts of building activities are SMALL for all categories.

As stated in Section 5.8, impacts of operation are related to potential exposure to etiological agents associated with cooling system operation, noise emissions from cooling tower operation, hazards associated with electric shock, and potential health and injury effects associated with transportation-related crashes. Other operational effects include those associated with worker related occupational injuries and fatalities. Overall, operations-related impacts on nonradiological occupational health are SMALL.

Most physical, nonradiological effects of construction and operation either diminish rapidly with distance or remain confined to the Project site and its ancillary off-site features (intake and discharge locations). Therefore, the primary GAI for nonradiological occupational health impacts is the Project site and its immediate surroundings for etiological agents, noise, EMFs, and electric shock, and the ROI (Forsyth, Guilford, Rockingham, and Stokes counties)—where the workforce primarily resides—for public- and transportation-related health issues (see Table 7.2-1).

While many of the past, present, and RFFAs listed in Table 7.1-2 have the potential to result in effects on nonradiological health, most RFFA projects potentially affecting etiological agents, noise, and EMFs and electric shock are located outside of the GAI. Relevant RFFAs in Table 7.1-2 potentially contributing to cumulative effects related to etiological agents, noise, EMFs and electric shock are limited to BCSS operation and BCSS deconstruction and closure. The existing operations of BCSS, including baseline effects related to each of these factors, are considered as appropriate in Section 2.8. As advanced reactors are completed and brought online, BCSS operations decrease in parallel to maintain a balanced level of regional power generation. Accordingly, thermal effluents of BCSS are diminished and ultimately ceased, as the advanced reactors become fully operational. Because thermal loading to Belews Lake is substantially reduced with advanced reactor operation relative to baseline conditions (Section 5.2.1), the potential for etiological related health effects is lower than the existing condition. The potential for etiological agents associated with cooling tower operation for the Project is assessed in Section 5.8.1. Additionally, as stated in Section 5.2.3, based on compliance with permitting programs and Duke Energy's Water Chemistry Program, the impact from cooling tower blowdown chemical constituents to the Belews Lake and the Dan River are minor. Future activities associated with BCSS retirement and decommissioning may contribute to some periodic increased noise levels in addition to the noise emissions from cooling towers for the Project. Additionally, because transmission systems on the Project site are essentially integrated into the existing established transmission system associated with BCSS, no substantive expansion would occur. Therefore, no cumulative effects related to EMF or electric shock would occur. Therefore, the cumulative effects of relevant RFFAs related to etiological agents, noise, EMFs and electric shock within the GAI are minor.

Other RFFAs outlined in Table 7.2-1 within the GAI may contribute to public and transportation-related health concerns, depending on the scale and duration of each project. Key influencing factors include workforce size, total hours worked, potential hazards during construction and

operation, emissions from equipment and vehicles, and transportation requirements for personnel and materials.

These cumulative impacts are expected alongside ongoing operations within the ROI. Worker health risks are managed through OSHA regulations and environmental programs, while existing transportation infrastructure and traffic systems help mitigate any effects on crash rates and injuries. As a result, the overall cumulative impact of these RFFAs on occupational and transportation-related health within the ROI are minor.

The cumulative impact of building and operation activities for the Project, combined with the effects associated with past, present, and RFFAs within the GAI (occupational as well as the transportation and public health-related GAI), on nonradiological health is SMALL for all categories.

7.2.9 RADIOLOGICAL HEALTH

The description of the affected environment in Section 2.9, Radiological Environment and Radiological Monitoring, serves as a baseline for the cumulative impacts assessment for radiological environment and radiological monitoring. Section 2.9 also describes potential background radiation exposure from natural sources. As described in Section 4.9, Radiological Health, and Section 5.9, Radiological Health during Normal Operation and Radioactive Waste Management, the radiological impacts on construction workers and members of the public from normal operation of the Project site are SMALL.

As shown on Table 7.1-1, the GAI for radiological health is defined as the 50-mi. (80-km) region of the Project site. Any releases of radioactive gases, particulates and direct radiation shine dose is dispersed, diluted, or otherwise attenuated as a function of the distance from the Project site. Their contribution is essentially indistinguishable from the naturally existing background radiation at distances outside the GAI.

Table 7.1-2 identifies past, present, and RFFAs projects considered in the cumulative effects analysis. While many of the past, present, and RFFAs listed in Table 7.1-2 receive small impacts from the Project site, no projects listed are expected to contribute to the cumulative effects related to radiological impacts.

The cumulative radiological impact of construction and operation activities from the Project, combined with the effects associated with past, present, and RFFAs within the GAI, on radiological health is SMALL for all categories discussed in this subsection.

7.2.10 NONRADIOACTIVE WASTE

Section 4.10 identifies nonradioactive waste generated during building activities and Section 5.10 identifies waste generated during operation. Generation, handling, and disposal of nonradioactive solid waste during building and operational activities are managed in accordance with all applicable state and local requirements and standards. All activities comply with measures outlined in the SPCC plans and regulated practices for managing liquid discharges, including wastewater, as well as the conditions of the NPDES permit with an approved SWPPP. Air emissions are minor and meet the requirements of the NCDEQ. Nonradioactive waste streams during operation of the Project and managed and treated prior to their discharge to the Dan River.

As is described in Sections 4.10.1 and 5.10.1 Project building phase activities and operations result in the generation of various types of solid, hazardous, and mixed wastes. Wastes are managed in accordance with Duke Energy's Environmental Programs and procedures to ensure waste is properly managed in conjunction with appropriate disposal. Winston-Salem/Forsyth County Utilities municipal solid waste landfill has sufficient existing permitted capacity to accommodate wastes generated within the service area for approximately 27 years. Other regional landfills may also be considered to support the waste disposal needs during the operations period. Therefore, because all solid, liquid, and gaseous waste generated at the Project site are handled and properly managed by Duke Energy in compliance with federal, state, and local regulations, the impacts on land, water, and air from building activities and operations is SMALL.

Cumulative effects of liquid wastes and air emissions are addressed in Sections 7.2.2 and 7.2.7, respectively. Therefore, this cumulative effect analysis focuses on land-based waste. As indicated in Table 7.1-1 the GAI for nonradioactive waste is focused on the Project Region.

All of the past, present, and RFFA projects listed in Table 7.1-2 have the potential to result in some generation of nonradiological waste. As listed in Table 7.1-2, the BCSS closure and BCSS deconstruction actions are located immediately adjacent to the Project site, and therefore, have the potential to have localized direct or indirect effects that may affect the same resources as those affected by the Project. The particular effects of the BCSS action on nonradioactive wastes include the deconstruction of all site structures, and the management and disposal of all solid and hazardous wastes within regional landfills in accordance with Duke Energy's Environmental Programs and relevant guidelines and regulations.

Other categories of actions listed in Table 7.1-2 that are expected to be generators of nonradioactive waste include the following:

- Energy projects (coal-fired, natural gas, natural gas pipelines, solar, transmission facilities, battery storage, petroleum)
- Development or improvement of recreational facilities
- Transportation projects
- Industrial projects
- Other projects
- Water and wastewater improvement projects

Each of these projects coupled with existing developments (industrial, commercial, recreational) have an impact on cumulative waste management within the Project Region. The cumulative impacts of nonradioactive waste destined for land-based treatment and disposal are primarily related to amount of waste generated by the Project and other reasonably foreseeable projects and the available capacity of area treatment and disposal facilities. Similar to the Project, nonradioactive waste generation is expected to be generally greater during construction of these projects as compared to operation. However, the individual contribution of nonradioactive waste (both nonhazardous and hazardous) by the Project and other projects in Table 7.1-2 within the GAI is expected to be minor. Other landfills with long-range capacity identified within the Project Region include the following:

- Alamance County Landfill, 65.5 approximate total permitted years remaining as of fiscal year 2022-2023.
- Davidson County Landfill, 34.7 approximate total permitted years remaining as of fiscal year 2022-2023.
- Rowan County Landfill, 61.2 approximate total permitted years remaining as of fiscal year 2022-2023.

Given the existing reported landfill capacity in the region and the scope of the RFFAs, construction and operation of these facilities are not expected to substantially contribute to the loss of waste disposal capacity in the GAI. Based on the availability and expected capacity of existing licensed disposal facilities within the GAI, the cumulative impact of building and operating activities from the Project on nonradioactive waste, added to the effects associated with past, present, and RFFAs within the GAI on nonradioactive waste, is SMALL. The impact of the building and operation of the Project is not a noticeable contributor to the cumulative impact on nonradioactive waste.

7.2.11 POSTULATED ACCIDENTS

As described in Section 5.11, the potential environmental impacts of a postulated accident from the operation of a surrogate reactor technology based on a plant parameter envelope approach would be SMALL. Section 5.11.1 considers DBAs and Section 5.11.2 considers severe accidents. A detailed accident analysis is to be performed at the construction permit or license application phase when the reactor technology is selected and the facility configuration is known.

Off-site doses are conservatively estimated considering a surrogate source term from the selected postulated accident expected to produce the highest post-accident dose at the EAB and low population zone (LPZ). Duke Energy has selected the surrogate source term from a postulated instrument line break accident to demonstrate compliance with the radiological consequence evaluation factors set forth in 10 CFR 52.17(a)(1)(ix) and 10 CFR 50.34(a)(1)(ii)(D). This accident scenario was modeled as the bounding DBA for off-site atmospheric release for comparison against the 25 roentgen equivalent man (rem) total effective dose equivalent (TEDE) limits for an individual located at any point on the boundary of the exclusion area for any two-hour period following the onset of the postulated fission product release and an individual located at any point on the outer boundary of the LPZ, who is exposed to the radioactive cloud resulting from the postulated fission product release (during the entire period of its passage) specified in 10 CFR 52.17(a)(1)(ix)(A) and (B). As shown in Table 5.11-2, the calculated accident doses from the selected bounding DBA meet the 25 rem TEDE limit specified in 10 CFR 52.17 at the EAB/LPZ.

Environmental impacts from severe accidents with damage to the reactor core and degradation of the containment system are evaluated in Section 5.11.2. Duke Energy requested that each of the potential reactor technology vendors provide information from the probabilistic risk assessment (PRA) for its design to allow the assessment of potential severe accident consequences. However, final PRA information was not available for any vendors at the time of preparation of this application. While information regarding severe accident release categories, source terms, and release frequencies was provided to Duke Energy from some vendors, information was not received from all vendors. Therefore, Duke Energy assessed the potential severe accident consequences of two vendors that provided sufficient information and presented the vendor with the most conservative results for the majority of the evaluated

consequence metrics. The PRA information for severe accidents, along with site-specific characteristics were used to estimate the impacts of severe accidents. Potential environmental consequences of severe accidents at nuclear power plants are evaluated using the MELCOR Accident Consequences Code System (MACCS) computer code along with site-specific meteorology, population, land usage, watershed index, and economic data. Economic costs include short-term relocation of people, decontamination of property and equipment, and interdiction of food supplies. The MACCS modeling provided doses from the air pathway and from water ingestion; other pathways were evaluated qualitatively. As discussed in Section 5.11.2, the dose risk from both surface water and groundwater pathways is expected to be less than the atmospheric pathway. The total calculated dose risk to the 50-mi. (80-km) population is less than the maximum, mean, and median dose risks for current generation reactors. Additionally, the early and latent cancer fatality risks meet the NRC Safety Goals, set by the NRC's Safety Goal Policy Statement (51 FR 30028), and the estimated number of people within 50 mi. (80-km) exceeding the dose limits of 25 rem (0.25 sieverts [Sv]) and 200 rem (2 Sv) is zero. Therefore, the environmental impacts of severe accidents are expected to be SMALL.

The cumulative analysis considers risk from both DBA and potential severe accidents at other existing and proposed nuclear power plants that have the potential to increase risk at any location within the geographic area of interest within 50 mi. (80 km) of the Project site. The 50-mi. (80-km) radius was selected to cover potential risk overlaps from two or more nuclear plants. There are no existing operating nuclear power facilities within a 50-mi. (80-km) radius of the Project site. The closest existing operating nuclear power plants to the Project site are the Shearon Harris Nuclear Power Plant in New Hill, NC, approximately 80 mi. (129 km) southeast, and the McGuire Nuclear Station in Huntersville, NC, approximately 76 mi. (122 km) southwest. Both the Shearon Harris Nuclear Power Plant and the McGuire Nuclear Station are owned and operated by Duke Energy. Based on this, the cumulative risks from both DBAs and potential severe accidents at any location within 50 mi. (80 km) of the Project site would be SMALL.

7.2.12 FUEL CYCLE, TRANSPORTATION, AND DECOMMISSIONING

The cumulative impacts from the fuel cycle, transportation activities, and decommissioning activities for the proposed advanced reactors at the Project site are discussed herein.

7.2.12.1 Fuel Cycle

Impacts from the uranium fuel cycle (UFC) for the Project site include the total of those operations and processes associated with the provision, utilization, and ultimate disposition of fuel. Duke Energy is considering six reactor technologies for potential construction at the Project site. Four of the six technologies under consideration are small modular reactors (SMRs) that are based on traditional light water reactor (LWR) technology and that use conventional fuel (i.e., UO_2 fuel pellets): GE Vernova Hitachi Nuclear Energy's BWRX300, NuScale's VOYGR, Holtec's SMR 300, and Westinghouse's AP300.

To estimate the environmental impacts of the UFC, 10 CFR 51.51 requires use of Table S-3, Table of Uranium Fuel Cycle Environmental Data, as the basis. As discussed in Section 6.1, Table S-3 environmental impacts (which are estimated for a reference 1000 MWe LWR with a capacity factor of 80 percent) must be scaled to the proposed plant using the effective electric output. Because each SMR listed above has a different power output, different technologies utilize differing numbers of units on the site and produce a different total output. For this analysis, the bounding value of 2250 MWe maximum gross output is used as the total site output (2100 MWe net output). The maximum capacity factor among the SMRs listed above is

the Westinghouse AP300, with a capacity factor of 97 percent or higher, and 97 percent has been used as the bounding value for this analysis. The fifth technology under consideration by Duke Energy for the Project site is the X-energy's Xe-100, which is a gas-cooled SMR using high-assay, low-enriched uranium (HALEU) TRi-structural ISOtropic (TRISO) fuel. The sixth technology under consideration by Duke Energy for the Project site is the TerraPower Natrium reactor, which is a sodium-cooled reactor using HALEU metallic fuel. The analysis considered an identical electric output and similar capacity factor (95 percent). Impacts for all technologies were assessed for land use, water use, fossil fuel impacts, chemical effluents, radiological effluents and waste, occupational dose and transportation dose.

As discussed in Section 6.1.1, the environmental effects from the UFC for any SMR technologies based on LWRs being considered would be SMALL. Additionally, as discussed in Section 6.1.2 and Section 6.1.3, the environmental effects from the UFC for an Xe-100 plant or a TerraPower Natrium plant at the Project site, respectively, are SMALL.

This cumulative analysis considers impacts over the UFC associated with operation of the Project along with impacts from past, present, and RFFAs that may contribute to cumulative impacts within the geographic area of interest. The geographic area of interest for impacts of the UFC is nationwide and with imported uranium, worldwide.

NUREG-2157, *Generic Environmental Impact Statement for Continued Storage of Spent Nuclear Fuel* examines the incremental impacts of continued storage on each resource area analyzed in NUREG-2157 in combination with other past, present, and RFFAs. Section 6.5, Table 6-4 of NUREG-2157 indicates ranges of potential cumulative impacts for multiple resource areas. These ranges are primarily driven by impacts from activities other than the continued storage of spent fuel at the reactor site; the impacts from these other activities would occur regardless of whether spent fuel is stored during the continued storage period. In the short term, which is the most likely time frame for fuel disposal, the potential impacts of continued at-reactor storage are SMALL and, therefore, are not anticipated to be a significant contributor to the cumulative impacts. Because the impacts during the short term are SMALL, continued storage would not be a significant contributor to the cumulative impacts. In the longer time frames for at-reactor storage, or in the less likely case of away-from-reactor storage, some of the impacts from the storage of spent fuel could be greater than SMALL. However, other federal and nonfederal activities occurring during the longer time frames, as noted in NUREG-2157, include uncertainties as well, contributing to the cumulative impacts. These uncertainties lead to the ranges in cumulative impacts as discussed throughout Chapter 6 of NUREG-2157. The overall cumulative impact conclusions would not be changed if the impacts of continued storage were removed. Based on the analysis and impact determination in NUREG-2157 the cumulative impacts from radiological wastes from the fuel cycle (which includes the impacts associated with spent fuel storage during operation and continued storage period) would be SMALL.

As noted, Duke Energy has not selected a reactor technology but is considering a variety of advanced reactors most of which are SMRs based on LWR technology and fuel type. The two non-LWR are based on high-temperature gas-cooled reactor technology using TRISO fuel and a sodium-cooled fast reactor using HALEU metallic fuel. NUREG-2157 was developed for impacts from LWR fuels and the applicability of NUREG-2157 to advanced reactors and their fuel types are under consideration but expected to be applicable to advanced reactor fuels. Furthermore, NUREG-2249, Initial, *Generic Environmental Impact Statement for Advanced Nuclear Reactors – Draft Report for Comment*, was provided to the Commission in November 2021 and offered for public comment in September 2024, evaluates the applicability of NUREG-

2157 and determined that the findings were applicable to non-LWR fuel, provided that the non-LWR fuel is stored in a manner that meets the regulatory requirements for spent fuel storage cask approval and fabrication in accordance with 10 CFR Part 72. Additionally, regarding non-LWR fuel, NUREG-2157 states the spent nuclear fuel from Fort Saint Vrain, a decommissioned high-temperature gas-cooled reactor with a pebble bed design, which is being stored in ISFSI, is within the scope of the generic environmental impact statement. Various non-LWR projects have been approved for construction in recent years including the Kairos Hermes (TRISO fuel) and Abilene Christian University (liquid fueled molten salt) by the Commission. Both environmental assessments found the environmental impacts of fuel storage on-site to be either within scope of NUREG-2157 or bounded by the impacts presented in NUREG-2157. Lastly, NUREG-2249 concludes that advanced nuclear reactor fuel cycles, both LWR and non-LWR, will have SMALL impacts, particularly for once-through fuel cycle options. This conclusion is based on improved fuel cycle technologies, improved reactor technologies, and waste and spent fuel inventories that are significantly different from what has been considered for LWR evaluations (e.g., Continued Storage Rulemaking) with respect to hazardous radionuclides. If a reactor technology using non-LWR fuel is selected, the fuel will be stored in a manner that meets the regulatory requirements in 10 CFR Part 72. Therefore, those conclusions remain valid and applicable in this context.

7.2.12.2 Transportation

Section 6.2 describes the environmental impacts of normal conditions of transport and postulated transportation accidents involving shipment of radioactive materials including unirradiated fuel, irradiate fuel, and radioactive waste to and from the Project site. Probable transportation routes were bounded by shipping unirradiated fuel from the Framatome fuel fabrication facility in Richland, WA because it is the furthest identified licensed fuel fabrication facility to be used from the list of technologies considered. The travel distance is approximately 2600 mi. (4184 km) and detailed shipment route link data was utilized from WebTRAGIS. Transportation routes were considered for both Waste Control Specialists facility near Andrews, TX (approximately 1460 mi. [2350 km]), and EnergySolutions disposal facility in Clive, UT (approximately 2100 mi. [3380 km]). The number of shipments of unirradiated fuel, irradiated fuel, and radioactive waste were modeled to determine impacts from transport after being normalized to the NRC's "reference reactor" using the guidance from Regulatory Guide 4.2. The normalized shipment values were 11 for unirradiated fuel, 16 for irradiated fuel, and 234 for radioactive waste.

This cumulative analysis considers impacts from postulated accidents associated with the transportation of fuel and waste for the Project site along with impacts from past, present, and RFFAs that may contribute to cumulative impacts within the geographic area of interest. The geographic area of interest for impacts of postulated transportation accidents is nationwide.

Nonradiological cumulative impacts of transportation are related to the increased traffic over commercial routes with the attendant increased risk of traffic, accidents, injuries, and fatalities. As described in Section 5.8.6, both surrounding roadway networks and local intersections would see a notable increase in traffic; however, the predicted crash rate increases are minor and not destabilizing to traffic safety. The overall cumulative impacts on traffic routes are SMALL.

Radiological cumulative impacts associated with transportation of fuel and waste from the Project site includes impacts from fuel and waste shipments from the Shearon Harris Nuclear Power Plant, the McGuire Nuclear Station, and the Catawba Nuclear Station, which are all within an approximate 100-mi. radius to the Project site. It is reasonable to assume fuel and

waste shipments will travel along similar transportation routes to and from these facilities along with the Project site. Like the shipments associated with the Project site described in Section 6.2, the impacts from each individual shipment would be minimal and, when combined with the impacts associated with the Project site, the total impact would also be minimal. Therefore, the cumulative impacts of transporting unirradiated fuel, along with irradiated fuel and radioactive waste to and from the Project site would be SMALL.

7.2.12.3 Decommissioning

Section 6.3 discusses the environmental impacts of decommissioning the Project site. Decommissioning the facilities includes removal of system, structures, and components, the management of radioactive materials, final disposal of radioactive waste, and eventual unrestricted property release or release under restricted conditions. The primary environmental impact is the use of land for off-site waste burial. Although the various decommissioning methods and alternatives have different impacts, including impacts from size and transport variations, impacts from decommissioning activities at the Project site are expected to be smaller than those during construction.

This cumulative analysis considers impacts from decommissioning activities at the Project site along with impacts from past, present, and RFFAs that may contribute to cumulative impacts within the geographic area of interest. The geographic area of interest for decommissioning impacts is the 50-mi. (80-km) radius for socioeconomic impacts from workers and nationwide for the final disposal of radioactive waste. There are no other nuclear facilities within a 50-mi. (80-km) radius of the Project site.

In NUREG-0586, *Generic Environmental Impact Statement on Decommissioning of Nuclear Facilities*, Supplement 1, the NRC found that the impacts from decommissioning due to radiation dose to workers and the public, waste management, water quality, air quality, ecological resources, and socioeconomics would be SMALL.

Duke Energy compared the activities analyzed in NUREG-0586 on the environmental impacts of decommissioning the existing fleet of domestic nuclear power reactors with those used by the Department of Energy to estimate decommissioning costs for advanced reactor designs and determined that the scope of activities is the same. Projected physical inventories associated with advanced reactor designs are generally less than those for currently operating power reactors due to advances in technology that simplify maintenance and benefit decommissioning. In addition, there are no other nuclear facilities within a 50-mi. (80-km) radius of the Project site to potentially have overlap in decommissioning activities. Therefore, the cumulative impacts from decommissioning the Project site would be SMALL.

Table 7.2-1
Cumulative Impacts on Environmental Resources, Including the Impacts of the Project

Resource Category	Project Impact Level
Land Use	MODERATE
Water-Related	
Hydrology – Surface Water	MODERATE
Hydrology – Groundwater Use	SMALL
Water Use – Surface Water	SMALL
Water Use – Groundwater Use	SMALL
Water Quality – Surface Water	LARGE (beneficial)
Water Quality – Groundwater	SMALL
Ecology	
Terrestrial Ecosystems	MODERATE
Aquatic Ecosystems	MODERATE
Socioeconomic	
Physical Impacts	SMALL to MODERATE (aesthetics)
Demography	SMALL
Economic Impacts	MODERATE (beneficial)
Community Infrastructure Impacts	SMALL
Historic and Cultural Resources	SMALL (with avoidance) to MODERATE (without avoidance, and mitigated)
Air Quality	SMALL (beneficial) for criteria pollutants and SMALL for GHGs
Nonradiological Health	SMALL
Radiological Health	SMALL
Nonradioactive Waste	SMALL
Postulated Accidents	SMALL
Fuel Cycle, Transportation, and Decommissioning	SMALL

7.3 IMPACT ASSESSMENT CONCLUSIONS

Duke Energy considered and assessed the potential cumulative impacts resulting from building, operation, and decommissioning of the Project together with other past, present, and RFFAs. The specific resources that could be affected by the Project and other past, present, and RFFAs in the GAI were assessed. The cumulative impacts are summarized in Table 7.2-1. The cumulative impacts for most of the resource areas are SMALL, although there are MODERATE or LARGE cumulative impacts for some resources, as described in the table.

Chapter 9 Environmental Impacts of Alternatives

9.0 INTRODUCTION

This chapter identifies and describes the alternatives to siting, constructing, and operating a new nuclear baseload generation plant, utilizing multiple advanced reactors, at the Belews Creek, North Carolina (NC) site (Project site). This chapter provides a thorough evaluation of the impacts associated with the no-action alternative, energy alternatives, alternative sites, and alternative plant and transmission systems to the proposed advanced reactors at the Project site. The proposed federal action is the issuance of an Early Site Permit (ESP) to Duke Energy under the provisions of Title 10 of the Code of Federal Regulations (CFR) Part 52 (10 CFR 52), approving the Project site as suitable for the deployment of multiple advanced reactors. Chapter 9 is divided into the following four sections:

- No-Action Alternative (Section 9.1)

  Section 9.1 describes the environmental impact if an ESP is not issued.

- Energy Alternatives (Section 9.2)

  Section 9.2 examines the potential environmental impacts associated with alternatives to the construction of a new baseload nuclear generating facility.

- Alternative Sites (Section 9.3)

  Section 9.3 describes and evaluates the alternative sites considered for the new plant.

- Alternative Plant Systems (Section 9.4)

  Section 9.4 describes and evaluates plant and transmission system alternatives to the new plant and transmission system.

9.1 NO-ACTION ALTERNATIVE

This section defines the No-Action Alternative and describes the consequences of adopting the No-Action Alternative. The purpose of the ESP is to approve the site for eventual construction and operation of a nuclear generating facility that utilizes multiple advanced reactors at the Project site. The Project would fill the need for carbon-free power in Duke Energy's Carolinas service territory.

Under the No-Action Alternative, the United States (U.S.) Nuclear Regulatory Commission (NRC) would not issue an ESP. Thus, the no-action would accomplish none of the benefits intended by the ESP process, which includes the following items:

- The resolution of siting and environmental issues before large investments of financial capital and human resources in new plant design and construction are made.
- The ability to reserve the site for future use for construction and operation of a nuclear plant.
- The resolution of issues related to the environmental impacts of construction and operation of new nuclear generation units constrained within the defined plant parameters.
- The facilitation of future decisions about whether to construct new nuclear power generation facilities at the Proposed site.

This No-Action Alternative would avoid no significant environmental impacts, because no such impacts are caused by site suitability determination. The only activities that are permissible under an ESP are limited work activities allowed by 10 CFR 50.10(e)(1), and those activities are permissible only if the final environmental impact statement concludes that the activities will not result in any significant environmental impacts that cannot be redressed. As discussed in Section 1.3.2., Duke Energy has not established a date for preconstruction activities and a limited work authorization application is not being included with this ESP.

Pursuance of new nuclear generation at the Project site provides the following ancillary benefits:

- Supports Duke Energy's ability to meet growing demands for baseload generation.
- Supports greenhouse gas emission reduction requirements established by NC Senate Bill 266 and NC House Bill 951 (NC, 2025).
- Facilitates the reduction of emissions from fossil fuel generation through the retirement of fossil fuel units within the Carolinas service territory.
- Creation of jobs and the associated positive impacts to the local economy.

As a rate-based utility, Duke Energy has a regulatory obligation to provide reliable electrical service within its service territory. A comprehensive analysis for the need for power is presented in the Duke Energy Carolinas Resource Plan (CRP) (Duke Energy, 2023) which demonstrates the need for reliable baseload generation. The NRC regulations [10 CFR 51.50(b)(2)] do not require a need for power to be included in the ESP; however, the extensive information included in the CRP provides confidence that the power generated by the proposed project will be produced and consumed in a manner consistent with the stated purpose of and need for the project. Forecasted load growth, driven by robust economic development, population increases, and electrification of transportation and other sectors, is expected to significantly outpace existing generating capacity, particularly as Duke Energy plans to retire over 8400 megawatts electric (MWe) (8.4 gigawatts electric [GWe]) of coal-fired generation by the mid-2030s. It is reasonable to expect that Duke Energy will act to meet this need for power through alternative generation or alternative sites. A range of alternative sites are evaluated in Section 9.3. If other generating sources were developed, either using alternative generation or at alternative sites, environmental impacts would eventually occur.

In summary, under the No-Action Alternative, the ESP would not be issued, and none of the intended benefits would be realized. Additionally, it is reasonable to expect that Duke Energy would act to meet the need for power by alternative means, and environmental impacts associated with new nuclear power generation or alternative energy sources would not be avoided. Therefore, the issuance of the ESP is preferable to the No-Action Alternative.

9.2 ENERGY ALTERNATIVES

This section is not required for an Early Site Permit Application.

9.3 ALTERNATIVE SITES

As required by 10 CFR 51.45(b)(3), this section provides an evaluation of alternatives to the Belews Creek, NC site for construction and operation of the new nuclear power plant. The National Environmental Policy Act (NEPA) mandates the evaluation of reasonable alternatives to a proposed action. This section summarizes the process used to select the Belews Creek, NC site as the proposed location for the new nuclear power plant and evaluates whether any Alternative Site is "environmentally preferable" to the Belews Creek, NC site, and if so, whether it is "obviously superior" for the eventual construction and operation of the new nuclear power plant.

9.3.1 SITE SELECTION PROCESS

A comprehensive site selection study for this Project was completed in 2024 and 2025. The objective of this study was to select a Proposed Site for the new nuclear power plant using a systematic process that considered relevant factors related to environmental acceptability, site safety engineering, and cost concerns. The study utilized the guidance outlined in Section 9.3 of NRC Regulatory Guide 4.2, Rev. 3, *Preparation of Environmental Reports for Nuclear Power Stations* and NUREG-1555, Initial, *Standard Review Plans for Environmental Reviews for Nuclear Power Plants*. It also followed the site selection procedures described in the Electric Power Research Institute (EPRI) report on site selection (EPRI, 2022), as well as considered the reactor site criteria in NRC Regulatory Guide 4.7, General Site Suitability for Nuclear Power Stations, Rev. 4. The process was consistent with other nuclear power plant siting studies as reported in licensing submittals to the NRC.

The site selection study included the following major tasks, as defined in NUREG-1555:

- Identify the Region of Interest - The Region of Interest is the area to be considered in searching for potential nuclear power plant sites.
- Identify Candidate Areas in the Region of Interest - Candidate Areas were identified by using exclusionary factors to eliminate areas within the Region of Interest.
- Identify Potential Sites - Potential Sites are specific locations within the Candidate Areas that are identified for preliminary assessment in establishing Candidate Sites.
- Screen Potential Sites to Identify Candidate Sites - Candidate Sites are those Potential Sites that are among the best sites that can reasonably be found for the siting of a nuclear power plant.
- Evaluate Candidate Sites - The Candidate Sites were evaluated numerically and ranked according to their overall favorability.
- Select Proposed and Alternative Sites - The preceding evaluations and other relevant factors were considered to select the Proposed and Alternative Sites.

The methods and results of these tasks are summarized in the following subsections.

9.3.1.1 Region of Interest

NUREG-1555 defines the Region of Interest as the area to be considered in searching for potential and candidate power plant sites. NUREG-1555 provides the following guidance on the selection of the Region of Interest:

> The Region of Interest is typically selected based on geographic boundaries (e.g., the state in which the Proposed Site is located) or the relevant service area for the proposed plant. In cases where the proposed plant will not have a service area, the applicant should define a reasonable Region of Interest and provide a justification. The Region of Interest must be more extensive if environmental diversity is substantially improved or if Candidate Sites do not meet initial threshold criteria (including the site criteria in 10 CFR Part 100) and added geographic areas will not increase costs substantially. The Region of Interest may be smaller if sufficient environmental diversity exists, threshold criteria are satisfied, and costs will be exorbitant for considering sites outside the State or relevant service area.

Duke Energy Progress, LLC (DEP) an indirect subsidiary of Duke Energy Corporation and Duke Energy Carolinas, LLC (DEC) (together referred to as "the Companies"), combined, make up the Carolinas service territory, hereby referred to as the Region of Interest. The Region of Interest encompasses a majority of NC and South Carolina (SC). The Region of Interest is shown in Figure 9.3-1.

DEC and DEP are both regulated public utilities primarily engaged in the generation, transmission, distribution, and sale of electricity in portions of NC and SC. The DEC service area covers approximately 24,000 square miles (sq. mi.) (62,160 square kilometers (sq. km)) and supplies electric service to 2,800,000 residential, commercial, and industrial customers. The DEP service area covers approximately 29,000 sq. mi. (75,110 sq. km) and supplies electric service to approximately 1,700,000 residential, commercial, and industrial customers.

The Region of Interest encompasses an area of approximately 53,000 sq. mi. (137,269 sq. km), including water areas. Major cities located within the Region of Interest include Durham, Greensboro, Raleigh, and Charlotte, NC, as well as Greenville, SC. Major waterbodies available as a potential source of cooling water for a nuclear power plant include the Catawba River, Cape Fear River, Dan River, Broad River, and the Yadkin-Pee Dee River. Major highways within the Region of Interest include Interstate Routes 95, 85, 40, 26, and 77. There are two major railroads in the Region of Interest, CSX Transportation (CSXT) and Norfolk Southern Railway (NS). Major land use categories found in the Region of Interest include residential, agricultural, urban, industrial, commercial, public facilities, parks, public and private recreation areas, natural areas, transportation, communications, utilities, government special designation, and education. Topographic features in the Region of Interest range from flat floodplains along rivers and coastal areas to steep bluffs, deep ravines, and mountain ranges. There are numerous military bases in the Region of Interest.

9.3.1.2 Identification of Candidate Areas

Candidate Areas were identified by constructing digitized Geographic Information System (GIS) maps of the entire Region of Interest and applying exclusionary criteria to eliminate areas considered unsuitable for nuclear power plant siting. The purpose of the exclusionary criteria was to narrow-down the region to be considered for power plant siting and allow the study to focus on areas that have the greatest probability of containing desirable sites. The exclusionary criteria covered major factors that make licensing, permitting, or development of a nuclear power plant impractical. Exclusionary criteria included:

- Areas within 25 miles (mi.) (40 kilometers [km]) of capable faults
- Areas more than 10 mi. (16 km) from a river with a mean annual flow of 800 cubic feet per second (cfs) or greater, or a waterbody with an area greater than or equal to 2000 ac. (809 ha)

- Areas within active military bases
- Areas that exceed a peak ground acceleration (PGA) of 0.6 g based on a two percent probability of exceedance within 50 years
- Areas within a 3-mi. (5-km) buffer with a population density of 500 people per sq. mi. or more
- Areas within protected lands
- Areas more than 20-mi. (32-km) from barge or rail transport

The application of the exclusionary criteria to the Region of Interest is illustrated in Figures 9.3-2 through 9.3-8. As illustrated in these figures, distance from barge and railway transport and active military bases eliminated relatively small parts of the Region of Interest, but proximity to water resources and capable faults, and high population density eliminated significant parts of the Region of Interest. Figure 9.3-9 shows the Candidate Areas that resulted from the exclusionary criteria.

9.3.1.3 Identification of Potential Sites

Potential Sites were identified by examining topographic maps and aerial photographs of the Candidate Areas to find specific locations that appeared, on the basis of high-level screening criteria, to be suitable for nuclear power plant siting. Other factors that were considered include:

- Proximity to a cooling water source
- Location in lower seismic risk areas
- Proximity to transmission
- Proximity from high-population and high-population-density areas
- Compatible land use
- Avoidance of ecologically sensitive and special designation areas
- Avoidance of wetlands to the extent practical
- Avoidance of special dedicated land uses (such as national parks, Indigenous lands, historic areas, and cemeteries)
- Proximity to transportation and heavy-haul infrastructure (such as rail lines and barge terminals)

Additionally, properties that were owned by Duke Energy, or partially owned by Duke Energy, which may have sufficient land and water resources available to support a nuclear power plant and were located within the Candidate Areas were identified for review. Prior to the establishment of the Candidate Areas, more than 30 preliminary sites were identified within the Region of Interest. Of those 30 preliminary sites, 21 were within the Candidate Areas. Of those 21 sites, 11 were considered suitable based on the above considerations.

9.3.1.4 Screening of Potential Sites

Candidate Sites were identified by examining the Potential Sites to determine whether they had any significant environmental or other issues that will make them impractical or undesirable for licensing, permitting, or development of a nuclear power plant. Issues considered in this evaluation included the following:

- Site Safety - The sites were reviewed with regard to major site safety issues, such as proximity to population centers, proximity to capable faults, PGA values at the site, and proximity to hazardous land issues.

- Environmental Acceptability - The sites were reviewed with regard to major environmental issues, such as proximity to environmentally sensitive areas, proximity to cultural resources, proximity to species of concern, and proximity to aquatic resources, such as wetlands and streams.
- Engineering and Cost - The sites were reviewed with regard to major engineering and cost issues, such as cooling water availability, drought tolerance, buildability, proximity to heavy haul, proximity to transmission, and if there are existing coal or nuclear facilities located at the site.

Based on the screening of the 11 Potential Sites, six sites, NC-03, NC-07, NC-11, NC-14, NC-18, and SC-06 have a larger number of potentially significant issues than the other sites, including certain issues that could be more problematic than those identified for the other sites. Therefore, these sites were eliminated from further consideration as Candidate Sites.

Five sites were found to have notably fewer potentially significant negative issues than the other sites. In addition, a qualitative evaluation of the potentially negative issues identified at these sites indicated that all of the issues were manageable and could reasonably be expected to be resolved. Each site also had other highly desirable characteristics. Therefore, the sites with significantly more potential negative issues were eliminated from further consideration, and the following sites were retained as Candidate Sites:

- NC-15 site
- Belews Creek, NC site
- NC-17 site
- NC-19 site
- SC-04 site

9.3.1.5 Evaluation of Candidate Sites

The Candidate Sites were evaluated in more detail in order to provide a quantifiable basis for comparison. The primary purpose of the evaluation was to develop numerical scores that will allow the Candidate Sites to be ranked according to their overall suitability for development of a nuclear power plant. The numerical scores covered 42 site characteristics related to Health and Safety Criteria (15 characteristics), Ecological Criteria (10 characteristics), Socioeconomic Criteria (four characteristics), and Engineering and Cost-Related Criteria (13 characteristics).

The site characteristics considered in the numerical scoring are listed in Table 9.3-1. An importance weighting factor was assigned to each site characteristic using the modified Delphi technique. A multidisciplinary team of 10 subject matter experts with expertise in geology, hydrology, ecology, socioeconomics, land use, licensing and engineering participated in an iterative workshop to assign weighting factors to each site characteristic.

The Candidate Sites were ranked according to the numerical scoring developed as described above. Based on total weighted scoring, the Belews Creek, NC site was the highest-ranked site, followed in order by sites NC-15, NC-19, NC-17, and SC-04. Based on total unweighted scoring, the NC-15 site was the highest-ranked site, followed in order by the Belews Creek, NC site, NC-19 site, NC-17 site, and SC-04 site.

9.3.1.6 Selection of Proposed and Alternative Sites

As described in the previous subsections, a standardized process was used to identify Candidate Areas, Potential Sites, and Candidate Sites. A systematic numerical scoring system was developed to provide an objective evaluation of the relative favorability of the Candidate Sites, using consistent criteria. The results of these evaluations indicate that all of the Candidate Sites are potentially licensable for a nuclear power plant, and that the Belews Creek, NC site is the most favorable Candidate Site with regard to the issues considered. The last step in the process was to incorporate business considerations and any other relevant additional factors into the site evaluations and the selection of a Proposed Site. Technical and business considerations were used to evaluate the five Candidate Sites, in addition to the Environmental Acceptability, Site Safety, and Engineering/Cost considerations, as described above. In some cases, these considerations correlate to lower construction or operation costs. A Proposed Site was selected based on the following discussion.

The Internal Revenue Code, 26 U.S.C. §§ 45U, 45Y, and 48E, provides production tax credits (PTC) or investment tax credits (ITC) for certain nuclear or clean electricity plants. The PTC or ITC may be increased by 10 percent (subject to certain limitations) if the facility is in an Energy Community as defined in 26 U.S.C. § 45(b)(11). As an example, a utility may receive an ITC equal to 30 percent of what was invested in building a nuclear plant (i.e., a zero-emissions energy production facility), plus an additional 10 percent for a total of 40 percent of the cost to build the plant if it is in or directly adjoins a census tract of a coal-fired generating facility that was retired after December 31, 2009. For this reason, the five Candidate Sites were screened down to the following three sites that are locations that have had or will have a retired coal-fired generation facility: the Belews Creek, NC site, the NC-17 site, and the NC-19 site.

When considering these three sites, additional comparative advantages can be identified based upon land access and population density in the vicinity of each site. The NC-17 site is comparatively less desirable than either the NC-19 site or the Belews Creek, NC site due to the lack of land ownership needed to develop a nuclear plant. Duke Energy does not currently own all of the land required to develop a nuclear facility at the NC-17 site. Further, the NC-19 site has a higher population density in the vicinity of the site than the Belews Creek, NC site. Based upon the above considerations, the Belews Creek, NC site was selected as the Proposed Site, with the NC-17 and NC-19 sites as Alternative Sites. Figure 9.3-10 shows the locations of the Belews Creek, NC site and the Alternative Sites.

9.3.2 ENVIRONMENTAL ASSESSMENT OF ALTERNATIVE SITES

The site selection process described above resulted in the selection of the Belews Creek, NC site as the Proposed Site. The environmental impacts of the Belews Creek, NC site are evaluated in detail in other sections of this Environmental Report. This subsection evaluates the environmental impacts of the Alternative Sites, using the resource categories suggested in NUREG-1555. The purpose of this evaluation is to determine if any of the Alternative Sites are “environmentally preferable” to the Belews Creek, NC site and, if so, whether any of the sites are “obviously superior” to the Belews Creek, NC site. Regulatory Guide 4.2 states, “An applicant is not expected to conduct detailed environmental studies for potential sites, only preliminary investigations using reconnaissance-level information.” The Alternative Sites are evaluated here based on publicly available information, including GIS mapping, and a review of government agency websites. In order to evaluate the environmental impacts of constructing and operating a nuclear power plant at the Alternative Sites, the general plant design described in Chapter 3 and the building and operation practices described in Chapters 4 and 5 were consistently applied to each site. This allowed for a comprehensive and qualitatively consistent assessment of environmental impacts. The potential impact of plant building activities and

operation on each resource category was assigned a significance level according to the criteria established in 10 CFR Part 51, Subpart A, Appendix B, Table B-1, footnote 3, as follows:

> SMALL - Environmental effects are not detectable or are so minor that they would neither destabilize nor noticeably alter any important attribute of the resource.
>
> MODERATE - Environmental effects are sufficient to alter noticeably, but not to destabilize, any important attributes of the resource.
>
> LARGE - Environmental effects are clearly noticeable and are sufficient to destabilize important attributes of the resource.

For some analyses, it was determined that the additional impact criteria established by the NRC in NUREG-1437, Rev. 2, *Generic Environmental Impact Statement for License Renewal of Nuclear Plant*, were appropriate, and those criteria were used to assign a significance level to certain impacts, as noted in the specific subsections below.

The following subsections summarize the evaluation of each Alternative Site, using consistent criteria and assumptions applied to the attributes and features of each Alternate Site. Table 9.3-8 summarizes the impacts to each resource for the Alternative Sites and the Belews Creek, NC site. Table 9.3-9 summarizes the cumulative impacts to each resource for the Alternative Sites and the Belews Creek, NC site.

9.3.2.1 Evaluation of the NC-17 site

The NC-17 site is a greenfield site located approximately 10-mi. (16-km) north of Roxboro, in Person County, NC. This site is located approximately 1-mi. (2-km) east of Hyco Lake which was constructed in the early 1960's by the Carolina Power and Light Company (now Duke Energy). Hyco Lake functions as a cooling reservoir for the Roxboro Steam Station, which is a four-unit, 2422 MW coal-fired plant. Hyco Lake covers approximately 3750 ac. (1518 ha) with 120-mi. (193-km) of shoreline. Duke Energy owns the land within which the reservoir is located and up to the 420-feet ((ft.) [130-m]) mark which is approximately 10 ft. (3 m) above full pool of the reservoir. Duke Energy does not currently own all of the NC-17 site. There is a secondary road, Route 1322 (Edwin Robertson Road), that is maintained by the NC Department of Transportation (DOT) that bisects the site parcel. US Highway 501 is a two lane, asphalt paved highway located 6-mi. (10-km) east of the site. The topography of the NC-17 site is comprised of numerous hills and valleys with some slopes that exceed 30 percent. The conceptual site boundary has an approximate total area of 569 ac. (230 ha).

The NC-17 site will require the following off-site features in order to support a nuclear power plant:

- Road access to the site is provided by existing public roads, but portions of those roads will have to be relocated around plant facilities.
- A NS mainline is adjacent to the site and there is a rail siding at the nearby existing Roxboro Steam Station. A new siding will need to be constructed if there is a need for onsite rail.
- Water for the nuclear power plant will be obtained via a new intake on Hyco Lake.
- The NC-17 site will utilize either the existing 230 kilovolt (kV) switchyard or the 500 kV substation for the Roxboro Steam Station and add improvements.

9.3.2.1.1 Land Use

Existing land use across the NC-17 site is predominately forested land, and pine plantation with some areas of rangeland. Limited infrastructure development and structures are present on the NC-17 site. The NC-17 site is located approximately 1-mi. (2-km) from Hyco Lake in Person County, NC. Duke Energy does not currently own all of this site and land will need to be acquired to construct a nuclear facility. Soils classified as prime or farmland of statewide importance cross much of the site (USDA NRCS, 2025). There are no residences identified within the conceptual site boundaries. The closest residence is approximately 1-mi. (2-km) away from the center point of the conceptual site boundaries. The site is zoned as Rural Conservation (Person County, 2025a).

The closest significant industrial land use to the NC-17 site is the existing Roxboro Steam Station which is approximately 3.5-mi. (6-km) from the center point of the conceptual site boundaries.

The development of a new nuclear plant at the NC-17 site will be sufficient to alter noticeably, but not to destabilize land use within the site and surrounding area as the existing land will be converted from rural conservation to industrial use. Due to this, the impact to land use is MODERATE for building activities. During operation, no new land use impacts will occur beyond those described above for building activities, so land use impact due to operation of the Project will be SMALL.

9.3.2.1.2 Water Resources

The NC-17 site is located within the Hyco Lake After Bay Reservoir-Hyco River watershed. The NC-17 site is 1-mi. (2-km) from Hyco Lake, a reservoir created from the damming of the Hyco River. Hyco Lake, was created as a cooling reservoir for the existing Roxboro Steam Station. Neither Hyco Lake nor the Hyco River are listed as a Section 303(d) impaired water by the U.S. Environmental Protection Agency (USEPA). The Hyco River, from the Hyco Lake dam to the NC, Virginia (VA) state line is classified by the NCDEQ as a Class C water. Class C waters are protected for uses such as aquatic life propagation, survival, and maintenance of biological integrity, wildlife, secondary contact recreation, and agriculture. The Hyco River, including the Hyco Lake from the dam to the source of Hyco Lake is classified as a WS-V-B water, which is defined as suitable for primary recreation. It is also suitable as water supply for use by industry to supply drinking water to their employees, but not to municipalities or counties with a raw drinking water supply source (NCDEQ 1999). The NC-17 site is not located over a sole source aquifer.

A 2023 water resources study was conducted to determine what capacity the NC-17 site could support based on a 15 gallons per minute (gpm) per MWe water consumption demand. It was determined that the NC-17 site will need a pumping station added to mitigate drought concerns for plant water consumption greater than 1200 MWe.

The NC-17 site is located approximately 1-mi. (2-km) east of Hyco Lake, so the only direct impact on the reservoir during building activities will be disturbance of a section of the shoreline and lake bottom for installation of required facilities. At a minimum, the required facilities include a water intake structure, a cooling water discharge structure, and a pumping station which will disturb a relatively small area of the shoreline and lake bottom. There is no commercial barge navigation on Hyco Lake or near the NC-17 site. The majority of the site is outside of the 100-year and 500-year floodplains, except for the southern portion of the NC-17 site that borders Ghent Creek.

Water-related impacts associated with building activities on the site itself are similar to the impacts of any large construction project. Potential impacts include direct physical alteration of local surface water bodies; indirect alteration of nearby surface water bodies due to increased runoff volumes or diversions of runoff; degradation of downstream surface water quality as a result of erosion and sedimentation or discharges of pollutants associated with building activities; and changes in groundwater flow patterns due to dewatering of excavations and soil retention management practices. Some existing streams on the site will be directly disturbed, and some adjacent streams will experience a temporary increase in sediment loading due to increased runoff of disturbed soil.

Groundwater withdrawal would not be mandatory at the NC-17 site, because Hyco Lake is capable of providing fresh water for plant uses. A detailed water study would be performed if development of the NC-17 site was anticipated.

Several federal, state, and local permits govern building activities that have the potential to impact water resources. Water-related impacts will be minimized by implementing best management practices (BMP), including erosion, grading, and sediment control measures; stormwater pollution prevention plans (SWPPP); spill prevention and countermeasure plans; and compliance with federal, state, and local regulations pertaining to disturbance of water bodies and pollution discharges.

Proposed hydrological alterations to the NC-17 site for building activities are minimal in terms of impact to surface water and groundwater. Impacts related to hydrological alterations to surface waters for Project operation are MODERATE because of the need for a pumping station to mitigate drought concerns at Hyco Lake. Impacts as a result of building activities and operation are SMALL for water use and water quality since stormwater and plant discharge leaving the site will follow natural contours using culverts and other water management structures, to maintain hydrologic conditions to the extent practicable.

9.3.2.1.3 Terrestrial Ecology

Any large construction project impacts terrestrial ecology primarily by disturbing natural habitats and making those habitats unavailable to plants and animals. Although building activities may result in direct mortality to some plants and animals, most animal species are able to move away to avoid direct impacts. Even those species, however, may experience population declines due to loss of habitat. In addition, noise, lights, and dust may cause some animals to leave areas near building activities. This is also experienced as a loss of usable habitat.

The evaluations conducted for terrestrial ecology were based on a desktop review of publicly available data. Site specific terrestrial habitat conditions are not generally known without a site survey.

The USEPA defines ecoregions in hierarchical levels from Level I to Level IV, increasing in detail as the level increases. The USEPA maintains the mapping of ecoregions (USEPA, 2025a). The NC-17 site is located within the Piedmont Level III Ecoregion. Additionally, the NC-17 site is located within the Northern Inner Piedmont Level IV Ecoregion, which is detailed as being dominated by pine (mostly loblolly and VA) on old field sites and pine plantations, while mixed oak forest is found in less heavily altered areas (USEPA, 2025b).

National Land Cover Database (NLCD) data indicates that the most prevalent land cover type found within the approximately 569 ac. (230 ha) NC-17 site is hay/pasture (~195 ac. [~79 ha]). Other common land cover types include deciduous forest (~106 ac. [~43 ha]), and mixed forest (~102 ac. [~41 ha]). The land cover within the 50-mi. (80-km) region of the NC-17 site is

primarily deciduous forest (~18,141 ac. [~7341 ha]), followed by hay/pasture (~16,154 ac. [~6537 ha]), mixed forest (~15,821 ac. [~6403 ha]), and evergreen forest (~14,189 ac. [~5742 ha]) (Table 9.3-2) (Dewitz, J. and USGS, 2021).

A review of U.S. Fish and Wildlife Service (USFWS) National Wetland Inventory (NWI) data was completed to determine on-site aquatic resources for the NC-17 site. Ghent Creek flows across the southern boundary of the NC-17 site. The USFWS NWI designates Ghent Creek as a perennial stream. Multiple intermittent tributaries flow southeast to Ghent Creek within the NC-17 site. Freshwater emergent and freshwater forested/ shrub wetlands border Ghent Creek. Two on-channel ponds are also indicated by the USFWS NWI to be within the NC-17 site. Ghent Creek is a tributary to the Hyco River, which eventually flows to the Dan River. In total, there are approximately 41 ac. (17 ha) and 5500 linear feet of streams within the NC-17 site.

The USFWS Information for Planning and Consultation (IPaC) report for the NC-17 site indicated that two terrestrial species proposed for listing, could be “potentially affected by activities at this location” (USFWS, 2025) (Table 9.3-4):

- Tricolored Bat (*Perimyotis subflavus*); proposed endangered
- Monarch Butterfly (*Danaus plexippus*); proposed threatened

A review of the IPaC report did not indicate that any federally designated or proposed critical habitat for terrestrial species is found on the NC-17 site.

Person County, North Carolina Natural Heritage Program (NCNHP) data for state-listed species was reviewed for the NC-17 site. Person County has eight state listed terrestrial endangered and threatened species (Table 9.3-4), excluding the previously listed species. All the state listed terrestrial species are vascular plants, which will require site specific surveys in order to determine presence within the NC-17 site.

Additionally, the Hyco Game Land, which is land leased by Duke Energy to the NC Wildlife Commission Game Lands Program, directly borders the NC-17 site. Multiple natural heritage natural areas are also within close vicinity of the NC-17 site including the Hyco/Ghent Hardwood Forest, the McGhees Mill Road Rare Plant Site, and the Storys Creek/Marlowe Creek Swamp.

Table 9.3-2 shows that the acreage of each habitat potentially affected by building activities is a relatively small percentage of the total acreage of that habitat available in the site vicinity. In addition, it appears that the NC-17 site has been subject to prior disturbance due to the presence of pine plantations and rangeland on the site. Therefore, habitat at the NC-17 site is considered lower quality relative to adjacent habitat. Detailed field studies are required to determine whether any federally listed or threatened species make significant use of the site, and as reconnaissance level data was used for this evaluation, such studies were not conducted for the NC-17 site. However, based on the relatively minor impacts on natural habitats described above, it is unlikely that any threatened or endangered species are significantly affected by building activities or operation. Disturbance to wetland and streams may occur as a result of building activities. Impacts to wetlands and streams are regulated by several federal, state, and local regulations and will be minimal. Based on the area affected, overall impacts on terrestrial habitats are noticeable. But, because of the availability of similar land cover types within the Project Vicinity, the prevalence of low-quality plant communities, and reduced quality of the existing habitats on the Project site, potential impacts on terrestrial land cover are noticeable but not destabilizing. Impacts to terrestrial ecology for building activities at the NC-17 site are MODERATE. Overall, the impacts of Project operation on terrestrial habitat

are minimized through the use of BMPs during landscape maintenance and transmission line operation and maintenance. Therefore, impacts are SMALL for Project operation.

9.3.2.1.4 Aquatic Ecology

The evaluations conducted for aquatic ecology were based on a desktop review of publicly available data. Site specific aquatic habitat conditions are not generally known without a site survey.

The USFWS IPaC report for the NC-17 site indicated that one aquatic species, the Green Floater, proposed for listing, could be "potentially affected by activities at this location" (USFWS, 2025). The Neuse River Dog, which is a federally threatened species, was not listed by the IPaC report, but was listed in Person County, NC NCNHP data.

- Neuse River Waterdog (*Necturus lewisi*); threatened
- Green Floater (*Lasmigona subviridis*); proposed threatened

A review of the IPaC report did not indicate that any federally designated or proposed critical habitat for aquatic species is found within the NC-17 site.

Person County, NC NCNHP data for state-listed species was reviewed for the NC-17 site. Person County has seven state-listed aquatic endangered and threatened species, excluding the federally listed aquatic species, previously discussed.

Some aquatic organisms that use this area could suffer direct impacts from building activities, but most organisms will move away from the area and be affected primarily by the loss of a limited amount of habitat. In addition, some aquatic species might be affected by increased turbidity and siltation resulting from building activities, but such effects will be temporary and localized. The area that will be subject to disturbance in the Hyco Lake is small, and building activity impacts on the Hyco Lake are regulated under federal, state, and local permits. Therefore, impacts on aquatic ecology due to building activities are SMALL.

Direct impacts of operation on aquatic ecosystems in Hyco Lake are similar to those at the Belews Creek, NC site. Potential impacts include impingement and entrainment associated with the Cooling Water Intake Structure, effects of cooling tower effluent constituents and thermal effluents, and effects of water-level fluctuations within Hyco Lake. Operational impacts to aquatic ecosystems include impacts related to on-site stormwater runoff and incidental spills. Impacts on-site are managed through stormwater management systems and, therefore, are minor. In Hyco Lake, impacts are associated with the intake and discharge structures operations, and changes in water levels. Impacts of the discharge(s) are expected to dissipate rapidly, limiting impacts on aquatic ecosystems. Impacts of intake operation are minimized through compliance with CWA Section 316(b) requirements.

Compliance with thermal discharge limits required under the operational NCDEQ NPDES permit will limit adverse impacts to aquatic biota.

Similarly, to the Belews Creek NC, site with the closure of the Belews Creek Stream Station (BCSS), with the closure of the Roxboro Steam Station adjacent to the NC-17 site, the aquatic ecological community within Hyco Lake will reflect a lake lacking significant thermal input from power generation, including recreationally important sport fish.

Impacts on aquatic species and habitats within Hyco Lake from operations, under normal operational conditions in which water levels are stabilized and consumptive losses are offset by makeup water intake structure pumping are minor. Potential impacts to aquatic species and

habitats from hydrologic alterations associated with increased water-level fluctuation under drought conditions within Hyco Lake relate to effects on aquatic macrophyte communities, benthic macroinvertebrates and mussels, effects on fish communities through alteration of habitats (e.g., spawning habitat, nursery areas, foraging habitat), and increased potential for proliferation of nuisance macrophytes. The balance of fish communities is not expected to shift in such a way that would promote the expansion of nonindigenous fish beyond those already present in Hyco Lake. Therefore, impacts on aquatic ecology due to operation of the Project is SMALL to MODERATE (during drought conditions).

9.3.2.1.5 Socioeconomics

This subsection evaluates the social and economic impacts that could result from building and operating the Project at the NC-17 site. The evaluation includes the impacts of building and operation activities and demands placed by the building and operation workforces on the NC-17 site and the surrounding region.

9.3.2.1.5.1 Physical Impacts

This subsection provides an analysis of physical impacts of building and operation activities associated with noise and vibration, odors, dust and air pollution, transportation, and aesthetics.

9.3.2.1.5.1.1 Noise and Vibration

Based on an examination of aerial photographs, the nearest sensitive receptors to the NC-17 site include a residence approximately 0.1-mi. (0.2-km) to the west and a Saddle Club to the south of the site boundary. The sensitive receptors are more than 50 ft. (15 m) from any area that may be subject to vibration related effects from blasting and are not expected to experience impacts from blasting. Appropriate measures will be taken to minimize noise impacts from building activities and operation of the Project to sensitive receptors. Therefore, building activity impacts from vibration and noise to nearby sensitive receptors are SMALL.

The impacts from operation are similar to those from building activities but somewhat reduced. Operating plant equipment will produce some noise, but the noise levels generally are lower than the levels associated with building activities. Therefore, the noise and vibration impact during operation is SMALL.

9.3.2.1.5.1.2 Odors, Dust, and Air Pollution

Based on a review of aerial photographs, there are no residences within the conceptual site boundary. The nearest sensitive receptors include a residence to the west and a Saddle Club to the south, both of which are approximately 0.1-mi. (0.2-km) from the edge of the conceptual site boundary. Similarly, to the Belews Creek, NC site, as described in Section 4.4.1.2, building activities are localized mostly to the NC-17 site because they are generated from ground-level or near-ground-level activities. Because air emissions from on-site building activities are generally released from near ground-level sources, impacts are potentially greatest at the nearest off-site receptors. The nearest sensitive receptors include residences and a church to the east, and a Saddle Club to the south. To minimize temporary air and dust emissions, BMPs will be implemented during building activities at the site. Additionally, building activities are subject to air permits under state and federal laws that address the impact of air emissions on sensitive receptors. This is further discussed in Section 9.3.2.2.8. The impacts of odor, dust, and air pollution are similar to those at the Belews Creek, NC site, and are SMALL.

The impacts of odors, dust, and air pollution during operation are similar to those of building activities but somewhat reduced. Periodic maintenance is required for both on-site and off-site facilities and the maintenance activities will create some dust, but these impacts are more

localized and of shorter duration than during building activities. Therefore, the impact of operation is SMALL.

9.3.2.1.5.1.3 Transportation

This subsection discusses the physical impacts on off-site roadways resulting from increased traffic during building activities for and operation of the Project.

Similarly, to the Belews Creek, NC site, as described in Section 4.4.1.3, during the building phase, deliveries and commuting construction workers will result in increased vehicle use on off-site roadways that may impact pavement and roadway physical conditions.

Route 1336 (McGhees Mill Road) and Route 1322 (Edwin Robertson Road) are both local roadways that represent points of ingress and egress into the NC-17 site. As a result, increased traffic associated with the Project will accelerate the deterioration of these local roads relative to other roads within the surrounding transportation network. Roadway repairs and improvements on Routes 1336 and 1322 and other roadways in the vicinity of the NC-17 site inadvertently affected by vehicles associated with the Project, may be necessary to reduce safety risks and restore pavement conditions. Any damage to public roads, markings, or signs caused by building activities will be repaired to preexisting conditions or better in accordance with state and local requirements. Therefore, physical impacts from building activities on the transportation network in the vicinity of the NC-17 site are SMALL.

The impacts of operation to transportation are similar to those from building activities, but somewhat reduced. Therefore, the impact of operation is SMALL.

9.3.2.1.5.1.4 Aesthetics

Aesthetics in the vicinity of the new plant could be affected by the visual intrusion of large industrial structures and equipment. During building activities, dust could create additional visual intrusions. During operation, water vapor plumes from the cooling towers will be readily visible at certain times. Given that the NC-17 site vicinity currently has predominantly rural scenery, building activities and operation of the Project will alter the existing visual conditions. However, the severity of visual impacts on the human population will depend primarily on the visibility of the plant and off-site facilities from sensitive viewing areas.

NUREG-1437 establishes the following criteria for judging the severity of aesthetic impacts:

> SMALL - No complaints from affected public about a changed sense of place or a diminution in enjoyment of the physical environment, and no measurable impact on socioeconomic institutions and processes.
>
> MODERATE - Some complaints from affected public about a changed sense of place or a diminution in enjoyment of the physical environment, and measurable impacts that do not alter the continued functioning of socioeconomic institutions and processes.
>
> LARGE - Continuing and widely shared opposition to the project based on a perceived degradation of the area's sense of place or diminution in enjoyment of the physical environment, and measurable social impacts that perturb the continued functioning of community institutions and processes.

The immediate area around the NC-17 site features several notable visual resources:

- Hyco Lake, a scenic body of water used to support power plant operation and recreation.
- Forested land.

- The Roxboro Steam Station, located to the east of the NC-17 site. The coal fired plant is a significant industrial feature in the area.
- Rural/low density residential lands to the south and west of the NC-17 site.
- A Saddle Club to the south of the NC-17 site.

These elements together create a diverse visual environment around the NC-17 site. Sensitive visual receptors, which are potentially affected by visual intrusions of the Project, include recreators on Hyco Lake, the Saddle Club, and residences south and west of the NC-17 site boundary.

Considering that the power plant and off-site facilities are at the closest 0.1-mi. (0.2-km) from the nearest sensitive viewing areas, and that building and operation activities will alter the existing predominately rural scenery in the immediate area, public complaints related to a changed sense of place and diminished enjoyment of the physical environment may occur but are unlikely to be widespread due to the already industrial nature of the surrounding facilities. It is unlikely that there will be general opposition to the Project based on perceived degradation of sense of place, and the Project will not impact the continued functioning of institutions and processes. Therefore, the aesthetic impact associated with building activities and operations is similar to that of the Belews Creek, NC site and is MODERATE.

9.3.2.1.5.1.5 Summary of Physical Impacts

The physical impacts from noise, odors, dust, and air pollution, and transportation from building and operations-related activities are SMALL. Additionally, new plant structures and related cooling tower plumes at the Project site noticeably affect the aesthetic qualities of the natural landscape for nearby residents and recreators near the NC-17 site. Thus, physical impacts on aesthetic quality from building activities and operation are MODERATE.

9.3.2.1.5.2 Demographic Impacts

Demographic impacts are associated with construction workers and operation workers moving into the region surrounding the NC-17 site, potentially causing changes in off-site land use and development patterns. Construction employment is inherently temporary, but construction workers sometimes move their families into the region, magnifying the population increase.

Per NUREG-1437, demographic impacts are expected to be SMALL if project related population growth represents less than 5 percent of the study area's total population, MODERATE if 5 to 20 percent, and LARGE if more than 20 percent.

As described in Section 4.4.2.1, it is estimated that the total peak workforce for building plus operations is 2676 workers. A conservative assumption that can be made is that the entire peak building phase workforce (2676 people) will move into and bring families into the 50-mi. (80-km) region surrounding the NC-17 site. Applying the average NC household size of 2.48 people per household (Section 4.4.2.2), the total population increase is 6636. Based on USCB American Community Survey (ACS) 5-year data from 2023, the population of the region within a 50-mi. (80-km) radius of the NC-17 site is 1,416,824. Using this population value and a population increase of 6636, population growth due to the building phase workforce is 0.5 percent. Therefore, the building activities related demographic impact in the 50-mi. (80-km) region is SMALL.

The number of operations workers will be less than that for building activities, so operations-related demographic impacts at the NC-17 site are SMALL.

9.3.2.1.5.3 Economic Impacts to the Community

This section describes the economic and tax impacts in the 50-mi. (80-km) Region of Interest around the NC-17 site during building activities and operation.

9.3.2.1.5.3.1 Economy

Impacts on the economy are caused primarily by the jobs provided to construction and operation workers. The wages paid to workers result in additional spending, which tends to stimulate the economy, particularly in the retail and service sectors. This can provide opportunities for new businesses and new jobs. These effects are considered to be beneficial and are expected to occur primarily in the area within which the workers reside.

Per NUREG-1437, economic impacts are considered SMALL if project related employment represents less than 5 percent of the study area's total employment, MODERATE if 5 to 10 percent, and LARGE if more than 10 percent.

It was conservatively estimated in section 9.3.2.1.5.2 that the entire peak workforce of 2676 workers would migrate into the 50-mi. (80-km) Region of Interest if a new plant were to be constructed at the NC-17 site.

Using the USCB ACS 5-year estimates from 2023 for the total employment (728,685) within a 50-mi. (80-km) radius of the NC-17 site and the conservative regional employment increase discussed above (2676), employment due to the building activities workforce is 0.4 percent. Therefore, the building activities related economic impact in the 50-mi. (80-km) region is SMALL**.**

The employment of the workforce over the building phase will have a positive economic effect on the county and surrounding region. Building phase activities on the NC-17 site will introduce millions of dollars into the economy and indirectly create jobs that help reduce unemployment and provide opportunities for service-related industries. These economic impacts are realized primarily within the 50-mi. (80-km) radius; therefore, the impact of building activities on the economy of the 50-mi. (80-km) radius is beneficial and noticeable. Economic impacts during building activities at the NC-17 site are SMALL, and beneficial.

Similarly, to the Belews Creek, NC site, Project operation at the NC-17 site will introduce millions of dollars into the economy annually and indirectly creates employment opportunities. The economic impact of operations is SMALL and beneficial.

9.3.2.1.5.3.2 Taxes

Property taxes, sales taxes, and other taxes paid during building and operation of the new plant will benefit the state and local jurisdictions that collect the taxes. The significance of tax impacts is determined primarily by regional conditions, and those conditions are essentially the same for the NC-17 site as for the Belews Creek, NC site, as both sites are within NC. Therefore, regional tax impacts are essentially the same at both sites.

The analysis summarized in Section 4.4.3.3 indicates that the tax impact of constructing the new plant at the Belews Creek, NC site is expected to be MODERATE and beneficial. The analysis summarized in Section 5.4.3.3 indicates that the tax impact of plant operation at the Belews Creek, NC site is also expected to be SMALL and beneficial. Therefore, the building activities related and operation related tax impact at the NC-17 site is expected to be MODERATE and beneficial during building activities, and SMALL and beneficial during operation.

9.3.2.1.5.3.3 Summary of Economic Impacts to the Community

Building and operational activities at the NC-17 site will introduce millions of dollars into the economy and creates jobs. These positive economic impacts are primarily realized within the 50-mi. (80-km) Region of Interest. Minor tax revenue impacts on local jurisdictions are accrued through increases in revenue generated from individual income taxes, sales and use taxes, and property taxes. Therefore, the economic and tax impacts are SMALL to MODERATE and beneficial during building activities and SMALL and beneficial during operation.

9.3.2.1.5.4 Community Infrastructure Impacts

This subsection provides the estimated impacts on infrastructure and community services, including transportation, recreation, housing, and public services.

9.3.2.1.5.4.1 Transportation

Transportation in the vicinity of the new plant is affected by the increase in vehicle traffic associated with building phase and operation workers commuting to the site and the delivery of materials and equipment to the site. The increase in vehicle traffic could cause delays on local roads. The severity of such impacts will depend primarily on the existing traffic volumes and level of service (LOS) on local roads compared with the expected volume of traffic related to the Project.

Road access to the NC-17 site is provided primarily by secondary public roadways. Route 1322 or Edwin Robertson Road bisects the site parcel. McGhees Mill Road or Route 1336 runs along the northern boundary of the site. Both roads are maintained by the NCDOT and are relatively narrow two-lane roads that appear to be used mostly by local traffic. US Highway 501 is a two lane, asphalt paved highway located 6-mi. (10-km) east of the site (NCDOT, 2025a).

NCDOT data (NCDOT, 2025b) indicates that the average daily traffic volume for all lanes in both directions on SR 1322 (Edwins Robertson Road) is 1400 vehicles and 650 vehicles for SR 1336 (Mcghees Mill Rd). US Highway 501 has an average daily traffic volume of 4800 vehicles.

As stated in Section 4.4.2.1, there is a peak employment period during which two advanced reactor units are being constructed while four advanced reactor units are operating. The assessment of impacts on traffic are based on this bounding condition. It is estimated that during peak employment 2546 vehicles are expected to enter and leave the construction site at the same time.

Considering the nature of the roads in the vicinity of the NC-17 site and the current volume of traffic on those roads, it is likely that the peak building traffic will noticeably alter existing transportation conditions (cause noticeable delays on local roads) but will not be sufficient to destabilize important transportation resources. Therefore, the transportation impacts associated with building activities are MODERATE. While transportation impacts during operation are less than that of building activities, there are LOS degradations on two lane roads and intersections that provide access to the Project site, therefore impacts will be SMALL within the broader transportation network but MODERATE on local roads providing access to the Project site.

9.3.2.1.5.4.2 Recreation

Recreational resources within the vicinity of the NC-17 site are potentially affected by building activities. Impacts may include (1) impaired recreational experience associated with the views of the building activities, (2) increased user demand associated with the projected increase in

population as a result of the in-migrating workforce and their families, and (3) possible access delays associated with increased traffic on local roadways.

Constructing the cooling and makeup water intake and process wastewater discharge structures requires working within Hyco Lake. This work may impact recreators; however, these activities only occur during a small portion of the overall building phase. Once construction of the water intake and process wastewater discharge structures completes, it will no longer hinder recreators. However, if building activities associated with installation of intake or discharge structures impede the use of Hyco Lake or associated features, Duke Energy will coordinate with the North Carolina Wildlife Resources Commission, as appropriate.

Recreation users of Hyco Lake may experience visual discord during building activities due to the presence of large equipment and building lighting. Although these building activities alter the undeveloped nature of the NC-17 site, existing industrial features such as the Roxboro Steam Station and associated infrastructure currently exists within the viewshed of recreators on Hyco Lake.

Recreational areas within the vicinity of the NC-17 site are also impacted by the increase in population associated with in-migrating workers and their families. Workers who relocate within the 50-mi. (80-km) region are expected to use recreational areas and outdoor activities at the same rates as the existing permanent population of the Region of Interest. Although the in-migrating population increases usage of recreational areas within the vicinity of the NC-17 site, the increase is minor compared to the existing population and is not anticipated to impede or disrupt current usage of recreational areas.

Overall, during the building phase, recreators may experience increased noise levels and visual discord from building activities at the NC-17 site. The increased noise levels and visual discord may be noticeable to individual recreators on Hyco Lake in areas adjacent to and north of the NC-17 site; however, it does not reflect an impact that is more broadly evident within the larger reaches of Hyco Lake and does not destabilize the overall recreational experience. Building activities are most noticeable to recreators on the lake while the intake and discharge structures are being built. Due to the minor increase from the in-migrating population, use of recreational facilities in the vicinity of the NC-17 site is anticipated to be similar to existing conditions. Because recreators of Hyco Lake are mobile, and the time frame for building activities is limited, impacts to recreation are SMALL.

Operational use of water from Hyco Lake for the Project will result in water level fluctuation, similarly to the Belews Creek, NC site. Additionally, because, the construction of the Project at the NC-17 site would result in the closure of the existing Roxboro Steam Station, water quality (notably, temperature) within Hyco Lake is normalized to that of other regional lakes that lack thermal inputs from power generation. Impacts from operation off the Project at the NC-17 site will neither destabilize nor noticeably alter any important attribute of the resource and are therefore SMALL to MODERATE.

9.3.2.1.5.4.3 Housing

Impacts on housing could be caused by construction and operation workers moving, either permanently or temporarily, into the region surrounding the NC-17 site. This influx of workers could decrease the availability of unoccupied housing units and increase the cost to buy or rent housing. The severity of such impacts will depend primarily on the existing availability of unoccupied housing units compared with the number of workers who will move into the area.

NUREG-1437 establishes the following criteria for judging the severity of housing impacts:

SMALL - Small and not easily discernible change in housing availability. Increases in rental rates or housing values equal or slightly exceed the statewide inflation rate.

MODERATE - Discernible but short-lived reduction in available housing units. Rental rates and housing values rise slightly faster than the inflation rate, but prices realign quickly once new housing units became available or project related demand diminishes.

LARGE – Project related demand for housing units results in very limited housing availability and increases in rental rates and housing values well above normal inflationary increases in the state.

In Section 4.4.2.1 it was conservatively estimated that the peak workforce for the Project would be 2676 workers. Based on USCB ACS 2023 5-year estimates, the total number of vacant housing units in the 50-mi. (80-km) region surrounding the NC-17 site was 68,036. The conservative estimate of in-migrating construction workers discussed above (2676) represents 3.9 percent of the unoccupied housing units in the region. Because a sizable percentage of the unoccupied housing units will remain available, it is very unlikely that there will be a discernible change in housing availability or increase in housing costs. Therefore, the building activities related housing impact in the 50-mi. (80-km) region is SMALL.

It is estimated in Section 5.4.2 that during operation, that a total number of 818 full-time employees will be needed to staff all units once operational. Using a conservative estimate that all of the workers will in-migrate to the surrounding 50-mi. (80 km) region, approximately 1.2 percent of the available vacant housing in the Region of Interest is expected to be occupied by this increased population. Overall, sufficient housing is available within the Region of Interest to accommodate both operations-related workers and temporary short-term workers. Therefore, impacts on housing due to operation are SMALL.

9.3.2.1.5.4.4 Public Services

Public services include police, fire, and medical services; social services; water supply and wastewater treatment facilities; and recreation facilities. Impacts on public services could be caused by construction and operation workers moving into the region surrounding the NC-17 site. This influx of workers could increase the demand for public services, potentially requiring local governments to add facilities, programs, and/or staff.

Per NUREG-1437, impacts on public services generally are considered to be SMALL if there is little or no need to add facilities, programs, and/or staff because of the influx of workers, and MODERATE or LARGE if additional facilities, programs, and/or staff are required.

As discussed in Section 9.3.2.1.5.2, the number of construction workers estimated to move into Person County and the 50-mi. (80-km) region is SMALL compared with the existing populations. Therefore, the building activities related impact on public services in Person County and the 50-mi. (80-km) region is SMALL. The number of workers needed for operation is less than that for building activities, therefore the impacts of operation on public services is SMALL.

9.3.2.1.5.4.5 Education

Impacts on education could be caused by construction and operation workers moving into and bringing school-aged children into the region surrounding the NC-17 site. This increase in the number of school-aged children could cause crowding of local schools and potentially require school systems to add facilities and/or staff.

NUREG 1437 indicates that impacts to education are:

SMALL – If project related increase in school enrollment represents 3 percent or less of the total school enrollment in affected school systems,

MODERATE – If project related increase in school enrollment represents 4 to 8 percent of the total school enrollment in affected school systems, and

LARGE – If project related increase in school enrollment represents more than 8 percent of the total school enrollment in affected school systems.

The NC-17 site is located within the Person County school district, which contains 2 preschools, 8 elementary schools, 3 middle schools, and 3 high schools. The student-teacher ratio is 15 to 1. As discussed in Section 4.4.4, 19 percent of the population in NC is between 5 to 19 years old (i.e., school age). Using this percentage and applying it to the total in-migrating population of 6636 persons, approximately 1261 persons are of school age. This is 0.42 percent of the current number of school aged children (269,197) within the 50-mi. (80-km) region surrounding the NC-17 site (USCB, 2023). The building activities related education impacts to the surrounding 50-mi. (80-km) region are SMALL.

The number of operational workers who will move into the 50-mi. (80 km) surrounding Region of Interest to the NC-17 site will be less than that of building activities. Impacts to education from operation are SMALL.

9.3.2.1.5.4.6 Summary of Community Infrastructure Impacts

Building and operation related impacts on community infrastructure are SMALL with the exception of MODERATE construction related impacts to transportation and SMALL to MODERATE operations related impacts to recreation.

9.3.2.1.6 NOT USED

Deleted (Executive Order, 2025a, 2025b).

9.3.2.1.7 Historical and Cultural Resources

As defined by the National Historic Preservation Act (NHPA) of 1966, as amended (54 U.S. Code (USC) §306108) and its implementing regulations 36 CFR 800.16(l)(1), historic properties are those properties deemed eligible for listing or that are already listed in the National Register of Historic Places (NRHP).

There are no NRHP listed sites within the conceptual boundary of the NC-17 site or within the immediate vicinity of the site. There are 12 listed NRHP sites within Person County. The closest NRHP listed site is the House on Wagstaff Farm which is approximately 4-mi. (6-km) from the NC-17 site. Due to its distance from the NC-17 site, the House of Wagstaff Farm will likely not be impacted by building activities. There are 19 NRHP listed sites within a 10-mi. (6-km) radius of the site, two of which are historic districts.

The NC Natural Heritage Program Data Explorer indicated that a surveyed feature, and a surveyed feature that is now gone were identified within the NC-17 site. However, these features were not listed on the NRHP. The evaluations conducted for historical and cultural resources were based on a desktop review of publicly available data. Site specific conditions are not generally known without a site survey.

The impact on historical and archaeological resources due to building activities is SMALL due to a lack of resources within the conceptual site boundaries.

The impacts of operation are similar to the impacts of building activities but somewhat reduced. The noise levels of operating plant equipment generally are lower than the levels associated with building activities. No new disturbance of historical and archaeological resources is expected to occur during operation. Therefore, the impact on historical and archaeological resources due to operation is SMALL.

9.3.2.1.8 Air Resources

The Clean Air Act (CAA) was enacted in 1970 to protect public health and welfare and authorizes the USEPA to set National Ambient Air Quality Standards (NAAQS) for six common pollutants, called criteria pollutants. There are also provisions to regulate hazardous air pollutants, which are pollutants that are harmful to human health and/or the environment, as well as greenhouse gases (GHGs), primarily carbon dioxide (CO_2) (42 United States Code §7401 et seq).

The CAA requires the USEPA to set NAAQS for pollutants considered to be harmful to public health and the environment. Primary NAAQS provide public health protection including protecting the health of sensitive populations (asthmatics, children, elderly, etc.). Secondary NAAQS provide public welfare protection against decreased visibility and damage to animals, crops, vegetation, and buildings (USEPA, 2025c).

NC reached full attainment with all NAAQS across the entire state in 2015 (NCDEQ, 2024 and USEPA 2025c). The most recent pollutant to be redesignated was ozone. On July 28, 2015, the USEPA redesignated to attainment the NC-portion of the Charlotte-Rock Hill, NC-SC, nonattainment area for the 2008 8-hour ozone NAAQS, effective August 27, 2015.

The CAA defines Class I areas as national parks greater than 6000 ac. (2428 ha.), wilderness areas greater than 5000 ac. (2023 ha), national memorial parks greater than 5000 ac. (2023 ha), and international parks that were in existence as of August 1977. These areas are potentially sensitive to visibility impairment. The USEPA states that a Class I visibility impact analysis is necessary for a major source within 62-mi. (100-km) of a Class I area (USEPA, 1990).

The USEPA promulgated the Regional Haze Rule to improve visibility in Class I areas in 1999 with the ultimate goal of restoring natural background visibility by 2064 (Federal Register Vol. 64, 1999). This rule was amended in 2005 to require certain industrial facilities to install emission controls to reduce emissions of air pollutants that reduce visibility (USEPA, 2025d; Federal Register Vol. 70, 2005). These pollutants include particulate matter with a diameter 2.5 microns or less ($PM_{2.5}$) and compounds that contribute to $PM_{2.5}$ formation, such as nitrogen oxides, sulfur dioxide, certain volatile organic compounds, and ammonia.

The closest Class I area to the NC-17 site is Shenandoah National Park, approximately 148-mi. (238-km) to the north. There are no Class I areas within 62-mi. (100-km) of the NC-17 site, therefore, no Class I areas are affected (USEPA, 2025d).

The NC-17 site is in an attainment area for all criteria pollutants, similarly to the Belews Creek, NC site. These two sites are similar from an air quality perspective. Sections 4.7 and 5.7 indicated the impacts to air resources from building activities and operation of the Belews Creek, NC site are SMALL. As such, the impacts of building activities on air quality are expected to be SMALL and temporary, and the impacts of facility operations on air resources are also expected to be SMALL for the NC-17 site.

9.3.2.1.9 Nonradiological Health

Non-radiological health impacts on the public and workers from building and operation activities at the NC-17 site are similar to those evaluated in Sections 4.8 and 5.8. They include the impacts of public and occupational health, the impacts of noise and vibration, and the impacts of transporting building materials and personnel to and from the Project site. Additional data required, based on applicable federal and state air quality and noise regulations, are provided during the building phase. The NC-17 site has characteristics that will require site-specific Health and Safety Plans for the building phases. Health impacts to workers from occupational injuries, noise, and electric fields are similar at the NC-17 site to those at the Belews Creek, NC site. The NC-17 site does not have characteristics that are expected to lead to fewer, or more, operational accidents than those expected at the Belews Creek, NC site. Due to the implementation of BMPs and compliance with regulations and permit conditions, non-radiological health impacts from building activities and operation are expected to be SMALL for all categories.

9.3.2.1.10 Radiological Health

This NC-17 site does not currently have operating nuclear facilities. Therefore, potential radiological exposures due to existing facilities are similar to that of the Belews Creek, NC site, and lower than the NC-19 site. Human health impacts are also dependent on population density near the proposed facility. The low population density near the NC-17 site should lessen potential health effects. Radiological health impacts for building activities and operation of the Belews Creek, NC site are discussed in Sections 4.9 and 5.9. Generally, dose rates will be within allowable limits. As such, human health impacts from radiological exposures during building activities and operation at the NC-17 site are expected to be SMALL.

9.3.2.1.11 Nonradioactive Waste Management

The impacts on the environment that could result from the generation, handling, and disposal of nonradioactive waste and mixed waste during building activities and operations at the NC-17 site would be similar to those at the Belews Creek, NC site, which is described in further detail in Sections 4.10 and 5.10. Therefore, impacts to land, water, and air from nonradioactive waste generated, handled, stored, and disposed of during building activities and operations are SMALL.

9.3.2.1.12 Environmental Impacts of Postulated Accidents

The potential environmental impacts from a postulated accident, considering both design-basis accidents (DBAs) and severe accidents, for the Belews Creek, NC site are described in Section 5.11. The DBAs and severe accidents analyzed to-date for the Belews Creek, NC site are applicable to the NC-17 site.

The NC-17 site is located in Person County, NC, and is situated approximately 1-mi. (2-km) east of Hyco Lake. The area is characterized generally as rolling hills, with elevations around 400 to 500 ft. (122 to 152 m) reaching a peak of about 820 ft. (250 m) to the south at a distance of 7-mi. (11-km) from the site. High pressure associated with the Bermuda anticyclonic circulation result in moderate wind speeds in the region (NOAA NCEI, 2022a.).

It is unlikely that differences in local meteorological conditions are sufficient to cause doses from DBAs for multiple advanced reactors at the NC-17 site to exceed regulatory limits or guidelines or the impacts from a similar accident at the Belews Creek, NC site. Therefore, the impacts for postulated accidents at the NC-17 site for operation are SMALL.

9.3.2.2 Evaluation of the NC-19 Site

The NC-19 site is comprised of two parcels located adjacent to the existing Shearon Harris Nuclear Plant approximately 20-mi. (32-km) southwest of Raleigh, in Wake County, NC. This site is located near Harris Lake which is a 4100 ac. (1659 ha) reservoir with a primary purpose of providing cooling water for the Shearon Harris Nuclear Plant, which is a single unit, 928 MW nuclear facility. Duke Energy currently owns all of the NC-19 site. U.S. Highway 1 which is maintained by the NCDOT is directly north of this site. The topography of the site is comprised of numerous hills and valleys with some slopes that exceed 30 percent. The conceptual site boundary has an approximate total area of 976 ac. (395 ha) for both parcels.

The NC-19 site will require the following off-site features in order to support a nuclear power plant:

- Road access to the site is provided by existing public roads. The eastern site will need to have a road extension of approximately 1-mi. (1.6-km) in order to connect to U.S. Highway 1.
- There are two parcels for the NC-19 site, and the east parcel contains a number of on-site rail sidings that serve the existing Shearon Harris Nuclear Plant. This industrial rail is ultimately served by CSXT. The second, west parcel will also be served by the rail siding at the existing Shearon Harris Nuclear Plant which is located 5.5-mi. (8.9-km) from the second parcel.
- A new makeup water pipeline will be constructed that will provide makeup water from the Cape Fear River to Harris Lake. The pipeline will be constructed in an existing right-of-way.
- It was assumed that the NC-19 site will utilize the existing 230 kV switchyard at the Shearon Harris Nuclear Plant.

9.3.2.2.1 Land Use

Existing land use across the western parcel at the NC-19 site is predominately evergreen forested land, with a large portion of planted pine plantation. Limited infrastructure development and structures are present on the western parcel of the NC-19 site. A moderate amount of infrastructure development and structures related to the existing Shearon Harris Nuclear Plant are present on the eastern parcel of the NC-19 site. The NC-19 site is located adjacent to Harris Lake in Wake and Chatham Counties, NC. Duke Energy currently owns this entire site, including the land needed for intake structures (Wake County, 2025a, Chatham County, 2025). Transmission and rail interconnect will primarily occur within the conceptual site boundaries. Soils classified as prime or farmland of statewide importance cross much of the site (USDA NRCS, 2025). There are no residences identified within the conceptual site boundaries, the closest residence is approximately 1.5-mi. (2.4-km) away from the center point of the conceptual site boundaries. The NC-19 site is zoned as industrial in the eastern parcel but is mainly zoned as residential in the western parcel (Wake County, 2025b, Chatham County, 2025).

The closest significant industrial land use to the NC-19 site is the existing Shearon Harris Nuclear Plant which is directly adjacent to the site.

While the eastern parcel related to the NC-19 is currently developed and used for the existing Shearon Harris Nuclear Plant, use of the NC-19 site will convert existing forested land and pine plantation on the western parcel to industrial use. The land use impacts are MODERATE for building activities as the western parcel will be converted to industrial use. During operation, no

new land use impacts will occur beyond those described above for building activities, so land use impact due to operation of the Project will be SMALL.

9.3.2.2.2 Water Resources

Water resources at the NC-19 site are located in the White Oak Creek watershed. The NC-19 site is adjacent to Harris Lake, a reservoir created from the impoundment of Buckhorn Creek, a tributary to the Cape Fear River. There is also an auxiliary reservoir located on Tom Jack Creek. The primary purpose of Harris Lake is to provide cooling water for the Shearon Harris Nuclear Plant and general operational water supply for the nuclear station. Secondary uses of the reservoir include recreational activities including fishing, boating, and hunting (NCDEQ, 2022). Harris Lake is not listed as impaired with the USEPA. However, the Cape Fear River from NC Highway 42 to Buckhorn Creek is listed as impaired for recreation from Chlorophyll a. Harris Lake is classified by the NCDEQ as a WS-V water, which is defined as suitable for water supply for use by industry to supply drinking water to their employees, but not to municipalities or counties with a raw drinking water supply source (NCDEQ 1999). The NC-19 site is not located over a sole source aquifer.

Currently, the site contains one 928 MW nuclear plant with closed cycle cooling. For additional nuclear power plants, Harris Lake will need to be raised beyond the current 220 ft. (67 m) level up to a maximum analyzed level of 240 ft. (73 m). A pumping station on the Cape Fear River will be needed to supplement the reservoir. Different locations are under consideration for an intake structure. The most likely of which would be an area at the retired Cape Fear Coal Plant.

There is no commercial barge navigation on Harris Lake or near the NC-19 site. The entirety of the site is outside of the 100-year and 500-year flood zones, except for the portions of the site that border Harris Lake.

Groundwater withdrawal would not be mandatory at the NC-19 site, because Harris Lake is capable of providing fresh water for plant uses. A detailed water study would be performed if development of the NC-19 site was anticipated.

Water-related impacts associated with building activities on the site itself are similar to the impacts of any large construction project. Potential impacts include direct physical alteration of local surface water bodies; indirect alteration of nearby surface water bodies due to increased runoff volumes or diversions of runoff; degradation of downstream surface water quality as a result of erosion and sedimentation or discharges of pollutants associated with building activities; and changes in groundwater flow patterns due to dewatering of excavations and soil retention management practices. The most potentially significant impact is that some existing streams on the site will be directly disturbed, and some adjacent streams will experience a temporary increase in sediment loading due to increased runoff of disturbed soil.

Several federal, state, and local permits will govern building activities that have the potential to impact water resources. Water-related impacts are minimized by implementing BMPs, including erosion, grading, and sediment control measures; SWPPPs; spill prevention and countermeasure plans; and compliance with federal, state, and local regulations pertaining to disturbance of water bodies and pollution discharges.

Proposed hydrological alterations to the NC-19 site for building activities are minimal in terms of impact to surface water and groundwater. Impacts related to hydrological alterations to surface waters for Project operation are MODERATE because of the need for a pumping station and because Harris Lake will need to be raised to support plant operation. Impacts as a result of building activities and operation are SMALL for water use and water quality since stormwater

and plant discharge leaving the site will follow natural contours using culverts and other water management structures, to maintain hydrologic conditions to the extent practicable.

9.3.2.2.3 Terrestrial Ecology

Any large construction project impacts terrestrial ecology primarily by disturbing natural habitats and making those habitats unavailable to plants and animals. Although building activities may result in direct mortality to some plants and animals, most animal species are able to move away to avoid direct impacts. Even those species, however, may experience population declines due to loss of habitat. In addition, noise, lights, and dust may cause some animals to leave areas near building activities. This is also experienced as a loss of usable habitat.

The evaluations conducted for terrestrial ecology were based on a desktop review of publicly available data. Site specific terrestrial habitat conditions are not generally known without a site survey.

The USEPA defines ecoregions in hierarchical levels from Level I to Level IV, increasing in detail as the level increases. The USEPA maintains the mapping of ecoregions (USEPA, 2025a). The NC-19 site is located within the Piedmont Level III Ecoregion. Additionally, the NC-19 site is located within the Triassic Basins Level IV Ecoregion which is detailed as having a mosaic of mixed and deciduous forest, pasture, cropland, and urban land cover (USEPA, 2025b).

NLCD data indicates that the land cover in the approximately 976 ac. (395 ha) NC-19 site is characterized predominantly by evergreen forest (798 ac. [323 ha]), which is the most prevalent land cover type. Other common land cover types include shrub scrub (42 ac. [17 ha]), developed low intensity (42 ac. [17 ha]) and developed open space (41 ac. [17 ha]). The most prevalent land cover type found within the 6-mi. (10-km) vicinity of the NC-19 site is evergreen forest (40,080 ac. [16,220 ha]), followed by mixed forest (16,039 ac. [6491 ha]), open water (8827 ac. [3572 ha]), and developed open space (5830 ac. [2359 ha]) (Table 9.3-3) (Dewitz, J. and USGS, 2021).

A review of USFWS NWI data was completed to determine on-site aquatic resources for the NC-19 site. Multiple intermittent tributaries flow southwest to the Cape Fear River within the NC-19 site. Multiple unknown perennial tributaries also flow southeast to Harris Lake within the NC-19 site. Freshwater forested/ shrub wetlands were observed to border the tributaries.

The USFWS IPaC report for the NC-19 site indicated that three federally listed species, and one species proposed for listing, could be “potentially affected by activities at this location” (USFWS 2025) (Table 9.3-5):

- Red-cockaded Woodpecker (*Dryobates borealis*); threatened
- Monarch Butterfly (*Danaus plexippus*); proposed threatened
- Harperella (*Ptilimnium nodosum*); endangered
- Michaux's Sumac (*Rhus michauxii*); endangered

A review of the IPaC report did not indicate that any federally designated or proposed critical habitat for terrestrial species is found on the NC-19 site.

State Listed Species

Wake and Chatham counties, NC NCNHP data for state-listed species were reviewed for the NC-19 site. Together, the two counties have 30 state listed threatened and endangered species,

excluding the previously listed federal species (Table 9.3-5). Additionally, the site overlaps with Harris Game Land, which is land leased by Duke Energy to the NC Wildlife Commission Game Lands Program.

Table 9.3-3 shows that the acreage of each habitat potentially affected by building activities is a relatively small percentage of the total acreage of the habitat available in the site vicinity. In addition, it appears that the eastern parcel of the NC-19 site has been subject to prior disturbance due to the presence of facilities related to the existing Shearon Harris Nuclear Plant. The western parcel also appears to be previously disturbed due to the presence of pine plantations on the site. Therefore, habitat at the NC-19 site is considered low quality relative to adjacent habitat. Detailed field studies are required to determine whether any federally listed or threatened species make significant use of the site, and as reconnaissance level data was used for this evaluation, such studies were not conducted for the NC-19 site. Based on the area affected, overall impacts on terrestrial habitats are noticeable. However, because of the availability of similar land cover types within the Project Vicinity, the prevalence of low-quality plant communities, and reduced quality of the existing habitats on the Project site, potential impacts on terrestrial land cover are noticeable but not destabilizing. Impacts to terrestrial ecology for building activities at the NC-19 site are MODERATE. Overall, the impacts of Project operation on terrestrial habitat are minimized through the use of BMPs during landscape maintenance and transmission line operation and maintenance. Therefore, impacts are SMALL. Disturbance to wetland and streams may occur as a result of building activities. However, impacts to wetlands and streams are regulated by several federal, state, and local regulations and are minimal.

9.3.2.2.4 Aquatic Ecology

The evaluations conducted for aquatic ecology were based on a desktop review of publicly available data. Site specific aquatic habitat conditions are not generally known without a site survey.

Federally Listed Species

The USFWS IPaC report for the NC-19 site indicates that one endangered aquatic species, could be “potentially affected by activities at this location” (USFWS, 2025). Additionally, the NCNHP also listed the following endangered, threatened, and candidate aquatic species with potential to be found in Chatham and Wake counties (Table 9.3-5):

- Dwarf Wedgemussel (*Alasmidonta heterodon*); endangered
- Green Floater (*Lasmigona subviridis*); proposed threatened
- Yellow Lance (*Elliptio lanceolata*); threatened
- Neuse River Waterdog (*Necturus lewisi*); threatened
- Caper Fear Shiner (*Notropis mekistocholas*); endangered
- Robust Redhorse (*Moxostoma robustum*); candidate
- Carolina Madtom (*Noturus furiosus*); endangered

A review of the IPaC report did not indicate that any federally designated or proposed critical habitat for aquatic species is found on the NC-19 site.

State Listed Species

Wake and Chatham counties, NCNHP data for state-listed species was reviewed for the NC-19 site. Wake and Chatham counties have 22 state-listed aquatic endangered and threatened species, excluding the previously listed federally listed aquatic species (Table 9.3-5).

Some aquatic organisms that use this area could suffer direct impacts from building activities, including the loss of habitat due to raising the elevation of Harris Lake, but most organisms will move away from the area and be affected primarily by the loss of a limited amount of habitat. In addition, some aquatic species might be affected by increased turbidity and siltation resulting from building activities, but such effects will be temporary and localized. The area that is subject to disturbance in Harris Lake is small and impacts to Harris Lake from building activities are regulated under federal, state, and local permits. Therefore, impacts on aquatic ecology due to building activities are SMALL.

Direct impacts of operation on aquatic ecosystems in Harris Lake include impingement and entrainment associated with the cooling water intake structure, effects of cooling tower effluent constituents and thermal effluents, and effects of water-level fluctuations within Harris Lake. Operational impacts to aquatic ecosystems include impacts related to on-site stormwater runoff and incidental spills. Impacts on-site are managed through stormwater management systems and, therefore, are minor. In Harris Lake, impacts are associated with the intake and discharge structures operations, and changes in water levels. Impacts of the discharge(s) are expected to dissipate rapidly, limiting impacts on aquatic ecosystems. Impacts of intake operation are minimized through compliance with CWA Section 316(b) requirements.

Compliance with thermal discharge limits required under the operational NCDEQ NPDES permit will limit adverse impacts to aquatic biota. In addition, raising the levels of Harris Lake may disrupt the aquatic ecology of streams that would be inundated by this action.

Impacts on aquatic species and habitats within Harris Lake from operations, under normal operational conditions in which water levels are stabilized and consumptive losses are offset by makeup water intake structure pumping are minor. Potential impacts to aquatic species and habitats from hydrologic alterations associated with increased water-level fluctuation under drought conditions within Harris Lake relate to effects on aquatic macrophyte communities, benthic macroinvertebrates and mussels, effects on fish communities through alteration of habitats (e.g., spawning habitat, nursery areas, foraging habitat), and increased potential for proliferation of nuisance macrophytes. The balance of fish communities is not expected to shift in such a way that would promote the expansion of nonindigenous fish beyond those already present in Harris Lake. Therefore, impacts on aquatic ecology due to operation of the Project is SMALL to MODERATE (during drought conditions).

9.3.2.2.5 Socioeconomics

This subsection evaluates the social and economic impacts that could result from constructing and operating the Project at the NC-19 site. The evaluation includes the impacts of building and operation activities and demands placed by the construction and operation workforces on the site and the surrounding region.

9.3.2.2.5.1 Physical Impacts

This subsection provides an analysis of the physical impacts of building activities and operation associated with noise and vibration, odors, dust and air pollution, transportation, and aesthetics.

9.3.2.2.5.1.1 Noise and Vibration

Based on an examination of aerial photographs, the nearest sensitive receptors to the NC-19 site include a residence located approximately 0.4-mi. (0.6-km) to the north of the site and a residence located approximately 0.3-mi. (0.5-km) south of the site. The sensitive receptors are more than 50 ft. (15 m) from any area that may be subject to vibration related effects from blasting and are not expected to experience impacts from blasting. Appropriate measures will be taken to minimize noise impacts from building activities and operation of Project to sensitive receptors. Additionally, a large, forested buffer will remain between the NC-19 site and any sensitive receptors which will further reduce noise impacts. Vibration and noise impacts during building activities to nearby sensitive receptors are SMALL.

The impacts from operation are similar to the impacts of building activities but somewhat reduced. Operating plant equipment will produce some noise, but the noise levels generally are lower than the levels associated with building activities. Therefore, the noise and vibration impact during operation is SMALL.

9.3.2.2.5.1.2 Odors, Dust, and Air Pollution

Based on a review of aerial photographs, there are no residences within the conceptual site boundary of the NC-19 site. The nearest sensitive receptor is a residence located approximately 0.3-mi. (0.5-km) to the south of the site. Similarly, to the Belews Creek, NC site, as described in Section 4.4.1.2, building activities are localized mostly to the NC-19 site because they are generated from ground-level or near-ground-level activities. Because air emissions from on-site building activities are generally released from near ground-level sources, impacts are potentially greatest at the nearest off-site receptors. The nearest sensitive receptors include residences to the north and south. To minimize temporary air and dust emissions, BMPs will be implemented during the construction of the site. Additionally, building activities are subject to air permits under state and federal laws that address the impact of air emissions on sensitive receptors. This is further discussed in Section 9.3.2.2.8. The impacts of odor, dust, and air pollution are similar to the Belews Creek, NC site, and are SMALL.

The impacts of odors, dust, and air pollution during operation are similar to the impacts of building activities but somewhat reduced. Periodic maintenance is required for both on-site and off-site facilities and the maintenance activities will create some dust, but these impacts will be more localized and of shorter duration than during construction. Therefore, the impact of operation is SMALL.

9.3.2.2.5.1.3 Transportation

This subsection discusses the physical impacts on off-site roadways resulting from increased traffic during building activities.

Similarly, to the Belews Creek, NC site, as described in Section 4.4.1.3, during the building phase, deliveries, and commuting construction workers result in vehicle use on off-site roadways that may impact pavement and roadway physical conditions.

Because U.S Highway 1 represents the only point of ingress and egress into the NC-19 site, all traffic is focused on this roadway segment. As a result, increased traffic related to the Project accelerates the deterioration of U.S. Highway 1 relative to other roads within the surrounding transportation network. Roadway repairs and improvements on U.S. Highway 1 and other roadways in the vicinity of the NC-19 site inadvertently affected by vehicles related to the Project, may be necessary to reduce safety risks and restore pavement conditions. Any damage to public roads, markings, or signs caused by building activities is repaired to preexisting

conditions or better in accordance with state and local requirements. Therefore, physical impacts from building and operation activities on the transportation network in the vicinity of the NC-19 site are SMALL.

9.3.2.2.5.1.4 Aesthetics

Aesthetics in the vicinity of the new plant could be affected by the visual intrusion of large industrial structures and equipment. During building activities, dust could create additional visual intrusions. During operation, water vapor plumes from the cooling towers will be readily visible at certain times. Given that the NC-19 site is located adjacent to an existing nuclear power plant, building activities and operation will not significantly alter the existing visual conditions.

NUREG-1437 establishes the following criteria for judging the severity of aesthetic impacts:

> SMALL - No complaints from affected public about a changed sense of place or a diminution in enjoyment of the physical environment, and no measurable impact on socioeconomic institutions and processes.
>
> MODERATE - Some complaints from affected public about a changed sense of place or a diminution in enjoyment of the physical environment, and measurable impacts that do not alter the continued functioning of socioeconomic institutions and processes.
>
> LARGE - Continuing and widely shared opposition to the project based on a perceived degradation of the area's sense of place or diminution in enjoyment of the physical environment, and measurable social impacts that perturb the continued functioning of community institutions and processes.

The immediate area around the NC-19 site features several notable visual resources:

- Harris Lake, a scenic body of water used to support nuclear power plant operation and recreation.
- Forested land.
- The Shearon Harris Nuclear Plant, located adjacent to the NC-19 site. This is a significant industrial feature in the area.
- Mid-density residential lands to the north and east of the NC-19 site.

These elements together create a diverse visual environment around the NC-19 site. Sensitive visual receptors, which are potentially affected by visual intrusions of the Project, include recreators on Harris Lake and residences north and east of the NC-19 site boundary.

Considering that the NC-19 site is located adjacent to an existing nuclear power plant within land already owned by Duke Energy, it is unlikely that there will be general opposition to the Project based on perceived degradation of sense of place, and the Project will not impact the continued functioning of institutions and processes. However, there will be a noticeable impact to aesthetics due to the conversion of previously vegetated land to industrial use. Therefore, the aesthetic impact associated with building activities and operation is similar to the Belews Creek, NC site and is MODERATE.

9.3.2.2.5.1.5 Summary of Physical Impacts

The physical impacts from noise, odors, dust, and air pollution, and transportation from building and operations-related activities are SMALL. Additionally, because existing vegetated land will be converted to industrial use, NC-19 site impacts to aesthetic quality are MODERATE.

9.3.2.2.5.2 Demographic Impacts

Impacts on demography are associated with construction workers and operation workers moving into the region surrounding the NC-19 site, potentially causing changes in off-site land use and development patterns. Construction employment is inherently temporary, but construction workers sometimes move their families into the region, magnifying the population increase.

Per NUREG-1437, demographic impacts are expected to be SMALL if project related population growth represents less than 5 percent of the study area's total population, MODERATE if 5 to 20 percent, and LARGE if more than 20 percent.

As described in Section 4.4.2.1, it is estimated that the total peak workforce for building plus operations is 2676 workers. A conservative assumption that can be made is that the entire peak building phase workforce (2676 people) will move into and bring families into Wake County, where the majority of the nearby population resides. Applying the average NC household size of 2.48 people per household (Section 4.4.2.2), the total population increase is 6636. Using the year 2020 population (1,129,410) of Wake County and the conservative population increase discussed above, population growth due to the in-migrating workforce is approximately 0.3 percent. Therefore, the building-related demographic impacts in Wake County are SMALL.

The number of in-migrating workers during operation of the plant will be less than that for building, so operations-related demographic impacts at the NC-19 site are also SMALL.

9.3.2.2.5.3 Economic Impacts to the Community

This section describes the economic and tax impacts in the 50-mi. (80-km) Region of Interest around the NC-19 site during building activities and operation.

9.3.2.2.5.3.1 Economy

Impacts on the economy are caused primarily by the jobs provided to construction and operation workers. The wages paid to workers result in additional spending, which tends to stimulate the economy, particularly in the retail and service sectors. This can provide opportunities for new businesses and new jobs. These effects are considered to be beneficial and are expected to occur primarily in the area within which the workers reside.

Per NUREG-1437, economic impacts are considered SMALL if project related employment represents less than 5 percent of the study area's total employment, MODERATE if 5 to 10 percent, and LARGE if more than 10 percent.

The employment of the workforce during building activities and operation of the nuclear plant will have a positive economic effect on both Wake and Chatham counties and the surrounding region. Building and operation activities at the NC-19 site will introduce millions of dollars into the economy and indirectly create jobs that help reduce unemployment and provide opportunities for service-related industries.

For this analysis, it was assumed that the majority of the in-migrating workforce will move to Wake County. According to USCB ACS 5 -Year estimates from 2023, Wake County's civilian labor force totaled 637,987. Of those labor force participants, 611,492 were employed and 26,495 were not, representing an unemployment rate of 3.9 percent. Using the county value for total employment (637,987) and the conservative county employment increase discussed above (2676), employment due to the building workforce is 0.4 percent. Therefore, the building-related economic impact in Wake County is SMALL and beneficial.

Similarly to the Belews Creek, NC site, Project operation at the NC-19 site will introduce millions of dollars into the economy annually and indirectly creates employment opportunities. The economic impact of operations is SMALL and beneficial.

9.3.2.2.5.3.2 Taxes

Property taxes, sales taxes, and other taxes paid during building and operation of the new plant will benefit the state and local jurisdictions that collect the taxes. The significance of tax impacts is determined primarily by regional conditions, and those conditions are essentially the same for the NC-19 site as for the Belews Creek, NC site, as both sites are within NC. Therefore, regional tax impacts are essentially the same at both sites.

The analysis presented in Section 4.4.3 indicates that the tax impact of constructing the new plant at the Belews Creek, NC site is expected to be MODERATE and beneficial. The analysis presented in Section 5.4.3.3 indicates that the tax impact of plant operation at the Belews Creek, NC site is also expected to be SMALL and beneficial. Therefore, the building activities related and operation related tax impact at the NC-19 site is expected to be MODERATE and beneficial during building activities, and SMALL and beneficial during operation.

9.3.2.2.5.3.3 Summary of Economic Impacts to the Community

Building and operational activities at the NC-19 site will introduce millions of dollars into the economy and creates jobs. These positive economic impacts are primarily realized within the Region of Interest, Minor tax revenue impacts on local jurisdictions are accrued through increases in revenue generated from individual income taxes, sales and use taxes, and property taxes. Therefore, the economic and tax impacts are SMALL to MODERATE and beneficial during building activities and SMALL and beneficial during operation.

9.3.2.2.5.4 Community Infrastructure Impacts

This subsection provides the estimated impacts on infrastructure and community services, including transportation, recreation, housing, and public services.

9.3.2.2.5.4.1 Transportation

Transportation in the vicinity of the new plant could be affected by the increase in vehicle traffic associated with construction and operation workers commuting to the site and the delivery of materials and equipment to the site. The increase in vehicle traffic could cause delays on local roads. The severity of such impacts will depend primarily on the existing traffic volumes and LOS on local roads compared with the expected volume of traffic related to the Project.

Road access to the NC-19 site is provided primarily by U.S. Highway 1, which is maintained by the NCDOT. This asphalt highway has two lanes of traffic, traveling east and west (NCDOT, 2025a).

NCDOT data (NCDOT, 2025b) indicates that the average daily traffic volume for all lanes in both directions on U.S. Highway 1 is 36,000 vehicles. As stated in Section 4.4.2.1, there is a peak employment period during which two advanced reactor units are being constructed while four advanced reactor units are operating. It is estimated that during peak employment 2546 vehicles are expected to enter and leave the building site at the same time.

Considering the nature of the roads in the vicinity of the NC-19 site and the current volume of traffic on those roads, it is likely that the peak building traffic will noticeably alter existing transportation conditions (cause noticeable delays on local roads) but will not be sufficient to destabilize important transportation resources. Therefore, the transportation impacts associated

with building activities are MODERATE. Impacts to transportation due to workforce traffic during operations are SMALL within the broader transportation network, but MODERATE on two-lane segments and intersections that provide access to the Project site due to the short duration of daily peak traffic and implementation of planned traffic management measures to reduce congestion and unstable conditions.

9.3.2.2.5.4.2 Recreation

Recreational resources within the vicinity of the NC-19 site are potentially affected by building activities at the NC-19 site. Impacts may include (1) impaired recreational experience associated with the views of the building activities, (2) increased user demand associated with the projected increase in population as a result of the in-migrating workforce and their families, and (3) possible access delays associated with increased traffic on local roadways.

Raising the level of Harris Lake beyond the current 220 ft. (67 m) level up to a maximum analyzed level of 240 ft. (73 m) will impact recreators. Approximately 279 ac. (98 ha) of recreation facilities at Harris Lake County Park and four boat ramps will be displaced by the rise to the Harris Lake water level. Because these areas will be displaced by the change in water level elevation, recreators who might have used these areas will have to relocate to other nearby recreation or related areas. However, these recreation areas will be replaced after building is complete.

Recreational areas within the vicinity of the NC-19 site are also impacted by the increase in population associated with in-migrating workers and their families. Workers who relocate to the Region of Interest are expected to use recreational areas and outdoor activities at the same rates as the existing permanent population of the Region of Interest. Although the in-migrating population increases usage of recreational areas within the vicinity of the NC-19 site, the increase is minor compared to the existing population and is not anticipated to impede or disrupt current usage of recreational areas.

Overall, during the building phase, recreators may experience increased noise levels and visual discord from building activities at the NC-19 site. The increased noise levels and visual discord may be noticeable to individual recreators on Harris Lake in areas adjacent to and north of the NC-19 site; however, it does not reflect an impact that is more broadly evident within the larger reaches of Harris Lake and does not destabilize the overall recreational experience. Recreators will also experience temporary impacts when the water level of Harris Lake is raised, however because these recreational facilities will be replaced, impacts from building activities are anticipated to be MODERATE.

Operational use of water from Harris Lake for the Project will result in water level fluctuation, similarly to the Belews Creek, NC site, and the impact will be SMALL to MODERATE.

9.3.2.2.5.4.3 Housing

Impacts on housing could be caused by construction and operation workers moving, either permanently or temporarily, into the region surrounding the NC-19 site. This influx of workers could decrease the availability of unoccupied housing units and increase the cost to buy or rent housing. The severity of such impacts will depend primarily on the existing availability of unoccupied housing units compared with the number of workers who will move into the area.

NUREG-1437 establishes the following criteria for judging the severity of housing impacts:

> SMALL - Small and not easily discernible change in housing availability. Increases in rental rates or housing values equal or slightly exceed the statewide inflation rate.

MODERATE - Discernible but short-lived reduction in available housing units. Rental rates and housing values rise slightly faster than the inflation rate, but prices realign quickly once new housing units became available, or project related demand diminishes.

LARGE – Project related demand for housing units results in very limited housing availability and increases in rental rates and housing values well above normal inflationary increases in the state.

Based on USCB ACS 2023 5-year estimates (USCB, 2023), the total number of vacant housing units in the 50-mi. (80-km) region surrounding the NC-19 site is 105,442. The conservative estimate of the peak workforce discussed in Section 4.4.2.1 (2676) represents 2.5 percent of the unoccupied housing units in the region. Because a sizable percentage of the unoccupied housing units will remain available, it is unlikely that there will be a discernible change in housing availability or increase in housing costs. Therefore, the building-related housing impact in the 50-mi. (80-km) region is SMALL.

It is estimated in Section 5.4.2 that during operation, a staff of 818 full time Project-related personnel will be utilized once all units are operational. Approximately 0.8 percent of the available vacant housing in the NC-19 site Region of Interest is expected to be occupied by this increased population. Overall, sufficient housing is available within the Region of Interest to accommodate both operations-related workers and temporary short-term workers. Therefore, impacts on housing due to operation are SMALL.

9.3.2.2.5.4.4 Public Services

Public services include police, fire, and medical services; social services; water supply and wastewater treatment facilities; and recreation facilities. Impacts on public services could be caused by building and operation workers moving into the region surrounding the NC-19 site. This influx of workers could increase the demand for public services, potentially requiring local governments to add facilities, programs, and/or staff.

Per NUREG-1437, impacts on public services generally are considered to be SMALL if there is little or no need to add facilities, programs, and/or staff because of the influx of workers, and MODERATE or LARGE if additional facilities, programs, and/or staff are required.

As discussed in Section 9.3.2.2.5.2, the number of construction and operation workers estimated to move into Wake County and the 50-mi. (80-km) region is SMALL compared with the existing populations. Therefore, the building activities and operations related impacts on public services in Wake County and the 50-mi. (80-km) region are SMALL.

9.3.2.2.5.4.5 Education

The NC-19 site is located within the North Central District 3 Wake and Chatham Counties school districts. Wake County School District contains 199 schools, with 120 elementary schools, 38 middle schools, 31 high schools, seven alternative schools, and three K-8, 6-12 schools. The student-teacher ratio is 15 to 1. USCB ACS 5-year estimates from 2023 for Wake County indicate that an estimated 197,361 children from kindergarten to 12th grade are enrolled in school. Chatham County School District contains 20 schools, with one alternative school, one K-4 school, one K-5 school, five K-8 schools, three middle schools, and five high schools. The student-teacher ratio is 15 to 1. USCB ACS 5-year estimates for Chatham County indicate that an estimated 12,133 children from kindergarten to 12th grade are enrolled in school (USCB 2023).

As discussed in Section 4.4.4.4.4, 19 percent of the population in NC is between 5 to 19 years old (i.e., school age). Using this percentage and applying it to the total in-migrating population of

6636 persons, approximately 1261 persons are of school age. As in previous sections, it was assumed that most of the in-migrating workforce will migrate to Wake County. An increase of 1261 school-aged children in Wake County will be 0.6 percent of the current number of school aged children (197,361) enrolled in Wake County (USCB, 2023).

NUREG 1437 indicates that impacts to education are:

> SMALL – If Project related increase in school enrollment represents 3 percent or less of the total school enrollment in affected school systems,
>
> MODERATE – If Project related increase in school enrollment represents 4 to 8 percent of the total school enrollment in affected school systems, and
>
> LARGE – If Project related increase in school enrollment represents more than 8 percent of the total school enrollment in affected school systems.

The increase in school enrollment due to the Project is less than 3 percent of the total school enrollment, therefore education impacts from building activities are SMALL.

The number of operation workers is estimated to be smaller than the number of construction workers, so the amount of corresponding school-aged children will also be less. Therefore, the operation-related education impacts in Wake County are SMALL.

9.3.2.2.5.4.6 Summary of Community Infrastructure Impacts

Operation-related impacts on all infrastructure and community services are SMALL to MODERATE within Wake County and the 50-mi. (80-km) Region of Interest.

9.3.2.2.6 NOT USED

Deleted (Executive Order, 2025a, 2025b).

9.3.2.2.7 Historical and Cultural Resources

As defined by the NHPA of 1966, as amended (54 USC. §306108) and its implementing regulations 36 CFR 800.16(I)(1), historic properties are those properties deemed eligible for listing or that are already listed in the NRHP. Issuance of an early site permit is subject to review and consultation under Section 106 of the NHPA which requires the applicant to “take into account the effect of the undertaking on any historic property” and afford the Advisory Council on Historic Preservation “a reasonable opportunity to comment with regard to the undertaking.” This subsection provides an evaluation of the NC-19 site regarding potential impacts to historic and cultural resources.

There are no NRHP listed sites within the conceptual site boundary or within the immediate vicinity of the site. The closest NRHP listed site is the New Hill Historic District which is approximately 2.5-mi. (4-km) from the NC-19 site. No NRHP listed sites will be impacted by building the Project at the NC-19 site. There are 23 NRHP listed sites within a 10-mi. (16-km) radius of the site, six of which are historic districts.

Siting a nuclear plant at the NC-19 site will require a formal cultural resources survey be conducted so that no archaeological or historic resources will be damaged during plant building activities. Mitigative measures will be performed to prevent permanent damage and ensure that any impacts to cultural resources from building activities or operation at the NC-19 site are SMALL.

9.3.2.2.8 Air Quality

The CAA was enacted in 1970 to protect public health and welfare and authorizes the USEPA to set NAAQs for six common pollutants, called criteria pollutants. There are also provisions to regulate hazardous air pollutants, which are pollutants that are harmful to human health and/or the environment, as well as GHGs, primarily CO_2 (42 United States Code §7401 et seq).

The CAA requires the USEPA to set NAAQS for pollutants considered to be harmful to public health and the environment. Primary NAAQS provide public health protection including protecting the health of sensitive populations (asthmatics, children, elderly, etc.). Secondary NAAQS provide public welfare protection against decreased visibility and damage to animals, crops, vegetation, and buildings (USEPA, 2025a).

NC reached full attainment with all NAAQS across the entire state in 2015 (NCDEQ, 2024, USEPA, 2025c). The most recent pollutant to be redesignated was ozone. On July 28, 2015, the USEPA redesignated to attainment the NC-portion of the Charlotte-Rock Hill, NC-SC, nonattainment area for the 2008 8-hour ozone NAAQS, effective August 27, 2015.

The CAA defines Class I areas as national parks greater than 6000 ac. (2428 ha), wilderness areas greater than 5000 ac. (2023 ha), national memorial parks greater than 5000 ac. (2023 ha), and international parks that were in existence as of August 1977. These areas are potentially sensitive to visibility impairment. The USEPA states that a Class I visibility impact analysis is necessary for a major source within 62-mi. (100-km) of a Class I area (USEPA, 1990).

The USEPA promulgated the Regional Haze Rule to improve visibility in Class I areas in 1999 with the ultimate goal of restoring natural background visibility by 2064 (Federal Register Vol. 64, 1999). This rule was amended in 2005 to require certain industrial facilities to install emission controls to reduce emissions of air pollutants that reduce visibility (USEPA, 2025c; Federal Register Vol. 70, 2005). These pollutants include particulate matter with a diameter 2.5 microns or less ($PM_{2.5}$) and compounds that contribute to $PM_{2.5}$ formation, such as nitrogen oxides, sulfur dioxide, certain volatile organic compounds, and ammonia.

The closest Class I area to the NC-19 site is the Linville Gorge Wilderness Area, approximately 213-mi. (343-km) away. There are no Class I areas within 62-mi. (100-km) of the NC-19 site, therefore, no Class I areas are affected (USEPA, 2025b).

The NC-19 site is an attainment area for all criteria pollutants, similarly to the Belews Creek, NC site. These two sites are similar from an air quality perspective. Sections 4.7 and 5.7 indicated the impacts to Air Quality building activities and operation at the Belews Creek, NC site are SMALL. As such, the impacts of building activities on air quality are expected to be SMALL and temporary, and the impacts of facility operations on air quality are also expected to be SMALL for the NC-19 site.

9.3.2.2.9 Nonradiological Health

Nonradiological health impacts on the public and workers from building and operation activities at the NC-19 site are similar to those evaluated in Sections 4.8 and 5.8. They include the impacts of public and occupational health, the impacts of noise and vibration, and the impacts of transporting building materials and personnel to and from the Project site. Additional data required, based on applicable federal and state air quality and noise regulations, are provided during the building phase. The NC-19 site has characteristics that will require site-specific Health and Safety Plans for the building phases. Health impacts to workers from occupational injuries, noise, and electric fields are similar at the NC-19 site to those at the Belews Creek, NC

site. The NC-19 site does not have characteristics that are expected to lead to fewer, or more, operational accidents than those expected at the Belews Creek, NC site. Due to the implementation of BMPs and compliance with regulations and permit conditions, non-radiological health impacts from building activities and operation are expected to be SMALL for all categories.

9.3.2.2.10 Radiological Health

A detailed evaluation of radiological health impacts requires site specific information (e.g., meteorological data) that is not available for the NC-19 site. This site does have existing operating nuclear facilities, therefore, potential radiological exposures due to existing facilities are higher than for the Belews Creek, NC site and the NC-17 site. Human health impacts are also dependent on population density near the proposed facility. There is a high population density in the vicinity of the NC-19 site which increases the potential for health effects. Radiological health impacts for building activities and operation at the Belews Creek, NC site are discussed in Sections 4.9 and 5.9. Radiological health impacts are expected to be slightly higher at the NC-19 site than at the Belews Creek, NC site, but not significantly so. Generally, dose rates will be within allowable limits and consequences would be SMALL at the NC-19 site.

9.3.2.2.11 Nonradioactive Waste Management

The impacts on the environment that could result from the generation, handling, and disposal of nonradioactive waste and mixed waste during building activities and operations at the NC-19 site would be similar to those at the Belews Creek, NC site, which is described in further detail in Sections 4.10 and 5.10. Therefore, impacts to land, water, and air from nonradioactive waste generated, handled, stored, and disposed of during building activities and operations are SMALL.

9.3.2.2.12 Environmental Impacts of Postulated Accidents

The potential environmental impacts from a postulated accident, considering both DBAs and severe accidents, for the Belews Creek, NC site are described in Section 5.11. The DBAs and severe accidents analyzed to-date for the Belews Creek, NC site are applicable to the NC-19 site.

The NC-19 site is approximately 16-mi. (26-km) southwest of Raleigh, NC. The site is also approximately 15-mi. (24-km) northeast of Sanford, NC. Harris Lake is adjacent to the site. Within a 5-mi. (8-km) radius the land is mostly wooded and within a 50-mi. (80-km) radius the land is mostly used for agricultural production. Meteorological data recorded at the Raleigh-Durham International Airport (KRDU) shows area mean wind speeds are generally moderate with an average annual mean speed of 6.4 mph (10.3 kph) and meteorological characteristics include stable conditions (NOAA NCEI, 2022b).

It is unlikely that differences in local meteorological conditions are sufficient to cause doses from DBAs for multiple advanced reactors at the NC-19 site to exceed regulatory limits or guidelines or the impacts from a similar accident at the Belews Creek, NC site. Therefore, the impacts from postulated accidents at the NC-19 site are SMALL.

9.3.2.3 Evaluation of Cumulative Impacts for the NC-17 Site

The NRC regulations in 10 CFR Part 51 implementing NEPA of 1969, as amended (42 U.S. Code § 4321 et seq.), require that the NRC consider the cumulative impacts of proposals under its review (10 CFR 51.71(d)). Cumulative impacts may result when the environmental effects associated with the proposed action are overlaid or added to temporary or permanent effects associated with past, present, and reasonably foreseeable future actions (RFFAs).

Cumulative impacts are defined as “significant effects on the environment that result from the incremental effects of the action when added to the effects of other past, present, and RFFAs regardless of what agency (federal or non-federal) or person undertakes such other actions. Cumulative effects can result from actions with individually minor but collectively significant effects taking place over a period of time.”

The purpose of this subsection is to identify any past, present, and RFFAs within the geographic area of interest (GAI) of each resource that could have cumulative impacts in conjunction with the Proposed Action. Potential impacts will include substantial changes to any of the analyzed resources which will not occur if the Project is not constructed. Table 9.3-6 lists the projects within the GAI for the NC-17 site.

9.3.2.3.1 Land Use

The GAI for land use impacts encompasses the site, the vicinity, and extent of offsite areas. The projects listed on Table 9.3-6 that are within the GAI include the Roxboro Steam Station, the Person County Energy Complex, the Enbridge – T-15 Reliability Project, and the Person County Mega Park. The Multi Resolution Land Characteristics Consortium, National Landcover Database report for Person County indicates that from 1985 to 2023 there was a 31 percent change in land cover within the county. The biggest change in land cover is the loss of deciduous forest (MRLC, 2025). Prior to construction of the Roxboro Steam Station and the impoundment of the Hyco River to form Hyco Lake, the approximately 6095-ac. (2467-ha) parcel of land the existing Roxboro Steam Station is located on, was converted from primarily agricultural land, rural residential, and woodlands to industrial use. The Enbridge – T-15 Reliability Project will predominantly parallel existing rights-of-way, which will result in minimal impacts to existing land use. The Person County Mega Park will permanently disturb approximately 175 ac. (71 ha) of land. The land where the Person County Mega Park is planned to be constructed is currently forested with some areas of rangeland and was rezoned from rural conservation to general industrial. Given the permanent conversion of forested, agricultural, and rural land to industrial use from the construction and operation of past, present and RFFAs in the GAI, the environmental effects from cumulative land use are sufficient to alter noticeably, but not to destabilize, any important attributes of land use within the GAI. In summary, the cumulative impact of building and operating activities from the Project on land use, added to the effects associated with past, present, and RFFAs within the GAI on land use is noticeable but not destabilizing and therefore MODERATE. Because of extensive past and present modification of land use within the GAI, and the Project site’s proximity to the adjacent existing industrial Roxboro Steam Station, the impact of building the Project is a noticeable, but not a destabilizing contributor to the cumulative impact on land use.

9.3.2.3.2 Water Resources

The GAI for water resources encompasses a 50-mi. (80-km) radius surrounding the NC-17 site. Any past, present, and RFFAs within a 50-mi. (80-km) radius of the NC-17 site are subject to federal, state, and local laws and regulations, which will limit impacts to surface waters and wetlands. One stream, Powells Creek is listed as impaired within the After Bay Reservoir-Hyco

River watershed. Powells Creek is listed as impaired for recreation, due to the presence of E. coli. Additionally, a review of the NLCD report for Person County indicated that 1.3 percent of Person County is wetland, and 0.09 sq. mi. of wetlands were lost between 1985 and 2023. The Roxboro Steam Station currently uses Hyco Lake as a cooling reservoir, however four coal-fired units at the existing Roxboro Stream Station are proposed to be replaced with two hydrogen capable natural gas units by 2030 which will use less water than the coal-fired units. Peak water use at Hyco Lake will occur between 2028 and 2033, when the natural gas units will be operational before the coal-fired units are retired. If the Project is to be operational around this same time, additional strain will be placed on Hyco Lake. Mayo Reservoir is a reservoir formed from the impoundment of Mayo Creek, a tributary to the Hyco River. Mayo Reservoir functions as the cooling water source for the Mayo Plant. Neither Mayo Reservoir nor Hyco Lake are listed as impaired by the USEPA. The Moriah Energy Center will use groundwater for employee facilities; however, groundwater will not be used for plant processes or natural gas liquefaction. Groundwater use will be minimal at this facility. Potential adverse impacts associated with building activities of the past, present, and RFFAs listed in Table 9.3-8 include construction-related discharges. However, these will be managed in accordance with an approved SWPPP, National Pollutant Discharge Elimination System (NPDES) permits for stormwater discharges, and BMPs will be implemented during construction activities. The incremental contribution of pre-construction and construction activities on surface water quality will be minimal.

Overall, the environmental effects from cumulative impacts to hydrology from past, present, and RFFAs are sufficient to alter noticeably, but not to destabilize, any important attributes to hydrology within the GAI. The cumulative impacts to hydrology are SMALL to MODERATE.

9.3.2.2.3.3 Terrestrial Ecology

The GAI for terrestrial ecology is 6 mi. (10 km). Most of the projects in Table 9.3-8 are further than 6 mi. (10 km) and will not contribute to cumulative impacts. As stated in Section 9.3.2.3.1, the construction of Roxboro Stream Station converted approximately 6095 ac. (2467 ha) of agricultural land, rural residential land, and woodlands to industrial use. This conversion resulted in the decrease of habitat for terrestrial species that rely on woodland habitat. Most of the work for the Person County Energy Complex will take place in previously developed or disturbed areas. Disturbance to wildlife will generally be related to noise, and movement, which will be confined to the immediate vicinity of the project. A review of aerial photographs indicated that the CertainTeed Roxboro Wallboard facility converted approximately 38 ac. (15 ha) of rangeland and forested areas to industrial use. None of the previously mentioned projects will impact any critical habitat, and all are subject to the Endangered Species Act of 1973. Construction and operation of the Project at the NC-17 site will contribute incrementally to the conversion of forest to other land uses and the fragmentation of forest habitats that have already occurred and are likely to continue due to other development in the GAI. The impact of building and operation activities on terrestrial ecosystems and wetlands results in degradation of quality habitat that is persistent. Because of habitat loss on the NC-17 site and associated impacts with wildlife, the impact of the building and operation of the Project would be a noticeable contributor to the MODERATE cumulative impact on terrestrial ecology.

9.3.2.2.3.4 Aquatic Ecology

Similar to the Belews Creek, NC site, the cooling system used at the NC-17 site will be a closed-cycle recirculating cooling system, which is considered to be the best available technology to minimize impingement mortality and entrainment. The Roxboro Steam Station will retire four coal-fired boilers and replace them with two new natural gas-fired combined cycle turbines as part of the Person County Energy Complex project. All four units are planned to be retired by the mid-2030s. If the Project were to be built and operated at the NC-17 site, it will

obtain its makeup water from Hyco Lake, which supplies water to the Roxboro Steam Station. This will decrease the amount of water withdrawn from Hyco Lake, and subsequently decrease the amount of impingement mortality and entrainment. Closure of the Roxboro Steam Station may also result in cooler water temperatures within Hyco Lake that reflect a natural condition, similarly to the Belews Creek, NC site. The cooler lake temperatures may affect the timing of spawning and will result in a shorter growth season that is expected to result in decreased fish condition that may also affect sport fish abundance and condition. In summary, the cumulative impact of building and operating activities from the Project on aquatic ecology, added to effects associated with past, present, and RFFAs within the GAI on aquatic ecology is noticeable but not destabilizing for Hyco Lake and the NC-17 site. Overall cumulative impacts on aquatic ecosystems are MODERATE. The impact of building the Project is a noticeable but not destabilizing contributor to the cumulative impact on aquatic ecosystems; the impact of operation of the Project is a noticeable contributor to the cumulative impact on aquatic ecology.

9.3.2.3.5 Socioeconomics

9.3.2.3.5.1 Physical Impacts

This subsection provides an analysis of cumulative physical impacts associated with noise and vibration, odors, dust and air pollution, transportation, and aesthetics.

9.3.2.3.5.1.1 Noise and Vibration

Cumulative noise impacts may occur if several large projects are under construction at the same time in close proximity. Construction of the Person County Energy Complex may occur at the same time as construction of the Project at the NC-17 site. Noise and vibration impacts will be additive but with proper mitigation measures, will not be noticeable. Cumulative impacts related to noise and vibration are SMALL.

9.3.2.3.5.1.2 Odors, Dust, and Air Pollution

All past, present, and RFFAs, will implement BMPs to minimize temporary air and dust emissions during building activities. Additionally, building activities are subject to air permits under state and federal laws that address the impact of air emissions on sensitive receptors. Cumulative impacts related to odors, dust, and air pollution are SMALL for building activities and operation.

9.3.2.3.5.1.3 Transportation

Building activities and operation of the Project at the NC-17 site in addition to past, present, and RFFAs will result in an increased usage of Routes 1336 and 1322 and other roadways in the vicinity of the NC-17 site. Roadway repairs and improvements on Routes 1336 and 1322 and other roadways in the vicinity of the NC-17 site inadvertently affected by vehicles related to the Project, may be necessary to reduce safety risks and restore pavement conditions. Any damage to public roads, markings, or signs caused by building activities will be repaired to preexisting conditions or better in accordance with state and local requirements.

Therefore, cumulative physical impacts from building and operation activities on the transportation network in the vicinity of the NC-17 site are SMALL for building activities and operation.

9.3.2.3.5.1.4 Aesthetics

The GAI for visual resources includes the 2-mi. (3-km) radius surrounding the NC-17 site. Within the 2-mi. (3-km) GAI, are the existing Roxboro Steam Station and CertainTeed Roxboro Wallboard Facility. Construction and operation of the Project at the NC-17 site will align with the

industrial nature of the beforementioned sites, however, the surrounding 2-mi. (3-km) is largely rural and forested, and the visual change will be noticeable. Cumulative impacts to aesthetics are MODERATE.

9.3.2.3.5.1.5 Summary of Physical Impacts

The cumulative physical impacts from noise and vibration, odors, dust, and air pollution, and transportation from building and operations-related activities are SMALL. Cumulative physical impacts on aesthetic quality from building activities and operations are MODERATE.

9.3.2.3.5.2 Demographic Impacts

The Moriah Energy Center is expected to bring in 300 specialized construction jobs and 12 specialized operator jobs.

It is unknown how many workers will be needed for the construction and operation of the Microsoft facility at the Person County Mega Park and for the construction of the Enbridge – T-15 Reliability Project.

The MVP Southgate Project will result in 220 jobs in NC, including direct, indirect, and induced jobs, however, not all of the workers will reside in Person County, and the 50-mi. (80-km) vicinity.

Transco's Southeast Supply Enhancement Project will result in 3000 direct and indirect jobs and 1300 full-time equivalent construction jobs. However, because this project extends from VA to NC, it is not anticipated that the majority of workers needed for this project will reside in Person County and the 50-mi. (80-km) vicinity.

The cumulative demographic impact of building and operating activities from the Project, when considered alongside the effects of past, present, and RFFAs is SMALL. This is primarily due to the relatively large existing population in the vicinity of the NC-17 site and the comparatively small size of the Project's workforce during building and operation. As a result, the Project is a minor contributor to the SMALL cumulative impact on demography.

9.3.2.3.5.3 Economic Impacts to the Community

As discussed in Section 9.3.2.3.5.2, there are multiple RFFAs within the vicinity of the NC-17 site. The economic stimulus created by the Project will be added to the economic stimulus created by the other projects in the area, increasing business opportunities and revenues, creating new jobs, and reducing unemployment in the economic region.

Cumulative impacts to the economy are MODERATE and beneficial during building activities and operation.

9.3.2.3.5.3.1 Taxes

The Moriah Energy Center is expected to bring in $1,000,000 in local and state tax revenue.

It is unknown how much local and state tax revenue will be generated by the Microsoft facility at the Person County Mega Park and the Enbridge – T-15 Reliability Project.

The MVP Southgate Project is expected to bring in $2,000,000 in state and local taxes to NC during building and $328,000 during operation.

Transco's Southeast Supply Enhancement Project will result in $63,500,000 in state taxes and $9,600,000 in local taxes.

Cumulative tax impacts are MODERATE, and beneficial during building and operation.

9.3.2.3.5.3.2 Summary of Economic Impacts to the Community

The cumulative economic impacts to the community are MODERATE and beneficial during building and operation activities.

9.3.2.3.6 Community Infrastructure Impacts

This subsection provides the estimated cumulative impacts on infrastructure and community services, including transportation, recreation, housing, and public services.

9.3.2.3.6.1 Transportation

Congestion at U.S. Highway 501 on and off ramps and along NC Highway 119, and Routes 1336 and 1322 will increase due to the similar construction time frames of the Person County Energy Complex, Enbridge – T-15 Reliability Project, and the Person County Mega Park. Additionally, SR-1333 from the intersection with Edwin Robertson Road south for approximately 3800 ft. will be abandoned as part of the Person County Mega Park Project. This will increase traffic on Edwin Robertson Road. Cumulative impacts will be MODERATE during building activities and SMALL during operation.

9.3.2.3.6.2 Recreation

Cumulative impacts related to recreation will mainly occur as a result from past, present, and RFFAs on Hyco Lake. Because recreators of Hyco Lake are mobile, and the construction time frame is limited, cumulative impacts to recreation from building activities are SMALL. Operations related impacts will be smaller than that of building activities, as such, operations related cumulative impacts are SMALL.

9.3.2.3.6.3 Housing

There are the 68,036 vacant housing units within the 50-mi. (80-km) region surrounding the NC-17 site. As previously discussed in Section 9.3.2.3.5.2, an influx of workers related to the construction and operation of past, present, and RFFAs is expected. The majority of these workers are not anticipated to relocate permanently to Person County or the surrounding 50-mi. (80-km) vicinity. Therefore, the cumulative impacts to housing will be SMALL.

9.3.2.3.6.4 Public Services

The listed RFFAs create jobs and are likely to bring in-migrating workers to the vicinity of the NC-17 site. The scale of which varies from relatively minor to potentially large Projects. Urban centers such as Durham, Greensboro, and Raleigh already possess the infrastructure, housing, schools, healthcare, and other services needed to accommodate these population increases without significant strain. Cumulative impacts to public services are SMALL.

9.3.2.3.6.5 Education

As described in Section 9.3.2.4.5.2, there are many RFFAs that will increase the population, and subsequently the number of school-aged children in Person County and the surrounding 50-mi. (80-km) region. Economic region school enrollment will increase when these children are added. These students will increase the economic region's enrollment. In any event, NC's education equalization programs, will mitigate capacity issues and personnel shortages in schools and districts. Cumulative impacts to education are SMALL.

9.3.2.3.6.6 Summary of Community Infrastructure Impacts

Cumulative community infrastructure impacts at the NC-17 site range from SMALL to MODERATE for building and operation activities.

9.3.2.3.7 NOT USED

Deleted (Executive Order, 2025a, 2025b).

9.3.2.3.8 Historical and Cultural Resources

As discussed in Section 9.3.2.1.7 there are no NRHP sites within the NC-17 site boundary. The GAI is a 0.5-mi. (0.8-km) radius around the NC-17 site. There are no listed projects on Table 9.3-8 within the 0.5-mi. (0.8-km) radius. Additionally, all projects will have to comply with Section 106 of the NHPA and will avoid impacts to NRHP listed sites to the extent feasible. Cumulative impacts on historic and cultural resources are SMALL for building activities and operation.

9.3.2.3.9 Air Quality

The GAI for cumulative impacts to air quality is Person County. Past, present, and RFFAs within Person County were considered in the cumulative impacts analysis. As discussed in Section 9.3.2.1.8, Person County is in attainment for all NAAQS, indicating small impacts from past projects. Any present or RFFAs will be subject to permitting and will not be expected to contribute to the exceedance of a NAAQS. Additionally, Duke Energy plans to retire coal-fired boilers at the existing Roxboro Steam Station in Person County. These units will be replaced with new natural gas-fired turbines. The transition away from burning coal at this facility will reduce overall air emissions, particularly nitrogen oxides and sulfur dioxide (NCDEQ, 2025a). Emissions from other projects in Person County that are listed in Table 9.3-8, will comply with Title V and any non-Title V permitting requirements. Standard control measures will be used to mitigate fugitive dust releases. It is, therefore, anticipated that the cumulative impacts to air quality from building activities and operations of any past, present, and RFFAs within Person County will be SMALL.

9.3.2.3.10 Nonradiological Health

Building activities and operation of the Project will contribute to cumulative non-radiological human health impacts when combined with the other projects in Person County. Effects to workers at nearby industries will be managed through compliance with Occupational Safety and Health Administration standards and implementation of industry safety programs. Therefore, cumulative impacts due to physical effects and occupational injuries are SMALL. The increased traffic congestion could increase the potential for a vehicle crash. The combination of occupational and traffic injuries from the nuclear plant and the other projects along with the increase in population in Person County from the projects will put additional pressure on medical services in Person County. The generation of non-radiological waste is also expected to be similar to the non-radiological waste generated at the Belews Creek, NC site for both building activities and plant operations. Building activities and operation of the Project at the NC-17 site will contribute to cumulative non-radiological waste impacts when combined with the other projects identified in Person County. It is expected that each industrial facility identified in Table 9.3-8 will comply with applicable Federal, State, and local regulations to ensure proper disposal of non-radiological waste. Non-radiological waste impacts from liquid, gaseous, and solid wastes will be SMALL, and mitigation will not be warranted for releases during normal activities. The implementation of adequate training and management practices are also expected to minimize the potential for accidental releases and the environmental impact of accidental releases. Cumulative impacts to non-radiological health during building and operation are SMALL.

9.3.2.3.11 Radiological Health

For the analysis of cumulative radiological impacts for the NC-17 site (which is similar to the analysis for the Belews Creek, NC site), the GAI is considered to be the area that has the potential to increase radiological exposure at any location within a 50-mi. (80-km) radius of the plant. As described in Section 5.9, the NRC historically has used 50-mi. (80-km) as the radius bounding the geographic area for evaluating doses to the public from routine releases from nuclear power plants. There are no nuclear power plants within 50-mi. (80-km) of the NC-17 site. Therefore, the cumulative impacts to radiological health at any location within 50-mi. (80-km) of the NC-17 site during building activities and operation are anticipated to be SMALL.

9.3.2.3.12 Nonradiological Waste

All of the past, present, and RFFA projects listed in Table 9.3-8 have the potential to result in generation of nonradiological waste. As listed in Table 9.3.8, the Person County Energy Complex project is located immediately adjacent to the NC-17 site and therefore, has the potential to have localized direct or indirect effects that may affect the same resources as those affected by the NC-17 site. However, the deconstruction of all site structures, and the management and disposal of all solid and hazardous wastes within regional landfills for the Person County Energy Complex project will occur in accordance with Duke Energy's Environmental Programs and relevant guidelines and regulations.

Each of the past, present, and RFFA projects coupled with existing developments (industrial, commercial, recreational) have an impact on cumulative waste management within the GAI. The cumulative impacts of nonradioactive waste destined for land-based treatment and disposal are primarily related to amount of waste generated by the Project and other RFFAs and the available capacity of area treatment and disposal facilities. Similar to the Belews Creek, NC site, nonradiological waste generation is expected to be generally greater during building activities as compared to operation. However, the individual contribution of nonradioactive waste (both nonhazardous and hazardous) by the Project and other projects in Table 9.3-8 within the GAI is expected to be minor. Other landfills with long range capacity identified within the GAI include the following:

- Upper Piedmont Regional Landfill, 34.2 approximate total permitted years remaining as of fiscal year 2022-2023.
- Orange County CDLF, 22.0 approximate total permitted years remaining as of fiscal year 2022-2023.

Given the existing reported landfill capacity in the region and the scope of the RFFAs, construction and operation of these facilities are not expected to substantially contribute to the loss of waste disposal capacity in the GAI. Based on the availability and expected capacity of existing licensed disposal facilities within the GAI, the cumulative impact of building and operating activities from the Project at the NC-17 site on nonradiological waste, added to the effects associated with past, present, and RFFAs within the GAI on nonradiological waste, is SMALL. The impact of the building and operation of the Project is not a noticeable contributor to the cumulative impact on nonradioactive waste.

9.3.2.3.13 Postulated Accidents

The cumulative analysis for the NC-17 site considers DBAs and severe accidents at other existing and proposed nuclear facilities that have the potential to increase risks at any location within the GAI. The GAI for impacts is within a 50-mi. (80-km) radius of the NC-17 site. There are no nuclear facilities within 50-mi. (80-km) of the NC-17 site. Therefore, the cumulative risks

from postulated accidents at any location within 50-mi. (80-km) of the NC-17 site during operation are anticipated to be SMALL.

9.3.2.4 Evaluation of Cumulative Impacts for the NC-19 Site

The purpose of this subsection is to identify any past, present, and RFFAs within the GAI of each resource that could have cumulative impacts in conjunction with the Proposed Action. Potential impacts include substantial changes to any of the analyzed resources which will not occur if the Project is not constructed. Table 9.3-7 lists the projects within the GAI for the NC-19 site.

9.3.2.4.1 Land Use

The GAI for land use impacts encompasses the site, the vicinity, and extent of off-site areas. The projects listed on Table 9.3-7 that are within the GAI include the Shearon Harris Nuclear Plant, the Longleaf Solar Center, Brickhaven Mine #2, Merry Oaks Site #1, and McGill Environmental. There has been a 44 percent change in land cover in Wake County from 1985 to 2023, according to the MRLC NLCD. The largest changes in land cover have occurred to forested land and agricultural lands. Chatham County has experienced a 33 percent change in land cover, with the greatest changes occurring to forested and agricultural land (MRLC, 2025). The prior listed projects have and will convert land from rural, agricultural, or forested land use to other uses. In summary, the cumulative impact of building and operating activities from the Project on land use, added to the effects associated with past, present, and RFFAs within the GAI on land use is noticeable but not destabilizing and therefore MODERATE. Because of extensive past and present modification of land use within the GAI, and the Project site's proximity to the adjacent existing industrial Shearon Harris Nuclear Plant, the impact of building the Project is a noticeable, but not a destabilizing contributor to the cumulative impact on land use.

9.3.2.4.2 Water Resources

The GAI for hydrology encompasses a 50-mi. (80-km) radius surrounding the NC-19 site. Any past, present, and RFFAs within a 50-mi. (80-km) radius of the NC-19 site will be subject to federal, state, and local laws and regulations, which will limit impacts to surface waters and wetlands. No waters are listed as impaired within the White Oak Creek Watershed. However, the Cape Fear River from NC Highway 42 to Buckhorn Dam is listed as impaired for aquatic life due to the presence of Chlorophyll a. Additionally, a review of the MRLC report for Wake County indicated that 4.4 percent of the land cover in Wake County is wetlands and 1.13 sq. mi. of wetlands were lost between 1985 and 2023 (MRLC, 2025). 1.6 percent of the land cover in Chatham County is wetlands and 0.32 sq. mi. of wetlands were lost between 1985 and 2023 (MRLC,2025). The Shearon Harris Nuclear Plant currently uses Harris Lake as a cooling reservoir. Potential adverse impacts associated with building activities of the other past, present, and RFFAs listed in Table 9.3-9 include construction related discharges. However, these are managed in accordance with an approved SWPPP, NPDES permits for stormwater discharges, and implementing BMPs during building. The incremental contribution of prebuilding and building activities on surface water quality will be minimal.

Overall, the environmental effects from cumulative impacts to hydrology from past, present, and RFFAs are sufficient to alter noticeably, but not to destabilize, any important attributes to hydrology within the GAI. The cumulative impacts to hydrology during building activities are MODERATE. The cumulative impacts to hydrology from operation are less than that of building activities as the projects listed in Table 9.3-7 will not cause a noticeable impact to hydrology in the GAI. Cumulative impacts for operation are SMALL.

9.3.2.4.3 Terrestrial Ecology

The GAI for terrestrial ecology is 6 mi. (10 km). Most of the projects in Table 9.3-7 are further than 6 mi. (10 km) and will not contribute to cumulative impacts. As stated in Section 9.3.2.2.3, the construction of the Shearon Harris Nuclear Plant converted primarily agricultural land, rural residential, and woodlands to industrial use. This conversion resulted in the decrease of habitat for terrestrial species that rely on woodland habitat. Disturbance to wildlife from operation will generally be related to noise, and movement, which are confined to the immediate vicinity of the Shearon Harris Nuclear Plant. The Longleaf Solar Center will also convert forested land to an industrial use. None of the projects listed in Table 9.3-9 will impact any critical habitat, and all are subject to the Endangered Species Act of 1973. The construction and operation of the NC-19 site will contribute incrementally to the conversion of forest to other land uses and the fragmentation of forest habitats that have already occurred and are likely to continue due to other development in the GAI. Cumulative impacts on terrestrial ecology are sufficient to alter noticeably, but not to destabilize, any important attributes of the resource and will be MODERATE.

9.3.2.4.4 Aquatic Ecology

Similar to the Belews Creek, NC site, a closed-cycle recirculating cooling system will be used at the NC-19 site. Closed-cycle recirculating cooling is considered the best available technology to minimize impingement mortality and entrainment. If the Project were to be built and operated at the NC-19 site, it will obtain its makeup water from Harris Lake, which also supplies water to the Shearon Harris Nuclear Plant. This will increase the amount of water withdrawn from Harris Lake, and a pumping station will need to be constructed on the Cape Fear River to supplement the reservoir. In addition, raising the level of Harris Lake may disrupt the aquatic ecology of streams that would be inundated by this action. In summary, the cumulative impact of building and operating activities from the Project on aquatic ecology, added to effects associated with past, present, and RFFAs within the GAI on aquatic ecology is noticeable but not destabilizing for Harris Lake and the NC-19 site. Overall cumulative impacts on aquatic ecosystems are MODERATE. The impact of building the Project is a noticeable but not destabilizing contributor to the cumulative impact on aquatic ecosystems; the impact of operation of the Project is a noticeable contributor to the cumulative impact on aquatic ecology.

9.3.2.4.5 Socioeconomics

9.3.2.4.5.1 Physical Impacts

This subsection provides an analysis of cumulative physical impacts associated with noise and vibration, odors, dust and air pollution, transportation, and aesthetics.

9.3.2.4.5.1.1 Noise and Vibration

Cumulative noise impacts may occur if several large projects were under construction at the same time in close proximity. No projects listed in Table 9.3-9 that are in close proximity to the NC-19 site will be constructed during a similar time frame. Cumulative impacts related to noise and vibration are SMALL for building activities and operation.

9.3.2.4.5.1.2 Odors, Dust, and Air Pollution

All past, present, and RFFAs, will implement BMPs to minimize temporary air and dust emissions during building activities. Additionally, building activities are subject to air permits under state and federal laws that address the impact of air emissions on sensitive receptors. Cumulative impacts related to odors, dust, and air pollution are SMALL for building activities and operation.

9.3.2.4.5.1.3 Transportation

Construction and operation of the Project at the NC-19 site and past, present, and RFFAs will result in an increased usage of U.S. Highway 1 and other roadways in the vicinity of the NC-19 site. Roadway repairs and improvements on U.S. Highway 1 and other roadways in the vicinity of the NC-19 site inadvertently affected by vehicles related to the Project, may be necessary to reduce safety risks and restore pavement conditions. Any damage to public roads, markings, or signs caused by building activities will be repaired to preexisting conditions or better in accordance with state and local requirements.

Therefore, cumulative physical impacts from building and operation activities on the transportation network in the vicinity of the NC-19 site are SMALL.

9.3.2.4.5.1.4 Aesthetics

The GAI for visual resources includes the 2-mi. (3-km) radius surrounding the NC-19 site. Within the 2-mi. (3-km) GAI, is the Shearon Harris Nuclear Plant, Brickhaven Mine No. 2, Merry Oaks Site #1, and the McGill Environmental composting facility. Building activities and operation of a nuclear plant at the NC-19 site will align with the industrial nature of the beforementioned sites. Additionally, an existing nuclear power plant is already located adjacent to the NC-19 site, which will further community acceptance. However, the Project will convert previously rural and undeveloped land to industrial use, which will cause a noticeable change to aesthetics. Cumulative impacts to aesthetics are MODERATE for building activities and operation.

9.3.2.4.5.1.5 Summary of Physical Impacts

The cumulative physical impacts from noise, odors, dust, and air pollution, and transportation from building and operations-related activities are SMALL. Cumulative physical impacts on aesthetic quality from building activities and operations are MODERATE.

9.3.2.4.5.2 Demography

As Wake County contains a large population center, it is unlikely that any noticeable impacts related to an influx of workers related to past, present, and RFFAs will be seen in Wake and Chatham counties and the surrounding 50-mi. (80-km) vicinity. Cumulative impacts to demography are SMALL for building activities and operation.

9.3.2.4.5.3 Economic Impacts to the Community

The economic stimulus created by the Project will be added to the economic stimulus created by the other projects in the area, increasing business opportunities and revenues, creating new jobs, and reducing unemployment in the economic region. As the surrounding 50-mi. (80-km) area to the NC-19 site already has a thriving economy associated with the nearby city of Raleigh, a noticeable impact to the economy is not anticipated for past, present and RFFAs. Cumulative impacts to the economy are SMALL and beneficial for building activities and operation.

9.3.2.4.5.3.1 Taxes

The NC-19 site property tax payment impacts for building activities and operation are anticipated to be MODERATE and beneficial and will be combined with the other project property taxes that will be paid in Wake and Chatham Counties. The cumulative impacts are also anticipated to be MODERATE and beneficial for Wake and Chatham Counties property taxing authorities.

9.3.2.4.5.3.2 Summary of Economic Impacts to the Community

The cumulative economic impacts to the community are SMALL to MODERATE and beneficial during building and operation activities.

9.3.2.4.5.4 Community Infrastructure Impacts

This subsection provides the estimated cumulative impacts on infrastructure and community services, including transportation, recreation, housing, and public services.

9.3.2.4.5.4.1 Transportation

Temporary increased traffic volumes on U.S. Highway 1 may result from building activities. Traffic congestion will increase from the combined workforces of the Shearon Harris Nuclear Plant and building activities at the NC-19 site and at the Longleaf Solar Center, which is also located off of U.S. Highway 1. During building, approximately 175 vehicles are anticipated to access the Longleaf Solar Center using U.S. Highway 1. At peak construction, the Project will employ approximately 150 workers. This will increase the number of vehicular traffic on U.S. Highway 1 by 325. As discussed in Section 9.3.2.2.5.4.1, the average daily traffic volume for all lanes in both directions on U.S. Highway 1 is 36,000 vehicles The increase in vehicles at peak construction is 0.9 percent of the average daily traffic volume. As a major highway, U.S. Highway 1 is more readily available to accommodate this influx in traffic. Cumulative impacts to transportation are SMALL.

9.3.2.4.5.4.2 Recreation

Cumulative impacts related to recreation will mainly occur as a result from past, present, and RFFAs on Harris Lake. Because recreators of Harris Lake are mobile, and the construction time frame is limited, cumulative impacts to recreation from building activities are SMALL. Operations related impacts are smaller than that of building activities, as such, operations-related cumulative impacts are SMALL.

9.3.2.4.5.4.3 Housing

Wake County has more available housing than Chatham County with 25,539 vacant and available housing units, including permanent and temporary housing, in the economic region. This level of vacant and available housing is sufficient to accommodate workers from the cumulative projects. Therefore, the cumulative impacts to housing and land use patterns in the economic region are SMALL for building activities and operation.

9.3.2.4.5.4.4 Public Services

The increased population is not anticipated to cause additional pressure on community services and infrastructure, as the increase in population will be a small percentage of the existing population. Water and wastewater resources in the economic region are anticipated to be sufficient to accommodate the cumulative in-migrating workforce populations. Same as for cumulative adverse impacts to police, fire, and medical services. Cumulative impacts to public services are SMALL during building activities and operation.

9.3.2.4.5.4.5 Education

Cumulative in-migration associated with the Project will not increase the number of school-age children by a substantial percentage. Wake County enrollment is 197,361 and Chatham County enrollment is 12,133 (USCB, 2023). As a county with a large population, Wake County has the capacity to mitigate any personnel shortages in schools and districts. Cumulative impacts to education are SMALL for building activities and operation.

9.3.2.4.5.4.6 Summary of Community Infrastructure Impacts

Cumulative community infrastructure impacts at the NC-19 site are SMALL for building and operation activities.

9.3.2.4.6 NOT USED

Deleted (Executive Order, 2025a, 2025b).

9.3.2.4.7 Historical and Cultural Resources

As discussed in Section 9.3.2.2.7 there are no NRHP sites within the NC-19 site boundary. The GAI is a 0.5-mi. (0.8-km) radius around the NC-19 site. The existing Shearon Harris Nuclear Plant is within the 0.5-mi. (0.8-km) radius. A review of the NC Natural Heritage Program Data Explorer did not indicate that any NRHP sites or surveyed sites have been removed previously from the Shearon Harris Nuclear Plant site boundary. Additionally, all projects will have to comply with Section 106 of the NHPA and will avoid impacts to NRHP listed sites to the extent feasible. Cumulative impacts on cultural resources are judged to be SMALL during building activities and operation.

9.3.2.4.8 Air Quality

The GAI for cumulative impacts to air quality are Wake and Chatham Counties. Past, present, and RFFAs within Wake and Chatham Counties were considered in the cumulative impacts analysis. As discussed in Section 9.3.2.2.8, all counties in NC are in attainment for all NAAQS, indicating small impacts from past projects. Any present or RFFAs are subject to permitting and will not be expected to contribute to the exceedance of a NAAQS. Emissions from other projects in Wake and Chatham Counties that are listed in Table 9.3-9, will comply with Title V and any non-Title V permitting requirements. Standard control measures will be used to mitigate fugitive dust releases. It is, therefore, anticipated that the cumulative impacts to air quality from building activities and operation of any past, present, and RFFAs within Wake and Chatham Counties are SMALL.

9.3.2.4.9 Nonradiological Health

Building activities and operation of the Project will contribute to cumulative non-radiological human health impacts when combined with the other projects in Wake and Chatham counties. Non-radiological health impacts will be managed through compliance with applicable U.S. Occupational Safety and Health Administration (OSHA) standards and implementation of industry safety programs. Therefore, cumulative impacts due to physical effects and occupational injuries will be SMALL. Increase traffic congestion from the Project and other RFFAs will increase the potential for a vehicle crash. The combination of occupational and traffic injuries from the nuclear plant and the other projects along with the increase in population in Wake and Chatham Counties from the projects will put additional pressure on medical services in the counties; however, given the existing infrastructure within the counties, cumulative impacts will be expected to be SMALL.

The generation of non-radiological waste is also expected to be similar to the non-radiological waste generated at the Belews Creek, NC site for both building activities and plant operations. Building activities and operation of the Project at the NC-19 site will contribute to cumulative nonradiological waste impacts when combined with the other projects identified in Wake and Chatham Counties. It is expected that each industrial facility in the surrounding area identified in Table 9.3-9 will comply with applicable federal, state, and local regulations to ensure proper disposal of non-radiological waste. Non-radiological waste impacts from liquid, gaseous, and solid wastes will be SMALL, and mitigation will not be warranted for releases during normal

activities. The implementation of adequate training and management practices are also expected to minimize the potential for accidental releases and the environmental impact of accidental releases. Cumulative impacts to non-radiological health are SMALL during building activities and operation.

9.3.2.4.10 Radiological Health

A detailed evaluation of radiological health impacts requires site specific information (e.g., meteorological data) that is not available for the NC-19 site. This site does have existing operating nuclear facilities, therefore, potential radiological exposures due to existing facilities will be higher than for the Belews Creek, NC site and the NC-17 site. Human health impacts are also dependent on population density near the proposed facility. There is a high population density in the vicinity of the NC-19 site which increases the potential for health effects. Radiological health impacts for the building and operation of the Belews Creek, NC site are discussed in Sections 4.9 and 5.9. As site specific information is not available for the NC-19 site it was assumed that radiological health impacts will be slightly higher than that of the Belews Creek, NC site, due to the previous discussion, but not significantly so. As such, cumulative human health impacts from radiological exposures during building and operation at the NC-19 site are expected to be SMALL.

9.3.2.4.11 Nonradiological Waste

Each of the past, present, and RFFA projects coupled with existing developments (industrial, commercial, recreational) have an impact on cumulative waste management within the GAI. The cumulative impacts of nonradioactive waste destined for land-based treatment and disposal are primarily related to amount of waste generated by the Project and other RFFAs and the available capacity of area treatment and disposal facilities. Similar to the Belews Creek, NC site, nonradiological waste generation is expected to be generally greater during building activities as compared to operation. However, the individual contribution of nonradioactive waste (both nonhazardous and hazardous) by the Project and other projects in Table 9.3-9 within the GAI is expected to be minor. Other landfills with long range capacity identified within the GAI include the following:

- Shotwell Landfill, Inc, 33.5 approximate total permitted years remaining as of fiscal year 2022-2023.
- Red Rock Disposal C&D Landfill, 51.2 approximate total permitted years remaining as of fiscal year 2022-2023.
- Greenway Waste Solutions of Apex, LLC, 51.2 approximate total permitted years remaining as of fiscal year 2022-2023.

Given the existing reported landfill capacity in the region and the scope of the RFFAs, construction and operation of these facilities are not expected to substantially contribute to the loss of waste disposal capacity in the GAI. Based on the availability and expected capacity of existing licensed disposal facilities within the GAI, the cumulative impact of building and operating activities from the Project at the NC-19 site on nonradiological waste, added to the effects associated with past, present, and RFFAs within the GAI on nonradiological waste, is SMALL. The impact of the building and operation of the Project is not a noticeable contributor to the cumulative impact on nonradioactive waste.

9.3.2.4.12 Postulated Accidents

The cumulative analysis for the NC-19 site considers DBAs and severe accidents at other existing and proposed nuclear facilities that have the potential to increase risks at any location within the GAI. The GAI for cumulative impacts is within a 50-mi. (80-km) radius of the NC-19 site. Located adjacent to the NC-19 site is the existing Shearon Harris Nuclear Plant. Potential postulated accidents at this facility have been evaluated, most recently as part of a 2008 license renewal, and a combined license application (COLA). The NRC specifically evaluated the Shearon Harris Nuclear Plant for severe accident impacts for license renewal considerations and concluded that the environmental impacts were of SMALL significance. The consequences could be severe, but because of their low likelihood of occurrence, the risk impact is classified as SMALL significance. Specifically, the following conclusions are found to remain valid for an advanced reactor design (i.e., AP1000) located at the Shearon Harris Nuclear Plant:

- The Shearon Harris plant risks for the atmospheric exposure pathway will be within the range of those considered as SMALL significance in Supplement 33 of NUREG-1437.
- The consequences of atmospheric fallout onto open bodies of water are of SMALL significance for the Shearon Harris Nuclear Plant.
- The consequences of releases to groundwater are of SMALL significance for the Shearon Harris Nuclear Plant.

The Shearon Harris Nuclear Plant site-specific MACCS2 analysis of severe accidents for the AP1000 reactor design shows that the 50-mi. (80-km) population dose risk of 2.20E-03 person-Sv/yr. (2.20E-01 person-rem/yr.) is significantly lower than that for current reactor designs and is less than 1 percent of that associated with the current Shearon Harris Nuclear Plant.

Therefore, the cumulative risks from postulated accidents at any location within 50-mi. (80-km) of the NC-19 site are anticipated to be SMALL during operation.

9.3.3 CONCLUSION

The Belews Creek, NC site was selected on the basis of a comprehensive site selection study, as described in Section 9.3.1. The numerical scores for the Candidate Sites and other objective evaluations indicate that, while multiple sites are suited for the construction of a new nuclear power plant, there are no other environmentally preferrable alternatives to the Belews Creek, NC site. A separate assessment of the environmental impacts for two potentially feasible Alternative Sites, as described in Section 9.3.2, determined that the Proposed and Alternative Sites are all suited for the construction of a new nuclear power plant. As indicated by Tables 9.3-8 and 9.3-9, there is not a substantive difference in impacts from the Proposed and Alternative Sites to indicate that any of the Alternative Sites are environmentally preferable and obviously superior to the Belews Creek, NC site.

Table 9.3-1
Candidate Site Criteria and Weight Factors
(Sheet 1 of 2)

Criteria	Sub-Criteria	Sub-Sub-Criteria	Weight Factor
Health and Safety Criteria	Accident Cause-Related	Geology/Seismology	9.15

Table 9.3-6
Past, Present, and RFFAs Considered in the Cumulative Analysis of the NC-17 Site
(Sheet 1 of 2)

Project Name	Description	Approximate Distance from the Site	Status
Other Energy Projects			
Roxboro Plant	A four-unit, 2462-MW coal-fired power plant. Expected to retire in 2033.	4 mi. (6 km) W	Past, present, and RFFA. This power plant began operation in 1966, with additions in 1973 and 1980. (Duke Energy, 2025a)
Mayo Plant	A single-unit, 713-MW coal-fired power plant.	7 mi. (11 km) NE	Past, present, and RFFA. Operational as of 1983. (Duke Energy, 2025b)
Woodsdale Solar Farm	3-MW capacity solar farm.	9 mi. (14 km) SE	Past, present, and RFFA. Operational as of 2018. (Monarch Private Capital, 2025)
Natural Gas Projects			
Enbridge – T-15 Reliability Project	A proposed 45-mi. (72 km) natural gas pipeline along mostly existing rights-of-way from Eden to Roxboro.	4 mi. (6 km) W	RFFA. Proposed to begin building in 2025, with the majority of building taking place in 2026 (Enbridge, 2025b)
MVP Southgate	A proposed 30-in. diameter underground pipe that will span approximately 31 mi. (50 km) to deliver natural gas into Rockingham County, NC.	42 mi. (68 km) SW	RFFA. Target in-service date of mid-2028 (MVP Southgate, 2025).
Transco's Southeast Supply Enhancement Project	A proposed approximately 55-mi. (89-km) pipeline from Virgina to NC. The NC scope of work would include a total of 28 mi. (45 km) of pipeline looping adjacent to existing Transco corridors located in Rockingham, Guilford, Forsyth, and Davidson Counties and additional compressor units in Cleveland, Iredell, and Davidson Counties.	46 mi. (74 km) SW	RFFA. Target building start date of fall 2026, target in service date of the end of 2027 (Williams, 2025).

Table 9.3-6
Past, Present, and RFFAs Considered in the Cumulative Analysis of the NC-17 Site
(Sheet 2 of 2)

Project Name	Description	Approximate Distance from the Site	Status
Person County Energy Complex	The replacement of four coal-fired units at the existing Roxboro Steam Station with two hydrogen-capable natural gas units.	4 mi. (6 km) W	RFFA. The units will enter service by 2028 and 2030. (Duke Energy. 2024)
Moriah Energy Center	A proposed 25-million-gallon Liquified Natural Gas storage facility.	22 mi. (35 km) SE	Present and RFFA. Building began in early 2024. The facility will enter service by 2027. (Enbridge, 2025a)
Transportation Projects			
Raleigh Regional Airport	Public airport in Person County.	15 mi. (24 km) S	Past, present, and RFFA. Operational as of 1987. (AirNav, 2025a)
Other Actions/ Projects			
Person County Mega Park	A 1350-ac. (546 ha) Mega Park, acquired by Microsoft. The plans for development are not yet known.	6 mi. (10 km) SE	RFFA. Proposed. (Person County, 2025b)
CertainTeed Roxboro Wallboard Facility	Gypsum manufacturing plant.	3 mi. (5 km) SW	Past, present, and RFFA. Operational as of 2012. (Person County, 2025c)

Table 9.3-7
Past, Present, and RFFAs Considered in the Cumulative Analysis of the NC-19 Site
(Sheet 1 of 2)

Project Name	Description	Approximate Distance from the Site	Status
Nuclear Projects			
Shearon Harris Nuclear Plant	A single-unit, 928-MW nuclear power plant located near New Hill, N.C.	Adjacent to the NC-19 site	Past, present, and RFFA. Operational as of 1987. (Duke Energy, 2025c)
Other Energy Projects			
Jordan Hydroelectric Project	Hydroelectric plant with two hydroelectric generators; combined, the generating modules produce about 16,900 MW annually.	7 mi. (11 km) NW	Past, present, and RFFA. Operational as of January 2012. (USACE, 2025).
Siler Solar	4.5-MW, 30-ac. (12-ha) solar facility in Chatham County, NC.	40 mi. (64 km) NW	Past, present, and RFFA. Operational as of December 2018. (Global Energy Monitor, 2025)
Longleaf Solar Center	Proposed 100-MW facility with 215,000 fixed-tilt solar panels.	4 mi. (6 km) E	RFFA. Building to begin 2026-2027. Project completion estimated in 2028. (Duke Energy, 2025d)
Transmission Projects			
Pittsboro Hanks Chapel 230 kV Substation	Grid improvement project to add a new substation and power line.	12 mi. (19 km) NW	Present and RFFA. Project building end date of October 2024. (Duke Energy, 2025e)
Lee-Milburnie Transmission line rebuild.	Project to upgrade and rebuild 40 mi. (64 km) of the existing Lee-Milburnie 230-kV transmission line.	24 mi. (39 km) NE	RFFA. Planned in-service date of 2031. (Center for Climate and Energy Solutions, 2025)
Mining Projects			
Brickhaven Mine No. 2 (Cherokee Sanford Group)	Former clay mine, that now functions as a coal ash landfill in Chatham County.	2 mi. (3 km) SW	Past, present, and RFFA. Functioning as a coal ash landfill since 2015. (NCDEQ, 2025b)

Table 9.3-7
Past, Present, and RFFAs Considered in the Cumulative Analysis of the NC-19 Site
(Sheet 2 of 2)

Project Name	Description	Approximate Distance from the Site	Status
Holly Springs Quarry (Heidelberg Materials, Aggregates)	Quarry in Wake County.	5-mi. (8-km) SE	Past, present, and RFFA. Unknown. (NCDEQ, 2025b)
Merry Oaks Site #1 (Triangle Brick Company)	Brick plant in Chatham County, with an annual capacity of 50 million bricks.	2-mi. (3-km) NW	Past, present, and RFFA. Operational as of 1991. (NCDEQ, 2025b)
Transportation Projects			
KRDU	International airport in Wake County, NC that spans across approximately 4800 ac. (1942 ha) of land.	20-mi. (32-km) NE	Past, present, and RFFA. Operational as of 1943. (AirNav, 2025b)
Sanford-Lee County Regional Airport	Public airport in Lee County, NC that spans across approximately 1250 ac. (506 ha) of land.	8-mi. (13-km) SW	Past, present, and RFFA. Operational as of 1999. (AirNav, 2025c)
Southern Wake Regional Airport	Public airport in Wake County, NC.	15-mi. (24-km) SE	Past, present, and RFFA. Operational as of 1975. (AirNav, 2025d)
Other Actions/ Projects			
MetOx International Inc. Production Facility	A proposed high-temperature superconducting wire major production facility in Chatham County, NC.	Unknown	RFFA. Building scheduled to begin in 2025. (MetOx, 2025)
Fred Smith Company - Holly Springs Plant	Asphalt mixing plant.	6-mi. (10-km) SE	Past, present, and RFFA. Unknown (Fred Smith Company, 2025)
Cape Fear Power Station	Retired coal-fired facility with five ash ponds, located in Moncure, NC.	4-mi. (6-km) SW	Past. Began operation in 1923, the last units retired began operating in 1956 and 1958. Retired in 2012. (Duke Energy, 2015)
McGill Environmental	Composting facility in Chatham County.	2-mi. (3-km) NW	Past, Present, and RFFA. Operational as of 2002. (McGill, 2025)

9.4 SYSTEM ALTERNATIVES

This section discusses system design alternatives for the heat-dissipation and circulating-water systems for the proposed Project site. This information is provided to enable a comparison of the environmental impacts of the proposed system to that of the select alternatives. Because a final reactor selection has not been made, a plant parameter envelope (PPE) approach to defining the various plant systems has been utilized. The cooling technology that is used in developing the PPE is mechanical draft cooling towers (MDCT). The proposed heat dissipation and circulating water systems for the new facility were initially presented in Chapter 3. Section 9.4.1 presents alternatives to the facility heat dissipation system, and Section 9.4.2 presents alternatives to the circulating water system. The evaluation of alternatives to plant systems is applicable to all technologies that were considered in the PPE.

9.4.1 HEAT DISSIPATION

There are multiple heat dissipation system alternatives, each having varying energy transfer mechanisms and, therefore, varying potential environmental impacts. This subsection utilizes the methodology presented in NUREG-1555 to perform an initial screening and eliminate technologies that are unsuitable for the Project site. Following the initial screening any remaining alternatives are reviewed to determine if they are environmentally preferable, equivalent, or inferior to the proposed heat dissipation system. The following subsections describe the proposed heat dissipation system and evaluate comparable alternatives.

9.4.1.1 Proposed Heat Dissipation System

The purpose of a heat dissipation system is to dissipate heat energy to the environment. To meet cooling requirements of the proposed advanced reactor units at the Project site and at the same time to provide environmental protection for the waters of Belews Lake, a closed system consisting of MDCT was selected as the preferred primary method of heat dissipation.

In this closed-loop tower system, the main circulating water pumps circulate water through the condenser, where waste heat is transferred from the turbine exhaust to the circulating water system and to the towers where the heat is transferred to the air. Air flow through the cooling tower is assisted by large fans. Water returning from the towers flows back to the circulating water pumps. Makeup is provided from Belews Lake to the circulating water system to account for water loss through evaporation, drift, and blowdown, as well as other miscellaneous plant systems. Blowdown flow is returned to Belews Lake through the Belews Lake discharge or sent to the Dan River based on operational determinations. Potential atmospheric effects from the operation of MDCT would include fogging and/or icing, as well as deposition or particulate matter (PM) release in the cooling tower plume.

9.4.1.2 Screening Alternatives to the Proposed Heat Dissipation System

The various heat dissipation system alternatives can be classified as one of two types of systems: once-through cooling system or closed-cycle cooling system. The following classes of heat dissipation systems were considered based on the recommendation of NUREG-1555:

- Once-through systems
- Closed-cycle systems
  - Natural draft cooling towers
  - Dry cooling towers
  - Wet-dry cooling towers (hybrid towers)

- Cooling ponds
- Spray ponds

In the following subsections, these alternative systems are evaluated for use at the Project site. Because all of these alternatives were either not feasible or environmentally desirable, detailed costs, operation and maintenance comparisons are not provided.

Belews Lake is a closed cooling water system supporting Belews Creek Steam Station (BCSS) operation. Duke Energy Carolinas, LLC intends to maintain that designation for future generation at the Project site. There are no planned alterations or increases in permitted capacity to the Makeup Water Intake Structure (MWIS) to support advanced nuclear being classified as new generation at an existing site.

9.4.1.2.1 Once-Through Cooling Systems

Once-through cooling systems involve the use of a large quantity of water which is withdrawn from a nearby water body, circulated through the condenser to absorb heat, and then discharged back into a water body. The water requirements for a once-through system are approximately 25,000 to 60,000 gallons of water per megawatt hour (MWh) of electricity produced (Macknick, 2012). Comparatively, the water used by the proposed closed-cycle cooling system is a maximum 43,131 gpm or approximately 1300 gallons/MWh, which is significantly less than once-through cooling.

Once-through cooling in support of nuclear development at the Project site is not viable since the CWA Section 316(b) compliance point is the Dan River and the MWIS that provides makeup water to the Belews Lake. This point does not have the capacity, nor the permitting allowed to support once-through cooling technology for the nuclear development. Therefore, once-through cooling technology is not a viable solution to heat dissipation and was eliminated from further consideration.

9.4.1.2.2 Closed-Cycle Cooling Systems

Closed-cycle cooling systems utilize much less water than once-through cooling systems, using only 500 to 13,000 gallons per MWh (Macknick, 2012). The water performing the cooling is recirculated through the main condenser, and the only additional water required is makeup water to account for expected system losses such as evaporation, blowdown, and drift. Examples of closed-cycle cooling systems include cooling towers (wet, dry, and wet-dry hybrid), cooling ponds, and spray ponds.

The following subsections describe the alternative closed-cycle cooling systems considered. Duke Energy conducted a feasibility study on different closed-cycle cooling technologies, from conventional wet-type to various hybrid type (mixture of dry and wet type) cooling towers. The focus of the study was on water savings capabilities within the confines of the site footprint and comparing cost estimation with each level of water savings. Various alternatives are discussed below.

9.4.1.2.3 Natural Draft Cooling Towers

Natural draft towers are essentially large chimneys designed to move air up through the structure by convection without the use of fans. As hot water is pumped into a natural draft cooling tower, it is distributed through packing or fill material inside the tower. The fill material provides an interface for evaporation of the water and heating of the air to take place. As the water is being distributed, the exposed, lower portion of the tower allows ambient air to pass over the cold-water basin at the bottom of the tower. This passing of ambient air over the cold-

water basin at the bottom of the tower and the evaporation/air heating taking place at the top of the tower create a temperature and density differential which results in a natural draft as less dense warmer air rises to the top. As this differential is being produced, the hyperbolic shape of the cooling tower itself facilitates the upward flow of air.

Natural draft cooling towers have very high construction costs but low operating costs, low auxiliary power requirements, and low noise impacts because there is no mechanical equipment needed to move the air. Therefore, they can be very practical and cost-effective for locations with access to very large water volumes where consistent cooling is required over an extended time period. Potential environmental impacts resulting from the operation of natural draft cooling towers include cloud development and plume shadowing. Ground level fogging and icing are generally not a problem with larger natural draft cooling towers.

Because Belews Lake provides an adequate water source, a natural draft cooling tower could be appropriate for consideration at the Project site. However, natural draft cooling towers require tall stacks to generate the airflow necessary for cooling. Natural draft towers are typically higher than 500 ft. tall and mechanical draft towers are typically 100 ft. tall (NRC, 2024). Due to the increased visual impact and the comparatively high construction cost, a natural draft tower is not preferable to a MDCT.

9.4.1.2.4 Dry Cooling Towers

Dry cooling towers utilize conduction and/or convection to dissipate heat to the atmosphere. The condenser coolant is enclosed within a piping network that has no direct air-to-water interface. The heat transfer process is based on the thermal transport properties of the piping material and the dry bulb temperature of the air. Either natural or mechanical draft techniques can be used to move the air. Because there are no evaporative or drift losses in this type of system, water loss for dry cooling towers is lower than for wet cooling towers, but some makeup water is required. Additionally, many of the problems associated with wet cooling systems, such as blowdown disposal, water availability, fogging and/or icing, are not applicable. Dry towers do have inherent technical obstacles, such as high turbine backpressure and possible freezing in cooling coils during periods of light load and startup.

Dry cooling technologies also have disadvantages related to reduced plant efficiency and lower power output, increased consumptive power use for fans, and increased footprint for the site layout. Boiling water reactor technology requires an indirect dry cooling design which further reduces efficiency. Given the limited areas available for a plant, the location of dry cooling towers within the existing site boundary would be challenging and require significant distance between the turbine building and the dry cooling towers. This would result in longer lengths of piping for turbine exhaust steam and higher turbine backpressure due to pressure loss in the exhaust lines. Dry cooling increases the overall cost by approximately three times compared to mechanical draft cooling towers and would result in the production of less power in a less reliable manner. This is consistent with evaluation by the USEPA that dry cooling was not the best available technology for minimizing adverse environmental impacts based on high capital, operating, and maintenance costs for dry cooling, the detrimental effects of dry cooling causes on electricity production, and no significant reduction in impingement and entrainment beyond the regulatory approach selected to offset these drawbacks (USEPA, 2001a). As a result, dry cooling is not considered a feasible alternative cooling solution.

9.4.1.2.5 Wet / Dry Cooling Towers (Hybrid Towers)

A wet/dry cooling tower, also referred to as a hybrid cooling tower, is composed of a wet section and a dry section. Consumptive water use for the hybrid wet/dry cooling alternative is bounded by the water use of the wet section.

Compared to full wet cooling towers, hybrid cooling towers reduce water-related impacts with less evaporation, makeup water, and blowdown while also reducing the visible plume associated with wet cooling towers. The advantages of the hybrid system are that it conserves water where water is limited and/or expensive.

The hybrid tower generally functions as a wet cooling tower, but has a dry section installed in the upper part of the tower. This upper section heats wet air coming from the lower wet zone, thereby reducing or eliminating the visible water vapor plumes typically associated with wet cooling towers. Thus, the additional heat transfer in the dry section reduces the heat transfer required in the wet section which reduces the overall evaporative loss and results in a variable degree of water consumption reduction.

In a hybrid cooling tower, fans may be located in the wet section as well as the dry section of the tower and may incorporate a hyperbolic shell which produces a natural draft effect that reduces power consumption. Water consumption for a hybrid tower is based on the water use of the wet section, which for the Project site results in a maximum water savings range of approximately 10-20 percent based on available construction space for hybrid towers. This design has a higher capital cost when compared to wet-type towers, although less capital cost when compared to dry cooling towers.

With hybrid towers, water use is inversely related to cost and power consumption (along with footprint). The cost increase for the hybrid systems versus the wet cooling systems does not overcome water use savings (USEPA, 2001b). The dry cooling portion of the hybrid tower is not as efficient as the wet cooling process because it requires the movement of a large amount of air through the heat exchangers to achieve the necessary cooling. This results in less net electrical power for distribution. Because water availability is not a primary issue at the Project site, a hybrid cooling tower is not a preferred heat dissipation technology for use at this site due to the increased cost for the level of water savings achieved.

9.4.1.2.6 Cooling Ponds

A cooling pond is a shallow reservoir with a large surface area used for removing heat from process water. Cooling ponds can be used to reduce the heat load to natural bodies of water from power plant discharge without the construction and operation costs associated with cooling towers. The natural body of water is not relied on for heat dissipation but is used as a source of makeup water to replace water lost to evaporation and as a receiving stream for blowdown from the cooling pond.

A cooling pond is typically used at locations where land is relatively inexpensive, cooling water is scarce or expensive, and/or where there are strict thermal loading restrictions. Impacts resulting from the discharge of heated water into a cooling pond include thermal impacts such as altered stratification and atmospheric impacts such as steam fogging and/or icing. Once cooled, water in the cooling pond can be reused, thereby reducing the overall quantity of water utilized.

While Belews Lake was originally constructed as a cooling water system to support the BCSS, Belews Lake currently supports many recreational activities, including fishing, boating, etc. In order to reduce heat transferred to the aquatic ecosystem and reduce intake flow velocity and

fish entrainment, direct cooling from Belews Lake is not considered. Cooling from MDCT is considered to reduce lake intake flows and reduce the heat discharged to the lake during plant operation.

9.4.1.2.7 Spray Ponds

Spray pond cooling technology utilizes a series of spray nozzles located in a relatively long and narrow pond. Water from the condenser is sprayed into the air, where it is cooled by evaporation, and then allowed to fall into the pond where it is drawn into the intake structure to be pumped back to the condenser. Water lost in spray ponds through the evaporation process requires makeup from a nearby source. Spray ponds require considerably less land use to dissipate the same amount of heat versus conventional cooling ponds. In general, land use as a function of plant output at power plants utilizing spray ponds is approximately 1 ac. per 15 MWe generated; therefore, approximately 150 ac. would be required at the Project site for a spray pond (U.S. AEC, 1973).

The evaporative heat transfer associated with spray ponds is less efficient than the proposed MDCT. Using the Belews Lake cooling water system to support a spray pond would result in increased heat transferred to the aquatic ecosystems and increased intake to offset evaporation that would affect currently supported recreational activities. Therefore, a spray pond heat dissipation system is not preferable to the proposed MDCT for the Project site.

9.4.1.3 Conclusions

As discussed in the above subsections, all of the alternative heat dissipation systems considered are either not feasible or not an environmentally preferable alternative to MDCT for the Project site. Once-through cooling is not a suitable alternative, and the alternative closed-system cooling technologies are not preferable to MDCT technology.

9.4.2 CIRCULATING WATER SYSTEM ALTERNATIVES

This subsection presents a discussion of alternatives to the following components of the circulating water system (CWS): intake systems, discharge systems, water supply and water treatment processes. This review only considers those alternatives that are applicable to the Project site and are compatible with the proposed heat dissipation system discussed in Section 3.4.

9.4.2.1 Proposed Circulating Water System

This subsection summarizes the components of the CWS proposed for the facility.

9.4.2.1.1 Intake System

The proposed water intake is described in Section 3.2.2.4.1. The two potential locations for the intake are shown in Figure 3.1-1. A single intake structure will service all plant complexes on the Project site. Figure 3.2-1 shows the section and plan views of the conceptual intake design.

The intake structure is designed to meet the bounding makeup water requirements of the heat dissipation system by drawing water directly from Belews Lake. As shown on Figure 3.2-1, the intake structure is constructed with the front face located at the existing lake shoreline. This common intake accommodates pumps and appropriate water screen technology. The design of the intake structure will comply with the CWA 316(b) regulations. The maximum water velocity at the intake and water screens will be less than 0.5 ft. per second, as required by the CWA, Section 316(b) Phase I requirements specified in 40 CFR 125.84.

9.4.2.1.2 Discharge

Conceptual discharge designs being considered are described in Section 3.2.2.4.4 and shown in Figure 3.1-1 and Figure 3.2-2. The proposed Project includes both a discharge to Belews Lake and a discharge to the Dan River. For the discharge to Belews Lake, the blowdown from the CWS is transported from the MDCT to the discharge through a pipeline. Discharge piping entering the lake is submerged and routed to the appropriate location and depth to mix with the bulk waters of the lake.

The discharge design routes cooling tower blowdown to the Dan River in an existing wastewater pipeline corridor adjacent to existing Outfall 006 as needed to serve as dilution flow for treated liquid radwaste. Additionally, operational flexibility is provided to divert blowdown flow to the Dan River to support water quality strategies.

The facility's discharges will be regulated by an NPDES permit. The NPDES permit will include discharge limits established to protect receiving waters and monitoring to ensure compliance with those limits. Temperatures and chemical concentrations for all discharges will be in compliance with the terms and conditions of the NPDES permit.

9.4.2.1.3 Water Supply

The proposed cooling water supply for operation of the Project site is described in Sections 3.2.2.3 and 3.4.1.1. The proposed water source is Belews Lake with supplemental makeup from the Dan River to Belews Lake available through the MWIS.

A water-use diagram for the conceptual facility is provided in Figure 3.2-4 Makeup from Belews Lake and discharge to both Belews Lake and the Dan River is shown in the water balance diagram. Makeup flow from the MWIS to Belews Lake will be performed as necessary based on lake level and operated in accordance with the limitations outlined in the existing NPDES permit. The intake withdraws a normal flow of 30,709 gpm, and a maximum of 43,131 gpm. The MDCT consumes some of this water through evaporation and drift. The drift rate is 1 gpm (normal) and 21 gpm (maximum), and the evaporation rate is 26,256 gpm (normal) and 32,580 gpm (maximum).

9.4.2.1.4 Water Treatment

The proposed treatment of the water for operation of the Project site is described in Section 3.2.3.2. Duke Energy uses a common, open cooling water chemistry program that describes the implementation for treatments, maintenance and testing best suited for the site-specific design and environment. Procedures specific to the Project site will be defined at the construction permit or license application stage once reactor technology is selected, water quality studies are completed, and NC NPDES permitting requirements are established.

9.4.2.2 Screening Alternatives to the Proposed Circulating Water System

The purpose of this subsection is to identify and analyze reasonable alternatives to the proposed CWS. The analysis of each alternative system is covered in separate subsections for the intake system, discharge system, water supply, and water treatment system.

Given the operation of BCSS is projected to overlap with operation of advanced reactor plant development for a period of time prior to planned BCSS retirement, options for intakes and discharges were evaluated based on both overlapping and separate operation of the two generation sources. With heat dissipation technology focused on evaporative cooling, the intake and discharge flows and discharge temperature effects on Belews Lake are far less than once-through cooling. Therefore, the placement of intakes and discharges had very broad options.

9.4.2.2.1 Intake System

The intake location was selected such that it is centrally located between the three plant complex locations and there is easy access to relatively deep water. Driving factors for placement of the intake were to centralize it to the three plant complexes to simplify piping and pumping efforts, proximity to reliable and multiple power sources, favorable topography at a shoreline location that has access to deep water within a short distance of the shoreline. Simplifying piping and pumping distance and ensuring access to deep water minimizes environmental impacts to the landscape and indigenous community.

9.4.2.2.2 Discharge

The driving factors for determining discharge locations, focused on simplification of operation by use of gravity flow of blowdown returned to Belews Lake, resulting in multiple discharges specific to each plant complex. Common discharge locations or potential holding ponds were evaluated although are less desired given the added infrastructure and operational impact to achieve these options.

The preferred discharge option is to have three separate discharges, one for each of the plant complexes, with blowdown being gravity fed to Belews Lake. The three locations were selected based on favorable topography, access to deeper water for mixing, and close proximity to support gravity feed with no discharge pump required. This preferred design minimizes environmental impact by limiting disturbances to the land and natural habitats as well as decreasing the impact of thermal discharge.

A second option considered for discharge is for a common discharge to Belews Lake for all three Plant Complexes. For this option, water is pumped to a single discharge point near the northern central part of the lake with access to deep water for mixing. While this is a less desired option, a holding pond with a common discharge was removed from consideration for the discharge location.

Due to the thermal discharge associated with the cooling tower blowdown discharge to the Dan River, the discharge to the Dan River will be a new submerged discharge to promote thermal mixing. The Dan River Outfall is to be located within the existing discharge pipe corridor and adjacent to Outfall 006 to limit the impacts on land and natural habitat disturbance.

9.4.2.2.3 Water Supply

CWS makeup water is to be withdrawn from Belews Lake. Water used is discussed in Section 3.2 and is summarized in Section 9.4.2.1.3. Alternative water supply sources, including groundwater, municipal water supply, and wastewater flows, were considered. Given that the expected water needs for plant operation range from an average of 30,709 gpm, and a maximum of approximately 43,131 gpm (or 44.2 to 62.1 million gallons per day), none of the alternative water supply sources considered have the capacity to support plant operations, and no further evaluation of these options was considered.

9.4.2.2.4 Water Treatment

Concentration of dissolved salts in makeup water resulting from evaporative water losses requires the discharge of a certain percentage of the mineral-rich stream (blowdown) and its replacement with fresh water (makeup). Nuclear power plants are required to obtain an NPDES permit to discharge effluents. These permits are renewed every five years by the state's water quality permitting agency. The periodic NPDES permit renewals provide the opportunity to require modification of power plant discharges or to alter discharge monitoring in response to water quality concerns. Effects of cooling tower discharges are considered to be of small

significance when water quality criteria (e.g., NPDES permits) are met. In considering the effects of closed-cycle cooling systems on water quality, the NRC evaluated the same issues that were evaluated for open-cycle systems. Based on review of literature and operational monitoring reports, consultations with utilities and regulatory agencies, and comments on the draft Generic Environmental Impact Statement for License -Renewal of Nuclear Plants, discharge of cooling tower effluents has not been a problem at existing nuclear plants.

As discussed in Section 9.4.2.1.4, specific anti-fouling methods are to be defined at the construction permit or license application stage, when a final plant technology is selected. The quantities and concentrations of chemicals to be used are to be in accordance with the NPDES permit application. Therefore, no alternative water treatment methods have been evaluated.

9.4.2.3 Conclusions

As discussed in the above subsections, alternative circulating water system components considered were either not able to support plant operation or were not an environmentally preferable alternative to the proposed design.

9.4.3 OTHER SYSTEM ALTERNATIVES

There was no consideration of alternative designs for other systems. Therefore, no proposed system alternatives are discussed in this subsection.

USACE	U.S. Army Corps of Engineers
USFWS	U.S. Fish and Wildlife Service

Chapter 10 Conclusions

10.0 INTRODUCTION

Section 101 of the National Environmental Policy Act of 1969 (NEPA) requires federal agencies to assess the environmental effects of proposed major federal actions prior to making decisions. Section 102 of NEPA establishes procedural requirements, applying that national policy to proposals for major federal actions significantly affecting the quality of the human environment by requiring federal agencies to prepare a detailed statement on: (1) the environmental impact of the proposed action; (2) any adverse effects that cannot be avoided; (3) alternatives to the proposed action; (4) the relationship between the proposed action's short-term use of environmental resources and the maintenance and enhancement of long-term productivity; and (5) any irreversible and irretrievable commitments of resources that would be involved in the proposed action.

The environmental consequences of construction and operation of advanced reactors at the Belews Creek, North Carolina (NC) site (Project site) are summarized in the following sections:

- Section 10.1: Impacts of the Proposed Action
- Section 10.2: Unavoidable Adverse Impacts
- Section 10.3: Relationship of Short-term Use of the Environment and Long-term Productivity
- Section 10.4: Irreversible and Irretrievable Commitments of Resources
- Section 10.5: Alternatives to the Proposed Action
- Section 10.6: Benefits and Costs

10.1 IMPACTS OF THE PROPOSED ACTION

The relative magnitude of impacts associated with building activities are discussed in Chapter 4 and summarized in Table 4.11-1. Impacts associated with operating the Project are discussed in Chapter 5 and summarized in Table 5.12-1. Chapter 7 describes the cumulative impacts associated with building activities, operations, and decommissioning of facilities when considered along with other past, present, and reasonably foreseeable future actions (RFFAs) in the geographic area of interest (GAI) for each resource.

The following sections provide a summary of the impacts from building activities, operations, and cumulative impacts associated with the Project.

10.1.1 LAND-USE IMPACTS

The anticipated on-site and off-site impacts to land use due to construction and operation are discussed in Sections 4.1 and 5.1, along with Section 7.2.1.

Land-use impacts from building activities associated with the Project result from permanent conversion of undeveloped forested land and developed land to industrial use, loss of prime farmland soils, and discontinuation of hunting leases on the Project site. As described in Section 4.1.1, noticeable land-use impacts from building activities are primarily due to the conversion of up to approximately 696 acres (ac.) (282 hectares [ha]) of forested land within the Project site to developed land for industrial use. Development of the Project site would be compatible with Belews Creek Steam Station (BCSS) on the adjacent property and is in compliance with current zoning in Stokes and Forsyth counties. Land-use impacts also result from construction within portions of the existing associated off-site wastewater pipeline corridor. Although building activities within the corridor disturb existing land cover, the overall use of the corridor for the pipeline does not change. No new off-site transmission corridors are needed for the Project.

In accordance with the Farmland Protection Policy Act, Duke Energy Carolinas, a limited liability company (LLC) (Duke Energy), coordinated with the United States (U.S.) Department of Agriculture's Natural Resources Conservation Service (NRCS) regarding impacts on prime and unique farmlands. Based on the Farmland Conversion Impact Rating (Form AD-1006) completed for the Project, impacts to prime and unique farmlands are expected to be minor, and no further consultation with the NRCS is required. Building activities affect recreational uses on the Project site because of the discontinuation of hunting leases. Hunting remains prohibited throughout operations. Because of the acreage of land that is converted from forest to industrial use, impacts from building activities noticeably alter, but do not destabilize, land use. Therefore, impacts on land use from building activities are MODERATE.

Approximately 906 ac. (367 ha) are disturbed during the operational life of the Project. Operation of the Project is consistent with applicable land-use planning and zoning, and no additional land is expected to be required to support operations. Operating the mechanical draft cooling towers (MDCTs) has the potential to affect nearby land through fogging, icing, and salt drift. However, the Seasonal and Annual Cooling Tower Impact analysis predicts no occurrences of fogging or plume rime icing, low rates of salt deposition, limited visual impacts, and insignificant levels of plume water deposition. In addition, development of an independent spent fuel storage installation (ISFSI) is being considered at the Project site to store spent fuel. The size and location of the ISFSI is currently undetermined. The facility will meet the requirements set forth in Title 10 Code of Federal Regulations (CFR) Part 72. The off-site wastewater pipeline corridor would continue to be managed as it is currently. Therefore, impacts on land use during operations are SMALL.

The cumulative impact of building and operating activities from the Project on land use, added to the effects associated with past, present, and RFFAs within the GAI on land use, is noticeable but not destabilizing and therefore MODERATE. Because of extensive past and present modification of land use within the GAI and the Project site's proximity to the adjacent existing industrial BCSS site, the impact of building the Project is a noticeable, but not a destabilizing contributor to the cumulative impact on land use. The impact of operating the Project is a minor contributor to the cumulative impact on land use.

10.1.2 WATER RESOURCES

10.1.2.1 Hydrologic Alterations

Impacts on surface waters and groundwater from hydrologic alterations are discussed in Sections 4.2.1, 5.2.1, and 7.2.2.

10.1.2.1.1 Surface Water

Building activities result in direct impacts of up to approximately 16,875 linear feet (ft.) (5144 linear meters [m]) of streams within the net disturbance area (NDA) and approximately 100 linear ft. (30.5 linear m) within the associated off-site wastewater pipeline. An additional approximately 1256 linear ft. (383 linear m) of streams on the Project site are indirectly impacted by building activities. Impacts within Belews Lake are localized to the intake, discharge, and associated lakebed piping structures. Stormwater runoff patterns across the NDA are affected, resulting in changes in stormwater runoff rates across the Project site.

Impacts to on-site aquatic habitats are mitigated in accordance with Sections 404, 401, and 402 of the Clean Water Act (CWA) and associated permits administered by the U.S. Army Corps of Engineers (USACE) and the North Carolina Department of Environmental Quality (NCDEQ). Implementation of design measures and best management practices (BMPs) during building activities, coupled with adherence to federal, state, and local permit conditions related to Sections 404, 401, and 402 of the CWA, reduce direct and indirect impacts on Belews Lake, Dan River, and stormwater runoff rates. For impacts that result from activities subject to permitting under Section 404 of the CWA and that cannot be reduced, Duke Energy implements specific compensatory mitigation measures in accordance with 33 CFR Part 332 "Compensatory Mitigation for Losses of Aquatic Resources." A National Pollutant Discharge Elimination System (NPDES) general construction permit with site-specific stormwater pollution prevention plan (SWPPP) is required and includes strategies to reduce erosion and control sedimentation at the Project site. The overall impacts of hydrologic alterations to surface waters are mitigated and are, therefore, SMALL.

The effects of Project operations on flow patterns within Belews Lake from intake, discharge, and makeup water intake structure (MWIS) operation are localized and minor. Additionally, the potential impacts of sediment transport into Belews Lake from the MWIS operation are negligible. Discharge into the Dan River results in localized changes in flow patterns and currents; however, total flow and discharge flow rates are regulated in conjunction with NCDEQ NPDES permitting requirements and are expected to be similar to the existing Outfall 006 wastewater discharge. Therefore, the hydrological impacts of discharge are minor. Pumping by the MWIS results in minor hydrologic alterations on the Dan River during higher flow conditions or when natural discharge is less than 110 cubic feet per second (cfs) (3.11 m^3/s), which are the most probable flow conditions.

Additionally, Project operations result in predicted water-level variations in Belews Lake resulting from increased consumptive use. Supplemental pumping by MWIS is a mitigating measure for Belews Creek level impacts. The predicted pattern of water-level variations during Project operations is similar to the BCSS Continuous Maximum Generation Condition, but operation of the Project results in somewhat greater drawdowns and an extended critical drought duration relative to the BCSS Continuous Maximum Generation Condition. Impacts on

water levels from Project operations are noticeable during periods of increased drought severity, but are not considered to be destabilizing. Lake hydrologic function and features are generally maintained by operation of the MWIS that mitigates the reduction in lake levels from the increased consumptive use.

The overall operational impacts from hydrologic alterations to surface waters are SMALL on the Dan River and Belews Lake for all Project operations except for the effects associated with consumptive use, including that on Belews Lake and MWIS operations on the Dan River. Under conditions in which water levels are stabilized and consumptive losses are offset by MWIS pumping, impacts on Belews Lake hydrology are SMALL. During periods of increased drought intensity, the impacts on Belews Lake hydrology are MODERATE. Pumping by the MWIS results in minor hydrologic alterations on the Dan River during higher flow conditions or when natural discharge is less than 110 cfs (3.11 m^3/s).

Because of extensive past and present modification of Belews Creek and its tributaries as a result of the impoundment of Belews Lake, the cumulative impact of building and operating the Project on surface water hydrology, added to the effects associated with past, present, and RFFAs within the GAI on surface water hydrology is MODERATE. The impact of building the Project is a minor contributor to the cumulative impact on surface water hydrology due to the mitigation of impacts to low-quality streams on-site, impacts to Belews Lake, and stormwater runoff changes. The impact of operation of the Project is a noticeable contributor to the cumulative impact on surface water hydrology in conjunction with periods of increased drought intensity.

10.1.2.1.2 Groundwater

Localized changes (decreases) in groundwater elevations may occur from dewatering during building activities. Once building activities are completed, dewatering is no longer needed, and the water table is returned to the static baseline conditions that Section 2.2.1 describes. Structure foundation development does not result in long-term impacts on groundwater levels, availability, or flow patterns. Development of new impervious surfaces on the Project site results in reduced infiltration and groundwater recharge in the immediate area of these structures and surfaces. In locations where groundwater recharge is affected, corresponding reductions in groundwater levels may occur; however, other lands within the NDA are expected to allow for varying degrees of groundwater infiltration and recharge. Therefore, impacts of hydrologic alteration of groundwater during building activities are SMALL.

During operations, there are few hydrologic alterations that affect groundwater availability. No groundwater use or dewatering occurs during operations that may affect local aquifers. Impervious surfaces from development of areas within the NDA results in reduced infiltration and groundwater recharge in the immediate area of new structures and pavement. In locations where groundwater recharge is affected, corresponding reductions in groundwater levels may occur. Other lands within the NDA are expected to allow for varying degrees of groundwater infiltration and recharge. Therefore, impacts on groundwater from hydrologic alterations during operations are SMALL.

The cumulative impact of the Project on groundwater hydrology, added to the effects associated with past, present, and RFFAs within the GAI, is minor and therefore SMALL. Because groundwater use by the Project is limited to the building phase and only results in localized

alterations from dewatering and reductions in infiltration because of the construction of new impervious surfaces, the impact of building and operation of the Project is not a significant contributor to the cumulative impact on groundwater hydrology.

10.1.2.2 Water Use Impacts

Impacts on surface water and groundwater from water use are discussed in Sections 4.2.2, 5.2.2, and 7.2.2.

10.1.2.2.1 Surface Water

During building activities, surface water is used for dust suppression, potable water, and concrete-batch plant operation. An estimated maximum of 500,000 gallons per day (gpd) (1,892,706 liters per day [lpd]) is drawn from Belews Lake for dust suppression and concrete-batch plant operation. This amount is negligible compared to the current volume of the lake. Potable water for building is obtained from either an existing or new water line connection with Winston-Salem/Forsyth County Utilities, and the maximum expected daily potable water usage is 61,622 gpd (233,264 lpd), which is within the capacity of the water supplier. Therefore, the impacts from surface water use during the building phase are SMALL.

During operations, Belews Lake consumptive water use increases. However, this increased use is supplemented by MWIS operation, and consumptive use in conjunction with Project operations does not adversely affect the availability of water for Project intake systems. Impacts on water use in Belews Lake are therefore SMALL. Although MWIS operation reduces the water available to downstream water users, this reduction does not compromise the overall availability or reliability of surface water to users downstream of the Project. Impacts of MWIS operation on downstream water use by communities are SMALL.

The cumulative impact of the Project on surface water use, added to the effects associated with past, present, and RFFAs within the GAI on surface water use is minor and therefore SMALL. Water used for dust suppression and potable water usage during building activities is minor, and the impact during operations is low due to the available capacity. The impact of both building and operation of the Project is a minor contributor to the cumulative impact on surface water use.

10.1.2.2.2 Groundwater

Groundwater is not used as a source of water for building activities. Therefore, the impacts from groundwater use are SMALL.

Likewise, groundwater is not used during operation of the Project, and no permanent dewatering system is planned for use during operations. Therefore, impacts of groundwater use from operations are SMALL.

The cumulative impact of the Project on groundwater use, added to the effects associated with past, present, and RFFAs within the GAI on groundwater use, is minor and therefore SMALL. Because groundwater is not used during building activities or operations, the impact of building and operation of the Project is negligible and not a significant contributor to the cumulative impact on groundwater use.

10.1.2.3 Water Quality Impacts

Impacts on surface water and groundwater quality are discussed in Sections 4.2.3, 5.2.3, and 7.2.2.

10.1.2.3.1 Surface Water

During building activities, impacts to surface water quality are controlled, localized, and temporary because of implementation of mitigative measures and engineering controls (e.g., BMPs, SWPPP, and Spill Prevention, Control, and Countermeasures [SPCC]). Therefore, impacts on surface water quality are SMALL.

Effects of operation on water quality within Belews Lake include the addition of cooling tower blowdown wastewater constituents, reduced thermal load, and supplemental pumping from the Dan River. The additional wastewater discharges are not expected to accumulate and will meet NPDES permitting limits and requirements with a regulatory mixing zone. Monitoring programs will be implemented to ensure regulatory compliance. Therefore, the overall impacts on surface water quality are considered SMALL.

The direct effects of operation on surface water quality in the Dan River include nonradioactive liquid discharges and the addition of cooling tower blowdown wastewater constituents and thermal load. Operational impacts to Dan River water quality are mitigated through engineering and administrative controls and monitoring programs. The additional wastewater discharges are managed within Section 402 NPDES permitting limits and requirements; therefore, overall impacts on surface water quality are SMALL.

The cumulative effects on surface water quality of BCSS closure in conjunction with the proposed Project are generally beneficial. Cessation of the inputs and discharges from natural gas and coal-fired electricity generation at BCSS and implementation of the Project reduce thermal inputs to Belews Lake and discharge of constituents to the Dan River compared to existing conditions, while remaining within federal and state permitted conditions. Added to the effects of all past, present, and RFFAs within the GAI, the cumulative impact of building and operating activities from the Project on surface water quality is noticeable and stabilizing, primarily due to the beneficial effects of BCSS closure. Because of adherence to regulations and permits by the NCDEQ and USACE, use of BMPs, and implementation of the SPCC plan and SWPPP, the impact of building and operation of the Project is minor and not a significant contributor to the cumulative impact on surface water quality. Overall impacts, therefore, are LARGE and beneficial.

10.1.2.3.2 Groundwater

In the unlikely event small amounts of oil-related substances are released into the environment during building activities, they would have a small, localized, temporary impact on groundwater. Because engineering controls (e.g., BMPs and SPCC) prevent or minimize the release of harmful effluents, and effluent concentrations are maintained at levels below permitted threshold limits that are established to be protective of water quality, impacts to groundwater quality are SMALL.

Likewise, during operations, engineering controls prevent or minimize the release of harmful effluents. Additionally, because concentrations of constituents in surface water are maintained at levels below permitted limits, any impacts to groundwater quality are SMALL.

The cumulative impact of the Project on groundwater quality, added to the effects associated with past, present, and RFFAs within the GAI on groundwater quality, is minor and therefore SMALL. Because engineering controls (e.g., BMPs and SPCC) prevent or minimize the release of harmful effluents, and effluent concentrations are maintained at levels below permitted limits that are established to be protective of water quality, the impact of building and operation of the Project is negligible and not a significant contributor to the cumulative impact on groundwater quality.

10.1.3 ECOLOGICAL RESOURCES

10.1.3.1 Terrestrial and Wetland Impacts

Impacts to terrestrial ecosystems and wetlands are discussed in Sections 4.3.1, 5.3.1, and 7.2.3.

Impacts of building activities on plant communities and terrestrial habitats are the result of alterations to existing habitats within the NDA. Although much of the habitat on-site is of low quality, there is suitable habitat within the Project Vicinity. However, higher-quality habitats on-site are also permanently impacted, and the composition of wildlife within the Project site is altered to naturalized communities. Impacts on wildlife are limited because of mitigation measures, BMPs, and the short duration of building activities. The only important habitat on the Project site consists of wetlands, as defined by U.S. Nuclear Regulatory Commission (NRC) guidance and discussed in Section 2.3.1.6. Impacts on wetland habitats are mitigated by BMPs and required federal or state mitigation. Impacts on important terrestrial species are mostly limited because many of these species are not found on the Project site, or there is limited impact on habitats and populations found within the Project Vicinity and Project Region. Consultation with the U.S. Fish and Wildlife Service (USFWS) and implementing appropriate conservation measures and other mitigative measures reduces impacts on terrestrial species found on the Project site or in adjacent areas. Overall, impacts on terrestrial ecology and wetlands from building activities are MODERATE due to the noticeable but not destabilizing impacts from the conversion of terrestrial ecosystems within the Project site.

Impacts to terrestrial ecology during operations are limited by the lack of habitat on-site because most of the Project site is developed, and wildlife communities are limited to small areas on the Project site such as the vegetated buffer areas around Belews Lake. Impacts associated with landscape maintenance activities, potential for invasive species establishment, noise emissions, cooling tower salt deposition, and potential for bird collisions with tall structures are minor and mitigated using BMPs and general landscape maintenance activities. Control methods limit impacts of invasive species to vegetation and native wildlife. Compliance with the Migratory Bird Treaty Act reduces impacts to birds during transmission or other maintenance activities. Impacts to important terrestrial species and habitats are also minor. Overall, impacts to terrestrial ecology and wetlands from operation are SMALL.

The cumulative impact of building and operating activities on terrestrial ecology and wetlands, added to the effects associated with past, present, and RFFAs within the GAI, is noticeable but

not destabilizing and therefore MODERATE. Because of extensive forest habitat loss on the Project site and associated impacts on wildlife, the impact of building and operation of the Project would be a noticeable contributor to this MODERATE cumulative impact.

10.1.3.2 Aquatic Impacts

Impacts to aquatic resources are discussed in Sections 4.3.2, 5.3.2, and 7.2.3.

Building activities result in direct impacts on up to approximately 16,875 linear ft. (5144 m) of streams within the NDA and 100 linear ft. (30.5 m) within the associated off-site wastewater pipeline. An additional approximately 1256 linear ft. (323 linear m) of streams on the Project site are indirectly impacted by building activities. The impacted streams are primarily first order, relatively small streams which are mostly intermittent in nature and do not demonstrate high quality habitat. Impacts on aquatic habitats in Belews Lake are minor based on the lack of high quality or unique habitats in the locations in which building activities are to occur. Impacts on most streams or other aquatic ecosystems are mitigated in accordance with permitting requirements. Impacts within Belews Lake are temporary and localized to the intake and discharge structures on the Project site.

Building activities have no direct impacts on important aquatic habitats (e.g., natural areas, managed areas, or other designated areas). Indirect impacts on aquatic communities from sedimentation, erosion, and incidental releases resulting from building activities are minimized under permitting and SWPPP requirements and through use of BMPs. In addition, Duke Energy will consult with USFWS and the State of NC regarding avoidance, minimization, and appropriate conservation measures to limit potential effects on proposed critical habitats within the Dan River. The overall impacts of building activities on aquatic resources are therefore SMALL.

Impacts of Project operations on aquatic species and habitats from impingement and entrainment associated with the cooling water intake structure and MWIS, cooling tower effluent constituents and thermal effluents in Belews Lake, and wastewater discharge in the Dan River, are SMALL. Impacts on aquatic species and habitats within Belews Lake from operations, under normal operational conditions in which water levels are stabilized and consumptive losses are offset by MWIS pumping, likewise are minor; however, impacts from reductions in water levels under drought conditions are MODERATE. Supplemental pumping from the MWIS in accordance with the limits established in the NCDEQ NPDES permit mitigates the reduction in lake levels and associated effects on near shore aquatic habitats and minimizes potential effects related to water-level fluctuations. The NCDEQ NPDES permit limits adverse impacts to aquatic ecology within the Dan River by maintaining river flow and habitat availability and minimizing entrainment and impingement.

The cumulative impact of building and operating the Project on aquatic ecology, added to effects associated with past, present, and RFFAs within the GAI is MODERATE. This conclusion accounts for the cumulative effects of past impoundment of Belews Creek and its resultant effects on the aquatic ecosystem within Belews Creek and its tributaries. The incremental contribution of building and operation of the Project is a minor contributor to the cumulative impact on aquatic ecosystems under normal conditions and noticeable in conjunction with the effects of increased drought intensity.

10.1.4 SOCIOECONOMICS

10.1.4.1 Physical Impacts

Physical impacts are discussed in Sections 4.4.1, 5.4.1, and 7.2.4.1.

Building-related noise and vibration impacts to off-site structures are minimal because of the distance from the closest residence to the areas where the activities causing noise and vibration take place. The nearest residence may be disrupted from the use of heavy machinery and vehicles; however, the use of this mobile equipment is intermittent. Emissions from building-related activities are controlled using minimization measures and by maintaining established regulatory limits. Any damage to public roads, markings, or signs caused by building activities is repaired to preexisting conditions or better, in accordance with state and local requirements. Impacts to aesthetics from building activities, including the introduction of new structures, use of equipment, and increased traffic in the Project Vicinity that impact viewsheds, are noticeable for nearby residents and recreators on Belews Lake but are not destabilizing. Therefore, physical impacts of building activities are SMALL for most factors, but MODERATE for aesthetics.

During operations, odors, dust and air pollution, thermal emissions, noise, and transportation have a SMALL physical impact. New plant structures and related cooling tower plumes at the Project site noticeably affect the aesthetic qualities of the natural landscape for nearby residents and recreators on Belews Lake. Thus, physical impacts on aesthetic quality from operations are MODERATE.

The cumulative physical impact of building and operation of the Project, added to the impacts associated with past, present, and RFFAs within the GAI on the physical environment is SMALL for all categories except for aesthetics which is MODERATE. The impact of building and operation of the Project is a noticeable contributor to the cumulative impact on aesthetics, whereas the remaining physical impacts from building and operation of the Project are minor contributors to the cumulative impact.

10.1.4.2 Demographic Impacts

Demographic impacts are discussed in Sections 4.4.2, 5.4.2, and 7.2.4.2.

The building-related population increases associated with the in-migration of workers and their families account for less than 1 percent of the Region of Influence's (ROI's) projected total population in 2030. Therefore, impacts to demographics associated with building activities are SMALL.

The operations-related population increases associated with the in-migration of operations workforce, together with the construction workforce that remain within the ROI, and their families, account for less than 1 percent of the ROI's projected total population in 2040. Therefore, impacts to demographics within the ROI associated with operation are SMALL.

The cumulative impact of building and operation of the Project on demography, added to the impacts of past, present, and RFFAs (including projected population growth within population centers in the ROI) within the GAI for demography is SMALL. Because of the much larger population within the ROI and the comparatively smaller workforces required during building and

operation of the Project, the impact of building and operation is a minor contributor to the cumulative impact on demography.

10.1.4.3 Economic Impacts to the Community

Economic impacts to the community are discussed in Sections 4.4.3, 5.4.3, and 7.2.4.3.

Building activities associated with the Project introduce millions of dollars into the economy and create both direct and indirect jobs. These positive economic impacts are primarily realized within the ROI. Minor tax revenue impacts on local jurisdictions are accrued through increases in individual income tax, sale of electricity tax, and sales and use tax. Therefore, the economic impacts are MODERATE and beneficial.

Operational activity introduces millions of dollars into the economy and creates jobs. These positive economic impacts are primarily realized within the ROI. Minor tax revenue impacts on local jurisdictions are accrued through increases in revenue generated from individual income tax, sales and use tax, and property tax. Therefore, the economic and tax impacts are SMALL and beneficial.

The cumulative economic impact of building and operation of the Project on the economy, added to the economic effects associated with past, present, and RFFAs in the GAI on the economy, is MODERATE and beneficial. The impact of the building and operation of the Project is a noticeable contributor to the cumulative impact on the economy in the GAI, primarily through job creation and increased local spending.

10.1.4.4 Community Infrastructure Impacts

Community infrastructure impacts are discussed in Sections 4.4.4, 5.4.4 and 7.2.4.4.

Building-related impacts on all infrastructure and community services are SMALL within the ROI, with the exception of traffic impacts due to increased commuters on roadways near the Project site at the beginning and end of their shifts. Impacts to transportation due to workforce traffic are SMALL within the broader transportation network, but MODERATE on two-lane segments and intersections that provide access to the Project site during daily peak traffic periods. Implementation of planned traffic management measures reduces congestion and unstable conditions.

Operations-related impacts on all infrastructure and community services are SMALL within the ROI, with the exception of impacts to traffic and recreation. Impacts to transportation due to operations traffic are SMALL within the broader transportation network, but MODERATE on two-lane segments and intersections that provide access to the Project site. Impacts on recreation are SMALL to MODERATE. Under conditions in which water levels in Belews Lake are stabilized and consumptive losses are offset by MWIS pumping, impacts on Belews Lake recreation are SMALL. However, impacts on Belews Lake recreation are MODERATE in conjunction with the effects of increased drought intensity and visual intrusion.

The cumulative effect on infrastructure and community services, when combined with past, present, and RFFAs within the GAI is considered SMALL based on the broader opportunities for recreation within the ROI. While the Project has noticeable effects on traffic and recreation at

Belews Lake (as described in Section 5.4.4.2), the Project is a minor contributor to the overall cumulative impact.

10.1.5 NOT USED

Deleted (Executive Order, 2025a, 2025b)

10.1.6 HISTORIC AND CULTURAL RESOURCES

Impacts on historic and cultural resources are discussed in Sections 4.6 and 5.6, along with Section 7.2.6.

Duke Energy has determined that based on the extent of the NDA indicated in Figure 3.3-1, and the location of archaeological sites as indicated in Figure 2.6-3, potential effects to archaeological sites [[ ]]^{CRI} can likely be avoided. If avoidance is not possible, archaeological mitigation including Phase III data recovery investigations will be developed in coordination with NCSHPO to address adverse effects to archaeological sites eligible for the NRHP under Criterion D. Avoidance of Branson Cemetery, ineligible for inclusion to the NRHP but protected under NC statute, is not possible. Accordingly, provisions regarding exhumation and repatriation provided by NC General Statute Chapter 65-106 will be followed as appropriate. Duke Energy plans to remove all graves in Branson Cemetery and relocate them to a new burial ground in accordance with an approved cemetery removal plan that includes delineation of the cemetery boundaries, generation of cemetery maps, and completion of historical and genealogical research. The plan will be developed in consultation with NCSHPO and in accordance with NC General Statute 65-106. Therefore, impacts on historic and cultural resources as a result of building activities are SMALL where avoidance of archaeological sites is possible and MODERATE with mitigation if sites cannot be avoided.

Operations have no impacts on historic structures. Operation of the advanced reactor units and supporting facilities occurs in areas that are disturbed during the building phase. Nonetheless, if ground-disturbing activities are undertaken beyond the NDA during operations, the potential exists for affecting undiscovered resources within the Project site. Mitigative measures developed in consultation with the NCSHPO and the NC Office of State Archaeology (OSA) are proposed for addressing previously undiscovered resources, and internal procedures will be followed for such discoveries. Therefore, impacts to archaeological sites during operations are SMALL. All cemetery relocation activities will be undertaken in advance of or during the building phase. Therefore, no cemetery will be present on the Project site during operations, and there are no impacts to cemeteries during operations.

The cumulative impacts of building and operating activities on historic and cultural resources, added to the effects associated with past, present, and RFFAs within the GAI, on historic and cultural resources are SMALL to MODERATE. The impact of building activities is a minor contributor to the cumulative impact on historic and cultural resources.

10.1.7 AIR RESOURCES

Impacts on local meteorology and air resources are discussed in Sections 4.7 and 5.7, along with Section 7.2.7.

The primary impacts on air quality during building activities are from dust generated by land clearing and construction, emissions from heavy equipment and machinery, concrete-batch plant operations, and emissions from vehicles used to transport workers and deliver materials to and from the site. Duke Energy develops and implements strategies to reduce emissions to ensure compliance with federal, state, and local regulations, including a dust control program. With implementation of these strategies, impacts on air quality from emissions of criteria pollutants and greenhouse gases are SMALL.

Operational impacts result from releases of heat and moisture from MDCTs, operation of auxiliary equipment (e.g., generators and auxiliary boilers), and mobile emissions from vehicles. No hours of ground fogging or plume rime icing are predicted from operation of the MDCTs, and salt drift deposition is predicted to be low and occur within the Project site. Visual impacts from operation of all MDCTs are limited and occur primarily on the Project site. Operation of the advanced reactors increases gaseous and particulate emissions to the air, primarily from cooling towers, auxiliary boilers, emergency equipment, and emergency power supply system diesel generators and gas turbines. The diesel generators/gas turbines and engine-driven emergency equipment are used intermittently and for brief durations. Nominal localized increases in emissions occur due to the increased numbers of cars, trucks, and delivery vehicles that travel to and from the Project site. Air emission sources during operations are managed in accordance with federal, state, and local air quality controls laws and regulations. The greenhouse gas emission footprint of a generic reactor are expected to be minor, an estimated 0.17 percent of the annual 2022 carbon equivalent emissions in the U.S. Accordingly, impacts to air resources from operation of the Project are SMALL.

Operation of the Project and BCSS closure result in a beneficial cumulative impact to air quality on the existing attainment status of regional air quality because emissions of criteria pollutants from the BCSS facility would cease. Additionally, the relatively small lifetime greenhouse gas emissions from the Project are offset by closure of the BCSS facility and replacement of natural gas and coal-fired electricity generated by this facility with electricity generated by the Project. In conjunction with the effects associated with all past, present, and RFFAs within the GAI, the cumulative impacts of building and operating activities on criteria pollutant and greenhouse gas emissions are SMALL. The impacts of building and operation of the Project are not significant contributors to the cumulative impact because air emissions are controlled through implementation of BMPs and in accordance with applicable federal and state regulations and permitting requirements.

10.1.8 NONRADIOLOGICAL HEALTH

Nonradiological health impacts on the public and workers are discussed in Sections 4.8 and 5.8, along with Section 7.2.8.

During building activities, nonradiological health and safety impacts are minimized through compliance with all applicable state and federal regulations. Based on a conservative analysis (see Section 4.8.2.1), noise levels at residences closest to the Project site are higher than 65 A-weighted decibels during building activities. However, noise levels attenuate rapidly with distance and decrease as equipment moves away from a receptor. For any particular receptor at or along the Project site boundary, exposure to high noise levels is variable and short term. As such, noise impacts from building activities are minor. The impact of building-related vibration on public health is minor. The addition of vehicles during the building phase on local

roads accessing the Project site results in a minor increase in crashes. Based on these impact determinations, the nonradiological health impacts of building activities are SMALL.

During operations, water temperatures in Belews Lake do not support conditions favorable to etiological agent establishment and growth. Therefore, potential effects associated with the development of etiological agents within Belews Lake resulting from operation of advanced reactors at the Project site are minor. Sanitary wastewater discharged to the Dan River complies with NPDES permit requirements. Because the on-site transmission lines comply with the National Electrical Safety Code and Duke Energy safety standards, impacts associated with potential electrical shock and impacts to the public attributable to electromagnetic frequency exposure from transmission system operations are minor. Operations result in cooling tower noise emissions that attenuate with distance; however, overall effects of noise are minor. The additional vehicles associated with operational traffic result in a minor increase in the risk of traffic accidents on the surrounding roadway network relative to the base condition. Therefore, impacts on nonradiological health are SMALL.

The cumulative nonradiological health impact of building and operation of the Project, combined with the effects associated with past, present, and RFFAs within the GAI is SMALL.

10.1.9 RADIOLOGICAL HEALTH DURING NORMAL OPERATIONS

Radiological health impacts on the public and workers are discussed in Sections 4.9 and 5.9, along with Section 7.2.9.

During building activities, construction workers may be exposed to direct radiation sources from plant buildings and facilities of operating units and radioactive gaseous effluents released through a controlled and monitored release point. As discussed in Section 4.9.3, construction workers are not expected to be exposed to radioactive liquid effluents. The annual radiation dose to construction workers is within the limits set in 10 CFR 20.1301 and 10 CFR 20.1302, which establish dose limits for individual members of the public, as noted in Section 4.9.4. As a result, construction workers are classified as members of the public and do not require additional monitoring. Therefore, impacts to construction workers from radiation exposure would be SMALL.

During normal operation of the Project, radiation and radiological effluents could be transmitted to plant workers and members of the public and biota occupying areas near the Project site. Radioactive effluent pathways to humans and nonhuman biota during normal operating conditions consist of:

- Small quantities of treated and diluted radioactive liquid effluent into the Dan River (i.e., liquid effluent)
- Radioactive gaseous effluent releases through a controlled and monitored release point
- Direct radiation from plant buildings of operating reactors.

While man and biota may be exposed to direct radiation from plant buildings of operating reactors, it is assumed that there is no significant direct radiation from plant buildings of operating reactors. This is a reasonable assumption considering that the annual direct radiation

dose contribution at the site boundary of a typical commercial nuclear pressurized water reactor power plant is the range of natural background radiation.

The exposure pathways for members of the public include liquid and gaseous effluents. Based on the doses for the maximally exposed individual (MEI) (i.e., a member of the public located at the Project site boundary) from liquid and gaseous effluents, the collective population dose resulting from normal operations is less than the estimated person-rem/yr exposure from natural background radiation, as discussed in Section 5.9.3. Therefore, impacts to members of the public from normal operation of the Project are SMALL.

The annual occupational dose to operational workers, including workers involved with major maintenance and outage activities, will be provided in the construction permit or license application. This dose will be maintained as low as is reasonably achievable (ALARA) in compliance with 10 CFR 20.1101.

Exposure of nonhuman biota near the Project site can occur through liquid or gaseous effluent exposure pathways. The calculated maximum biota dose, discussed in Section 5.9.5.3 and presented in Table 5.9-17, is 148 millirems per year (mrem/yr), which is above the 25 mrem/yr whole-body limit prescribed by 40 CFR Part 190. Use of exposure guidelines, such as 40 CFR Part 190, which apply to members of the public, in unrestricted areas, is considered very conservative when evaluating calculated doses to biota. When actions taken to protect humans from radiation and radioactive materials are not adequate to protect biota in accordance with 4.j(2)(b) of the Department of Energy (DOE) Order 458.1 (DOE, 2011), an alternative approach may be used to demonstrate that the dose rates to representative biota populations do not exceed the dose rate criteria in Table 2.2 of DOE-STD-1153-2002 (DOE, 2022). The dose rate criteria in Table 2.2 of DOE-STD-1153-2002 are 1 rad/day for aquatic biota and 0.1 rad/day for terrestrial biota. As indicated in Table 5.9-17, all biota analyzed for the Project site are within the dose limits of 1 rad/day (1000 mrad/day) for aquatic biota and 0.1 rad/day (100 mrad/day) for terrestrial biota.

Although many of the past, present, and RFFAs identified in Table 7.1-2 are affected by the Project site, none of these projects are expected to contribute to cumulative effects related to radiological health impacts. Therefore, based on the impacts analysis in Sections 4.9 and 5.9, the cumulative impact of construction and operation activities on radiological health, in consideration with past, present, and RFFAs in the GAI, is SMALL.

10.1.10 NONRADIOACTIVE WASTE MANAGEMENT

Impacts that may result from the generation, handling, and disposal of nonradioactive waste are discussed in Sections 4.10 and 5.10, along with Section 7.2.10.

During building activities, management of solid wastes complies with all applicable federal, state, and local requirements and standards. BMPs minimize the generation of solid waste and decrease potential impacts on downstream water quality. The potential for spills of petroleum or industrial chemicals are managed through SPCC plans. Air emissions are managed in compliance with applicable regulatory limits defined by the National Primary and Secondary Ambient Air Quality Standards (40 CFR Part 50). Duke Energy implements a dust control program and develops strategies to reduce emissions to ensure compliance with federal, state,

and local regulations. Therefore, the impacts on land, water, and air from nonradioactive waste during building activities are SMALL.

Although the reactor technology has not been selected, Duke Energy uses site-specific operational procedures and administrative guidelines to manage all solid, hazardous, and mixed waste generated from the site during operation in accordance with federal and state regulations. The impacts of sanitary wastes and liquid effluents on water quality in the Dan River and Belews Lake are managed through engineering controls in accordance with an NPDES permit. Impacts of discharge of small quantities of treated and diluted radioactive liquid effluent to the Dan River are discussed in Section 10.1.9. Stormwater discharges are managed through a separate NPDES stormwater permit and controlled and minimized using BMPs. Air emissions are intermittent during operations and managed to adhere to prevention of significant deterioration standards and other federal, state, and local air quality control regulations. Therefore, impacts on land, water, and air from nonradioactive waste during operations are SMALL.

The cumulative impact of building and operating activities from the Project on nonradiological waste based on the availability and expected capacity of existing licensed disposal facilities within the GAI, added to the effects associated with past, present, and RFFAs within the GAI on nonradiological waste, is SMALL. The impact of the building and operation of the Project is not a noticeable contributor to the cumulative impact on nonradioactive waste. Given the existing reported landfill capacity in the Project Region and the scope of the RFFAs, construction and operation of these facilities are not expected to substantially contribute to the loss of waste disposal capacity in the GAI.

10.1.11 ENVIRONMENTAL IMPACTS OF POSTULATED ACCIDENTS

As discussed in Section 5.11, the environmental impacts from a postulated accident at the Project site, considering both design basis and severe accidents, are anticipated to be SMALL.

Off-site radiological consequences of design basis accidents are assessed based on a surrogate accident source term associated with one of the potential advanced reactor technologies. The design basis accident source term is shown in Table 5.11-1. The resulting doses shown in Table 5.11-2 are within the acceptance criteria in 10 CFR 50.34. Therefore, the environmental impacts of design basis accidents at the Project site are anticipated to be SMALL.

The environmental risks of severe accidents are evaluated based on source terms and probabilities determined from the Probabilistic Risk Assessment (PRA). The MELCOR Accident Consequences Code System (MACCS) computer code is used to estimate severe accident risks based on-site-specific meteorology, population, and land-use data. The doses for the applicable environmental exposure pathways demonstrate that the individual prompt and latent cancer fatality risks meet the NRC's Safety Goals. The calculated population dose risk is less than the maximum, median, and mean dose risk for current operating reactors. Therefore, the environmental impacts of postulated severe accidents for the Project site are anticipated to be SMALL.

10.2 UNAVOIDABLE ADVERSE IMPACTS

The direct, indirect, and cumulative impacts of building and operating the Project are summarized in Section 10.1. This section and Tables 10.2-1 and 10.2-2 summarize the unavoidable adverse impacts of building and operating the Project. Unavoidable impacts are those adverse impacts that cannot be avoided or for which there are no practical means of further mitigation.

Mitigation measures and controls that are required as part of regulatory compliance, NPDES permits, or SPCC plans or implemented separately by Duke Energy are designed to reduce, manage, or eliminate the negative effect of building and operational activities. When properly implemented, BMPs can effectively control pollutants, manage stormwater, prevent erosion, and protect natural habitats. Tables 10.2-1 and 10.2-2 discuss residual unavoidable building and operational impacts that occur after mitigation or for which no mitigation measures or controls have been identified.

10.2.1 UNAVOIDABLE ADVERSE IMPACTS OF BUILDING

Impacts from building activities are described in Chapter 4. Table 4.11-1 summarizes those impacts and identifies the mitigation measures and controls that may be implemented to reduce or eliminate impacts. As noted in Table 4.11-1, most of the impacts are SMALL because they are either not detectable or do not destabilize or noticeably alter any important attribute of the resource. Table 10.2-1 summarizes the building-related impact determination for each resource, the mitigation and control measures available to avoid or reduce those impacts, and the remaining unavoidable adverse impacts after mitigation and control measures are applied.

As noted in Table 10.2-1, building activities result in the conversion of up to approximately 696 ac. (282 ha) of forested land within the Project site to industrial use. This conversion is necessary to support building of permanent structures, including the power block, switchyard and transmission system, cooling tower areas, water systems, access roads and parking areas, and other plant facilities, as well as temporary changes to support building activities (such as stormwater management features, material laydown, and parking areas). Public access to the Project site for hunting is discontinued during building activities and throughout operation of the Project.

Building activities result in unavoidable adverse impacts to natural and cultural resources within the Project site, including:

- Direct effects on up to approximately 16,875 linear ft. (5144 linear m) of streams and associated functions on the Project site and 100 linear ft. (30.5 m) of streams within the off-site wastewater pipeline.

- Indirect impacts to the function of up to approximately 1256 linear ft. (323 linear m) of connected streams extending outside the NDA.

- Localized alteration of the Belews Lake shoreline and lakebed and the Dan River associated with construction of in-water structures.

- Localized changes in groundwater levels from dewatering during excavation and reduced infiltration and groundwater recharge near new impervious surfaces.
- Displacement of wildlife and loss of less mobile fauna due to land clearing, grading, excavation, filling, and loss of habitat.
- Direct impacts of up to approximately 2.45 ac. (0.99 ha) of wetlands within the Project site and 0.26 ac. (0.11 ha) within the off-site wastewater pipeline area.
- Impacts to tricolored bat foraging and roosting habitat and monarch butterfly foraging habitat. These species are proposed for federal listing as endangered and threatened, respectively.
- Direct and indirect impacts on aquatic biota and habitats in Project site streams, Belews Lake, and the Dan River associated with the placement of fill material, flow alteration, and increased sedimentation.
- Potential non-avoidance of any NRHP-eligible archaeological site.
- Relocation of Branson Cemetery.

Building activities also impact nearby residential and recreational receptors, community infrastructure and waste management. Building activities result in variable and short-term noise levels above 65 dBA, disruptive vibration levels, air emissions of gaseous pollutants and particulate matter, and visual intrusions for nearby sensitive receptors. Throughout the building period, there is increased traffic on the roads and intersections that provide access to the Project site. The commuting workforce and deliveries that cause the increased traffic also reduce the level of service. Building activities also result in a minor reduction in landfill capacity from the disposal of construction debris, general waste, metal waste, and equipment waste.

10.2.2 UNAVOIDABLE ADVERSE IMPACTS OF OPERATION

Operational impacts are discussed in detail in Chapter 5. Table 5.12-1 summarizes operational impacts and identifies measures and controls available to reduce or eliminate those impacts. As noted above for building-related impacts, most impacts from operations are considered SMALL and minimized through compliance with permit requirements and implementation of BMPs. Table 10.2-2 summarizes the operations-related impact determination for each resource, the mitigation and control measures available to reduce these impacts, and the remaining adverse impacts after mitigation and control measures are applied.

As noted in Table 10.2-2, seasonal fluctuations in water level resulting from operational use of cooling water from Belews Lake impact water recreators and aquatic biota along nearshore areas of the lake. Increased consumptive use of lake water results in a predicted minimum water level that is lower than that under modeled BCSS operational scenarios. Lake water-level drawdowns are noticeable during periods of increased drought severity but are not considered to be destabilizing. However, increased consumptive use of water extends the critical drought duration compared to the BCSS full generation scenario. Consumption of surface water from Belews Lake does not preclude the capacity of the lake to continue to provide a reliable source of cooling water in support of thermoelectric power generation.

Discharge flows in the Dan River adjacent to existing Outfall 006 result in localized changes in flow patterns, currents, and total flow, and operation of the MWIS results in minor effects to river discharge downstream. Unavoidable adverse effects on recreation in the Dan River are minor and localized. Hydrologic alterations in the river result in minor impacts to water availability for downstream water users. However, the capacity of these users, including the Town of Madison, to obtain water is not diminished provided they have implemented water supply systems capable of withdrawing water during minimum 7Q10 low flow conditions in compliance with 15A NCAC 18C.0403, as discussed in Section 5.2.2.1.2.1. Other unavoidable adverse impacts of operations on surface waters identified in Table 10.2-2 are localized and minimized through compliance with permit requirements and use of BMPs. Operation of the Project results in unavoidable physical impacts, impacts to community infrastructure, and air quality that are minimized through compliance with permit requirements and use of BMPs, where appropriate. These impacts include air emissions, an increase in noise levels from cooling tower operation, minimal physical deterioration of roadways providing access to the Project site, and noticeable visual intrusions from the presence of plant structures and cooling tower plumes. Commuting workers and operational traffic increase traffic on roadways and intersections providing access to the Project site. Fluctuating water levels, noise, and visual intrusions affect recreation on Belews Lake, and operation of the MWIS results in limited effects on recreation in the Dan River.

Radiological exposure to the occupational workforce and the public from the release of gaseous and liquid effluents is within regulatory limits. Exposure to terrestrial and aquatic ecosystems from effluent releases is within the 0.1 rad/day (100 mrad/day) and 1 rad/day (1000 mrad/day) whole-body dose rate criteria from Table 2.2 of DOE-STD-1153-2002. Monitoring programs are implemented for the occupational workforce to maintain the annual occupational dose ALARA in compliance with 10 CFR 20.1101, and off-site monitoring is conducted to evaluate off-site exposure for members of the public and nonhuman biota.

Table 10.2-1
Unavoidable Adverse Environmental Impacts from Construction of the Project
(Sheet 1 of 12)

Resource Area	Summary Impact Determination	Mitigation Measures and Controls	Unavoidable Adverse Impact
4.1 Land-Use Impacts			
4.1.1 On-site Impacts	MODERATE	• Grade each Plant Complex area to balance earthwork cut and fill quantities to the greatest extent practical. • Dispose of all building material in accordance with federal, state, and local regulatory requirements. • BMPs for erosion and sedimentation control are developed and installed prior to building activities and will be maintained throughout construction. • Obtain appropriate county approvals for zoning as per Table 1.4-2. • Public access to Duke Energy-owned docks, landings, and launch ramps on Belews Lake will be restored after building activities are complete.	• Conversion of up to approximately 696 ac. (282 ha) of forested land to an industrial use. • Disturbance of approximately 906 ac. (367 ha). • Generation of general waste, metal waste, and equipment waste. • Conversion of prime farmland. • Discontinuation of hunting on the Project site. • Temporary disruption of public access to Duke Energy-owned docks, landings, and launch ramps on Belews Lake during building activities.
4.1.2 Off-site Impacts	SMALL	• BMPs for erosion and sedimentation control are developed and installed prior to building activities and will be maintained throughout construction.	• None.

Table 10.2-1
Unavoidable Adverse Environmental Impacts from Construction of the Project
(Sheet 2 of 12)

Resource Area	Summary Impact Determination	Mitigation Measures and Controls	Unavoidable Adverse Impact
4.2 Water Resources			
4.2.1 Hydrologic Alterations			
Surface Water	SMALL	• Implement avoidance, minimization, and mitigation measures in accordance with CWA Section 402 and 404 permitting by NCDEQ and U.S. Army Corps of Engineers (USACE), respectively. • Implement BMPs to stabilize soils, control sedimentation and stormwater flows, and remove construction debris to minimize indirect impacts to streams outside the NDA. • Implement a stormwater management system that complies with regulatory requirements for site design. • Comply with NCDEQ permit for land disturbance and stormwater management. Implement BMPs and USACE 404 permit at completion of building activities. • Use temporary features to facilitate building and/or protect water quality during construction. These features will comply with relevant regulations, agency approvals, and typical standards for construction related to erosion control and sedimentation. • Use erosion control measures (such as riprap) placed in proximity to the building area.	• Direct effects on up to approximately 16,875 linear ft. (5144 linear m) of streams and associated functions on the Project site and 100 linear ft. (30.5 m) within the associated off-site wastewater pipeline. • Indirect effects to the function of up to approximately 1256 linear ft. (323 linear m) of portions of streams that extend outside the NDA to the confluence with Belews Lake. • Effects to local stormwater drainage patterns from building activities within the NDA. • Localized and short-term increases in turbidity and sediment deposition and alteration of the Belews Lake shoreline and bottom associated with building intake and discharge structures. • Localized sediment disturbance and alteration of the Dan River associated with building outfall in discharge wastewater pipeline corridor. • Alteration of floodplains from installation of the wastewater pipeline.

Table 10.2-1
Unavoidable Adverse Environmental Impacts from Construction of the Project
(Sheet 3 of 12)

Resource Area	Summary Impact Determination	Mitigation Measures and Controls	Unavoidable Adverse Impact
		• Obtain and comply with site-specific terms of USACE permit for placement of fill. • Use BMPs to minimize impacts from use of heavy equipment in the floodplain and revegetate or rehabilitate the floodplain after installation of the wastewater pipeline.	
Groundwater	SMALL	• No mitigation measures or controls needed.	• Localized changes in groundwater levels from dewatering during excavation. • Reduced infiltration and groundwater recharge in the immediate area of new impervious surfaces.
4.2.2 Water Use Impacts			
Surface Water	SMALL	• Specific measures and controls are not needed.	• Use of surface water for concrete mixing, dust suppression, and other building-related activities.
Groundwater	SMALL	• No mitigation measures or controls needed.	• None.
4.2.3 Water Quality Impacts			
Surface Water	SMALL	• Use BMPs in addition to compliance with conditions in an NCDEQ-issued CWA Section 402 permit and other controls to protect affected water bodies. • Use BMPs to minimize erosion and sedimentation and establish and implement a SWPPP. • Comply with NCDEQ NPDES general construction permit requirements to discharge stormwater associated with building activities and implement an SWPPP.	• Erosion and sedimentation associated with impacts to and alteration of on-site streams, Belews Lake, and the Dan River from building activities. • Stormwater runoff from building activities.

Table 10.2-1
Unavoidable Adverse Environmental Impacts from Construction of the Project
(Sheet 4 of 12)

Resource Area	Summary Impact Determination	Mitigation Measures and Controls	Unavoidable Adverse Impact
		• Establish and implement an SPCC Plan for construction practices. • Use best construction practices to maintain equipment and prevent spills and leaks.	
Groundwater	SMALL	• Comply with NCDEQ NPDES permit to discharge water from groundwater dewatering associated with building activities. • Establish and implement an SPCC Plan for construction practices.	• None.
4.3 Ecological Resources			
4.3.1 Terrestrial Ecosystems and Wetlands	MODERATE	• Use erosion controls and follow BMPs to control erosion from disturbed land and reduce impacts to nearby waters. • Conduct periodic monitoring and control measures. • Minimize or avoid tree clearing during nesting season from April to July or use Duke Energy compliance recommendations. • Minimize the amount of nighttime light, using downshielding, avoiding landscape lighting features, and using only low-pressure sodium, high-pressure sodium, or light-emitting diode light sources. • Comply with NCDEQ and USACE 404 permit mitigation measures to achieve no net loss objectives.	• Direct impacts to terrestrial flora and fauna and habitat loss due to building activities including land clearing, grading, excavation, and filling; displacement of wildlife and loss of less mobile fauna. • Direct impacts to 2.45 ac. (0.99 ha) of wetlands within the Project site and 0.26 ac. (0.11 ha) within the associated off-site wastewater pipeline area. • Indirect impacts to wetlands outside of the NDA associated with hydrologic alterations, erosion and sedimentation, encroachment of invasive species, and habitat function.

Table 10.2-1
Unavoidable Adverse Environmental Impacts from Construction of the Project
(Sheet 5 of 12)

Resource Area	Summary Impact Determination	Mitigation Measures and Controls	Unavoidable Adverse Impact
		• Implement BMPs, such as erosion and sedimentation controls that limit the transport of sediment to wetlands via stormwater, compliance with 33 CFR Part 332 Compensatory Mitigation for Losses of Aquatic Resources, which promotes the national goal of "no net loss" of wetland acreage and functions. • Implement tree-clearing restrictions or consult with USFWS and conduct surveys. Conduct culvert surveys. • Consult with USFWS regarding potential effects to the monarch butterfly if this species becomes federally listed. • Avoid disturbance within 660 ft. (201 m) of bald eagle nest during nesting season. Coordinate with the USFWS prior to construction and implement applicable conservation measures.	• Direct impacts to tricolored bat (proposed for federal listing as endangered) and foraging and roosting habitat due to clearing during building activities. • Impacts to foraging habitat on the Project site for the monarch butterfly (proposed for federal listing as threatened).

Table 10.2-1
Unavoidable Adverse Environmental Impacts from Construction of the Project
(Sheet 6 of 12)

Resource Area	Summary Impact Determination	Mitigation Measures and Controls	Unavoidable Adverse Impact
4.3.2 Aquatic Ecosystems	SMALL	• Comply with NCDEQ and USACE 404 permit guidelines. Use BMPs to control erosion and limit the amount of soil and sediment entering surface waters. Develop and implement a SWPPP for collection, mitigation, and control of stormwater runoff in accordance with state and federal regulations and permit requirements. • Designate storage areas for fuel and lubricants on the Project site that are equipped with appropriate spill containment measures in accordance with SPCC plans. • Use BMPs such as cofferdams, silt curtains, wattles, or turbidity curtains to contain and control sedimentation. Maintain approximate 100-ft. (30.5-m) vegetated buffer around Belews Lake. Shoreline stabilization and buffer zones are protective of native aquatic species and habitats. • Consult with USFWS and NCWRC regarding avoidance, minimization, and appropriate conservation measures.	• Direct impacts on aquatic biota in Project site streams as well as indirect impacts by flow alteration and increased sedimentation and turbidity from building activities. • Impacts to aquatic habitats and biota in Belews Lake due to dredging, increases in turbidity and sediment deposition during installation of intake and discharge structures and associated pipelines. • Impacts to Dan River habitat due to physical habitat alteration, direct effects to or avoidance of aquatic biota.

Table 10.2-1
Unavoidable Adverse Environmental Impacts from Construction of the Project
(Sheet 7 of 12)

Resource Area	Summary Impact Determination	Mitigation Measures and Controls	Unavoidable Adverse Impact
4.4 Socioeconomic Impacts			
4.4.1 Physical Impacts (includes noise, odors, dust, air pollution, physical transportation impacts, and visual intrusions)	SMALL to MODERATE	• Comply with Clean Air Act National Ambient Air Quality Standards and regulatory limits. • Use BMPs and properly maintain construction equipment and vehicles to control emissions. • Use BMPs to minimize dust generation and implement dust control measures by watering roadways and exposed areas. • Repair damage to public roads, markings, or signs caused by building activities to preexisting conditions or better in accordance with state and local requirements. • Maintain natural existing buffers to screen views of the Project site, including an approximately 100-ft. (30.5-m) wide vegetated buffer zone along the edge of the Project site. • Implement light shielding to the extent practicable.	• Vibration effects to off-site residences and structures from building-related blasting and equipment use below the threshold for risk of minor cosmetic damage to fragile buildings. • Increase in emissions of on-site gaseous and particulate pollutants from construction vehicles and equipment, delivery vehicles, and personal vehicles. • Increase in emissions of fugitive dust and fine particulate matter from earth-moving activities, concrete-batch plant operation, and vehicular traffic on recently disturbed areas or unpaved roads. • Deterioration of public roads used by Project-related traffic while building activities are ongoing. • Visual and aesthetic effects during building activities, including lighting for nighttime building and security.
4.4.2 Demographic Impacts	SMALL	• None.	• Potential effects related to in-migration of workers and their families.

Table 10.2-1
Unavoidable Adverse Environmental Impacts from Construction of the Project
(Sheet 8 of 12)

Resource Area	Summary Impact Determination	Mitigation Measures and Controls	Unavoidable Adverse Impact
4.4.3 Economic Impacts to the Community	MODERATE (Beneficial)	• None.	• None.
4.4.4 Community Infrastructure (includes transportation, housing, and public services)	SMALL to MODERATE	• Implement traffic management measures, including a traffic control mitigation plan. • Coordinate with the NCWRC, as appropriate, if construction of the cooling water intake and discharge structures impede use of Belews Lake or associated facilities, including marinas. • Maintain natural existing buffers to screen views of the Project site. • Implement light shielding to the extent practicable. • Access disruptions are mitigated by traffic management measures and a traffic control mitigation plan and restored when building activities are completed.	• Increased traffic on roads and intersections providing access to the Project site. • Disruption of recreational experience from building activities, including visual intrusions. • Increased user demand for recreational resources from in-migrating workforce and their families. • Possible access delays or disruptions because of increased traffic on local roadways and building activities. • Discontinuation of hunting on the Project site. • Increase in demand for public services from in-migrating individuals and their families.

Table 10.2-1
Unavoidable Adverse Environmental Impacts from Construction of the Project
(Sheet 9 of 12)

Resource Area	Summary Impact Determination	Mitigation Measures and Controls	Unavoidable Adverse Impact
4.5 Not Used[(a)]	N/A	• N/A	• N/A
4.6 Historic and Cultural Resources	SMALL to MODERATE	• Implement procedures for addressing inadvertent cultural resource discoveries per Duke Energy Cultural Resources Procedure. • Implement avoidance measures for any NRHP-eligible archaeological sites as required. • If required, develop Phase III data recovery investigations in coordination with NCSHPO for any NRHP-eligible archaeological site that cannot be avoided. • Consult with the NCSHPO, NCOSA, and Catawba Indian Nation and implement mitigative measures as appropriate, if previously unknown archaeological resources or human remains are discovered during any building activities. Human remains would be treated in accordance with all state and federal laws. • Conduct archival research on the cemetery, including its history and associated records. • Follow provisions regarding exhumation and repatriation provided by NC General Statute Chapter 65-106 as appropriate. • Develop cemetery relocation plan in consultation with NCSHPO that includes delineation of the cemetery boundaries, generation of cemetery maps, and completion of historical and genealogical research.	• Impacts to archaeological sites eligible for listing on the NRHP if avoidance is not possible. • Relocation of Branson Cemetery.

Table 10.2-1
Unavoidable Adverse Environmental Impacts from Construction of the Project
(Sheet 10 of 12)

Resource Area	Summary Impact Determination	Mitigation Measures and Controls	Unavoidable Adverse Impact
4.7 Air Resources	SMALL	• No further mitigation would be warranted beyond the mitigation strategies discussed for air emissions in Section 4.4.1 and row 4.4 of this table.	• Impacts from dust generated by land-clearing and building activities, emissions from heavy equipment and machinery, concrete-batch plant operations, and emissions from vehicles used to transport workers and deliver materials to and from the site.
4.8 Nonradiological Health	SMALL	• Implement the SPCC plan; conduct equipment maintenance and stabilize roads and soil stockpiles to minimize fugitive dust. • Adhere to NRC, OSHA, state, and Duke Energy safety standards and provisions for worker safety. • Implement worker safety training and require use of personal protective equipment. • Use common practices to mitigate noise, including noise reduction devices on heavy equipment and limiting driving speeds. • Implement traffic management measures including a traffic control mitigation plan.	• Noise levels above 65 dBA at nearby sensitive residential and recreational receptors. • Short-term and intermittent disruptive vibration levels. • Increased traffic on roads and intersections providing access to the Project site.
4.9 Radiological Health	SMALL	• None.	• Exposure to construction workers is within established regulatory limits.

Table 10.2-1
Unavoidable Adverse Environmental Impacts from Construction of the Project
(Sheet 11 of 12)

Resource Area	Summary Impact Determination	Mitigation Measures and Controls	Unavoidable Adverse Impact
4.10 Nonradioactive Waste Management			
4.10.1 Impacts to Land	SMALL	• Implement policies and procedures under Duke Energy's Environmental Programs to properly manage waste to ensure safe handling and minimize environmental impacts. • Properly dispose of waste in accordance with federal, state, and local regulatory requirements. • Recycle metal waste and other materials to the fullest extent possible to reduce impacts on local municipal solid waste landfills and facilities. • Implement BMPs to minimize waste generation from on-site construction vehicles.	• Minor reduction in landfill capacity.
4.10.2 Impacts to Water	SMALL	• Implement an SPCC Plan and associated BMPs to minimize the occurrence of spills and limit their effects on surface water. • Adhere to the NCDEQ NPDES Construction Stormwater Permit requirements to minimize impacts from stormwater runoff into receiving water bodies. • Maintain portable sanitary facilities on-site and properly dispose of sanitary waste until a permanent connection to the sanitary waste treatment facility is functional.	• None.
4.10.3 Impacts to Air	SMALL	• Building-related emissions are typically limited to the vicinity. • Implement air emissions mitigation measures to ensure compliance with applicable regulatory limits defined by the National Primary and Secondary Ambient Air Quality Standards (40 CFR Part 50) and state and local regulations.	• Air emissions from building activities including gaseous pollutants and particulate matter.

Table 10.2-1
Unavoidable Adverse Environmental Impacts from Construction of the Project
(Sheet 12 of 12)

Note:

(a) Deleted (Executive Order, 2025a, 2025b).

Key: BMP = best management practice; CFR = Code of Federal Regulations; NCDEQ = North Carolina Department of Environmental Quality; NCOSA = North Carolina Office of State Archeology; NCWRC = North Carolina Wildlife Resources Commission; NDA = net disturbance area; NPDES = National Pollutant Discharge Elimination System; NRC = Nuclear Regulatory Commission; NRHP = National Register of Historic Places; OSHA = U.S Occupational Safety and Health Administration; NCSHPO = North Carolina State Historic Preservation Office; SPCC = Spill Prevention, Control, and Countermeasures; SWPPP = stormwater pollution prevention plan; USACE = U.S. Army Corps of Engineers; USFWS = U.S. Fish and Wildlife Service

Table 10.2-2
Unavoidable Adverse Environmental Impacts from Operation of the Project
(Sheet 1 of 13)

Resource Area	Summary Impact Determination	Mitigation Measures and Controls	Unavoidable Adverse Impact
5.1 Land-Use Impacts			
5.1.1 On-site Impacts	SMALL	• No mitigation measures or controls are needed.	• None.
5.1.2 Off-site Impacts	SMALL	• No mitigation measures or controls are needed.	• None.
5.2 Water Resources			
5.2.1 Hydrologic Alterations			
Surface Water	SMALL (MODERATE under drought conditions)	• Manage stormwater and minimize discharge of sediment and site runoff to Belews Lake through an engineered stormwater collection system and sediment and erosion control measures. • Comply with the requirements of the NCDEQ NPDES permit for discharge of stormwater associated with industrial activity. • Comply with the monitoring and BMP requirements from 15A NCAC 02H.1017 and incorporate these into future permitting and stormwater management operational programs as applicable. • Regulate supplemental pumping from the Dan River in conjunction with NCDEQ NPDES permitting requirements consistent with existing BCSS permitted conditions. • Regulate discharge flows in conjunction with NCDEQ NPDES permitting requirements.	• Minor hydrologic alterations, including flow patterns and sedimentation, where stormwater is discharged to Belews Lake. • Variable lake water levels and a lower predicted minimum level during operations compared to modeled BCSS operational scenarios as a result of increased consumptive use. Lake water-level drawdowns are noticeable during periods of increased drought severity but are not considered to be destabilizing. • Extended critical drought duration compared to the BCSS full generation scenario.

Table 10.2-2
Unavoidable Adverse Environmental Impacts from Operation of the Project
(Sheet 2 of 13)

Resource Area	Summary Impact Determination	Mitigation Measures and Controls	Unavoidable Adverse Impact
		• Install cautionary signage to mark outfall and intake locations in the Dan River for watercraft awareness.	• Localized and minor effects on flow and circulation patterns in Belews Lake as a result of intake, discharge, and MWIS operations. • Negligible sedimentation impacts on Belews Lake from sediment entrainment from the Dan River during MWIS operations. • Localized changes in flow patterns, currents, and total flow in the Dan River due to discharge adjacent to existing Outfall 006. • Minor hydrologic alterations in the Dan River from MWIS operations that affect river discharge downstream.
Groundwater	SMALL	• No mitigation measures or controls are identified due to limited affects.	• Reduced infiltration and groundwater recharge in immediate area of new structures and impervious surfaces.
5.2.2 Water Use Impacts			
Surface Water	SMALL	• Regulate intermittent discharge flows to the Dan River in conjunction with NCDEQ NPDES permitting requirements. • Comply with NPDES permit limits for water withdrawals from the Dan River.	• Belews Lake water use as supplemented by MWIS operation is increased compared to the BCSS Continuous Maximum Generation Condition. While water use is noticeable during periods of increased drought severity this water use

Table 10.2-2
Unavoidable Adverse Environmental Impacts from Operation of the Project
(Sheet 3 of 13)

Resource Area	Summary Impact Determination	Mitigation Measures and Controls	Unavoidable Adverse Impact
			does not preclude the capacity for Belews Lake to continue to provide a reliable source for cooling water in support of thermoelectric power generation; therefore, impacts on water use are minor. • Minor impacts to water availability and reliability for downstream water users along the Dan River.
Groundwater	SMALL	• No mitigation measures or controls are needed.	• None.
5.2.3 Water Quality Impacts			
Surface Water	SMALL	• Manage stormwater through an engineered stormwater collection system and sediment and erosion control measures. • Comply with NPDES permit requirements, maintain an operational SWPPP and SPCC, and implement stormwater BMPs. • Conduct thermal and chemical monitoring programs, as applicable, for surface water at the Project site and Dan River. • Mitigate water quality impacts by rapid mixing and adherence to NPDES permitting requirements in Belews Lake and by administrative and engineering controls as needed to meet NPDES requirements, monitoring programs, dilution effects, and mixing within the pipeline prior to mixing within the Dan River.	• Minor impacts to water quality in on-site streams from industrial stormwater. • Minor water quality impacts on Belews Lake from cooling tower blowdown, including temperature changes and constituents. • Localized, temporary impact on Belews Lake water quality from MWIS operation. • Minor water quality impacts in the Dan River from cooling tower blowdown and wastewater discharge, including temperature changes, nonradioactive liquid waste discharges, and radwaste.

Table 10.2-2
Unavoidable Adverse Environmental Impacts from Operation of the Project
(Sheet 4 of 13)

Resource Area	Summary Impact Determination	Mitigation Measures and Controls	Unavoidable Adverse Impact
Groundwater	SMALL	• Minimize potential for accidental spills by containment systems and established procedures in SPCC plan pursuant to Title 40 CFR Part 112 to minimize the release of constituents associated with accidental spills.	• None.
5.3 Ecological Resources			
5.3.1 Terrestrial and Wetland Impacts	SMALL	• Use BMPs including following the label-recommended pesticide/herbicide usage and application method and rates, only using licensed herbicide/pesticide applicators, maintaining ground cover in corridors, prohibiting herbicide usage around wetlands, and avoiding mowing and other heavy equipment operation within wetlands. • Monitor disturbed lands to identify and control areas that are dominated by invasive species. Control methods may include using pesticides/herbicides, hand-pulling, or mechanical treatment as applicable. • Implement an SPCC plan pursuant to 40 CFR Part 112 to minimize the release of constituents associated with accidental spills on wetlands. • Comply with the Migratory Bird Treaty Act. May use bird diverters and avian safe insulator assemblies to reduce the frequency of bird collisions and ensure reliable transmission system operation. • Schedule transmission line activities to minimize harm to pollinators when possible by limiting mowing to the fall or winter when flowers are not blooming. Incorporate mitigation measures to limit artificial light impact.	• Impacts to plant communities and wetlands from landscape maintenance activities such as pesticide/herbicide use and mowing within the Project site and off-site wastewater pipeline corridor. • Impacts to wildlife from operational noise. Noise sensitive wildlife are expected to avoid areas within the NDA and other habitats characterized by elevated noise levels. • Occasional bird collisions with tall structures. Bird collisions with nuclear power plant structures occur at rates that are unlikely to affect local or migratory bird populations. • Minor impacts to wildlife from transmission line maintenance due to the limited frequency of maintenance activities. Bird collisions with transmission lines may occur during operations.

Table 10.2-2
Unavoidable Adverse Environmental Impacts from Operation of the Project
(Sheet 5 of 13)

Resource Area	Summary Impact Determination	Mitigation Measures and Controls	Unavoidable Adverse Impact
		• Conduct mowing in the fall or winter when pollinator foraging habitat (flowers) are not blooming, controlling invasive species, and following the label-recommended pesticide/herbicide usage. • Update the Project site's existing Bald Eagle Nest Management Plan as appropriate.	• Minor impacts to wildlife from EMFs. • Limited impacts to pollinators from mowing, pesticide use, and artificial lighting. • Limited impacts on tricolored bat (*Perimyotis subflavus,* proposed for federal listing as endangered) from reduced habitat suitability, noise levels from cooling tower operations, and low risk of collision with tall structures. • Limited impacts on habitats that may be used as foraging habitats by monarch butterfly (*Danaus plexippus*, proposed for federal listing as threatened) and other pollinators. • Limited impacts to bald eagle (*Haliaeetus leucocephalus*) from behavioral effects associated with avoidance of developed high-activity areas and infrequent collisions with structures or powerlines.

Table 10.2-2
Unavoidable Adverse Environmental Impacts from Operation of the Project
(Sheet 6 of 13)

Resource Area	Summary Impact Determination	Mitigation Measures and Controls	Unavoidable Adverse Impact
5.3.2 Aquatic Impacts	SMALL (MODERATE under drought conditions)	• Comply with requirements of the site-specific NPDES permit for stormwater discharges and relevant federal, state, and local stormwater regulations. Implement stormwater BMPs. • Implement an SPCC plan pursuant to 40 CFR Part 112 to minimize the release of constituents associated with accidental spills. • Intake structure is designed to meet the impingement requirements in regulations adopted to implement Section 316(b) of the CWA. • Increase supplemental pumping from the MWIS in accordance with the limits established in the NCDEQ NPDES permit to mitigate the reduction in lake levels and near shore aquatic habitats and minimize potential effects related to water-level fluctuations. • Comply with thermal discharge limits required under the operational NCDEQ NPDES permit to limit adverse impacts to aquatic ecology. • Comply with NPDES permit requirements and use technologies and design features to minimize impacts of the MWIS and discharge operations. • Operate the intake structure in compliance with Section 316(b) of the CWA in regard to impingement and entrainment. • Comply with regulatory stipulations required under the operational NPDES permit to limit adverse impacts to aquatic ecology.	• Limited impacts to aquatic ecosystems in on-site streams from stormwater runoff. • Impingement and entrainment of organisms by the intake structure on Belews Lake and MWIS at the confluence of Belews Creek and the Dan River. A relatively small proportion of eggs, larvae, or adults of aquatic species are impacted. Minor proportions of populations are affected. • Impacts to aquatic biota along nearshore areas of Belews Lake from seasonal fluctuations in surface water levels and changes in water circulation patterns. Effects of lake water-level drawdowns are increased under modeled extreme drought conditions. • Minor, localized impacts to aquatic ecosystems in Belews Lake from thermal discharges. • Limited direct impacts to aquatic species in the Dan River from operation of the MWIS and wastewater discharge.

Table 10.2-2
Unavoidable Adverse Environmental Impacts from Operation of the Project
(Sheet 7 of 13)

Resource Area	Summary Impact Determination	Mitigation Measures and Controls	Unavoidable Adverse Impact
		• Design liquid waste processing systems and apply administrative and engineering controls to manage concentrations of constituents within effluents in compliance with the site-specific NCDEQ NPDES permit. • Consult with the USFWS, State of NC, and USACE and implement appropriate avoidance, minimization, and conservation measures to limit potential effects on proposed critical habitat for green floater for any activities related to maintenance or material removals at the MWIS.	• Localized loss of benthic habitat and loss of less mobile organisms during maintenance activities at the Dan River MWIS. • Minor water quality impacts on aquatic biota in Belews Lake and the Dan River associated with operational effluents. • Limited impacts to proposed critical habitat for green floater from maintenance activities at the MWIS that affect benthic habitat.
5.4 Socioeconomics			
5.4.1 Physical Impacts (includes noise, odors, dust, air pollution, physical transportation impacts, and visual intrusions)	SMALL to MODERATE (AESTHETICS)	• Manage air emission sources in accordance with federal, state, and local air quality control laws and regulations. • Maintain an approximate 100-ft. (30.5-m) vegetative buffer along most of the shoreline of Belews Lake.	• Minor effects from increase in noise level from cooling tower operation. • Air emissions, including dust, during operations do not exceed the NAAQS for criteria pollutants. • Minimal operations-related impacts on road conditions from physical deterioration.

Table 10.2-2
Unavoidable Adverse Environmental Impacts from Operation of the Project
(Sheet 8 of 13)

Resource Area	Summary Impact Determination	Mitigation Measures and Controls	Unavoidable Adverse Impact
			• Minor to noticeable, but not destabilizing, visual intrusions of structures and cooling tower plumes depending on the location of the observer and atmospheric conditions.
5.4.2 Demographic Impacts	SMALL	• None.	• None.
5.4.3 Economic Impacts to the Community	SMALL (beneficial)	• None.	• None.
5.4.4 Community Infrastructure Impacts (includes transportation, recreation, housing, and public services)	SMALL to MODERATE (RECREATION under drought conditions, AESTHETICS, and TRANSPORTATION)	• Implement relevant traffic management measures from building phase. • Regulate supplemental pumping from the Dan River in conjunction with NCDEQ NPDES permitting requirements consistent with existing BCSS permitted condition. • Work with the North Carolina Water Resources Commission to extend public boat ramps during low water conditions as necessary. • Post cautionary signage to minimize impacts on recreators. • Design discharge structure to be low profile to limit effects on recreators.	• Increased traffic on roadways and intersections providing access to the Project site. • Impacts to recreation on Belews Lake from fluctuating water levels, and visual intrusions. • Limited effects of the discharge structure on paddlers or recreators in the Dan River. • Limited effects on recreation in the Dan River during MWIS operations.

Table 10.2-2
Unavoidable Adverse Environmental Impacts from Operation of the Project
(Sheet 9 of 13)

Resource Area	Summary Impact Determination	Mitigation Measures and Controls	Unavoidable Adverse Impact
5.5 Not Used[(a)]	N/A	N/A	N/A
5.6 Historic and Cultural Resources	SMALL	• Comply with mitigative measures developed in consultation with the NCSHPO and NCOSA.	• Potential effects to undiscovered archaeological resources within the Project site if ground-disturbing activities occur outside of the NDA.
5.7 Air Resources	SMALL	• Conduct air dispersion modeling, if required, to demonstrate that Project emissions do not result in exceedances of the NAAQS. • Stagger work shifts, require delivery vehicles to shut down engines while off-loading, restrict idling times of on-site vehicles, use electric and hybrid vehicles, and support and promote van/carpooling and other commuter programs.	• Particulate emissions and plumes from MDCT. • Emissions from operation of auxiliary equipment (e.g., generators and auxiliary boilers), and mobile emissions from operations-related traffic. • Nominal localized increases in vehicular emissions. • Small lifetime GHG emissions footprint compared to annual GHG emissions in the state of NC. • Small emissions of ozone and smaller amounts of nitrogen oxides produced by transmission lines during corona discharges.

Table 10.2-2
Unavoidable Adverse Environmental Impacts from Operation of the Project
(Sheet 10 of 13)

Resource Area	Summary Impact Determination	Mitigation Measures and Controls	Unavoidable Adverse Impact
5.8 Nonradiological Health	SMALL	• Comply with discharge limitations established in the site-specific NPDES permit. • Comply with National Electrical Safety Code standards for transmission lines. • Adhere to Duke Energy's robust safety culture, established internal safety guides and procedures, and NRC requirements and Occupational Safety and Health Administration safety standards. • Implement traffic management mitigation measures identified in Section 4.4.4.1.	• Low potential for impacts from etiological agents. • Minor water quality impacts from operational and sanitary wastewater discharges. • Minor effects from the increase in noise level from cooling tower operation. • Minor human health effects from predicted increases in vehicle crash rates at intersections providing access to the Project site.
5.9 Radiological Health			
5.9.1 Exposure Pathways	SMALL	• None.	• Releases to the environment from gaseous and liquid effluents are within regulatory limits. • Exposure from direct radiation is negligible.
5.9.2 Radiation Doses to Members of the Public	N/A	• N/A	• N/A

Table 10.2-2
Unavoidable Adverse Environmental Impacts from Operation of the Project
(Sheet 11 of 13)

Resource Area	Summary Impact Determination	Mitigation Measures and Controls	Unavoidable Adverse Impact
5.9.3 Impacts to Members of the Public	SMALL	• Implement off-site monitoring in accordance with the radiological environmental monitoring program to evaluate off-site exposure.	• Exposure to the public from the release of gaseous and liquid effluents are within design objective of Title 10 CFR Part 50 Appendix I and within the regulatory limits of Title 40 CFR Part 190.
5.9.4 Occupational Doses to Workers	SMALL	• Develop monitoring programs for the occupational workforce to maintain the annual occupational dose ALARA in compliance with 10 CFR 20.1101.	• Occupational workforce exposure is within regulatory limits.
5.9.5 Impacts to Biota Other than Members of the Public	SMALL	• Implement off-site monitoring in accordance with the radiological environmental monitoring program to evaluate off-site exposure.	• Exposure to terrestrial and aquatic ecosystems from the release of gaseous and liquid effluents is within the 25 millirem per year whole-body limit prescribed by Title 40 CFR Part 190 and less than 100 mrad/day (threshold cited in NUREG-1555 per scientific literature).
5.10 Nonradioactive Waste Management			
5.10.1 Impacts to Land	SMALL	• Manage wastes in accordance with all applicable federal, state, and local requirements and standards and Duke Energy Environmental Programs' policies and procedures and dispose of wastes within landfills having sufficient capacity.	• Minor reduction in landfill capacity.

Table 10.2-2
Unavoidable Adverse Environmental Impacts from Operation of the Project
(Sheet 12 of 13)

Resource Area	Summary Impact Determination	Mitigation Measures and Controls	Unavoidable Adverse Impact
5.10.2 Impacts to Water	SMALL	• Control and monitor discharges associated with all liquid discharges (sanitary waste and liquid effluents) in accordance with NPDES permit requirements. • Manage stormwater discharges in accordance NPDES stormwater permit requirements and minimize discharges using BMPs.	• Discharge of sanitary wastewater to the Dan River. • Discharge of nonradioactive liquid effluent waste streams to Belews Lake or the Dan River. • Increased discharge of stormwater runoff from the Project site.
5.10.3 Impacts to Air	SMALL	• Manage and dispose of hazardous waste in accordance with the Resource Conservation and Recovery Act to minimize air emissions.	• Gaseous emissions from equipment associated with auxiliary systems such as diesel generators and auxiliary boilers would be within the NAAQS for criteria pollutants. • Particulate matter emissions from cooling towers. • Minimal air emissions from hazardous wastes.
5.11 Environmental Impacts of Postulated Accidents	SMALL	• The calculated dose consequences of design basis accidents at the Project site were found to be within regulatory limits. • The calculated probability-weighted dose risk of severe accidents at the Project site were found to be less than the maximum, median, and mean dose risk for current operating reactors and the individual prompt and latent cancer fatality risks are below the NRC safety goals.	• Radioactive releases and doses comply with regulatory limits.

Table 10.2-2
Unavoidable Adverse Environmental Impacts from Operation of the Project
(Sheet 13 of 13)

(a) Deleted (Executive Order, 2025a, 2025b).

Key: ac. = acre; ALARA = as low as is reasonably achievable; BMP = best management practice; CFR = Code of Federal Regulations; CWA = Clean Water Act; ft. = feet; GHG = greenhouse gases; ha = hectare; m = meter; NAAQS = National Ambient Air Quality Standards; NCSHPO = North Carolina State Historic Preservation Office; NDA = net disturbance area; NPDES = National Pollutant Discharge Elimination System; NRC = U.S. Nuclear Regulatory Commission; NCOSA = North Carolina Office of State Archaeology; ROW = right-of-way; SPCC = spill prevention, control, and countermeasures; USACE = U.S. Army Corps of Engineers; USFWS = U.S. Fish and Wildlife Service

10.3 RELATIONSHIP OF SHORT-TERM USE OF THE ENVIRONMENT AND LONG-TERM PRODUCTIVITY

This section examines the relationship between the short-term use of environmental resources and the maintenance and enhancement of long-term environmental productivity. It compares the short-term benefits and uses of these resources for the generation of electricity with their potential long-term impacts on environmental productivity. For purposes of this analysis, the environmental impacts associated with the construction, operation, and timely decommissioning of the Project are considered short-term uses of the environment and long-term productivity is that which occurs beyond decommissioning.

Impacts that cease or could be reversed following decommissioning of the Project are considered short term because the affected resources would be restored to their role in supporting long-term productivity. These include short-term impacts to water resources; ecological resources; socioeconomics; air resources; and nonradiological health. Additionally, once the Project is decommissioned, use of radioactive materials ceases. Therefore, radiological health impacts also are considered short-term impacts.

Impacts that cannot be reversed or impacts that continue past decommissioning are considered long term. Long-term impacts associated with the Project consist of unavoidable adverse impacts or irreversible and irretrievable commitments of resources during building and operations. Such impacts include long-term impacts to land use, water resources, historic properties, and nonradioactive waste management, and commitment of materials, water, energy, and uranium fuel, as discussed in Section 10.4.

Production of carbon-free power in the Carolinas' service territory is the principal short-term benefit resulting from building and operation of the Project. As noted in Section 1.2.2, Duke Energy is responding to the requirements of North Carolina's House Bill 951 (HB951), which mandates net-zero emissions by 2050 (NCGA, 2021). The Project serves as a demonstration of advanced reactor technology as a viable option for production of carbon-free electricity in NC and elsewhere. In addition to the benefits to the electrical grid associated with reliable, carbon-free electricity generation, building and operation of the Project results in short-term economic benefits to households, other businesses, and local governments in the local area and Project Region through employment, expenditures, and tax revenues. These short-term benefits offset the long-term impacts to the environment from building and operation of the Project. Furthermore, the economic productivity of the Project site, when used for electricity generation, would be considerably larger than the economic productivity from other probable long-term uses for the site, including forested open space, agriculture/forestry, recreational use, and rural residential use (see Section 5.4.3.1).

10.4 IRREVERSIBLE AND IRRETRIEVABLE COMMITMENTS OF RESOURCES

The predicted irreversible and irretrievable commitment of resources that will be involved with the construction and operation of the reactor units and associated facilities are described in this section. The phrase “irreversible commitments of resources” refers to environmental resources that are irreparably changed by building or operation activities and could not be restored to their present status by practical means at some later time. “Irretrievable commitments of resources” applies to material resources that, when used by construction or operation, cannot by practical means be recycled or restored for other uses. The commitment of resources summarized in this section are discussed in Chapters 4, 5, and 6.

10.4.1 IRREVERSIBLE COMMITMENTS OF RESOURCES

In the building and operation of any electric-generating station, few environmental resources are irreversibly committed to the facility beyond its operational life. Most commitments of environmental resources at or in proximity to the Project site that were identified for the building, operating, and decommissioning phases could be restored after the closure and decommissioning. No irreversible commitments of environmental resources were identified for the following resource areas discussed in Chapters 4, 5, and 6: terrestrial ecosystems and wetlands; aquatic ecosystems; socioeconomic resources (including physical impacts, demographic impacts, economic impacts to the community, and community infrastructure); air resources; nonradiological health; and radiological health. Impacts to these resources during building activities and operations are within regulatory or permitted thresholds, as applicable. Following closure and decommissioning, impacts to these resources cease, and the resource could be restored or used for other uses, as appropriate.

The irreversible commitments of resources resulting from the building and operation of the Project are discussed below.

10.4.1.1 Land-Use Impacts

Up to approximately 906 ac. (367 ha) of primarily forested land is disturbed and in industrial use during the operational life of the Project radioactive and nonradioactive wastes. Once the Project is decommissioned, the majority of the Project site could be used for future industrial or nonindustrial land use. However, construction of the Project results in irreversible commitment of on-site prime farmland soils. The Project site is not currently used for farming and, based on the Farmland Conversion Impact Rating form completed in consultation with the NRCS, impacts to prime farmland are expected to be minor. Land committed to the disposal of radioactive and nonradioactive wastes is committed to that use and cannot be used for other purposes.

Development of an ISFSI is being considered at the Project site to store spent fuel, which requires the irreversible commitment of land resources on the Project site. The size and location of the ISFSI is currently undetermined; however, this facility remains in place and operational following decommissioning, resulting in the irreversible commitment of land resources at the Project site. The ISFSI is governed by applicable regulations for regulated waste disposal facilities.

10.4.1.2 Water Related Impacts

Construction of the Project causes direct effects on up to approximately 16,875 linear ft. (5144 linear m) of streams on the Project site and 100 linear ft. (30.5 m) within the off-site wastewater pipeline, resulting in loss of these stream segments and functions. Construction also causes indirect effects to approximately 1256 linear ft. (323 linear m) of streams between the Project site and the confluence with Belews Lake. Avoidance, minimization, and mitigation measures, including compensatory mitigation, are implemented during building activities in accordance with Section 402 and 404 permitting issued by the NCDEQ and USACE, respectively. Additionally, following decommissioning, Project site topography and stormwater drainage patterns are restored to the degree practicable. However, this analysis assumes that streams on the Project site and their functions are irreversibly committed as a result of construction of the Project.

10.4.1.3 Historic Properties

Five sites within the APE were recommended as ineligible for listing on the NRHP and received concurrence from the NCSHPO. Four sites remain in consultation with the NCSHPO. Impacts to any NRHP-eligible archaeological site resulting from building activities are minimized through avoidance. If avoidance is not possible, archaeological mitigation including Phase III data recovery investigations will be developed in coordination with NCSHPO to address adverse effects to archaeological sites eligible or listed under Criterion D. Building activities result in impacts to Branson Cemetery which is determined to be ineligible for NRHP inclusion. Duke Energy has undertaken work to conduct archival research with respect to Branson Cemetery, including its history and associated records. Duke Energy plans to remove all graves in Branson Cemetery and relocate them to a new burial ground in accordance with an approved cemetery relocation plan that includes delineation of the cemetery boundaries, generation of cemetery maps, and completion of historical and genealogical research. Provisions regarding exhumation and repatriation of human remains provided by North Carolina General Statute Chapter 65-106 will be followed as appropriate.

Building activities at the Project site and operation of the Project may result in irreversible commitment of undiscovered archaeological resources as a result of ground-disturbing activities. Consistent with Duke Energy Cultural Resources Procedures, if an inadvertent discovery of a cultural resource (e.g., graves or grave sites, archaeological sites, historical artifacts, etc.) is made, then appropriate mitigative measures to address potential effects to these previously unknown cultural resources will be developed in consultation with the Catawba Indian Nation, NCSHPO, and NCOSA. Mitigation could include Phase III data recovery and repatriation of any Native American human remains, funerary objects, sacred objects, or objects of cultural patrimony. Any remaining in situ cultural resources associated with previously undiscovered archaeological sites could be irreversibly committed during construction or operation of the Project if those sites cannot be avoided.

10.4.1.4 Nonradioactive Waste Management

Nonradioactive wastes generated by the building, operation, and decommissioning of the Project require the irreversible commitment of disposal capacity at off-site disposal facilities. Solid, hazardous, and mixed waste generated during all phases of the Project that cannot be recycled is disposed of in licensed landfills having sufficient capacity, resulting in the irreversible

commitment of disposal space at these facilities. Disposal facilities used for nonradioactive wastes are governed by applicable regulations.

10.4.2 IRRETRIEVABLE COMMITMENTS OF RESOURCES

Construction of multiple advanced reactors on the Project site requires use of building materials that are considered irretrievable commitments of resources unless they are recycled when the plant is decommissioned. Construction materials used for the plant are expected to be similar to previous nuclear projects and similar to those required for any major, multiyear construction project. However, the actual commitment of construction resources (e.g., concrete, steel, and other building materials) depends on the reactor design selected by Duke Energy in the application for a construction permit or combined license for the facility.

Irretrievable environmental commitments resulting from the Project include:

- Construction materials and irradiated materials
- Consumption of energy
- Consumption of uranium fuel

10.4.2.1 Construction and Irradiated Materials

Building activities require materials such as concrete, rebar, steel, cables, and piping. Because some of this material may be reused or recycled (if uncontaminated) or decontaminated for future use at decommissioning, the reused or recycled portion does not constitute an irretrievable commitment of resources. However, throughout the operational life of the Project, some materials may become contaminated or irradiated, and therefore, cannot be reused or recycled. Radioactive waste created during the operation and decommissioning of the Project is routinely collected and shipped off-site and is not considered an irretrievable environmental commitment. The types of construction materials used for most of the building of the Project are similar to those used for any major new construction project. The amount of such materials accounts for a relatively small incremental increase in the overall availability of such materials; therefore, even if this material is eventually disposed, use of these construction materials in such quantities is small with respect to availability of these resources on a larger scale.

10.4.2.2 Consumption of Fossil Fuels

During building, nonrenewable energy in the form of fossil fuels (i.e., gas, oil, and diesel) and electricity generated from fossil fuels is consumed to power vehicles and equipment. Fossil fuels are required during operation for ancillary equipment and vehicle use. The total energy consumed during building and operation is minimal compared to total fossil fuel consumption in the United States.

10.4.2.3 Consumption of Uranium

As described in Chapter 6, operation of the Project requires the mining and refining of uranium ores to produce and supply fuel for the nuclear reactors. Uranium fuel cycle impacts include irretrievable water and fuel consumption. At the end of its operational use, uranium fuel is

placed in long-term storage pending a decision by the U.S. government regarding recycling. This Environmental Report assumes that no recycling option is available, and that stored fuel is ultimately disposed of as spent fuel. Final disposal of spent fuel is an irretrievable commitment of resources; therefore, the depletion of uranium ores from operation of the Project is an irretrievable commitment of resources.

As of August 2023, the United States had 93 operating commercial nuclear reactors at 54 nuclear power plants (EIA, 2023a). Owners and operators of these plants purchased a total of 55.9 million pounds (25,800 tons) of uranium from U.S. and foreign suppliers in 2024(EIA, 2024). Uranium, the most commonly used fuel in nuclear power plants, is a common metal with economically recoverable reserves in the western United States, Canada, Central Asia, Africa, and South America (EIA, 2023b). The maximum anticipated market requirements for uranium, including contracted purchases of uranium and unfilled demand, for 2024 through 2033 are 433 million pounds of uranium (EIA, 2024). The availability of uranium ore and existing stockpiles of uranium combined with the availability of U.S. and foreign suppliers suggests that the addition of the Project as a consumer of uranium resources by itself does not result in a significant commitment of worldwide uranium resources.

10.5 ALTERNATIVES TO THE PROPOSED ACTION

Chapter 9 describes the alternatives considered for the Project site. This section provides a high-level summary of those alternatives.

10.5.1 NO-ACTION ALTERNATIVE

The No-Action Alternative, whereby the NRC does not issue an Early Site Permit (ESP) for the Project site is evaluated in Section 9.1. The No-Action Alternative would avoid no significant environmental impacts, because no such impacts are caused by site suitability determination. The No-Action Alternative would also prevent the following benefits:

- The resolution of siting and environmental issues before large investments of financial capital and human resources in new plant design and construction are made.
- The ability to bank a site on which a nuclear plant may be located.
- The resolution of issues related to the environmental impacts of construction and operation of new nuclear generation units constrained within the defined plant parameters.
- The facilitation of future decisions about whether to construct new nuclear power generation facilities at the proposed site.

Thus, the issuance of the ESP for the Project is preferrable to the No-Action Alternative. Given the planned retirement of the BCSS discussed in Chapter 1, Duke Energy would reasonably be expected to replace the power through other means and environmental impacts associated with new nuclear generation would not be avoided.

10.5.2 ENERGY ALTERNATIVES

This section is not required for an Early Site Permit Application.

10.5.3 ALTERNATIVE SITES

Alternative sites and the site selection process are discussed in Section 9.3. The Project site was selected on the basis of a standardized and comprehensive site selection study which considered relevant factors related to environmental acceptability, site safety engineering, and cost concerns. Five Candidate Sites were screened down to three locations that had or will have retiring coal-fired generation facility: the Project site, the NC-17 site, and the NC-19 site. The Project site was selected as the proposed site and the NC-17 site and the NC-19 site were selected as Alternative Sites. A separate Environmental Assessment was completed for the two Alternative Sites.

- The NC-17 site is an approximately 569 ac. greenfield site located in Person County, NC. The site is located near Hyco Lake, which functions as a cooling reservoir for the Roxboro Steam Station. The site is comprised of numerous hills and valleys with some slopes that exceed 30 percent grade. The site is comparatively less desirable to the

Project site because Duke Energy does not own all of the land required for a new nuclear generation plant.

- The NC-19 site is an approximately 976 ac. greenfield site located in Wake County, NC. The site is located near Harris Lake, which provides cooling water for Shearon Harris Nuclear Plant. The site is comprised of numerous hills and valleys with some slopes that exceed 30 percent grade. Duke Energy owns all of the NC-19 site. The NC-19 site has a higher population density in the vicinity of the site compared to the Project site.

The Project site was selected based on the comprehensive evaluation of the siting study. Multiple sites met the criteria for suitability; however, quantitative scoring and objective analysis indicated that the Project site was the most suitable for the new nuclear plant and therefore selected as the proposed site. Additionally, a separate environmental impact assessment was conducted for two potentially feasible Alternative Sites, which concluded that neither site is environmentally preferable to the Project site. Therefore, the Alternative Sites are not obviously superior to the Project site.

10.5.4 SYSTEM ALTERNATIVES

Alternatives to heat-dissipation systems and circulating water systems are evaluated in Section 9.4 in order to compare the environmental impacts of the proposed system to that of the selected alternatives.

10.5.4.1 Heat Dissipation

Once-through systems and closed-cycle systems, including natural draft cooling towers, dry cooling towers, wet-cooling towers, cooling pounds, and spray pods, were considered in the systems alternatives analysis. The alternative heat-dissipation systems considered are either not feasible or not an environmentally preferable alternative to MDCT for the Project site. Once-through cooling is not a suitable alternative, and the alternative closed-system cooling technologies are not preferable to MDCT technology.

10.5.4.2 Circulating Water System Alternatives

Only alternatives that are applicable to the Project site and are compatible with the proposed heat-dissipation system were considered in the circulating water system alternatives analysis. Alternative circulating water system components considered were either not able to support plant operation or were not an environmentally preferable alternative to the proposed design.

10.6 BENEFITS AND COSTS

10.6.1 BENEFITS

10.6.1.1 Power Supply Benefits

The deployment of advanced nuclear reactors at the Project site supports Duke Energy's strategy to meet growing energy needs while transitioning to carbon-free generation. This section summarizes the benefits related to the regional power supply.

Chapter 1 states that the Project site has a bounding gross electrical output of 2250 megawatts electric (MWe) with a total bounding thermal output of 6250 megawatts thermal (MWt).

As Section 1.2.2 notes, Duke Energy plans to retire over 8400 megawatts (MW) (8.4 gigawatts [GW]) of dispatchable coal-fired generation in the coming decades. This includes the BCSS, a 2220 MWe dual-fuel power generation facility capable of operating on both coal and natural gas. The Duke Energy 2023 Carolinas Resource Plan (CRP), as well as the 2025 Carolinas Resource Plan that was most recently submitted in October 2025, outlines the company's strategy to achieve carbon reduction and resource planning goals while meeting demand. The CRP is the framework for replacing aging coal plants in a manner that ensures economic benefits for the Carolinas, while meeting growing demand for clean energy. Over the next 15 years, Duke Energy projects a 35,000-gigawatt hours increase in electricity demand within North and South Carolina, further underscoring the need for reliable, carbon-free power.

The addition of baseload energy from advanced reactors at the Project site replaces baseload coal-fired generation from the BCSS with clean, reliable, carbon-free generation and helps maintain system reliability by providing baseload power in the Carolinas service territory.

10.6.1.2 Emission Reduction Benefits

Given concerns regarding climate change and carbon emissions, as well as emissions of sulfur oxides (SO_x), nitrogen oxides (NO_x), and particulates, nuclear power generation provides an important environmental benefit by reducing emissions of carbon and other pollutants, when compared to coal-fired and natural gas-fired plants. The operation of advanced reactor units at the Project site does not result in direct emissions of air pollutants associated with global warming and climate change (e.g., NO_x, SO_x, carbon dioxide) or methyl mercury. As described in Section 5.7.2, emissions associated with the Project are limited to relatively small amounts of criteria pollutants from auxiliary systems (including auxiliary boilers, diesel generators/gas turbines, and engine-driven emergency equipment) and workforce transportation, as well as particulate emissions from cooling towers.

Thus, the Project represents substantial emission reduction benefits compared to fossil fuel alternative power sources. As Section 1.2.2 describes the purpose and need of the Project includes replacing the existing coal and natural gas generation capacity with multiple advanced reactors, which will be integrated into the existing power grid. This transition to carbon-free energy will help meet growing demand for reliable, baseload power in the region of interest, while also addressing the critical need for reduced carbon emissions. The Duke Energy CRP is the framework for replacing aging coal plants in a manner that ensures economic benefits for the Carolinas, while meeting growing demand for clean energy. Duke Energy is also responding

to the requirements of HB951, which mandates net-zero carbon emissions by the year 2050 (NCGA, 2021).

10.6.1.3 Economic Benefits

Additional important benefits from the building and operation of the Project include socioeconomic effects such as increases in purchases of local and regional goods and services, local and regional direct and indirect employment, and tax revenues to local taxing jurisdictions.

As detailed in Section 4.4.3.1, economic benefits associated with building are linked to both direct expenditures, such as costs for materials, equipment, and labor, and indirect effects arising from the spending and purchases of goods and services by the workforce. The Economics and Statistics Division of the U.S. Bureau of Economic Analysis (BEA) provides Regional Input-Output Modeling System (RIMS II) regional multipliers for industry employment and earnings. The BEA RIMS II multipliers were obtained for the ROI (Rockingham, Stokes, Forsyth, and Guilford counties) and used to evaluate impacts on employment and economic output based on total employment and total expenditure for a single Plant Complex.

Based on the workforce needed for a single Plant Complex (2096 workers), building the Project results in the creation of approximately 1437 indirect jobs within the ROI. Most indirect jobs are service-related, and those jobs are filled by the existing workforce in the ROI. Some of these indirect jobs could benefit unemployed or underemployed workers in the ROI. Overall, based on Bureau of Labor Statistics labor force data, the combined approximately 3533 jobs (direct and indirect employment) represent 0.7 percent of the total labor force in the ROI.

As Section 4.4.3.1.2 notes, total building expenditures for the single Plant Complex are estimated to be approximately $5 billion. Applying the RIMS II multiplier for construction industry output to building expenditures results in a total economic output of approximately $9.3 billion across local industries. This includes goods and services produced in the ROI during the building phase and indirect effects related to worker spending. The economic impacts during building are conservatively analyzed based on a single Plant Complex (two advanced reactor units). However, as Duke Energy is evaluating reactor technologies that could lead to deploying multiple reactor units across three Plant Complexes, substantially greater economic effects within the ROI and Project Region are possible. While specialized nuclear materials are likely to be sourced from outside the Project Region, portions of the generic building material expenditures can be obtained in the ROI. These expenditures are primarily realized within the ROI, introducing billions of dollars into the economy and indirectly creating jobs that help reduce unemployment and provide opportunities for service-related industries.

Likewise, as described in Section 5.4.3.1.2, employment and purchases associated with the Project during operations also support employment in other sectors of the local economy. Based on the operations workforce needed for a single Plant Complex (339 workers), approximately 935 indirect jobs are created within the ROI. The combined approximately 1274 jobs (direct and indirect employment) represent 0.2 percent of the total labor force within the ROI.

Capital expenditures, the purchase of goods and services, and payment of wages and salaries to the operations workforce has a multiplier effect through an increase in business activity, particularly in retail and service industries. The in-migrating operations workforce and their families purchase goods and services from within the ROI, thereby creating an expanded

economic effect that results in an increase in business activity. For a single Plant Complex (two reactor units) payroll is estimated to be approximately $30.5 million annually, resulting in a total economic output of approximately $62.4 million across local industries annually. During the operations phase, the construction-related workforce that remains within the ROI is expected to earn salaries comparable to those received during the building phase, resulting in additional spending within the ROI.

As detailed in Sections 4.4.3.2 and 5.4.3.2, building and operations-related activities, purchases, and labor force expenditures generate tax revenues. The in-migrating building and operations workforces for one Plant Complex generate a minor increase in income tax revenue of $2.2 million during building and $1.2 million during operations, annually, compared to the revenue from the existing employed population in the ROI. Project activities have a multiplier effect on spending within the ROI that may result in new business developments. Therefore, there may be a minor increase in franchise taxes due to the indirect spending. Expenditures by the in-migrating workforce and their families on items subject to sales and use taxes lead to further increases in sales tax revenues in the ROI. Additionally, improvements made to the Project site suggest a potential increase in future property tax obligations; however, the exact amount of these obligations is currently unknown.

10.6.2 COSTS

The costs associated with new plant building and operation are broken down into internal and external costs. Internal costs are those expended by the applicant in support of the building and operation of a new plant and are generally expressed in monetary values. External costs are the environmental costs that result from the building and operation of the new plant, and are expressed in terms of monetary, quantitative, and qualitative values.

10.6.2.1 Internal (Monetary) Costs

10.6.2.1.1 Building Costs

Based on the methodology published in the Idaho National Laboratory (INL)'s Meta-Analysis of Advanced Nuclear Reactor Cost Estimations (INL, 2024), the capital cost for building a single Plant Complex is estimated to be approximately $5.1 billion, while the cost for a full build out of multiple reactor units across three Plant Complexes is estimated to be approximately $15.2 billion. This capital cost estimate includes pre-construction costs (e.g., land and land rights, permits and licensing, plant studies and reports), direct costs (e.g., structures and improvements, reactor systems, electrical equipment, initial fuel inventory), indirect services costs (e.g., factory and field indirect costs, factory and construction supervision, shipping and transportation, engineering services), and supplementary costs (e.g., taxes, insurance, fees).

10.6.2.1.2 Operation Costs

Based on the INL methodology (INL, 2024), annualized operational costs for a single Plant Complex are estimated to be approximately $148 million, while the estimate for operation of a full build out of multiple reactor units across three Plant Complexes is approximately $443 million annually. These estimates include nuclear fuel costs as well as non-fuel operation and maintenance costs such as plant staff salaries, insurance, regulatory fees, and

decommissioning and decontamination funding. All values are annual estimates in 2022 dollars and are not escalated for the anticipated start of operations.

10.6.2.2 External Costs

External costs are those environmental and societal costs that remain after mitigation and controls have been considered. The environmental impacts of building and operation of advanced reactors at the Project site are described in Chapters 4 and 5, respectively. Section 10.2 identifies unavoidable adverse impacts of the proposed action (i.e., impacts after consideration of proposed mitigation actions) and Section 10.4 identifies irreversible and irretrievable commitments of resources and materials. Table 10.6-2 summarizes these costs.

10.6.3 BENEFIT-COST BALANCE

Tables 10.6-1 and 10.6-2 summarize benefits and costs of the Project which are described in Section 10.1. As detailed in Sections 10.2 and 10.4, the external costs of plant building and operation are reduced by continuing efforts to avoid and minimize impacts to environmental resources. Design features, BMPs, permitting, controls, and mitigation measures reduce environmental impacts to SMALL or MODERATE. The benefits of the Project are significant with respect to power generation, carbon emission reduction, and economic benefits in the long-term of the licensing period. Therefore, the benefits of the Project are greater than the economic and environmental costs.

Table 10.6-1
Monetary and Nonmonetary Benefits of the Project

Category of Benefit	Description of Benefit
Power Supply	• Generates a bounding gross electrical output of 2250 MWe, with a total bounding thermal output of 6250 MWt.
Emission Reduction	• Reduced emissions of criteria pollutants such as SO_x, NO_x, and particulates when compared to coal-fired and natural gas-fired plants.
Economics	
Construction Workers	• Creation of approximately 3533 direct and indirect jobs over the building period.
Building Expenditure	• The total building expenditure results in an estimated total economic value added of approximately $9.3 billion across all local industries.
Operations Workers	• 339 full-time operations workers for one Plant Complex create an incremental increase of approximately 935 indirect jobs within the ROI for at least 40 years of plant operations.
Operations Earnings	• Payroll for operations workers for one Plant Complex results in a total economic output of approximately $62.4 million across local industries annually.
Taxes	• Increased tax revenue from individual income taxes ($2.2 million during building and $1.2 million during operations, annually), franchise taxes, sales and use taxes, and property taxes support improvements to public infrastructure and social services.

Table 10.6-2
Internal and External Costs of the Project
(Sheet 1 of 5)

Category of Cost	Description of Cost
Internal/Monetary Costs	
Building Costs	• Capital cost of approximately $5.1 billion for a single Plant Complex or approximately $15.2 billion for a full build out across three Plant Complexes.
Operation Costs	• Annualized operational costs of approximately $148 million for a single Plant Complex, or approximately $443 million for a full build out across three Plant Complexes.
External Costs	
Land Use	• Disturbance of approximately 906 ac. (367 ha) during building and conversion of up to approximately 696 ac. (282 ha) of forested land to industrial use. • Conversion of prime farmland. • Discontinuation of hunting on the Project site. • Temporary disruption of public access to Duke Energy-owned docks, landings, and launch ramps on Belews Lake during building activities.
Surface Water Alterations	• Loss of up to approximately 16,875 linear ft. (5144 linear m) of streams and associated functions on the Project site from fill activities and 100 linear ft. (30.5 m) within the associated off-site wastewater pipeline. • Indirect impacts to the function of up to approximately 1256 linear ft. (383 linear m) of portions of streams that extend outside the net disturbance area to the confluence with Belews Lake. • Effects to local stormwater drainage patterns from building activities within the NDA. • Minor hydrologic alterations, including flow patterns and sedimentation, where stormwater is discharged to Belews Lake. • Localized and short-term increases in turbidity and sediment deposition and alteration of the Belews Lake shoreline and bottom associated with building intake and discharge structures, and localized and minor effects on flow and circulation patterns in Belews Lake as a result of intake, discharge, and MWIS operations.

Table 10.6-2
Internal and External Costs of the Project
(Sheet 2 of 5)

Category of Cost	Description of Cost
	• Variable lake water levels and a lower predicted minimum level during operations compared to modeled BCSS operational scenarios as a result of increased consumptive use. Lake water-level drawdowns are noticeable during periods of increased drought severity but are not considered to be destabilizing. • Extended critical drought duration compared to the BCSS full generation scenario. • Negligible sedimentation impacts on Belews Lake from sediment entrainment from the Dan River during MWIS operations. • Localized sediment disturbance and alteration of the Dan River associated with building outfall in discharge wastewater pipeline corridor, and changes in flow patterns, currents, and total flow in the Dan River due to discharge adjacent to existing Outfall 006. • Minor hydrologic alterations in the Dan River from MWIS operations that affect river discharge downstream.
Groundwater Alterations	• Localized changes in groundwater levels from dewatering during excavation. • Reduced infiltration and groundwater recharge in the immediate area of new impervious surfaces.
Water Use	• Use of surface water for concrete mixing, dust suppression, and other building-related activities. • Increased cooling water use from Belews Lake, as supplemented by MWIS operation, compared to the BCSS Continuous Maximum Generation Condition. • Minor, localized effects on recreational use of the Dan River due to MWIS operation and discharge from wastewater pipeline. • Minor impacts to water availability and reliability for downstream water users along the Dan River.
Water Quality	• Erosion and sedimentation associated with impacts to and alteration of on-site streams, Belews Lake, and the Dan River from building activities. • Minor impacts to water quality from building activities and from industrial stormwater. • Minor water quality impacts on Belews Lake from cooling tower blowdown, including temperature changes and chemical constituents. • Localized, temporary impact on Belews Lake water quality from MWIS operation. • Minor water quality impacts in the Dan River from cooling tower blowdown and wastewater discharge, including temperature changes, nonradioactive liquid waste discharges, and radwaste.

Table 10.6-2
Internal and External Costs of the Project
(Sheet 3 of 5)

Category of Cost	Description of Cost
Terrestrial Ecology	• Direct impacts to terrestrial flora and fauna and habitat loss due to building activities including land clearing, grading, excavation, and filling; displacement of wildlife and loss of less mobile fauna. • Direct impacts to 2.45 ac. (0.99 ha) of wetlands within the Project site and 0.26 ac. (0.11 ha) within the associated off-site wastewater pipeline area. • Indirect impacts to wetlands outside of the NDA associated with hydrologic alterations, erosion and sedimentation, encroachment of invasive species, and habitat function. • Impacts to plant communities and wetlands from landscape maintenance activities such as pesticide/herbicide use and mowing within the Project site and off-site wastewater pipeline corridor. • Minor impacts to wildlife from operational noise; transmission line maintenance; electromagnetic fields; mowing, pesticide use, and artificial lighting, and occasional bird collisions with tall structures. • Direct impacts to tricolored bat (proposed for federal listing as endangered) and foraging and roosting habitat due to clearing during building activities, as well as limited impacts relating to reduced habitat suitability, noise levels from cooling tower operations, and low risk of collision with tall structures. • Impacts foraging habitat on the Project site for the monarch butterfly (proposed for federal listing as threatened). • Limited impacts to bald eagle from behavioral effects associated with avoidance of developed high-activity areas and infrequent collisions with structures or powerlines.
Aquatic Ecology	• Direct impacts on aquatic biota in Project site streams as well as indirect impacts by flow alteration and increased sedimentation and turbidity from building activities. • Impacts to aquatic habitats and biota in Belews Lake due to dredging, increases in turbidity and sediment deposition during installation of intake and discharge structures and associated pipelines. • Limited impacts to aquatic ecosystems in on-site streams from stormwater runoff. • Impacts to aquatic biota along nearshore areas of Belews Lake from seasonal fluctuations in surface water levels and changes in water circulation patterns during operation. Effects of lake water-level drawdowns are increased under modeled extreme drought conditions. • Impingement and entrainment of organisms by the intake structure on Belews Lake and MWIS at the confluence of Belews Creek and the Dan River. • Minor, localized impacts to aquatic ecosystems in Belews Lake from thermal discharges.

Table 10.6-2
Internal and External Costs of the Project
(Sheet 4 of 5)

Category of Cost	Description of Cost
	• Minor water quality impacts on aquatic biota in Belews Lake and the Dan River associated with operational effluents. • Impacts to aquatic species and benthic habitat in the Dan River from physical alteration during building or maintenance activities, operation of the MWIS, and wastewater discharge. • Limited impacts to proposed critical habitat for green floater from maintenance activities at the MWIS that affect benthic habitat.
Socioeconomics and Community Infrastructure	• Potential effects related to in-migration of workers and their families including increase in demand for public services and recreational resources. • Visual and aesthetic effects, including lighting for nighttime building activities and security, and visual intrusions of structures and cooling tower plumes. • Deterioration of public roads used by Project-related traffic. • Increased traffic on roads and intersections providing access to the Project site during building and operation. • Impacts to recreation on Belews Lake from fluctuating water levels, noise, and visual intrusions, as well as limited effects to recreation on the Dan River from the discharge structure and MWIS operations.
Historic and Cultural Resources	• Unavoidable impacts to Branson Cemetery. • Impacts to any NRHP-eligible archaeological sites if avoidance is not possible. • Potential effects to undiscovered archaeological resources within the Project site if ground-disturbing activities occur outside of the NDA.
Air Resources	• Impacts from dust generated by land-clearing and building activities, emissions from heavy equipment and machinery, concrete-batch plant operations, and emissions from vehicles used to transport workers and deliver materials to and from the site during building activities. • Particulate emissions and plumes from MDCT. • Emissions from operation of auxiliary equipment (e.g., generators and auxiliary boilers), and vehicular emissions. • Small lifetime GHG emissions footprint. • Small emissions of ozone and smaller amounts of nitrogen oxides produced by transmission lines during corona discharges.

Table 10.6-2
Internal and External Costs of the Project
(Sheet 5 of 5)

Category of Cost	Description of Cost
Nonradiological Health	• Noise levels above 65 dBA at nearby sensitive residential and recreational receptors during building activities. • Short-term and intermittent disruptive vibration levels during building activities. • Minor effects from the increase in noise level from cooling tower operation. • Low potential for impacts from etiological agents. • Minor water quality impacts from operational and sanitary wastewater discharges. • Predicted increases in vehicle crash rates at intersections providing access to the Project site.
Radiological Health	• Releases to the environment from gaseous and liquid effluents are within regulatory limits. • Exposure to the public, to occupational workforce, and to terrestrial and aquatic biota are within regulatory limits.
Nonradioactive Waste	• Minor reduction in landfill capacity during building. • Discharge of sanitary wastewater to the Dan River and of nonradioactive liquid effluent waste streams to Belews Lake or the Dan River.

I. INTRODUCTION

A. PURPOSE

The purpose of this Emergency Plan is to describe the provisions established by Duke Energy for responding to a radiological emergency at the Belews Creek, North Carolina (NC) site (Project site) and addresses emergency preparedness in support of the Duke Energy Early Site Permit Application (ESPA).

This Plan establishes the concepts, evaluation and assessment criteria, and protective actions that are necessary to limit and mitigate the consequences of potential or actual radiological emergencies. It has been prepared to establish the procedures and practices for management control over unplanned or emergency events that may occur at the Project site and considers the consequences of non-radiological emergencies such as security threats or breaches, fires, electrical system disturbances, and severe weather events.

To maintain consistency throughout the Duke Energy fleet, this Plan references applicable emergency preparedness processes that are described in EP-ALL-EPLAN, Duke Energy Common Emergency Plan, Revision 5. The Duke Energy Common Emergency Plan has been approved by the U.S. Nuclear Regulatory Commission (NRC) to support all the Duke Energy operating nuclear facilities in Safety Evaluation Report (SER) dated August 26, 2021 (NRC, 2021).

In accordance with 10 CFR Part 52 (b)(2)(i), this Plan provides major features of the emergency plan. This Plan describes a performance-based emergency preparedness program and addresses pertinent requirements and associated guidance contained in 10 CFR 50.160, “Emergency Preparedness for Small Modular Reactors, Non-Light Water Reactors, and Non-Power Production or Utilization Facilities” and Regulatory Guide 1.242, “Performance-Based Emergency Preparedness For Small Modular Reactors, Non Light-Water Reactors, and Non-Power Production Or Utilization Facilities”. 10 CFR 50.160 and guidance contained in Regulatory Guide 1.242 provide a technology-inclusive, risk-informed, and consequence-oriented emergency preparedness approach for SMRs and non-light water reactors (non-LWRs). This Plan has been developed based on design and site-specific information; and provides sufficient information to ensure compatibility of the proposed emergency plan for on-site areas with facility design features, site layout, and site features. A glossary with a list of abbreviations, acronyms, and definitions to support this Plan is located in Appendix 1.

In the development of this Plan, Duke Energy has considered the applicable guidance provided in the following documents:

- Regulatory Guide 1.242, Revision 0, “Performance-Based Emergency Preparedness For Small Modular Reactors, Non-Light Water Reactors, And Non-Power Production Or Utilization Facilities” (RG 1.242).
- Regulatory Guide 1.101, Revision 6, “Emergency Planning and Preparedness for Nuclear Power Reactors” (RG 1.101).
- NUREG-0654/FEMA-REP-1, Revision 2, “Criteria for Preparation and Evaluation of Radiological Emergency Response Plans and Preparedness in Support of Nuclear Power Plants” (NUREG-0654).
- Section 13.3 of Regulatory Guide 1.70, Revision 3, “Standard Format and Content of Safety Analysis Reports for Nuclear Power Plants” (RG 1.70).
- Section 13.3 of NUREG-0800, “Standard Review Plan for the Review of Safety Analysis Reports for Nuclear Power Plants” (NUREG-0800).

Additional references to support development of this Plan are described in Appendix 2.

The NRC requires a level of emergency preparedness commensurate with the potential consequences to public health, safety, common defense, and security at the Project site.

The Project site Radiological Emergency Preparedness Program consists of the Emergency Plan, Emergency Plan Implementing Procedures (EPIPs), and associated program administrative documents. The Plan outlines the basis for response actions that would be implemented in an emergency. The EPIPs are maintained separately and are used to guide those responsible for implementing emergency response actions. They are designed to ensure emergencies are properly evaluated, notifications are made, and assessment of on-site protective actions is performed. Plant operating procedures for abnormal and emergency operation and control are in place and are designed to ensure implementation of the EPIPs but are not included in the EPIPs. A typical list of EPIPs and supporting procedures is provided in Appendix 3. Specific EPIPs will be developed to support implementation of the Emergency Plan when Duke Energy determines a design technology for the site.

B. SCOPE

As discussed in Site Safety Analysis Report (SSAR), Section 13.3 of this ESPA, when Duke Energy makes its technology selection for the Project site, the selected reactor technology vendor will be required to provide a confirmatory acceptance analysis at the permit or license application stage. This analysis will confirm that the public dose, as defined in 10 CFR 20.1003, does not exceed the limit of 10 mSv (1 rem) total effective dose equivalent (TEDE) over 96 hours from the release of radioactive materials from the facility considering accident likelihood and source term, timing of the accident sequence, and meteorology per 10 CFR 50.33(g)(2). This will result in the plume exposure pathway Emergency Planning Zone (EPZ) being within the aggregate of the three-plant complex Exclusion Area Boundaries (EABs) identified in Figure I-1. The analysis will be performed in accordance with the methodology described in Regulatory Guide 1.242, Appendices A and B. With the plume exposure pathway EPZ located within the EABs, evacuation of the public during the first 96 hours of the accident is not required. The overall scope of this Plan delineates the actions necessary to safeguard on-site personnel (within the EABs) and minimize damage to property.

This Plan provides information regarding emergency preparedness and response planning and describes organizational responsibilities, capabilities, actions, and guidelines for Duke Energy during a radiological emergency. This Plan describes facility features, capabilities, equipment, and responsibilities and the processes Duke Energy will use to:

- Detect an emergency condition.
- Evaluate the severity of the problems.
- Notify applicable off-site agencies of the emergency condition.
- Activate emergency organizations.
- Evaluate possible off-site consequences, if applicable.
- Mitigate the consequences of the emergency.

Because Duke Energy's authority is limited to Duke Energy owned and controlled property, the state and county agencies are responsible for ordering and implementing actions off-site to protect the health and safety of the public, as necessary. As addressed in the Federal Emergency Management Agency (FEMA) Comprehensive Preparedness Guide 101, "Developing and Maintaining Emergency Operations Plans" (CPG-101), if determined appropriate, government officials may utilize a Comprehensive Emergency Management Plan (CEMP) approach to emergency planning to implement ad hoc protective actions to protect the public beyond the Duke Energy owned and controlled property. The FEMA all hazards approach combines emergency management, technical assistance, and resources for both radiological and non-radiological emergencies (FEMA, 2021).

This Plan serves to limit damage to facilities and property and provides for the restoration of facilities in the event of an emergency. This Plan does not provide guidance for actual plant equipment manipulations. These instructions are contained in site-specific normal and emergency operating procedures, as required by technical specifications and other regulatory guidance. This Plan provides for maintenance of performance, identification and evaluation of emergency situations, protective measures, communications, command and control, emergency response facility staffing and operations, radiological assessment, public information, coordination with the safeguards contingency plan, drills and exercises, and training of emergency response personnel. A process for reentry from a declared emergency is also described in this Plan.

C. PLANNING BASIS

As described earlier, this Emergency Plan addresses pertinent requirements and associated guidance in 10 CFR 50.160 "Emergency Preparedness for Small Modular Reactors, Non-Light Water Reactors, and Non-Power Production or Utilization Facilities" and Regulatory Guide 1.242, "Performance-Based Emergency Preparedness for Small Modular Reactors, Non-Light Water Reactors, and Non-Power Production or Utilization Facilities."

This Plan has been written following a format similar to Regulatory Guide 1.242 to minimize the need for cross-referencing and to aid in the review process. Appendix 4 provides a cross-reference between information contained in the Plan and 10 CFR 50.160 requirements and Regulatory Guide 1.242 evaluation criteria.

This Plan provides information which is generic for six proposed design technologies.

D. SITE LOCATION AND DESCRIPTION

The Project site is located primarily in Sauratown Township, in the southeastern corner of Stokes County, NC, with a small portion in Belews Creek Township, Forsyth County, NC. All proposed nuclear units will be in Stokes County. The Belews Creek, NC Site, adjacent to Belews Lake, is approximately 14 miles (mi.) northeast of Winston-Salem, NC, and approximately 19 mi. northwest of Greensboro, NC. The total site is approximately 1187 acres (ac). Access to the project site is available by road using the Duke Power Steam Plant Rd, via Pine Hall Rd or Craig Rd, via State Highway 65.

The SSAR, Section 2, provides additional information regarding the physical characteristics of the proposed site, including the preliminary site layout, population distribution, and potential hazards in the site vicinity. The Environmental Report provides detailed information addressing land use and other features of the proposed site and surrounding area.

Figure I-1 provides a site layout map of the Project site depicting the proposed design technologies and site access.

E. PLUME EXPOSURE PATHWAY EMERGENCY PLANNING ZONE (EPZ) BOUNDARY

Duke Energy is developing a performance-based emergency preparedness program using 10 CFR 50.160 and applying for an Early Site Permit under 10 CFR Part 52. For SMR and Non-LWR applicants seeking an early site permit under 10 CFR Part 52 and complying with the performance-based approach in 10 CFR 50.160, the criteria for defining the plume exposure pathway EPZ are specified in 10 CFR 50.33(g)(2). Specifically, the plume exposure pathway EPZ is the area in which public dose is projected to exceed 1 rem TEDE over the first 96 hours from the release of radioactive materials from the facility, considering accident likelihood and source term, timing of the accident sequence, and meteorology. In addition, the plume exposure pathway EPZ is the area in which predetermined, prompt protective measures are necessary. Due to the state of the reactor designs of the technologies being considered in this ESPA, the analysis used to determine whether the criteria in 10 CFR 50.33(g)(2)(i)(A) and (B) are met, and if they are met, the size of the plume exposure pathway EPZ, is not available from the reactor technology vendors. When Duke Energy makes its technology selection for the Project site, the selected reactor technology vendor will be required to provide a confirmatory acceptance analysis at the permit or license application stage. This analysis will confirm that the public dose, as defined in 10 CFR 20.1003, does not exceed the limit of 10 mSv (1 rem) total effective dose equivalent over 96 hours from the release of radioactive materials from the facility considering accident likelihood and source term, timing of the accident sequence, and meteorology per 10 CFR 50.33(g)(2). This will result in the plume exposure pathway EPZ being within the aggregate of the

three-plant complex EABs identified in Figure I-1. The analysis will be performed in accordance with the methodology described in Regulatory Guide 1.242, Appendices A and B. With the plume exposure pathway EPZ located within the EABs, evacuation of the public during the first 96 hours of the accident is not required.

Figure I-1 identifies the EABs as the Plume Exposure Pathway EPZ for all proposed technologies.

F. INGESTION RESPONSE PLANNING

Although the Project site plume exposure pathway EPZ is bounded by the exclusion area boundaries, ingestion response planning is required to safeguard the food ingestion pathway in the unlikely event of a radiological release at the site. Due to the technological enhancements inherent in SMRs and Non-LWRs and stringent NRC operational guidelines, the probability of such a release is considered very low. In the event of a radiological release, the principal exposure sources would include contaminated water and food products such as milk or fresh vegetables.

While ingestion response is not required in the early phase of an emergency, longer-term concerns necessitate planning for intermediate and late-phase responses. Local, state, and federal resources support monitoring, analysis, interdiction, and embargo efforts when necessary to protect the food and water supply. As described earlier, state, and local governmental agencies in areas affected by a radiological release may implement a CEMP and rely on all- hazards planning frameworks for ingestion response (FEMA, 2021).

1. State of North Carolina and Counties

   Under the North Carolina Radiological Emergency Preparedness Plan (NCREP), the State assumes direction and control during the transition from early to intermediate phases of a radiological emergency. This shift is due to the complexity of recovery efforts, multiple affected jurisdictions, significant federal involvement, and broader economic consequences. County officials, as applicable depending on location of the radiological release, will actively participate in decision-making and provide local leadership and coordination. The State Emergency Response Team (SERT) will oversee the coordination of federal response.

   The NC Department of Agriculture and Consumer Services (NCDA&CS) is the lead agency for food safety, and the North Carolina Department of Environmental Quality (NCDEQ) is the lead agency for water safety with federal agencies supporting both.

   NCDA&CS has the authority to embargo contaminated food products to protect public health. As a part of the SERT, NCDA&CS will work with the state Radiation Protection Section (RPS) to identify areas requiring an embargo or restrictions. Areas subject to embargoes will initially be based on projected contamination and refined following sampling and analysis. Restrictions may be applied to crops in the field and processing plants in or serving potentially contaminated areas. County public health agencies from the affected county or counties will oversee restaurant and grocery store safety.

The Cooperative Extension Service (CES) from the affected county or counties will coordinate with the NCDA&CS and other state agencies to assess contamination risks to livestock, milk, feed, and crops. The CES will work with local farmers and NCDA&CS to determine processes for agricultural remediation and disposition of food/feed products with radioactive contamination identified above safe levels. A coordinated response among farmers, CES, and state agencies is essential to mitigate impacts on agricultural production.

The NCDEQ, Division of Water Resources, ensures public water system safety by working with local authorities to prevent radiologically contaminated source water from entering supplies. Public works departments will assess radiation levels in source water and determine if water treatment intakes require closure.

Other state agencies, including the Division of Marine Fisheries, Department of Game and Inland Fisheries, North Carolina Wildlife Resources Commission, and Food and Drug Protection Division will support ingestion response planning as needed.

2. Commonwealth of Virginia

Under the Commonwealth of Virginia Radiological Emergency Response Plan (COVRERP) and Emergency Operations Plan, the State of Virginia may provide similar ingestion response planning support if required.

The Department of Agriculture and Consumer Services obtains milk samples from dairy farms, meat samples from packing firms, and food samples from retail and wholesale establishments as requested and submits them for laboratory analysis. This agency also coordinates the control and disposition of radiologically contaminated food, milk, and animal feed and the disposition of farm animals affected by radiological contamination; and provides advice on and coordinates the disposition or use of farm crops, lands, and equipment that have been radiologically contaminated.

Additional State of Virginia agencies will provide ingestion response support as required.

3. Federal Resources

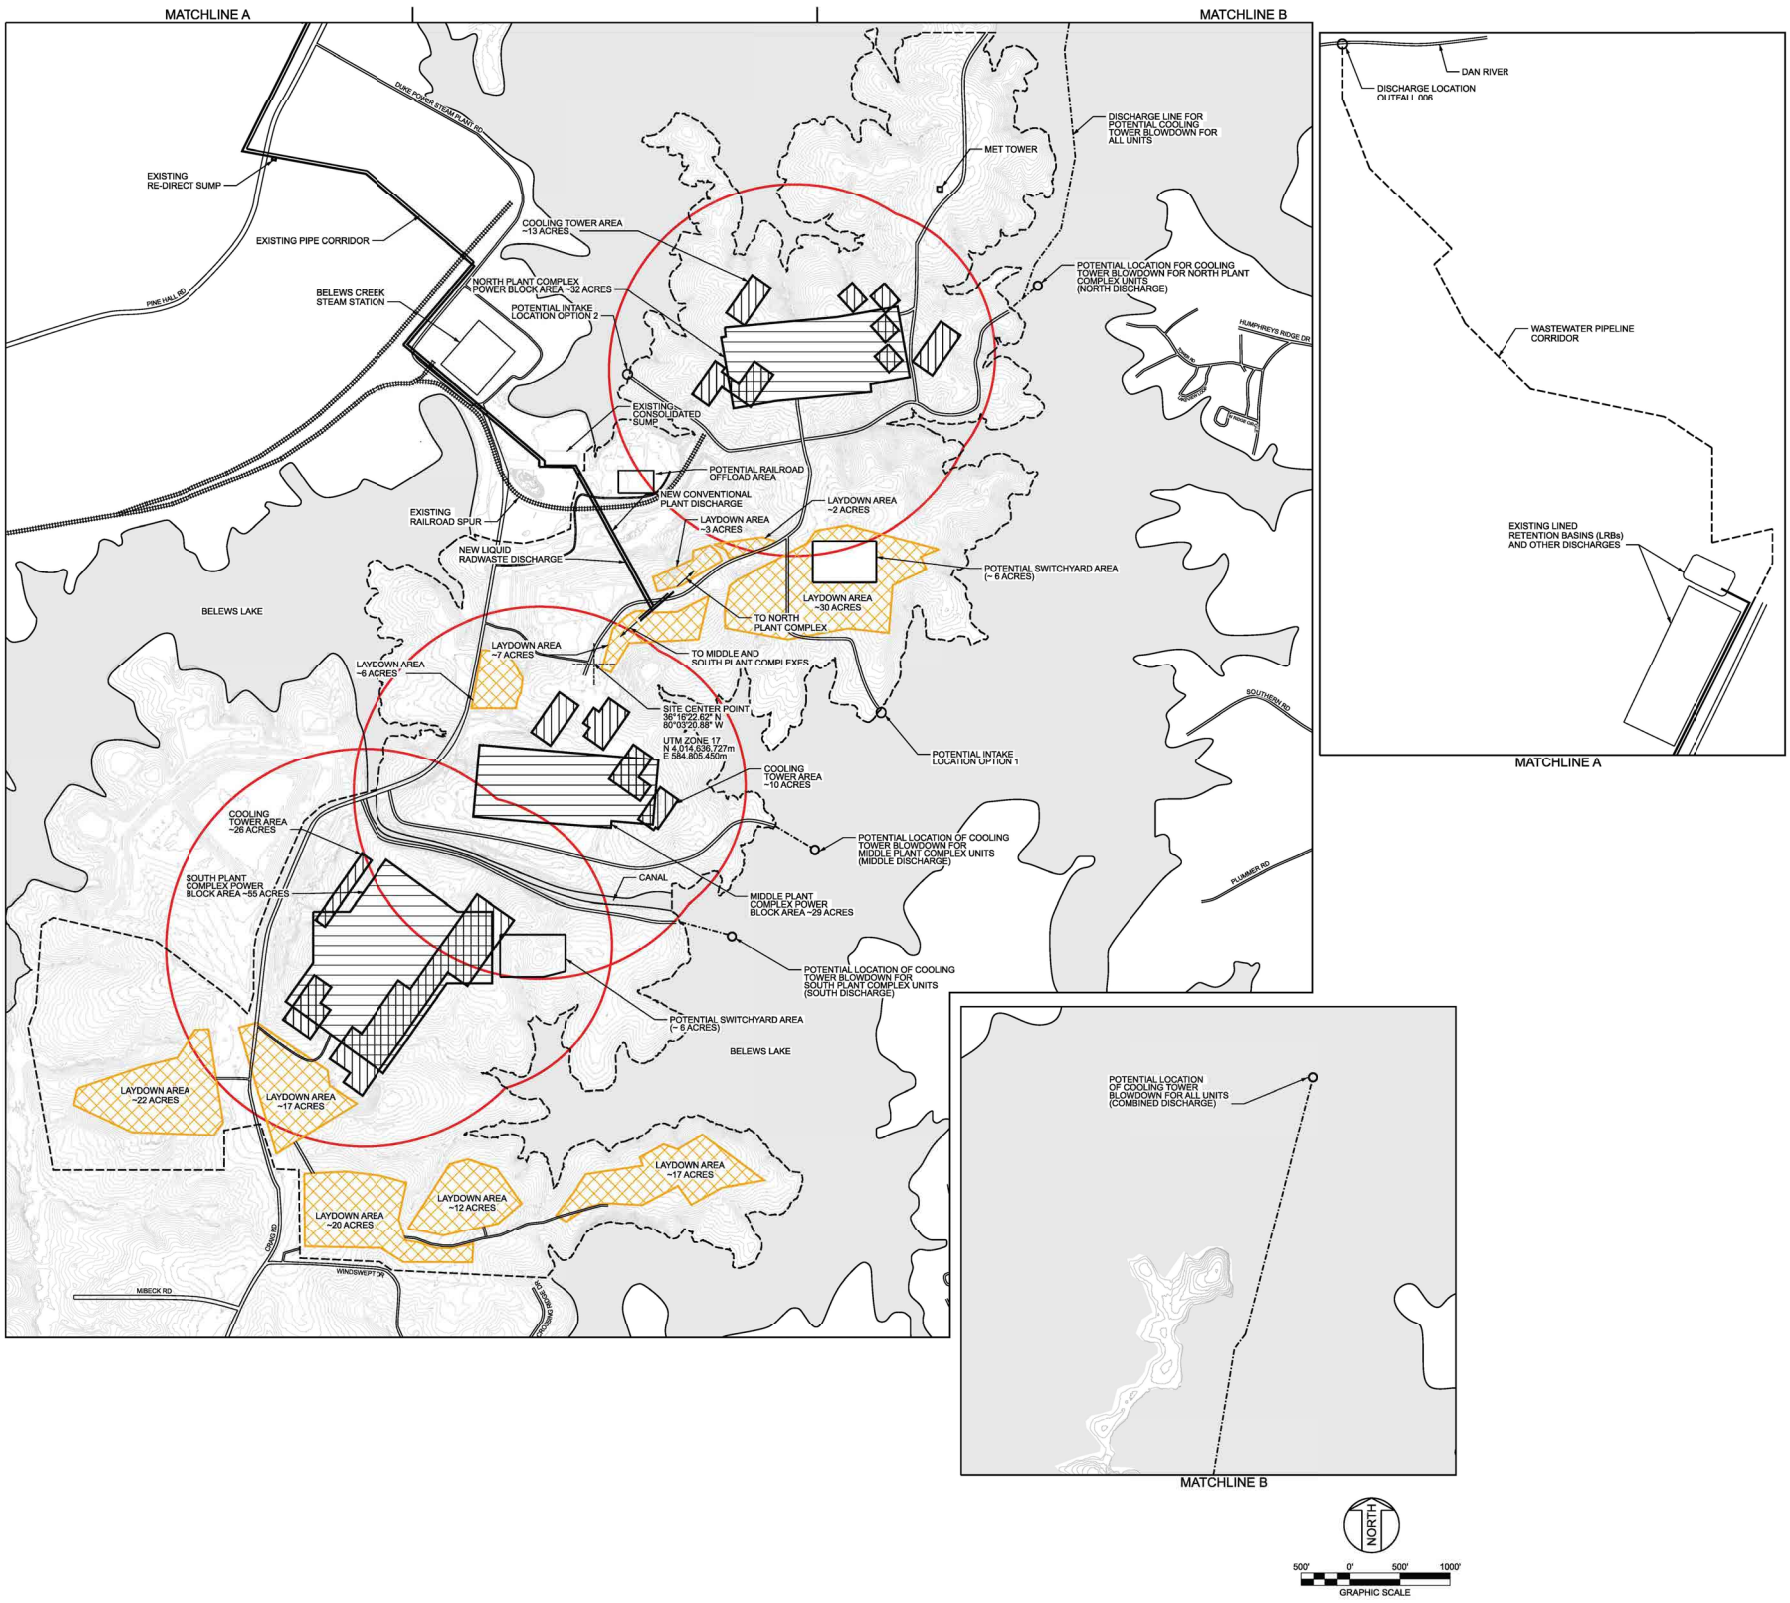
Federal resources are available to support radiological emergency event response, including events that may impact ingestion response planning. Federal resources include the Federal Radiological Monitoring and Assessment Center (FRMAC) and

the Advisory Team for Environment, Food and Health, as well as sampling and testing laboratories.

The FRMAC will assist the state lead agencies in efforts to preserve food and water safety and includes:

- U.S. Department of Agriculture.
- U.S. Environmental Protection Agency (USEPA).
- U.S. Food and Drug Administration (FDA).
- FEMA.

Figure I-1. Project Site Layout - Proposed Design Technologies



Legend:

- EXCLUSION AREA BOUNDARY (EAB)
- SITE BOUNDARY (NOTE 1)
- LAKEBED PIPING
- PROPOSED LAYDOWN AREA

Note 1: Total of the Site Boundary is approximately 1187 acres.

Note 2: Exclusion Area Boundaries (EABs) are also the location of the Plume Exposure Pathway Emergency Planning Zone (EPZ).

II. EMERGENCY MANAGEMENT ORGANIZATION / CONCEPT OF OPERATIONS

A. ASSIGNMENT OF RESPONSIBILITY

Under normal conditions, the Project site Vice President is in charge of activities at the site; and the Plant Manager is responsible for safe efficient operation of the plant.

In the event of an emergency or accident situation at the site, the Control Room shift crew under the direction of the Shift Manager coordinates emergency response activities. When an abnormal situation occurs, the Shift Manager using operating and emergency procedures and based on his/her background, training, and experience, determines whether the emergency conditions result in an Emergency Classification Level (ECL) of an Unusual Event, Alert, or Site Area Emergency (SAE). The Shift Manager assumes the role of Emergency Coordinator (EC) and directs emergency response from the Control Room. At an Alert or SAE classification, the Shift Manager augments the Emergency Response Organization (ERO) with on call personnel and initiate activation of the On-site Emergency Response Facility (OERF). When the OERF is staffed and declared operational, ERO members in the OERF relieve shift personnel of emergency response functions which are not directly associated with plant operations and provide technical support to the Control Room.

Staffing and primary responsibilities of Control Room and OERF personnel for emergency response functions are further described in Section III.G.

B. OFF-SITE AGENCY SUPPORT

In the event of a declared emergency at the Project site, the Federal, State, and local organizations described below can provide support as needed.

1. Federal

   Control, responsibility, and interface of federal organizations is governed by the National Response Framework (NRF) and the Nuclear/Radiological Incident Annex to the NRF when they are called to respond to an event at a nuclear power plant.

   The NRF provides the federal government's concept of operations for responding to radiological emergencies, outlines federal policies and planning assumptions, and specifies authorities and responsibilities of each federal agency that may have a significant role in emergency response.

   a. Nuclear Regulatory Commission (NRC)

      The NRC acts as primary authority for radiological events involving NRC licensed facilities and is the technical lead for the federal government's response to the event. The NRC maintains an Incident Response Plan (IRP) with objectives to provide for protection of the public health and safety, property, and the

environment from effects of radiological incidents that may occur at licensed facilities. The objectives of the agency plan set forth the organizational and management concepts and responsibilities needed to ensure that the NRC has an effective emergency response program. The NRC is prepared to recommend appropriate protective actions for the public and technical actions to the licensee. FEMA acts as the lead federal agency for off-site non-technical concerns.

During an incident, the Chairman of the Commission is the senior NRC authority for all aspects of a response. The Chairman transfers control of the emergency response activities to the Director of Site Operations when deemed appropriate.

All NRC Regions as well as Headquarters are prepared to respond to potential emergencies and have developed plans and procedures for responding to radiological incidents involving NRC licensees. Each Region and Headquarters has established and maintains an Incident Response Center designed to centralize and coordinate emergency response functions. Each Region is prepared to send a team of qualified specialists to the scene; and all necessary supplies and equipment needed for emergency response will be provided and maintained by the NRC. Adequate communications are established to link the licensee, Headquarters, and the Region. There are established lines of communications with state and local government and other federal agencies.

b. FEMA

Per the Federal Response Plan (FRP), FEMA is responsible for the overall coordination of a multi-agency federal response to a significant radiological incident. The primary role of FEMA is to support the state by coordinating delivery of federal non-technical assistance. FEMA coordinates state requests for federal assistance, identifying which federal agency can best address specific needs. If deemed necessary, FEMA will establish a Federal Response Center where it will manage assistance activities.

c. Department of Homeland Security (DHS)

DHS coordinates preparedness activities within the United States to respond to and recover from terrorist attacks, major disasters, and other emergencies. As part of these responsibilities, the Secretary coordinates with federal agencies to provide for federal unity of effort for domestic incident management.

d. U.S. Department of Energy (DOE)

In response to an event at a nuclear power plant and in cooperation with other federal and state agencies, DOE will manage the FRMAC to provide monitoring data and interpretations, including exposure rate controls, dose projections, and other requested radiological assessments to the primary authority and the states. DOE arranges consultation and support services through appropriate federal agencies to all other entities (e.g., private contractors). In cooperation with other federal and state agencies, DOE also provides personnel and equipment to perform radiological monitoring in support of other response activities, support for treatment of radiologically injured or contaminated personnel, and modeling for atmospheric dispersion.

If Duke Energy, the NRC, or the affected state(s) deem that assistance from DOE is necessary or desirable, the affected state(s) would notify the appropriate DOE operations office.

e. Federal Bureau of Investigation (FBI)

The FBI can provide support through its statutory responsibility based in Public Law and the U.S. code, and through a memorandum of understanding for cooperation with the NRC. Notification to the FBI of emergencies in which they would have an interest will be through provisions in the Project site's security plan, or by the NRC.

f. National Weather Service (NWS)

The NWS provides meteorological information during emergency situations, if required. Data available will include existing and forecasted surface wind directions, wind speed with azimuth variability, and ambient surface air temperature. There are NWS offices located in Greensboro, NC and Raleigh, NC.

g. U.S. Geological Survey (USGS)

The USGS maintains the National Earthquake Information Center (NEIC) which can be reached on the USGS website. The NEIC rapidly determines the location and size of all destructive earthquakes worldwide and immediately disseminates this information to concerned national and international agencies, scientists, and the general public. The NEIC is used as one of several sources to evaluate seismic events that may impact the site.

h. USEPA

The USEPA assists with field radiological monitoring/sampling and non-plant related recovery and reentry guidance.

2. State Organizations

If deemed necessary, Duke Energy coordinates emergency response actions with North Carolina state emergency response organizations. These organizations employ the National Incident Management System (NIMS) and the Incident Command System (ICS). Control, responsibility, and interface of the state organizations is governed by their respective emergency plans and emergency operating procedures. State organizations may become involved in ingestion response activities in the event of a radiological release at the site as described earlier in Section I.F.

The Governor has the authority to direct and control the state emergency management program which includes the responsibility for planning and ordering appropriate protective actions if applicable. During a declared state of disaster, the Governor has the authority to use all available state resources reasonably necessary to cope with emergencies. The Governor's representatives coordinate as necessary with Duke Energy and with county government officials.

The Department of Public Safety (DPS) functions as the state Emergency Management Coordinator and has overall management responsibility for radiological emergency response planning and development; updating the North Carolina Radiological Emergency Response Plan; and coordinating activities with Duke Energy. The Department coordinates emergency response activities for the State and other government response agencies. The Department through the State Highway Patrol, in conjunction with the North Carolina Division of Emergency Management, provides the initial 24-hour emergency notification point for the state.

The North Carolina Division of Emergency Management (NCEM) is the responsible organization within the DPS to prepare and maintain a State Radiological Emergency Response Plan for Duke Energy sites in coordination with the Departments of Environmental Quality (NCDEQ), NCDA&CS and NCDHHS and other interested agencies. The NCEM is the lead response agency with the state government and coordinates activities of the SERT at the State Emergency Operations Center (SEOC) in Raleigh. Personnel in the SEOC will confer with Duke Energy during an emergency event to determine appropriate emergency response activities if required.

The RPS is located within the NCDHHS and is the lead state agency for the collection and analysis of radiation monitoring reports and of environmental air, foliage, food, and water samples. The DPS is responsible for dose assessments and

projections and personnel radiological monitoring outside a Duke Energy site and other functions described in the state plan.

3. County Organizations

   County organizations may provide support during an emergency using their all hazards plans and/or emergency operations plans, including support for ingestion response planning (FEMA, 2021). The counties coordinate assistance and cooperation with related agencies in other counties, Duke Energy, state, and federal agencies. If deemed necessary, county Emergency Operations Centers (EOCs) may be activated to serve as the primary coordinating center for local government response within the county's jurisdiction and for coordination between counties.

   Off-site emergency response agencies may be called to the site for events requiring firefighting, medical, or law enforcement support as needed. If an emergency is due to a hostile action-based event, a near site Incident Command Post (ICP) may need to be established. Section IV.B of this Plan describes the set-up of an ICP and coordination between the site and off-site agencies.

4. Private Sector Organizations

   Contractor and private organizations may be requested to provide technical assistance during an emergency but are not used to provide additional personnel for positions on the ERO or perform an operational role.

   Duke Energy may obtain technical support from the reactor design technology vendor during emergencies and may procure other vendor support as needed.

III. PERFORMANCE BASED FRAMEWORK

A. MAINTENANCE OF PERFORMANCE

Duke Energy is required to demonstrate effective response in drills and exercises for emergency and accident conditions at the Project site and ensures this by assigning and training individuals at the site on their specific emergency response functions. Additional information describing the ERO Training Program is located in Section III.G.2. Drills and exercises provide opportunities to develop and maintain skills and test the effectiveness of the ERO to respond to events ranging from minor to severe accidents. Additional discussion on the drill and exercise program is in Section III.G.3.

B. PERFORMANCE MONITORING

A process is in place at Duke Energy for maintaining a performance monitoring program to demonstrate the effectiveness of the implementation of the Project site Emergency Plan to carry out effective response to emergency and accident conditions. Drills and exercises are used to train and to evaluate performance of the ERO. The Duke Energy Drill and Exercise Program identifies all objectives and evaluation criteria that may be used for a drill or exercise. Specific performance metrics and objectives for each of the emergency response functions have been developed and are used for evaluation to demonstrate capabilities to maintain and perform the emergency response functions described in 10 CFR 50.160 and Regulatory Guide 1.242 as described below:

- Event Classification and Mitigation - This metric measures the ability to assess, classify, monitor, and repair facility malfunctions in accordance with the emergency plan to return the facility to safe conditions.
- Protective Actions - This metric measures the ability to implement and maintain protective actions for on-site personnel for emergency conditions and recommend protective actions to off-site authorities as conditions warrant.
- Communications - This metric measures the ability to establish and maintain effective communications with the ERO and make notifications to response personnel and organizations who may have responsibilities for responding during emergencies.
- Command and Control - This metric measures the ability to establish and maintain effective command and control for emergencies by using a supporting organizational structure with defined roles, responsibilities, and authorities for directing and performing emergency response functions.

- Staffing and Operations - This metric measures the ability to establish staffing for the facility necessary to implement the roles and responsibilities defined in the emergency plan.
- Radiological Assessment - This metric measures the ability to assess radiological conditions in and around the facility during emergencies, including radiological conditions, protective equipment, core or vessel damage, and releases.
- Reentry - This metric measures the ability to develop and implement reentry plans for accessing the facility after emergencies.
- Critique and Corrective Actions - This metric measures the ability to evaluate drills and exercises (or responses to actual emergencies) to identify weaknesses or deficiencies in ERO performance and the EP program.

The objectives are scheduled for demonstration at no greater than 12-month intervals, and there are at least two demonstration attempts for the objective in an 8-quarter period. Types of activities in which objectives can be demonstrated; evaluation criteria and performance thresholds; guidance for determining acceptable performance; and a description of performance metrics (including updating and maintenance of metrics) are described in an emergency plan administrative procedure.

Duke Energy conducts post-activity critiques to identify performance weaknesses and deficiencies and captures these in a corrective action process. If a performance metric requires corrective action, Duke Energy conducts an activity to demonstrate the effectiveness of the corrective actions taken to improve performance as described in an emergency plan administrative procedure.

More discussion on the drill and exercise program is described in Section III.G.3.

C. EVENT CLASSIFICATION AND MITIGATION

Duke Energy has established the following three (3) ECLs at the Project site:

- Notification of Unusual Event (NOUE).
- Alert.
- SAE.

The emergency classifications are graded according to severity, and immediate actions are taken to cope with the situation. If conditions warrant, escalation to a higher class, or termination occurs during the course of an emergency.

Duke Energy uses a variety of methods to identify emergency situations and to categorize them. As indicated in the Project site EPIPs, emergencies can be caused by natural disasters such as tornadoes or floods, hazards such as aircraft crashes, releases of toxic gases or breaches of plant security, as well as conditions involving plant systems directly. An off-site chemical hazards survey has been performed to identify any hazardous materials stored or shipped near the site and is described in SSAR, Section 2.2.

Recognition of the emergency classification is primarily a judgement matter for plant personnel. The Initiating Conditions (ICs) used for recognizing and declaring the emergency classification are based on specific measurable values or observable conditions defined as Emergency Action Levels (EALs). These can be combinations of specific instrument readings (including their rate of change), annunciator warnings, time periods certain conditions exist, etc. Duke Energy uses EALs as thresholds for determining the emergency classifications.

To adequately assess the emergency condition, the Control Room and OERF have the necessary equipment and instrumentation installed to make available essential plant information on a continuous basis. Evaluation of plant conditions is accomplished through the monitoring of plant parameters both from indication in the Control Room and within the plant. The resources available to provide initial and continuing information for accident assessment throughout the course of an event include plant parameter display systems, chemistry monitoring systems, area and process radiation monitoring systems, meteorological displays, fire detection panels, and emergency response personnel.

Additional actions to prevent or mitigate the consequences of an emergency are addressed in the Abnormal Operating Procedures (AOPs) and Emergency Operating Procedures (EOPs).

NOTE: When Duke Energy determines a design technology for the Project site, a set of EALs describing plant-specific ICs and specific instrument readings as appropriate for the various ECLs will be developed similar to NEI-99-01, “Development of Emergency Action Levels for Non-Passive Reactors” which has been approved by the NRC. At that time, examples of plant conditions, instrument readings, and parameters required for determination of the EALs, and their recommended emergency classes will be described in an EPIP. This procedure will also specify notifications and information to be provided to off-site organizations, as required. The EAL scheme is design specific and is documented in an EAL Technical Basis Document. If an EAL scheme is ever changed, the new EALs will be submitted to the NRC for approval before implementation.

The three (3) ECLs are described as follows**:**

1. NOUE

   Events are in progress or have occurred which indicate a potential degradation of the level of safety of the plant or indicate a security threat to facility protection has been initiated. No releases of radioactive material requiring off-site response or monitoring are expected unless further degradation of safety systems occurs.

2. Alert

   Events are in progress or have occurred which involve an actual or potential substantial degradation of the level of safety of the plant or a security event that involves probable life-threatening risk to site personnel or damage to site equipment because of HOSTILE ACTION. Any releases are expected to be limited to small fractions of the USEPA PAG exposure levels.

3. Site Area Emergency

   Events are in progress or have occurred which involve actual or likely major failures of plant functions needed for protection of the public or HOSTILE ACTION that results in intentional damage or malicious acts: 1) toward site personnel or equipment that could lead to the likely failure of or 2) that prevent effective access to equipment needed for the protection of the public. Any releases are not expected to result in exposure levels which exceed USEPA PAG exposure levels beyond the EAB.

Duke Energy has and maintains the capability to assess, classify, and declare an emergency condition within 15 minutes after the availability of indications to plant operators that an EAL threshold has been met or exceeded in accordance with an EPIP. The 15-minute time requirement to declare events will not be construed as a grace period to attempt to restore conditions to avoid declarations.

An emergency classification may be downgraded to a lower classification in accordance with guidelines and criteria as described in EPIPs. Reduction of an emergency classification level is not a requirement, and direct entry into recovery is desirable. However, there may be some occasions when it is more appropriate to reduce the classification level. The NRC should be advised of the decision to downgrade the emergency.

Termination of the emergency is authorized and conducted in accordance with the EPIPs. Considerations for entry into recovery must be performed before exiting the emergency event. When a classified event is terminated, a reentry and recovery phase will be entered which is discussed in Section III.I.

Duke Energy maintains procedures that include immediate actions to be taken that are consistent for any declared ECL. These procedures describe, in detail, required actions, activation of the ERO (if required), notification to the NRC, and notification to other off-site agencies if required. Additional notifications to plant management, corporate communications staff, and supporting agencies are described in procedures.

D. PROTECTIVE ACTIONS

1. Radiological Exposure Control /Protective Measures

The Radiation Protection Section at the Project site is responsible for on-site radiation protection activities. Procedures are in place to implement the requirements of Title 10 Code of Federal Regulations, Part 20, and other required standards as well as requirements and policies in Duke Energy radiological control procedures. Radiation Protection personnel provide surveillance during normal plant operation as well as emergency situations and advise key plant personnel on radiological matters for routine and emergency conditions.

The limiting doses to occupational workers during routine plant operations are located in Duke Energy radiological control procedures. If possible, Duke Energy maintains these limits during emergency operations. If these standards cannot be met during emergencies, on-site exposure guidelines for emergency workers are consistent with USEPA-400/R-17/001 PAG Manual: Protective Action Guidelines and Planning Guidance for Radiological Incidents and are further described in an EPIP.

The EC is responsible for authorizing exposures in excess of 10 CFR 20 limits in accordance with EPIPs and radiation protection procedures. Authorizations are documented as part of the emergency exposure controls process. Any personnel dose in excess of five (5) rem TEDE shall be handled in accordance with the Duke Energy radiological protection plan.

If individuals are expected to receive an exposure in excess of normal occupational limits, then dose extensions are determined and approved on a task basis. Approval is required before emergency workers are allowed to exceed normal occupational radiation dose limits.

All efforts should be made to utilize respiratory protective equipment by qualified workers to minimize ingestion and/or inhalation of radionuclides and to maintain internal exposure below the limits specified in 10 CFR 20, Appendix B. However, if an unplanned incident involves the accidental or potential ingestion or inhalation of radioactive iodine, potassium iodide (KI) is maintained and available for distribution. The process for administration of KI to Duke Energy and vendor employees is described in EPIPs. Ingestion of stable iodine will be recommended for emergency

workers if a dose of 5 rem Committed Dose Equivalent (CDE)-thyroid from radioiodine is expected.

Personnel monitoring equipment (such as direct reading dosimeters, wrist dosimetry, and/or finger dosimetry) is issued to and worn by Duke Energy radiation worker qualified personnel who may be required to work in Radiological Controlled Areas (RCAs) (as described in 10 CFR 20 and radiation protection procedures) as a record of radiation exposure. Other radiation detection devices are available for use by emergency workers as described in radiation protection procedures.

Duke Energy implements adequate protective measures so that dose, considering both internal and external pathways, is maintained As Low As Reasonably Achievable (ALARA) in accordance with specific plant procedures, including issuing respiratory protection equipment and protective clothing to personnel. Internal dose is minimized by using respiratory protection equipment consistent with maintaining the TEDE.

Personnel are not permitted to enter any area where dose rates are unknown or unmeasurable with either instruments or dosimetry.

Personnel dose records are documented and managed in accordance with radiation protection procedures.

Radiation Protection personnel in the OERF have the responsibility to monitor and assess the radiation doses received by ERO personnel on a 24-hour per day basis throughout a declared event.

Radiation safety controls are established 24 hours per day to contain the spread of loose surface radioactive contamination. Contamination control limits and contamination on personnel; action levels for decontamination of personnel and equipment; and disposal of contaminated waste are described in radiation protection procedures.

Under emergency conditions when a release of activity has occurred, eating, drinking, smoking, and chewing will be not permitted until the EC, with input from Radiation Protection, has determined that it is safe to do so based on habitability surveys.

Emergency teams that must enter areas where they might be expected to receive higher than normal doses will be briefed on the task assigned; the planned route to the destination; allowed dose and dose rates; and other instructions in accordance with radiation protection procedures. During dispatch, if the monitored dose or dose rates, or stay times exceed the limits set for the task, the team will communicate with the Control Room or OERF for further direction or will return to the area from where

they were dispatched. Once their task has been completed, team personnel will follow monitoring and personnel decontamination procedures as specified by Radiation Protection.

Non-Duke Energy emergency workers supporting on-site activities will be issued dosimetry and/or be monitored by radiation protection personnel when responding to areas where a dose of radiation may be received. This process will be implemented by ERO radiation protection and site security personnel.

2. Protective Action Notification

The Project site assembly alarm and Public Address (PA) system is used to alert and notify on-site personnel of an emergency condition within 15 minutes. Security personnel with portable loudspeakers may be used, as available, to augment the PA system and check evacuation of outlying areas for other individuals, including those who may be on or passing through the Owner Controlled Area (OCA). The PA system is supplemented by using normal and emergency communications systems.

Notification of individuals who are in public access areas, on or passing through the site, or within the OCA, is performed by site Security in accordance with EPIPs. Visitors within the Protected Area are escorted by a permanently badged individual. The escort is responsible for informing the visitors of what to do in the event of an emergency and for taking action to evacuate the visitors from the site, as necessary.

3. Site Evacuation and Accountability

A site evacuation of all non-essential personnel inside the Protected Area is conducted at a SAE classification level unless delayed due to safety issues. Non-essential personnel inside the Protected Area will typically exit to the OCA by following normal Radiation Protection and Security processes; be accounted for as they exit; and evacuate the site.

Note: A process is in place controlled by Security to perform a rapid evacuation of the Protected Area without monitoring and assembly if conditions warrant.

Site personnel evacuating the Protected Area will be monitored for contamination and typically decontaminated, if necessary, as they leave the Protected Area. If conditions do not allow for decontamination of personnel prior to exiting the Protected Area, they will be directed to an off-site location designated by Duke Energy.

Personnel evacuating the site from outside the Protected Area will be monitored at a location designated by Duke Energy as required by event conditions.

All personnel within the Protected Area will be accounted for within 30 minutes of the declaration of a SAE classification (or lower classification if deemed appropriate by the EC), in accordance with EPIPs. After accountability of personnel is initially completed by Security, accountability will be maintained continuously for the duration of the emergency.

A range of protective actions to protect on-site personnel during a Hostile Action event is developed to ensure continued availability to safely shut down the reactor(s) and perform functions described in this Plan. The range of protective actions is contained in the Project site abnormal procedures which are classified security sensitive. Accountability may be delayed during a Hostile Action event if the EC, in consultation with Security, determines that performing accountability could be detrimental to the safety of plant personnel. If accountability is delayed, then accountability should be performed as soon as conditions permit.

During the accountability process, any missing individuals will be identified by Security, and search and rescue procedures will be implemented to locate unaccounted for persons in accordance with plant procedures.

4. Medical Support

Facilities, equipment, medical supplies, and trained personnel are available for first aid and emergency medical treatment of ill or injured individuals on-site.

Guidance for medical assistance is located in a Project site plant procedure, and a process is in place to coordinate the care, disposition, and reporting of injuries known or suspected to be associated with excess levels of radiation exposure or contamination. Immediate lifesaving and disability-limiting procedures take precedence over noncritical decontamination and dosimetry assessment measures. Emergency treatment of injured personnel will normally be performed on the scene.

The on-shift Medical Emergency Response Team (MERT) (assisted by Radiation Protection personnel) is available to:

- Provide first aid/emergency medical treatment for ill or injured individuals on-site, including those who may have been exposed to or contaminated with radioactive material.
- Minimize injury during the rescue, treatment, and transport of injured individuals, while minimizing radiological hazards and exposure to the victim.
- Advise and protect attending personnel from unacceptable and unnecessary radiological hazards and exposures.

- Identify, document, and control radiation exposure and contamination hazards associated with the emergency.

a. Transportation of Injured Personnel

When transportation of an injured person by ambulance is indicated, transport may be provided by a local ambulance service. The MERT leader coordinates the request for off-site ambulance assistance through the Shift Manager or the EC if the OERF is activated**.**

Radiation monitoring services are provided by Duke Energy personnel whenever it becomes necessary to use an ambulance service for the transportation of contaminated individuals. Injured personnel are evaluated for radiological contamination and packaged to control contamination prior to transport to a medical facility in accordance with radiation protection procedures. Duke Energy personnel will assist with decontamination of transport vehicles if necessary.

b. Off-site Medical Facilities

The ESPA E. Plan will be revised when Duke Energy moves forward with a Construction Permit or Operating License application. At that time, arrangements will be made with off-site medical facilities for the medical treatment of contaminated, injured personnel, and contact information will be described in procedures.

Duke Energy personnel may be available to assist medical personnel with decontamination, radiation exposure, and contamination control. Hospitals will be equipped, and hospital personnel may be trained to address contaminated, injured individuals. Training of medical support personnel may be conducted to include basic training on the nature of radiological emergencies, diagnosis and treatment, and follow-up medical care with support from Duke Energy if requested. Radiological controls capability, including isolation of contamination, assessment of contamination levels, radiation exposure monitoring for medical facility staff, collection of contaminated waste, and decontamination of treatment areas will be described in radiation protection and hospital procedures.

5. Off-site Protective Actions

As addressed in FEMA Comprehensive Preparedness Guide 101, “Developing and Maintaining Emergency Operations Plans” (CPG-101), if determined appropriate, off-site government officials may utilize a CEMP approach to emergency planning to implement ad hoc protective actions to protect the public (FEMA, 2021).

E. COMMUNICATIONS

The Project site has the capability to establish prompt communications and maintain communications between the emergency response facilities, ERO personnel, and principal response organizations (federal and state and county if required). EPIPs describe the use of communications systems during an emergency; and emergency plan administrative procedures provide additional details describing testing and maintenance of communications systems.

Communication systems are available to facilitate normal and emergency communications within the plant; between the plant and emergency response facilities; between the plant and the NRC; and between the plant and off-site emergency response organizations, if required.,

Redundant systems are provided to ensure continuous communication between entities and personnel.

Voice communications systems are available and include:

- Private Branch Exchange (PBX).
- Satellite Telephones.
- Cellular Telephones.
- Radios (on-site).
- PA System.

Provisions exist for communications with the NRC, other Duke Energy sites, and state/county governments (if required). The Project site has the following voice communication systems available for use by the ERO for performing emergency communications:

1. Private Branch Exchange (PBX)

   A PBX is a full-featured telephone system that provides internal calling services for one or more locations. The PBX terminates commercial phone lines from a carrier (e.g., AT&T, Verizon, CenturyLink, etc.) to provide inbound and outbound calling capabilities between Duke Energy and external parties. PBX systems have a number of mechanisms which make them resistant to failure including redundant power connections, redundant network connections, and server hardware installed in geographically diverse locations. PBX is the generic terminology used in the

Emergency Plan to describe the normal telephone systems used throughout Duke Energy.

PBX is the primary means of communication between the Control Room, OERF, and Security. PBX lines may be used for notifications to Off-site Response Organizations (OROs), if required. PBX lines may also be used to request support from off-site emergency response agencies (i.e., local law enforcement, fire departments, ambulance companies, and medical facilities).

2. NRC Communication Links

PBX is the primary means of communication with the NRC. Alternate communication methods are available from the Control Room and OERF if needed. Additional information describing NRC communications is located in Section IV.C. The following communication methods (or equivalent communication methods that are compatible with NRC communication systems) include:

a. NRC Emergency Notification System (ENS) - This communications line provides a communications link to the NRC Operations Center in Rockville, Maryland, and is used for notifications and communications during a classified emergency. This link is available in the Control Room and OERF.

b. NRC Health Physics Network (HPN) – This communications line provides a communications link with the NRC to provide radiological information and is normally available in the OERF.

c. NRC Reactor Safety Counterpart Link (RSCL) – This communications line provides a communications link for the NRC to conduct internal NRC discussions on plant equipment conditions separate from Duke Energy.

d. Protective Measures Counterpart Link (PMCL – This communications line provides a communications link for the NRC to conduct internal NRC discussions on radiological releases, meteorological conditions, and the need for protective actions.

e. Management Counterpart Link (MCPL) (Executive Bridge Line) – This communications line provides a communications link for any NRC internal discussions between the NRC Executive Team Director or Executive Team members and the NRC response team leader or top-level Duke Energy management at the site.

3. Satellite Telephones

   A satellite phone is any fixed or mobile telephone capable of sending and receiving phone calls through orbiting satellites. A satellite phone provides an alternate means of communication between:

   a. Control Room and OERF.
   b. Control Room and OERF when contacting the NRC.
   c. Control Room and OERF for contacting OROs (if required).

4. Cellular Telephones

   A cellular telephone is any mobile telephone (non-Duke Energy or Duke Energy provided) capable of sending and receiving calls through ground-based cell sites.

   Cellular telephones are an alternate means of communication between:

   a. Control Room and OERF.
   b. Control Room and OERF when contacting the NRC.
   c. Control Room and OERF for contacting OROs (if required).

5. Radios (On-site)

   Radios are standard fixed and mobile transceivers that allow point-to-point communications on-site. Radios are an alternate means of communication between the Control Room, OERF, and Security.

6. Plant PA System

   The on-site PA system can broadcast a message via speakers located throughout the site and is used to alert and notify on-site personnel of an emergency condition. It is used to notify site personnel of emergency declarations, provide additional means to notify the ERO, and facilitate on-site protective actions for personnel.

7. ERO Notification

The Project site uses a dedicated notification system to rapidly notify the ERO simultaneously using several methods. The vendor supplied notification system is designed with redundant power and geographic separation. Activation of the ERO notification system is performed by on-shift personnel in accordance with an EPIP. Alternate methods to activate the ERO are in place using an automated dial out system, or individual callouts of needed personnel using any of the calling methods that are available. All ERO members assigned to the Project site are notified and expected to respond on an All Call - All Come basis.

ERO members will be notified at an Unusual Event classification or higher and given plant status and emergency event information. The ERO may be instructed to standby or report to the plant for an Unusual Event emergency declaration if warranted by the EC. At an Alert classification or higher, the ERO is instructed to report to the OERF and begin facility activation.

Testing of communications equipment at the Project site is conducted on a frequency and documented in accordance with emergency plan administrative procedures, and includes the following:

- Systems used to communicate from the Control Room and OERF to NRC Headquarters will be tested monthly. This testing may be performed as part of a drill or exercise.
- Cellular telephones and satellite telephones will be tested on a designated frequency.
- The Emergency Response Data System (ERDS) (or equivalent data transmission system that is compatible with NRC data transmission systems) will be verified to be connected and transmitting data on a quarterly basis.

F. COMMAND AND CONTROL

1. Authority Over the Emergency Response Organization (ERO)

The EC in command and control is the designated Duke Energy individual who has overall authority and responsibility, management ability, and technical knowledge for coordinating all emergency response activities at the Project site.

During an emergency, the Shift Manager in the Control Room initially assumes the function of EC and is in overall command and control of Duke Energy's response to the emergency including all emergency response functions. If the OERF is activated and operational, another individual qualified as EC relieves the Shift Manager and assumes command and control of the emergency.

Command and control involve management of emergency response functions through leadership, use of authority, and concise, effective communication techniques. Command and control during an emergency require reflective, objective, and knowledgeable decision-making abilities to achieve optimum results. Control during an event involves verification and assurance that actions occur in conformity with a predetermined plan, and in accordance with established principles based on available information and feedback and must be viewed from a “big picture” perspective.

2. Criteria for Assuming Command and Control

The transition of command and control and non-delegable responsibilities from the Shift Manager (EC in the Control Room) to the EC in the OERF should occur simultaneously. However, this process may occur separately depending on the readiness of the OERF to activate and the and status of events in progress (e.g., hostile action-based events or natural disasters).

The Shift Manager acting as EC is relieved of command and control as soon as possible after the declaration of an Alert or higher classification (or Unusual Event if requested by the Shift Manager). Command and control of the emergency does not transfer until the following criteria have been met:

- Adequate staffing levels are present in support of the following non-delegable responsibilities:
    - Event classification, reclassification, or termination.
    - Authorization of emergency exposure controls in excess of 5 rem TEDE and the issuance of KI for Duke Energy emergency workers per USEPA-400.
    - On-site protective actions.
    - Notification of the NRC and state/county emergency management (if required).
    - Approval of information that may be released to the public.
- The staff has been fully briefed on the status of the event and the currently proposed plan of action.
- A formal turnover between the EC relinquishing Command and Control and the EC in the OERF assuming Command and Control has been made.

The EC provides leadership and direction to ERO members in performance of their emergency response functions using formal communication techniques and protocols to ensure effective and accurate information is transmitted.

The EC maintains an awareness of the emergency situation continuously and throughout the event and through termination of the emergency in accordance with EPIPs and supporting procedures.

G. STAFFING AND OPERATIONS

1. Staffing

In the event of an emergency at the Project site, the activation of the on-site ERO is required. The overall ERO is comprised of the Shift Manager in the Control Room, Emergency Coordinator located in the OERF, a Control Room staff of Operations personnel, and additional support staff located in the OERF. The ERO is responsible for on-site response to an emergency condition and augments the shift operations crew. The Shift Manager directs on-site activities including the functions of Control Room operations, technical assessment, emergency mitigation analysis, on-site radiation surveys, and dose tracking for site personnel. The on-site organization is assisted by Duke Energy corporate personnel for public information activities and other support if needed.

Initially the on-duty Shift Manager (SM) assumes the emergency response position of EC and directs emergency response from the Control Room. The EC position and responsibilities are transferred to another qualified EC in the OERF if the facility is activated. Upon OERF activation, the EC and the OERF staff provide technical support to the Control Room as part of their overall response to the emergency.

The on-shift staff is continually present on a 24-hour per day basis.

The requirements for on-shift operations staff, security force staff, and fire brigade/first aid staff are controlled by site licensing and administrative documents. Positions from these departments are described in the Emergency Plan only when assigned an emergency preparedness function that is performed during an event. Site procedures provide details of the normal site organization, including reporting relationships.

The normal on-shift complement is trained to handle emergency situations (e.g., initiate implementation of the Plan; perform initial accident assessment and emergency classification, notifications, and communications; and initiate protective actions) until the augmented ERO arrives. The ERO is composed of a broad spectrum of personnel with specialties in operations, maintenance, engineering, health physics, material control, fire protection, security, and emergency preparedness and are available and trained to augment on-shift personnel in an emergency.

The normal shift complement is described in site licensing and administrative documents. Deviation from the normal shift complement is allowed as long as the minimum shift complement, as described, is maintained and appropriate action is taken.

Duke Energy maintains a depth to the ERO that is capable of providing continuous 24-hour per day operation over an extended period of time. Key functions will be maintained throughout a declared emergency by providing relief of on-shift and augmented ERO positions by qualified individuals. Shift rotations for a protracted period will be designated by an assigned ERO member during an event.

The proposed minimum ERO staffing and primary responsibilities for the Project site are described below.

Note: The proposed ERO may change after Duke Energy determines the specific design technology for the site and an on-shift staffing analysis is performed in accordance with NEI 10-05, Assessment of On-Shift Emergency Response Organization Staffing and Capabilities (NEI, 2011), or a similar staffing assessment.

a. Control Room

1) Shift Manager

- Provide overall ERO command and control until relieved.
- Evaluate plant conditions and approve EAL classifications until relieved.
- Authorize personnel dose extensions for Duke Energy emergency workers until relieved.
- Evaluate and assess plant data and on-site radiological data in the development of on-site protective actions (as required) until relieved.
- Direct all radiation protection activities, including on-site monitoring team activities until relieved.
- Approve information that may be released to the public until relieved.

2) Shift Communicator

- Perform ENS communications to the NRC including emergency classification status and plant information until relieved.
- Activate or confirm activation of ERDS or equivalent data transmission system that is compatible with NRC data transmission systems.
- Perform other off-site notifications as required.

3) Shift Radiation Protection (RP) Qualified Individual

- Provide RP coverage for responders accessing potentially unknown radiological environments.
- Provide in-plant and on-site surveys as directed.
- Control dosimetry and radiologically controlled area (RCA) access.

4) Security Supervisor / Alarm Station Operator (ASO)

- Coordinate security-related activities and information with the Shift Manager.
- Perform site accountability.
- Coordinate response activities with Local Law Enforcement Agencies (LLEA) as needed.

b. On-site Emergency Response Facility (OERF)

1) Emergency Coordinator (EC)

- Provide overall ERO command and control.
- Evaluate plant conditions and approve EAL classifications until relieved.
- Authorize personnel dose extensions for Duke Energy emergency workers.
- Evaluate and assess plant data and on-site radiological data in the development of on-site protective actions as required.
- Approve information that may be released to the public.

2) Emergency Communicator

- Perform ENS communications to the NRC including emergency classification status and plant information.
- Activate or confirm activation of ERDS, or equivalent data transmission system that is compatible with NRC data transmission systems.
- Perform other off-site notifications if required.

3) Security Coordinator

- Coordinate security-related activities and information with the EC.
- Perform site accountability.
- Coordinate response activities with LLEA as needed.

4) Plant Engineer
    - Provide engineering coverage for Core/Thermal Hydraulics, electrical and Instrumentation and Control equipment, and mechanical equipment.
5) Radiological Assessment Manager (RAM)
    - Evaluate and assess on-site radiological data in the development of on-site protective actions and recommend on-site protective actions to the EC.
    - Direct all on-site radiation protection activities, including on-site field monitoring team activities if required.
    - Monitor and determine the magnitude of any radioactive releases and initiate dose assessment/projections if conditions warrant.
6) Damage Control Supervisor
    - Supervise OERF activities related to electrical and Instrumentation and Control (I&C) equipment and to mechanical equipment.
7) RP Qualified Individual
    - Provide RP coverage for responders accessing potentially unknown radiological environments.
    - Provide in-plant and on-site surveys.
    - Control dosimetry and radiologically controlled area (RCA) access.
8) Maintenance Technicians (2)
    - Provide mechanical and electrical support for ECCS equipment, event mitigation, and equipment repair as directed.
9) Public Information Officer (PIO)
    - Provide site event and response information to public information staff.
    - Provide technical assistance for the development of information to be released to the public.
    - Serve as the primary communications path to the Joint Information System (JIS).

Other support during an emergency is coordinated on an as-needed basis and as requested by the EC. The Public Information Officer (PIO) can support media relations during an emergency remotely. Information Technology (IT) personnel are also located remotely and can be requested as required.

The ERO is comprised of on-shift personnel who are always located at the site, or augmenting personnel located either on-site or off-site who are on duty at all times.

Table III.G-1 provides a description of proposed ERO positions required to meet minimum staffing and full augmentation of the on-shift complement at an Alert or higher classification, and the major tasks assigned to each position. The full augmentation staffing levels are used as a planning basis to cover a wide range of possible events. As stated earlier, the proposed ERO may change after Duke Energy determines the specific design technology for the site and an on-shift staffing analysis is performed in accordance with NEI 10-05, Assessment of On-Shift Emergency Response Organization Staffing and Capabilities (NEI, 2011), or similar staffing assessment.

2. Emergency Response Organization (ERO) Training

Radiological emergency response training is provided to personnel who may be called on to assist in an emergency as described in emergency plan administrative procedures. Initial training and periodic retraining is conducted for members of the ERO. Training is also offered to off-site organizations that may be called upon to assist the site in the event of an emergency.

Responsibilities for implementing the training program reside with site or corporate training departments, depending on the position or type of training needed. Training is conducted by qualified training personnel or Subject Matter Experts (SMEs). Administration of the training program includes student registration, or attendance records, to track training participation for both initial and requalification for each member of the ERO. ERO training participation is tracked utilizing a database to ensure responding members are properly trained and qualified to respond in the event of an emergency and to notify individuals of training that is coming due and expired training.

ERO personnel who are responsible for responding to an emergency receive the appropriate level of plant access training, training on basic emergency response procedures, communication, evacuation, as well as specialized training specific to their role in the organization. The training program for ERO personnel is developed based on position-specific responsibilities.

The ERO Training Program ensures a consistent program is in place to support the training, qualification, continuing training, and requalification of individuals who may be called on for assistance during an emergency. Specific emergency response task training prepared for response positions is described in lesson plans and position specific guides. Job task analyses are used to develop learning objectives, create

lesson plans, and position-specific guides. The lesson plans, position-specific guides, and written tests (if applicable) are contained in the ERO Training Program.

Requalification training for on-site ERO members consists of periodic ERO update/refresher training and periodic participation in drills. In addition to Duke Energy periodic ERO update/refresher training, personnel assigned to selected on-site ERO positions will receive training specific to their position if a decline in performance is noted in drills or to maintain proficiency.

Members of the ERO receive periodic performance-based emergency response training which is generally provided by participation in a performance drill. Drills allow individuals an opportunity to demonstrate the ability to perform their assigned emergency response functions. During drills, on-the-spot correction of erroneous performance may be made, and a demonstration of the proper performance offered by the drill Controller.

Training is evaluated in accordance with the principles of Systematic Approach to Training (SAT) practices when applicable to ensure effectiveness and to identify areas that need improvement or correction.

Revisions to the training program are identified with feedback from trainees undergoing training and critique items during drills. ERO training is also reviewed during EP assessments at the Duke Energy sites. During assessments, ERO and EP staff performance is reviewed and appropriate revisions to the training program are made using the principles of the SAT process.

Training sessions (e.g., drills) providing performance-enhancing opportunities for key positions must be critiqued in order to identify weak or deficient areas that need correction for the key skills demonstrated. Critiques are documented such that the adequacy and evaluation of key skills demonstrated is sufficiently justified.

3. General Employee Training

All personnel with unescorted plant access are provided with initial orientation training on the notification and instruction methods used in the event of an emergency including the method of notification (for example plant evacuation alarm) and instructions sufficient for proper evacuation of the site. Additionally, all badged individuals receive initial orientation on the basic principles of radiological safety including the effects of radiation and, as appropriate, the use of protective clothing, equipment, and devices.

4. Drills and Exercises

The Duke Energy drill and exercise program is described in emergency plan administrative procedures and serves the following three purposes to ensure the effectiveness of the Emergency Preparedness program to protect the health and safety of site personnel and the public:

- Develop and maintain the skills of emergency responders.
- Test the effectiveness of emergency plans and procedures, facilities and equipment, and training.
- Demonstrate the adequacy of emergency plans and procedures to respond to events ranging from minor to severe accidents**.**

The program provides direction for the scheduling, preparation, conduct, evaluation, and critique of Duke Energy Emergency Preparedness drills and exercises. Drills are used to provide performance enhancing opportunities to train and retrain facility personnel in emergency responsibilities. A variety of drills are performed including:

- Integrated facility drills – Drills incorporating multiple facilities or with any off-site organization that may be used for training or instruction.
- Communication drills – Activities that drill the use of communication equipment and procedures to communicate facility status and emergency conditions and that may be used to verify contact information, protocols, and reliability.
- Fire drills – Drills conducted in accordance with the Fire Protection Program (evaluated outside the EP program).
- Medical emergency drills – Activities that drill the use of first aid and emergency medical response for contaminated individuals or other industrial accidents.
- Radiological monitoring drills – Activities that drill the use of equipment and procedures to determine the adequacy of equipment, training, and procedures for radiological monitoring of processes, effluents, releases, samples, contamination, and dose assessments.

Evaluated exercises are used to demonstrate proficiency in the major portions of the emergency plan and, as such, cannot be used for training and instruction. Participation in an evaluated exercise is not required before assignment to an ERO role.

All drills and exercises are critiqued to identify weak or deficient areas that need correction for the key skills demonstrated. Critiques are documented such that the adequacy and evaluation of key skills demonstrated is sufficiently justified. The critique process is further described in Section III.J.

The drill and exercise program provides key metrics to be included in the performance monitoring metrics as discussed in Section III.B.

Table III.G-1. Project Site Proposed Emergency Response Organization (ERO) Staffing and Augmentation Plan

Emergency Preparedness Function	On-Shift	On-site Emergency Response Facility (OERF) Alert or Greater Augment within 120 minutes [2]
Command and Control	Shift Manager (1)	Emergency Coordinator (1)
Communications	Shift Communicator (1)	Emergency Communicator (1)
Radiation Protection	Radiation Protection Technician (1)	RP Qualified Individual (1) (In addition to on-shift RP)
Supervision of RP Staff and Site Radiation Protection	Shift Manager [1]	Radiological Assessment Manager (1)
Dose Assessment/Projections	Shift Manager [1]	Radiological Assessment Manager [1]
Emergency Classifications	Shift Manager [1]	Emergency Coordinator [1]
Engineering	Shift Manager [1]	Plant Engineer (1)
Security	Security Supervisor (1) Security Staff [3]	Security Coordinator (1)
Repair Team Activities	Not applicable	Maintenance Technicians (2)
Supervision of Repair Team Activities	Not applicable	Damage Control Supervisor (1)
Media Information	Not applicable	Public Information Officer (1) [4]
Information Technology (IT) [5]	Not applicable	Not applicable

[1] Assigned as a collateral function.

[2] Specified On-site ERF personnel should be capable of performing their required functions within 120 minutes of an Alert or higher EAL classification. Emergency response facility activation timing is not the concern: instead, it is whether the facility staff is performing the stated function(s) within the time specified.

[3] Per the site security plan.

[4] Remote responder - not required to respond to OERF.

[5] IT personnel monitor critical digital assets remotely and respond any time an issue is identified.

H. RADIOLOGICAL ASSESSMENT

1. Radiological Conditions

   Process Radiation Monitors (PRMs) are used for the measurement of radioactive noble gas, iodine, and particulate concentrations in gaseous effluent pathways and for gross radioactivity in other gaseous and fluid streams. Some PRMs have local alarms to notify individuals in the surrounding area of changing conditions.

   Area Radiation Monitors (ARMs) are used for the direct measurement of in-plant dose rates and allow in-plant dose rate determinations to be made remotely without requiring local hand-held meter surveys. This information may be used initially to aid in the determination of plant area accessibility. ARMs have local alarms to notify individuals in the surrounding area of changing radiological conditions. When an alarm occurs, personnel are trained to exit the area.

   Process and area radiation monitor data and alarm status is available in the Control Room and OERF.

   Portable radiation monitoring equipment is available for uses such as area monitoring, sampling, personnel surveys, and continued accident assessment and is maintained in accordance with radiation protection procedures.

   Air samples will be collected and analyzed in accordance with radiation protection procedures.

   Major changes in radiological conditions or radiation monitor alarms will be communicated to site personnel, including any protective actions, in accordance with Operations procedures.

2. Protective Equipment

   Individuals entering a Radiologically Controlled Area (RCA) are issued personnel monitoring devices capable of measuring the dose received from external sources of ionizing radiation. The official and permanent record of accumulated deep dose equivalent is normally obtained from a DLR badge. Personnel are also assigned self-reading dosimeters to provide a day-to-day indication of deep dose equivalent. Self-reading dosimeters have alarms with the setpoints determined based on the task to be performed and the areas to be entered. The alarms notify the individual of a dose or dose rate condition that is unexpected and may be set higher during emergencies based on the conditions, and in accordance with radiation protection procedures.

   Protective clothing is a normal use item for work in a contaminated area. Radiation Protection will determine protective clothing requirements for responders in accordance with radiation protection procedures. Sets of protective clothing are

available at the normal RCA dress out area and in emergency kits located in various areas of the plant.

Respiratory protection devices may be required in any situation arising from plant operations where an airborne radioactivity condition exists or potentially exists. In such cases, the air is monitored, and the necessary protective devices specified according to the concentration and type of airborne contaminants present and estimated radiation dose following ALARA principles. During an emergency, monitoring is conducted in accordance with radiation protection procedures. Precautions are taken to keep airborne contamination to a minimum by using proper ventilation and prior decontamination of equipment or work areas. Respiratory protection equipment is maintained by Radiation Protection.

Radiological monitoring kits are emergency kits located in various areas of the plant. Radiation Protection periodically inventories, inspects, and replenishes the kits in accordance with radiation protection procedures.

Radioprotective drugs in the form of KI tablets are available on-site. If the EC, with support from Radiation Protection, determines that consumption of KI is necessary, tablets will be issued to impacted individuals. The approval, issuance, and use of KI is described in EPIPs.

Fire-fighting equipment on-site includes portable extinguishers, hose stations, sprinkler systems, deluge systems, and fire hydrants. The Fire Protection System is described in detail in the Project site Fire Hazards Analysis. Training and use of equipment is performed in accordance with the Fire Protection Program.

3. Core or Vessel Damage

The Project site ERO monitors plant parameters using information provided by plant data transmittal systems to assess the status of reactor fuel using core damage assessment procedures.

The extent of core damage is continually monitored to determine what state the core is in:

- No damage
- Clad failure
- Fuel melt

If clad failure or fuel melt is indicated, the Plant Engineer in the OERF can coordinate performance of a detailed analysis assisted by other engineering personnel as needed. This data is used to:

- Evaluate the risk and possible consequences of the accident.

- Support prioritization of mitigation activities.
- Determine the potential quality (type) and/or quantity (%) of source term available for release in support of projected off-site doses and protective action recommendations.
- Support the determination of radiological protective action for ongoing activities.
- Support the determination of radiological protective actions that should be considered for long term recovery activities.

The ERO also monitors plant data transmittal systems to evaluate the status of containment integrity, systems used to mitigate the release of radioactive material to the environment, and to identify leakage of radioactive material from plant systems, structures, and components.

4. Releases

During normal operations the Control Room has access to all Process Radiation Monitors (PRMs) which are used for the measurement of radioactive noble gas, iodine, and particulate concentrations in gaseous effluent pathways and for gross radioactivity in other gaseous and fluid streams. Process and radiation monitor data and alarm status are available in the Control Room and OERF. For some events, Operations procedures require monitoring certain process monitors and may be required to trend those due to the possibility of a radioactive release occurring. Radiation Protection may be requested to perform surveys.

If an alarm is received or the Control Room is notified by Radiation Protection of an unmonitored radiological release, Operations personnel will respond based on conditions in accordance with appropriate procedure(s).

Meteorological data is collected at the Project site and includes wind speed, wind direction, and a measure of atmospheric stability. The data is directly available in the Control Room and OERF. The National Weather Service (NWS) serves as a backup for obtaining meteorological information if requested.

Monitor indications, sampling results, meteorological data, and certain plant parameters are used to assess the radioactivity released to the environs as described in EPIPs.

When manual sampling is performed, collected samples are obtained in accordance with procedures and transported promptly to the Project site laboratory/counting room which is the primary location for radiological sampling analysis activities. The site laboratory is the central point for receipt and analysis of on-site samples; includes equipment for chemical and radiological analyses; and has the capability of

quantitative analysis of liquid and air samples and qualitative analysis of terrestrial samples.

Additional facilities for counting and analyzing samples are available at unaffected Duke Energy nuclear sites or state and federal laboratory services. These laboratories can act as backup facilities if the Project site's counting room and laboratory become unusable or the capacity or capability of the plant's laboratory is exceeded.

The ERO performs long-term or continuing accident assessment; formulates protective responses; and implements long-term on-site monitoring. Radiological data gathered from the release is analyzed and communicated to the ERO for further projected actual and integrated dose assessment, planning recovery efforts, and on-site protective actions.

In addition to contamination and dose rate measurements, the change out of TLDs and air sampler cartridges can be performed. Other actions may include soil, water, and vegetation sampling.

I. REENTRY

Once the EC has declared that an emergency condition has passed, general plans and procedures are established at the Project site for reentry and recovery which consider existing and potential conditions.

Actions prior to reentry include a review of available radiation survey data and determination of site areas affected by radiological hazards; review of radiation dose history of personnel scheduled for recovery operations; review of available survey equipment and other activities as described in plant procedures.

If the emergency condition is due to a security threat, including hostile action, the EC will coordinate reentry of ERO personnel into the site through Site Security and discussions with the Incident Commander located at the ICP. The IC will then notify and coordinate site access with local law enforcement. Reentry of personnel to the site is coordinated via communications between the plant (EC and Security Coordinator); the ICP Incident Commander, and the FBI.

When the EC, in consultation with other Duke Energy personnel, has determined that the thresholds of an emergency declaration are no longer met, steps will be taken to terminate directly from the event and transition to a state of recovery operations in accordance with an EPIP.

An example recovery organization is described in an EPIP and may be modified or supplemented as necessary to fit the particular emergency situation. Recovery activities would be managed similar to an outage, except that certain activities unique to the post-

accident situation may be managed by the recovery organization. The organization would function as a matrix management organization to coordinate activities with the normal company organization and may be located at the OERF or some other location, as appropriate.

Typical primary positions in the Recovery Organization include the following:

- Recovery Director- Overall management of recovery activities and high-level coordination with federal and state/county governments (if needed).
- On-site Recovery Manager – Directs recovery activities on-site to restore the plant to pre-accident conditions.
- Company Spokesperson or Public Information Officer – Directs the public information program during the recovery process.
- Other support – Other individuals or groups assigned specific tasks to support activities during the Recovery Phase as applicable.

Other site management and supervisory personnel will interface with recovery operations as necessary and as warranted.

The recovery organization, under the direction of the Recovery Director, will develop a recovery plan; assess and determine overall damage; identify resources and equipment needed to complete needed repairs; and perform other activities to support recovery as described in an EPIP.

The EC will inform members of the OERF, site organization, and off-site agencies (as applicable) that recovery operations are being initiated and that activities associated with bringing the plant to a safe shutdown condition are completed.

J. CRITIQUE AND CORRECTIVE ACTIONS

During conduct of a drill or exercise, qualified Duke Energy evaluators who have the skills and knowledge to effectively evaluate the participants evaluate drill/exercise performance objectives against measurable demonstration criteria in accordance with drill/exercise emergency plan administrative procedures.

As soon as possible following the conclusion of drills and exercises, or an actual emergency event, a critique is conducted by participants and qualified evaluators to evaluate the ability of the ERO to implement the Emergency Plan and demonstrate emergency response functions. Areas evaluated include ERO performance, response to procedures, and adequacy of facilities and equipment. The written critique documents the ability of the ERO to respond to an emergency or sequence of events and may identify the need for changes to the Plan, procedures, equipment, facilities, or other

components of the Emergency Preparedness (EP) program. The goal is to identify any issues and follow up with corrective actions as required.

The EP staff prepares a written critique report following a drill, exercise, or actual event to document whether the objectives were successfully demonstrated. Failed or degraded performance objectives are entered into the Corrective Action Program (CAP). Failed or degraded demonstration criteria, improvement items, and recommendations for improvement are dispositioned within the critique report and may be entered into the CAP. The EP Manager or designee then approves the critique reports.

Objectives and demonstration criteria that are not adequately accomplished are described in the critique report and entered into the CAP for trend tracking and/or corrective action. The significance of any identified issue; the action(s) taken to resolve the issue; and the schedule for issue closure are determined by the EP Manager through the CAP process. The EP staff is responsible for initiating changes to the Plan or supporting procedures resulting from drill/exercise critiques or from an actual emergency.

If issues affect departments other than EP, then the EP manager or designee coordinates with the respective department heads for assignment of corrective actions and due dates, as appropriate.

If the Plan is not satisfactorily tested during an exercise to determine that the ERO has maintained key skills specific to emergency response, then a remedial exercise may be requested.

The EP group maintains critique reports as documentation for the completion of performance objectives in accordance with emergency plan administrative procedures.

In addition to identification during drills and exercises, emergency response capabilities associated with facilities, equipment, processes, and ERO staffing are monitored via tests, inventories, and inspections. These activities are controlled in accordance with site procedures. Discrepancies are entered into the CAP as required by procedures. In some cases, immediate compensatory actions may be necessary to maintain the emergency response capability.

IV. ON-SITE PLANNING ACTIVITIES

A. PUBLIC INFORMATION

In response to an emergency at the Project site, Duke Energy has established a process for coordinating and disseminating information to the public and media through a JIS in accordance with EPIPs and company procedures.

The JIS is activated at an Alert level emergency classification or higher by Duke Energy Corporate Communications personnel to ensure that emergency event information is coordinated with State, and affected county public information staff for dissemination to the media and general public. The JIS may be activated, if deemed necessary, at an Unusual Event declaration. The JIS provides the necessary structure and mechanism for organizing, developing, integrating, and delivering coordinated messages using established plans, procedures, and strategies.

A Public Information Officer (PIO) is assigned to the ERO as the primary communications link from the plant to the JIS. The PIO provides emergency event status and technical input to the public information staff in Corporate Communications to support development of information to be released to the news media and general public.

News releases are designed to be a written confirmation of an event at the site and are public information. Information is developed and released as clearly, concisely, and quickly as possible using various methods, including media briefings, news conferences, and social media posts.

During the initial stages of an emergency, responses to media questions relating to plant status are handled by the Corporate Communications team; and the normal Duke Energy media interaction and news release process is followed. When the OERF is activated, Corporate Communications response procedures are implemented for gathering and disseminating information. Duke Energy, State and affected county representatives (as applicable) coordinate and agree on information to be released to the media prior to news conferences. News releases are approved by the Company Spokesperson or the site EC if the Company Spokesperson is not available. Once approved and shared within the JIS, news releases are distributed to the media.

When news conferences and media briefings are scheduled, a designated Company Spokesperson (assisted by Corporate Communications/Nuclear Communications representatives, as needed) updates the media with plant and event status and company information, and State and county Public Information Officers (PIOs) address public response and actions, as applicable.

Interactions with the media may occur at various locations and with various agencies depending on the extent of response. News conferences/media briefings are conducted to keep the media informed with the most current and up to date information about events and response to the incident. PIOs from all agencies responding to the emergency are encouraged to participate in news conferences/media briefings to discuss their activities.

Traditional social media and customer response lines are monitored through the JIS to identify and address public concerns and rumors or inaccurate information. A Corporate Communications liaison works with PIOs from all agencies responding to the emergency via the JIS to acknowledge and determine the origin of rumors and coordinates a response to address rumors or correct any misinformation.

B. COORDINATION WITH SAFEGUARDS CONTINGENCY PLAN

The Project site safeguards contingency plan describes how the site will implement the physical protection program to defend against threats to the facility, up to and including the design basis threat of radiological sabotage. The safeguards contingency plan is intended to maintain effectiveness during the implementation of the Emergency Plan.

If Security is initially notified of a security threat (e.g., waterborne, land, or aircraft), Security personnel refer to security procedures to analyze the type of threat and immediate actions including notifications to the Control Room and other required agencies including the FBI (if applicable). If the security threat indicates a Hostile Action at the site, the Shift Manager (or EC in the OERF if applicable) refers to the emergency classification EPIP and supporting documents, classifies the emergency, and initiates notifications as required including the NRC.

If an ICP is established by the OROs, the EC selects individuals, normally from Operations, Security, and Radiation Protection, to act as ICP Liaison(s) to coordinate response efforts and provide communications, logistics, and site-specific information to/from the ICP in accordance with an EPIP.

A range of protective actions to protect on-site personnel during a Hostile Action event is developed to ensure the continued ability to safely shut down the reactor(s) and perform the functions in the Emergency Plan. This range of protective actions is described in the Project site abnormal procedures which are classified security sensitive.

An Alternate Emergency Facility (AEF) is a facility dedicated for use by Duke Energy and accessible to ERO personnel in the event of a security or hostile action threat when access to the Project site is restricted. When the ERO is notified of a security event, personnel responding from off-site may be requested to report to the AEF until access to the site is deemed safe. The AEF provides a location for the ERO to assist the plant in the management and control of emergency response activities. When event conditions indicate it is safe to access the site, reentry to the site will be coordinated by site personnel with Security and off-site law enforcement agencies. Duke Energy has not yet identified an AEF for locating ERO personnel to support an emergency at the site. The specific location of the AEF and capabilities to support emergency response functions will be described in an update to the Plan when Duke Energy moves forward for a Construction Permit or Operating License application as applicable.

During a security or hostile action event at the site, the general public and news media are kept informed of the emergency status using the Duke Energy JIS as described in Section IV.A, and via off-site agency public information officers.

C. COMMUNICATIONS WITH THE NRC

As described in Section III.E, communication systems are available to facilitate normal and emergency communications between the plant and the NRC, including redundant systems to ensure continuous communications capability if required. Notifications to the NRC are made in accordance with 10 CFR 50.72 and described in EPIPs.

Notifications from the site to the NRC are performed using the ENS telephone system (or equivalent system that is compatible with NRC communications systems) as soon as possible and not later than one hour after declaration of an emergency. If this system is inoperable, an alternate method such as commercial telephone line, cellular, or satellite telephone is available.

The Control Room and OERF is staffed and capable of maintaining continuous communication with the NRC, if requested, and on a case-by-case basis. Open communication lines can be staffed by knowledgeable personnel (for example, personnel with operations background and radiological knowledge) to ensure efficient and effective information flow.

The ERDS system (or equivalent system that is compatible with NRC data transmission systems) is continuously operated. When an event occurs, personnel verify system operation as soon as possible but not later than one hour after declaration of an Alert classification or higher in accordance with 10 CFR 50.72(a)(4). This system is always activated and can supply the NRC with selected meteorological data points on a near real time basis.

As described in Section III.E, there are other communication systems that link the plant to the NRC, including links for the NRC to conduct internal discussions on plant equipment issues separate from Duke Energy and for internal discussions on radiological releases, meteorological conditions, and the need for protective actions. There may also be a link available for NRC internal discussions between the NRC Executive Team Director or Executive Team members and the NRC response team leader or top-level Duke Energy management at the site.

D. EMERGENCY FACILITY OR FACILITIES

1. On-site Emergency Response Facility (OERF)

The OERF provides a location for personnel who are responsible for management and technical support of plant operations during emergency conditions. The OERF also functions to relieve the on-shift personnel of peripheral duties and communications not directly related to reactor system manipulations and to prevent congestion in the Control Room. The Project site has a dedicated OERF for use during emergency situations to implement emergency actions and analyze and mitigate accident conditions. The OERF is sized to accommodate ERO personnel and NRC representatives. State and county emergency management personnel are not expected to report to the OERF.

The OERF is required to be activated within 120 minutes following the declaration of an Alert or higher classification. The OERF may be activated for an Unusual Event classification, if deemed necessary. When activated, the primary functions of the OERF include:

- Prompt relief of the on-shift ERO emergency response activities.
- Coordination of site emergency response actions.
- Assessment of plant status and potential off-site impact.
- Dose assessment and projections, if applicable.
- Continued evaluation of event classification.
- Communications with the NRC and OROs (if required).

The OERF has display, print out, or trend records of comprehensive data necessary to monitor reactor system status and to evaluate plant system abnormalities. In-plant radiological parameters and meteorological parameters are also available.

The OERF has access to drawings and other records, including general arrangement diagrams, piping and instrumentation diagrams, electrical schematics, and plant procedures.

The OERF has communication capabilities that provide reliable voice communications to the Control Room, NRC, and OROs (if required). Additional information describing OERF communications systems is provided in Section III.E and IV.C.

In order to minimize congestion in the Control Room during emergencies, the OERF also provides a location separate from the Control Room where plant maintenance, operations, radiation protection, and other plant emergency support personnel will assemble and stand by to assist as needed.

When the OERF is activated, dosimetry, radiation survey equipment, and Radiation Work Permits (RWPs) will be provided to response personnel as required. In the event of personnel contamination, decontamination will be performed in the area normally designated for this purpose.

Emergency supplies are provided in the OERF or another accessible location to OERF personnel. Additional supplies and Duke Energy resources can be obtained from other unaffected plants upon request.

If the OERF is deemed uninhabitable, the OERF may be relocated to other locations as determined by the EC.

Site-specific location and other details associated with the OERF will be described in an update to the Emergency Plan when Duke Energy determines the design technology for the proposed plant.

2. Alternate Emergency Facility (AEF)

   The AEF is a facility dedicated for use by Duke Energy and designed to be accessible to ERO personnel in the event the OERF becomes uninhabitable or in the event of a Security or Hostile Action threat or severe weather event (such as a flood or tornado) if access to the site is deemed unsafe. The AEF provides a location for the ERO to assist the plant in the management and control of emergency response activities. Duke Energy has not yet identified an AEF for locating ERO personnel to support an emergency at the site. The specific location of the AEF and capabilities to support emergency response functions will be described in an update to the Plan when Duke Energy moves forward for a Construction Permit or Operating License application as applicable.

3. Decontamination Facility

   The Project site has facilities available for decontamination of personnel including those with minor injuries. The specific location of the decontamination facility(s) will

be described in an update to the Plan when Duke Energy determines the design technology for the proposed plant.

4. Laboratories

The Project site laboratory/counting room is the primary location for radiological sampling analysis activities. The site laboratory is the central point for receipt and analysis of on-site samples and includes equipment for chemical and radiological analyses. The site laboratory has the capability of quantitative analysis of liquid and air samples, and qualitative analysis of terrestrial samples. The specific location of the site laboratory/counting room will be described in an update to the Plan when Duke Energy determines the design technology for the proposed plant.

Additional facilities for counting and analyzing samples are available at unaffected Duke Energy nuclear sites or State and federal laboratory services and can act as backup facilities if the Project site counting room and laboratory become unusable, or the capacity or capability of the plant's laboratory is exceeded.

5. Processes, Equipment, and Supplies

Systems and equipment are available on-site to allow continuing assessment and monitoring of unusual or emergency situations. The following geophysical phenomena monitors are available:

- Seismic monitoring for earthquake detection.
- Meteorological tower equipped with thermometers, anemometers, wind vanes, etc., for assessment of weather conditions.
- Indicators for monitoring hydrologic conditions at Belews Lake.

Area, process, and effluent radiological monitors are provided in the plant for continuing assessment of radiological levels. These devices can be used to recognize emergency situations; perform continuing assessment; and may be supplemented by portable radiological monitoring devices and periodic sampling and laboratory analysis. Process instrumentation (based on the plant design) may be used to monitor the status of the plant and detect unusual conditions. A more detailed description of this instrumentation will be described in an update to the Plan when Duke Energy determines the design technology for the proposed plant.

The fire detection system is designed to quickly detect visible or invisible smoke (or other products of combustion) and/or heat in designated areas of the plant. The fire alarm communication systems and subsystems are located at strategic points throughout the plant to warn personnel of a nuclear incident or emergency conditions. Existing plant alarm systems are sufficiently audible to alert personnel in

the event of a fire or need for assembly. Fire-fighting equipment on-site includes portable extinguishers, hose stations, sprinkler systems, deluge systems, and fire hydrants. Fire detection system and equipment will be described in detail in the Fire Protection Program.

The Project site will have sufficient equipment and supplies for the operation of the site emergency facilities. In addition, emergency kits are maintained at the site; and routine inventories are performed to verify contents, inspect, and operationally check equipment/instruments in accordance with plant procedures. Sufficient reserves of instruments and equipment are maintained to replace those removed from emergency kits or lockers for calibration or repair. Sufficient portable radiation monitoring equipment is available for uses such as area monitoring, sampling, personnel surveys, and continued accident assessment. The Radiation Protection section is responsible for the maintenance, calibration, and storage of radiological equipment and instruments.

E. SITE FAMILIARIZATION TRAINING

Duke Energy supports initial training and annual retraining for off-site organizations that may be called upon to assist in an emergency at the Project site, if requested. These agencies include law enforcement personnel, fire department personnel, ambulance company, and hospital personnel.

Training of off-site organizations and agencies includes:

- Site familiarization and general layout of the plant.
- An overview of Emergency Preparedness.
- The notification process for the off-site organization, if required.
- The identity of the individual in the on-site ERO who will control off-site support activities.
- Basic radiation protection principles.
- The expected role of the off-site organization during emergency response activities.
- Site access procedures (as applicable).

Security will support site walkdowns for local law enforcement agencies (LLEAs) to familiarize them with relevant capabilities and the locations of key resources. Fire Protection will support walkdowns for fire departments to familiarize them with site capabilities and location of key equipment and resources.

F. EMERGENCY PLAN MAINTENANCE

Duke Energy has a process in place for maintaining and making changes to the Project site Emergency Plan and EPIPs, including methods to account for facility changes and methods used to conduct independent reviews of the program.

Project site EP personnel and management are responsible for the development, maintenance, review, and updating of the site Emergency Plan.

All Duke Energy EP staff members are provided formal professional development training or activities commensurate with their duties and experience and are required to take initial and periodic retraining to qualify for their positions. Initial training consists of classroom training, reading for awareness, and reading with discussion. Periodic retraining is performed at least biennially through related training, workshops, information exchange meetings with other licensees, and conferences held by industry and government agencies, as available, to maintain current knowledge of the overall planning effort. Other continuing training opportunities include observing exercises at other sites or attending courses, such as Duke Energy technical training, which will enhance plant operational working knowledge. In addition to the above training, EP staff members should complete training on the Applicability Determination process and 10 CFR 50.54(q) process per fleet procedures, as directed by supervision. All EP staff member training is documented in accordance with fleet procedures and training files, as appropriate.

Any changes that are made to the Project site Emergency Plan and EPIPs are evaluated and made in accordance with the change process described in 10 CFR 50.54(q) and Regulatory Guide 1.219, Guidance on Making Changes to Emergency Plans for Nuclear Power Reactors (RG 1.219).

The Project site Plan and procedures required to maintain and implement the Plan are reviewed and certified to be current on an annual basis and updated if necessary. Any changes due to regulatory revisions, issues identified by drills and exercises or actual events, or other updates are incorporated into the Plan. Changes are processed in accordance with 10 CFR 50.54(q) requirements and fleet document control/records management procedures.

Approved changes to the Plan and EPIPs are transmitted in accordance with the distribution list maintained in an electronic document management system. Changes to the Plan and EPIPs are submitted to the NRC in accordance with 10 CFR 50.4.

Appendix 3 provides a typical list of procedures required to maintain and implement the Plan that are considered part of the Plan but are maintained separately.

An independent review is performed for the Project site Emergency Preparedness program, as required in accordance with 10 CFR 50.54(t) and the Duke Energy Quality Assurance Program.

All program elements are reviewed by individuals who have no direct responsibility for the implementation of the emergency preparedness program either:

- At intervals not to exceed 12 months or,
- As necessary, based on an assessment by the licensee against performance indicators, and as soon as reasonably practicable after a change occurs in personnel, procedures, equipment, or facilities that potentially could adversely affect emergency preparedness, but no longer than 12 months after the change. In any case, all elements of the emergency preparedness program must be reviewed at least once every 24 months.

This review must include an evaluation for adequacy of interfaces with State and local governments (as required) and of licensee drills, exercises, capabilities, and procedures. The results of the review, along with recommendations for improvement, must be documented, reported to the licensee's corporate and plant management, and retained for a period of 5 years.

An emergency telephone directory containing contact numbers for the emergency response facilities and support organizations that are identified in the Plan and supporting procedures is reviewed routinely as described in procedures and updated as needed. Personnel use a document revision request process to identify changes needed to the emergency telephone directory.

ERO personnel are contacted quarterly and requested to validate and update their contact information as necessary in the Duke Energy human resources database. EP staff members update call out information in the dedicated ERO callout system at least quarterly using data from the Duke Energy human resources database.

The Duke Energy Corrective Action Program (CAP) is used to capture all events that do not meet program regulations, requirements, or are otherwise conditions adverse to quality. Changes in plant configuration are evaluated for their impact on the effectiveness of the Plan through the Applicability Determination process specified in Regulatory Affairs procedures and, if required, the 10 CFR 50.54(q) process specified in emergency plan administrative procedures.

V. HAZARD ANALYSIS OF CONTIGUOUS OR NEARBY FACILITIES

A hazard analysis survey has been performed to determine if there are any credible hazards from contiguous or nearby facilities that would adversely impact the implementation of the Project site Emergency Plan. This survey was performed using the guidance contained in NRC Regulatory Guide 1.78, “Evaluating the Habitability of a Nuclear Power Plant Control Room During a Postulated Hazardous Chemical Release,” Revision 2, December 2021.

This survey considered all sources within a five-mile radius and chemicals stored in a radius larger than five miles at large facilities or along major roadways as these may be transported within five miles of the site. The survey looked at:

- Facilities
- Roadways
- Railways
- Pipelines
- Waterways

Research was conducted to identify planned industrial facilities that, when completed, could become a potential hazard to the site.

The survey revealed locations, types of hazardous material, amount of hazardous material stored which if released to the environment could impact plant operations, prevent egress from the site, or prevent access to the site.

This survey will be used not only in evaluating Control Room habitability but the development of the EAL Scheme, EPIPs and site procedures. Site protective actions for the hazard will be included within the procedures. Any special protective clothing or equipment to be stored on-site will be identified.

Further discussion on this survey and other hazards that may impact safe operation of the proposed plant can be found in the SSAR, Section 2.2.

DUKE ENERGY
EMERGENCY PLAN

APPENDIX 1

GLOSSARY

GLOSSARY

Term	Definition
Abnormal Operating Procedures (AOPs)	Specific procedures that provide step-by-step instructions to guide plant operations during potential or actual emergency situations.
Accident	Any unforeseen, or unintentional occurrence or mishap resulting in, or potentially resulting in, physical injury or injury due to radiation exposure or excessive exposure to radioactive materials.
Activated (ERO)	The ERO has been notified of a declared event and instructed to respond to an emergency facility/location.
Activated (Facility)	The facility has met minimum staffing requirements, key systems and equipment is verified operational, and the ERO personnel are performing their assigned emergency response functions.
Alert	Events are in progress or have occurred which involve an actual or potential substantial degradation of the level of safety of the plant or a security event that involves probable life-threatening risk to site personnel or damage to site equipment because of HOSTILE ACTION. Any releases are expected to be limited to small fractions of the USEPA PAG exposure levels.
Alternate Emergency Facility (AEF)	The AEF is a facility dedicated for use by Duke Energy and designed to be accessible to ERO personnel in the event the OERF becomes uninhabitable or in the event of a Security or Hostile Action threat or severe weather event (such as a flood or tornado) if access to the site is deemed unsafe. The AEF provides a location for the ERO to assist the plant in the management and control of emergency response activities.

Annual or annually	Occurring once per calendar year.
Augmented (ERO)	The ERO is divided into two categories – on-shift and augmented. The augmented ERO relieves the shift personnel of emergency response functions.
Biennial or biennially	Once per two calendar years.
Calendar Year	Period beginning January 1 and ending December 31.
CEMP (Comprehensive Emergency Management Plan)	Beyond the EABs, ad hoc actions following a release are addressed using a CEMP. Also referred to as an emergency operations plan (EOP), CEMP is addressed in FEMA Comprehensive Preparedness Guide (CPG) 101, “Developing and Maintaining Emergency Operations Plans”. CPG 101 is the foundation for State, territorial, Tribal, and local emergency planning in the United States. It promotes a common understanding of the fundamentals of risk-informed planning and decision making and helps planners at all levels of government in their efforts to develop and maintain viable, all-hazards, all-threats emergency plans. An EOP is flexible enough for use in all emergencies. It describes how people and property will be protected; details who is responsible for carrying out specific actions; identifies the personnel, equipment, facilities, supplies, and other resources available; and outlines how actions will be coordinated. A CEMP is often referred to as a synonym for “all-hazards emergency planning” (FEMA, 2021).
Command and Control	Management of emergency response functions within a particular context (e.g., an ERF) through leadership and use of authority.
Concept of Operations	Delineation of an organization’s roles and responsibilities and how the organization will function to accomplish those responsibilities.

Containment	A physical structure surrounding a reactor that is designed to prevent or control the release of radioactive material.
Containment Closure	The procedurally defined actions taken to secure containment and its associated structures, systems, and components as a functional barrier to fission product release under shutdown conditions.
Contamination	Undesirable radioactive material (with a potentially harmful effect) that is either airborne or deposited in (or on the surface of) structures, objects, soil, water, or living organisms (people, animals, or plants) in a concentration that may harm people, equipment, or the environment.
Control Room	The area in a nuclear power plant from which most of the plant power production and emergency safety equipment can be operated remotely.
Corrective Action (Non-Emergency)	A concrete, actionable step that is intended to resolve EP program gaps and shortcomings experienced in drills, exercises, or actual events.
Decontamination	A process used to reduce, remove, or neutralize radiological, chemical, or biological contamination to reduce the risk of exposure.
DHS	U.S. Department of Homeland Security.
DOE	U.S. Department of Energy
Dose Rate	The radiation dose delivered per unit of time, measured for example in rem per hour.
Dosimeter	A small portable instrument (such as a film badge, thermoluminescent dosimeter, or electronic dosimeter) used to measure and record the total accumulated personal dose of ionizing radiation.

Dosimetry	The theory and application of the principles and techniques involved in measuring and recording doses of ionizing radiation.
Drill	A coordinated, supervised activity usually employed to validate a specific operation or function in a single agency or organization. Drills are commonly used to provide training on new equipment, develop or validate new policies or procedures, or practice and maintain current skills.
EAB	Exclusion Area Boundary.
EC	Emergency Coordinator
Emergency Action Level (EAL)	A predetermined, site-specific, observable threshold for an initiating condition that, when met or exceeded, places the plant in a given Emergency Classification Level (ECL).
Emergency Classification Level (ECL)	One of a set of names or titles established by the NRC for grouping off-normal events or conditions according to potential or actual effects or consequences and resulting in on-site and off-site response actions. The three (3) ECLs in ascending order of severity, are: Notification of an Unusual Event (NOUE), Alert, and Site Area Emergency (SAE).
Emergency Operating Procedures (EOPs)	Step-by-step procedures for direct actions taken by licensed reactor operators to mitigate and/or correct an off-normal plant condition through the control of plant systems.

Emergency Plan Implementing Procedures (EPIPs)	The set of specific, step-by-step instructions that define how the Emergency Plan is activated and executed during an emergency. EPIPs provide a systematic process for handling emergencies including assurance that emergencies are properly evaluated and classified; notifications are performed; and protective actions are assessed and implemented as needed.
Emergency Release	An unplanned, quantifiable airborne radiological release to the environment attributed to the emergency event.
Emergency Response Data System (ERDS)	A direct, near-real-time electronic data link between the licensee's on-site computer system and the NRC Operations Center that provides for the automated transmission of a limited data set of selected plant parameters.
Emergency Response Organization (ERO)	The personnel assigned to perform tasks and activities associated with implementation of the licensee's emergency plan for coping with emergencies.
Environmental Protection Agency (USEPA)	The mission of the USEPA is to protect human health and the environment. The USEPA is responsible for coordinating Federal environmental response and cleanup for nuclear/radiological accidents.
Evaluation	The process of observing exercise performance to identify strengths and opportunities for improvement in a plant's emergency preparedness and response capabilities.
Exclusion Area	An Exclusion Area is an area specified for the purpose of reactor site evaluation in accordance with 10 CFR 100. It is an area of such size that an individual located at any point on its boundary for two hours immediately following onset of the postulated release would not receive a total radiation dose to the whole body in excess of 25 rem or a total radiation dose in excess of 300 rem to the thyroid from iodine exposure.

Exercise	An instrument to train for. assess, practice, and improve performance in prevention, protection, mitigation, response, and recovery capabilities. Exercises can be used for testing and validating policies, plans, procedures, training, equipment, and interagency agreements; clarifying and training personnel in roles and responsibilities; improving interagency coordination and communications; improving individual performance; identifying gaps in resources; and identifying opportunities for improvement.
Exposure Rate	The rate of charge production from ionizing radiation per unit mass of air (e.g., the amount of gamma radiation that an individual would be exposed to in one hour as measured in air), commonly expressed in roentgens per hour (R/h) or milliroentgens per hour (mR/h).
FBI	Federal Bureau of Investigation
Federal Emergency Management Agency (FEMA)	The agency responsible for establishing Federal policies for and coordinating emergency planning, management, mitigation, and assistance functions of executive agencies. FEMA assists state, local, and tribal government agencies in emergency planning. Its primary role is coordinating Federal, state, local, and tribal governments, and volunteer response actions. FEMA is part of DHS.
Federal Organization	An agency or department of the U.S. Federal Government, or its component(s), having a role in emergency planning and preparedness.
FRMAC	Federal Radiological Monitoring and Assessment Center

Hostile Action	An act directed toward a nuclear power plant or its personnel that includes the use of violent force to destroy equipment, take hostages, and/or intimidate the licensee to achieve an end. This includes attack by air, land, or water using guns, explosives, projectiles, vehicles, or other devices to deliver destructive force.
Incident Command Post (ICP)	The physical location at or near the incident site where primary tactical command functions are performed and led by the Incident Commander and staff. The ICP serves as the central point for managing direct, on-scene control of tactical operations, planning, and communications for the incident.
Initiating Condition (IC)	A plant state or situation that indicates a radiological emergency, or event(s) that could lead to a radiological emergency, has occurred.
Joint Information System (JIS)	A structured approach to organizing, integrating, and delivering information which ensures that timely, accurate, accessible, and consistent messages can be delivered across multiple jurisdictions and/or disciplines to the media, nongovernmental organizations, and the private sector. Critical supporting elements of the JIS include plans, protocols, procedures, and structures used to provide public information.
Key Skill	A capability necessary for implementing emergency response functions to protect public health and safety. A listing of key skills is provided in NSIR-DPR-ISG-01, Interim Staff Guidance, Emergency Planning for Nuclear Power Plants.

Licensee	The utility or organization that has received from the NRC (1) a license to construct or operate a commercial NPP, (2) an ESP for a commercial NPP, (3) a combined license for a commercial NPP, or (4) any other NRC license that is now or may become subject to requirements for radiological emergency planning and preparedness activities.
Monthly	Once per calendar month.
National Incident Management System (NIMS)	A systematic, proactive approach to guide all levels of government, non-governmental organizations, and the private sector to work together to prevent, protect against, mitigate, respond to, and recover from the effects of incidents. NIMS provides stakeholders across the whole community with a shared vocabulary, systems, and processes to successfully deliver the capabilities described in the National Preparedness System. NIMS provides a consistent foundation for dealing with all incidents, ranging from daily occurrences to incidents requiring a coordinated federal response.
National Response Framework (NRF)	The guiding principles, roles, and structures that enable all domestic incident response partners to prepare for and provide a unified national response to disasters and emergencies. It describes how the Federal government, states, tribal governments, communities, and private sector work together to coordinate a national response. The framework builds upon the scalable, flexible, and adaptable concepts identified in NIMS, which provides a template for managing incidents.
Non-Essential Personnel	Those personnel that are not required to fill ERO positions and are not needed for ERO functions.
NC	North Carolina
NCDA&CS	North Carolina Department of Agriculture and Consumer Services

Notification of Unusual Event (NOUE)	Events are in progress or have occurred which indicate a potential degradation of the level of safety of the plant or indicate a security threat to facility protection has been initiated. No releases of radioactive material requiring off-site response nor monitoring are expected unless further degradation of safety systems occurs.
U.S. Nuclear Regulatory Commission (NRC)	U. S. Nuclear Regulatory Commission, the federal agency that regulates commercial nuclear power plants and other uses of nuclear materials, such as nuclear medicine, through licensing, inspection, and enforcement of its requirements.
NRC Site Team	NRC regional personnel who may be activated for on-site assessment and face-to-face coordination with licensee, state, local, and tribal governments, and Federal responders.
Off-site	Outside the boundaries of the Owner Controlled Area (OCA).
On-site	Inside the Protected Area of a nuclear power plant.
On-site Emergency Response Facility (OERF)	An on-site facility that provides plant management and technical support to the reactor operating personnel located in the control room during emergency conditions; and provides a location for maintenance and other support personnel to gather as a ready resource to support emergency response actions.
Owner Controlled Area (OCA)	All areas contiguous to the commercial nuclear power plant that are owned or leased by the licensee (of by any of its associated business units) over which the licensee exercises control. The OCA is usually larger than, and encompasses, the exclusion area.
PA	Public Address

Performance-Based	A regulatory approach that focuses on desired, measurable outcomes rather than prescriptive processes, techniques, or procedures. For EP, the performance-based approach focuses on licensee demonstration of required emergency response functions.
Plume Exposure Pathway Emergency Planning Zone (EPZ)	The area in which public dose as defined in Title 10 of the Code of Federal Regulations,10 CFR) 20.1003, “Definitions”, is projected to exceed 10 mSv (1 rem) TEDE over 4 days (96 hours) from the release of radioactive materials from the facility, considering accident likelihood and source term, timing of the release sequence, and meteorology. It is also the area in which predetermined, prompt protective measures are necessary.
Potassium Iodide (KI)	A prophylactic compound containing a stable (i.e., non-radioactive) form of iodine that can be used effectively to block the uptake of radioactive iodine by the thyroid gland in a human being.
Procedures	An organization’s documented implementing instructions for managing its internal response to emergencies and coordinating its external response with other organizations. The term “procedures” as used in this document, included implementing procedures, standard operating procedures, administrative procedures, maintenance procedures, and testing procedures.
Projected Dose	The prediction of the dose that a population or individual could receive.
Protected Area	The nuclear power plant area under continuous access monitoring and control by the licensee, and armed protection as described in the site security plan.
Protective Action	An action taken to avoid or reduce projected dose.
Protective Action Guide (PAG)	A projected dose to an individual in the general population that warrants the implementation of a protective action.

Quarterly	Once per calendar quarter. Calendar quarters are defined as January-March, April-June, July-September, and October-December.
Rad	Radiation absorbed dose, the basic unit of absorbed radiation dose.
Radiation Protection	The protection of people from the effects of exposure to ionizing radiation, and the means for achieving this.
Recovery	The post-emergency activities in which the plant conditions are assessed, and the plant is returned to an operational mode.
Re-entry	Workers going into relocation or radiologically contaminated areas on a temporary basis under controlled conditions.
Roentgen (r)	A unit of exposure of gamma (or X-ray) radiation in field dosimetry. One roentgen is essentially equal to one rad (see “rad”). A unit for measuring the amount of radiation energy imparted to a volume of air. The roentgen can be used only to measure X-rays of gamma rays.
Roentgen Equivalent Man (rem)	The quantity of ionizing radiation of any type which, when absorbed by man or other mammals, produces a physiological effect equivalent to that produced by the absorption of 1 roentgen of X-ray or gamma radiation.
RPS	Radiation Protection Section
Semi-Annual or semiannually	Twice per calendar year. Twice defined as once in the first six months of the calendar year, and again, once in the second 6 months of the calendar year.
SERT	State Emergency Response Team

Site Area Emergency (SAE)	Events are in progress or have occurred which involve actual or likely major failures of plant functions needed for protection of the public or HOSTILE ACTION that results in intentional damage or malicious acts:1) toward site personnel or equipment that could lead to the likely failure of or 2) that prevent effective access to, equipment needed for the protection of the public. Any releases are not expected to result in exposure levels which exceed USEPA Protective Action Guide (PAG) exposure levels beyond the EAB.
Site Boundary	The line that encompasses the Project site where Duke Energy proposes to construct and operate multiple advanced reactors on one or more of three plant complexes as identified on Figure I-1. The Project site is owned by Duke Energy and is bounded on the north, east, and west by Belews Lake, also owned by Duke Energy. It should be noted that in addition to Belews Lake, Duke Energy owns land beyond the Site Boundary which includes the Belews Creek Steam Station, a two-unit, 2220 megawatts electric (MWe) fossil fuel plant.
Site Safety Analysis Report (SSAR)	The report required by 10 CFR 52.17(a)(1) to be included in each application for an Early Site Permit. The SSAR includes a description of the facility, the maximum levels of thermal and radiological effluents, and a description of seismic, meteorological, hydrologic, and geologic characteristics of the proposed site.
Total Effective Dose Equivalent (TEDE)	The sum of deep dose equivalent (for external exposures) and committed effective dose equivalent (for internal exposures)
Weekly	Once per calendar week, defined as Monday through Sunday.

GLOSSARY

Term	Definition
CFR	Code of Federal Regulations
DEC	Duke Energy Carolinas, LLC
DEP	Duke Energy Progress, LLC
ESP	Early Site Permit
LLC	Limited Liability Company
NRC	U.S. Nuclear Regulatory Commission

Section 1 Introduction and Background

Duke Energy Carolinas, LLC (DEC), referred to herein as “Duke Energy,” a wholly-owned subsidiary of Duke Energy Corporation, is submitting this application for an Early Site Permit (ESP) for the Belews Creek, North Carolina site to the U.S. Nuclear Regulatory Commission (NRC) in accordance with the requirements of Title 10 of the Code of Federal Regulations (CFR) Part 52 (10 CFR Part 52) Subpart A, “Early Site Permits.” Duke Energy is the applicant for this ESP. Duke Energy Progress, LLC (DEP) an indirect subsidiary of Duke Energy Corporation, and DEC (together referred to as “the Companies”) combined make up the Carolinas service territory within the region of interest.

Part 7 of this application identifies any exemptions requested under 10 CFR 52.7, “Specific Exemptions.” In accordance with 10 CFR Part 52, an applicant for an ESP may request exemptions from applicable requirements of Part 52. Exemptions from the requirements of other parts of the regulations that apply by virtue of 10 CFR Part 52 are governed by the exemption requirements of those parts (e.g., 10 CFR 50.12, “Specific Exemptions,” governs exemptions from 10 CFR Part 50 requirements). Variances under 10 CFR 52.93 and departures under 10 CFR 52.63 are not applicable to this ESP application.

As described in Section C.1.7 of Regulatory Guide 1.206, any such exemption request, if applicable, would clearly state its scope and purpose, include justification based on applicable regulatory requirements and guidance, and provide a technical and regulatory evaluation addressing safety significance and acceptance criteria. If an exemption request were submitted, it would be evaluated against the specific exemption criteria in 10 CFR 50.12 and would identify whether NRC approval or an exemption is required.

Section 2 Exemptions

The ESP application submitted herein has been reviewed, and it has been determined that no exemptions from the applicable requirements of 10 CFR are necessary for consideration by the NRC under the provisions of 10 CFR 52.7 and the exemption criteria set forth in 10 CFR 50.12. Variances under 10 CFR 52.93 and departures under 10 CFR 52.63 are not applicable to this ESP application. No NRC approval is required in this regard.

Section 1 Introduction and Background

Duke Energy Carolinas, LLC (DEC), referred to herein as "Duke Energy," a wholly-owned subsidiary of Duke Energy Corporation, is submitting this application for an Early Site Permit (ESP) for the Belews Creek, North Carolina (NC) site (Project site) to the U.S. Nuclear Regulatory Commission (NRC) in accordance with the requirements of Title 10 of the Code of Federal Regulations (CFR) Part 52 (10 CFR Part 52) Subpart A, "Early Site Permits." Duke Energy is the applicant for this ESP. Duke Energy Progress, LLC (DEP) an indirect subsidiary of Duke Energy Corporation, and DEC (together referred to as "the Companies") combined make up the Carolinas service territory within the region of interest.

Part 10 of this application provides information related to Duke's Quality Assurance Program. The applicable Duke Energy Topical Report is: DUKE-QAPD-001, *Quality Assurance Program Description Operating Fleet* (hereby referred to as QAPD). The QAPD and associated procedures provide for control of Duke Energy's activities that have the potential to affect the quality of safety-related structures, systems, and components (SSCs) of the proposed advanced reactors at the Project site. Requirements for an ESP QAPD are set forth in 10 CFR 52.17(a)(1). The current revision of the Duke QAPD has been previously submitted to the NRC and assigned the Accession number of ML24319A007.

Section 2 Quality Assurance Program Description

The QAPD is the top-level Quality Assurance (QA) document that applies to Duke Energy's fleet and that defines the quality policy and assigns major functional responsibilities. The QAPD applies to Duke Energy's personnel, organizations, and contractors performing activities within the scope of the QAPD that could affect the quality of safety-related SSCs. The QAPD also addresses the site-related activities associated with the preparation of the Early Site Permit Application (ESPA).

The QAPD applies to site suitability quality assurance activities associated with the ESPA, including designing, procuring, handling, testing, siting, inspecting, storing, training, and shipping. The QAPD is based on American National Standards Institute (ANSI) N18.7 and the ANSI N45.2 series standards in lieu of ANSI / American Society of Mechanical Engineers (ASME) Nuclear Quality Assurance (NQA)-1.

The QAPD has been evaluated in relationship to NUREG-0800, Section 17.5 and found to be in compliance with the Standard Review Plan (SRP) with following two exceptions:

- Section S, Items 2 and 3 – Per the QAPD, the Chief Nuclear Officer (CNO) is responsible for quality assurance and is the highest level of management responsible for establishing Duke Energy Corporation's nuclear policies, goals, and objectives. The qualifications of the CNO meet the intent of Section S, Item 2 qualifications for management of the implementation of the QA plan. Section S, Item 3 individuals responsible for planning, implementing, and maintaining the QA plan are qualified in accordance with the QAPD and are the same personnel for the operating plants. These qualifications meet the intent of Section S, Item 3 of the SRP.

- Section V, Item 1e – The QAPD does not commit to NRC Generic Letter (GL) 91-05, *Licensee Commercial-Grade Dedication Programs*. The QAPD commits to other dedication guidelines, such as GL 89-02, *Actions to Improve the Detection of Counterfeit and Fraudulently Marked Products*, and Regulatory Guide (RG) 1.164, *Dedication of*

Commercial-Grade Items for Use in Nuclear Power Plants. The current QAPD meets the intent of Section V, Item 1e of the SRP.

Section 1 Introduction and Background

Duke Energy Carolinas, LLC (DEC), referred to herein as “Duke Energy,” a wholly-owned subsidiary of Duke Energy Corporation, is submitting this application for an Early Site Permit (ESP) to the U.S. Nuclear Regulatory Commission (NRC) in accordance with the requirements of Title 10 of the Code of Federal Regulations Part 52 (10 CFR 52) Subpart A, “Early Site Permits.” Duke Energy is the applicant for this ESP. Duke Energy Progress, LLC (DEP), an indirect subsidiary of Duke Energy Corporation, and DEC (together referred to as “the Companies”) combined make up the Carolinas service territory within the region of interest.

Part 11 is a placeholder for supplemental information that may be identified during the review and preparation of the ESP application. This supplemental information, if needed, will supplement the standard information identified in Parts 1 through 10.

The supplemental information may include additional information on specific regulatory issues and other information deemed appropriate by Duke Energy or requested by the NRC to facilitate their review and approval of this ESP application.

Section 2 Supplemental Information

The ESP application submitted herein has been reviewed, and it has been determined that no supplemental information is currently needed to support the application.
