When any manual scram push button is depressed, a control room annunciation is initiated and a process computer record is produced to identify the tripped RPS trip logic.

Identification of the mode switch in shutdown position scram trip is provided by the manual scram annunciator and the process computer trip logic identification printout.

Partial or full closure of any MSIV or turbine stop valve causes a change in the status of position indicator lights in the control room. These indications are not a part of the RPS, but they do provide the operator with valid information pertinent to the valve status. Partial or full closure of one or both valves in a particular set of two main steam lines initiates a control room annunciator when the trip setpoint has been exceeded. A turbine stop valve closure trip will be indicated if an RPS channel is tripped by a two-out-of-four valve closure combination. This information is displayed on panel 1AC803 (reactor control annunciator panel) and on the main turbine annunciator panel (1BC807). The closed position of each turbine stop valve is also indicated in the control room using a position switch independent of those used in the RPS logic and powered from a separate electrical power source. This same condition permits identification of the tripped channels in the form of a typed record from the process computer or by visual observation of the valve position indicator lights.

NMS annunciators provided in the control room indicate the NMS RPS trip. The process computer provides a typed record of the tripped NMS channel as well as identification of individual IRM and APRM channel trips.

Two control room annunciators are provided to identify the tripped portions of the RPS in addition to the previously described trip channel annunciators:

a. A1 or A2 trip logics tripped

b. B1 or B2 trip logics tripped

These same functions are connected through independent auxiliary contacts of the scram contactors to the process computer to provide a typed record of the relay operations.

7.2.2.1.2.3.1.20 RPS - IEEE 279 (1971), Paragraph 4.20 - Information Readout

The data presented to the control room operator for each of the RPS trip variables complies with this design and provide accurate, complete, and timely information pertinent to the status of the RPS. The design minimizes the development of conditions that would cause anomalous indications that are confusing to the operator.

7.2.2.1.2.3.1.21 RPS - IEEE 279 (1971), Paragraph 4.21 - System Repair

During periodic testing of the sensor channels for the following RPS trip variables, the operator can determine any defective component and replace it during plant operation:

a. SDV high water level trip

b. Reactor vessel low water level trip

c. Drywell high pressure trip

d. Reactor vessel high pressure trip

During periodic testing of the sensor channels for the trip variables listed below, all defective components can be identified. Replacement and repair of failed sensors can only be accomplished during reactor shutdown. All other components can be replaced, repaired, or adjusted during plant operation.

a. MSIV closure trip

b. Turbine stop valve closure trip

c. Left blank intentionally.

d. Neutron monitoring (APRM) system trip (including OPRM trip)

e. Neutron monitoring (IRM) system trip

f. Turbine control valve fast closure trip

Replacement of IRM and LPRM detectors must be accomplished during plant shutdown. Repair of the remaining portions of the NMS may be accomplished during plant operation by appropriate bypassing of the defective instrument channel. The design of the system facilitates rapid diagnosis and repair.

7.2.2.1.2.3.1.22 RPS - IEEE 279 (1971), Paragraph 4.22 - Identification of Protection Systems

Each system logic cabinet is identified distinctively as being in the protection system, and the particular redundant portion is listed on a distinctive marker plate. Cabling outside the cabinets is identified specifically as RPS wiring. An identification scheme is used to distinguish between redundant cables and raceways. Redundant racks are identified by the identification marker plates of instruments on the racks. Control room devices are identified by tags on the panels. These tags indicate the function of the device.

7.2.2.1.2.3.2 RPS - IEEE 308 (1971) - Criteria for Class 1E Electrical Systems for Nuclear Power Generating Stations

The RPS is a fail-safe logic system, and its power supplies are non-Class 1E. The backup scram circuitry is powered by Class 1E power. The backup scram circuitry is designed to meet the requirements of IEEE 308 (1971).

7.2.2.1.2.3.3 RPS - IEEE 317 (1972) - Electric Penetration Assemblies in Containment Structures for Nuclear Power Generating Stations

See the discussion of Regulatory Guide 1.63 in Section 8.1.6.1.12.

7.2.2.1.2.3.4 RPS - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1 Electric Equipment for Nuclear Power Generating Stations

IEEE 323 (1971) is satisfied by complete qualification testing and certification of all essential components. Records covering all essential components are maintained.

7.2.2.1.2.3.5 RPS - IEEE 336 (1971) - Installation, Inspection, and Testing Requirements for Instrumentation and Electric Equipment During the Construction of Nuclear Power Generating Stations

See Chapter 17.

7.2.2.1.2.3.6 RPS - IEEE 338 (1971) - Criteria for the Periodic Testing of Nuclear Power Generating Station Protection Systems

IEEE 338 (1971) is satisfied by being able to test the RPS from sensors to the scram contactors at any time during plant operation. The tests are performed in overlapping portions.

7.2.2.1.2.3.7 RPS - IEEE 344 (1971) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Station

IEEE 344 (1971) is satisfied by all Class 1 RPS equipment as described in Section 3.10.

The above does not apply to turbine stop valve and control valve fast closure trips during or after an SSE, as discussed in Section 7.2.1.2.8.

7.2.2.1.2.3.8 RPS - IEEE 379 (1972) - Guide for the Application of the Single Failure Criterion to Nuclear Power Generating Station Protection Systems

IEEE 379 (1972) requirements are satisfied by considering the different single failure modes and carefully designing all potential violations of the single failure criterion out of the system.

7.2.2.1.2.3.9 RPS - IEEE 384 (1974) - Criteria for Separation of Class 1E Equipment and Circuits

See Section 7.1.2.7.11.

The standard requires that redundant sensors and their connections to the process system be sufficiently separated to ensure that functional capability of the protection system is maintained despite any single design basis event or resulting effect.

The RPS conforms to IEEE 384 except for the requirement that redundant sensors and their connections to the process system be sufficiently separated to ensure that functional capability of the protection system is maintained despite any single design basis event or resulting effect. The above does not apply to the turbine stop valve and control valve fast closure trips in a nonseismic turbine enclosure during or after an SSE, as discussed in Section 7.2.1.2.8.

Additional details of the separation criteria used for the RPS are provided in Sections 8.1.6.1.14 and 7.1.2.2.

7.2.2.1.2.4 RPS Power Generation Design Bases

The RPS is a one-out-of-two-twice logic system, which inherently provides both reliability of action and availability of function. This permits testing during reactor operation without causing a scram.

7.2.2.1.3 RPS Additional Design Considerations Analyses

7.2.2.1.3.1 RPS Spurious Rod Withdrawals

Spurious control rod withdrawals do not normally cause a scram.A control rod withdrawal block may occur, however. Rod block is discussed in Section 7.6.1.4 and is not part of the RPS. A scram does occur, however, if the spurious control rod withdrawal causes the average flux to exceed the trip setpoint.

7.2.2.1.3.2 Loss of Plant Instrument Air System

Loss of plant instrument air causes opening of the scram valves on the hydraulic control units, resulting in a scram.

7.2.2.1.3.3 Loss of Cooling Water to Vital Equipment

There is no loss of cooling water that affects the RPS.

7.2.2.1.3.4 Plant Load Rejection

Electrical grid disturbances could cause a significant loss of load that would initiate a turbine-generator overspeed trip and control valves fast closure, resulting in a reactor scram. The reactor scram occurs to anticipate an increase in reactor vessel pressure that is due to shutting off the path of steam flow to the turbine. Any additional increase in pressure is prevented by the SRVs that open to relieve reactor pressure and close as pressure is reduced. The RCIC or HPCI systems automatically actuate and provide vessel makeup water if required.

The fuel temperature or pressure boundary thermal-hydraulic limits are not exceeded during the event, as described in Chapter 15.

7.2.2.1.3.5 Turbine Trip

Initiation of turbine trip by the turbine system closes the turbine stop valves initiating a reactor scram. The stop valve scram anticipates a reactor pressure or power scram that is due to the closure of turbine stop valves. Any additional increase in reactor vessel pressure is prevented by the SRVs that open to relieve reactor vessel pressure and close as pressure is reduced. The RCIC and HPCI automatically actuate and provide vessel makeup water if a low water level occurs.

Initiation of turbine trip by loss of condenser vacuum causes simultaneous closure of the turbine stop valves and MSIVs initiating a reactor scram.

The fuel temperature, pressure boundary, and thermal-hydraulic limits are not exceeded during these events, as described in Chapter 15.

Table 7.2-2

TRIP SYSTEM CHANNELS REQUIRED FOR FUNCTIONAL PERFORMANCE OF RPS

This table shows the normal and minimum number of trip system channels required for the functional performance of the RPS. The "normal" column lists the normal number of channels provided per trip system. The "minimum" column lists the minimum number of trip system operable channels required to maintain functional performance.

Channel Description	Normal	Minimum
Neutron monitoring system (APRM)(4)(5)	4	3
Neutron monitoring system APRM 2-out-of-4 voter (5)	2	2
Neutron monitoring system (IRM)(1)	4	3
Nuclear system high pressure	2	2
Drywell high pressure	2	2
Reactor vessel low water level	2	2
SDV high water level	2	2
Manual scram	2	2
Each MSIV position(2)	1/valve	1/valve
Each turbine stop valve position(3)	1/valve	1/valve
Turbine control valve fast closure, trip oil pressure low (3)	2	2
Reactor mode switch shutdown position	2	2

(1) Not required in run and shutdown modes
(2) Not required in shutdown, refuel and startup modes
(3) Not required when reactor power is less than 29.5% of rated power
(4) APRM channels, including OPRM trip, provide input to both RPS trip systems via the 2-out-of-4 voters.
(5) Not required in shutdown and refuel modes.

7.3 ENGINEERED SAFETY FEATURE SYSTEMS

Safety-related instrumentation and controls for ESF systems are described in this section. Instrumentation and controls for systems that support ESF systems are also described.

7.3.1 DESCRIPTION

The following systems are part of the ESF:

a. Emergency core cooling systems

b. Primary containment and reactor vessel isolation control system

c. Deleted

d. RHR containment spray mode

e. RHR suppression pool cooling mode

f. Containment atmospheric control system

g. Standby gas treatment system

h. Reactor enclosure recirculation system

i. Reactor enclosure isolation system

j. Habitability and control room isolation

k. Emergency service water system

l. RHR service water system

m. Control enclosure chilled water system

n. Class 1E power system

o. Safety-related equipment area cooling ventilation systems:

    1. SGTS filter room and access area unit coolers

    2. Diesel generator enclosure ventilation system

    3. Spray pond pump structure ventilation system

    4. ESF switchgear and battery rooms cooling system

    5. ECCS pump compartment unit coolers

    6. Auxiliary equipment room ventilation system

p. Drywell Unit Coolers

7.3.1.1 System Description

7.3.1.1.1 Emergency Core Cooling Systems - Instrumentation and Controls

The ECCS is a network of the following systems:

a. HPCI system

b. ADS

c. Core spray system

d. LPCI mode of the RHR system

The purpose of ECCS instrumentation and controls is to initiate appropriate responses from the system to ensure that the fuel is adequately cooled if there is a DBA. The cooling provided by the system restricts the release of radioactive materials from the fuel by preventing or limiting the extent of fuel damage following situations in which coolant is lost from the RCPB.

The ECCS instrumentation detects a need for core cooling systems operation, and the trip systems initiate the appropriate response. The ECCS instrumentation and controls are classified as Safety Class 2, seismic Category I, Quality Group B, and electric Class 1E.

Not included in this section is a discussion of measures that are taken to protect the low pressure ECCS from the high pressure RCS. The high pressure/low pressure interlocks are examined in Section 7.6.

The instrumentation and controls of the ECCS network system are powered by the 125 V dc and 120 V ac systems. The redundancy and separation of these systems are consistent with the redundancy and separation of the ECCS functional requirements. The power sources for the ECCS network systems are described in detail in Chapter 8.

7.3.1.1.1.1 High Pressure Coolant Injection System - Instrumentation and Controls

7.3.1.1.1.1.1 HPCI System Identification

When actuated, the HPCI system pumps water from either the CST or the suppression pool to the reactor vessel via a core spray line and a feedwater line. The HPCI system includes a turbine-driven pump, a dc motor-driven auxiliary oil pump, a gland seal condenser condensate pump, a gland seal condenser vacuum pump, automatic valves, control devices, sensors, and logic circuitry. The arrangement of equipment and control devices is shown in drawings M-55 and M-56. These drawings identify both nonsafety-related and safety-related parts of this system.

7.3.1.1.1.1.2 HPCI Equipment Design

Pressure and level transmitters used in the HPCI system are located on racks in the reactor enclosure. The only active component for the HPCI system located inside the primary containment is the inboard HPCI system turbine steam supply line isolation valve. The rest of the HPCI system control and instrumentation is located outside the primary containment. A full flow functional test of the system can be conducted during normal reactor power operation; however, the controls are

configured such that the system can be realigned automatically to fulfill its safety function regardless of the test being conducted.

There are three exceptions:

a. The HPCI flow controller auto/manual feature in the manual mode sets the HPCI system at selected flow rate; the operator can select auto if required. This feature is for operator flexibility during system operation.

b. Steam inboard/outboard isolation valves. Closure of either or both of these valves requires operator action to properly sequence their opening. An alarm sounds when either of these valves leaves the fully open position.

c. HPCI test switch in F006 and F007 position and test plug J1 or J10 inserted results in the HPCI system being inoperable. Depending on whether the test switch is in F006 or F007 position, one of the two series discharge valves are interlocked closed, preventing high pressure core injection. If the test switch is in F006, it disables both the F006 (discharge to core spray) and F105 (discharge to feedwater). HPCI OUT-OF-SERVICE annunciator sounds in the control room in indicate HPCI in test.

7.3.1.1.1.1.3 HPCI Initiating Circuits

Reactor vessel low water level is monitored by four level sensors that sense the difference between the pressure due to a constant reference leg of water and the pressure due to the actual height of water in the vessel as shown in drawing M-42. Each level sensor provides an input to a trip unit. Refer to Figure 7.3-26 for a diagram of level sensor connections. The four trip units are connected in a one-out-of-two-twice logic to provide an automatic HPCI initiation signal. Two lines, attached to taps above and below the water level on the reactor vessel, are required for the differential pressure measurement for each pair of level sensors. The lines terminate outside the primary containment and inside the reactor enclosure. The sensors are physically separated from the ADS sensors and tap off the reactor vessel at points widely separated from the ADS sensors. These same lines are also used for pressure and water level instruments for other systems. A similar arrangement of the ADS instrumentation initiates the ADS system. The arrangement ensures that no single event can prevent reactor vessel low water level from initiating both the HPCI system and the ADS.

Primary containment pressure is monitored by four pressure sensors that are mounted on an instrument rack outside the drywell, but inside the reactor enclosure. Pipes from the drywell interior to the sensors provide the sensing lines. Each drywell high pressure sensor provides an input into a trip unit. The four trip units are connected in a one-out-of-two-twice logic to provide an automatic HPCI initiation signal. The relay contacts from the trip units are arranged so no single event can prevent containment high pressure from initiating the HPCI system and ADS. The sensors are physically separated from the ADS pressure sensors and tap off the containment at points widely separated from the ADS pressure sensors.

The HPCI system controls automatically start the HPCI system from the receipt of a reactor vessel low water level signal (level 2) or primary containment drywell high pressure signal and bring the system to its design flow rate within 60 seconds. The system can also be initiated by use of a system-level remote manual switch or an individual remote manual switch for each valve and the auxiliary oil pump which provides the initial hydraulic fluid for the turbine stop and governor valves. In all initiation modes, the system is prevented from operating above high water level (level 8) using one-out-of-two-twice logic. The controls then function to provide design makeup water flow to the

reactor vessel until the amount of water delivered to the reactor vessel is adequate (level 8), at which time the HPCI system automatically shuts down. The system is designed to automatically cycle between these two levels. The controls are arranged to allow remote manual startup, operation, and shutdown.

The HPCI turbine is functionally controlled as shown in drawings E41-1030-F-004, E41-1030-F-005, E41-1030-F-006, E41-1030-F-007, E41-1030-F-008, and E41-1030-F-009. A speed governor limits the turbine speed to its maximum operating level. A control governor receives a HPCI system flow signal and adjusts the turbine steam control valve so that the design HPCI system pump discharge flow rate is obtained. drawings E41-1030-F-004, E41-1030-F-005, E41-1030-F-006, E41-1030-F-007, E41-1030-F-008, and E41-1030-F-009 shows the various modes of turbine control. The flow signal used for automatic control of the turbine is derived from a differential pressure measurement across a flow element in the HPCI system pump discharge line. The governor controls the pressure applied to the hydraulic operator of the turbine control valve, which in turn controls the steam flow to the turbine. Hydraulic pressure is supplied for both the turbine control valve and the turbine stop valve by the dc-powered auxiliary oil pump during startup and then by the shaft-driven hydraulic oil pump when the turbine reaches operating speed.

Upon receipt of an initiation signal, the auxiliary oil pump starts, providing hydraulic pressure for the turbine stop valve and turbine control valve hydraulic operator. Because there is no flow in the HPCI system, the flow signal runs the control governor to the high speed stop. As hydraulic oil pressure is developed, the turbine stop valve and the turbine control valve open, and the turbine accelerates toward the speed setting of the control governor. As HPCI system flow increases, the flow signal adjusts the control governor setting so that design flow is maintained. The turbine is automatically shut down by tripping the turbine stop valve closed if any of the following conditions are detected:

a. High turbine exhaust pressure (one-out-of-two)

b. Low HPCI pump suction pressure (one-out-of-one)

c. High reactor water level (one-out-of-two-twice)

d. Turbine overspeed signal (one-out-of-one mechanical)

e. Low steam supply pressure (two-out-of-two)

f. HPCI autoisolation signals (one-out-of-two logic for turbine trip, for isolation one channel closes the inboard valve and one channel closes the outboard valve).

g. Remote manual trip

In each division, an auto isolation signal is initiated by any of the following:

a. Steam supply line - high flow (one-out-of-one logic trip)

b. High turbine exhaust diaphragm pressure (two-out-of-two logic trip)

c. High equipment or piping area temperature or high equipment area delta temperature (one-out-of-six logic trip)

d. Low steam supply pressure (two-out-of-two logic trip)

Precautions taken to preclude spurious HPCI system turbine isolation are:

a. Using coincident logic isolation trip circuits for low steam supply and high turbine exhaust diaphragm pressure.

b. Using trip time delay circuits (Reference NUREG-0737, Item II.K.3.15).

c. Using safety-grade instrumentation and control equipment.

d. Selecting trip settings far enough from normal operating values to avoid spurious trips, yet close enough to protect equipment.

The HPCI test return to condensate storage line valve HV-55-*F011 is normally kept closed except during HPCI or RCIC system flow testing. If during testing either a low reactor water level (level 2) or high drywell pressure condition initiates HPCI system operation, valve HV-55-*F011 and in series test return valve HV-55-*F008 are automatically closed. In addition, HPCI valve HV-55-*F011 is automatically closed if one of the HPCI or RCIC pump suppression pool suction valves HV-55-*F041, HV-49-*F029 or F031 fully opens. The *F011 is not automatically closed if the suppression pool to pump suction PCIV, HV-055 *F042 is open.

The preferred source of water for the HPCI is the CST. The HPCI system will realign to suppression pool suction upon receipt of a CST low level or suppression pool high level signal. Either of these signals open the HPCI suppression pool suction valves HV-55-*F041 and F042, if closed, which in turn sends a signal to close the CST suction valve HV-55-*F004 when both are fully open.

Turbine overspeed indicates a malfunction of the turbine control mechanism. High turbine exhaust pressure indicates a condition that threatens the physical integrity of the turbine casing. Low pump suction pressure warns that cavitation and lack of cooling can cause damage to the pump, which could place it out-of-service. A turbine trip is initiated for abnormal conditions so that, if the causes of the abnormal condition can be found and corrected, the system can be restored to service. The trip settings are selected far enough from normal values so that a spurious turbine trip is unlikely, but not so close that damage occurs before the turbine is shut down. Turbine overspeed is detected by a standard turbine overspeed electronic device for indication and a mechanical-hydraulic device for tripping the turbine. Two pressure sensors are used to detect high turbine exhaust pressure; either sensor can initiate turbine shutdown. One pressure sensor is used to detect low HPCI system pump suction pressure.

High water level in the reactor vessel indicates that the HPCI system has performed satisfactorily in providing makeup water to the reactor vessel. Further increase in level could result in HPCI system turbine damage caused by gross carryover of moisture. The reactor vessel high water level setting that trips the turbine (level 8) is near the top of the steam separators and is sufficient to prevent gross moisture carryover to the turbine. Four level 8 trip units, connected to appropriate sensors, arranged in a one-out-of-two-twice configuration, are required to initiate a turbine shutdown. Refer to Figure 7.3-26 for a diagram of level sensor connections.

Low steam supply pressure is detected by two pressure sensors, both of which must trip to initiate a turbine shutdown. This low pressure indicates that there is insufficient energy in the steam for the turbine to function.

The control scheme for the turbine auxiliary oil pump is shown in drawings E41-1030-F-004, E41-1030-F-005, E41-1030-F-006, E41-1030-F-007, E41-1030-F-008, and E41-1030-F-009. System controls are arranged for automatic or manual control. Upon receipt of an HPCI system initiation

signal, the auxiliary oil pump starts and provides hydraulic pressure to open the turbine stop valve and the turbine control valve. As the turbine gains speed, the shaft-driven oil pump begins to supply hydraulic pressure. When the pressure supply by the shaft-driven oil pump is sufficient, the auxiliary oil pump automatically stops. Should the shaft-driven oil pump malfunction, causing oil pressure to drop, the auxiliary oil pump restarts automatically.

The operation of the gland seal condenser components (gland seal condenser condensate pump (dc), gland seal condenser vacuum pump (dc), and gland seal condenser water level instrumentation) prevents outleakage from the turbine shaft seals. Startup of this equipment is automatic, as shown in drawings E41-1030-F-004, E41-1030-F-005, E41-1030-F-006, E41-1030-F-007, E41-1030-F-008, and E41-1030-F-009. Failure of this equipment does not prevent the HPCI system from providing water to the reactor vessel.

7.3.1.1.1.1.4 HPCI Logic and Sequencing

Either reactor vessel low water level (level 2) or primary containment (drywell) high pressure can automatically start the HPCI system as indicated in drawings E41-1030-F-004, E41-1030-F-005, E41-1030-F-006, E41-1030-F-007, E41-1030-F-008, and E41-1030-F-009. Reactor vessel low water level is an indication that reactor coolant is being lost and that the fuel is in danger of being overheated. Primary containment high pressure is an indication that a breach of the nuclear system process barrier has occurred inside the drywell.

The scheme used for initiating the HPCI system is shown in drawings E41-1030-F-004, E41-1030-F-005, E41-1030-F-006, E41-1030-F-007, E41-1030-F-008, and E41-1030-F-009. The components required for HPCI system initiation are powered by dc buses.

Instrument settings for the HPCI system controls and instrumentation are listed in Table 7.3-1. The reactor vessel low water level setting for HPCI system initiation is selected high enough above the active fuel to start the HPCI system in time both to prevent excessive fuel cladding temperatures and to prevent more than a small fraction of the core from reaching the temperature at which gross fuel failure occurs. The water level setting is sufficiently below normal levels so that spurious HPCI system startups are avoided. The primary containment high pressure setting is selected to be as low as possible without inducing a spurious HPCI system startup. The logic diagram for BOP portions of the HPCI system is shown in drawing M-55FD.

7.3.1.1.1.1.5 HPCI Bypasses and Interlocks

To prevent the turbine-pump from being damaged by overheating at reduced HPCI pump discharge flow, a pump discharge minimum flow line is provided to route the water being discharged from the pump to the suppression pool. The minimum flow is controlled by an automatic, dc MOV whose control scheme is shown in drawings E41-1030-F-004, E41-1030-F-005, E41-1030-F-006, E41-1030-F-007, E41-1030-F-008, and E41-1030-F-009. On high HPCI flow, stop valve closure, or steam supply valve closure, the valve is closed, and on low flow, provided pump discharge pressure is above a pressure permissive setpoint (indicates pump is running) the valve is opened. The flow transmitter and trip units that measure the pressure difference across a flow element in the HPCI pump discharge pipeline provide the control signal for this valve.

To prevent the HPCI steam supply pipeline from filling up with water and cooling, a condensate drain pot, steam line drain, and appropriate valves are provided in a drain pipeline arrangement just upstream of the turbine supply valve. The control scheme is shown in drawings E41-1030-F-004, E41-1030-F-005, E41-1030-F-006, E41-1030-F-007, E41-1030-F-008, and E41-1030-F-009. The controls position valves so that during normal operation steam line drainage is routed to the

main condenser. Upon receipt of a HPCI initiation signal and subsequent steam supply valve opening, the drainage path is isolated. The water level in the steam line condensate drain pot is controlled by a level switch, a flow orifice, and an air-operated steam trap bypass drain valve that allows condensate to flow out of the pot.

During test operation, the HPCI pump discharge is routed to the CST. Two dc MOVs are installed in the pump discharge to the CST pipeline. The piping arrangement is shown in drawing M-55. The control scheme for the two valves is shown in drawings E41-1030-F-004, E41-1030-F-005, E41-1030-F-006, E41-1030-F-007, E41-1030-F-008, and E41-1030-F-009. Upon receipt of an HPCI system initiation signal, the two valves close and remain closed. Valve F011 is interlocked closed if the HPCI F041 or RCIC F029 or F031 valves are fully open. Numerous indications pertinent to the operation and condition of the HPCI system are available to the control room operator. Drawings M-55, M-56, E41-1030-F-004, E41-1030-F-005, E41-1030-F-006, E41-1030-F-007, E41-1030-F-008, and E41-1030-F-009 show the various indications provided.

Suction is normally taken from the CST. If the level in the CST falls to a low level or the nonseismic pipeline from the CST breaks, a level sensor in the vertical run of pipe from the grade down to the HPCI pump compartment initiates an automatic realignment of pump suction piping to the suppression pool. The logic for automatic operation of the suction valves is shown by drawings E41-1030-F-004, E41-1030-F-005, E41-1030-F-006, E41-1030-F-007, E41-1030-F-008, and E41-1030-F-009. Also, high suppression pool level will cause an automatic realignment of the suction source from the CST to the suppression pool.

7.3.1.1.1.1.6 HPCI Redundancy and Diversity

The HPCI system is actuated either by reactor vessel low water level (level 2) or by primary containment (drywell) high pressure. Both of these conditions could result from a LOCA. The redundancy of the HPCI system initiating circuits is consistent with the design of the HPCI system.

7.3.1.1.1.1.7 HPCI Actuated Devices

The HPCI actuated devices are automatically controlled by logic circuitry or manually controlled by switches in the control room. MOVs are provided with appropriate limit and/or torque switches to turn off the motors when the fully open or fully closed positions are reached. Valves that are automatically closed on isolation signals are equipped with remote manual reset devices so that they cannot be reopened without operator action. All essential components of the HPCI system controls operate on dc power or ac power supplied by an inverter that is part of the ECCS.

To ensure that the HPCI system can be brought to design flow rate within 60 seconds from receipt of the initiation signal, the following maximum operating times for essential HPCI system valves are provided by the valve operation mechanisms:

a.	HPCI system turbine steam supply valve	20 sec
b.	HPCI system pump discharge valves (except F105 valve	20 sec 40 sec)
c.	HPCI system pump minimum flow bypass valve	15 sec

The operating time is the time required for the valve to travel from the fully closed to the fully open position or vice-versa. Because the two HPCI system steam supply line isolation valves are normally open and because they are intended to isolate the HPCI system steam line if there is a break in that line, their operating time requirements are based on isolation requirements. These are described in Section 7.3.1.1.2.4.1.2. A normally closed dc MOV is located in the turbine steam supply line just upstream of the turbine stop valve. The control scheme for this valve is shown in

drawings E41-1030-F-004, E41-1030-F-005, E41-1030-F-006, E41-1030-F-007, E41-1030-F-008, and E41-1030-F-009. Upon receipt of an HPCI system initiation signal, this valve opens and remains open until closed by operator action from the control room.

Two normally open isolation valves are provided in the steam supply line to the turbine. The control diagram is shown in drawings E41-1030-F-004, E41-1030-F-005, E41-1030-F-006, E41-1030-F-007, E41-1030-F-008, and E41-1030-F-009. The valves automatically close upon receipt of an HPCI system turbine steam line high flow signal, an HPCI system turbine steam supply low pressure signal, high turbine exhaust diaphragm pressure, high steam line space temperature, HPCI equipment room ventilation inlet/outlet high differential temperature, or high area temperature.

Three pump suction valves are provided in the HPCI system. One valve provides pump suction from the CST; the other two provide suction from the suppression chamber. The CST is the preferred source. All valves are operated by dc motors. The control arrangement is shown in drawings E41-1030-F-004, E41-1030-F-005, E41-1030-F-006, E41-1030-F-007, E41-1030-F-008, and E41-1030-F-009. Although the CST suction valve is normally open, an HPCI system initiation signal opens it if it is closed. If the water level in the CST falls below a preselected level, the suppression chamber suction valves automatically open. When both suppression chamber valves are fully open, the CST suction valve automatically closes. Two level sensors are used to detect the CST low water level condition. Either sensor can cause the suppression chamber suction valve to open. The suppression chamber suction valve also automatically opens, and the CST suction valve closes if a high water level is detected in the suppression chamber.

Two level sensors monitor the suppression pool water level. Either sensor can initiate the opening of the suppression chamber suction valves. If open, the suppression chamber suction valves automatically close upon receipt of the signals that initiate HPCI system steam line isolation.

Two dc motor-operated HPCI system pump discharge injection valves (F006, F105) are downstream of a single pump discharge shutoff valve (F007). The control scheme for these valves is shown in drawings E41-1030-F-004, E41-1030-F-005, E41-1030-F-006, E41-1030-F-007, E41-1030-F-008, and E41-1030-F-009and is arranged to open upon receipt of HPCI system initiation signals. The injection valves close following a turbine trip signal.

To prevent damage by overheating at reduced HPCI system pump flow, a pump discharge minimum flow bypass is provided by an automatic, dc MOV whose control scheme is shown in drawings E41-1030-F-004, E41-1030-F-005, E41-1030-F-006, E41-1030-F-007, E41-1030-F-008, and E41-1030-F-009. On HPCI system high flow, stop valve closure or steam supply valve closure, the valve is closed; on low flow, provided pump discharge pressure is above a pressure permissive setpoint (indicates pump is running), the valve is opened. Flow sensors that measure the pressure difference across a flow element in the HPCI system pump discharge line provide the signals to control this valve. There is also an interlock provided to shut the minimum flow bypass whenever the turbine is tripped due to the subsequent stop valve closure. This is necessary to prevent drainage of the CST into the suppression pool.

To prevent the HPCI system steam supply line from filling up with water and cooling, a condensate drain pot, steam line drain, and appropriate valves are provided in a drain line arrangement just upstream of the turbine supply valve. The control scheme is shown in drawings E41-1030-F-004, E41-1030-F-005, E41-1030-F-006, E41-1030-F-007, E41-1030-F-008, and E41-1030-F-009. The controls position valves so that, during normal operation, steam line drainage is routed to the main condenser. Upon receipt of an HPCI system initiation signal, the drainage path is isolated. The water level in the steam line condensate drain pot is controlled by a steam trap and secondarily by a level switch and an AOV that opens to allow condensate to flow out of the pot.

During test operation, the HPCI system pump discharge can be routed to the CST. The dc MOVs are installed in the pump discharge test line. The piping arrangement is shown in drawing M-55. The control scheme for the valves is shown in drawings E41-1030-F-004, E41-1030-F-005, E41-1030-F-006, E41-1030-F-007, E41-1030-F-008, and E41-1030-F-009. Upon receipt of an HPCI system initiation signal, the valves close and remain closed. The F011 is interlocked closed if the HPCI F041 or RCIC F029 or F031 valves are fully open. Indications pertinent to the operation and condition of the HPCI system are available to the plant operator. Drawings M-55, M-56, E41-1030-F-004, E41-1030-F-005, E41-1030-F-006, E41-1030-F-007, E41-1030-F-008, and E41-1030-F-009 show the indications provided.

7.3.1.1.1.1.8 HPCI Separation

Separation within the ECCS is designed so that no single occurrence can prevent core cooling when required. Control and instrumentation equipment wiring is segregated into separate divisions designated 1, 2, 3, and 4. Similar separation requirements are also maintained for the control and motive power required. Separation is as follows:

Division 1	Division 2	Division 3	Division 4
Core spray A	Core spray B	Core spray C	Core spray D
RHR "A" (including	RHR "B" HPCI outboard isolation valve)	RHR "C" inboard isolation	RHR "D" HPCI (including valves)
ADS "A"		ADS "C"	

The ADS, combined with the low pressure ECCS (CS and RHR), is considered a backup for HPCI. A complete description of the physical independence between divisions is given in Section 7.1.2.2.

7.3.1.1.1.1.9 HPCI Testability

The HPCI system has components that are not activated or tested during normal operation with an integrated testing procedure. These components are tested using manual test methods which allow for independent checking of individual system components. This testing includes verification of flow using the installed return piping such that the turbine and pump are operated. A system functional test, including simulated automatic actuation of the system, with verification that automatic valves in the injection flow path move to the correct position, is also performed. Associated sensors and circuits are monitored to verify proper operation. The frequency of these tests and the parameters to be verified are identified in the Technical Specifications.

The HPCI instrumentation and control system is capable of being tested during normal unit operation to verify the operability of each system component. Testing of the initiation sensors that are located outside the drywell is accomplished by valving out each sensor, one at a time, and applying a test pressure source. This verifies the operability of the sensor. Trip units located in the auxiliary equipment room are calibrated individually by a calibration source with verification of setpoint by a digital readout located on the calibration module.

a. Calibration and test controls for the sensors are located in the reactor enclosure. Calibration and test controls for the trip units are located in the auxiliary equipment room. To gain access to the calibration points of each sensor, a cover plate must be removed. The control room operator is responsible for granting access to the calibration points. Only properly qualified plant personnel are granted access for testing or calibration adjustments.

   In addition to the above tests, operability of the sensors can be verified by cross-checking instrument readouts in the auxiliary equipment room at any time during operation.

b. Test jacks are provided to test the logic. Annunciation is provided in the control room whenever a test plug is inserted in a jack to indicate to the control room operator that the HPCI system is in the test status. Operation of the test plug switches can initiate or isolate the HPCI system. Injection into the reactor on an initiation signal is prevented by an interlock, actuated only when the test plug is inserted, which prevents the opening of one of the HPCI discharge valves. The test can be repeated with the other discharge valve interlocked closed. The manual initiation switch can also be tested at this time. This sequence of tests ensures that all components are tested. A logic test of the HPCI does not interfere with the operation of other ECCS equipment if required by an initiation signal.

c. The functional performance of the HPCI system can be verified by pumping water from the CST, through the full flow test lines, and back to the CST. If a LOCA were to occur during this mode of operation, the valve line-up would automatically be changed so that water can be pumped to the reactor.

During the above testing, the operation of the HPCI system can be observed in the control room by panel lamps, indicators, recorders, annunciators, and computer printout.

7.3.1.1.1.1.10 HPCI Environmental Considerations

The only HPCI system control component located inside the primary containment that must remain functional in the environment resulting from a LOCA is the control mechanism for the inboard isolation valve on the HPCI system turbine steam line. The environmental capabilities of this valve are discussed in Section 7.3.1.1.2.12. The HPCI system control and instrumentation equipment located outside the primary containment is selected in consideration of the normal and accident environments in which it must operate. These conditions are discussed in Section 3.11.

7.3.1.1.1.1.11 HPCI Operational Considerations

7.3.1.1.1.1.11.1 HPCI General Information

The HPCI system is not required for normal operations. Under abnormal or accident conditions, initiation and control are automatically provided for at least 10 minutes if required. After that time, operator action can assist the automatic controls to sustain core cooling.

7.3.1.1.1.1.11.2 HPCI Reactor Operator Information

A detection system continuously confirms the integrity of the HPCI injection piping to the reactor vessel. The HPCI discharge to the reactor vessel is through a CS system line and sparger and feedwater line. A differential pressure sensor measures the pressure difference between the two CS system injection lines. If the CS piping is sound, the pressure difference is very small between these lines. If integrity is lost, increasing differential pressure initiates an alarm in the main control room. Pressure in the HPCI pump suction line is monitored by pressure transmitters, which initiate

alarms in the control room on high or low suction pressure and also provide signals to indicators in the control room. Sufficient level, flow, pressure, and valve position information is available in the control room for the operator to assess the HPCI system operation as shown in drawings M-55, M-56, E41-1030-F-004, E41-1030-F-005, E41-1030-F-006, E41-1030-F-007, E41-1030-F-008, and E41-1030-F-009.

7.3.1.1.1.1.11.3 HPCI Setpoints

See Chapter 16 for safety setpoints.

7.3.1.1.1.2 Automatic Depressurization System - Instrumentation and Controls

7.3.1.1.1.2.1 ADS Identification

The ADS automatically controls five of the SRVs that are installed on the main steam lines inside the primary containment. Table 1 in drawing M-41 identifies which SRVs are controlled by the ADS. The valves are dual-purpose in that they relieve pressure by normal mechanical action or by automatic action of an electric-pneumatic control system. The relief by normal mechanical action is intended to prevent overpressurization of the RCPB. The depressurization by automatic action of the control system is intended to reduce the pressure during a LOCA in which the HPCI system is not available so that the CS system and/or LPCI system can inject water into the reactor vessel.

7.3.1.1.1.2.2 ADS Equipment Design

The control system consists of pressure and water level sensors arranged in trip systems that control dual solenoid valves. The dual solenoid valves control the pneumatic pressure applied to an actuator that controls the SRV directly. An accumulator is included with the control equipment to store pneumatic energy for SRV operation. Cables from the sensors lead to the control structure, where the logic arrangements are formed in cabinets. The electrical control circuitry is powered by dc from the plant safeguard batteries. The power supplies for the redundant control circuits are selected and arranged to maintain tripping ability if there is an electrical power circuit failure. Electrical elements in the control system energize to cause the opening of the SRV. The instrument gas supply to the accumulators is furnished from a seismic Category I gas supply if the normal supply is lost. Seismic Category I backup gas supply is required to be connected at all times during normal operation.

7.3.1.1.1.2.3 ADS Initiating Circuits

The pressure and level sensors used to initiate ADS are separated from those used to initiate the HPCI system. Drawing M-42 lists sensors with common transmitters. The ADS function is initiated automatically by low reactor water level and high drywell pressure signals or low reactor water level with the high drywell pressure bypass timer timed out. The ADS function can also be initiated by system-level remote manual switches. In either mode, the ADS valves are prevented from opening unless both pumps in either of the two CS loops, or any of the four RHR pumps, are running. In addition, each individual ADS valve can be opened manually without restriction from permissive sensors.

Reactor vessel low water level (level 1) is monitored by four level sensors that sense the difference between the pressure due to a constant reference leg of water and the pressure due to the actual height of water in the vessel as shown in drawing M-42. Each level sensor provides an input to a trip unit. Two pairs of lines, attached to taps above and below the water level on the reactor vessel, are required for the differential pressure measurement for the level sensors. The lines terminate outside the primary containment and inside the reactor enclosure. They are physically

separated from the HPCI sensors and tap off the reactor vessel at points widely separated from the HPCI sensors. These same lines are also used for pressure and water level instruments for other systems. Two additional level sensors are piped individually to confirm reactor vessel low water level (level 3) so that an instrument line break inside containment does not inadvertently initiate autoblowdown. The relay contacts from the trip units are arranged so that a set of sensors sensing low water level initiates the ADS system and a separate pair of sensors initiates the HPCI. This arrangement ensures that no single event due to reactor vessel low water level can prevent the initiation of both the HPCI system and the ADS.

Primary containment pressure is monitored by four pressure sensors that are mounted on instrument racks outside the drywell, but inside the reactor enclosure as shown in drawing M-42. Pipes from the drywell interior to the sensors provide the sensing lines. Each drywell high pressure sensor provides an input into a trip unit. The sensors are grouped in a manner similar to the level sensors and are electrically arranged so that no single event due to primary containment high pressure can prevent the initiation of both the HPCI and the ADS systems.

Discharge pressure on the CS and RHR pumps is monitored by twelve pressure sensors; one sensor is at the discharge of each CS pump as shown in drawing M-52 and two sensors are at the discharge of each RHR pump as shown in drawing M-51. Each pressure sensor provides an input to a trip unit.

The primary containment high pressure signals are arranged to seal-in the control circuitry; they must be manually reset to clear. The level sensing logic and the pump discharge pressure signals do not seal-in.

A timer is used in each of the two ADS trip systems. The time delay setting before actuation of the ADS is long enough so that the HPCI system has time to operate, yet not so long that the LPCI and CS systems are unable to adequately cool the fuel if the HPCI system fails to start. An alarm in the control room is annunciated when either of the timers is timing. Resetting the ADS initiating signals recycles the timers. A manual reset switch is provided in each trip system to reset the timer to delay ADS initiation.

Within each trip system, if the reactor level is restored before the timer times out, the timer automatically resets, and autodepressurization is aborted. Should additional reactor level dips occur below the setpoints, the timer is again initiated.

7.3.1.1.1.2.4 ADS Logic and Sequencing

Two initiation signals and one permissive signal are used for the ADS: reactor vessel low water level; drywell high pressure; and RHR and/or CS pumps running. If all signals are present, the ADS SRVs will open after the ADS timer runs out. If the high drywell pressure signal is not present, the ADS SRVs can open after the high drywell pressure bypass timer and ADS timer run out (Figure 7.3-4). There are two reactor vessel low water level signals associated with the ADS system; one (level 3) prevents undesired system operation, and the other (level 1) initiates the ADS. Primary containment high pressure indicates a breach in the RCPB inside the drywell. A permissive signal indicating RHR or CS pump discharge pressure is also required. Discharge pressure on any one of the RHR pumps or both pumps of either CS loop is sufficient to give the permissive signal, which permits automatic depressurization when the LPCI or CS systems are operating.

The ADS is composed of four logics, arranged with the A and E logics in ADS trip system A and the C and G logics in ADS trip system C. Each trip system controls one of the two solenoid valves

associated with each SRV. As shown in Figure 7.3-4, both logics in a trip system must be enabled to energize the solenoid valves associated with that trip system.

After receipt of the initiation signals and a delay provided by timers, one or both of the solenoid valves are energized. This allows pneumatic pressure from the accumulator to act on the cylinder operator. The pneumatic cylinder operator holds the relief valve open. Lights in the control room indicate when the solenoid valves are energized to open an SRV.

Manual reset circuits are provided in the ADS initiation logic. By manually resetting the initiation signal, the delay timers are recycled. The operator can use the reset push buttons to delay or prevent the automatic opening of the relief valves if such delay or prevention is prudent.

The operator's decision to use the manual reset circuits is based on the following criteria:

a. ADS logic shall not be reset prior to system initiation unless spurious initiation is verified.

b. ADS logic may be reset after system initiation if reactor vessel level is greater than Level 1 and sufficient water delivery capability exists to maintain this level.

The EOPs written in accordance with the BWROG EPGs further address operator intervention concerning the ADS function.

A manual inhibit switch is provided in each division of the ADS initiation logic. By placing this switch in the inhibit position, the automatic depressurization will be inhibited, and it will be indicated by a white status light and annunciator window in the control room. If the ADS has already begun and is sealed-in, the inhibit switch does not break the seal-in and does not terminate the ADS.

A manual initiation switch is provided in the control room for each ADS logic. The design minimizes the components that are common to both the manual and automatic logics. The manual initiation signal is sealed-in until reset by the operator.

Once opened by an ADS initiation, the ADS SRVs will return to their normal (closed) position if both ADS reset buttons dedicated to valve closure are depressed. If, however, the ADS initiating signal has not reset or the signal recurs, a subsequent time-delayed ADS trip and valve opening logic sequence will commence.

Activating both ADS divisional reset circuits is an acceptable operating method to prevent or limit inadvertent ADS valve actuation. This is considered to be a deliberate operator action and the only expedient means to close the ADS valves.

Control switches are available in the control room for manual operation of each SRV.

Two ADS trip systems are provided as shown in Figure 7.3-4. Division 1 sensors for low reactor water level and high drywell pressure initiate ADS A, and Division 3 sensors initiate ADS C.

The dual solenoids 'A' and 'B', on the pilot valve for each ADS SRV are individually controlled by ADS trip systems A and C, respectively.

The reactor vessel low water level initiation setting for the ADS is selected to depressurize the reactor vessel in time to allow adequate cooling of the fuel by the LPCI system or CS system following a LOCA in which the HPCI system fails to perform its function adequately. The primary containment high pressure setting selected is as low as possible without inducing a spurious

initiation of the ADS. This provides timely depressurization of the reactor vessel if the HPCI system fails to start or fails after it successfully starts following a LOCA.

The pump discharge pressure setting used as a permissive for depressurization is selected to ensure that at least one of the RHR pumps, or both pumps of either CS loop, have received electrical power, have started, and are capable of delivering water into the vessel. The setting is high enough to ensure that the pump or pump pair delivers at near-rated flow, yet not so low as to provide an erroneous signal that the pump or pump pair is running when it actually is not.

7.3.1.1.1.2.5 ADS Bypasses and Interlocks

It is possible for the operator to manually delay the depressurizing action by the trip system reset switches. This would reset the timers to zero seconds and prevent depressurization until the timers have timed out. The operator would make this decision based on an assessment of other plant conditions. ADS is interlocked with the CS and RHR systems by pressure sensors located on the discharge of these pumps. This interlock ensures that at least one of the RHR pumps or both pumps of either CS loop are capable of delivering water into the vessel. Although the ac interlock is common to both the automatic and manual ADS initiation circuits, ADS initiation is not compromised because each of the trip systems is duplicated (ADS A and ADS C). For a failure of the ADS to occur, this interlock would have to fail in each of the ADS trip systems.

The high drywell pressure bypass timer is actuated on low water level (level 1). When this timer runs out, the high drywell pressure trip is bypassed, and the ADS timer is initiated on low water level alone. If the low water level signal clears before the high drywell pressure bypass timer runs out, the bypass timer will automatically reset.

7.3.1.1.1.2.6 ADS Redundancy and Diversity

The ADS has two independent and redundant trip systems. Each trip system controls one of the two independent and redundant solenoid valves associated with each ADS valve. The initiating circuits for each trip system are redundant, as verified by the circuit description of this section.

7.3.1.1.1.2.7 ADS Actuated Devices

The five SRVs associated with the ADS are equipped with remote manual switches so that the entire system can be operated manually as well as automatically. The valves also prevent RCPB overpressurization by their built-in mechanical action.

7.3.1.1.1.2.8 ADS Separation

ADS is a Division 1 (ADS A) and Division 3 (ADS C) system except that only one set of relief valves is supplied. Each relief valve can be actuated by either of two solenoid valves supplying gas to the relief valve operator. One of the solenoid valves is actuated by trip system A and the other by trip system C. Logic relays, manual controls, and instrumentation are mounted so that Division 1 and Division 3 separation is maintained. A complete description of the physical independence between divisions is given in Section 7.1.2.2.

7.3.1.1.1.2.9 ADS Testability

The ADS has two divisional trip systems, and either one can initiate automatic depressurization. Each trip system has two trip logics, both of which must trip to initiate ADS. Four test jacks are provided, one in each trip logic. During testing, only one trip logic is actuated at a time to prevent spurious ADS operation. The test plug switch disables one trip logic of a trip system while the other

is undergoing test. Actuation of appropriate trip units in the trip logic being tested closes one of the two series relay contacts in the valve solenoid circuit. This causes a panel light to come on, indicating proper trip logic operation and also continuity of the solenoid electrical circuit. Testing of the other trip logic and trip system is similar. Annunciation is provided in the control room whenever a test plug is inserted in a jack to indicate to the reactor operator that the ADS is in a test status. Testing in one division of the ADS does not interfere with automatic operation of the other division if required by an initiation signal.

Integrated testing of the ADS solenoid valves and circuitry is not performed with the plant operating at power, which is consistent for safety systems where the final actuating device(s) would cause temporary modification of plant processes such as fluid injection or discharge. The Technical Specifications provide for a functional partially integrated test without valve actuation. The transmitter/ trip units that provide sensory inputs to the ADS are checked by station personnel. The logic chain up to the solenoid is tested by manually inserting a trip signal and observing the trip logic lights which indicate both continuity of the solenoid circuit and proper trip logic operation

7.3.1.1.1.2.10 ADS Environmental Considerations

The signal cables, solenoid valves, and SRV operators are the only essential control and instrumentation equipment for the ADS located inside the primary containment. These items operate in the most severe environment resulting from a design basis LOCA (Section 3.11). Gamma and neutron radiation have been considered in the selection of these items. Equipment located outside the primary containment operates in an appropriate environment. The environmental conditions for these areas are discussed in Section 3.11.

7.3.1.1.1.2.11 ADS Operational Considerations

7.3.1.1.1.2.11.1 ADS General Information

The instrumentation and controls of the ADS are not required for normal plant operations. When automatic depressurization is required, it is initiated automatically or manually by the circuits described in this section.

7.3.1.1.1.2.11.2 ADS Reactor Operator Information

Recorders and indicators in the control room provide information regarding reactor water level and drywell pressure.

Each manual and automatic ADS input is provided to the annunciator system. Annunciation is also provided on initiation of the ADS timers, tripping of each logic, and system out-of-service indication. All interface with the annunciator system is through isolated contacts.

7.3.1.1.1.2.11.3 ADS Setpoints

See Chapter 16 for safety setpoints.

7.3.1.1.1.3 Core Spray System - Instrumentation and Controls

7.3.1.1.1.3.1 CS System Identification

The CS system consists of two independent and redundant spray loops as illustrated in drawing M-52.

7.3.1.1.1.3.2 CS Equipment Design

The two spray loops are physically and electrically separated so that no single physical or electrical event makes both loops inoperable. Each loop includes two ac motor-driven pumps, each with a separate suction path from the suppression pool, necessary control and instrumentation devices and valves, and a discharge path connected directly to the reactor which is common to both pumps. Each pump supplies 50% of the required core spray flow so either loop can satisfy 100% of the core spray design requirements. The controls and instrumentation for the CS system include the sensors, relays, wiring, and valve operating mechanisms used to start, operate, and test the system. Except for the testable check valve and the bypass valve in each spray loop that are inside the primary containment, the sensors and valve operating mechanisms for the CS system are located in the reactor enclosure. Testable check valves are described in Chapter 6. Cables from the sensors are routed to the control structure, where the logic circuitry is assembled in electrical panels. Each pump, associated suction valve, instrumentation, control and motive devices are assigned to separate electrical safety divisions. Each division is fully separated (including instrumentation, control, and power cables) from each of the other divisions as required by the LGS electrical separation criteria. Logic and motive power for each division is supplied from safeguard power sources within the division. The remaining devices and valves in each loop are assigned to the same safety divisions as the pumps in that loop to provide adequate separation between the redundant loops. Control power for each of the CS pumps comes from separate dc buses. The electrical equipment in the control room for one CS loop is separated from that used for the other loop.

7.3.1.1.1.3.3 CS Initiating Circuits

Trip units associated with two reactor vessel low water level sensors and two drywell high pressure sensors in conjunction with two reactor low pressure sensors are electrically connected in a one-out-of-two-twice arrangement for each CS pump as shown in Figure 7.3-9, so that no single event can prevent initiation of CS.

The following discussion describes the initiation and operation of the 'A' core spray loop. The 'B' loop is initiated and operated similarly and independently of the 'A' loop. The 'A' loop is automatically initiated when a LOCA condition (low reactor vessel level or high drywell pressure coincident with low reactor vessel pressure) exists. The 'A' core spray loop can also be manually initiated by arming and depressing the 'A' and 'C' core spray initiation switches ('B' & 'D' switches for B loop).

Upon receipt of either of the above loop initiation signals in their respective divisions of initiation logic, the 'A' and 'C' core spray pumps start automatically, the core spray test return line to the suppression pool is automatically isolated, and a signal to open the inboard and outboard loop injection valves is initiated. However the normally-closed inboard injection valve (also refereed to as the injection valve) and the normally-open outboard injection valves are interlocked to prevent opening if reactor pressure is greater than the pressure permissive setpoint (determined by monitoring reactor pressure) or if power is not available at the 4 kV bus to which the 'A' core spray pump is connected.

When the 4 kV bus is energized and reactor pressure has decreased to below the pressure permissive setpoint the injection valves will automatically open. The pressure permissive setpoint prevents overpressurizing the low pressure portions of core spray.

Each of the components in the core spray flow path can also be manually operated from the control room by means of the component's individual control switch. The inboard injection valve is interlocked to prevent opening unless; either its respective loop initiation signal with 4kV power and

pressure permissive is present (as described above), or the associated outboard injection valve is closed.

Reactor vessel low water level is monitored by eight level sensors that sense the difference between the pressure that is due to a constant reference leg of water and the pressure that is due to the actual height of water in the vessel. Each level sensor provides an input to a trip unit located in the control structure. Refer to Figure 7.3-26 for a diagram of level sensor connections. The lines terminate outside the primary containment and inside the reactor enclosure.

Drywell pressure is monitored by eight sensors mounted on instrument racks in the reactor enclosure. Four sensing lines that terminate in the reactor enclosure allow the sensors to measure the drywell interior. Each drywell high pressure sensor provides an input to a trip unit located in the control structure.

Reactor pressure is monitored by twelve pressure sensors mounted on racks in the reactor enclosure. Four of the pressure sensors are used to develop system initiation signals, four are used in development of injection value open-permissive interlocks, four provide inputs to both system initiation and injection valve open-permissive interlock logic. Four sensing lines that terminate in the reactor enclosure allow the sensors to measure the reactor vessel. Each pressure sensor provides an input to a trip unit located in the control structure.

The CS initiation signal also initiates the corresponding diesel generator.

7.3.1.1.1.3.4 CS Logic and Sequencing

The control scheme for the CS system is illustrated in Figure 7.3-9. The logic of BOP portions of the CS system is shown in drawing M-52FD. Trip settings are given in Chapter 16. The overall operation of the system following the receipt of an initiating signal is as follows:

a. Test bypass valves are closed and interlocked to prevent opening.

b. If offsite ac power is available, the CS pumps in one loop start after a 10 second delay, and the CS pumps in the other loop start after a 15 second delay.

c. If offsite ac power is not available, the CS pumps in both spray loops start 7 seconds after standby power becomes available for loading.

d. The pump minimum flow bypass valves open as soon as the core spray pumps start.

e. When reactor vessel pressure drops to a preselected value, valves open in the pump discharge lines, allowing water to be sprayed over the core.

f. When pump discharge flow is greater than a preselected value, the pump minimum flow bypass valves shut, directing full flow into the reactor vessel.

Three initiating variables are used for the CS system: reactor vessel low water level; drywell high pressure; and reactor vessel low pressure.

The CS initiation logic is a one-out-of-two-twice network using level and pressure sensors. The initiation signal is generated when:

a. Both level sensors are tripped.

b. Four pressure sensors are tripped (two high drywell pressure and two low reactor vessel).

c. Either of two combinations of one level sensor and two pressure sensors (one high drywell and one low reactor vessel) are tripped.

The CS system can also be manually initiated.

Once an initiation signal is received by the CS control circuitry, the signal is sealed-in until manually reset. The seal-in feature is shown in Figure 7.3-9.

The pressure permissive signal for opening the respective injection valve is provided by four division (1) or four division (2) pressure sensors that monitor reactor vessel pressure. Two of these sensors are the ones described in Section 7.3.1.1.1.3.3, to initiate the CS system in conjunction with high drywell pressure. The other two sensors are located on the same sensing lines and provide signals to trip units located in the control structure. These pressure signals are arranged in a one-out-of-two-twice logic.

7.3.1.1.1.3.5 CS Bypasses and Interlocks

The CS pump motors and inboard injection valves are provided with manual override controls that allow the operator to control the system following automatic initiation.

A pressure transmitter is installed upstream of each pump discharge check valve. These pressure signals are used in the ADS to indicate that core spray pumps are running, allowing actuation of the ADS.

The CS initiation signal also initiates the corresponding diesel generator and is used to trip the drywell chillers.

7.3.1.1.1.3.6 CS Redundancy and Diversity

As described in Section 7.3.1.1.1.3.4, sufficient redundancy and diversity of initiation signals is provided to prevent a single failure from preventing initiation of the CS system. Core spray is a four-pump, two-loop system that is backed up by the four-loop LPCI mode of the RHR system. Each of the two CS loops is independent.

Each loop of either core spray or LPCI in itself is not designed to sustain a single failure and still perform its design functions. Single failures such as: loss of one division of safeguard power, logic failure in one division, or an instrument failure in one division can disable one loop of core spray and/or one loop of LPCI including both manual and automatic operation of those loops. For a DBA coincident with a worst case single failure, the most demanding and limiting scenarios on low pressure ECCS are:

a. A pipe break that is not part of the low pressure ECCS and a single diesel generator failure. Three LPCI loops and one core spray loop would remain.

b. A low pressure ECCS pipe break and a single diesel generator failure. If the pipe break is in core spray, three LPCI loops would remain. If the pipe break is in LPCI, one core spray loop and two LPCI would remain.

For either scenario, the remaining low pressure ECCS loops are more than sufficient to satisfy the low pressure coolant flow requirements to the reactor.

The above scenarios are more demanding on the low pressure ECCS than the failure of any one core spray or LPCI instrument. Hence, the consequences of a single core spray or LPCI instrument failure are bounded by the consequences for the above scenarios. Because the low pressure ECCS is designed with sufficient redundancy and separation to perform their design functions in the worst case single failure scenarios, no design changes are required to reduce the consequence of a single failure of a core spray or LPCI instrument.

7.3.1.1.1.3.7 CS Actuated Devices

The control arrangements for the CS pumps are shown in Figure 7.3-9. The circuitry provides for detection of normal power available, so that all pumps are automatically started in sequence. Each pump can be manually controlled by a control room remote switch or the automatic control system. The CS pump motors are provided with overload and undervoltage protection. Overload relays are sized so as to maintain power as long as possible without immediate damage to the motors or emergency power system.

Flow-measuring instrumentation is provided in the discharge line of each set of core spray pumps. This instrumentation provides flow indication in the control room.

Except where otherwise specified, the remainder of the description of the CS system refers to one spray loop. The second CS loop is identical. The control arrangements for the various automatic valves in the CS system are indicated in Figure 7.3-9. All MOVs can be controlled from the control room and are equipped with limit and torque switches to turn off the valve motor when the valve reaches the limits of movement and provide control room indication for valve position.

Each automatic valve can be operated from the control room. Overload protection is provided to valve motors in accordance with Section 8.1.6.1.19. The valves in the suction paths from the suppression pool are key-locked open and require no automatic action to line-up CS suction.

Upon receipt of an initiation signal, the test bypass valve is automatically closed and interlocked shut. The injection valves are automatically opened when reactor vessel pressure drops to a preselected value; the setting selected is low enough so that the low pressure portions of the CS system are not overpressurized, yet is high enough to open the valves in time to provide adequate cooling for the fuel. The full stroke operating times of the MOVs are selected to be rapid enough to ensure proper delivery of water to the reactor vessel following a DBA.

A flow sensor on the discharge of each set of pumps provides a signal to operate the minimum flow bypass line valve for each loop. When the flow reaches the value required to prevent pump overheating, the valves close and all flow is directed into the sparger.

7.3.1.1.1.3.8 CS Separation

The CS system consists of four pumps, each with its own independent logic and control power source. The sensors used to initiate one core spray pump are separated from those used to initiate the other core spray pumps. The locations of the instrumentation and controls components are provided in Table 1.7-3.

Logics for the A and B loop valves are powered by the 125 V dc buses A and B, respectively.

A complete description of the physical independence between divisions is given in Section 7.1.2.2.

7.3.1.1.1.3.9 CS Testability

The CS System has components that are not activated or tested during normal operation with an integrated testing procedure. The components are tested using manual test methods which allow for independent checking of individual components. This testing includes verification of flow using the installed test piping such that the motors and pumps are operated. A system function test, including automatic actuation of the system, with verification that automatic valves in the injection flow path move to the correct position, is also performed. Associated sensors and circuits are monitored to verify proper operation. The frequency of these tests and the parameters to be verified are identified in the Technical Specifications.

The CS system is capable of being tested during normal operation by an overlapping series of tests. All sensors are individually valved out of service and subjected to a test pressure. This verifies the operability of the sensors as well as the calibration range. The trip units mounted in the auxiliary equipment room are calibrated individually by a calibration source with verification of setpoint by a digital readout located on the calibration module.

a. Calibration and test controls for the sensors are located in the reactor enclosure. Calibration and test controls for the trip units are located in the auxiliary equipment room. To gain access to the calibration points of each sensor, a cover plate must be removed. The control room operator is responsible for granting access to the calibration points. Only properly qualified plant personnel are granted access for testing or calibration adjustments.

   In addition to the above tests, the operability of the sensors can be verified by cross-checking instrument readouts in the auxiliary equipment room at any time during operation.

b. Test jacks are provided to test the logic. Annunciation is provided in the control room whenever a test plug is inserted in a jack to indicate to the control room operator that the CS system is in the test status. Operation of the test plug switches initiates the system. Injection into the reactor is prevented by an interlock actuated when the test plug is inserted. This will prevent the automatic opening of either the inboard or the outboard injection valve, depending on the position of the test switch that is used to select which valve to test. The manual initiation switches can also be tested. This sequence of tests ensures that all components are tested. A logic test of one CS loop does not interfere with the operation of the other CS loop if required by an initiation signal.

c. The functional performance of CS components can be verified by pumping water to the suppression pool through the full flow test line. If a LOCA were to occur during this mode of operation, the valve line-up would automatically be changed so that water can be pumped to the reactor.

During the above testing, CS operation can be observed in the control room by panel lamps, indicators, recorders, annunciators, and computer printout.

7.3.1.1.1.3.10 CS Environmental Considerations

The testable check valves are the only control and instrumentation components for the CS system that are located inside the primary containment that must operate in the environment resulting from a LOCA. All other components of the CS system that are required for system operation are outside

the drywell and are selected in consideration of the normal and accident environments in which they must operate. The environmental conditions for the areas where the equipment is located are provided in Section 3.11.

7.3.1.1.1.3.11 CS Operational Considerations

7.3.1.1.1.3.11.1 CS General Information

The CS system is not required for normal plant operation. When it is required for accident conditions it is automatically initiated by the circuitry described in this section. No operator action is required for at least 10 minutes following initiation. After this time, operator action can assist the automatic controls to sustain core cooling.

7.3.1.1.1.3.11.2 CS Reactor Operator Information

Sufficient temperature, flow, pressure, and valve position indications are available in the control room for the operator to accurately assess CS system operation. Valves have indications of fully open, intermediate, and fully closed position. The pump has indications for pump running and pump stopped. Alarm and indication devices are shown in drawing M-52 and Figure 7.3-9. A detection system continuously confirms the integrity of the CS A and B injection line piping to the reactor vessel. A differential pressure sensor measures the pressure difference between the two injection lines. If the CS A and B piping is sound, the pressure difference will be very small between these lines. If integrity is lost, an increase in differential pressure initiates an alarm in the control room. Pressure in each CS pump suction line is monitored by a local pressure indicator to determine suction head and pump performance. Pressure in the discharge line of each CS loop is monitored by a pressure indicator in the control room to determine pump performance.

7.3.1.1.1.3.11.3 CS Setpoints

See Chapter 16 for safety setpoints.

7.3.1.1.1.4 LPCI Mode of the RHR System - Instrumentation and Controls

7.3.1.1.1.4.1 LPCI System Identification

LPCI is an operating mode of the RHR system. The RHR system and its operating modes are discussed in Sections 5.4 and 6.3. Because the LPCI mode of the RHR system is designed to provide water to the reactor vessel following the design basis LOCA, the controls and instrumentation for it are discussed herein.

7.3.1.1.1.4.2 LPCI Equipment Design

Drawing M-51 shows the entire RHR system, including the equipment used for LPCI operation. This drawing identifies nonsafety-related parts of this system. Control and instrumentation required for the operation of the LPCI mode are electric Class 1E and seismic Category I.

The instrumentation for LPCI operation controls other valves in the RHR. This ensures that the water pumped from the suppression pool by the main system pumps is routed directly to the reactor. These interlocking features are described in this section.

LPCI, an operating mode of the RHR system, consists of four independent and redundant loops. Each loop contains a separate suction path from the suppression pool, a motor-driven pump, necessary control and instrumentation devices and valves, and a separate injection path that

discharges directly into the reactor. Drawing M-51 shows the locations of instruments, control equipment, and LPCI components. Except for the LPCI testable check valves, the components pertinent to LPCI operation are located outside the primary containment.

Each loop is assigned to a separate electrical safety division. Logic and motive power for each division is supplied from safeguard power sources within that division. Each safety division is fully separated (including instrumentation, control, and power cables) from each of the other safety divisions as required by the LGS electrical separation criteria. Each LPCI pump will supply 100% of the loop design flow. Power for the main system pumps is supplied from ac buses that can receive standby ac power. Motive power for each of the injection valves, one in each loop, used during LPCI operation comes from a separate bus that can be automatically connected to standby power sources. Control power for all LPCI components, except valves, comes from the dc buses. Redundant trip systems are powered from different dc buses.

LPCI is arranged for automatic operation and for remote manual operation from the control room. The equipment provided for manual operation of the system allows the operator to take action independent of the automatic controls if there is a LOCA.

7.3.1.1.1.4.3 LPCI Initiating Circuits

Two automatic initiation signals are provided for the LPCI mode of operation of the RHR systems: reactor vessel low water level and drywell high pressure with a reactor vessel low pressure permissive. Either will initiate the LPCI mode of operation. The same sensors and trip units used for initiation of the CS system are used to initiate LPCI.

The low water level or high drywell pressure coincident with reactor low pressure initiation signal for LPCI is a one-out-of-two-twice arrangement as described in Section 7.3.1.1.1.3.3 for the CS system.

Drawing M-42 can be used to identify the instrument rack used for the sensors. Table 1.7-3 can be used to determine the location of the sensors, and drawings E11-1030-F-001, E11-1030-F-002, and E11-1030-F-003 can be used to determine the functional use of each sensor in the control circuitry for LPCI components. Instrument characteristics are given in Table 7.3-4.

The following discussion describes the initiation and operation of the 'A' LPCI loop only. The three remaining loops are initiated and operated similarly and each loop is initiated and operated independently of the other loops. The 'A' LPCI loop is automatically initiated when LOCA condition (reactor vessel low level or containment high pressure coincident with reactor low pressure) exists. LPCI can be manually initiated from the control room by arming and depressing the loop initiation switch.

Upon receipt of the LOCA or manual initiation signal, the 'A' RHR pump is automatically started. The necessary valves required to isolate non-LPCI portions of the RHR system from the LPCI flow path are automatically closed. A signal to open the 'A' LPCI injection valve is initiated, however the valve is interlocked to prevent opening if reactor pressure is greater than the RHR piping design maximum pressure (determined by monitoring the ΔP across the injection valve) or if power is not available at the 4 kV bus to which the 'A' RHR pump motor is connected. When the 4 kV bus is energized and reactor pressure has decreased to below the RHR piping design maximum pressure, the injection valve will automatically open and allow low pressure coolant injection.

Each of the components in the LPCI flow path can also be manually operated from the control room by means of each component's individual control switch. Again the LPCI valve is interlocked to prevent opening if reactor pressure is greater than the RHR piping design maximum pressure.

The interlocks and control devices used in this manner are the same as those used for automatic operation.

7.3.1.1.1.4.4 LPCI Logic and Sequencing

The control scheme for LPCI operation is illustrated in drawings E11-1030-F-001, E11-1030-F-002, and E11-1030-F-003. The logic for BOP portions of the LPCI system is shown in drawing M-51FD.

Three variables are used for LPCI: reactor vessel low water level, drywell high pressure, and reactor vessel low pressure.

The LPCI initiation logic is a one-out-of-two-twice network using appropriately connected trip units from level and pressure sensors. The initiation signal is generated when:

a. Both level sensor trip units are tripped.

b. Four pressure sensor trip units are tripped (two high drywell pressure and two low reactor vessel pressure).

c. Either of two other combinations of one level sensor trip unit and two pressure sensor (one high drywell and one low reactor vessel) trip units are tripped.

LPCI operation can also be manually initiated.

Once an initiation signal is received by the RHR control circuitry, the signal is sealed-in until manually reset. The seal-in feature is shown in drawings E11-1030-F-001, E11-1030-F-002, and E11-1030-F-003.

The overall LPCI operating sequence following the receipt of an initiation signal is as follows:

a. If offsite ac power is available, the C and D RHR pumps start immediately, taking suction from the suppression pool. The other two pumps start after a 5 second delay to limit the loading of the power sources. If offsite ac power is lost, standby power sources become available, and all pumps start immediately.

b. Valves used in other RHR modes are automatically positioned so that the water pumped from the suppression pool is routed correctly.

c. The LPCI injection valves automatically open when the differential pressure across the valves decreases to less than a pre-established value.

d. When reactor vessel pressure has dropped to a value at which the RHR pumps are capable of injecting water into the reactor, water is delivered to the reactor vessel via four independent loops.

e. An open signal is applied to the RHR heat exchanger bypass valves for the first 3 minutes following LPCI initiation to ensure that full injection flow is available, then it is removed to permit the operator to manually throttle flow for other modes of operation.

f. The valves in the suction paths from the suppression pool are key-locked open and require no automatic action to line-up LPCI suction.

g. The valves at the primary containment penetration in the pump minimum flow recirculation return lines to the suppression pool and in the full flow test return line to the suppression pool are normally open. These valves can be repositioned only by a key-locked switch in the control room. The logic for these valves is shown in drawing M-51FD.

7.3.1.1.1.4.5 LPCI Bypasses and Interlocks

Two pressure transmitters are installed in each pump discharge pipeline to verify that the pumps are operating following an initiation signal. The pressure signal is used in the ADS to verify availability of low pressure core cooling. The pressure instruments are located upstream of the pump discharge check valves. Limit switches from the system suction valves are used to trip the RHR pump motors if a suction flow path is not established. The system pump motors are provided with overload protection. The overload relays maintain power on the motors as long as possible without harming the motors or jeopardizing the emergency power system.

The RHR pump motors and injection valves are provided with manual override controls that allow the operator to control the system following automatic initiation.

The valves that allow the diversion of water for suppression pool spray are automatically closed upon receipt of an LPCI initiation signal. The manual controls for these valves are interlocked so that opening the valves by manual action is not possible unless the reactor vessel injection valve in its respective RHR loop is closed or the LPCI initiation signal is not present. The valves that allow diversion of water for containment spray are normally closed. The manual controls for these valves are interlocked so that opening both valves in one drywell spray loop by manual action is not possible unless an LPCI initiation signal is present, the reactor vessel injection valve in its respective RHR loop is closed, and drywell pressure is high. The sensors used to monitor drywell pressure for LPCI initiation are also used in the drywell spray logic. The trip setting is selected to be as low as possible yet provide indication of abnormally high drywell pressure. The drywell pressure switches are arranged in a one-out-of-two logic arrangement as shown in drawings E11-1030-F-001, E11-1030-F-002, and E11-1030-F-003.

7.3.1.1.1.4.6 LPCI Redundancy and Diversity

The LPCI is redundant in that four separate loops are provided. Failure of any one loop still allows three pumps to supply water to the reactor.

The LPCI mode of operation is initiated by either reactor vessel low water level or primary containment high pressure coincident with low reactor vessel pressure. These two initiating signals are diverse indications of a LOCA. Diversity for LPCI is provided by the CS system.

7.3.1.1.1.4.7 LPCI Actuated Devices

The functional control arrangement for the RHR pumps is shown in drawings E11-1030-F-001, E11-1030-F-002, and E11-1030-F-003. The circuitry provides for detection of normal power available so that all pumps are automatically started in sequence. The operator can manually control the pumps from the control room, thus permitting the operator to use the pumps for other purposes such as containment cooling. Controls for the pumps are discussed in Section 7.3.1.1.1.4.5.

All automatic valves used in the LPCI function are equipped with remote manual test capability. The entire system can be operated from the control room. All MOVs are equipped with limit and

torque switches to turn off the motors when the valve reaches the limits of movement and to provide control room indication. Valves that have vessel and containment isolation requirements are described in Section 7.3.1.1.2. Overload protection is provided to valve motors in accordance with Section 8.1.6.1.19.

The RHR pump suction valves from the suppression pool are normally open. To reposition the valves, a key-lock switch must be turned in the control room. On receipt of an LPCI initiation signal, other RHR system valves are signaled to open or close, as required, even though they may normally be left in the proper position to ensure that the RHR pump discharge is correctly routed. Included in this set of valves are the valves that, if not closed, would permit the RHR system pumps to take suction from the reactor recirculation loops and pump water to the reactor during normal shutdown cooling operation.

A timer similar to that used in the LPCI system pump control circuitry cancels the LPCI open signal to the heat exchanger bypass valves after a 3 minute delay, which is time enough to permit satisfactory start of the LPCI system. The signal cancellation allows the operator to control the flow through the heat exchangers for other postaccident purposes. Cancelling the open signal does not cause the bypass valves to close.

A flow sensor on the discharge of each pump provides a signal to operate the minimum flow bypass valve in that loop. When the flow has been established above the value required to prevent pump overheating, the valves close and all flow is directed into the reactor.

7.3.1.1.1.4.8 LPCI Separation

Four separate logics located in separate panels and powered by four 125 V dc buses are used. Control power for pumps A through D is from the corresponding 125 V dc buses A through D. AC power for A through D pump motors is supplied from the corresponding A through D 4160 V buses.

A complete description of the physical independence between divisions is given in Section 7.1.2.2.

7.3.1.1.1.4.9 LPCI Testability

The LPCI mode of the RHR system has components that are not activated or tested during normal operation with an integrated testing procedure. These components are tested using manual test methods which allow for independent checking of individual system components. This testing includes verification of flow using the installed test piping such that the motors and pumps are operated. A system function test, including automatic actuation of the system, with verification that automatic valves in the injection flow path move to the correct position, is also performed. Associated sensors and circuits are monitored to verify proper operation. The frequency of these tests and the parameters to be verified are identified in the Technical Specifications.

The RHR system is capable of being tested during normal plant operation by an overlapping series of tests:

a. All sensors can be individually valved out-of-service and subjected to a test pressure. This verifies the operability of the sensors as well as the calibration range. The trip units mounted in the auxiliary equipment room can be calibrated individually by a calibration source with verification of setpoint by a digital readout located on the calibration module.

   Calibration and test controls for the sensors are located in the reactor enclosure. Calibration and test controls for the trip units are located in the auxiliary equipment

room. To gain access to the calibration points of each sensor, a cover plate must be removed. The control room operator is responsible for granting access to the calibration points. Only properly qualified plant personnel are granted access for testing or calibration adjustment.

In addition to the above tests, the operability of the sensors can be verified by cross-checking instrument readouts in the auxiliary equipment room at any time during operation.

b. Test jacks are provided to test the logic. Annunciation is provided in the control room whenever a test plug is inserted in a jack to indicate to the control room operator that the RHR system is in the test status. Operation of the test plug switches initiates LPCI. Injection into the reactor is prevented by an interlock, actuated only when the test plug is inserted, which prevents the opening of the LPCI discharge valve. After the RHR pump is tripped, the LPCI discharge valve can be opened to ensure its operability. The manual initiation switches can also be tested. This sequence of tests ensures that all components are tested. A logic test of one LPCI loop does not interfere with the operation of the other LPCI loops if required by an initiation signal.

c. Functional performance of LPCI components can be verified by pumping water to the suppression pool through the full flow test line. If a LOCA were to occur during this mode of operation, the valve line-up would automatically be changed so that water can be pumped to the reactor.

During the above testing, LPCI operation can be observed in the control room by panel lamps, indicators, recorders, annunciators, and computer printout.

7.3.1.1.1.4.10 LPCI Environmental Considerations

The only control components pertinent to LPCI operation that are located inside the drywell are those controlling the air-operated testable check valves on the injection lines. Other equipment, located outside the primary containment, is selected in consideration of the normal and accident environments in which it must operate. The environmental conditions for the areas where the equipment is located are provided in Section 3.11.

7.3.1.1.1.4.11 LPCI Operational Considerations

7.3.1.1.1.4.11.1 LPCI General Information

LPCI is a mode of the RHR system. The pumps, valves, piping, etc., used for LPCI are also used for other modes of the RHR system. The LPCI mode is not required for normal operation. When it is required for accident conditions, it is initiated automatically by the circuitry described in this section. No operator action is required for at least 10 minutes following initiation. The operator may manually control the RHR system after a 3 minute delay (for the RHR heat exchanger bypass valve open command timers) to use its capabilities in the other modes of the RHR system, provided the core is being cooled by other portions of the ECCS.

7.3.1.1.1.4.11.2 LPCI Reactor Operator Information

Sufficient temperature, flow, pressure, and valve position indications are available in the control room for the operator to accurately assess the LPCI system operation. A detection system continuously confirms the integrity of the injection line piping to the reactor vessel. Differential

pressure sensors sense the pressure differential between injection lines of RHR A and C loops and between the B and D loops. If the piping is sound, the pressure differential is very small between these lines. If integrity is lost, an increase in differential pressure initiates an alarm in the control room. Valves have indications of fully open, intermediate, and fully closed positions. Pumps have indications for pump running and pump stopped. Alarm and indication devices are shown in drawings M-51, E11-1030-F-001, E11-1030-F-002, and E11-1030-F-003.

7.3.1.1.1.4.11.3 LPCI Setpoints

See Chapter 16 for safety setpoints.

7.3.1.1.1.5 Manual Shutdown of ECCS Pumps

Design provisions in the ECCS allow the operator to manually shut down the ECCS pumps after they have been automatically started.

The HPCI pump-turbine driver can be stopped after starting automatically, and in the presence of an automatic signal, by: (1) closing the system supply isolation valves or (2) pressing the isolation push button, which closes the steam supply valves, the pump discharge valve, and the pump suction valve (from the suppression pool) and trips the HPCI turbine.

Provisions in the core spray and RHR systems allow the operator to stop any of the pumps after an automatic start signal. There are also provisions in both systems to allow the operator to close the injection valves after they have been signalled open. Operator action is required to reopen the injection valve or to restart the stopped pump as long as the original accident signal is still present and has not been reset.

7.3.1.1.2 Primary Containment and Reactor Vessel Isolation Control System - Instrumentation and Controls

7.3.1.1.2.1 PCRVICS Identification

The PCRVICS includes the instrument channels, trip logics, and actuation circuits that activate valve closing mechanisms associated with the valves that, when closed, effect isolation of the primary containment or reactor vessel or both. The following description of the PCRVICS instrument channels and logic circuits are applicable to the Nuclear Steam Supply Shutoff System, and the Plant Leak Detection System unless noted otherwise.

PCRVICS provides initiation to the following systems:

a. SGTS (Section 7.3.1.1.7)

b. REIS and HVAC support system (Section 7.3.1.1.9)

The purpose of the system is to prevent the gross release of radioactive materials to the environment from the fuel or a break in the RCPB. The PCRVICS automatically isolates the appropriate pipelines that penetrate the primary containment whenever monitored variables exceed preselected setpoints. All other pipelines that penetrate primary containment are manually isolated. The power generation objective of this system is to prevent spurious closure of isolation valves as a result of single failure. A list of valves closed by PCRVICS is provided in Table 6.2-17.

7.3.1.1.2.2 PCRVICS Power Sources

Power for the system instrument channels except for the Leak Detection System (Refer to Section 7.6.1.3.2) are supplied from the two nonessential electrical buses that supply the RPS trip systems.

Power for the isolation logics of the isolation control system and MSIVs are supplied from the two nonessential electrical buses that supply the RPS trip systems. Each bus has its own inverter and can receive alternate power from an alternate power source. Each bus can be supplied from only one of its power sources at any given time. Additional details of these power sources are given in Section 7.2.1.1.3.

The MSIV electrical control power is supplied as follows:

	Inboard (Div 1)	Outboard (Div 2)
Solenoid 1	RPS Bus A	RPS Bus B
Solenoid 2	125 V dc Bus A	125 V dc Bus B

A pressurized pneumatic supply is required for motive power to open the MSIVs. The power to close these valves is provided by pneumatic and spring force .

Motor-operated isolation valves and solenoid pilot valves for air-operated isolation valves receive power from essential emergency buses. Power for the operation of any two valves mounted in series is supplied from independent essential sources.

Direct solenoid-operated main steam, RHR and reactor water sample valves are energized open against spring pressure by essential 120 vac instrument power. Spring pressure provides closure force.

7.3.1.1.2.3 PCRVICS Equipment Design

The isolation valve arrangement for pipelines that penetrate containment is discussed in Section 6.2.4. The general valve arrangements are as follows:

a. Pipelines that penetrate primary containment and communicate directly with the reactor vessel have two isolation valves: one inside primary containment and one outside primary containment.

b. Pipelines that connect directly to the containment atmosphere and penetrate the primary containment have two valves outside the containment.

The MSIV controls include pneumatic piping and an accumulator for the AOVs as the isolation motive power source in addition to the springs. Pressure, temperature, and water level sensors are mounted on instrument racks or locally in either the reactor enclosure or the turbine enclosure. Valve position switches are mounted on MOVs and AOVs. Switches are encased to protect them from environmental conditions. All signals transmitted to the control room are electrical (no pipe from the nuclear system penetrates the control room). The sensor cables and logic power supply cables are routed to cabinets in the auxiliary equipment room, where the system logic is located.

All instrument line penetrations of the containment are equipped with automatic isolation valves. These excess flow check valves automatically isolate due to high flow if there is a break in the instrument line downstream of the valve.

7.3.1.1.2.4 PCRVICS Initiating Isolation Signals

The isolation trip settings of primary containment and reactor vessel isolation control system are listed in Chapter 16. The FCDs (drawings B21-1030-F-002, B21-1030-F-002, B21-1030-F-003,

B21-1030-F-004, B21-1030-F-005, E11-1030-F-001, E11-1030-F-002, E11-1030-F-003, E41-1030-F-004, E41-1030-F-005, E41-1030-F-006, E41-1030-F-007, E41-1030-F-008, E41-1030-F-009, E51-1030-F-004, E51-1030-F-005, E51-1030-F-006, E51-1030-F-007, E51-1030-F-008, E51-1030-F-009, and G31-1020-F-001) and the P&IDs (drawings M-41, M-42, M-44, M-49, M-51, and M-55) illustrate how these signals initiate closure of isolation valves. Additional logic is shown in drawings M-51FD, M-52FD, M-55FD, M-57FD, M-59FD, and M-61FD.

7.3.1.1.2.4.1 PCRVICS - Reactor Vessel Low Water Level

7.3.1.1.2.4.1.1 Subsystem Identification

A low water level in the reactor vessel could indicate that reactor coolant is being lost through a breach in the RCPB and that the core is in danger of becoming overheated as the reactor coolant inventory diminishes.

Three reactor vessel low water level isolation trip settings are used to complete the isolation of the primary containment and the reactor vessel.

The first (and highest) low water level isolation setting (level 3) is the same water level setting as the RPS scram setting. This setting initiates selected isolations at the earliest indication of a possible breach in the RCPB, yet the setting is far enough below normal operational levels to prevent spurious isolation. RHR shutdown cooling piping is isolated when reactor vessel low water level falls to level 3.

The second (middle) reactor vessel low water level isolation setting (level 2) is the same water level setting at which the RCIC and HPCI systems are initiated. The setting selected is low enough to allow the removal of heat from the reactor for a predetermined time following the scram and high enough to complete isolation in time for the operation of ECCS if there is a large break in the RCPB. The pipelines that are isolated when the reactor vessel water level falls to this second setting are listed below.

a. RWCU

b. CAC including H_2O_2 sample lines

c. TIP

d. Main steam sample

e. HPCI pump flush (isolation signal generated by the HPCI system logic circuits)

f. Deleted

g. Drywell sump drains

h. Suppression pool cleanup

i. Drywell radiation sample

j. Recirculation loop sample

The third (and lowest) of the reactor vessel low water level isolation settings (level 1) is the water level setting used to initiate RHR, core spray, and ADS, and to start the diesel generators. The

pipelines that are isolated when the reactor vessel water level falls to this third setting are the main steam, main steam line drain, containment instrument gas, RHR heat exchanger vent valves (Unit 2 only), suppression pool spray, drywell chilled water, and core spray pump test and flush.

Reactor vessel low water level signals used by NSSS and RPS are initiated from eight differential pressure sensors, four sensors for the level 1 and level 2 trip and four sensors for the level 3 trip, as shown in drawing M-42. They sense the difference between the pressure caused by a constant reference leg of water and the pressure caused by the actual water level in the vessel.

Four of the eight sensors are used in the measurement of level 1 and 2. Signals from these sensors are used by NSSS only. Each sensor is connected to different reference leg. Sensors A and B share a common variable leg. Sensors C and D share a common variable leg. The remaining four sensors are used in the measurement of level 3 and are used by both NSSS and RPS. Each of these sensors is connected to different reference and variable legs. The variable legs are different from those used by the level 1 and 2 sensors. Refer to Figure 7.3-26 for a diagram of level sensor connections. This arrangement ensures that no single physical event can prevent isolation, if required.

7.3.1.1.2.4.2 PCRVICS

7.3.1.1.2.4.3 PCRVICS - Main Steam Line Temperature in Outboard MSIV Room and Turbine Enclosure Main Steam Tunnel High Ambient Temperature

High ambient temperature in the areas in which the main steam lines are located outside of the primary containment could indicate a leak in a main steam line. The automatic closure of various valves prevents the excessive loss of reactor coolant and the release of a significant amount of radioactive material from the RCPB. Turbine Enclosure Main Steam Tunnel High Ambient Temperature will alarm and subsequently be monitored by Operations and manual action will be taken as needed per T.S. 3/4.7.9.

See Section 7.6.1.3.3.2.2 for a detailed description of this system.

7.3.1.1.2.4.4 PCRVICS - Main Steam Line High Flow

Main steam line high flow could indicate a breach in a main steam line. Automatic closure of isolation valves prevents excessive loss of reactor coolant and release of significant amounts of radioactive material from the RCPB.

The main steam line high flow trip setting selected is high enough to permit isolation of one main steam line for testing at rated power without causing an automatic isolation of the other steam lines, yet low enough to permit detection of a steam line break.

High flow in each main steam line is sensed by four differential pressure sensors that sense the pressure difference across the flow element in that line.

Refer to Section 7.6.1.3.3.2.3 for a detailed description of this system.

7.3.1.1.2.4.5 PCRVICS - Main Steam Line Low Pressure

7.3.1.1.2.4.5.1 Subsystem Identification

Low steam pressure at the turbine inlet while the reactor is operating could indicate a malfunction of the steam pressure controller in which the turbine control valves or turbine bypass valves

become fully open and cause rapid depressurization of the reactor vessel. From part-load operating conditions, the rate of decrease of saturation temperature could exceed the allowable rate of change of vessel temperature. A rapid depressurization of the reactor vessel while the reactor is near full power could result in undesirable differential pressures across the channels around some fuel bundles of sufficient magnitude to cause mechanical deformation of channel walls. Such depressurizations, without adequate preventive action, could require thorough vessel analysis or core inspection before returning the reactor to power operation.

The steam pressure at the turbine inlet is monitored to forestall these effects and thus preclude the necessity of requiring analysis and/or inspection.

The low steam pressure isolation setting selected is far enough below normal turbine inlet pressures to prevent spurious isolation, yet high enough to provide timely detection of a pressure controller malfunction. Although this isolation function is not required to satisfy any of the safety design bases for this system, the discussion is included to complete the listing of isolation functions.

Main steam line low pressure is monitored by four pressure sensors that sense pressure downstream of the outboard MSIVs. The sensing point is located at the header that connects the four steam lines upstream to the turbine stop valves. Each sensor provides a signal to one isolation logic.

7.3.1.1.2.4.5.2 Subsystem Power Supplies

See Figures 7.3-1 and 7.3-2.

Logic channels A and C and one pilot solenoid of the inboard (Division 1) MSIVs are supplied from RPS bus A 120 V ac. The second pilot solenoid of the inboard MSIV is supplied from a Division I, Class 1E 125 V dc station battery.

Logic channels B and D and one pilot solenoid of the outboard (Division 2) MSIVs are supplied from RPS bus B 120 V ac. The second pilot solenoid of the outboard MSIV is supplied from a Division II, Class 1E 125 V dc station battery.

7.3.1.1.2.4.5.3 Subsystem Initiating Circuits

Four pressure channels, one for each main steam line, monitor main steam line pressure. Each channel is associated with one of four trip logics. The locations of the pressure sensors provide the earliest practicable detection of low main steam line pressure.

7.3.1.1.2.4.5.4 Subsystem Logic and Sequencing

When a predetermined decrease in main steam line pressure is detected, trip signals are transmitted to the PCRVICS. The PCRVICS initiates closure of all main steam line isolation drain valves.

Four instrumentation channels are provided to ensure protective action when required and to prevent inadvertent isolation resulting from instrumentation malfunctions. The output trip signal of each instrumentation channel initiates a trip logic. The output trip signals of the trip logics are combined in one-out-of-two-twice configuration for the MSIVs and two-out-of-two configuration for the drain valves as shown in Figures 7.3-1 and 7.3-2. Trip logics A or C and B or D are required to initiate main steam line isolation. Trip logics A and B or C and D are required to initiate main steam line drain isolation. Failure of any one trip logic does not result in inadvertent action.

7.3.1.1.2.4.5.5 Subsystem Redundancy and Diversity

Redundancy of trip initiation signals for low pressure is provided by four pressure sensors, one for each main steam line. Each pressure sensor is associated with one of four trip logics. Two pressure trip channels are supplied from one 120 V ac bus A and the other two are supplied from 120 V ac bus B.

7.3.1.1.2.4.5.6 Subsystem Bypasses and Interlocks

The main steam line low pressure trip is bypassed by the reactor mode switch in the shutdown, refuel, and startup modes of reactor operation. In the run mode, the low pressure trip function is operative.

There are no interlocks to other systems for main steam line low pressure trip signals.

7.3.1.1.2.4.5.7 Subsystem Testability

Testability is discussed in Sections 7.3.2.2.2.3.1.9 and 7.3.2.2.2.3.1.10.

7.3.1.1.2.4.5.8 Environmental Considerations

This subsystem is designed and has been qualified to meet the environmental conditions indicated in Section 3.11. The seismic qualification of this subsystem in discussed in Section 7.3.2.2.2.3.1.5.

7.3.1.1.2.4.6 PCRVICS - Drywell High Pressure

7.3.1.1.2.4.6.1 Subsystem Identification

High pressure in the drywell could indicate a breach of the RCPB inside the drywell. The automatic closure of various valves prevents the release of significant amounts of radioactive material from the primary containment.

The drywell high pressure isolation setting selected is as low as possible without inducing spurious isolation trips. Based on a BWROG generic analysis, the containment isolation pressure setpoint is based on an analytic limit of approximately 2 psig (drywell pressure).

Fluctuations in the atmospheric barometric pressure as well as heat inputs (from such sources as pumps) during normal operation can result in containment pressure increases on the order of 1 psi. Consequently, the analytic limit of 2 psig provides a 1 psi margin above the maximum expected operating pressure. The 1 psi margin to isolation has proved to be a suitable value to minimize the possibility of spurious containment isolation. At the same time, it is such a low value (particularly in view of the small drywell volume) that it provides a sensitive and positive means of detecting and protecting against breaks and leaks in the RCS.

7.3.1.1.2.4.6.2 Subsystem Power Supplies

Logic channels A and C and one pilot solenoid of the inboard (Division 1) MSIVs are supplied from RPS bus A 120 V ac. The second pilot solenoid of the inboard MSIV is supplied from a Division I, Class 1E 125 V dc station battery.

Logic channels B and D and one pilot solenoid of the outboard (Division 2) MSIVs are supplied from RPS bus B 120 V ac. The second pilot solenoid of the outboard MSIV is supplied from a Division II, Class 1E 125 V dc station battery.

See Figures 7.3-1 and 7.3-2.

7.3.1.1.2.4.6.3 Subsystem Initiating Circuits

Drywell pressure is monitored by four pressure sensors that are mounted on instrument racks outside the primary containment. Instrument sensing lines that terminate in the reactor enclosure connect the sensors with the drywell interior. Redundant sensors are physically separated and electrically connected to the isolation control systems so that no single event prevents isolation because of primary containment high pressure.

7.3.1.1.2.4.6.4 Subsystem Logic and Sequencing

When a predetermined increase in drywell pressure is detected, trip signals are transmitted to the PCRVICS for generation of isolation signals. The following lines are isolated for a high drywell pressure condition.

a. Drywell and drywell sump drain discharge toradwaste

b. Containment purge and vent

c. TIP system

d. Containment atmosphere sampling

e. Containment instrument gas

f. HPCI pump flush (isolation signal generated by the HPCI system logic circuits)

g. HPCI vacuum relief (isolation signal generated by the HPCI system logic circuits if low steam pressure condition exists)

h. RCIC vacuum relief (isolation signal generated by the RCIC system logic circuits if low steam pressure condition exists)

i. Suppression pool cleanup

j. Drywell radiation sample

k. Drywell chilled water

l. Reactor enclosure cooling water

Four instrumentation channels are provided to ensure protective action when required and to prevent inadvertent isolation resulting from instrumentation malfunctions. The output trip signals of the instrumentation channels are combined in two-out-of-two logics. Instrumentation channels A and B or C and D are required to initiate isolation of either inboard or outboard valves, respectively. Thus, failure of any one channel does not result in inadvertent action.

7.3.1.1.2.4.6.5 Subsystem Redundancy and Diversity

Redundancy of trip initiation signals for drywell high pressure is provided by pressure switches installed at different locations around the drywell. Wiring from redundant instruments is separated.

Each pressure switch is associated with one logic. Two pressure sensors are supplied from RPS bus A, and the other two are supplied from RPS bus B.

Diversity of trip initiation signals for line breaks inside the primary containment is provided by drywell high pressure and reactor low water level. An increase in drywell pressure or a decrease in reactor water level initiates isolation.

7.3.1.1.2.4.6.6 Subsystem Bypasses and Interlocks

There are no bypasses or interlocks for drywell high pressure trip signals.

7.3.1.1.2.4.6.7 Subsystem Testability

Testability is discussed in Section 7.3.1.1.2.11.

7.3.1.1.2.4.6.8 Environmental Considerations

This subsystem is designed and has been qualified to meet the environmental conditions indicated in Section 3.11. In addition, this subsystem has been seismically qualified as described in Section 3.10.

7.3.1.1.2.4.7 PCRVICS - Reactor Enclosure Ventilation Exhaust Radiation Monitoring System - Instrumentation and Controls

The purpose of this system is to indicate when excessive amounts of radioactivity exist in the reactor enclosure ventilation exhaust and to provide signals for initiation of appropriate action so that the release of radioactive gases to the environment is limited to levels below the guidelines of published regulations. The radiation monitoring system is described in Section 11.5. The system consists of four independent channels monitoring the reactor zone.

See Section 7.6.1.1.2 for a detailed description of this system.

7.3.1.1.2.4.8 PCRVICS - Refueling Area Ventilation Exhaust Radiation Monitoring System - Instrumentation and Controls

The purpose of this system is to indicate when excessive amounts of radioactivity exist in the refueling area ventilation exhaust and to provide signals for initiation of appropriate action so that the release of radioactive gases to the environment is limited to levels below the guidelines of published regulations. The radiation monitoring system is described in Section 11.5. The system consists of independent channels, monitoring the refueling area.

See Section 7.6.1.1.3 for a detailed description of this system.

7.3.1.1.2.4.9 PCRVICS - RWCU System High Differential Flow

High differential flow in the RWCU system could indicate a breach of the RCPB in the cleanup system. The flow at the inlet to the system (suction from "B" recirculation line and bottom head drain) is compared with the flow at the outlets of the system (discharge to feedwater, main condenser, radwaste and CST). High differential flow initiates isolation of the cleanup system.

See Section 7.6.1.3.3.4.2 for a detailed description of this system.

7.3.1.1.2.4.10 PCRVICS - RWCU System Area High Temperature and Differential Temperature

High temperature in the equipment room areas of the RWCU system could indicate a breach in the RCPB in the cleanup system. High ambient temperature and high differential temperature in the equipment area ventilation system initiates isolation of the RWCU system.

See Section 7.6.1.3.3.4.3 for a detailed description of this system.

7.3.1.1.2.4.11 PCRVICS - Main Condenser Low Vacuum Trip

7.3.1.1.2.4.11.1 Subsystem Identification

A main steam line isolation valve trip from a low condenser vacuum instrumentation system is provided.

The main turbine condenser low vacuum signal could indicate a leak in the condenser. Initiation of automatic closure of selected valves will prevent excessive loss of reactor coolant and the release of significant amounts of radioactive material from the RCPB.

The turbine condenser low vacuum trip setting selected is far enough above the normal operating vacuum to prevent spurious isolation, yet low enough to provide an isolation signal before the rupture of the condenser and subsequent loss of reactor coolant and release of radioactive material. There are four main condenser sensors that provide an isolation trip signal to the main steam line isolation valve logic channels.

7.3.1.1.2.4.11.2 Subsystem Power Supplies

See Figures 7.3-1 and 7.3-2.

7.3.1.1.2.4.11.3 Subsystem Initiating Circuits

Four vacuum sensors monitor the main condenser vacuum. Each vacuum sensor is associated with one of four separate trip logics. Four vacuum sensors are installed to provide the earliest practicable detection of a main condenser leak.

7.3.1.1.2.4.11.4 Subsystem Logic and Sequencing

When a predetermined decrease in main condenser vacuum is detected, trip signals are transmitted to the PCRVICS. The PCRVICS initiates closure of all main steam line isolation and drain valves.

Four vacuum sensors with associated trip units are provided to ensure protective action when required and to prevent inadvertent isolation resulting from instrumentation malfunctions. The output signals of the trip logics are combined in one-out-of-two-twice logic for the MSIVs and two-out-of-two logics for the main steam line drain valves. Trip logics A or C and B or D are required to initiate main steam line isolation. Trip logics A and B or C and D are required to initiate main steam line drain isolation. Failure of any one trip logic does not result in inadvertent isolation action.

7.3.1.1.2.4.11.5 Subsystem Redundancy and Diversity

Redundancy of trip initiation signals for low condenser vacuum is provided by four vacuum sensors. Each pressure signal is associated with one of four logics. Two vacuum sensors are supplied by one power source, and the other two are supplied from a different power source.

Diversity of trip initiation signals is not required or provided.

7.3.1.1.2.4.11.6 Subsystem Bypasses and Interlocks

Main condenser low vacuum trip can be bypassed manually when the turbine stop valve is less than 90% open.

There are no interlocks to other systems from the main condenser low vacuum trip signals.

7.3.1.1.2.4.11.7 Subsystem Testability

Testability is discussed in Section 7.3.2.2.2.3.1.10.

7.3.1.1.2.4.11.8 Environmental Considerations

This subsystem is designed and has been qualified to meet the environmental conditions indicated in Section 3.11. The seismic qualification for this subsystem is discussed in Section 7.3.2.2.2.3.1.5.

7.3.1.1.2.4.12 PCRVICS - HPCI System Isolation Signals

The HPCI system is constantly monitored for leaks by the following types of monitoring circuits:

a. Equipment area and pipe chase area ambient and differential temperature monitoring

b. HPCI steam flow rate monitoring

c. HPCI turbine exhaust diaphragm pressure monitoring

When limiting conditions are attained an HPCI autoisolation signal is initiated and an annunciator activated in the control room.

Refer to Section 7.6.1.3.3.5 for a description of the leak detection functions of these subsystems.

HPCI area temperatures are monitored by instrumentation of the LDS. Monitored temperatures include the following.

a. HPCI pipe chase area ambient temperatures

b. HPCI emergency area cooler ambient temperature

c. HPCI area vent air differential temperature.

The common HPCI/RHR steam line connecting the reactor vessel main steam line and the HPCI turbine is monitored by differential pressure sensors which signal a high steam flow rate condition.

The HPCI turbine exhaust diaphragm is monitored by pressure sensors which signal a high pressure condition.

For a detailed discussion see Section 7.6.1.3.3.5.5.

7.3.1.1.2.4.13 PCRVICS - RCIC System Isolation Signals

The RCIC system is constantly monitored for leaks by the following types of monitoring circuits:

a. Equipment area and pipe chase area ambient and differential temperature monitoring

b. RCIC steam flow rate monitoring

c. RCIC steam line pressure monitoring

d. RCIC turbine exhaust diaphragm pressure monitoring

When limiting conditions are attained an RCIC autoisolation signal is initiated and an annunciator activated in the control room.

Refer to Section 7.6.1.3.3.3 for a description of the leak detection functions of these subsystems.

RCIC area temperatures are monitored by instrumentation of the LDS. Monitored temperatures include the following:

a. RCIC pipe chase area temperatures

b. RCIC emergency area cooler ambient temperature

c. RCIC area vent air differential temperature

The RCIC steam line connecting the reactor vessel main steam line and the RCIC turbine is monitored by differential pressure sensors which signal a high steam flow rate condition.

The RCIC steam line connecting the nuclear boiler and the RCIC turbine is monitored by two pressure sensors which signal a low steam supply pressure condition.

The RCIC turbine exhaust diaphragm is monitored by pressure sensors which signal a high pressure condition.

For a detailed discussion see Section 7.6.1.3.3.3.6.

7.3.1.1.2.5 PCRVICS Instrumentation

Sensors providing inputs to the PCRVICS are not used for the automatic control of the process system, thereby achieving separation of the protection and process systems. Redundant channels are physically separated and electrically independent to reduce the probability that a single physical event would prevent isolation. Redundant channels for each monitored variable provide inputs to different isolation trip systems. The functions of the sensors in the isolation control system are shown in Figures 7.3-1 and 7.3-2. Table 7.3-5 lists instrument characteristics.

7.3.1.1.2.6 PCRVICS Initiating Circuits

Solenoid valves which are controlled by the PCRVICS for automatic isolation generally utilize actuator solenoids which are energized during normal service. The logic circuitry signalling automatic isolation is generally arranged such that when a monitored parameter reaches its trip setpoint, the associated trip logic contact opens. When the proper combination of logic trips occur, the actuator trip relay de-energizes, de-energizing the valve actuator solenoid. The system also has system level manual initiation switches that isolate all automatically controlled isolation valves. This general arrangement is applicable to the following valve discussions.

The MSIV actuators each have two actuator solenoids. For automatic valve closure, both solenoids must be de-energized. Each solenoid receives inputs from two separate trip logics, either of which can de-energize the solenoid.

Four RPS instrument channels are provided for each monitored parameter used in the MSIV trip logic. The redundant instrument channels are independent and separate. A and C trip logic relays control one solenoid in each of the inboard and outboard MSIVs on each main steam line. Channels B and D trip logic relays control the other solenoid in the inboard and outboard MSIVs.

Closure of the inboard and outboard main steam line drain isolation MOVs is initiated by the MSIV trip logic relays, utilizing two-out-of-two logic. Logic relays A and B initiate closure of the inboard isolation valve and relays C and D initiate closure of the outboard isolation valve.

Closure of the inboard and outboard RHR discharge to radwaste isolation valves and RHR process sampling isolation valves is initiated by low reactor vessel water level and high drywell pressure signals, utilizing two-out-of-two logic. Logic trip A closes the inboard valves, and logic trip B closes the outboard valves.

Closure of the inboard RHR shutdown cooling suction valves, as well as the RHR shutdown cooling injection-testable check valve and bypass valve is initiated by logic trip A. Closure of the outboard RHR shutdown cooling suction, and RHR shutdown cooling injection outboard throttling MOVs is initiated by logic trip B. Tripping requires two-out-of-two logic for low reactor vessel water level signal or the one-out-of-two logic for reactor high pressure (low pressure permissive to open) signals.

Closure of outboard drywell chiller water isolation valves HV-87-120A&B, 121A&B, 220A&B and 221A&B, and the inboard drywell chilled water isolation valves is initiated by any one of the following conditions in a two-out-of-two logic: reactor level below level 1 trip; high drywell pressure. Outboard drywell chilled water isolation valves HV-87-124A&B, 125A&B, 224A&B, and 225A&B do not receive isolation signals. These valves are normally closed in accordance with the Technical Specifications and Technical Requirements Manual.

Closure of the inboard and outboard reactor water sample AOVs and reactor steam sample AOVs is initiated by low reactor vessel water level utilizing two-out-of-two logic. Logic trip A closes the inboard valves and logic trip B closes the outboard valves.

Retraction of the TIP drives is initiated by low reactor vessel water level 2 and high drywell pressure in a two-out-of-two logic. Logic trip A initiates retraction of the TIP system drives.

Closure of the primary containment purge valves is initiated by any one of the following conditions in a two-out-of-two logic: reactor level below level 2; high drywell pressure; high radiation in the reactor enclosure ventilation exhaust duct; high radiation in the refueling floor ventilation exhaust duct.

Closure of the inboard and outboard RWCU isolation MOVs is initiated by low reactor vessel water level utilizing two-out-of-two logic or by high area temperature or high differential RWCU flow. Logic trip A closes the inboard valve and logic trip B closes the outboard valves.

Closure of the inboard PCIG suction valve is initiated by any one of the following conditions in a two-out-of-two logic: Reactor level below level 1 trip; high drywell pressure; high radiation in the reactor enclosure ventilation exhaust duct.

Closure of the primary containment atmosphere sample isolation valves and the post-LOCA hydrogen recombiner isolation valves is initiated by any one of the following conditions: Reactor level below level 2 trip; high drywell pressure; high radiation in the reactor enclosure ventilation exhaust duct; high radiation in the refueling floor ventilation exhaust duct.

Closure of outboard PCIG isolation valves not on ADS gas supply lines is initiated by any one of the following conditions in a two-out-of-two logic: Reactor level below level 1 trip; high drywell pressure; high radiation in the reactor enclosure ventilation exhaust duct.

Closure of the RHR suppression pool spray line, the core spray pump test and flush line, and the RHR heat exchanger vent valve discharge lines (Unit 2 only) is initiated by high drywell pressure and low reactor vessel pressure or low reactor vessel water level in a two-out-of-two logic.

Closure of the suppression pool cleanup pump suction valves is initiated by high drywell pressure or low reactor vessel water level in a two-out-of-two logic. The HPCI system logic circuits also initiate closure of the HPCI Pump Flush valve for high drywell pressure or low reactor vessel water level in a one-out-of two-twice logic.

Closure of the drywell equipment drain sump and floor drain sump isolation valves is initiated by any one of the following conditions in a two-out-of-two logic: reactor level below level 2; high drywell pressure.

The circuitry controlling isolation of the HPCI and RCIC systems differs from the general arrangement of the systems previously discussed in that the logic trip relays must be energized to initiate valve isolation.

The sensors which monitor leakage in the HPCI system and the common HPCI/RHR steam line and associated logic circuitry are discussed in subsections 7.3.1.1.2.4.12 and 7.6.1.3.3.5. Closure of the outboard HPCI steam supply isolation MOV is controlled by logic trip B (division 2) and the inboard steam supply isolation MOV by logic trip D (division 4).

The sensors and logic circuits which monitor leakage in the RCIC system and signal the automatic isolation logic circuitry are discussed in Sections 7.3.1.1.2.4.13 and 7.6.1.3.3.3. Closure of the outboard RCIC steam supply line isolation and steam line warm-up isolation MOVs is controlled by logic trip A and the inboard steam supply line isolation MOV by logic trip C.

7.3.1.1.2.7 PCRVICS Bypasses and Interlocks

An automatic bypass of the main steam line low pressure signal is effected in all modes of operation except run mode (Section 7.3.1.1.2.4.5.6). The low condenser vacuum trip can be manually bypassed when the turbine stop valves are less than 90% open to allow the condenser vacuum to be established.

Key locked switches in the control room provide bypass of isolation signals to the CAC and PCIG containment isolation valves which may be bypassed. Any time a bypass switch is moved to a position that would cause an isolation signal bypass, this condition is annunciated.

Interlocks initiate the SGTS, isolate the reactor building ventilation system, and trip the drywell purge valves and purge fan units. There are no interlocks involved in manual operation of the PCRVICS.

7.3.1.1.2.8 PCRVICS Redundancy and Diversity

7.3.1.1.2.8.1 Main Steam Lines

Redundancy is provided by instruments monitoring each essential variable as follows:

a. Four differential pressure transmitters and associated switches, one set in each of four trip logics, monitor low reactor vessel level.

b. Left blank intentionally.

c. Sixteen differential pressure transmitters and associated switches, one set of four in each of four trip logics, monitor high steam line flow.

d. Thirty-six temperature sensors and associated switches, one in each of the four trip logics, monitor high temperature along the main steam line in the Outboard MSIV room. Eight sets in each of the four alarm logics, monitor high temperature along the main steam line in the turbine building main steam tunnel.

e. Four pressure transmitters and associated switches, one set in each of four trip logics, monitor low pressure in the main steam lines.

f. Four pressure transmitters and associated switches, one set in each of four trip logics, monitor low condenser vacuum.

Diversity in main steam line monitoring is provided by main steam line high flow and low reactor vessel level, for the gross release of RCPB fluid.

7.3.1.1.2.8.2 RWCU

Redundancy is provided by instruments monitoring each essential variable as follows:

a. Four differential pressure transmitters and associated switches, one set of two in each of two trip logics, monitor low reactor vessel level.

b. Two instrument channels, one in each of two trip logics, monitor differential flow in the RWCU system.

c. Two instrument channels, one in each of two trip logics, monitor high ambient and differential temperature in the area of the RWCU system.

Diversity in RWCU system monitoring is provided by differential flow, and high ambient or differential temperature. Low reactor vessel level monitoring provides additional diversity for gross release of RCPB fluid.

7.3.1.1.2.8.3 RHR

Redundancy is provided by instruments monitoring each essential variable as follows:

a. Four differential pressure transmitters and associated switches, one set of two in each of two trip logics, monitor low reactor vessel level.

b. Four pressure transmitters and associated switches, one set of two in each two trip logics, monitor high drywell pressure.

Diversity in RHR system monitoring is provided by low reactor vessel level and high drywell pressure.

7.3.1.1.2.8.4 HPCI

Redundancy is provided by instruments monitoring each essential variable as follows:

a. Two instrument channels, one in each of two trip logics, monitor high temperature in HPCI equipment area and in the vicinity of the steam line.

b. Two differential pressure transmitters and associated switches, one set in each of two trip logics, monitor high steam line flow.

c. Four pressure transmitters and associated switches, two sets in each of two trip logics, monitor high turbine diaphragm exhaust pressure.

d. Four pressure transmitters and associated switches, two sets in each of two trip logics, monitor low steam supply pressure.

e. Four pressure transmitters and associated switches, two sets in each of two trip logics, monitor high drywell pressure.

Diversity in HPCI monitoring is provided as follows: the steam lines by area and steam line space temperature; the vacuum relief line by high drywell pressure, and low reactor pressure.

7.3.1.1.2.8.5 RCIC

Redundancy is provided by instruments monitoring each essential variable as follows:

a. Two instrument channels, one in each of two trip logics, monitor high temperature in RCIC equipment area and in the vicinity of the steam line.

b. Two differential pressure transmitters and associated switches, one set in each of two trip logics, monitor high steam line flow.

c. Four differential pressure transmitters and associated switches, two sets in each of two trip logics, monitor high turbine exhaust diaphragm pressure.

d. Four pressure transmitters and associated switches, two sets in each of two trip logics, monitor low reactor pressure.

e. Four pressure transmitters and associated switches, two sets in each of two trip logics monitor high drywell pressure.

Diversity in RCIC monitoring is provided as follows: the steam lines by area and steam line space temperature; the vacuum relief line by high drywell pressure, and low reactor pressure.

7.3.1.1.2.8.6 Core Spray

There are no core spray isolation signals.

7.3.1.1.2.8.7 Containment Atmospheric Control System

Redundancy is provided by instruments monitoring each essential variable as follows:

a. Four differential pressure transmitters and associated switches, one set of two in each of two trip logics, monitor low RPV water level.

b. Four pressure transmitters and associated switches, one set of two in each of two trip logics, monitor high drywell pressure.

c. Four radiation monitors, two in each of two trip logics, monitor high refueling floor exhaust duct radiation.

d. Four radiation monitors, two in each of two trip logics, monitor high reactor building exhaust duct radiation.

Diversity in CAC system is provided by RPV water level, and drywell pressure.

7.3.1.1.2.8.8 Containment Instrument Gas

Redundancy is provided by instruments monitoring each essential variable as follows:

a. Four radiation monitors, two in each of two trip logics, monitor high reactor enclosure radiation.

b. Four differential pressure transmitters and associated switches, two sets in each of two trip logics, monitor low RPV water level.

c. Four pressure transmitters and associated switches, two sets in each of two trip logics, monitor high drywell pressure.

Diversity in monitoring these lines is provided by RPV water level, and drywell pressure.

7.3.1.1.2.8.9 Recirculation Loop Sample

Redundancy is provided by instruments monitoring each essential variable as follows:

a. Four differential pressure transmitters and associated switches, two sets in each of two trip logics, monitor low RPV water level.

There is no diverse isolation signal for this line.

7.3.1.1.2.8.10 Other Lines That Penetrate Containment

Redundancy is provided by instruments monitoring each essential variable as follows:

a. Four differential pressure transmitters and associated switches, one set of two in each of two trip logics, monitor RPV low water level.

b. Four pressure transmitters and associated switches, one set of two in each of two trip logics, monitor drywell pressure.

Diversity in monitoring these lines is provided by RPV water level, and drywell pressure.

7.3.1.1.2.9 PCRVICS Actuated Devices

To limit the radiological consequences and reduce reactor vessel water inventory loss as a result of a pipeline break, the valve closing mechanisms are designed to meet the minimum closing rates specified in Table 6.2-17.

The MSIVs are spring and pneumatic closing, piston-operated valves. They close on loss of pneumatic pressure to the valve operator. This is a fail-safe design. The control arrangement is shown in Figure 7.3-3. Closure time for the valves is adjustable between 3 seconds and 10 seconds. Each valve is piloted by two three-way, solenoid-operated valves, one powered by 120 V ac and the other powered by 125 V dc. An accumulator located close to each isolation valve provides pneumatic pressure for valve closing if there is failure of the normal air supply system. The spring is capable of closing the valve without the aid of the pneumatic pressure if accumulator integrity is lost. The logic channel and trip logic relays for the instrumentation used in the systems described are high reliability relays. The relays are selected so that the continuous load does not exceed 50% of the continuous-duty rating. For the minimum number of channels required for functional performance, see Chapter 16, Technical Specifications.

The MOVs used in the PCRVICS are operated by energizing the valve operator motor windings so as to cause motor rotation in the desired direction. Typically, manual valve operation is controlled using a three-position spring return-to-normal switch.

The valves close automatically on receipt of a safety signal. Valve closure is permitted when the valve is fully open or when the seating torque is below the setpoint. A seal-in feature is provided which ensures that autoclosure is completed once initiated. The closure signal also inhibits valve opening.

Valve opening is permitted when the open/inhibit signal is removed and if either the valve is fully closed or if the valve is not fully open and the seating torque is below the setpoint.

Overload protection is provided to valve motors in accordance with Section 8.1.6.1.19.

7.3.1.1.2.10 PCRVICS Separation

Redundant sensor devices are separated physically so that no single failure (open, closure, or short) can prevent the safety action. By the use of separated raceways, the single failure criterion is met from the sensors to the logic cabinets in the auxiliary equipment room. The logic cabinets are so arranged that redundant equipment and wiring are not present in the same bay of a cabinet. Redundant equipment and wiring can be present in control room panels where separation is achieved by surrounding redundant wire and equipment in metal encasements. A bay is a cabinet section separated from other cabinet sections by a fire barrier. Normally the barrier is of full cabinet height and depth. From the logic cabinets to the isolation valves, separated cable trays or a conduit) are employed to complete adherence to the single failure criterion. A complete description of the physical independence between divisions is given in Section 7.1.2.2.

7.3.1.1.2.11 PCRVICS Testability

Portions of PCRVICS are not activated or tested during normal operation with an integrated testing procedure. These portions of the system are tested using manual test methods which allow for independent checking of individual components. This testing includes monitoring of installed sensors and circuits to verify proper operation, to assure that isolation will occur when needed. The frequency of these tests and the parameters to be verified are identified in the Technical Specifications.

PCRVICS is capable of complete testing in overlapping portions during power operation. Operation of the level, pressure, flow, differential flow, and vacuum sensors may be verified by cross-comparison of instrument channels. In addition, these transmitters may be valved out of service one at a time and functionally tested using a test pressure source. The channel trip units and trip relays can be calibrated and tested by injecting a calibration signal.

The operation of the isolation temperature sensors can be verified by cross-comparison of instrument channels. They can also be functionally tested by applying a heat source to the temperature sensing elements. Control room indications of logic trip include annunciation, panel lights, and computer printout. The condition of each sensor is indicated by at least one of these methods in addition to annunciators common to sensors of one variable.

The MSIV logic relays can be tested either by tripping a transmitter or trip unit or by actuating the manual isolation switch in a given logic division. The MSIV indicator lights and trip annunciators indicate a logic trip. Other isolation valve logic can be likewise tested in conjunction with logic test switches provided for this purpose. Indicator lights will indicate a logic trip.

The MSIVs mechanical components can be tested manually to any position at full power in a "slow test" mode. This "slow test" is used to exercise the valve mechanical components, one valve at a time. Full closure, simulating actual autoisolation conditions, can be performed on individual MSIVs when shutdown or at reduced power level by placing the MSIV selector switch in the closed position. This tests the isolation solenoids and valve mechanical components at full isolation speed. In either test, the valve closure can be verified by valve position indicator lights.

Other PCRVICS valve testing must be split into two sections. The motor controls and mechanical components for MOVs that are isolated under normal reactor conditions may be tested only at shutdown. Motor controls and valves that are not normally isolated can be tested by tripping the control logic and verifying valve closure by valve position indicator lights.

7.3.1.1.2.12 PCRVICS Environmental Considerations

The physical and electrical arrangement of the PCRVICS was selected so that no single physical event can prevent achievement of isolation functions. Motor operators for valves inside the drywell are of the totally-enclosed type; those outside the containment have weatherproof-type enclosures. Solenoid valves, whether used for direct valve isolation or as an air pilot, are provided with watertight enclosures. All cables and operators are capable of operation in the most unfavorable ambient conditions anticipated for normal operations. Temperature, pressure, humidity, and radiation are considered in the selection of equipment for the system. Cables used in high radiation areas have radiation-resistant insulation. Shielded cables are used where necessary to eliminate interference from magnetic fields.

Special consideration has been given to isolation requirements during a LOCA inside the drywell. Components of the PCRVICS that are located inside the drywell and must operate during a LOCA

are the cables, control mechanisms, and valve operators of isolation valves inside the drywell. These isolation components are required to be functional in a LOCA environment Section 3.11. Electrical cables are selected with insulation designed for this service. Closing mechanisms and valve operators are considered satisfactory for use in the PCRVICS only after completion of environmental testing under LOCA conditions or submission of evidence from the manufacturer describing the results of suitable prior tests.

7.3.1.1.2.13 PCRVICS Operational Considerations

7.3.1.1.2.13.1 PCRVICS General Information

The PCRVICS is not required for normal operation. This system automatically isolates the appropriate pipeline when one of the monitored variables exceeds preset limits. No operator action is required for at least 10 minutes following automatic initiation. The operator can manually close all other isolation valves.

All automatic isolation valves can be closed by manual operation of switches in the control room.

7.3.1.1.2.13.2 PCRVICS Reactor Operator Information

In general, once isolation is initiated, the valve continues to close even if the condition that caused isolation is restored to normal. The reactor operator must manually reset the tripped logic and operate switches in the control room to reopen a valve that has been automatically closed. The HPCI and RCIC steam line isolation valves are exceptions as discussed in Section 7.1.2.11. Unless a manual bypass under administrative control is provided, the operator cannot reopen the valve until the conditions that initiated isolation have cleared.

A trip of a PCRVICS channel is annunciated in the control room so that the reactor operator is immediately informed of the condition. All motor-operated and air-operated isolation valves have open/ closed indicating lights.

In addition, isolation of any excess flow check valve is annunciated in the control room.

Inputs to annunciators and the process computer are electrically and physically isolated from safety circuits so that no malfunction of the annunciating or computing equipment can functionally disable the system. Direct signals from the isolation system sensors are not used as inputs to annunciating or data logging equipment.

7.3.1.1.2.13.3 PCRVICS Setpoints

See Chapter 16 for the safety setpoint information.

7.3.1.1.3 Main Steam Isolation Valve Leakage Control System - Instrumentation and Controls

7.3.1.1.3.1 Information in this section has been deleted.

7.3.1.1.4 RHR Containment Spray Mode - Instrumentation and Controls

7.3.1.1.4.1 RHR-CSM System Identification

Containment spray is an operating mode of the RHR system. It is designed to condense steam in the suppression pool air volume and/or the drywell atmosphere. The system is manually initiated when necessary.

The RHR system including containment spray is shown in drawing M-51.

7.3.1.1.4.2 RHR-CSM Classification

The RHR containment spray mode is classified as safety Class 3, seismic Class I, and electrical Class 1E.

7.3.1.1.4.3 RHR-CSM Power Sources

Power for the two RHR system pumps used for containment spray is supplied from two independent ac buses that can receive standby ac power. Motive and control power for the two loops of containment spray instrumentation and control equipment are the same as those used for LPCI A and LPCI B (Section 7.3.1.1.1.4.2).

7.3.1.1.4.4 RHR-CSM Equipment Design

Control and instrumentation for the following equipment is required for this mode of operation:

a. Two RHR system pumps

b. Pump suction valves

c. Containment spray discharge valves

d. Valves used to shut off flow paths used for other modes of RHR system operation

The controls and instrumentation for containment spray operation ensure that water is routed from the suppression pool to the containment spray system for use in the drywell and/or suppression pool air volumes.

Containment spray operation uses two pump loops, each loop with its own separate discharge valves. All components pertinent to containment spray operation are located outside of the drywell. The system can be operated so that the spray can be directed to the drywell and/or suppression pool air volume.

7.3.1.1.4.5 RHR-CSM Initiating Circuits

a. Containment Spray A

Drywell spray is initiated manually by means of two remote manual switches, one for each injection valve. Both injection valves may be opened if drywell pressure exceeds the setpoint, the LPCI injection valve is fully closed, and either a LOCA signal is present or the LPCI mode of operation has been manually started.

If any of these required permissives is missing, one of the two injection valves can be opened (for testing) only if the other injection valve is closed. Suppression pool spray is manually initiated from the control room if the LPCI injection valve is fully closed.

Drywell pressure (permissive for manual initiation) is monitored by two pressure sensors mounted in instrument racks outside the primary containment.

Cables from these sensors are routed to trip units in the control structure.

The two drywell pressure sensors are electrically connected so that no single sensor failure can prevent initiation of containment spray A. The drywell pressure sensors and trip units used in the containment spray initiating circuits are the same ones used for LPCI initiation. Additional details concerning these instruments are in Section 7.3.1.1.1.4.3 and Table 7.3-4.

b. Containment Spray B

Initiation of containment spray B is identical to that of "A".

7.3.1.1.4.6 RHR-CSM Logic and Sequencing

Containment spray is manually initiated provided that certain permissive conditions are satisfied as shown in drawings E11-1030-F-001, E11-1030-F-002, and E11-1030-F-003.

The operating sequence of containment spray following receipt of the necessary initiating signals is as follows:

a. The containment spray discharge valves open.

b. The RHR system pumps continue to operate.

c. Valves in other RHR modes are manually positioned or remain as positioned during LPCI.

The containment spray system continues to operate until the operator closes the containment spray injection valves. The operator can then initiate another mode of RHR.

7.3.1.1.4.7 RHR-CSM Bypasses and Interlocks

No bypasses are provided for the containment spray system.

The drywell spray injection valves are interlocked such that the system cannot be manually initiated unless drywell pressure exceeds the setpoint, the LPCI injection valve is fully closed, and either a LOCA signal is present or the LPCI mode of operation has been manually initiated. The open circuit of each drywell spray injection valve has an interlock that permits opening one valve for testing if the other valve in its respective loop is closed.

Since the outboard suppression pool spray injection valves may be open for several modes of RHR system operation, the injection valves are signaled to close on a LOCA signal. Once closed, the valves can be opened manually to initiate suppression pool spray as described in Section 7.3.1.1.4.5. The manual opening signal is interlocked with the LOCA signal to keep the valve open until the LPCI signal is manually reset.

7.3.1.1.4.8 RHR-CSM Redundancy and Diversity

Redundancy is provided for the containment spray function by two separate logics, one for each loop. Redundancy of initiation permissive sensors is described in Section 7.3.1.1.4.5 under "Initiating Circuits."

No diversity is provided for the initiation sensors.

7.3.1.1.4.9 RHR-CSM Actuated Devices

Drawings E11-1030-F-001, E11-1030-F-002, and E11-1030-F-003 shows the functional control arrangement of the containment spray system.

The RHR A and RHR B loops are used for containment spray. Therefore, the pump and valves are the same for LPCI and containment spray function except that each has its own discharge valve. See Section 7.3.1.1.1.4.7 for specific information.

7.3.1.1.4.10 RHR-CSM Separation

Separation is as discussed for LPCI mode in Section 7.3.1.1.1.4.8.

Containment spray uses Division I (RHR A) and Division II (RHR B) equipment. Manual controls, logic circuits, cabling, and instrumentation for containment spray are mounted so that Division I and Division II separation is maintained.

7.3.1.1.4.11 RHR-CSM Testability

The containment spray mode of the RHR system has components that are not activated or tested during normal operation with an integrated testing procedure. These components are tested using manual test methods which allow for independent checking of individual system components. This testing includes verification of suppression chamber spray flow such that the motors, pumps and valves are operated. Associated sensors and circuits are monitored to verify proper operation. Drywell spray injection valves are checked independently and separately by manual initiation. The frequency of these tests and the parameters to be verified are identified in the Technical Specifications.

The containment spray mode is capable of being tested up to the last discharge valve during normal operation. During testing, only one of the drywell spray discharge valves is opened at a time to prevent discharging water into the drywell. Each valve can be individually opened to verify operability.

7.3.1.1.4.12 RHR-CSM Environmental Considerations

See Section 3.11 for environmental qualifications of the system equipment.

7.3.1.1.4.13 RHR-CSM Operational Considerations

7.3.1.1.4.13.1 RHR-CSM General Information

Containment spray is a mode of the RHR and is not required during normal operation.

7.3.1.1.4.13.2 RHR-CSM Reactor Operator Information

Sufficient pressure, temperature, flow, and valve position indications are provided in the control room for the operator to accurately assess containment spray operation. Alarms and indications are shown in drawings M-51, E11-1030-F-001, E11-1030-F-002, and E11-1030-F-003.

All valves necessary for proper containment spray mode operation have indications of fully open, intermediate, and fully closed positions. Numerous RHR system performance parameters are

monitored, including pump discharge pressure, heat exchanger inlet and outlet temperatures, and system flow.

Annunciators are provided to indicate an out-of-service condition, pump running or pump stopped, and abnormal system performance.

7.3.1.1.4.13.3 RHR-CSM Setpoints

The setpoint for the drywell pressure permissive is in the Technical Specifications.

7.3.1.1.5 RHR Suppression Pool Cooling Mode - Instrumentation and Controls

7.3.1.1.5.1 RHR-SPCM System Identification

Suppression pool cooling is an operating mode of the RHR system. It is designed to provide the capability of removing heat from the suppression pool water volume. The system is manually initiated when necessary.

7.3.1.1.5.2 RHR-SPCM Power Sources

Control, instrumentation, and logic power for the two loops of the suppression pool cooling mode of the RHR are the same as those used for LPCI A and LPCI B (Section 7.3.1.1.1.4.2).

7.3.1.1.5.3 RHR-SPCM Equipment Design

Control and instrumentation for the following equipment is required for this mode of operation:

a. Two RHR pumps

b. Pump suction valves

c. Suppression pool discharge valves

d. Two RHR heat exchangers

Suppression pool cooling uses two pump loops, each loop with its own separate discharge valve. All components pertinent to suppression pool cooling operation are located outside of the drywell.

The suppression pool cooling mode is manually initiated from the control room. This mode is put into operation to maintain the water temperature in the suppression pool within specified limits.

7.3.1.1.5.4 RHR-SPCM Initiating Circuits

Initiation of either suppression pool cooling loop is performed manually by the control room operator by activating the manual override to clear any LOCA signal.

7.3.1.1.5.5 RHR-SPCM Logic and Sequencing

There is no engineering safety feature logic or sequencing associated with the suppression pool cooling mode. It is initiated manually. A discussion of suppression pool cooling mode is provided in Section 6.2.2.2.

7.3.1.1.5.6 RHR-SPCM Bypasses and Interlocks

No bypasses are provided for the suppression pool cooling mode. The MOVs isolating suppression pool cooling flow are interlocked to close when the reactor low water level setpoint is reached, or when the drywell high pressure and reactor low pressure setpoints are reached. This action automatically lines up the RHR system for coolant injection.

7.3.1.1.5.7 RHR-SPCM Redundancy and Diversity

Redundancy is provided for the suppression pool cooling function by two separate logics, one for each loop. There is no diversity provided.

7.3.1.1.5.8 RHR-SPCM Actuated Devices

Drawings E11-1030-F-001, E11-1030-F-002, and E11-1030-F-003 (RHR FCD) shows the functional control arrangement of the suppression pool cooling mode.

The RHR A and RHR B loops are utilized for suppression pool cooling. Therefore, the pump and valves are the same for LPCI and suppression pool cooling except that each has its own discharge valves.

7.3.1.1.5.9 RHR-SPCM Separation

Suppression pool cooling is a Division I (RHR A) and a Division II (RHR B) system. Manual control, logic circuits, cabling, and instrumentation for suppression pool cooling are mounted so that Division I and Division II separation is maintained.

7.3.1.1.5.10 RHR-SPCM Testability

Suppression pool cooling is capable of being tested during normal operation; however, the suppression pool cooling mode of the RHR system is a manually actuated mode whose components are operated during normal plant operation. In addition, the associated system components are tested using manual test methods which allow for independent checking of individual system components. This testing includes verification of flow such that the motors, pumps and valves are operated. Associated sensors and circuits are monitored to verify proper operation. The frequency of these tests and the parameters to be verified are identified in the Technical Specifications.

Testing for functional operability can be accomplished by manual testing of each loop. Adequate indication in the form of panel lamps and annunciators is provided in the control room. Testing of instrumentation and equipment shared by the core spray system and LPCI mode of RHR is discussed in Sections 7.3.1.1.1.3.9 and 7.3.1.1.1.4.9.

7.3.1.1.5.11 RHR-SPCM Environmental Conditions

Refer to Sections 3.10 and 3.11 for identification and environmental qualification of the systems' components.

7.3.1.1.5.12 RHR-SPCM Operational Considerations

7.3.1.1.5.12.1 RHR-SPCM General Information

Suppression pool cooling is a mode of the RHR and may be operated during normal operation to maintain the suppression pool temperature within specified operating limits.

7.3.1.1.5.12.2 RHR-SPCM Reactor Operator Information

Sufficient temperature, flow, pressure, and valve position indications are available in the control room for the operator to accurately assess suppression pool cooling operation. Alarms and indications are shown in drawings E11-1030-F-001, E11-1030-F-002, and E11-1030-F-003.

The temperature of the suppression pool is continuously monitored by the SPTMS as described in Appendix 3A.15.1.

7.3.1.1.5.12.3 RHR-SPCM Setpoints

There are no operating setpoints for this manually initiated mode of RHR; however, there are setpoints associated with other modes of RHR which will take precedence over the operation of this mode.

7.3.1.1.6 Containment Atmospheric Control System - Instrumentation and Controls

7.3.1.1.6.1 CAC System Description

The CAC system incorporates features for accomplishing a number of functions, including purging and venting of the primary containment, limitation of the differential pressure between drywell and wetwell, monitoring of hydrogen and oxygen concentrations in the primary containment, and control of hydrogen concentration in the primary containment after a LOCA.

The purging and venting function of the CAC system is accomplished by a high volume purge. The purging and venting function of the CAC system is not safety-related. This function is accomplished by the reactor enclosure HVAC system discussed in Section 7.7.

The monitoring of hydrogen and oxygen concentrations in the primary containment and control of hydrogen concentrations in the primary containment after a LOCA is accomplished by the CGCS, which is discussed in Section 7.3.1.1.6.1.2.

The limitation of the differential pressure between drywell and wetwell function is accomplished by the PCVR subsystem, which is discussed in Section 7.3.1.1.6.1.1.

7.3.1.1.6.1.1 Primary Containment Vacuum Relief System - Instrumentation and Controls

7.3.1.1.6.1.1.1 PCVR System Identification

The PCVR system consists of four PCVR valve assemblies that are provided to limit the degree to which suppression chamber pressure can exceed drywell pressure. The assemblies are located in the suppression chamber, each assembly being mounted on the side of a downcomer. Each assembly consists of two 24 inch (nominal diameter) vacuum relief valves mounted in series. When suppression chamber pressure exceeds drywell pressure by a specified amount, the vacuum relief valves open automatically and allow air from the suppression chamber to enter the

downcomer and flow upward into the drywell, thereby equalizing pressure above and below the diaphragm slab. The PCVR system is shown in Figure 9.4-6.

7.3.1.1.6.1.1.2 PCVR System Power Sources

The PCVR valves are check valves and do not require electrical power to perform their safety function and therefore are not supplied with safeguard power. Since the solenoid valves are used for remote actuation of the primary containment vacuum relief valves for testing purposes only, the solenoid valves are powered from a non-Class 1E bus. The separation criteria for the test circuitry is given in Section 8.1.

7.3.1.1.6.1.1.3 PCVR Equipment Design

Equipment design is described in Section 9.4.5.

7.3.1.1.6.1.1.4 PCVR Initiating Circuits

There are no initiating circuits.

7.3.1.1.6.1.1.5 PCVR Logic and Sequencing

No sequencing is provided for this system.

7.3.1.1.6.1.1.6 PCVR Bypasses and Interlocks

No bypasses or interlocks are provided for this system.

7.3.1.1.6.1.1.7 PCVR Redundancy and Diversity

Redundancy is given by the divisionalized system design. Four independent PCVR valve assemblies are provided. Each assembly consists of two vacuum relief valves mounted in series. Diversity is not required for this system.

7.3.1.1.6.1.1.8 PCVR Actuated Devices

The vacuum relief valves are the only actuated devices.

7.3.1.1.6.1.1.9 PCVR Separation

The test circuitry for each valve is separated from the other valves.

7.3.1.1.6.1.1.10 PCVR Testability

The system is designed to allow periodic testing of all four pairs of PCVR valves to ensure their functional capability. This is accomplished by opening each valve by remote actuation of the solenoid valve. One test selector switch per solenoid valve permits the independent testing of each relief valve. A momentary test push button causes a selective opening of the valve. The valve closes again when the selector switch is returned to the normal position.

Lights indicating the status of the relief valve position verify the operation.

The primary containment vacuum relief valves are tested from the vacuum breaker test panel located in the reactor enclosure.

7.3.1.1.6.1.1.11 PCVR Environmental Considerations

See Table 3.11 for environmental considerations.

7.3.1.1.6.1.1.12 PCVR Operational Considerations

7.3.1.1.6.1.1.12.1 PCVR General Information

This system functions automatically during normal operation. The ability to test during normal operation is not a requirement.

7.3.1.1.6.1.1.12.2 PCVR Reactor Operator Information

Initiation of the system is annunciated in the control room.

7.3.1.1.6.1.1.12.3 PCVR Setpoints

Refer to Chapter 16 for the opening set pressure of the valves.

7.3.1.1.6.1.2 Combustible Gas Control Subsystem - Instrumentation and Controls

7.3.1.1.6.1.2.1 CGCS Identification

The CGCS is described in Section 6.2.5. The safety-related function of this system is to control the oncentration of combustible gases (hydrogen, oxygen) in the containment after a LOCA. Two redundant thermal hydrogen recombiners are provided for this purpose. In the following discussion, when CGCS is used, it refers to the hydrogen recombiner, H_2/O_2 analyzers, and the isolation valves in the piping to and from the recombiners.

7.3.1.1.6.1.2.2 CGCS Power Sources

The CGCS power is provided from Class 1E ac buses.

7.3.1.1.6.1.2.3 CGCS Equipment Design

Equipment design is described in Section 6.2.5.

7.3.1.1.6.1.2.4 CGCS Initiating Circuits

The CGCS is manually initiated from the control room. There is no automatic system initiation. The combustible gas analyzer is designed to operate either in standby or continuous mode during normal operation. However, the combustible gas analyzer is required to continuously monitor hydrogen and oxygen concentrations in the primary containment following a LOCA. The combustible gas analyzers will automatically trip on a LOCA. Following the LOCA, the analyzers are realigned to continuously sample the concentration of combustible (Hydrogen & Oxygen) gases.

7.3.1.1.6.1.2.5 CGCS Logic and Sequencing

See the recombiner and isolation valve logic shown in drawing M-57FD and electrical schematics listed in Table 1.7-1.

The recombiner is manually started and continues to run until manually shut down by the operator or until tripped by one of the following conditions:

a. System inlet pressure high

b. Blower inlet temperature high

c. Heater wall temperature very high

d. Reaction chamber shell temperature very high

e. Return gas temperature high

The recombiner heaters are energized by interlock when the blower is started, and continues to run until the blower is shutdown by the operator or until tripped by one of the following conditions:

a. High gas temperature two-thirds through heater

b. High heater outlet gas temperature

c. Blower inlet gas flow low

d. Spray water inlet valve not full open

The Post-LOCA Recombiners also receive a trip signal from the PCIS upon actuation of containment isolation.

There is no sequencing for this system since it is manually initiated.

7.3.1.1.6.1.2.6 CGCS Bypasses and Interlocks

When in standby, an indicating light in the control room indicates that the recombiner is ready for operation. The light goes out and an alarm sounds if any condition arises that would prevent the recombiner from starting. In addition, a trickle heater keeps the blower and heater section warm during standby. If the trickle heater fails, the general recombiner trouble alarm annunciates.

A level switch is provided in the containment hydrogen recombiner outlet piping that alerts the operator in the control room if the level exceeds a preset value. This alarm is to protect the recombiner from flooding that is due to a leak in the associated cooling water piping.

The recombiners are not interlocked with any other system. However, the recombiners shutdown automatically, and the drywell isolation valves and recombiner isolation valves close on a containment isolation signal. This signal can be bypassed in the control room. The valves can be reopened to permit recombiner operation by key-lock switch (bypass is alarmed). The isolation signal is described in Section 7.3.1.1.2.

7.3.1.1.6.1.2.7 CGCS Redundancy and Diversity

The two hydrogen recombiners are identical, physically and functionally. They feed from independent electrical sources and use different piping for connection to the containment.

7.3.1.1.6.1.2.8 CGCS Actuated Devices

No devices are actuated by this system.

7.3.1.1.6.1.2.9 CGCS Separation

The controls and instrumentation circuits are physically and electrically separated for each recombiner and associated isolation valves. The A recombiner, isolation valves to the A recombiner, and the A water supply valve are in Division III. The B recombiner, isolation valves to the B recombiner, and B water supply valve are in Division IV.

7.3.1.1.6.1.2.10 CGCS Testability

The CGCS tested in accordance with the test requirements of the maintenance program and the Technical Requirements Manual (TRM).

7.3.1.1.6.1.2.11 CGCS Environmental Considerations

The sensors and transmitters of the CGCS are located in the reactor building. Remaining controls and instrumentation are located on the control panel in the control room. See Section 3.11 for environmental considerations.

7.3.1.1.6.1.2.12 CGCS Operational Considerations

7.3.1.1.6.1.2.12.1 CGCS General Information

The combustible gas control function of the CAC system is not required for normal plant operation. It is manually initiated after a LOCA to control the amount of combustible gases (hydrogen, oxygen) in the containment.

7.3.1.1.6.1.2.12.2 CGCS Reactor Operator Information

The operator is provided with sufficient indication to assess accurately the condition of the CGCS. Alarms for both the recombiners and the analyzers alert the operator of abnormal conditions. CGCS instrumentation is discussed in Section 6.2.5.6

7.3.1.1.6.1.2.12.3 Deleted

7.3.1.1.7 Standby Gas Treatment System - Instrumentation and Controls

7.3.1.1.7.1 SGTS Identification

The SGTS provides the means to control reactor enclosure and refueling floor pressure at a negative value with reference to the outside atmosphere. For description and operation of the SGTS, see Section 6.5.1.

7.3.1.1.7.2 SGTS Power Sources

The power for the instruments and controls associated with the SGTS is supplied from the Class 1E 120 V ac system. See Chapter 8 for a description of the electrical system.

7.3.1.1.7.3 SGTS Equipment Design

Equipment design is described in Section 6.5.1.

7.3.1.1.7.4 SGTS Initiating Circuits

The initiating circuits of the SGTS are the reactor enclosure isolation system and the refueling area isolation system. Section 7.3.1.1.9 and 7.3.1.1.17 gives a discussion of the isolation systems.

7.3.1.1.7.5 SGTS Logic and Sequencing

The two SGTS subsystems are normally set up with both sets of filter valves open. When an isolation signal exists, both of the SGTS fans are started and the associated controls are activated to open or modulate appropriate dampers and valves. The flow control of the operating SGTS uses the lowest appropriate reactor enclosure zone pressure to atmospheric pressure differential as a setpoint to ensure that the reactor enclosure pressure is less than atmospheric. This prevents reactor enclosure exhaust to the outside other than through the SGTS. See drawing M-76FD for the logic diagram.

7.3.1.1.7.6 SGTS Bypasses and Interlocks

The hand switch of each SGTS fan when in the off position and the hand switch of each filter train when in the close position provide input to a control room alarm. The SGTS fans are interlocked with the respective reactor enclosure and refueling floor isolation system.

7.3.1.1.7.7 SGTS Redundancy and Diversity

Controls and instrumentation are provided on a one-to-one basis with the mechanical equipment they serve to maintain the redundancy of the equipment. Diversity is not applicable.

7.3.1.1.7.8 SGTS Actuated Devices

No additional devices or systems are actuated by the SGTS.

7.3.1.1.7.9 SGTS Separation

The controls, instrumentation, and power supplies of the SGTS are physically and electrically separated for each of the filter and fan systems. See Section 8.1.6.1 for a discussion of electrical system separation.

7.3.1.1.7.10 SGTS Testability

The SGTS initiating circuits do not employ specific test features. SGTS initiating testing requirements are defined by Technical Specifications, and are implemented in conjunction with testing of the reactor enclosure and refueling floor isolation logics, and employ overlap with NSSSS testing to verify SGTS operability for all initiating conditions.

7.3.1.1.7.11 SGTS Environmental Consideration

The controls for the SGTS equipment are located in the control enclosure. The environmental consideration for this area and a qualification summary is provided in Section 3.11.

7.3.1.1.7.12 SGTS Operational Considerations

7.3.1.1.7.12.1 SGTS General Information

The SGTS is required to maintain the reactor enclosure and the refueling area at negative pressure under isolation conditions and to filter reactor enclosure exhaust taken from the RERS and the refueling area exhaust. Section 6.5.1 gives system function.

7.3.1.1.7.12.2 SGTS Reactor Operator Information

The operator is provided with fan motor status, a fan system trouble annunciator, filter heater inlet and outlet temperatures, carbon filter outlet air temperature, heater trouble alarm, two carbon filter preignition alarms and carbon filter fire alarm.

7.3.1.1.7.12.3 Deleted

7.3.1.1.8 Reactor Enclosure Recirculation System - Instrumentation and Controls

7.3.1.1.8.1 RERS Identification

The recirculation system filters and mixes the air in the reactor enclosure during isolation conditions. For description and operation of the recirculation system, see Sections 6.5.1 and 9.4.2.

7.3.1.1.8.2 RERS Power Sources

The power for the instruments and controls associated with the recirculation system is supplied from the Class 1E 120 V ac system. See Chapter 8 for a description of the electrical system.

7.3.1.1.8.3 RERS Equipment Design

Equipment design is described in Section 6.5.1.

7.3.1.1.8.4 RERS Initiating Circuits

The initiating circuit of the recirculation system is the REIS. Section 7.3.1.1.9 gives a discussion of the isolation systems. An operating train is stopped by low air flow, and the standby train is initiated.

7.3.1.1.8.5 RERS Logic and Sequencing

Two redundant systems are set up in auto-standby fashion. When an initiation signal exists, the lead (auto-selected) system automatically starts and the other system remains on standby. An air flow switch in the discharge duct monitors the operation of the lead fan. If the lead fan fails and the system loses air flow, the lead fan is tripped, the standby fan starts, after a time delay, to eliminate transient response. See drawing M-76FD for the logic diagram.

7.3.1.1.8.6 RERS Bypasses and Interlocks

The hand switch of each recirculation system, when in the off position, provides input to a control room alarm.

7.3.1.1.8.7 RERS Redundancy and Diversity

To maintain the redundancy of the mechanical equipment, controls and instrumentation are provided on a one-to-one basis with the mechanical equipment they serve. Diversity is not applicable.

7.3.1.1.8.8 RERS Actuated Devices

Recirculation exhaust isolation valves HV-76-109 and HV-76-110 are actuated when their respective recirculation system starts. See Sections 6.5.1 and 9.4.2 for a description of operation.

7.3.1.1.8.9 RERS Separation

The controls, instrumentation, and power supplies of the recirculation system are physically and electrically separated for each of the fan systems. See Section 8.1.6.1.14 for a discussion of electrical system separation.

7.3.1.1.8.10 RERS Testability

The RERS initiating circuits do not employ specific test features. RERS initiation testing requirements are defined by Technical Specifications, and are implemented in conjunction with testing of the reactor enclosure isolation logic, and employ overlap with NSSSS testing to verify RERS operability for all initiating conditions.

7.3.1.1.8.11 RERS Environmental Considerations

The controls for the recirculation system are located in the reactor enclosure and the control enclosure. The environmental considerations for these areas and a control qualification summary is provided in Section 3.11.

7.3.1.1.8.12 RERS Operational Considerations

7.3.1.1.8.12.1 RERS General Information

The recirculation system is required to filter and mix the air in the reactor enclosure under isolation conditions. See Section 6.5.1.3 for system function.

7.3.1.1.8.12.2 RERS Reactor Operator Information

The operator is provided with fan motor status, a charcoal temperature detection failure alarm, carbon filter inlet air temperature, filter system differential, two carbon filter preignition alarms, and carbon filter fire alarm.

7.3.1.1.8.12.3 Deleted

7.3.1.1.9 Reactor Enclosure Isolation System - Instrumentation and Controls

7.3.1.1.9.1 REIS Identification

The REIS provides signals to isolate the reactor enclosure and start the recirculation and SGTS systems under emergency conditions. For description and operation of the isolation system, see Section 9.4.2.

7.3.1.1.9.2 REIS Power Sources

The power for the instruments and controls associated with the isolation system is supplied from the Class 1E 120 V ac system. See Chapter 8 for a description of the electrical system.

7.3.1.1.9.3 REIS Equipment Design

Equipment design is described in Section 9.4.2.

7.3.1.1.9.4 REIS Initiating Circuits

Each trip logic of the reactor enclosure isolation system may be manually initiated or automatically initiated in a protective function mode as follows:

a. A trip logic may be initiated on low reactor water level (level 2) or high drywell pressure.

b. A trip logic may be initiated by high radiation sensed by both of the two gamma sensors located in the reactor enclosure exhaust duct. (Section 7.6.1.1.2)

c. A trip logic may be initiated by loss of reactor enclosure differential pressure with respect to pressure external to the building.

7.3.1.1.9.5 REIS Logic and Sequencing

Each trip logic of the redundant isolation system is normally held in an energized (fail-safe) mode so that an initiating signal or loss of power de-energizes the trip logic and starts all the related systems. The isolation signal seals-in upon initiation, and removal of the initiating signal does not deactivate the channel. The trip logic may be reset to a normal condition only if the initiating condition, other than low building differential pressure, is no longer present. A key-lock reset is provided to bypass low building differential pressure to re-establish it with the normal ventilation system. See drawing M-76FD for the logic diagram.

7.3.1.1.9.6 REIS Bypasses and Interlocks

The hand switch of each isolation system, when in the RESET position, provides input to a control room alarm. The isolation system is interlocked with the SGTS and the RERS.

7.3.1.1.9.7 REIS Redundancy and Diversity

To maintain the redundancy of the mechanical equipment, controls and instrumentation are provided on a one-to-one basis with the mechanical equipment they serve.

The diversity of the NSSS-furnished LOCA signal is used.

7.3.1.1.9.8 REIS Actuated Devices

The SGTS, RERS, and the reactor enclosure isolation valves are actuated by this system. See Sections 7.3.1.1.7 and 7.3.1.1.8, respectively, for descriptions of the actuated systems.

7.3.1.1.9.9 REIS Separation

The controls, instruments, and power supplies of the isolation system are physically separated and electrically independent for each of the redundant trip channels. See Section 8.1.6.1 for a discussion of electrical system separation.

7.3.1.1.9.10 REIS Testability

Verification of the operability of the initiating circuits may be made as follows:

a. By tripping the individual radiation monitor circuits

b. By tripping the differential pressure input circuits

c. By manually initiating the channels with hand switches located in the control room

d. By tripping the LOCA signal circuits (REIS only)

The REIS system may be tested as discussed above during plant operation.

7.3.1.1.9.11 REIS Environmental Considerations

The controls for the isolation systems are located in the reactor enclosure and the control enclosure. The environmental considerations for these areas are in Section 3.11.

7.3.1.1.9.12 REIS Operational Considerations

7.3.1.1.9.12.1 REIS General Information

The isolation systems are required to provide for reactor enclosure isolation during emergency conditions. See Sections 6.5.1 and 9.4.2 for system function.

7.3.1.1.9.12.2 REIS Reactor Operator Information

The operator is provided with an isolation initiation alarm and an isolation incomplete alarm in the control room for each of the two redundant isolation system logics. In addition, a common system (REIS and RAIS) "armed/bypassed" alarm is provided in the control room.

7.3.1.1.9.12.3 REIS Setpoints

Refer to Technical Specifications for REIS radiation setpoints.

7.3.1.1.10 Habitability and Control Room Isolation System - Instrumentation and Controls

7.3.1.1.10.1 HCRIS Identification

The control room isolation system provides means to isolate the control room from radiation or chlorine entering through the control room ventilation system. The emergency fresh air system

provides a means of pressurizing the control room during radiation isolation. The control room HVAC system provides the proper environment for the control room and adjacent areas. For description and operation, see Sections 9.4.1.1 and 6.4.

7.3.1.1.10.2 HCRIS Power Sources

Power for the instruments and controls associated with the isolation system, the emergency fresh air system, and the control room HVAC system is supplied from the Class 1E 120 V ac system. See Chapter 8 for a description of the electrical system.

7.3.1.1.10.3 HCRIS Equipment Design

Equipment design is described in Section 9.4.

7.3.1.1.10.4 HCRIS Initiating Circuits

The control room isolation system is initiated by outside air high-high radiation (Section 11.5) or a high concentration of chlorine gas (manual initiation). The control room supply and return fans initiate identically to the auxiliary equipment room ventilation system (Section 7.3.1.1.15.6). The CREFAS is initiated by the isolation signals.

7.3.1.1.10.5 HCRIS Logic and Sequencing

Two modes of isolation are provided: complete intake and exhaust isolation of the control room upon chlorine detection (manual initiation), and intake air diverted through the emergency fresh air supply system upon radiation detection and control room isolation. See Sections 9.4 and 6.4 for details. The control room supply and return fans operate identically to the auxiliary equipment room ventilation system (Section 7.3.1.1.15.6), except the control room supply fans do not trip on high fan discharge temperature. See drawing M-78FD for the HCRIS control logic diagram.

7.3.1.1.10.6 HCRIS Bypasses and Interlocks

The hand switch of each fan in the emergency fresh air system and the control room HVAC system, when in the OFF position, provides input to a control system alarm. One hand switch of each isolation channel, when in the TEST position, provides input to a control system alarm. The isolation system is interlocked with the emergency fresh air system to maintain ventilation within the control room during isolation. The control room HVAC supply fans are interlocked with the purge system, and the chilled water pumps in a way identical to the auxiliary equipment room ventilation system (Section 7.3.1.1.15.6).

7.3.1.1.10.7 HCRIS Redundancy and Diversity

To maintain the redundancy of the mechanical equipment, controls and instrumentation are provided on a one-to-one basis with the mechanical equipment they serve.

7.3.1.1.10.8 HCRIS Actuated Devices

The associated control enclosure chilled water system pumps are actuated by the control room HVAC supply fans (Section 7.3.1.1.13).

7.3.1.1.10.9 HCRIS Separation

The controls, instrumentation, and power supplies of the isolation system, emergency fresh air system, and control room HVAC are physically separated and electrically independent for each of the redundant trip channels. See Section 8.1.6.1.14 for a discussion of the electrical system separation.

7.3.1.1.10.10 HCRIS Testability

Verification of the operability of the initiating circuits of the isolation system may be made as follows:

a. By tripping the individual radiation monitor circuits

b. By manually initiating the channels by hand switches located in the control room. Verification of the operability of the initiating circuits of the emergency fresh air system may be made as follows:

   1. By putting each fan in the AUTO mode and tripping the isolation channel

   2. By putting each fan in the STANDBY mode and tripping the isolation channel when the other fan is shut down

   Verification of the operability of the initiating circuits of the control room HVAC fans may be made by putting each fan in the AUTO mode when the other fan of the pair is shut down. In addition, all fans may be manually tested by hand switches from the control room.

The HCRIS may be tested as discussed above during plant operation.

7.3.1.1.10.11 HCRIS Environmental Consideration

The controls for these systems are located in the control enclosure. The environmental consideration for this area and the control qualification summary is provided in Section 3.11.

7.3.1.1.10.12 HCRIS Operational Considerations

7.3.1.1.10.12.1 HCRIS General Information

The control room HVAC system is required for normal operation of the control room. The isolation system and the emergency fresh air system are required for emergency operation of the control room.

7.3.1.1.10.12.2 HCRIS Reactor Operator Information

Alarms that are common to all four redundant trip channels are provided in the control room for Chlorine Isolation Initiated, Radiation Isolation Initiated, Isolation System Armed, Isolation Not Complete, and Isolation Circuit In Test.

The information provided for the control room HVAC system is identical to the auxiliary equipment room ventilation system (Section 7.3.1.1.15.6).

The following safety-related information is provided for the emergency fresh air system:

a. Fan motor status and damper position status.

b. System flow rate indication

c. Carbon filter leaving air temperature

7.3.1.1.10.12.3 HCRIS Setpoints

For setpoints, see Chapter 16.

7.3.1.1.11 Emergency Service Water System - Instrumentation and Controls

7.3.1.1.11.1 ESW Identification

The ESW system is described in Section 9.2.2. This system provides cooling water to the diesel generator units, RHR pumps, and room coolers required during emergency conditions to safely shut down the plant. The ESW system is shown in drawing M-11.

7.3.1.1.11.2 ESW Power Sources

The power for the ESW pump motors and its associated loop MOVs is supplied from Class 1E ac buses. Control power for the ESW pumps is supplied from Class 1E dc buses. Instrumentation power is supplied from Class 1E ac buses.

7.3.1.1.11.3 ESW Equipment Design

Equipment design is described in Section 9.2.2.

7.3.1.1.11.4 ESW Initiating Circuits

Start signals from both the Unit 1 and Unit 2 diesel generators in the same electrical division initiate the auto start of the associated ESW pump. The diesel generator that supplies power to the ESW pump in a loop provides two start signals. The first signal monitors bus voltage and diesel generator speed. The second signal monitors bus voltage and diesel generator output breaker position. The diesel generator in the same division that does not supply power to the associated ESW pump only provides the start signal associated with bus voltage and diesel generator speed. The start signals have different time delays to ensure proper load sequencing. Diesel generators D11 and D21 start ESW pump A (Division I); D12 and D22 start ESW pump B (Division II); D13 and D23 start ESW pump C (Division III); and D14 and D24 start ESW pump D (Division IV).

A start signal from each ESW pump initiates the associated loop valve action.
Manual control for all four pumps and remote-operated loop configuration control valves is available in the control room. Manual control of ESW pump A and specific A ESW and A RHRSW return header valves is available on the remote shutdown panel. In addition, the "B" and "C" ESW pump can be operated using local controls located at the "B" and "C" ESW pump motor circuit breaker cubicles.

7.3.1.1.11.5 ESW Logic and Sequencing

See drawing M-11FD for the logic diagram and Table 1.7-1 for reference to the electrical schematic diagrams.

See Chapter 8 for the diesel generator control circuits.

Automatic start of each pump is initiated on the following conditions:

a. Forty-five seconds after the associated diesel generator bus breaker is in and closed and the bus voltage is available

b. Fifty-three seconds after the associated diesel generator is operating (i.e. speed detection) and the bus voltage is available

The time delay is for bus loading considerations.

The starting of an ESW pump automatically opens or closes the associated cooling water loop configuration valves. Also, the start signal closes the cooling tower inlet to the associated pump wet pit and opens the sluice gate from the spray pond. The return valve from the ESW system to the cooling tower is closed, and the associated return valves to the spray pond are opened.

Once an ESW pump is started, it continues to operate until any of the following conditions occurs:

a. Manually stopped by the operator in the control room or, for pump A, from the remote shutdown room, or for pumps B and C, from the local circuit breaker cubicle.

b. Bus lockout

c. Phase overcurrent

d. Ground fault

e. Bus undervoltage

During Unit 1 operation and Unit 2 construction, ESW supplies and returns to Unit 2 were valved off. During this period ESW pumps "C" and "D" were temporarily powered from safeguard buses D13 and D14, respectively.

7.3.1.1.11.6 ESW Bypasses and Interlocks

An interlock is provided so that if an ESW pump is running and a LOCA signal is initiated the pump trips and restarts automatically after a time delay on the signals described in Section 7.3.1.1.11.5. This interlock is for diesel generator loading considerations.

7.3.1.1.11.7 ESW Redundancy and Diversity

To maintain the redundancy of the mechanical equipment described in Section 9.2.2, controls are provided on a one-to-one basis with the mechanical equipment.

MCR instrumentation of each process loop is redundant to the other process loop.

7.3.1.1.11.8 ESW Actuated Devices

The devices actuated by the initiation of the ESW pumps are the loop valving and the water source and return valving and/or sluice gates.

7.3.1.1.11.9 ESW Separation

The controls and instrumentation are physically and electrically separated for each of the four ESW pumps. ESW pump A controls and instruments are in Division I; ESW pump B is in Division II; ESW pump C is in Division III; and ESW pump D is in Division IV.

The controls for the ESW valves are assigned to various divisions so that a single active failure cannot disable a complete ESW loop. In cases where two valves are in series to shut off a flow path, the valves are assigned to two different divisions. Likewise, in cases where two valves are used to provide redundant flow paths in a single loop, the valves are assigned to two different divisions.

Loop A valves are in Divisions I and III, and loop B valves are in Divisions II and IV. The manual control loop selection valves for each diesel generator are in the same division as the associated diesel generator.

Loop A pressure and differential flow indication are in Division I, and the Loop B instruments are in Division II.

7.3.1.1.11.10 ESW Testability

Verification of operability of initiation circuits is made when the associated diesel generator is tested. Circuits that are actuated by ESW pump starts are tested by manipulating the associated components to the nonsafety-related positions, starting the ESW pump and verifying the proper safety-related position is obtained.

7.3.1.1.11.11 ESW Environmental Considerations

The control equipment for the ESW system is located in the reactor enclosure, diesel generator enclosures, spray pond pump house, control enclosure, and the control room. See Section 3.11 for environmental considerations.

7.3.1.1.11.12 ESW Operational Considerations

7.3.1.1.11.12.1 ESW General Information

The ESW system is not required for normal operation. The system is initiated automatically on a signal based on the status of the diesel generators.

7.3.1.1.11.12.2 ESW Reactor Operator Information

The operator is provided with pump motor status and valve position indicators for the ESW system in the control room. An indicator is provided for each loop to show the differential between the loop inflow and the loop return flow. Also, pump A status and position indication for certain loop A valves is provided in the remote shutdown room.

In addition, the following nonsafety-related instrumentation and alarms are provided in the main control room:

a. ESW loop A discharge header pressure indication

b. ESW loop B discharge header pressure indication

c. Control room annunciators:

1. ESW loop A(B) high differential flow
2. Pump discharge pressure low (one/pump)
3. Diesel generator compartment flooding (one/diesel generator)
4. Pump control transferred to remote shutdown panel (pump A only)
5. Pump motor overcurrent (one/pump)
6. Pump autostart (one/pump)
7. ESW system out of service (one/pump)
8. Division I (II, III, and IV) any ESW auto initiated valve not fully open/closed
9. Division I (II, III, and IV) ESW MOVs overload or loss of power

d. Plant computer alarms

1. ESW pump motor high bearing temperature
2. ESW pump motor high stator temperature

See Section 7.4.1.4 for a description of the indications provided on the remote shutdown panel.

7.3.1.1.11.12.3 ESW Setpoints

There are no safety setpoints for the ESW system.

7.3.1.1.12 RHR Service Water System - Instrumentation and Controls

7.3.1.1.12.1 RHRSW Identification

The RHRSW system is described in Section 9.2.3. This system provides cooling water to the RHR heat exchangers of both units. The RHRSW system is shown in drawing M-12.

7.3.1.1.12.2 RHRSW Power Sources

The power for the RHRSW pump motors and cooling water loop MOVs is supplied from Class 1E ac buses. Control power for the RHRSW pump motors is supplied from Class 1E dc buses. Instrumentation power is supplied from Class 1E ac buses.

7.3.1.1.12.3 RHRSW Equipment Design

Equipment design is described in Section 9.2.3.

7.3.1.1.12.4 RHRSW Initiating Circuits

The RHRSW system is a manually initiated system. However, as noted in Section 7.3.1.1.12.5, the common ESW and RHRSW supply and return valves and the spray pond sluice gates are automatically oriented to the spray pond on a start signal from the ESW system.

Manual controls for the RHRSW pumps, cooling water loop valves, and the spray pond sluice gate are available in the control room. Also, manual control of the "A" and "C" RHRSW pumps and the cooling water loop A valves and associated sluice gates is available in the remote shutdown room. In addition, the "B and D" RHRSW pumps can be operated using local controls located at "B and D" RHRSW pumps motor circuit breaker cubicle.

7.3.1.1.12.5 RHRSW Logic and Sequencing

See drawings M-12FD and M-51FD for the RHRSW and the RHR heat exchanger inlet and outlet valve logic diagrams and Table 1.7-1 for reference to electrical schematic diagrams.

The RHRSW pumps are started manually. Once a pump is started, it continues to operate until any of the following conditions occurs:

a. Manually stopped by the operator in the control room, or, for pumps A and C, from the remote shutdown room

b. Bus lockout

c. Phase overcurrent

d. Ground fault

e. Bus undervoltage

f. Associated cooling water loop heat exchanger return line high radiation signal

g. High pump discharge pressure

Each RHR heat exchanger inlet and outlet valve is opened manually from the control room. The loop A RHR heat exchanger inlet and outlet valves can also be manually operated from the remote shutdown room.

The system is normally aligned to the spray pond for cooling water source and loop return. However, the system can be manually aligned to the cooling towers, if available. The starting of the ESW system, the cooling water source, and return for the ESW and RHRSW system automatically aligns to the spray pond if the systems are not already in that mode. Manual alignment of the loop A valve to the cooling tower or the spray pond is also available in the remote shutdown room.

7.3.1.1.12.6 RHRSW Bypasses and Interlocks

A key-locked manual switch bypass is provided to inhibit the ESW signal that automatically aligns the ESW and RHRSW system from the cooling tower mode to the spray pond mode. This bypass is provided to permit alignment to the cooling tower if available. A control room alarm indicates that the ESW system is out-of-service whenever this bypass is activated.

A key-locked manual bypass switch is provided to inhibit the high radiation signal of the monitor in the associated cooling water loop return to provide the capability to restart the pumps. The bypass switch will also bypass the high discharge pressure trip of the pumps. A control room alarm indicates that the high radiation and high discharge pressure trips are bypassed.

7.3.1.1.12.7 RHRSW Redundancy and Diversity

Controls are provided on a one-to-one basis with the mechanical equipment described in Section 9.2.3.

Instrumentation of each process loop is redundant to the other process loop.

7.3.1.1.12.8 RHRSW Actuated Devices

Starting an RHRSW pump does not actuate any associated components. The actuation of loop valving, the water source and return valving, and/or sluice gates is limited by ESW pump start.

7.3.1.1.12.9 RHRSW Separation

The controls and instrumentation are physically and electrically separated for each RHRSW loop. The controls for the loop A RHR heat exchanger inlet valves and for RHRSW pumps A and C are in Division I, and controls for RHRSW pumps B and D, and the loop B RHR heat exchanger inlet valves are in Division II. Controls for the loop A RHR heat exchanger outlet valve are Division III and the controls for loop BRHR heat exchanger are in Division IV.

The controls of the RHRSW Loop A valves that are common with the ESW system are in either Division I or III, and the Loop B valves that are common with the ESW system are in either Division II or IV as described in Section 7.3.1.1.11.9.

Similarly the Loop A instrumentation for pressure, flow, and radiation is in either Division I or III, and the Loop B instrumentation is in either Division II or IV.

7.3.1.1.12.10 RHRSW Testability

The RHRSW system is capable of being tested during normal plant operation by the manual testing of each RHRSW loop component. Manual control switches with status lights are provided in the control room for the system pumps and valves.

7.3.1.1.12.11 RHRSW Environmental Considerations

The control equipment for the RHRSW system is located in the spray pond pump house, and control structure. See Section 3.11 for environmental considerations.

7.3.1.1.12.12 RHRSW Operational Considerations

7.3.1.1.12.12.1 RHRSW General Information

The RHRSW system is not required for normal plant operations. The RHRSW system is required for normal plant shutdowns. The system is manually initiated to supply cooling water to the RHR heat exchangers.

7.3.1.1.12.12.2 RHRSW Reactor Operator Information

The operator is provided with pump motor status and valve position indication for the RHRSW system components in the control room. A recording of the radiation level of each of the RHRSW return loops is provided.

In addition, the following nonsafety-related instrumentation and alarms are provided in the control room:

a. RHRSW pumps A and C discharge header pressure indicator. This pressure indication is also provided in the remote shutdown room.

b. RHR heat exchanger service water outlet pressure indicator (one/heat exchanger). This pressure indication is also provided in the remote shutdown room.

c. RHR heat exchanger service water outlet temperature recording (one/heat exchanger)

d. Control room annunciators:

1. RHRSW pump discharge low pressure (one/pump)

2. RHRSW pump discharge high pressure (one/pump)

3. RHRSW header low pressure (two/loop)

4. RHRSW pump motor high bearing or stator temperature alarms. Alarms are via the plant computer (three/pump motor).

5. RHRSW pump control transferred to the remote shutdown panel (pumps A and C only)

6. RHRSW pump motor overcurrent (one/motor)

7. RHRSW high radiation trip signal bypassed (one/loop)

8. RHR heat exchanger service water valves not open (one/loop)

9. RHR out-of-service (input from each RHRSW loop)

10. DELETED

11. RHRSW drain high/low level

12. Spray pond MOVs overload on loss of power (one/ division)

7.3.1.1.12.12.3 RHRSW Setpoints

There are no safety setpoints for the RHRSW system.

7.3.1.1.13 Control Enclosure Chilled Water System - Instrumentation and Controls

7.3.1.1.13.1 CECWS Identification

The CECWS provides chilled water to the control room air supply fan cabinets, the auxiliary equipment room air supply fan cabinets, the emergency switchgear and battery room air supply fan cabinets, and the SGTS room and access area unit coolers. For description and operation, see Section 9.4.1.

7.3.1.1.13.2 CECWS Power Sources

The power for the instruments and controls associated with the CECWS is supplied from the Class 1E 120 V ac system. See Chapter 8 for a description of the electrical system.

7.3.1.1.13.3 CECWS Equipment Design

Equipment design is described in Section 9.4.1.

7.3.1.1.13.4 CECWS Initiating Circuits

The CECWS chillers and pumps may be manually started from hand switches in the control room. The circulating water pumps, when in the auto mode, can be started by any one of the five fan units served by the CECWS. The chiller can be automatically started, when in the auto mode, by the starting of its circulating water pump.

7.3.1.1.13.5 CECWS Logic and Sequencing

One circulating water pump and its associated chiller are started manually to correspond with the cooling coils in use. The other pump and chiller remain in a standby mode. If a fan unit fails or is shut down, its standby unit starts and sends a signal to its corresponding circulating water pump and chiller to start. If a pump or chiller shuts down, the corresponding fan units shut down due to high temperature, except for the main control room fan unit(s). The operating main control fan unit can be manually shut down if required, which causes the standby fan unit to start and send a signal to the corresponding circulating water pump and chiller to start.

Upon receipt of a LOCA signal the operating chiller is automatically tripped, and the operating circulating pump continues to run. The standby circulating pump automatically starts approximately 116 seconds (126 sec if LOOP/LOCA) later. Both chillers automatically start approximately 167 seconds (117 if LOOP/LOCA) later. See drawing M-90FD for the control logic diagram.

7.3.1.1.13.6 CECWS Bypasses and Interlocks

The hand switch of each pump, when in the "off" position, provides input to a computer alarm. The hand switch of each chiller, when in the off position, provides input to a control system alarm. Each safeguard channel pump and chiller is interlocked with each other and with the 5 fan/coil units that are serviced by it.

7.3.1.1.13.7 CECWS Redundancy and Diversity

To maintain the redundancy of the mechanical equipment, the controls and instrumentation are provided on a one-to-one basis with the mechanical equipment they serve. Diversity is not applicable.

7.3.1.1.13.8 CECWS Actuated Devices

The pump and chiller can be actuated by each other under certain circumstances as described in Section 7.3.1.1.13.4.

7.3.1.1.13.9 CECWS Separation

The controls, instrumentation, and power supplies of the CECWS are physically and electrically separated for each of the redundant systems. See Section 8.1.6.1 for the electrical system separation.

7.3.1.1.13.10 CECWS Testability

Verification of the operability of the initiating circuits may be made as follows:

a. By manually testing the pumps and chillers by hand switches located in the control room.

b. By putting the chiller and pump pair in the automatic mode and starting one of the 5 fan units interlocked with that pair.

7.3.1.1.13.11 CECWS Environmental Consideration

The controls for the CECWS are located in the control enclosure; the environmental consideration for this area and control qualification summary is provided Section 3.11.

7.3.1.1.13.12 CECWS Operational Considerations

7.3.1.1.13.12.1 CECWS General Information

The CECWS is required for normal and emergency operation of its service areas.

7.3.1.1.13.12.2 CECWS Reactor Operator Information

The operator is provided with pump motor status and flow indication for the pumps. Chiller motor status, and entering and leaving chilled water temperature indication is provided for the chillers. A chilled water return high temperature alarm is also provided to the computer.

7.3.1.1.13.12.3 Deleted

7.3.1.1.14 Class 1E Power System

Descriptions of the standby power system and supporting system can be found in the following:

a. See Section 8.3.1 for a description of the onsite Class 1E ac power systems.

b. See Section 8.3.2 for a description of the onsite Class 1E dc power system.

c. See Section 9.5.5 for the diesel generator cooling water system.

d. See Section 9.5.6 for the diesel generator starting system.

e. See Section 9.5.7 for the diesel generator lubrication system.

f. See Section 9.5.8 for the diesel generator combustion air intake and exhaust system.

7.3.1.1.15 Safety-Related Equipment Area Cooling Ventilation Systems - Instrumentation and Controls

7.3.1.1.15.1 SGTS Filter Room and Access Area Unit Coolers - Instrumentation and Controls

7.3.1.1.15.1.1 SGTS-UC System Identification

The SGTS unit coolers provide cooling to the SGTS filter room and access areas. For description and operation, see Section 9.4.1.

7.3.1.1.15.1.2 SGTS-UC Power Sources

The power for the instruments and controls associated with the SGTS unit coolers is supplied from the Class 1E 120 V ac system. See Section 8 for a description of the electrical system.

7.3.1.1.15.1.3 SGTS-UC Equipment Design

Equipment design is described in Section 9.4.1.

7.3.1.1.15.1.4 SGTS-UC Initiating Circuits

Each of the unit coolers may be initiated as follows:

a. The tripping of the high temperature switch in auto mode

b. The tripping of the high-high temperature switch in the standby mode

7.3.1.1.15.1.5 SGTS-UC Logic and Sequencing

When the temperature of the area exceeds the high temperature setting, the lead fan starts. If the temperature continues to rise, the standby fan starts. When a fan starts, air flow is sensed by differential pressure instrumentation which sends a signal to start the associated control structure chilled water pump and chiller and opens the chilled water coil inlet valve. Once started, a fan runs until the area temperature drops below the low temperature setting. See drawings M-78FD for the control logic diagram.

7.3.1.1.15.1.6 SGTS-UC Bypasses and Interlocks

The hand switch of each unit, when in the off position, provides input to a computer alarm. The unit coolers are interlocked with the control enclosure chilled water pumps.

7.3.1.1.15.1.7 SGTS-UC Redundancy and Diversity

To maintain the redundancy of the mechanical equipment, controls and instrumentation are provided on a one-to-one basis with the mechanical equipment they serve. Diversity is not applicable.

7.3.1.1.15.1.8 SGTS-UC Actuated Devices

The associated control enclosure chilled water system pumps are actuated by the unit coolers. See Section 7.3.1.1.13 for a description of CECWS controls.

7.3.1.1.15.1.9 SGTS-UC Separation

The controls, instrumentation, and power supplies of the SGTS unit coolers are physically and electrically separated for each of the units. See Section 8.1.6.1 for a discussion of electrical system separation.

7.3.1.1.15.1.10 SGTS-UC Testability

Verification of the operability of the initiating circuits may be made as follows:

a. The fans can be manually tested by hand switches from the local control panel.

b. In the auto mode, the unit can be started by tripping the high temperature switch.

c. In the standby mode, the unit can be started by tripping the high-high temperature switch.

7.3.1.1.15.1.11 SGTS-UC Environmental Considerations

The controls for the subject equipment are located in the control enclosure. The environmental considerations for this area and the control qualification summary is provided in Section 3.11.

7.3.1.1.15.1.12 SGTS-UC Operational Considerations

7.3.1.1.15.1.12.1 SGTS-UC General Information

The SGTS unit coolers are required to maintain environmental conditions in their service areas when the SGTS fan is operating.

7.3.1.1.15.1.12.2 SGTS-UC Reactor Operator Information

The following safety-related information is provided on a local control panel:

a. Fan motor status for each unit cooler

b. Area temperature for each unit cooler

In addition, a fan trouble alarm is relayed to the computer alarm for each unit cooler.

7.3.1.1.15.1.12.3 Deleted

7.3.1.1.15.2 Diesel Generator Enclosure Ventilation System - Instrumentation and Controls

7.3.1.1.15.2.1 DGEVS System Identification

The diesel generator enclosure ventilation system cools the diesel generator cells and equipment. For description and operation, see Section 9.4.6.

7.3.1.1.15.2.2 DGEVS Power Sources

The power for the instruments and controls associated with the diesel generator enclosure ventilation system is supplied from the Class 1E 120 V ac system. See Chapter 8 for a description of the electrical system.

7.3.1.1.15.2.3 DGEVS Equipment Design

Equipment design is described in Section 9.4.6.

7.3.1.1.15.2.4 DGEVS Initiating Circuits

Each of the four diesel generators has its own corresponding ventilation system which may be initiated in a protective function mode as follows:

a. The starting of an associated diesel and the receipt of a temperature permissible (temperature >36°F)

b. The initiation of the high temperature switch will start the standby fan if the diesel is running.

c. With the diesel not running, the initiation of the high- high temperature switch will start both the lead and standby fans.

7.3.1.1.15.2.5 DGEVS Logic and Sequencing

When the diesel start signal is initiated and the cell temperature exceeds the thermostat setting, the lead fan starts. If the temperature continues to rise, the standby fan starts.

Once started, a fan runs until the cell temperature drops below the low temperature switch setting. The fan blades modulate to maintain the discharge air temperature setting. See drawings M-81FD for the control logic diagram.

7.3.1.1.15.2.6 DGEVS Bypasses and Interlocks

The hand switch of each ventilation fan, when in the off position, provides input to a local panel alarm that is relayed to the control room.

The diesel generator enclosure fans are interlocked with their respective diesel start signal.

7.3.1.1.15.2.7 DGEVS Redundancy and Diversity

To maintain the redundancy of the mechanical equipment, controls and instrumentation are provided on a one-to-one basis with the mechanical equipment they serve. Diversity is not applicable.

7.3.1.1.15.2.8 DGEVS Actuated Devices

No additional devices or systems are actuated by the diesel generator enclosure ventilation system.

7.3.1.1.15.2.9 DGEVS Separation

The controls, instrumentation, and power supplies of the diesel generator enclosure ventilation fans are physically and electrically separated for each of the fan systems. See Section 8.1.6.1 for a discussion of electrical system separation.

7.3.1.1.15.2.10 DGEVS Testability

Verification of the operability of the initiating circuits may be made as follows:

a. By manually testing the fans by hand switches from the local panel

b. In the auto mode, by tripping the diesel start signal or the cell high-high temperature switch

c. In the standby mode, by tripping the diesel start signal and cell high temperature switch or by tripping the cell high-high temperature switch

7.3.1.1.15.2.11 DGEVS Environmental Consideration

The controls for the subject equipment are located in the diesel generator enclosure. The environmental consideration for these areas and a control qualification summary is provided in Section 3.11.

7.3.1.1.15.2.12 DGEVS Operational Considerations

7.3.1.1.15.2.12.1 DGEVS General Information

The diesel generator enclosure ventilation system is required for normal operation and testing of the diesel generators when the plant is in operation.

7.3.1.1.15.2.12.2 DGEVS Reactor Operator Information

The operator is provided with a fan system trouble alarm.

7.3.1.1.15.2.12.3 Deleted

7.3.1.1.15.3 Spray Pond Pump Structure Ventilation System - Instrumentation and Controls

7.3.1.1.15.3.1 SPPSVS System Identification

The spray pond pump structure ventilation system provides ventilation and heating for the ESF pumps located in the spray pond pump structure. For description and operation, see Section 9.4.7.

7.3.1.1.15.3.2 SPPSVS Power Sources

The power for the instruments and controls associated with the spray pond pump structure ventilation system is supplied from the Class 1E 120 V ac system.

7.3.1.1.15.3.3 SPPSVS Equipment Design

Equipment design is described in Section 9.4.7.

7.3.1.1.15.3.4 SPPSVS Initiating Circuits

Each of the fans may be initiated or stopped in a protective function mode as follows:

a. The initiation of a high temperature switch (for cooling)

b. The initiation of a low temperature switch (for heating)

c. The tripping of a low temperature switch (for cooling)

d. The tripping of a high temperature switch (for heating)

7.3.1.1.15.3.5 SPPSVS Logic and Sequencing

Each train of the SPPSVS may be operated in either the Run or Standby mode. See drawings M-81FD for control logic diagrams and Table 1.7-1 for reference to electrical schematic diagrams. Fans in the run mode operate continuously and structure temperature is controlled automatically by a temperature controller that modulates dampers which mix outside and recirculated air. If temperature drops below setpoint, heaters will be energized automatically.

As the SPPSVS temperature rises;

a. Fans in Run mode run continuously. Dampers are energized and modulated when structure temperature exceeds a high temperature setpoint.

b. Fans in the Standby mode have a higher setpoint, and will start if the temperature rises above the automatic setpoint.

As the SPPSVS temperature decreases;

a. Fans in the Run mode will operate continuously. Dampers are deenergized when structure temperature exceeds a low temperature setpoint, and the associated heaters will be energized.

b. Fans in the Standby mode also have a lower setpoint; they will start if the temperature falls below the automatic setpoint, and the associated heaters will be energized.

c. In all modes of operation, if structure temperature continues to decrease, the SPPSVS will be automatically tripped before reaching the freezing point.

Fans that have started in the Run mode will operate continuously. Fans that have started in the standby mode will stop after the initiating temperature switch has reset.

7.3.1.1.15.3.6 SPPSVS Bypasses and Interlocks

The hand switch of each fan, when in the off position, provides input to a control room alarm.

The electric heating coils are interlocked with the LOCA signals and trip off upon receipt of these signals.

7.3.1.1.15.3.7 SPPSVS Redundancy and Diversity

To maintain the redundancy of the mechanical equipment, controls and instrumentation are provided on a one-to-one basis with the mechanical equipment they serve. Diversity is not applicable.

7.3.1.1.15.3.8 SPPSVS Actuated Devices

No additional devices or systems are actuated by the spray pond pump structure ventilation system.

7.3.1.1.15.3.9 SPPSVS Separation

The controls, instrumentation, and power supplies for the spray pond pump structure ventilation fans are physically and electrically separated for each of the fan systems. See Section 8.1.6.1.14 for a discussion of the electrical system separation.

7.3.1.1.15.3.10 SPPSVS Testability

Verification of operability of the cooling modes initiation circuits may be made when the applicable pumps are operationally tested. Verification of operability of the heating mode initiating circuits may be made by tripping the low temperature switch. The units may be manually tested by hand switches located in the control room.

7.3.1.1.15.3.11 SPPSVS Environmental Consideration

The controls for the subject equipment are located in the control enclosure and the spray pond pump structure. The environmental consideration for these areas and the control qualification summary is provided in Section 3.11.

7.3.1.1.15.3.12 SPPSVS Operational Considerations

7.3.1.1.15.3.12.1 SPPSVS General Information

The spray pond pump structure ventilation system is required for normal heating and cooling of the pump structure as well as for safeguard cooling of the pumps enclosed therein.

7.3.1.1.15.3.12.2 SPPSVS Reactor Operator Information

The operator is provided with fan motor status, building high temperature annunciator, and a fan system trouble annunciator.

7.3.1.1.15.3.12.3 Deleted

7.3.1.1.15.4 Emergency Switchgear and Battery Rooms Cooling System - Instrumentation and Controls

7.3.1.1.15.4.1 ESBRCS System Identification

The ESBRCS provides ventilation and cooling to the emergency switchgear rooms, inverter rooms, battery rooms, and the chiller equipment rooms in the control structure. For description and operation, see Section 9.4.1. See Chapter 8 for a description of the electrical system.

7.3.1.1.15.4.2 ESBRCS Power Sources

The power for the instruments and controls associated with the ESBRCS is supplied from the Class 1E 120 V ac system.

7.3.1.1.15.4.3 ESBRCS Equipment Design

Equipment design is described in Section 9.4.1.

7.3.1.1.15.4.4 ESBRCS Initiating Circuits

Each of the fans may be initiated in a protective function mode as follows: a standby fan may be automatically started by a low flow signal.

7.3.1.1.15.4.5 ESBRCS Logic and Sequencing

See drawings M-78FD for the control logic diagram.

One fan is started manually, and the other is placed on standby. An operating fan may be shut down automatically due to the following:

a. Loss of flow

b. Discharge temperature exceeding setpoint

c. Discharge temperature below setpoint

The standby fan starts upon detection of a loss of flow in the primary fan system and sends a signal to start the associated control structures chilled water pump and chiller. When a fan is operating, its temperature controls operate its cooling coil to maintain a constant environment in its service area.

7.3.1.1.15.4.6 ESBRCS Bypasses and Interlocks

The hand switch of each fan, when in the off position, provides input to a local panel alarm that is relayed to the control room. The fans are interlocked with the control enclosure chilled water pumps. Operation of a fan initiates operation of the associated chilled water pump.

7.3.1.1.15.4.7 ESBRCS Redundancy and Diversity

To maintain the redundancy of the mechanical equipment, controls and instrumentation are provided on a one-to-one basis with the mechanical equipment they serve. Diversity is not applicable.

7.3.1.1.15.4.8 ESBRCS Actuated Devices

The associated control enclosure chilled water system pumps are activated by the emergency switchgear and battery rooms supply fan units. These pumps are described in Section 7.3.1.1.13.4.

7.3.1.1.15.4.9 ESBRCS Separation

The controls, instrumentation, and power supplies of the emergency switchgear and battery rooms supply fans are physically and electrically separated for each of the fan systems. See Section 8.1.6.1 for a discussion of the electrical system separation.

7.3.1.1.15.4.10 ESBRCS Testability

Verification of the operability of the initiating circuits may be made as follows:

a. By putting each fan in the auto mode when the complementary fan of the pair is shut down

b. By manually testing the fans by hand switches located in the control room

7.3.1.1.15.4.11 ESBRCS Environmental Consideration

The controls for the subject equipment are located in the control enclosure. The environmental consideration for these areas and the control qualification summary is provided in Section 3.11.

7.3.1.1.15.4.12 ESBRCS Operational Considerations

7.3.1.1.15.4.12.1 ESBRCS General Information

The emergency switchgear and battery rooms HVAC system is required for normal operation of its service areas.

7.3.1.1.15.4.12.2 ESBRCS Reactor Operator Information

The operator is provided with a relayed fan system trouble alarm.

7.3.1.1.15.4.12.3 Deleted

7.3.1.1.15.5 ECCS Pump Compartment Unit Coolers - Instrumentation and Controls

7.3.1.1.15.5.1 ECCS-UC System Identification

The ECCS pump compartment unit coolers provide cooling to the core spray, HPCI, and RHR pump rooms. For description and operation, see Section 9.4.2.

7.3.1.1.15.5.2 ECCS-UC Power Sources

The power for the instruments and controls associated with the ECCS pump compartment unit coolers is supplied from the Class 1E 120 V ac system. See Chapter 8 for a description of the electrical system.

7.3.1.1.15.5.3 ECCS-UC Equipment Design

Equipment design is described in Section 9.4.2.

7.3.1.1.15.5.4 ECCS-UC Initiating Circuits

Each of the fans may be initiated in a protective function mode as follows:

a. A unit cooler will start when the respective pump starts.

b. A unit cooler may be manually started from the local control panel.

c. A fan may be started by the initiation of a high temperature switch.

7.3.1.1.15.5.5 ECCS-UC Logic and Sequencing

See drawings M-76FD for the control logic diagram.

When each pair of unit coolers is set up in a lead lag mode, automatic start is initiated under the following conditions:

a. When the area temperature exceeds 100°F, the lead fan starts.

b. When the area temperature exceeds 110°F, the standby fan starts.

The starting of a fan automatically opens a valve in the ESW system to supply cooling water to the unit.

The fan shuts down when the area temperature drops to 80°F.

7.3.1.1.15.5.6 ECCS-UC Bypasses and Interlocks

The hand switch of each fan, when in the off position, provides input to a local panel alarm that is relayed to the control room.

7.3.1.1.15.5.7 ECCS-UC Redundancy and Diversity

To maintain the redundancy of the mechanical equipment, controls and instrumentation are provided on a one-to-one basis with the mechanical equipment they serve. Diversity is not applicable.

7.3.1.1.15.5.8 ECCS-UC Actuated Devices

No additional devices or systems are actuated by the ECCS pump compartment unit coolers.

7.3.1.1.15.5.9 ECCS-UC Separation

The controls, instrumentation, and power supplies are physically and electrically separated for each of the ECCS unit coolers. See Section 8.1.6.1 for a discussion of the electrical system separation.

7.3.1.1.15.5.10 ECCS-UC Testability

Verification of operability of initiation circuits may be made when the applicable pumps are operationally tested. The units may be manually tested by hand switches located on local control cabinets.

7.3.1.1.15.5.11 ECCS-UC Environmental Consideration

The controls for the subject equipment are located in the reactor enclosure. The environmental consideration for this area and the control qualification summary is provided in Section 3.11.

7.3.1.1.15.5.12 ECCS-UC Operational Considerations

7.3.1.1.15.5.12.1 ECCS-UC General Information

The ECCS pump compartment unit coolers are not required for normal cooling of these areas when the ECCS pumps are not operating.

7.3.1.1.15.5.12.2 ECCS-UC Reactor Operation Information

The operator is provided with a relayed unit cooler system trouble alarm.

7.3.1.1.15.5.12.3 ECCS-UC Setpoints

For setpoints, see Section 7.3.1.1.15.5.5 (logic and sequencing).

7.3.1.1.15.6 Auxiliary Equipment Room Ventilation System - Instrumentation and Controls

7.3.1.1.15.6.1 AERVS System Identification

The auxiliary equipment room ventilation system provides ventilation and cooling to the auxiliary equipment room, computer room, remote shutdown room, control enclosure fan room, SGTS access area, and SGTS room. For description and operation, see Section 9.4.1.

7.3.1.1.15.6.2 AERVS Power Sources

The power for the instruments and controls associated with the auxiliary equipment room ventilation system is supplied from the Class 1E 120 V ac system.

7.3.1.1.15.6.3 AERVS Equipment Design

Equipment design is described in Section 9.4.1.

7.3.1.1.15.6.4 AERVS Initiating Circuits

Each of the supply fans can be initiated in a protective function mode as follows: a standby fan can be started by a low condition sensed in the other fan's INTAKE.

Each of the return fans can be initiated in a protective function mode as follows: a standby fan can be started by a low condition sensed in the other fan's INTAKE.

7.3.1.1.15.6.5 AERVS Logic and Sequencing

See drawings M-78FD for the control logic diagram. One supply and one return fan are started manually. The other fan in each pair is put on standby. An operating supply fan can be shut down automatically, due to the following:

a. Loss of flow

b. Discharge temperature exceeding setpoint

c. Discharge temperature below setpoint

The standby supply fan starts upon detection of loss of flow in the primary fan system and sends a signal to start the associated control structure chilled water pump and chiller. A return fan shuts down upon detection of loss of flow in its own system. When a supply fan is operating, its temperature controls operate its cooling and Class II heating and humidifying equipment to maintain a constant environment in its service area.

7.3.1.1.15.6.6 AERVS Bypasses and Interlocks

The hand switch of each fan, when in the off position, provides input to a control system alarm. The supply fans are interlocked with the control enclosure chilled water pumps and the supply fan low temperature cut-out is interlocked with the control enclosure purge system. The purge system, described in Section 9.4.1, is not an ESF. It has been upgraded to safeguard power status for convenience in interfacing with the control enclosure HVAC systems.

7.3.1.1.15.6.7 AERVS Redundancy and Diversity

To maintain the redundancy of the mechanical equipment, controls and instrumentation are provided on a one-to-one basis with the mechanical equipment they serve. Diversity is not applicable.

7.3.1.1.15.6.8 AERVS Actuated Devices

The associated control enclosure chilled water pumps are actuated by the supply fans.

7.3.1.1.15.6.9 AERVS Separation

The controls, instrumentation, and power supplies of the AERVS are physically and electrically separated for each of the fan systems. See Section 8.1.6.1 for a discussion of the electrical system separation.

7.3.1.1.15.6.10 AERVS Testability

Verification of the operability of the initiating circuits can be made as follows:

a. By putting each fan in the auto mode when the complementary fan of the pair is shut down

b. By manually testing the fans by hand switches located on local control cabinets

7.3.1.1.15.6.11 AERVS Environmental Consideration

The controls for the subject equipment are located in the control enclosure. The environmental consideration for this area and the control qualification summary is provided in Section 3.11.

7.3.1.1.15.6.12 AERVS Operational Considerations

7.3.1.1.15.6.12.1 AERVS General Information

The auxiliary equipment room ventilation system is required for normal operation of its service areas.

7.3.1.1.15.6.12.2 AERVS Reactor Operator Information

The following safety-related information is provided on a local control panel that has a trouble alarm relayed to the control room:

a. Fan motor status and damper position status for the supply and return fans

b. Supply fan electric heater leaving air temperatures

c. Supply fan leaving air temperature

The following nonsafety-related information is also provided on the local control panel:

a. Supply fan mixed air entering temperature

b. Auxiliary equipment room humidity level

c. Return fan leaving air temperature

7.3.1.1.15.6.12.3 Deleted

7.3.1.1.16 Drywell Unit Coolers - Instrumentation and Controls

7.3.1.1.16.1 DUC System Identification

The drywell unit coolers provide cooling and atmosphere mixing in the primary containment. For description and operation, see Section 9.4.5. Atmosphere mixing is the only safety-related function of this system.

7.3.1.1.16.2 DUC Power Sources

The power for the instruments and controls associated with the drywell unit coolers is supplied from the Class 1E 120 V ac system.

7.3.1.1.16.3 DUC Equipment Design

Equipment design is described in Section 9.4.5.

7.3.1.1.16.4 DUC Initiating Circuits

Each of the fans can be initiated or stopped in a protective function mode as follows:

a. A fan can be manually started from the control room.

b. A standby fan can be automatically started by a low flow signal.

7.3.1.1.16.5 DUC Logic and Sequencing

See drawings M-77FD for the control logic diagram.

Each pair of fans is set up in a run/auto mode.

The run fan is manually started and normally operates continuously. If loss of flow is detected by the flow switch, the unit is shut down and the autofan starts. Each fan may be manually stopped from the control room.

7.3.1.1.16.6 DUC Bypasses and Interlocks

The hand switch of each fan, when in the off position, provides input to a computer alarm.

7.3.1.1.16.7 DUC Redundancy and Diversity

To maintain the redundancy of the mechanical equipment, controls and instrumentation are provided on a one-to-one basis with the mechanical equipment they serve. Diversity is not applicable.

7.3.1.1.16.8 DUC Actuated Devices

No additional devices or systems are actuated by the drywell unit coolers.

7.3.1.1.16.9 DUC Separation

The controls, instrumentation, and power supplies of the drywell unit coolers are physically and electrically separated for each redundant pair of fans. See Section 8.1.6.1 for discussion of electrical system separation.

7.3.1.1.16.10 DUC Testability

Verification of operability of the initiation circuits may be made by putting each fan in the auto mode when the complementary fan of the pair is shut down. The units may be manually tested by hand switches located in the control room.

7.3.1.1.16.11 DUC Environmental Considerations

The controls for the subject equipment are located in the control enclosure, the reactor enclosure, and primary containment. The environmental considerations for these areas and the control qualification summary is provided in Section 3.11.

7.3.1.1.16.12 DUC Operational Considerations

7.3.1.1.16.12.1 DUC General Information

The drywell unit coolers are required to maintain uniform mixing of combustible gases in the drywell.

7.3.1.1.16.12.2 DUC Reactor Operator Information

The operator is provided with fan motor status and a fan system trouble alarm. In addition, the following nonsafety-related instrumentation and alarms are provided in the control room for each pair of fans:

a. Drywell area temperature (unit cooler inlet temperature) indicator

b. Unit cooler supply temperature indicator

c. Unit cooler temperature trouble

7.3.1.1.16.12.3 Deleted

7.3.1.1.17 Refueling Area Isolation System - Instrumentation and Controls

7.3.1.1.17.1 RAIS Identification

The RAIS provides signals to isolate the refueling area and start the SGTS under emergency conditions. A description and operation of the isolation system are given in Section 9.4.2.

7.3.1.1.17.2 RAIS Power Sources

The power for the instruments and controls associated with the isolation system is supplied from the Class 1E 120 V ac system. Chapter 8 gives a description of the electrical system.

7.3.1.1.17.3 RAIS Equipment Design

Equipment design is described in Section 9.4.2.

7.3.1.1.17.4 RAIS Initiating Circuits

Each channel of the isolation system may be manually initiated or automatically initiated in a protective function mode as follows:

a. A channel may be initiated by high radiation sensed by both of the two gamma sensors located in the refueling area exhaust duct.

b. A channel may be initiated by loss of refueling area differential pressure with respect to outside pressure.

7.3.1.1.17.5 RAIS Logic and Sequencing

Each channel of the redundant isolation system is normally held in an energized (fail-safe) mode so that an initiating signal or loss of power activates the channel and starts all the related systems. The isolation signal seals-in upon initiation, and removal of the initiating signal does not deactivate the channel. The channel may be reset to a normal condition only if the initiating condition, other than low building differential pressure, is no longer present. A key-lock reset is provided to bypass low building differential pressure to re-establish it with the normal ventilation system. Drawings M-76FD shows the logic diagram.

7.3.1.1.17.6 RAIS Bypasses and Interlocks

The hand switch of each isolation system, when in the RESET position, provides input to a control room alarm. The isolation system is interlocked with the SGTS exhaust fan start and SGTS filter valves auto change-over circuit.

7.3.1.1.17.7 RAIS Redundancy and Diversity

To maintain the redundancy of the mechanical equipment, controls and instrumentation are provided on a one-to-one basis with the mechanical equipment they serve.

7.3.1.1.17.8 RAIS Actuated Devices

The SGTS and the refueling area isolation are actuated by this system. Section 7.3.1.1.7 gives a description of the actuated system.

7.3.1.1.17.9 RAIS Separation

The controls, instruments, and power supplies of the isolation system are physically separated and electrically independent for each of the redundant trip channels. Section 8.1.6.1 gives a discussion of electrical system separation.

7.3.1.1.17.10 RAIS Testability

Verification of the operability of the initiating circuits may be made as follows:

a. By tripping the individual radiation monitor circuits

b. By tripping the differential pressure input circuits

c. By manually initiating the channels with hand switches located in the control room

The RAIS system may be tested as discussed above during plant operation.

7.3.1.1.17.11 RAIS Environmental Considerations

The controls for the isolation system are located in the refueling area, reactor enclosure, and the control enclosure. The environmental considerations for these areas are in Section 3.11.

7.3.1.1.17.12 RAIS Operational Considerations

7.3.1.1.17.12.1 RAIS General Information

The isolation systems are required to provide for refueling area isolation during emergency conditions. Sections 6.5.1 and 9.4.2 give system function.

7.3.1.1.17.12.2 RAIS Reactor Operator Information

The operator is provided with an isolation initiation alarm and an isolation incomplete alarm in the control room for each of the two channels. In addition, a common system (REIS and RAIS) "armed/bypassed" alarm is provided in the control room.

7.3.1.1.17.12.3 RAIS Setpoints

Refer to Technical Specifications for RAIS radiation setpoints.

7.3.1.2 IEEE 279 (1971) Design Basis Information

IEEE 279 (1971) defines the requirements for design bases. Using the IEEE 279 format, the following nine paragraphs fulfill the requirement for systems and equipment described in this section. Additional design basis information is given in Section 7.1.

7.3.1.2.1 IEEE 279 Design Basis Information - Conditions

The plant conditions that require protective action involving the systems of this section and other sections are examined and presented in Chapter 15.

7.3.1.2.2 IEEE 279 Design Basis Information - Variables

The plant variables that require monitoring to provide protective action are:

a. HPCI (Section 7.3.1.1.1.1.)

1. Reactor vessel water level
2. Primary containment pressure

b. ADS (Section 7.3.1.1.1.2.)

1. Reactor vessel water level
2. Primary containment pressure
3. Core spray and RHR pump discharge pressure

c. Core Spray (Section 7.3.1.1.1.3)

1. Reactor vessel water level
2. Primary containment pressure
3. Reactor vessel pressure

d. LPCI (Section 7.3.1.1.1.4)

1. Reactor vessel water level
2. Primary containment pressure
3. Reactor vessel pressure

e. PCRVICS (Section 7.3.1.1.2)

See Table 7.3-5.

f. Deleted

g. Containment Spray (Section 7.3.1.1.4)

1. Reactor vessel water level
2. Primary containment pressure
3. Reactor vessel pressure

h. CAC System (Section 7.3.1.1.6)

1. Containment hydrogen concentration
2. Containment oxygen concentration

7.3.1.2.3 IEEE 279 Design Basis Information - Number and Location of Sensors with Spatial Dependence Only

For the minimum number of channels required for functional performance, see the Technical Specifications. There are no sensors in the ECCS, PCRVICS, or RHR/containment spray systems that have a spatial dependence. Therefore, location information is not relevant.

7.3.1.2.4 IEEE 279 Design Basis Information - Operational Limits

Prudent operational limits for each safety-related variable trip setting are selected to be far enough above or below normal operating levels so that a spurious ESF initiation is prevented. It is then verified by analysis that the release of radioactive materials, following postulated gross failures of the fuel, or the nuclear system process barrier, is kept within acceptable bounds. Design basis operational limits as referenced in Chapter 16 are based on operating experience and constrained by the safety design basis and the safety analyses.

7.3.1.2.5 IEEE 279 Design Basis Information - Margin Between Operational Limits

The margin between operational limits and the limiting conditions for ESF systems operation are those parameters listed in Chapter 16. The margin includes the consideration of calibration error, sensor accuracy, response times, and sensor and setpoint drift. Annunciators are actuated at the setpoints to alert the reactor operator of the onset of unsafe conditions.

7.3.1.2.6 IEEE 279 Design Basis Information - Levels Requiring Protective Action

Levels requiring protective action for the ESF systems are provided in Chapter 16.

7.3.1.2.7 IEEE 279 Design Basis Information - Range of Energy Supply and Environmental Conditions of Safety Systems

See Section 3.11 for environmental conditions and Chapter 8 for the range of energy supply.

PCRVICS channel, logic, and MSIV 120 V ac power is provided by the RPS uninterruptible power source discussed in Section 7.2.1.1.3.

ECCS 125 V dc power is provided by the station safeguard batteries. ECCS 120 V ac power is provided by the instrument ac system.

ESF system MOV power is supplied from MCCs connected to the safeguard power system.

7.3.1.2.8 IEEE 279 Design Basis Information - Malfunctions, Accidents, and Other Unusual Events That Could Cause Damage to the Safety System

a. Floods

   The structures containing ESF systems components are designed to meet the PMF at the site location. This ensures that the structures remain watertight under PMF conditions, including wind-generated wave action and wave run-up (Section 3.4.1).

b. Storms and tornados

   The structures containing ESF components are designed to withstand the meteorological events described in Section 3.3.2. Superficial damage may occur to

miscellaneous station property during a postulated tornado, but this does not impair the ESF capabilities.

c. Earthquakes

The structures containing ESF components are seismically qualified as described in Section 3.7 and 3.8 and are designed to remain functional during and following a SSE. Seismic qualification of instrumentation and electrical equipment is discussed in Section 3.10.

d. Fires

If there is a fire, the redundant portions of the systems are separated by fire barriers to protect the ESF systems. If a fire were to occur within one of the sections or in the area of one of the panels, the ESF systems functions would not be affected by the fire. The use of separation and fire barriers ensures that, even though some portion of the systems may be affected, the ESF systems continue to provide the required protective action.

The ESFs are protected by different fire detection systems (heat and smoke detectors). The fire detection and the fire suppression systems are not ESF.

For further fire protection discussion, see Section 9.5.1.

e. LOCA

The following ESF components are located inside the drywell and are affected by a design basis LOCA:

1. Reactor vessel pressure, reactor vessel water level instrument taps and sensing lines, and drywell pressure sensing lines

2. Most inboard isolation valves and the SRVs, actuators, actuated equipment, and cables

3. Drywell unit coolers and associated cables

This equipment, which is located outside the containment, and the remainder of the ESF equipment is environmentally qualified to remain functional during and following a LOCA as discussed in Section 3.11

f. Pipe Break Outside Containment

This condition does not prevent ESFs from performing their safety functions (Section 3.6).

g. Feedwater Break

This condition does not prevent the ESFs from performing their safety functions (Section 3.6).

h. Missiles

See Section 3.5.

7.3.1.2.9 IEEE 279 Design Basis Information - Minimum Performance Requirements

The minimum performance requirements are identified in Chapter 16 for each of the ESF systems. These requirements include those for accuracy, which is accounted for in setpoint selection, in addition to the system response times. The instrument ranges of the initiating variables are contained in Tables 7.3-1, 7.3-2, 7.3-3, and 7.3-4 and are selected to accurately span normal, abnormal, and accident conditions. The ESF systems performance has been analyzed to bound the systems instrument capability.

See Table 7.3-5 for PCRVICS performance requirements.

Within ECCS, performance requirements refer only to a system as a whole and not specifically to individual components, except for ECCS instrument accuracy and range.

7.3.1.3 Final System Drawings

The following final system drawings are included in the UFSAR:

a. Piping and instrumentation diagrams

b. Functional control diagrams

c. Instrument and electrical drawings

d. Instrument location drawings

e. Logic diagrams

Electrical schematic diagrams are supplied under separate cover as the regulations allow. A list of the drawings is provided in Section 1.7.

There are no design basis differences for the subject systems between the PSAR and the FSAR. Direct comparison between the PSAR and FSAR verifies this.

Changes in the following areas have been made in the system design between the PSAR and the FSAR:

a. Analog transmitters and trip units replace the switches used in the ESF initiating circuits.

b. Additional testability has been designed into the ESF logic to allow complete testing.

c. Physical separation is maintained by the use of four divisions as opposed to the two divisions described in the PSAR.

d. The LPCI mode of RHR injects directly into the reactor instead of the recirculation piping.

e. The HPCI injects into the core spray sparger instead of the feedwater sparger.

f. The SRVs have dual solenoids. This allows the ADS to meet the single failure criteria.

g. Four additional diesel generators have been added to eliminate the sharing of diesels between units.

h. Additional bypass and inoperable status indication has been provided.

i. MSIV closure on low condenser vacuum has been added.

j. The isolation logic for the reactor water sample lines and the main steam line sample lines have been changed from initiation by low water level.

k. HPCI and RCIC steam line isolation valves no longer receive an automatic opening signal on system initiation.

l. The MSIV-LCS was replaced with the MSIV Leakage Alternate Drain Pathway.

m. CAC - containment recombiners included.

7.3.2 ANALYSIS

Presented below is an analysis to demonstrate how the various general functional requirements and specific regulatory requirements listed under the ESF design bases (Section 7.1.2) are satisfied.

7.3.2.1 Emergency Core Cooling Systems - Instrumentation and Controls

7.3.2.1.1 ECCS General Functional Requirements Conformance

a. Design basis 7.1.2.1.3.1.a

Chapter 15 and Chapter 6 evaluate the individual and combined capabilities of the emergency core cooling systems. For the entire range of the RCPB break sizes, the cooling systems prevent fuel cladding temperatures from exceeding 2200°F.

b. Design basis 7.1.2.1.3.1.b

Instrumentation for the ECCS must respond to the potential inadequacy of core cooling regardless of the location of a breach in the RCPB. Such a breach inside or outside the containment is sensed by reactor low water level. The reactor vessel low water level signal is the only ECCS initiating function that is completely independent of breach location. Consequently, it can actuate HPCI, CS, and LPCI.

The other major initiating function, drywell high pressure, is provided because pressurization of the drywell results from any significant RCPB breach anywhere inside the drywell. Consequently, it can actuate HPCI, CS, and LPCI.

Initiation of the ADS, which employs both reactor vessel low water level and drywell high pressure in coincidence, requires that the RCPB breach be inside the drywell. This control arrangement is satisfactory in view of the automatic isolation of the reactor vessel for breaches outside the drywell.

c. Design basis 7.1.2.1.3.1.c

An evaluation of ECCS controls shows that no operator action is required earlier than 10 minutes after a LOCA to initiate the correct responses of the ECCS. However, the control room operator can manually initiate every essential operation of the ECCS. Alarms and indications in the control room allow the operator to assess situations that require the ECCS and verify the responses of each system. This arrangement limits safety dependence on operator judgment, yet provides sufficient information for operator action when such action is determined to be necessary.

Capability for emergency core cooling following a postulated accident may be verified by observing the following indications:

a. Annunciators for HPCI, CS, LPCI, and ADS sensor and logic trips

b. Flow and pressure indications for each HPCI, CS, and LPCI

c. Valve position lights indicating open or closed valves

d. Relief valve position may also be inferred from reactor pressure indications

e. Process computer logging of trips in the emergency core cooling network

f. Relief valve discharge pipe temperature monitors and alarm

A NSOA is provided for the ECCS in Chapter 15.

7.3.2.1.2 ECCS Specific Regulatory Requirements Conformance

The conformance of the transmitter trip unit system is covered by Licensing Topical Report NEDO-21697A.

7.3.2.1.2.1 ECCS Conformance to Regulatory Guides

7.3.2.1.2.1.1 ECCS - Regulatory Guide 1.6 (1971) - Independence Between Redundant Standby (Onsite) Power Sources and Between Their Distribution Systems (Safety Guide 6)

See Section 8.1.6.1.1.

7.3.2.1.2.1.2 ECCS - Regulatory Guide 1.11 (1971) - Instrument Lines Penetrating Primary Reactor Containment (Safety Guide 11)

Instrument lines have automatic isolation.

7.3.2.1.2.1.3 ECCS - Regulatory Guide 1.22 (1972) - Periodic Testing of Protection System Actuation Functions (Safety Guide 22)

Conformance to this regulatory guide is achieved by providing system and component testing capability, either during reactor power operation or shutdown.

Facilities for testing are provided so that the equipment can be operated in various test modes to confirm that it operates properly when called upon. Testing incorporates all elements of the system

under one test mode or another, including sensors, logic, actuators, and actuated equipment. The testing is planned to be performed at intervals so that there is an extremely low probability of failure in the periods between tests. During testing there are always enough channels and systems available for operation to provide proper protection.

7.3.2.1.2.1.4 ECCS - Regulatory Guide 1.29 (1978) – Seismic Design Classification

Instrumentation is classified as seismic Category I and is covered under Section 3.10.

7.3.2.1.2.1.5 ECCS - Regulatory Guide 1.30 (1972) - Quality Assurance Requirements for the Installation, Inspection and Testing of Instrumentation and Electric Equipment (Safety Guide 30)

See Section 8.1.6.1.5.

7.3.2.1.2.1.6 ECCS - Regulatory Guide 1.32 (1977) - Criteria for Safety-Related Electric Power Systems for Nuclear Power Plants

Conformance is described in the conformance to GDC 17 and industry standard IEEE 308 (1971).

7.3.2.1.2.1.7 ECCS - Regulatory Guide 1.47 (1973) - Bypassed and Inoperable Status Indication for Nuclear Power Plant Safety Systems

Indication is provided in the control room to inform the operator that a system is inoperable. Annunciation is provided to indicate that either a system or a part of a system is not operable. Indicator lights indicate the reason why the system is not operable. Conditions expected to occur more than once per year are automatically alarmed. In addition, there is a switch in the control room that the operator can use to manually bring up the system out-of-service annunciator.

All the annunciators can be tested by depressing the annunciator test switches on the control room bench boards.

The importance of providing accurate information for the reactor operator and reducing the possibility for the indicating equipment to adversely affect its monitored safety system is discussed in the following paragraphs:

a. Individual indicators are arranged together on the control room panel to indicate what function of the system is out-of-service, bypassed, or otherwise inoperable. All bypass and inoperability indicators, both at a system level and component level, are grouped only with those items that prevent a system from operating if needed.

b. As a result of design, preoperational testing, and startup testing, no erroneous bypass indication is anticipated.

c. These indication provisions serve to supplement administrative controls and aid the operator in assessing the availability of component and system level protective actions. This indication does not directly provide safety functions.

d. The annunciator initiation signals are provided by contacts and cannot prevent required protective actions.

e. Each indicator can be individually tested and is provided with dual lamps. Testing of these indicators is accomplished when the associated equipment is periodically tested.

7.3.2.1.2.1.8 ECCS - Regulatory Guide 1.53 (1973) - Application of the Single Failure Criterion to Nuclear Power Plant Protection Systems

Compliance with Regulatory Guide 1.53 (1973) is achieved by specifying, designing, and constructing the ECCS so that it meets the single failure criterion described in section 4.2 of IEEE 279 (1971), "Criteria for Protection Systems for Nuclear Power Generating Stations," and IEEE 379 (1972), "IEEE Trial Use Guide for the Application of the Single Failure Criterion to Nuclear Power Generating Station Protection Systems." Redundant sensors, instrument tubing, wiring, logic, actuators, and power supplies are used to ensure that a single failure in any portion of the ESF system does not prevent protective action. Separated divisions are employed, so that a fault affecting one division does not prevent the other division from operating properly.

7.3.2.1.2.1.9 ECCS - Regulatory Guide 1.62 (1973) - Manual Initiation of Protective Actions

Means are provided for manual initiation of emergency core cooling at the system level through the following armed push button switches:

a. HPCI: one switch in Division 2

b. ADS A: two switches in Division 1

c. ADS C: two switches in Division 3

d. CS A: one switch in Division 1

e. CS C: one switch in Division 3

f. CS B: one switch in Division 2

g. CS D: one switch in Division 4

h. RHR A: one switch in Division 1

i. RHR B: one switch in Division 2

j. RHR C: one switch in Division 3

k. RHR D: one switch in Division 4

Operation of these switches accomplishes the initiation of all actions performed by the automatic initiation circuitry.

These switches are located in the control room on the designated ECCS division portions of the reactor core cooling vertical board and are easily accessible to the operator so that action can be taken expeditiously.

The ADS system initiation is interlocked to prohibit the ADS valves from opening unless both pumps in either of the two CS loops, or any of the four RHR pumps are running. However, each individual ADS valve can be remote-manually operated from the control room independent of interlocks. A failure in the automatic, manual, or common portions of the ADS protective function

logic will not prevent the performance of a protective action by redundant system or component level controls located in the control room.

ECCS systems are not required to meet single failure criterion. A failure in the automatic, manual, or common portions of an individual ECCS loop protective function will not prevent the performance of the protective action because ECCS function will be met by a redundant loop.

The HPCI system is not required to meet single failure criteria. ADS and low pressure injection systems, CS and LPCI, provide the HPCI backup safety functions in the event of a HPCI system failure. A failure in the automatic, manual, or common portions of the HPCI protective function logic will not prevent the performance of a protective action by redundant systems or component level controls located in the control room.

7.3.2.1.2.1.10 ECCS - Regulatory Guide 1.63 (1978) - Electric Penetration Assemblies in Containment Structures for Light-Water-Cooled Nuclear Power Plants

See Section 8.1.6.1 for a discussion of the degree of conformance.

7.3.2.1.2.1.11 ECCS - Regulatory Guide 1.75 (1978) - Physical Independence of Electric Systems

See Section 7.1.2.2.3 for separation criteria.

7.3.2.1.2.1.12 ECCS - Regulatory Guide 1.89 (1974) - Qualification of Class 1E Equipment for Nuclear Power Plants

See Section 3.11.

7.3.2.1.2.1.13 ECCS - Regulatory Guide 1.97 (1980) - Instrumentation for Light-Water-Cooled Nuclear Power Plants to Assess Plant and Environs Conditions During and Following an Accident

See Section 7.5.2.5.1.1.2 for a discussion of the degree of conformance.

7.3.2.1.2.1.14 ECCS - Regulatory Guide 1.100 (1977) - Seismic Qualification of Electric Equipment for Nuclear Power Plants

Conformance with this regulatory guide is discussed in Section 3.10.

7.3.2.1.2.1.15 ECCS - Regulatory Guide 1.105 (1976) - Instrument Setpoints

See Section 7.1.2.5.25 for a discussion of the degree of conformance.

7.3.2.1.2.1.16 ECCS - Regulatory Guide 1.118 (1978) - Periodic Testing of Electric Power and Protection Systems

See Section 7.1.2.5.26 for a discussion of the degree of conformance.

7.3.2.1.2.2 ECCS - Conformance to 10CFR50, Appendix A, General Design Criteria

7.3.2.1.2.2.1 ECCS - GDC 1 - Quality Standards and Records

The quality assurance program for the system ensures sound engineering in all phases of design and construction through conformity to regulatory requirements and design bases described in the license application. The quality assurance program during construction is discussed in the

document "Limerick Generating Station Units 1 and 2; Summary Description of the Quality Assurance Program for Design and Construction," referenced in FSAR Section 17.1.

Documents are maintained that demonstrate that all the requirements of the quality assurance program are being satisfied. These records will be maintained during the life of the operating licenses.

7.3.2.1.2.2.2 ECCS - GDC 2 - Design Bases for Protection Against Natural Phenomena

Wind and tornado loadings are discussed in Section 3.3, flood design is described in Section 3.4, and seismic qualification of instrumentation and electrical equipment is discussed in Section 3.10.

7.3.2.1.2.2.3 ECCS - GDC 3 - Fire Protection

The fire protection system and its design basis are discussed in Section 9.5.1, and fire protection in the cable systems is described in Section 8.3.3.

7.3.2.1.2.2.4 ECCS - GDC 4 - Environmental and Dynamic Effects Design Bases

The system is designed to accommodate the effects of and be compatible with the environmental conditions associated with normal operation, maintenance, testing, and postulated accidents, including LOCAs.

The system is appropriately protected against dynamic effects including the effects of missiles, pipe whipping, and discharging fluids that may result from equipment failures. Missile protection is discussed in Section 3.5, pipe whip in Section 3.6, and environmental qualification of equipment in Section 3.11.

7.3.2.1.2.2.5 ECCS - GDC 10 - Reactor Design

The ECCS has been designed with appropriate margin to ensure that acceptable fuel design limits are not exceeded during any condition of normal operation, including the effects of anticipated operational occurrence.

7.3.2.1.2.2.6 ECCS - GDC 13 - Instrumentation and Control

Conformance to this requirement is achieved by monitoring appropriate variables over the range expected and providing emergency core cooling as required to maintain the variables within the prescribed ranges.

7.3.2.1.2.2.7 ECCS - GDC 17 - Electric Power Systems

See Chapters 8.3.1.2.1 and 8.3.2.2.1.

7.3.2.1.2.2.8 ECCS - GDC 18 - Inspection and Testing of Electric Power Systems

See Chapters 8.3.1.2.1 and 8.3.2.2.1

7.3.2.1.2.2.9 ECCS - GDC 19 - Control Room

Controls and instrumentation are provided in the control room.

7.3.2.1.2.2.10 ECCS - GDC 20 - Protection Systems Functions

The system is automatically initiated after a LOCA as evidenced by high drywell pressure or reactor vessel low water level displayed in the control room.

7.3.2.1.2.2.11 ECCS - GDC 21 - Protection System Reliability and Testability

The components used are selected to meet specific requirements to ensure high functional reliability. The system can be tested and failures determined during normal plant operations.

7.3.2.1.2.2.12 ECCS - GDC 22 - Protection System Independence

The four divisions are independent and physically separated with separate instruments and controls to provide assurance that the protective function is not lost.

7.3.2.1.2.2.13 ECCS - GDC 23 - Protection System Failure Modes

The system is designed to tolerate malfunctions. See the NSOA provided for the ECCS in Chapter 15.

7.3.2.1.2.2.14 ECCS - GDC 29 - Protection Against Anticipated Operational Occurrences

The ECCS network is designed to remain functional during anticipated operating occurrences and initiate protective action if accident conditions develop (Section 7.3.2.1.2.3.1.1).

7.3.2.1.2.2.15 ECCS - GDC 33 - Reactor Coolant Makeup

Reactor coolant makeup for small breaks is provided to ensure that specified acceptable fuel design limits are not exceeded.

7.3.2.1.2.2.16 ECCS - GDC 35 - Emergency Core Cooling

The system initiates emergency core cooling (Section 6.3).

7.3.2.1.2.2.17 ECCS - GDC 37 - Testing of Emergency Core Cooling System

Testing the ECCS conforms to the criteria as demonstrated in Sections 6.3.4, 7.3.2.1.2.3.1.9, and 7.3.2.1.2.3.1.10.

7.3.2.1.2.3 ECCS Conformance to Industry Codes and Standards

The conformance of the transmitter trip unit system is covered by Licensing Topical Report NEDO-21617-A.

7.3.2.1.2.3.1 ECCS - IEEE 279 (1971) - Criteria for Protection Systems for Nuclear Power Generating Stations

Compliance of the ECCS with IEEE 279 (1971) is detailed below.

7.3.2.1.2.3.1.1 ECCS - IEEE 279 (1971), Paragraph 4.1 - General Functional Requirement

The ECCS is automatically initiated by instruments that sense the requirement for the initiation of protective action. The following systems are individually initiated by automatic means:

a. HPCI

b. ADS

c. CS

d. LPCI mode of the RHR system

This automatic initiation is accomplished with precision and reliability commensurate with the overall ECCS objective and is effective over the full range of environmental conditions cited below:

a. Power supply voltages -

ECCS:

Equipment is designed to operate over the voltage ranges specified in Section 8.3.1 for ac power, and Section 8.3.2 for dc power.

HPCI:

Tolerance is provided to complete loss of station ac power, but not loss of the dc source of power for the HPCI system.

ADS:

Tolerance is provided to complete loss of station ac power.

CS:

Tolerance is provided to complete loss of ac or dc power within one division.

LPCI:

Tolerance is provided to ac power supply failure so that failures cannot negate successful low pressure cooling. Dc power supply failure affects only one LPCI division.

b. Power supply frequency -

HPCI:

System control does not depend on ac power sources.

ADS:

No ac controls are used.

CS:

Excessive frequency reduction is indicative of an onsite power supply failure, and equipment shutdown in that division is required. Core spray equipment is designed to operate over the frequency range specified in Section 8.3.1.

LPCI:

Excessive frequency reduction is indicative of an onsite power supply failure, and equipment shutdown in that division is required. LPCI equipment is designed to operate over the frequency range specified in Section 8.3.1.

c. Temperature -

HPCI, ADS, CS, and LPCI:

These are operable at all temperatures that can result from any design basis LOCA. Also see Section 3.11.

d. Humidity -

HPCI, ADS, CS, and LPCI:

These are operable at all humidities, including steam, that can result from a LOCA. Also see Section 3.11.

e. Pressure -

HPCI, ADS, CS, and LPCI:

These are operable at all pressures resulting from a LOCA as required. Also see Section 3.11.

f. Radiation -

HPCI, ADS, CS, and LPCI:

These are designed to operate at all radiation levels expected for any design basis LOCA. Also see Section 3.11.

g. Vibration -

HPCI, ADS, CS, and LPCI:

Tolerance to conditions is stated in Section 3.10.

h. Malfunctions -

Overall ECCS:

Network tolerance to any single component failure to operate on command

i. Accidents -

HPCI, ADS, CS, and LPCI:

Network tolerance to all DBAs without malfunction

j. Fire -

Overall ECCS:

Network tolerance to raceway fires in a single division

k. Explosion -

HPCI, ADS, CS, and LPCI:

Explosions are not defined in design bases.

l. Missiles -

ADS:

Separate routing of the ADS conduits within the drywell reduces to a very low probability the potential for missile damage to more than one conduit to ADS or damage to the pilot solenoid assemblies of ADS valves.

Overall ECCS:

Network tolerance to any single missile destroying pipe, raceway, cabinet, or equipment in one division

m. Lightning -

HPCI, ADS, CS, and LPCI:

Ungrounded dc system not subject to lightning strikes

CS and LPCI:

Tolerance to lightning damage of ac power system is limited to one auxiliary bus system. See comments under (a) and (b).

n. Flood -

HPCI, ADS, CS, and LPCI:

All control equipment is located above level by design or below level in watertight compartments.

o. Earthquake -

HPCI, ADS, and LPCI:

Tolerance to conditions stated in Section 3.10

p. Wind and tornado -

HPCI, ADS, CS, and LPCI:

Seismic Category I structure houses all control equipment. See Section 3.3 for wind loadings.

q. System response time -

HPCI, ADS, CS, and LPCI:

Response times are within the requirements of need to start ECCS.

r. System accuracies -

HPCI, ADS, CS, and LPCI:

Accuracies are within those needed for correct timely action.

s. Abnormal ranges of sensed variables -

HPCI, ADS, CS, and LPCI:

Sensors are designed for the expected ranges and rates of change of variables.

7.3.2.1.2.3.1.2 ECCS - IEEE 279 (1971), Paragraph 4.2 - Single Failure Criterion

a. HPCI:

The HPCI system, by itself, is not required to meet the single failure criterion. The single failure criterion is met by providing separation between ADS and HPCI systems. The control logic circuits for the HPCI system initiation and control are housed in a single relay cabinet, and the power supply for the control logic and other HPCI system equipment is from a single dc power source. The control logic for the ADS is housed in cabinets and is powered by sources that are separate from both the HPCI initiation logic and the HPCI isolation logic.

Physical separation of instrument lines is provided so that no single instrument rack destruction or single instrument line or pipe failure can prevent both HPCI and ADS initiation. Wiring separation between divisions also provides tolerance to wireway destruction, including shorts, opens, and grounds of the wireways in a single division.

b. ADS:

The ADS system, comprised of two independent sets of controls consisting of two channels each for the two pilot solenoids, meets the single failure criterion. Tolerance to the following single failures or events has been incorporated into the control system design and installation:

1. Single open circuit

2. Single short circuit

3. Single relay failure to pickup

4. Single relay failure to drop out

5. Single module failure (including multiple shorts, opens, and grounds)

6. Single control relay cabinet destruction (including multiple shorts, opens, and grounds)

7. Single instrument rack destruction (including multiple shorts, opens, and grounds)

8. Single raceway destruction (including multiple shorts, opens, and grounds)

9. Single control power supply failure (any mode)

10. Single control circuit failure

11. Single sensing line (pipe) failure

12. Single electrical component failure

c. CS:

The CS system, comprising two independent sets of controls for the two physically separated pumping systems, meets the single failure criterion. Tolerance to the following single failures or events has been incorporated into the control system design and installation:

1. Single open circuit

2. Single short circuit

3. Single relay failure to pickup

4. Single relay failure to drop out

5. Single module failure (including multiple shorts, opens, and grounds)

6. Single control relay cabinet destruction (including multiple shorts, opens, and grounds)

7. Single instrument rack destruction (including multiple shorts, opens, and grounds)

8. Single raceway destruction (including multiple shorts, opens, and grounds)

9. Single control power supply failure (any mode)

10. Single motive power supply failure (any mode)

11. Single control circuit failure

12. Single sensing line (pipe) failure

13. Single electrical component failure

d. LPCI:

Redundancy in equipment and control logic circuitry is provided so that it is highly unlikely that the complete LPCI subsystem can be rendered inoperative.

Four control logic circuits are provided. Control logic "A" initiates loop A pumps and valves. Control logic "B" initiates loop B pumps and valves. Control logics "C" and "D" initiate pumps C and D, respectively. Tolerance to the following single failures or events is provided in the control system design and installation.

1. Single open circuit

2. Single short circuit

3. Single relay failure to pickup

4. Single relay failure to drop out

5. Single module failure (including multiple shorts, opens, and grounds)

6. Single control relay cabinet destruction (including multiple shorts, opens, and grounds)

7. Single local instrument rack destruction (including multiple shorts, opens, and grounds)

8. Single raceway destruction (including multiple shorts, opens, and grounds)

9. Single control power supply failure

10. Single motive power supply failure

11. Single control circuit failure

12. Single sensing line (pipe) failure

13. Single electrical component failure

7.3.2.1.2.3.1.3 ECCS - IEEE 279 (1971), Paragraph 4.3 - Quality of Components and Modules

a. HPCI:

The discussion in this section regarding CS system equipment applies equally to the HPCI system.

b. ADS:

Components used in the ADS control system have been carefully selected for the specific application. Ratings have sufficient conservatism to ensure that there is no significant deterioration over the lifetime of the plant.

These components are subjected to the manufacturer's normal quality control and undergo functional testing on the panel assembly floor as part of the integrated module test before shipment of each panel. Only components that have demonstrated a high degree of reliability and serviceability in other functionally similar applications are selected for use in the ADS.

Furthermore, a quality control and assurance program is required to be implemented and documented by equipment vendors, which complies with the requirements set forth in 10CFR50, Appendix B.

c. CS:

Components used in the CS control system have been carefully selected on the basis of suitability for the specific application. All of the sensors and logic relays are of the same types used in the RPS discussed in Section 7.2.1.1. Ratings have sufficient conservatism to ensure that there is no significant deterioration during anticipated duty over the lifetime of the plant.

These components are subjected to the manufacturer's normal quality control and undergo functional testing on the panel assembly floor as part of the integrated module test before shipment of each panel. Only components that have demonstrated a high degree of reliability and serviceability in other functionally similar applications are selected for use in the CS control system.

Furthermore, a quality control and assurance program is required to be implemented and documented by equipment vendors, which complies with the requirements set forth in 10CFR50, Appendix B.

d. LPCI:

The discussion in this section regarding CS system equipment applies equally to the LPCI subsystem.

7.3.2.1.2.3.1.4 ECCS - IEEE 279 (1971), Paragraph 4.4 - Equipment Qualification

The ECCS safety-related controls and instrumentation have been qualified according to the requirements outlined in IEEE 323-1971 as highlighted in Section 7.1.2.7.4. The conditions for which the equipment has been qualified are those identified in Sections 3.10 and 3.11. The conditions identified cover normal, abnormal, and accident environments both inside and outside the drywell.

7.3.2.1.2.3.1.5 ECCS - IEEE 279 (1971), Paragraph 4.5 - Channel Integrity

The ECCS control system is designed to tolerate the spectrum of failures listed under the general requirements, meets the single failure criterion, and has been qualified for the accident environment and thus satisfies the channel integrity objective of this paragraph.

7.3.2.1.2.3.1.6 ECCS - IEEE 279 (1971), Paragraph 4.6 - Channel Independence

a. HPCI, ADS:

Channel independence for the initiation sensor is provided by electrical and mechanical separation of the ADS and HPCI. The ADS sensors A and E for reactor vessel water level, for instance, are located on one local instrument rack identified as Division 1 equipment, and the ADS sensors C and G are located on another instrument rack widely separated from the first and identified as Division 3 equipment. The HPCI sensors B and F are located on an instrument rack widely separated from the ADS instruments and identified as Division 2 equipment. The sensors of each division have a common pair of process taps that are widely separated from the corresponding taps of equipment in other divisions.

The disabling of one or both sensors in one location does not disable the control for both HPCI and ADS initiation. Likewise, HPCI sensors used for the inboard isolation valve logic are identified as Division 4 equipment and are separated from the ADS instruments. This ensures that failures cannot cause a false HPCI isolation at the same time that the ADS is disabled. Channel independence does not strictly apply to the HPCI system when considered alone, since the ADS is redundant to the HPCI.

Logic relays for the ADS are separated into Division 1 and Division 3 located in separate cabinets. ADS controls are separated on the control panels.

b. CS:

Channel independence of the sensors for each variable is provided by electrical isolation and mechanical separation. The sensors used to initiate each core spray pump are located on instrument panels widely separated from each other and are identified as belonging in one of four divisions. Sensor taps for each division are widely separated from each other. The disabling of one or all sensors in one location does not disable the control for both of the two CS loops.

Relay cabinets for each CS division are in separate physical divisions. Each division is complete in itself, with its own station battery, control and instrument power bus, power distribution buses, and MCCs. The divisional split is carried all the way from the process taps to the final control element, and includes both control and motive power supplies. Although there are only two sensors for each variable in each division, the drywell pressure and reactor water level sensors backup each other so that the logic for each division is one-out-of-two-twice, energized to operate.

c. LPCI:

Channel independence of the sensors for each variable is provided by electrical isolation and mechanical separation. The A and E, B and F, C and G, and D and H sensors for reactor vessel low water level, for instance, are located on racks that are identified as division 1, 2, 3, and 4 equipment and are widely separated from each other. The sensors of each division have a common process tap, which is widely separated from the corresponding tap for sensors of other divisions. Disabling of one or all sensors in one location does not disable the control for the other division.

Relay cabinets for each division are in a separate location from that of other divisions, and each division is complete in itself, with its own station battery, control and instrument power bus, power distribution buses, and MCCs. The divisional split is carried all the way from the process taps to the final control element and includes both control and motive power supplies.

Although there are only two sensors for each variable in each division, these sensors back each other up as described in the preceding paragraph describing core spray independence.

7.3.2.1.2.3.1.7 ECCS - IEEE 279 (1971), Paragraph 4.7 - Control and Protection System Interaction

The HPCI, ADS, CS, and LPCI systems are designated as safety systems and are designed to be independent of plant control systems.

7.3.2.1.2.3.1.8 ECCS - IEEE 279 (1971), Paragraph 4.8 - Derivation of System Inputs

a. HPCI:

Inputs that start the HPCI system are direct measures of the variables that indicate the need for high pressure core cooling, i.e., reactor vessel low water level or high drywell pressure. Reactor vessel water level and drywell pressure sensors are described in this section for the CS system and apply equally to the HPCI system.

b. ADS:

Inputs that start the ADS are direct measures of the variables that indicate both the need and acceptable conditions for rapid depressurization of the reactor vessel, i.e., the reactor vessel low water level is verified by high drywell pressure and at least one low pressure core cooling subsystem developing adequate discharge pressure plus adequate time delay to allow HPCI to operate if available. Reactor vessel water level and drywell pressure sensors are described in this section for the CS system and apply equally to the ADS system.

c. CS:

Inputs that start the CS system are direct measures of the variables that indicate the need for low pressure core cooling, i.e., reactor vessel low water level or high drywell pressure, coincident with reactor low pressure. The reactor vessel water level is sensed by level indicating sensors that are operated by the differential pressure between a reference leg and the pressure due to the actual height of water in the vessel.

Drywell high pressure is sensed by transducers on separate sensing lines connected to the four separate penetrations. Each sensing line has its own root valve, and each pressure sensor has its own instrument valve. Eight reactor vessel pressure sensors are used for the low pressure injection valve opening permissive. Four of the sensors used for the open permissive, plus four other reactor pressure sensors, in conjunction with drywell pressure are used in system initiation. These sensors are on four separate instrument lines going through the drywell at four different locations (Refer to Figure 7.3-26 for a diagram of level sensor

connections). Trip units connected to these sensors provide a signal to the logic for the CS system valve opening permissives.

d. LPCI:

Inputs that initiate the LPCI mode are the same as those described above for CS. The permissive for opening the injection valves is derived from ΔP sensors across the injection valves.

7.3.2.1.2.3.1.9 ECCS - IEEE 279 (1971), Paragraph 4.9 - Capability for Sensor Checks

All HPCI, ADS, CS, and LPCI sensors are of the pressure-sensing type and are installed with calibration taps and instrument valves to permit testing during normal plant operation or during shutdown.

The reactor low pressure sensors can be checked for operability during plant operation by closing the instrument valve and bleeding off pressure to the low pressure actuation point to observe channel trip.

The reactor vessel level sensors and the drywell high pressure sensors can be checked by application of gas pressure from a low pressure source (instrument air or inert gas bottle) after closing the instrument valve and opening the calibration valve.

7.3.2.1.2.3.1.10 ECCS - IEEE 279 (1971), Paragraph 4.10 - Capability for Testing and Calibration

a. HPCI:

The discussion in this section regarding CS system testing and calibration applies equally to the HPCI system, except that the turbine (rather than the pump) is started by opening the steam inlet valve. One of the injection valves is kept closed during the test. The operability of the closed injection valve can be verified by repeating the test with the other valve interlocked closed or by opening it when the HPCI turbine is not operating.

b. ADS:

The ADS is not tested in its entirety during actual plant operation, but provisions are incorporated so that operability of all elements of the system can be verified at periodic intervals. The system is designed such that there is no isolation between the RPV and the ADS valves which prevents testing without depressurizing the RPV. The operability of each individual MSRV may be verified by the individual control switches on the control room panels, preferably during plant shutdown. Sensor open circuit or short circuit failures are immediately detected and annunciated by action from the trip units. In addition, the analog transmitter outputs can be monitored in the auxiliary equipment room and can be cross-checked by comparison with the other redundant channels that monitor the same parameter. Therefore, transmitters need only be surveillance tested once per operating cycle.

The ADS uses safety-grade instrumentation and control equipment. All parts of the system except the valves can be checked during operation. The entire system can be tested during shutdown. Testing the circuitry is accomplished at the control relay cabinets by test jacks, switches, and indicator lights while exercising one logic at a time. The test method is described in detail in Section 7.3.1.1.1.2.9.

c. CS:

The CS control system is capable of being completely tested during normal plant operation to verify that each element of the system, active or passive, is capable of performing its intended function. Sensors can be exercised by applying test pressures. Logic relays can be exercised by means of plug-in test switches used alone or in conjunction with single sensor tests. Pumps can be started by the appropriate breakers to pump water against system check valves or return it to the suppression pool through test valves, while the reactor is at pressure. MOVs can be exercised by the appropriate control relays and starters, and all indications and annunciations can be observed as the system is tested. Check valves are testable by a remotely operable pneumatic piston. CS water is not actually introduced into the vessel, except initially before fuel loading.

d. LPCI:

The discussion in this section regarding CS system testing and calibration applies equally to the LPCI subsystem.

7.3.2.1.2.3.1.11 ECCS - IEEE 279 (1971), Paragraph 4.11 - Channel Bypass or Removal from Operation

a. HPCI:

Calibration of a sensor that introduces a single instrument channel trip does not cause a protective action without the coincident trip of a second channel. Removal of a sensor or trip unit from operation during calibration does not prevent the redundant instrument channel from functioning if accident conditions occur.

b. ADS:

Calibration of each sensor introduces a single instrument channel trip. This does not cause a protective action without the coincident trip of the other channel. Removal of an instrument channel from service during calibration is brief and does not significantly increase the probability of failure to operate. Removal of a sensor or instrument channel from operation during calibration does not prevent the redundant division from functioning if accident conditions occur. The manual reset buttons can interrupt the autodepressurization for a limited time. However, releasing either one of the two reset buttons allows automatic timing and action to restart if the permissives so dictate.

c. CS:

The discussion in this section regarding HPCI channel bypass is equally applicable to the CS system.

d. LPCI:

The discussion in this section regarding HPCI channel bypass is equally applicable to the LPCI mode.

7.3.2.1.2.3.1.12 ECCS - IEEE 279 (1971), Paragraph 4.12 - Operating Bypasses

a. HPCI:

There are no operating bypasses in the HPCI system.

b. ADS:

When the high drywell pressure bypass timer runs out, the high drywell pressure trip is bypassed and ADS is initiated on low water level alone.

c. CS:

There are no operating bypasses in the CS system.

d. LPCI:

There are no operating bypasses in the LPCI mode.

7.3.2.1.2.3.1.13 ECCS - IEEE 279 (1971), Paragraph 4.13 - Indication of Bypasses

HPCI, ADS, CS, LPCI:

Automatic indication, accompanied by an audible alarm, is provided in the control room to inform the operator that the ECCS and the systems actuated or controlled by the ECCS are inoperable. Manual capability also exists in the control room to activate each system level indicator provided.

7.3.2.1.2.3.1.14 ECCS - IEEE 279 (1971), Paragraph 4.14 - Access to Means for Bypassing

LPCI, HPCI, ADS, CS:

Access to switchgear, MCCs, and valves is procedurally controlled by the following means:

a. Seals (or locks) on valves, administrative procedure on instrument valves.

b. Lockable breaker control switch handles in the MCCs.

The logic test plugs are under the administrative control of plant supervisory personnel.

7.3.2.1.2.3.1.15 ECCS - IEEE 279 (1971), Paragraph 4.15 - Multiple Setpoints

This section is not applicable to the HPCI, ADS, CS, or LPCI systems because all trip setpoints are fixed.

7.3.2.1.2.3.1.16 ECCS - IEEE 279 (1971), Paragraph 4.16 - Completion of Protective Action Once It is Initiated

a. HPCI:

The final control elements for the HPCI system are essentially bistable, i.e., MOVs stay open or closed once they have reached their desired position even though their starter may drop out, which occurs when the limit of valve travel is reached. In the case of the turbine, the autoinitiation signal is electrically sealed-in. Thus protective action, once initiated (i.e, once flow is established), must go to completion

or continue until terminated by deliberate operator action or automatically stopped on vessel high water level or system malfunction trip signals.

b. ADS:

Each of the redundant autodepressurization control subsystems seals-in electrically and remains energized until manually reset by one of the two reset push buttons.

c. CS:

The final control elements for the CS system are essentially bistable, i.e., pump breakers stay closed without control power, and MOVs stay open once they have reached their open position even though the motor starter may drop out, which occurs when the valve open limit is reached. If there is an interruption in ac power, the load sequencing timers recycle, resulting in a time delay for pump restart and completion of the MOVs' motion. Thus, protective action, once initiated, goes to completion or continues until terminated by deliberate operator action.

d. LPCI:

The discussion provided in this section for the CS system is equally applicable to the LPCI mode.

7.3.2.1.2.3.1.17 ECCS - IEEE 279 (1971), Paragraph 4.17 - Manual Initiation

The emergency core cooling system (HPCI, ADS, CS and LPCI) as a whole meets IEEE 279, paragraph 4.17 because each individual subsystem has a provision for its own manual initiation. In addition, no single failure in the initiation portion of the network of systems will prevent manual or automatic initiation of redundant portions of the network.

a. HPCI:

The HPCI has a manual initiation armed push button in parallel with the automatic initiation logic. In addition, each piece of HPCI system actuation equipment required to operate the pumps and valves is capable of manual initiation from the control panel in the control room, although failures of active components or a control circuit failure that produces a turbine trip may disable the manual actuation of the HPCI system. In no event can failure of the automatic, manual, or common control circuit for the HPCI system disable the ADS, which provides backup to the HPCI system.

b. ADS:

The ADS has four manual initiation switches. One switch is in each of the four logics. Both switches for one trip system have to be closed to manually initiate the ADS. To further preclude inadvertent actuation, each switch is equipped with a collar that must be turned before the electrical contacts of the push button are effective. Thus, to initiate the ADS manually, the operator must turn two collars and depress two push buttons. Whenever a collar is turned, an annunciator is actuated. The switches have the low pressure ECCS pumps running as a permissive interlock.

The ADS automatic initiation delay timer is provided to give HPCI ample time to automatically restore vessel level so that ADS actuation is not needed. This delay timer is not provided for manual initiation since the operator does not initiate ADS

until he/she determines it necessary. No single failure in the automatic, manual, or common portion of the ADS can prevent ADS initiation.

c. CS:

The CS system can be manually initiated at the system level in the control room. Each piece of CS system actuation equipment, such as a pump, valve, breaker, or starter, is capable of individual manual initiation electrically from the control panel in the control room.

Failures within the logic circuitry of a single CS logic may cause the failure of one CS loop. In no event can failure of the automatic, manual, or common portions of the control circuit for one CS loop disable the electrical control circuit for the other CS loop.

d. LPCI:

The discussion provided in this section for the CS system is equally applicable to the LPCI mode.

The HPCI, ADS, CS, and LPCI systems of ECCS share permissive logic between automatic and system level manual initiation logic. The design is acceptable because the individual subsystems of ECCS are not required to meet the single failure criterion. The ECCS function will be met with one of its subsystems inoperative.

7.3.2.1.2.3.1.18 ECCS - IEEE 279 (1971), Paragraph 4.18 - Access to Setpoint Adjustments, Calibration, and Test Points

The adjustable setpoint for the HPCI system flow controller is in the control room and is administratively controlled.

Setpoint adjustments for the HPCI, ADS, CS, and LPCI system trip units are integral with the trip units and cannot be changed without removal of a bar key-locked over these adjustments. Access to control relay cabinets is under administrative control.

7.3.2.1.2.3.1.19 ECCS - IEEE 279 (1971), Paragraph 4.19 - Identification of Protective Actions

For HPCI, ADS, LPCI, and CS, protective actions are directly indicated and identified by annunciator operation or instrument channel trip unit indicating lights.

7.3.2.1.2.3.1.20 ECCS - IEEE 279 (1971), Paragraph 4.20 - Information Readout

a. HPCI:

The HPCI control system is designed to provide the operator with accurate and timely information pertinent to its status. The design minimizes conditions that could cause anomalous indications confusing to the operator. Periodic testing is the means provided for verifying the operability of the components and, by proper selection of test periods compatible with the historically established reliability of the components tested, complete and timely indications are made available. Sufficient information is provided on a continuous basis so that the operator can have a high degree of confidence that the HPCI function is available and/or operating properly.

Annunciators are provided as shown on the functional control diagram, drawings E41-1030-F-004, E41-1030-F-005, E41-1030-F-006, E41-1030-F-007, E41-1030-F-008, and E41-1030-F-009. In addition to these, there are other indications for the HPCI system in the control room. These indications include:

1. Valve position lights
2. Pump suction pressure indicator
3. Pump discharge pressure indicator
4. Pump flow indicator
5. Turbine exhaust line pressure indicator
6. Turbine steam supply pressure indicator
7. Turbine steam supply pipe area temperature indicator
8. Turbine speed indicator
9. Shaft vibration indication
10. Temperature recorder for:
    (a) Oil cooler discharge temperature
    (b) High pressure bearing oil temperature
    (c) Low pressure bearing oil temperature
    (d) Thrust bearing temperature
    (e) Pump oil temperature

b. ADS:

The information provided to the operator pertinent to ADS status is as follows:

1. Annunciators shown in drawings B21-1030-F-002, B21-1030-F-002, B21-1030-F-003, B21-1030-F-004, and B21-1030-F-005
2. Logic command position lights for each valve
3. Recorder for relief valve discharge pipe temperature

From the foregoing it can be seen that the change of state of any active component from its normal condition is called to the operator's attention; therefore, the indication is considered to be complete and timely. The condition of the ADS pertinent to plant safety is also considered to be adequately covered by the indications and alarms delineated above (Section 7.3.1.1.1.2.11.2).

c. CS:

The CS control system is designed to provide the operator with accurate and timely information pertinent to its status. The design minimizes conditions that could cause anomalous indications confusing to the operator. Testing is the means provided for verifying the operation of the components, and the test period is properly selected to be compatible with the historically established reliability of the components tested. In addition, trip units are provided with analog indications that allow operability checks through channel cross-comparisons. Sufficient information is provided on a continuous basis so that the operator can have a high degree of confidence that the CS function is available and/or operating properly. Annunciation is provided as shown in Figure 7.3-9. In addition to those annunciators, other indications are included on the main control panel as follows:

1. Valve position lights for each MOV
2. Pump breaker position lights for each pump
3. Position lights for the locked open valves in the drywell
4. Position lights for the testable check valves
5. Flow indication of loop flow in each loop
6. Indication of pump discharge pressure for each loop
7. CS pump current meter for each pump.

d. LPCI:

The LPCI control mode is designed to provide the operator with accurate and timely indication of its status. Signals are not transmitted to other systems if doing so

could cause indications confusing to the operator. Operability of components is verified by periodic testing. Sufficient information is continuously provided to enable the operator to be confident that the LPCI mode is available and/or operating properly.

Annunciators are provided as shown on the functional control diagram, drawings E11-1030-F-001, E11-1030-F-002, and E11-1030-F-003.

7.3.2.1.2.3.1.21 ECCS - IEEE 279 (1971), Paragraph 4.21 - System Repair

The HPCI, ADS, CS, and LPCI control systems are designed to permit repair or replacement of components.

Recognition and location of a failed component is accomplished during periodic testing. The simplicity of the logic makes the detection and location of the component relatively easy, and components are mounted in such a way that they can be conveniently replaced in a short time.

7.3.2.1.2.3.1.22 ECCS - IEEE 279 (1971), Paragraph 4.22 - Identification of Protection Systems

The ECCS panels for HPCI, ADS, CS, and LPCI are distinctively identified as being in the protection system. Cables and raceways are distinctively colored according to their divisional assignment.

7.3.2.1.2.3.2 ECCS - IEEE 308 (1974) - Criteria for Class 1E Electrical Systems for Nuclear Power Generating Stations

Class 1 ac and dc power supply system ECCS loads are physically separated and electrically isolated into independent load groups so that safety actions provided by redundant counterparts are not compromised. See Section 8.1.6.2.

7.3.2.1.2.3.3 ECCS - IEEE 317 (1972) - Electric Penetration Assemblies in Containment Structures for Nuclear Power Generating Stations

See Section 8.1.

7.3.2.1.2.3.4 ECCS - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1E Electrical Equipment for Nuclear Power Generating Stations

See Section 3.11.2.

7.3.2.1.2.3.5 ECCS - IEEE 336 (1971) - Installation, Inspection, and Testing Requirements for Instrumentation and Electric Equipment During the Construction of Nuclear Power Generating Stations

See Section 8.1.6.1 and Table 7.1-3.

7.3.2.1.2.3.6 ECCS - IEEE 338 (1975) - Criteria for the Periodic Testing of Nuclear Power Generating Station Protection Systems

The design of the ECCS permits periodic testing as described in Sections 7.3.1.1.1.1.9, 7.3.1.1.1.2.9, 7.3.1.1.1.3.9, and 7.3.1.1.1.4.9.

7.3.2.1.2.3.7 ECCS - IEEE 344 (1971) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations

See Section 3.10.

7.3.2.1.2.3.8 ECCS - IEEE 379 (1972) - Guide for the Application of the Single Failure Criterion to Nuclear Power Generating Station Protection Systems

The single failure criterion of IEEE 279 (1971), paragraph 4.2, as further defined in IEEE 379 (1972), "Application of the Single Failure Criterion to Nuclear Power Generating Station Protection Systems," is met as described in Section 7.3.2.1.2.3.1.2.

The redundancy of the control equipment for the ECCS is consistent with the redundancy of the cooling systems themselves, as shown in Figure 7.3-6. The arrangement of the initiating signals for the ECCS is shown in Figures 7.3-4 and 7.3-5.

An evaluation of the control schemes for each ECCS component shows that no single control failure can prevent the combined cooling systems from providing the core with adequate cooling. In performing this evaluation, the redundancy of components and cooling systems was considered.

For the minimum number of channels required for functional performance, see the Technical Specifications. The determinations of these minimums considered the use and redundancy of sensors in control circuitry and the reliability of the controlled equipment in any individual cooling system.

The control arrangement used for the ADS is designed to avoid spurious actuation (Table 7.3-9). The ADS relief valves are controlled by two trip logics per trip system; both trip logics must be in the tripped state to allow system initiation. Low pressure injection system operation must also be verified.

The conditions represented by Tables 7.3-8, 7.3-9, 7.3-10, and 7.3-11, and the Technical Specifications are a result of a functional analysis of each individual ECCS. Because of the redundant methods of supplying cooling water to the fuel in a LOCA and because fuel cooling must be ensured in such a situation, the minimum trip channel conditions in the Technical Specifications exceed those required operationally to ensure core cooling capability.

The only equipment protective devices that can interrupt planned ECCS operation are those that must act to prevent complete failure of the component or system. In no case can the action of a protective device prevent other redundant cooling systems from providing adequate cooling to the core.

Manual controls for the ECCS systems are located in the control room and are under supervision of the control room operator.

Some controls for one LPCI loop are located in the remote shutdown control room. Access to these controls is administratively controlled. Transfer of control to the remote shutdown panel is alarmed in the control room.

Components located inside the drywell and essential to ECCS performance are qualified to operate in the drywell environment resulting from a LOCA. Essential instruments located outside the drywell are qualified for the environment in which they must perform their essential function.

7.3.2.1.2.3.9 ECCS - IEEE 384 (1974) - Criteria for Separation of Class 1E Equipment and Circuits

Refer to Section 7.1.2.7.11.

7.3.2.1.3 ECCS Additional Design Considerations Analyses

As defined in Regulatory Guide 1.70, paragraph 7.3.2, the following considerations are addressed.

a. Loss of the plant instrument air system does not prevent the ECCS from performing its protective function.

b. Loss of cooling water to any single piece of vital equipment does not prevent the ECCS from performing its protective function.

7.3.2.2 Primary Containment and Reactor Vessel Isolation Control System - Instrumentation and Controls

7.3.2.2.1 PCRVICS General Functional Requirements Conformance

The PCRVICS is analyzed in this section. This system is described in Section 7.3.1.1.2, and that description is used as the basis for this analysis. The safety design bases and specific regulatory requirements of the system are stated in Section 7.1.2.1.2. This analysis shows conformance to the requirements given in that section.

The PCRVICS, in conjunction with other safety systems, is designed to provide timely protection against the onset and consequences of the gross release of radioactive materials from fuel and RCPBs. Chapter 15 identifies and evaluates postulated events that can result in gross failure of fuel and RCPB. The consequences of such gross failures are described and evaluated. Chapter 15 also evaluates a gross breach in a main steam line outside the containment during operation at rated power. The evaluation shows that the main steam lines are automatically isolated in time to prevent the loss of coolant from being great enough to allow the uncovering of the core. This is true even if the longest closing time of the valve is assumed.

The shortest possible main steam line valve closure time is 3 seconds. The transient resulting from a simultaneous closure of all MSIVs in 3 seconds during reactor operation at rated power is discussed in Chapter 15.

7.3.2.2.2 PCRVICS Specific Regulatory Requirements Conformance

The conformance of the transmitter/trip unit system is covered by Licensing Topical Report NEDO 21617-A.

7.3.2.2.2.1 PCRVICS Conformance to Regulatory Guides

7.3.2.2.2.1.1 PCRVICS - Regulatory Guide 1.11 (1971) - Instrument Lines Penetrating Primary Reactor Containment (Safety Guide 11)

The PCRVICS system is in conformance with this guide, except that position indication of excess flow check valves is provided locally, rather than in the control room as suggested in paragraph C.1.c. of the regulatory guide. However, annunciation in the control room is provided upon isolation of any excess flow check valve.

7.3.2.2.2.1.2 PCRVICS - Regulatory Guide 1.22 (1972) - Periodic Testing of Protection System Actuation Functions (Safety Guide 22)

Facilities for testing are provided so that the equipment can be operated in various test modes to confirm that it will operate properly when required. Testing incorporates all elements of the system under one test mode or another, including sensors, logic, actuators, and actuated equipment. The testing is planned to be performed at intervals so that there is an extremely low probability of failure in the periods between tests. During testing there are always enough channels and systems available for operation to provide proper protection.

a. MSIV:

   The MSIVs, associated logic, and sensor devices may be tested from the sensor device to one of the two solenoids required for valve closure. The valve may be exercised closed with a slow-acting test solenoid to verify that there are no obstructions to the valve stem at full power. Before performing a valve closure using two fast-acting, main solenoids, a reduction in power is necessary to avoid reactor scram.

b. Other isolation valves:

   Except for the MSIVs, all isolation valves may be tested from sensor to actuator during plant operation. The test may cause isolation of the process lines involved, but this is tolerable.

c. PRPM subsystem:

This subsystem conforms to Regulatory Guide 1.22 in that provisions that allow periodic testing of individual channels have been built into the monitoring instruments and the trip systems.

7.3.2.2.2.1.3 PCRVICS - Regulatory Guide 1.29 (1978) - Seismic Design Classification

All electrical and mechanical devices and circuitry between process instrumentation and protective actuators and monitoring of systems important to safety are classified as seismic Category I (Section 3.2).

See Section 7.1.2.5.6.

7.3.2.2.2.1.4 PCRVICS - Regulatory Guide 1.30 (1972) - Quality Assurance Requirements for the Installation, Inspection, and Testing of Instrumentation and Electric Equipment (Safety Guide 30)

See Section 8.1.6.1.5.

7.3.2.2.2.1.5 PCRVICS - Regulatory Guide 1.47 (1973) - Bypassed and Inoperable Status Indication for Nuclear Power Plant Safety Systems

a. MSIV and other isolation valves:

Automatic indication is provided in the control room to inform the reactor operator that a system is inoperable. Annunciation is provided to indicate that a system or part of a system is not operable.

Control switches are provided to manually initiate the system out of service annunciator, for situations that are not automatically annunciated.

Instruments that form part of a one-out-of-two-twice logic can be removed from service for calibration. Removal of the instrument from service is indicated in the control room by manual actuation of the "system out-of-service" annunciator.

Bypassing is not allowed in the trip logic or actuator logic. CAC system isolation valves associated with POST-LOCA combustible gas control may be overridden using key-locked bypass switches. Isolation signals to the CIGS isolation valves associated with long term operation of ADS valves may also be overridden using key-locked bypass switches.

b. These indication provisions serve to supplement administrative controls and aid the operator in assessing the availability of component and system level protective actions.

c. Each annunciator can be tested and is provided with dual lamps.

7.3.2.2.2.1.6 PCRVICS - Regulatory Guide 1.53 (1973) - Application of the Single Failure Criterion to Nuclear Power Plant Protection Systems

MSIV and other isolation valves:

Compliance with Regulatory Guide 1.53 is achieved by specifying, designing, and constructing the engineered safeguards systems to meet the single failure criterion, section 4.2 of IEEE 279 (1971), and IEEE 379 (1972). Redundant sensors, wiring, instrument tubing, logic, actuators, and power supplies are used to insure that a single failure in any portion of the PCRVICS does not prevent protective action.

7.3.2.2.2.1.7 PCRVICS - Regulatory Guide 1.62 (1973) - Manual Initiation of Protective Actions

MSIV and other isolation valves:

Means are provided in the control room for manual initiation of reactor isolation at the system level through the use of four armed push button switches.

Operation of these switches accomplishes the initiation of all actions performed by the automatic initiation circuitry.

The equipment common to initiation of both manual reactor isolation and automatic isolation is kept to a minimum through implementation of manual reactor isolation as close as practicable to the final devices (relays) of the protective system. No single failure in the manual, automatic, or common portions of the protection system prevents initiation of reactor isolation by manual or automatic means.

Manual initiation of reactor isolation, once initiated, goes to completion as required by IEEE 279 (1971), section 4.16.

7.3.2.2.2.1.8 PCRVICS - Regulatory Guide 1.63 (1978) - Electric Penetration Assemblies in Containment Structures for Light-Water-Cooled Nuclear Power Plants

See Section 8.1.6.1.12.

7.3.2.2.2.1.9 PCRVICS - Regulatory Guide 1.75 (1978) - Physical Independence of Electric Systems

See Section 8.1.6.1.14 for a discussion of the degree of conformance.

7.3.2.2.2.1.10 PCRVICS - Regulatory Guide 1.89 (1974) - Qualification Class 1E Equipment for Nuclear Power Plants

The qualification of Class 1E equipment for the PCRVICS is covered by Section 3.11.

7.3.2.2.2.1.11 PCRVICS - Regulatory Guide 1.97 (1980) - Instrumentation for Light-Water-Cooled Nuclear Power Plants to Assess Plant and Environs Conditions During and Following an Accident

See Section 7.5.2.5.1.1.2 for a discussion of the degree of conformance.

7.3.2.2.2.1.12 PCRVICS - Regulatory Guide 1.100 (1977) - Seismic Qualification of Electric Equipment for Nuclear Power Plants

Conformance with this regulatory guide is covered by Section 3.10.

7.3.2.2.2.1.13 PCRVICS - Regulatory Guide 1.105 (1976) - Instrument Setpoints

See Section 7.1.2.5.25 for a discussion of the degree of conformance.

7.3.2.2.2.1.14 PCRVICS - Regulatory Guide 1.118 (1978) - Periodic Testing of Electric Power and Protection Systems

See Section 7.1.2.5.26 for a discussion of the degree of conformance.

7.3.2.2.2.2 PCRVICS Conformance to 10CFR50, Appendix A, General Design Criteria

7.3.2.2.2.2.1 PCRVICS - GDC 1 - Quality Standards and Records

See Section 7.1.2.6.1.

7.3.2.2.2.2.2 PCRVICS - GDC 2 - Design Bases for Protection Against Natural Phenomena

See Section 7.1.2.6.2.

7.3.2.2.2.2.3 PCRVICS - GDC 3 - Fire Protection

See Section 7.1.2.6.3.

7.3.2.2.2.2.4 PCRVICS - GDC 4 - Environmental and Dynamic Effects Design Bases

See Section 7.1.2.6.4.

7.3.2.2.2.2.5 PCRVICS - GDC 10 - Reactor Design

See Section 7.1.2.6.6.

7.3.2.2.2.2.6 PCRVICS - GDC 13 - Instrumentation and Control

a. MSIV and other isolation valves: The integrity of the reactor core and the RCPB is ensured by monitoring the appropriate plant variables and automatically closing various isolation valves if the variables exceed predetermined values.

b. Instrumentation is provided to monitor variables and systems over their anticipated ranges for normal operation, anticipated operational occurrences, and accident conditions.

7.3.2.2.2.2.7 PCRVICS - GDC 19 - Control Room

See Section 7.1.2.6.10.

7.3.2.2.2.2.8 PCRVICS - GDC 20 - Protection System Functions

a. MSIV and other isolation valves: The PCRVICS automatically isolates the appropriate process lines.

b. DELETED

c. PRPM subsystem: The subsystem conforms to GDC 20 in that activation of the trip circuit results in alarm annunciator activation and, depending on the specific trip, a

trip signal being sent to the plant vent system, the SGTS, and the containment system.

7.3.2.2.2.2.9 PCRVICS - GDC 21 - Protection System Reliability and Testability

MSIV, other isolation valves, and PRPM subsystems: The high reliability components are separated into four instrument and logic channels so that no single failure can incapacitate the system. Testing is covered in the discussion on conformance to Regulatory Guide 1.22 (Section 7.3.2.2.2.1.2).

7.3.2.2.2.2.10 PCRVICS - GDC 22 - Protection System Independence

a. MSIV and other isolation valves: Four redundant instrument and logic channels are physically separated so that no single failure can prevent an isolation. Functional diversity of sensed variables is used.

b. PRPM subsystem: This subsystem conforms to GDC 22 in that the effects of natural phenomena and normal operation (including testing) do not result in the loss of protection.

7.3.2.2.2.2.11 PCRVICS - GDC 23 - Protection System Failure Modes

a. MSIV and other isolation valves: The system logic and actuator signals are fail-safe. The MOVs will fail "as-is" on loss of power.

b. PRPM subsystem: This subsystem conforms to GDC 23 in that the trip circuits associated with each channel are specifically designed to fail-safe if there is loss of power.

7.3.2.2.2.2.12 PCRVICS - GDC 24 - Separation of Protection and Control Systems

MSIV, other isolation valves, and PRPM subsystems: The system has no control functions. The equipment is physically separated from the control system equipment to the extent that no single failure in the control system can prevent isolation.

7.3.2.2.2.2.13 PCRVICS - GDC 29 - Protection Against Anticipated Operational Occurrences

MSIV, other isolation valves, and PRPM subsystems: No anticipated operational occurrences prevent this equipment from performing its safety function. No anticipated operational occurrence can prevent an isolation.

7.3.2.2.2.2.14 PCRVICS - GDC 34 - Residual Heat Removal

Isolation signals are provided for the shutdown cooling subsystem of the RHR system.

7.3.2.2.2.3 PCRVICS Conformance to Industry Codes and Standards

The conformance of the transmitters/trip unit system is covered by Licensing Topical Report NEDO-21617.

7.3.2.2.2.3.1 PCRVICS - IEEE 279 (1971) - Criteria for Protection Systems for Nuclear Power Generating Systems

7.3.2.2.2.3.1.1 PCRVICS - IEEE 279 (1971), Paragraph 4.1 - General Functional Requirement

a. PCRVICS: The PCRVICS initiates automatic closure of specific isolation valves from trip signals generated by specified process variables and maintains the valves in a closed position without further application of power until a manual reset is permissible.

The control system is capable of initiating appropriate action and accomplishing it in a time commensurate with the need for valve closure. Total time, from the point where a process out-of-limits condition is sensed to the energizing or de-energizing of appropriate valve actuators, is less than 1.0 second. The closure time of valves ranges upward from a minimum of 3 seconds for the MSIVs, depending on the urgency for isolation considering the possible release of radioactivity. Thus it can be seen that the control initiation time is at least one order of magnitude lower than the minimum required valve closure time. The chosen speed of the sensors and valve actuators is compatible with the isolation function considered.

The minimum performance requirements are identified in Chapter 16 for the PCRVICS. These requirements include those for accuracy, which is accounted for in setpoint selection, in addition to the system response times. The instrument ranges of the initiating variables are contained in Table 7.3-5 and are selected to accurately span normal, abnormal, and accident conditions. The PCRVICS performance has been analyzed to bound the system's instrument capability.

The reliability of the isolation control system is compatible with the reliability of the actuated equipment (valves).

The PCRVICS equipment is designed for the full range of environmental conditions enumerated as follows:

1. Power supply voltage - Tolerance exists to any degree of power supply failure in one motive power system or one control power system. The PCRVICS is designed to operate over the range of voltage specified in Sections 8.3.1 and 8.3.2.

2. Power supply frequency - Tolerance exists to any degree of power supply failure in one power system or one control power system. The PCRVICS is designed to operate at the range of frequency specified in Section 8.3.1.

3. Temperature - The system operates within the required time limit at all temperatures that could result from an accident.

4. Humidity - The system operates within the required time limit at humidities (steam) that can result from a LOCA.

5. Radiation - PCRVICS equipment operates at all radiation levels expected and defined in Section 3.11.

6. Pressure - As required, the system operates at all pressures resulting from a LOCA.

7. Vibration - Tolerance to conditions is stated in Section 3.10.

8. Malfunctions - The system is tolerant to any single component malfunction.

9. Accidents - Tolerance exists for any DBA without malfunction of either subsystem.

10. Fire - The system is tolerant to any raceway fire in one division, or fire within a single enclosure.

11. Explosion - Explosions are not defined in design bases.

12. Missiles - The system has tolerances to any single missile destroying no more than one pipe, raceway, or cabinet.

13. Lightning - Tolerance to lightning damage is limited to one auxiliary bus system.

14. Flood - All control equipment is located above flood level by design.

15. Earthquake - Tolerance to conditions is stated in Section 3.10.

16. Wind and tornado - A seismic Class I structure houses all isolation control equipment. See Section 3.3 for wind loadings.

17. System response time - Responses are within the requirements dictated by the need to initiate the PCRVICS.

18. System accuracies - Accuracies are within those needed for correct timely action.

19. Abnormal ranges of sensed variables - Sensors are not subject to saturation when overranged.

b. DELETED

c. Reactor enclosure radiation monitoring system: The subsystem detects and promptly indicates excessive radiation in the reactor enclosure. On detection, an isolation is effected (Section 11.5).

d. Refueling floor radiation monitoring subsystem: The physical location and monitoring characteristics of the refueling floor radiation monitoring channels are adequate to detect abnormal amounts of radioactivity in the refueling floor exhaust duct and to initiate isolation. The redundancy and arrangement of channels ensure that no single failure can prevent isolation when required. During refueling operation (including criticality tests) the monitoring system acts as an engineered safeguard against the consequences of a refueling accident and a rod-drop accident. The response of the refueling floor radiation monitoring subsystem to a refueling accident is presented in Chapter 15.

The purpose of this subsystem is to initiate isolation of potentially contaminated refueling area ventilation effluent paths and initiate SGTS if there are excessive amounts of radioactive gases and particulate in the refueling area. For each of the two channels, two high-high radiation trips perform the following:

1. Close one of the two sets of Refueling Area supply and Refueling Area exhaust isolation valves.

2. Close one of the two sets of drywell and suppression pool purge and vent valves

3. Initiate one of two SGTS fans

Alternative trip functions are achieved by each of the two channels.

7.3.2.2.2.3.1.2 PCRVICS - IEEE 279 (1971), Paragraph 4.2 - Single Failure Criterion

a. PCRVICS: Tolerance to the following single failures is incorporated into the isolation control system design and installation:

1. Single open circuit

2. Single short circuit

3. Single relay failure to pickup

4. Single relay failure to drop out

5. Single module failure (including multiple shorts, opens, and ground)

6. Single control cabinet bay destruction (including multiple shorts, opens, and grounds)

7. Single instrument panel destruction (including multiple shorts, opens, and grounds)

8. Single raceway destruction (including multiple shorts, opens, and grounds)

9. Single control power supply failure (any mode)

10. Single motive power supply failure (any mode)

11. Single control circuit failure

12. Single sensing line (pipe) failure

13. Single electrical component failure

b. PRMS: This criterion is met, since there are two independent channels that initiate redundant equipment. One failure affects only one channel.

The single failure criterion is met by the use of redundant sensors and logic to provide isolation functions and by seismic and environmental testing of the subsystem components. A single failure in any portion of the subsystem channel circuitry or trip system logic does not prevent a required isolation function from being accomplished.

Two separate power supplies are provided to ensure that a single power failure does not cause a spurious isolation; however, a complete power failure causes an isolation to occur.

7.3.2.2.2.3.1.3 PCRVICS - IEEE 279 (1971), Paragraph 4.3 - Quality of Components and Modules

a. PCRVICS: Components used in the isolation system are carefully selected on the basis of suitability for the specific application. All of the sensors and logic relays are of the same types used in the RPS. Ratings are selected with sufficient conservatism to ensure against significant deterioration during anticipated duty over the lifetime of the plant as illustrated below:

1. Switch and relay contacts carry no more than 50% of their continuous current rating.

2. Isolation control is de-energized to trip, instead of energized to trip, and is thus made to call attention to the failures that may occur in coil circuits, connections, or contacts.

3. Instrumentation and controls are heavy duty industrial types that have been subjected to type qualification testing and the manufacturer's normal quality control; components and systems undergo functional testing on the panel assembly floor as part of the integrated module test before shipment of each panel. Only components that have demonstrated a high degree of reliability and serviceability in other functionally similar applications or have been qualified by tests are selected for use in the isolation system.

Furthermore, a quality control and assurance program is required to be implemented and documented by equipment vendors to comply with the requirements set forth in 10CFR50, Appendix B.

b. PRMS: The sensor and converters as well as the indicator and trip units have been used in other BWR power plants.

7.3.2.2.2.3.1.4 PCRVICS - IEEE 279 (1971), Paragraph 4.4 - Equipment Qualification

The PCRVICS safety-related controls and instrumentation have been qualified according to the requirements outlined in IEEE 323 (1971) (as highlighted in Section 7.1.2.7.4.) The conditions for which the equipment has been qualified are those identified in Sections 3.10 and 3.11. The identified conditions cover normal, abnormal, and accident environments both inside and outside the drywell.

7.3.2.2.2.3.1.5 PCRVICS - IEEE 279 (1971), Paragraph 4.5 - Channel Integrity

a. PCRVICS: The isolation system is designed to withstand the spectrum of failures listed under the general requirements, with the following exceptions. The structures containing PCRVICS components, except the turbine enclosure, are seismic Category I as described in Sections 3.7 and 3.8. The turbine enclosure is designed to withstand an SSE without structural elements

exceeding yield strength. The only PCRVICS components located in the nonseismic Category I turbine enclosure are the sensors and associated cables for the main steam high temperature leak detection MSIV alarm main steam line low

pressure MSIV trip, and low condenser vacuum MSIV trip (Table 7.3-6). Because reactor low level, and main steam line high flow are diverse to these MSIV isolation variables, placing these sensors or cables in the turbine enclosure does not compromise the ability of the PCRVICS to provide protective action when required.

b. PRMS: The channel components are operable under the predetermined normal and abnormal circumstances.

The trip channel components are selected to fulfill these minimum requirements.

7.3.2.2.2.3.1.6 PCRVICS - IEEE 279 (1971), Paragraph 4.6 - Channel Independence

The redundant trip channels of this protective function are electrically isolated and physically separated to meet this design requirement.

Channel independence for redundant sensors exposed to each process variable is provided by electrical and mechanical separation. Physical separation is maintained between redundant elements of the PCRVICS to ensure that no credible single failure can prevent the safety action.

7.3.2.2.2.3.1.7 PCRVICS - IEEE 279 (1971), Paragraph 4.7 - Control and Protection System Interaction

a. PCRVICS: There is no control function in the system. It is strictly a protection system. There are no transmissions of signals from this protection system equipment to control system equipment, therefore no isolation is required. No single random failure of a control system can prevent the isolation safety function.

b. PRMS: The four monitors for this protective function comply with this design requirement. Isolated contacts are used to provide isolation signals to close appropriate valves. Separation of inboard and outboard circuitry prevents postulated failures from impairing subsystem operation.

7.3.2.2.2.3.1.8 PCRVICS - IEEE 279 (1971), Paragraph 4.8 - Derivation of System Inputs

a. PCRVICS: The inputs that initiate isolation valve closure are direct measures of loss-of-coolant related variables that indicate a need for isolation, namely, reactor vessel low level, drywell high pressure, and pipe break detection. Pipe break detection is effected by measuring main steam line high flow or main steam line Outboard MSIV room temperature to detect loss of coolant rather than actual physical damage to the pipe itself. Turbine Enclosure Main Steam Tunnel High Ambient Temperature will alarm and subsequently be monitored by Operations and Manual action will be taken as needed per T.S. 3/4.7.9.

b. PRMS: The measurement of radiation of each of the designated exhaust plenums is the appropriate variable to use to determine radioactive releases into the containment.

7.3.2.2.2.3.1.9 PCRVICS - IEEE 279 (1971), Paragraph 4.9 - Capability for Sensor Checks

a. PCRVICS: The RCPB instruments can be checked by cross- comparing instrument channels, or the instruments can be checked one at a time by application of simulated signals. These include level, pressure, temperature, and flow. During operation, radiation sensors are cross-checked, and during shutdowns they may be

bench calibrated. Temperature sensors used for leak detection are cross-checked periodically against other channels to provide assurance of operability.

b. PRMS: Due to the two-out-of-two configuration of the trip logic, one channel at a time may be removed from service to perform periodic tests.

7.3.2.2.2.3.1.10 PCRVICS - IEEE 279 (1971), Paragraph 4.10 - Capability for Testing and Calibration

a. PCRVICS: All active components of the PCRVICS can be tested or calibrated during plant operation. Pressure and level instrument channels can be cross-checked or valved out of the system and calibrated with a test signal. The radiation and temperature sensors can be cross-checked for verification or operability, and since they are used with reference to background, they do not require actual sensitivity verification on a frequent basis. The sensors may be bench calibrated during shutdown. The log radiation monitor can be tested by placing the monitor switch out of the "operate" position.

b. PRMS: An internal trip test circuit, adjustable over the full range of the trip circuit, is provided. The test signal is fed into the indicator and trip unit input so that a meter reading is provided in addition to a trip. All trip circuits are the latching-type and must be manually reset at the front panel.

Facilities for calibrating these monitor units are provided. It is a test unit designed for use in the adjustment procedure for the area radiation monitor sensor and converter unit. It provides several gamma radiation levels between 1 mrem/hr and 250 mrem/hr. The calibration unit source is an approved source.

A cavity in the calibration unit receives the sensor and converter unit. Located on the back wall of the cylindrical lower half of the cavity is a window through which radiation from the source emanates. A chart on each unit indicates the radiation levels available from the unit for the various control settings.

7.3.2.2.2.3.1.11 PCRVICS - IEEE 279 (1971), Paragraph 4.11 - Channel Bypass or Removal from Operation

a. PCRVICS: Valving out and calibration of each sensor is annunciated by manual activation of the system out-of- service annunciator by the operator as well as individual sensor and channel trip annunciators. Calibration of a single sensor does not cause a protective action.

In the case of the MOVs, automatic or manual closure can be prevented by shutting off electric power to the motor starters. This action is indicated by annunciation in the control room.

b. PRMS: During the periodic testing of any given channel, the controls associated with a monitor permit the monitor to be tested for proper operation, and the two-out-of-two trip system logic prevents system level protective action. The two-out-of-two trip system logic channel, when in the test mode, provides an inoperative trip signal to meet the single failure requirements.

To bypass a channel for calibration, it is switched out of the "operate" position. This results in a downscale alarm and actuation of the upscale trip, thereby making

isolation possible in the vent that high radiation would cause an upscale trip in the remaining channel of the same logic. Whenever instrument trouble occurs, the downscale alarm sounds.

The above discussion is applicable to the RMS in Section 7.6 that initiates protective functions. In all cases, removal of the monitor from service causes actuation of the channel input to the system trip logic. In all cases, except the MSL-RMS, instrument trouble does not actuate the individual channel trip but causes a downscale alarm. The MSL-RMS isolation logic is configured such that either an upscale or downscale trip will cause a channel trip.

Administrative procedures are followed in all cases to remove from service a channel that is alarmed due to instrument trouble to ensure that system protective function is not inhibited.

In all cases, except the RHRSW-RMS, removal from service of one channel does not result in inadvertent actuation of the protective function. The RHRSW-RMS are arranged in a one-out-of-one logic configuration, and their removal from service will initiate protective action. Administrative procedures are followed in all cases to prevent removal from service of more than one channel at a time. For the RHRSW-RMS that trip the RHRSW pumps, bypass switches are provided as described in Section 7.3.1.1.12.6 that allow inhibiting the upscale trips.

7.3.2.2.2.3.1.12 PCRVICS - IEEE 279 (1971), Paragraph 4.12 - Operating Bypasses

a. PCRVICS: The isolation valve control system has two bypasses. One is the main steam line low pressure operating bypass, which is imposed by the mode switch in the other-than-run mode. The mode switch cannot be left in this position above 15% of rated power without initiating a neutron flux scram. Therefore the bypass is removed by the normal operational sequence, in accordance with the intent of IEEE 279 (1971), although it is a manual action that removes it, rather than an automatic one.

The low condenser vacuum bypass is imposed by a manual bypass switch in conjunction with closure of the turbine stop valves. Bypass removal is accomplished automatically by the opening of the turbine stop valves and manually by placing the bypass switch in normal position. Hence, the bypass is considered an operating bypass in accordance with IEEE 279 (1971).

Isolation signals to the CAC system isolation valves associated with POST-LOCA combustible gas control and to the CIGS isolation valves associated with long term operation of the ADS valves may be overridden by key-locked bypass switches by manually placing the switches in the bypass position after an isolation signal. The bypass switches are normally key-locked in the normal position to allow isolation of the applicable valves upon receipt of an isolation signal.

b. PRMS: This design requirement is not applicable to this protective function.

7.3.2.2.2.3.1.13 PCRVICS - IEEE 279 (1971), Paragraph 4.13 - Indication of Bypasses

a. PCRVICS: The operating bypasses of the main steam line isolation valve closure trip and main condenser low vacuum trip are indicated in the control room.

The operating bypasses of the CAC system and CIGS valves isolation signal are indicated in the control room by annunciation of the bypassed condition and by valve position indicating lights.

Instrument bypass from calibration and certain other bypass conditions cannot be automatically annunciated. They are manually indicated by operator actuation of the system out-of-service annunciator.

b. PRMS: A downscale annunciation is produced during the monitor tests with the PRMS front panel controls. Substitution of the process input with a simulated input to the monitor produces downscale and upscale annunciation in the control room under specific conditions of the tests.

7.3.2.2.2.3.1.14 PCRVICS - IEEE 279 (1971), Paragraph 4.14 - Access to Means for Bypassing

a. PCRVICS: The mode switch and condenser vacuum bypass switch are centrally located in the control room and are key-locked.

The CAC system and CIGS isolation valves bypass switches are centrally located in the control room and are key-locked.

b. PRMS: During the periodic test, administrative control procedures must be followed to remove one monitor from service and subsequently return it to service.

7.3.2.2.2.3.1.15 PCRVICS - IEEE 279 (1971), Paragraph 4.15 - Multiple Setpoints

Paragraph 4.15 of IEEE 179 (1971) is not applicable, because all setpoints are fixed.

7.3.2.2.2.3.1.16 PCRVICS - IEEE 279 (1971), Paragraph 4.16 - Completion of Protective Action Once It Is Initiated

a. PCRVICS: All isolation actions are sealed-in by logic, so valves go to the close position completing the protective action. Manual reset action is provided by independent reset switches, so that inboard valves can be reset independently of outboard valves. This feature is incorporated only to augment the electrical separation of the inboard and outboard valves and not because of any need to reset them separately.

b. PRMS: The monitor output trip circuit remains in a tripped state whenever the gamma radiation level exceeds the established setpoint.

7.3.2.2.2.3.1.17 PCRVICS - IEEE 279 (1971), Paragraph 4.17 - Manual Initiation

a. PCRVICS: The PCRVICS has four divisionally separated manual initiation switches that separately activate four MSIV logics and initiate the isolation system at the system level.

The logic for manual initiation is one-out-of-two-twice for the MSIVs. The manual initiation logic for other isolation valves is one-out-of-one by activating one of the system manual initiation switches (S28A for inboard, S28B for outboard), or two-out-of-two by activating both of the subsystem manual initiation switches.

Redundant manual controls are separated so that a single failure does not inhibit an isolation. The separation of redundant devices is maintained in both the manual and automatic portion of the system so that no single failure in either the manual or automatic portions can prevent an isolation by either manual or automatic means.

b. PRMS: This design requirement is not applicable to this protective function.

7.3.2.2.2.3.1.18 PCRVICS - IEEE 279 (1971), Paragraph 4.18 - Access to Setpoint Adjustments, Calibration, and Test Points

a. PCRVICS: Setpoint adjustments for the PCRVICS system sensors are integral with the trip unit located in the auxiliary equipment room, with suitable key-locked barriers, and are therefore under the administrative control of the operator.

b. PRMS: Access to the monitors is under the administrative control of plant personnel.

Operation of the monitor front panel controls, whether for calibration or test purposes, results in a downscale annunciation from the channel in the control room.

7.3.2.2.2.3.1.19 PCRVICS - IEEE 279 (1971), Paragraph 4.19 - Identification of Protective Actions

a. PCRVICS: Any one of the sensor relays actuates an annunciator, so that no single channel "trip" goes unnoticed. In addition, indicator lights are provided to show instrument channel trip. This combination of annunciation and visible verification relay actuation fulfills the requirements of this criterion.

b. PRMS: Actuation of any radiation monitor to produce a tripped condition initiates a control room annunciation for this protective function.

7.3.2.2.2.3.1.20 PCRVICS - IEEE 279 (1971), Paragraph 4.20 - Information Readout

a. PCRVICS: The information presented to the reactor operator by the isolation control system is as follows:

1. Annunciation of each process variable that has reached a trip point

2. Computer readout of trips on main steam line Outboard MSIV room temperature or main steam line high flow

3. Annunciation of steam leaks in each of the systems monitored, namely, main steam, cleanup, and RHR

4. Open and closed position indicator lights for each isolation valve

5. Annunciation of any excess flow check valve isolation

b. PRMS: Actuation of any radiation monitor to produce a tripped condition initiates a control room annunciation for this protective function.

This information is considered to fulfill the requirements for information readout.

7.3.2.2.2.3.1.21 PCRVICS - IEEE 279 (1971), Paragraph 4.21 - System Repair

a. PCRVICS: The components that are expected to have a moderate need for replacement are designed for convenient removal. These include the temperature signals, amplifier units, and thermocouples. The amplifier units are of the circuit card or replaceable module construction, and the temperature sensors are replaceable units. Pressure, vessel level, flow, and temperature, sensors can be replaced in a reasonable length of time. The pressure, level, and flow devices are considered to be permanently installed although they have nonwelded connections at the instrument, which allows replacement. Failures can be detected during periodic testing, and replacement time is nominal.

   The main steam tunnel temperature sensors are not accessible during normal plant operation because of radiation from the main steam lines. However, duplicate sensors are provided that may be substituted for a failed sensor during operation. The failed sensor can be replaced during shutdown.

b. PRMS: The one-to-one relationship of detector, monitor, and trip circuitry permits the operator to identify a faulty channel and determine the defective component.

   Provisions are made to facilitate repair of the channel components during plant operation.

7.3.2.2.2.3.1.22 PCRVICS - IEEE 279 (1971), Paragraph 4.22 - Identification of Protection Systems

a. PCRVICS: Panels and racks that house isolation system equipment are identified by a distinctive color marker plate identifying the equipment as being in the protective system and listing the system name and designation of the particular redundant portion of the system. Cables, conduits, and raceways are color coded, displaying the appropriate redundant portion of the system.

b. PRMS: Special identification is provided for these monitors by special colored marker plates that identify the RPS division with which the units are associated. Cables, conduits, and raceways are color coded, displaying the appropriate redundant portion of the system.

   Control room devices are identified by tags on the panels. These tags indicate the functions of the devices.

7.3.2.2.2.3.2 PCRVICS - IEEE 308 (1974) - Criteria for Class 1E Electrical Systems for Nuclear Power Generating Station

Class 1E ac power supply systems are physically separated and electrically isolated into redundant load groups so that safety actions provided by redundant counterparts are not compromised (Section 8.3). The fail-safe logic for PCRVICS is powered from a non-Class 1E source.

7.3.2.2.2.3.3 PCRVICS - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1E Electric Equipment for Nuclear Power Generating Stations

Conformance of the components of the PCRVICS are covered by Section 7.1.2.7.4.

7.3.2.2.2.3.4 PCRVICS - IEEE 338 (1975) - Criteria for the Periodic Testing of Nuclear Power Generating Station Protection Systems

The system is completely testable in overlapping segments during reactor operation. The tests test the sensors through to the final actuators, demonstrate independence of channels, and detect failures.

7.3.2.2.2.3.5 PCRVICS - IEEE 344 (1971) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations

The seismic qualification of components of the PCRVICS is covered by Section 3.10. This standard does not apply to the low steam line pressure MSIV trip, high condenser pressure MSIV trip, and high steam line temperature MSIV trip during or after an SSE as discussed in Section 7.3.2.2.2.3.1.5.

7.3.2.2.2.3.6 PCRVICS - IEEE 379 (1972) - Guide for the Application of the Single Failure Criterion to Nuclear Power Generating Station Protection Systems

The single failure criterion of IEEE 279 as defined by IEEE 379 (1972) is fully complied with in the design of the PCRVICS. All redundant sensors cabling, logic and actuators are physically separated so that any credible single failure cannot incapacitate the safety function. Section 7.3.2.2.2.3.1.2 contains more information.

7.3.2.2.2.3.7 PCRVICS - IEEE 384 (1974) - Criteria for Separation of Class 1E Equipment and Circuits

See Section 7.1.2.7.11 for discussion of degree of conformance.

7.3.2.2.3 PCRVICS Additional Design Considerations Analyses

As defined in Regulatory Guide 1.70, paragraph 7.3.2, the following considerations are addressed:

a. Loss of the plant instrument air system does not prevent the PCRVICS from performing its protective function.

b. Loss of cooling water to any single piece of vital equipment does not prevent the PCRVICS from performing its protective function.

7.3.2.3 Information in this section has been deleted.

7.3.2.4 RHR - Containment Spray Mode - Instrumentation and Controls

7.3.2.4.1 RHR-CSM General Functional Requirements Conformance

The following analysis shows how the RHR-CSM meets the safety design bases identified in Section 7.1.2.1.30.1. When the RHR system is in the containment spray cooling mode, the pumps take suction from the suppression pool, pass it through the RHR heat exchangers and inject it through spray spargers located in the upper drywell and in the suppression pool air space. Operation of this system condenses steam present in these areas and mixes the drywell atmosphere to prevent pockets of hydrogen accumulation. The system is manually initiated as described in Section 7.3.1.1.4.5.

7.3.2.4.2 RHR-CSM Specific Regulatory Requirements Conformance

7.3.2.4.2.1 RHR-CSM Conformance to Regulatory Guides

7.3.2.4.2.1.1 RHR-CSM - Regulatory Guide 1.11 (1971) - Instrument Lines Penetrating Primary Reactor Containment (Safety Guide 11)

Instrument lines penetrating the primary reactor containment have excess flow check valves to isolate the lines in the event of line rupture.

7.3.2.4.2.1.2 RHR-CSM - Regulatory Guide 1.22 (1972) - Periodic Testing of Protection System Actuation Functions (Safety Guide 22)

Conformance to this regulatory guide is achieved by providing system and component testing capability, either during reactor power operation or shutdown.

7.3.2.4.2.1.3 RHR-CSM - Regulatory Guide 1.29 (1978) - Seismic Design Classification

All electrical and mechanical devices and circuitry between process instrumentation, protective actuators, and monitoring of systems important to safety are classified as Seismic Category I.

7.3.2.4.2.1.4 RHR-CSM - Regulatory Guide 1.30 (1972) - Quality Assurance Requirements for the Installation, Inspection, and Testing of Instrumentation and Electric Equipment (Safety Guide 30)

See Section 8.1.6.1.5.

7.3.2.4.2.1.5 RHR-CSM - Regulatory Guide 1.32 (1977) - Criteria for Safety-Related Electric Power Systems for Nuclear Power Plants

Conformance is described in the conformance to IEEE 308 (1971).

7.3.2.4.2.1.6 RHR-CSM - Regulatory Guide 1.47 (1973) - Bypassed and Inoperable Status Indication for Nuclear Power Plant Safety Systems

Indication and annunciation is provided in the control room to inform the operator that a system or part of a system is inoperable. See Section 7.3.1.1.4.13.2 for a discussion of the bypass indication capability provided.

7.3.2.4.2.1.7 RHR-CSM - Regulatory Guide 1.53 (1973) - Application of the Single Failure Criterion to Nuclear Power Plant Protection Systems

The system is designed with two independent and redundant portions to ensure that no single failure can prevent the safety function.

7.3.2.4.2.1.8 RHR-CSM - Regulatory Guide 1.62 (1973) - Manual Initiation of Protective Actions

System initiation is manual from the control room. Interlocks are provided to prevent inadvertent manual initiation during normal reactor power operation. The manual controls are easily accessible to the operator so that action can be taken in an expeditious manner. Operation of the manual initiation accomplishes all of the actions performed by the automatic initiation circuitry.

No single failure in the manual, automatic or common portion of the protection system will prevent initiation by manual means. Manual initiation, once initiated, goes to completion as required by IEEE 279 (1971), section 4.16, unless overridden by a higher priority safety function, such as LPCI mode.

7.3.2.4.2.1.9 RHR-CSM - Regulatory Guide 1.75 (1978) - Physical Independence of Electric Systems

See Section 7.1.2.5.19 for a discussion of the degree of conformance.

7.3.2.4.2.1.10 RHR-CSM - Regulatory Guide 1.89 (1974) - Qualification of Class 1E Equipment for Nuclear Power Plants

The identification and qualification of Class 1E equipment is discussed in Section 3.11.

7.3.2.4.2.1.11 RHR-CSM - Regulatory Guide 1.97 (1980) - Instrumentation for Light-Water-Cooled Nuclear Power Plants to Assess Plant and Environs Conditions During and Following an Accident

See Section 7.5.2.5.1.1.2 for a discussion of the degree of conformance.

7.3.2.4.2.1.12 RHR-CSM - Regulatory Guide 1.100 (1977) - Seismic Qualification of Electric Equipment for Nuclear Power Plants

See Section 3.10 for a discussion of the degree of conformance.

7.3.2.4.2.1.13 RHR-CSM - Regulatory Guide 1.105 (1976) - Instrument Setpoints

See Section 7.1.2.5.25 for discussion of the degree of conformance.

7.3.2.4.2.1.14 RHR-CSM - Regulatory Guide 1.118 (1978) - Periodic Testing of Electric Power and Protection Systems

See Section 7.1.2.5.26 for discussion of the degree of conformance.

7.3.2.4.2.2 RHR-CSM Conformance to 10CFR50, Appendix A, General Design Criteria

7.3.2.4.2.2.1 RHR-CSM - GDC 1 - Quality Standards and Records

All systems required for safety are designed and built in accordance with an established quality assurance program.

7.3.2.4.2.2.2 RHR-CSM - GDC 2 - Design Bases for Protection Against Natural Phenomena

All systems required for safety have been designed to withstand the effects of natural phenomena without losing the capacity to perform their safety functions.

7.3.2.4.2.2.3 RHR-CSM - GDC 3 - Fire Protection

All systems and components required for safety have been designed and are located to minimize the probability and effect of fires and explosions. Materials that are heat-resistant and noncombustible are used wherever practicable.

7.3.2.4.2.2.4 RHR-CSM - GDC 4 - Environmental and Dynamic Effects Design Bases

All safety-related systems and components are designed to withstand and function within the environmental conditions resulting from normal operations, maintenance, testing, and postulated accidents, including LOCAs. These systems and components are appropriately protected against dynamic events such as missiles and pipe whip.

7.3.2.4.2.2.5 RHR-CSM - GDC 13 - Instrumentation and Control

Instrumentation is provided to monitor variables and systems over their anticipated ranges for normal operation, anticipated operational occurrences, and accident conditions to ensure adequate safety.

7.3.2.4.2.2.6 RHR-CSM - GDC 19 - Control Room

A control room is provided where actions can be taken to operate the nuclear power unit under normal and abnormal conditions.

7.3.2.4.2.2.7 RHR-CSM - GDC 22 - Protection System Independence

The protection systems are designed to be redundant and diverse.

7.3.2.4.2.2.8 RHR-CSM - GDC 24 - Separation of Protection and Control Systems

The protection systems are separated from the control systems to the extent that failure of any single control system component or channel, or failure or removal from service of any single protection system component or channel which is common to both, leaves intact a system satisfying all reliability, redundancy, and independence requirements of the protection system.

7.3.2.4.2.2.9 RHR-CSM - GDC 29 - Protection Against Anticipated Operational Occurrences

The protection and reactivity control systems are designed to ensure an extremely high probability of fulfilling their safety functions in the event of anticipated operational occurrences.

7.3.2.4.2.2.10 RHR-CSM - GDC 38 - Containment Heat Removal

This mode is provided to assure heat removal from the reactor containment following any LOCA.

7.3.2.4.2.2.11 RHR-CSM - GDC 40 - Testing of Containment Heat Removal System

The containment heat removal system is designed to permit appropriate periodic and functional testing including the controls which bring the system into operation.

7.3.2.4.2.3 RHR-CSM Conformance to Industry Codes and Standards

7.3.2.4.2.3.1 RHR-CSM - IEEE 279 (1971) - Criteria for Protection Systems for Nuclear Power Generating Stations

7.3.2.4.2.3.1.1 RHR-CSM - IEEE 279 (1971), Paragraph 4.1 - General Functional Requirement

a. Autoinitiation - Containment spray is not automatically initiated, however, its safety function is adequately ensured by manual initiation.

b. Appropriate Action - Appropriate action for the containment spray control system is defined as activating equipment for introducing water into the containment spray spargers.

c. Precision - The term precision does not apply strictly to the containment spray mode because of the wide range of setpoint values that could give the appropriate signal to allow manual initiation.

d. Reliability - Reliability of the control system is compatible with the controlled equipment.

e. Performance Under Adverse Conditions -

1. Power Supply Voltage - Tolerance is provided to any degree of ac power supply voltage fluctuation within one division such that voltage regulation failures in one division cannot prevent successful containment cooling. Dc power supply failure will likewise affect only one of the two containment spray divisions.

2. Power Supply Frequency - Same as Item e.1 above. Excessive frequency reduction is indicative of an onsite power supply failure, and equipment shutdown in that division is required.

3. Temperature - The RHR-CSM is operable at all temperatures that can result from any DBA.

4. Humidity - The RHR-CSM is operable at humidities (steam) that can result from any DBA.

5. Pressure - The RHR-CSM is operable at all pressures resulting from any DBA.

6. Vibration - Tolerance to such conditions is as stated in Section 3.10.

7. Malfunctions - Tolerance to any single component failure is provided.

8. Accidents - Tolerance to all DBAs has been provided.

9. Fire - Tolerance to a single raceway or enclosure fire or mechanical damage has been provided.

10. Explosions - Explosions are not defined in design basis.

11. Missiles - Tolerance to any single missile destroying no more than one pipe, raceway, or electrical enclosure has been provided.

12. Lightning - Tolerance to lightning damage of ac power system limited to one auxiliary bus system has been provided. See comments under Item e.1.

13. Flood - All control equipment is located above flood level by design or protected against flooding.

14. Earthquake - Tolerance has been provided to conditions stated in Section 3.10 and seismic Class 1 structures are used to house all control equipment.

15. Wind and Tornado - The structures containing ESF components have been designed to withstand meteorological events described in Section 3.3.2. Superficial damage may occur to miscellaneous station property during a postulated tornado, but this will not impair ESF capabilities.

16. System Response Time - Responses are within the requirements of the need to start containment spray. Manual initiation has been shown to be acceptable for initiation of this RHR mode.

17. System Accuracies - Accuracies are within those needed for proper system functioning and operational display.

18. Abnormal Ranges of Senses Variables - Sensors do not saturate when overranged.

7.3.2.4.2.3.1.2 RHR-CSM - IEEE 279 (1971), Paragraph 4.2 - Single Failure Criterion

Two 100% capacity systems are provided. Redundancy in equipment and control logic circuitry is provided so that a single failure will not render the complete containment spray system inoperative.

Two division logics are provided. Division 1 logic is provided to initiate loop A equipment and Division 2 logic is provided to initiate loop B equipment.

Tolerance to the following single failures or events is provided in the sensing channels, trip logic, actuator logic, and actuated equipment so that these failures will be limited to the possible disabling of the initiation of only one loop:

a. Single open circuit

b. Single short circuit

c. Single component failure open

d. Single component failure shorted or grounded

e. Single module failure (including multiple shorts, opens, and grounds)

f. Single electrical enclosure involvement (including multiple shorts, opens and grounds)

g. Single raceway destruction (including multiple shorts, opens, and grounds)

h. Single control power supply failure

i. Single motive power supply failure

j. Single control circuit failure

k. Single sensing line (pipe) failure

l. Single electrical component failure.

7.3.2.4.2.3.1.3 RHR-CSM - IEEE 279 (1971), Paragraph 4.3 - Quality of Components and Modules

Components used in the containment spray control mode have been carefully selected for their specific application. Ratings have sufficient conservatism to ensure against significant deterioration during anticipated duty over the lifetime of the plant.

These components are subjected to the manufacturers' normal quality control and undergo functional testing on the panel assembly floor as part of the integrated module test prior to shipment of each panel assembly. Only components which have demonstrated a high degree of reliability and serviceability in other functionally similar applications or which have been qualified by tests are selected for use.

Furthermore, a quality control and assurance program is required to be implemented and documented by equipment vendors, which complies with the requirements set forth in 10CFR50, Appendix B.

7.3.2.4.2.3.1.4 RHR-CSM - IEEE 279 (1971), Paragraph 4.4 - Equipment Qualification

No components of the containment spray system are required to operate in the drywell environment. Sensory equipment is located outside the drywell and is capable of accurate operation with wider variations in ambient temperature than results from normal or abnormal (loss of ventilation and LOCA) conditions. All components used in the containment spray system have demonstrated reliable operation in similar nuclear power plant protection systems or industrial operation (Section 3.11.2).

7.3.2.4.2.3.1.5 RHR-CSM - IEEE 279 (1971), Paragraph 4.5 - Channel Integrity

The containment spray system instrument channels are designed to maintain necessary functional capability under extreme conditions, thus satisfying the objective of channel integrity.

7.3.2.4.2.3.1.6 RHR-CSM - IEEE 279 (1971), Paragraph 4.6 - Channel Independence

Channel independence of the sensors for each variable is provided by electrical isolation and mechanical separation. The A and E sensors for reactor vessel low water levels, for instance, are located on one local instrument panel that is identified as Division 1 equipment, and the B and F sensors are located on a second instrument panel, widely separated from the first and identified as Division 2 equipment. The A and E sensors have a common process tap which is widely separated from the corresponding tap for sensors B and F. Disabling of one or all sensors in one location does not disable the control for the other division.

Relay cabinets for Division 1 are in a separate physical location from that of Division 2. Each division is complete in itself, with its own station battery, control and instrument bus, power distribution buses, and MCCs. The divisional split is carried all the way from the process taps to the final activated equipment, and includes both control and motive power supplies.

Although there are only two sensors for each variable in each division, these sensors back up each other as described in the preceding paragraph.

7.3.2.4.2.3.1.7 RHR-CSM - IEEE 279 (1971), Paragraph 4.7 - Control and Protection System Interaction

The containment spray system is a safety system designed to be independent of plant control systems.

7.3.2.4.2.3.1.8 RHR-CSM - IEEE 279 (1971), Paragraph 4.8 - Derivation of System Inputs

The inputs which are permissive for the containment spray system are direct measures of the variables that indicate the need for containment cooling. Drywell high pressure is sensed by drywell pressure sensors. Low reactor vessel water (level 1) is sensed by vessel water level sensors. Reactor low pressure is sensed by vessel pressure sensors.

7.3.2.4.2.3.1.9 RHR-CSM - IEEE 279 (1971), Paragraph 4.9 - Capability for Sensor Checks

All sensors are of the pressure-sensing type and are installed with calibration taps and instrument valves to permit testing during normal plant operation or during shutdown. The drywell high pressure sensors can be checked only by application of gas pressure from a low pressure source (instrument air or inert gas bottle) after closing the instrument valve and opening the calibration valve.

The trip units mounted in the control structure are calibrated separately by introducing a calibration source and verifying the setpoint through the use of a digital readout on the trip calibration module.

7.3.2.4.2.3.1.10 RHR-CSM - IEEE 279 (1971), Paragraph 4.10 - Capability for Testing and Calibration

The containment spray system is capable of being completely tested during normal plant operation to verify that each element of the system, active or passive, is capable of performing its intended function. MOVs can be exercised by the appropriate control logic and starters, and all indications and annunciations can be observed as the system is tested.

The pumps can be started by use of the control switches in the control room. Sensors can be exercised by applying test pressures. Logic relays can be exercised by means of plug-in test switches used alone or in conjunction with single sensor tests.

7.3.2.4.2.3.1.11 RHR-CSM - IEEE 279 (1971), Paragraph 4.11 - Channel Bypass or Removal from Operation

Calibration of each sensor will induce a single instrument channel trip. This does not cause a protective function.

Removal of a sensor from operation during calibration does not prevent the redundant instrument channels from functioning if accident conditions occur. Removal of an instrument channel from service during calibration will be brief.

7.3.2.4.2.3.1.12 RHR-CSM - IEEE 279 (1971), Paragraph 4.12 - Operating Bypasses

Containment spray has no operating bypasses.

7.3.2.4.2.3.1.13 RHR-CSM - IEEE 279 (1971), Paragraph 4.13 - Indication of Bypasses

See Section 7.1.2.7.1.

7.3.2.4.2.3.1.14 RHR-CSM - IEEE 279 (1971), Paragraph 4.14 - Access to Means for Bypassing

Access to switchgear, MCCs, and instrument valves is procedurally controlled by the following means:

a. Administrative control of access to instrument valves

b. Lockable doors on emergency switchgear rooms

7.3.2.4.2.3.1.15 RHR-CSM - IEEE 279 (1971), Paragraph 4.15 - Multiple Setpoints

There are no multiple trip settings.

7.3.2.4.2.3.1.16 RHR-CSM - IEEE 279 (1971), Paragraph 4.16 - Completion of Protective Action Once It Is Initiated

The final control elements for the containment spray system are essentially bistable, i.e., pump breakers stay closed without control power, and MOVs stay open once they have reached their open position, even though the motor starter may drop out (which will occur when the valve open limit switch is reached.

Thus, once initiated, protective action will go to completion and continue until terminated by deliberate operator action or in the use of the suppression pool spray.

7.3.2.4.2.3.1.17 RHR-CSM - IEEE 279 (1971), Paragraph 4.17 - Manual Initiation

Containment spray is a manually initiated system.

7.3.2.4.2.3.1.18 RHR-CSM - IEEE 279 (1971), Paragraph 4.18 - Access to Setpoint Adjustments, Calibration, and Test Points

Setpoint adjustments for the containment spray system sensors are integral with the trip units located in the auxiliary equipment room and cannot be changed without removal of covers over these adjustments. Access to test points in the control relay cabinets is under administrative control. Because of these restrictions, compliance with this requirement of IEEE 279 is considered complete.

7.3.2.4.2.3.1.19 RHR-CSM - IEEE 279 (1971), Paragraph 4.19 - Identification of Protective Actions

Protective actions are directly indicated and identified by annunciator operation and trip unit indicator lights. This combination of annunciation and visible verification fulfills the requirements of this criterion.

7.3.2.4.2.3.1.20 RHR-CSM - IEEE 279 (1971), Paragraph 4.20 - Information Readout

Sufficient information is provided on a continuous basis so that the operator can have a high degree of confidence that the containment spray function is available and/or operating properly. The design minimizes conditions that could cause inconsistent indications confusing to the operator.

7.3.2.4.2.3.1.21 RHR-CSM - IEEE 279 (1971), Paragraph 4.21 - System Repair

The containment spray control system is designed to permit repair or replacement of components.

All devices in the system are designed for a 40 year lifetime under the imposed duty cycles with periodic maintenance. Since this duty cycle is composed mainly of periodic testing rather than operation, lifetime is more a matter of "shelf life" than active life. However, all components are selected for continuous-duty plus thousands of cycles of operation, far beyond that anticipated in actual service. The pump breakers are an exception to this with regard to the large number of operating cycles available. Nevertheless, even these breakers should not require contact replacement within 40 years, assuming periodic pump starts each 3 months.

Recognition and location of a failed component will be accomplished during periodic testing. The simplicity of the logic will make the detection and location relatively easy, and components are mounted in such a way that they can be conveniently replaced in a short time.

7.3.2.4.2.3.1.22 RHR-CSM - IEEE 279 (1971), Paragraph 4.22 - Identification of Protection Systems

A nameplate distinctively identifies the equipment as being in the protective system for each logic cabinet and instrument panel that is part of the containment spray system. The nameplate shows the division to which each panel or cabinet is assigned.

Identification of cables and raceways is discussed in Section 8.3.1.3.

Panels in the control room are identified by tags which indicate the system and logic contained in each panel.

7.3.2.4.2.3.2 RHR-CSM - IEEE 308 (1974) - Criteria for Class 1E Electrical Systems for Nuclear Power Generating Stations

Class 1E power supply system containment spray loads are physically separated and electrically isolated into independent load groups so that safety action provided by redundant counterparts are not compromised. Refer to Section 8.1.6.1.6 for details of the Class 1E power system.

7.3.2.4.2.3.3 RHR-CSM - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1E Electric Equipment for Nuclear Power Generating Stations

Refer to Section 7.1.2.7.4 for a discussion of system compliance to this standard.

7.3.2.4.2.3.4 RHR-CSM - IEEE 336 (1971) - Installation, Inspection, and Testing Requirements for Instrumentation and Electric Equipment During the Construction of Nuclear Power Generating Station

See Section 8.1.6.1.5.

7.3.2.4.2.3.5 RHR-CSM - IEEE 338 (1975) - Criteria for the Periodic Testing of Nuclear Power Generating Station Protection Systems

The design of the containment spray cooling system permits periodic testing as described in Sections 7.3.1.1.4.10 and 7.3.2.4.3.1.10.

7.3.2.4.2.3.6 RHR-CSM - IEEE 344 (1971) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations

Refer to Section 7.1.2.7.7 for a discussion of system compliance to this standard.

7.3.2.4.2.3.7 RHR-CSM - IEEE 379 (1972) - Guide for the Application of the Single Failure Criterion to Nuclear Power Generating Station Protection Systems

The single failure criterion of IEEE 279 (1971), paragraph 4.2 as further defined in IEEE 379 (1972), "Application of the Single Failure Criterion to Nuclear Power Generating Station Protection System," is met as described in Section 7.3.2.4.2.3.1.2.

7.3.2.4.2.3.8 RHR-CSM - IEEE 384 (1974) - Criteria for Separation of Class 1E Equipment and Circuits

Independence of containment spray equipment is demonstrated in the Section on conformance to IEEE 279 (1971), paragraph 4.6 and IEEE 308 (1976). See Sections 7.3.1.1.4.10 and 7.3.2.4.2.3.1.6.

7.3.2.4.3 RHR-CSM Additional Design Considerations Analyses

As defined in Regulatory Guide 1.70, paragraph 7.3.2, the following considerations are addressed:

a. Loss of the plant instrument air system does not prevent the containment spray mode from performing its protective function.

b. Loss of cooling water to any single piece of vital equipment does not prevent the containment spray mode from performing its protective function.

7.3.2.5 RHR - Suppression Pool Cooling Mode – Instrumentation and Controls

7.3.2.5.1 RHR-SPCM General Functional Requirements Conformance

The following analysis shows how the safety design bases identified for the RHR-SPCM in Section 7.1.2.1.32.1 are met. The RHR-SPCM is designed to limit the water temperature in the suppression pool such that the temperature immediately after a blowdown does not exceed the established limit when reactor pressure is above the limit for cold shutdown. During this mode of operation, water is pumped from the suppression pool, through the RHR system heat exchangers, and back to the suppression pool. The RHR-SPCM thus maintains the suppression pool as a heat sink for reactor and containment blowdown and as a source of water for ECCS, containment spray, and shutdown cooling.

7.3.2.5.2 RHR-SPCM Specific Regulatory Requirements Conformance

7.3.2.5.2.1 RHR-SPCM Conformance to Regulatory Requirements

7.3.2.5.2.1.1 RHR-SPCM - Regulatory Guide 1.22 (1972) - Periodic Testing of Protection System Actuation Functions (Safety Guide 22)

Conformance to this guide is discussed in Section 7.3.2.4.2.1.2.

7.3.2.5.2.1.2 RHR-SPCM - Regulatory Guide 1.29 (1978) - Seismic Design Classification

Conformance to this guide is discussed in Section 7.3.2.4.2.1.3.

7.3.2.5.2.1.3 RHR-SPCM - Regulatory Guide 1.30 (1972) - Quality Assurance Requirements for the Installation, Inspection and Testing of Instrumentation and Electric Equipment (Safety Guide 30)

Conformance to this guide is discussed in Section 7.3.2.4.2.1.4.

7.3.2.5.2.1.4 RHR-SPCM - Regulatory Guide 1.32 (1977) - Criteria for Safety-Related Electric Power Systems for Nuclear Power Plants

Conformance is described in the conformance to IEEE 308 (1971).

7.3.2.5.2.1.5 RHR-SPCM - Regulatory Guide 1.47 (1973) - Bypassed and Inoperable Status Indication for Nuclear Power Plant Safety Systems

Conformance to this guide is discussed in Section 7.3.2.4.2.1.6.

7.3.2.5.2.1.6 RHR-SPCM - Regulatory Guide 1.53 (1973) - Application of the Single Failure Criterion to Nuclear Power Plant Protection Systems

The system is designed with two independent and redundant portions to assure that no single failure can prevent the safety function.

7.3.2.5.2.1.7 RHR-SPCM - Regulatory Guide 1.62 (1973) - Manual Initiation of Protective Actions

System initiation is manual from the control room. The manual controls are easily accessible to the operator so that required actions can be performed quickly. Once initiated, system initiation goes to completion unless overridden by a higher priority function or interlock.

7.3.2.5.2.1.8 RHR-SPCM - Regulatory Guide 1.63 (1978) - Electric Penetration Assemblies in Containment Structures for Light-Water-Cooled Nuclear Power Plants

The electric penetration assemblies are designed so that the containment structure can, without exceeding the design leakage rate, accommodate the calculated pressure, temperature and other environmental conditions resulting from any LOCA.

7.3.2.5.2.1.9 RHR-SPCM - Regulatory Guide 1.75 (1978) - Physical Independence of Electric Systems

Conformance to this guide is discussed in Section 8.1.6.1.14.

7.3.2.5.2.1.10 RHR-SPCM - Regulatory Guide 1.89 (1974) - Qualification of Class 1E Equipment for Nuclear Power Plants

Conformance to this guide is discussed in Section 3.11.

7.3.2.5.2.1.11 RHR-SPCM - Regulatory Guide 1.97 (1980) - Instrumentation for Light-Water-Cooled Nuclear Power Plants to Assess Plant and Environs Conditions During and Following An Accident

Conformance to this guide is discussed in Section 7.5.2.5.1.1.2.

7.3.2.5.2.1.12 RHR-SPCM - Regulatory Guide 1.100 (1977) - Seismic Qualification of Electric Equipment for Nuclear Power Plants

Conformance to this guide is discussed in Section 3.10.

7.3.2.5.2.1.13 RHR-SPCM - Regulatory Guide 1.105 (1976) - Instrument Setpoints

Conformance to this guide is discussed in Section 7.1.2.5.25.

7.3.2.5.2.1.14 RHR-SPCM - Regulatory Guide 1.118 (1978) - Periodic Testing of Electric Power and Protection Systems

Conformance to this guide is discussed in Section 7.1.2.5.26.

7.3.2.5.2.2 RHR-SPCM - Conformance to 10CFR50, Appendix A, General Design Criteria

Conformance to GDC 1, 2, 3, 4, 13, 19, 22, 24, 29, 38, and 40 is described in Section 7.3.2.4.2.2.

7.3.2.5.2.3 RHR-SPCM Conformance to Industry Codes and Standards

7.3.2.5.2.3.1 RHR-SPCM - IEEE 279 (1971) - Criteria for Protection Systems for Nuclear Power Generating Stations

7.3.2.5.2.3.1.1 RHR-SPCM - IEEE 279 (1971), Paragraph 4.1 - General Functional Requirement

a. Autoinitiation - The suppression pool cooling mode has no autoinitiation feature, but is manually initiated from the control room. Proper and timely system operation is assured with manual initiation, because sufficient time and information is available to the operator. The monitored parameters which would indicate satisfactory system performance, or operator error include fluid temperature, flow, pressure, and valve positions.

b. Appropriate Protective Action - The suppression pool cooling instrumentation and controls allow manual initiation of cooling flow to control suppression pool temperature.

c. Precision - Since suppression pool cooling is manually initiated based on one or more parameters, precision does not strictly apply to this system's control circuitry.

d. Reliability - Reliability of the control system is compatible with controlled equipment.

e. Performance Under Adverse Conditions -

1. Power supply voltage and frequency - An electrical fault in one division cannot impair proper suppression pool cooling mode operation due to the redundant control circuits, each being supplied by different power sources.

2. Temperature - The suppression pool cooling mode is designed to function properly in the high temperature environment expected during DBAs.

3. Humidity - The system is designed to function properly in the high humidity (steam) environment expected during DBAs.

4. Pressure - The system is designed to function properly in the full range of pressures expected during DBAs.

5. Vibration - Tolerance to environmentally induced vibration (earthquake, wind) is discussed in Section 3.10.

6. Accidents - The system is tolerant to any DBA.

7. Fire - The system is tolerant to a fire in a single division raceway or enclosure.

8. Explosions - Explosions are not defined in the design basis.

9. Missiles - The system is tolerant to any single missile destroying no more than one pipe, raceway, or electrical enclosure.

10. Lighting - The system is tolerant to lightning damage to one auxiliary ac bus.

11. Flood - All instrumentation and controls are located above flood level or are protected from flood damage.

12. Earthquake - All control equipment is housed in a seismic Class I structure. Tolerance to earthquake damage is discussed in Section 3.10.

13. Wind and Tornado - The structures containing ESF components have been designed to withstand meteorological events described in Section 3.3.2. Superficial damage may occur to miscellaneous station property during a postulated tornado, but this will not impair ESF capabilities.

14. System Response Time - Manual initiation has been shown to provide adequate response time for initiation of this RHR mode.

15. System Accuracies - Instrumentation accuracy is covered in the Technical Specifications.

16. Ranges of Monitored Parameters - Instrument sensors and processing equipment are capable of displaying the full ranges of parameters expected during DBAs.

7.3.2.5.2.3.1.2 RHR-SPCM - IEEE 279 (1971), Paragraph 4.2 - Single Failure Criterion

Two independent fluid systems are provided, each with the capacity for removing the total design heat load. Two division logic networks are provided: Division 1 logic initiates loop A equipment and Division 2 logic initiates loop B equipment.

Redundancy in equipment and control logic circuitry is provided so that a single failure will not interfere with proper operation of the redundant portions of the system.

Tolerance to specific single failures or events is discussed in Section 7.3.2.4.2.3.1.2.

7.3.2.5.2.3.1.3 RHR-SPCM - IEEE 279 (1971), Paragraph 4.3 - Quality of Component and Modules

Components used in the RHR-SPCM have been carefully selected for their specific applications. Ratings have sufficient conservatism to prevent significant deterioration during expected duty over the lifetime of the plant.

These components are subjected to the manufacturer's normal quality control and undergo functional testing on the panel assembly floor as part of the integrated module test prior to shipment of each panel assembly. Only components which have demonstrated a high degree of

reliability and serviceability in other functionally similar applications, or which have been qualified type testing, are selected for use. Additionally, equipment vendors are required to implement and document a quality control and assurance program in accordance with the requirements of 10CFR50, Appendix B.

7.3.2.5.2.3.1.4 RHR-SPCM - IEEE 279 (1971), Paragraph 4.4 - Equipment Qualification

Components of the suppression pool cooling mode instrumentation have undergone qualification testing to evaluate their suitability for reliable service in their installed locations, or have demonstrated reliable operation in similar nuclear power plant installations and industrial applications (Section 3.11).

No component of the control system is required to operate in the drywell environment. Sensory equipment is located outside the drywell and is capable of accurate operation in wide variations of environmental conditions.

7.3.2.5.2.3.1.5 RHR-SPCM - IEEE 279 (1971), Paragraph 4.5 - Channel Integrity

The RHR-SPCM instrumentation and controls are designed to remain operable under extreme environmental conditions as detailed in Section 3.11.

7.3.2.5.2.3.1.6 RHR-SPCM - IEEE 279 (1971), Paragraph 4.6 - Channel Independence

Channel independence is maintained for all suppression pool cooling control circuitry. Channel sensor instrumentation is physically and electrically separated and identified as belonging to the respective divisions. Relay cabinets are physically and electrically separated. Each division has its own battery, control and instrumentation bus, power distribution buses, and MCCs.

7.3.2.5.2.3.1.7 RHR-SPCM - IEEE 279 (1971), Paragraph 4.7 - Control and Protection System Interaction

The RHR-SPCM is a safety function and is independent of plant control systems.

7.3.2.5.2.3.1.8 RHR-SPCM - IEEE 279 (1971), Paragraph 4.8 - Derivation of System Inputs

The inputs to the interlock circuit for suppression pool cooling flow control are the same as those used for LPCI (Section 7.3.1.1.1.4.4 and 7.3.1.1.1.4.5)

7.3.2.5.2.3.1.9 RHR-SPCM - IEEE 279 (1971), Paragraph 4.9 - Capability for Sensor Checks

Discussion of checks on sensors used in the interlock circuit are discussed in Section 7.3.1.1.1.4.9.

7.3.2.5.2.3.1.10 RHR-SPCM - IEEE 279 (1971), Paragraph 4.10 - Capability for Testing and Calibration

The RHR-SPCM can be tested completely during normal plant operation to verify that each element of the system, active or passive, is capable of performing its intended function. MOVs can be exercised by the appropriate control logic and starters, and all indications and annunciations can be observed during the test.

7.3.2.5.2.3.1.11 RHR-SPCM - IEEE 279 (1971), Paragraph 4.11 - Channel Bypass or Removal from Operation

The suppression pool cooling controls have no operating bypasses.

7.3.2.5.2.3.1.12 RHR-SPCM - IEEE 279 (1971), Paragraph 4.12 - Operating Bypasses

The suppression pool cooling controls have no operating bypasses.

7.3.2.5.2.3.1.13 RHR-SPCM - IEEE 279 (1971), Paragraph 4.13 - Indication of Bypasses

The suppression pool cooling controls have no operating bypasses.

7.3.2.5.2.3.1.14 RHR-SPCM - IEEE 279 (1971), Paragraph 4.14 - Access to Means for Bypassing

Since there are no bypasses, this criterion is not strictly applicable. Means of disabling instrumentation and controls is administratively controlled, including control of access to instrument valves and emergency switchgear.

7.3.2.5.2.3.1.15 RHR-SPCM - IEEE 279 (1971), Paragraph 4.15 - Multiple Setpoints

There are no multiple trip settings.

7.3.2.5.2.3.1.16 RHR-SPCM - IEEE 279 (1971), Paragraph 4.16 - Completion of Protective Action Once It Is Initiated

The final control elements for the containment spray mode are essentially bistable; for example, MOVs stay open once they have reached their open position even after the motor starter drops out. Thus, once manually initiated, an action will go to completion and will continue unless deliberately terminated by the operator, or overridden by a higher priority function or interlock.

7.3.2.5.2.3.1.17 RHR-SPCM - IEEE 279 (1971), Paragraph 4.17 - Manual Initiation

Suppression pool cooling is manually initiated. Each separated loop is independently controlled by the operator.

7.3.2.5.2.3.1.18 RHR-SPCM - IEEE 279 (1971), Paragraph 4.18 - Access to Setpoint Adjustments, Calibration, and Test Points

The suppression pool cooling mode does not require setpoints.

7.3.2.5.2.3.1.19 RHR-SPCM - IEEE 279 (1971), Paragraph 4.19 - Identification of Protective Actions

Suppression pool cooling flow initiation is indicated by the Full Flow Test Return Valve indicating lights and flow indicators on the control panel.

7.3.2.5.2.3.1.20 RHR-SPCM - IEEE 279 (1971), Paragraph 4.20 - Information Readout

Continuous reading indications are provided to enable the operator to verify proper system operation. The design minimizes the possibility of confusion due to inconsistent indications.

7.3.2.5.2.3.1.21 RHR-SPCM - IEEE 279 (1971), Paragraph 4.21 - System Repair

The suppression pool cooling mode is designed for efficient maintainability. Easy recognition of malfunctioning equipment is provided through proper test procedures. Accessibility is provided for the sensors and controls to facilitate repair or adjustment.

7.3.2.5.2.3.1.22 RHR-SPCM - IEEE 279 (1971), Paragraph 4.22 - Identification of Protection Systems

Nameplates distinctively identify the equipment as being in the protective system for each logic cabinet and instrument panel that is part of the RHR system. The nameplates also indicate the division to which each panel or cabinet is assigned. Panels in the control room are identified by tags which indicate the system and logic contained therein. Identification of cables and raceways is discussed in Section 8.3.1.3.

7.3.2.5.2.3.2 RHR-SPCM - IEEE 308 (1974) - Criteria for Class 1E Electrical Systems for Nuclear Power Generating Stations

Class 1E electrical loads in the suppression pool cooling instrumentation and control system are physically separated and electrically isolated into independent load groups. A failure in one group will not interfere with proper operation of the redundant portions of the system. Details of the Class 1E power system are discussed in Section 8.1.6.1.6.

7.3.2.5.2.3.3 RHR-SPCM - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1E Electric Equipment for Nuclear Power Generating Stations

Refer to Section 7.1.2.7.4 for a discussion of system compliance to this standard.

7.3.2.5.2.3.4 RHR-SPCM - IEEE 336 (1971) - Installation, Inspection, and Testing Requirements for Instrumentation and Electric Equipment During the Construction of Nuclear Power Generating Stations

See Section 8.1.6.1.5.

7.3.2.5.2.3.5 RHR-SPCM - IEEE 338 (1975) - Criteria for the Periodic Testing of Nuclear Power Generating Station Protection Systems

The capability for testing the suppression pool cooling instrumentation and control system is discussed in Sections 7.3.1.1.1.4.9 and 7.3.1.1.5.10.

7.3.2.5.2.3.6 RHR-SPCM - IEEE 344 (1971) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations

Refer to Section 7.1.2.7.7 for a discussion of system compliance to this standard.

7.3.2.5.2.3.7 RHR-SPCM - IEEE 379 (1972) - Guide for the Application of the Single Failure Criterion to Nuclear Power Generating Station Protection Systems

The single failure criterion of IEEE 279 (1971), paragraph 4.2 as further defined in IEEE 379 (1972), "Application of the Single Failure Criterion to Nuclear Power Generating Station Protection System," is met as described in Section 7.3.2.5.2.3.1.2.

7.3.2.5.2.3.8 RHR-SPCM - IEEE 384 (1974) - Criteria for Separation of Class 1E Equipment and Circuits

Independence of suppression pool cooling equipment is demonstrated in the Section on conformance to IEEE 279 (1971), paragraph 4.6 and IEEE 308 (1974) (Sections 7.3.2.5.2.3.1.6 and 7.3.2.5.2.3.2).

7.3.2.5.3 RHR-SPCM Additional Design Considerations Analyses

As defined in Regulatory Guide 1.70, paragraph 7.3.2, the following considerations are addressed:

a. Loss of the plant instrument air system does not prevent the containment spray mode from performing its protective function.

b. Loss of cooling water to any single piece of vital equipment does not prevent the containment spray mode from performing its protective function.

7.3.2.6 Containment Atmospheric Control System – Instrumentation and Controls

7.3.2.6.1 CAC Primary Containment Vacuum Relief System - Instrumentation and Controls

7.3.2.6.1.1 PCVR General Functional Requirements Conformance

The following analysis shows how the PCVR meets the safety design bases identified in Section 7.1.2.1.16.2.1.

The simplicity of design of the primary containment vacuum relief valve assemblies ensures their ability to operate when necessary to limit the differential pressure across the diaphragm slab. The valves are of the swing-check configuration and require no motive power other than the differential pressure across the valve.

The use of two valves in series within each assembly prevents failure of any single valve in the stuck open position from compromising the pressure-suppression capability of the primary containment.

7.3.2.6.1.2 PCVR Specific Regulatory Requirements Conformance

7.3.2.6.1.2.1 PCVR Conformance to Regulatory Guides

7.3.2.6.1.2.1.1 PCVR - Regulatory Guide 1.22 (1972) - Periodic Testing of Protection System Actuation Functions (Safety Guide 22)

A valve operator is provided to test the operation of the valve and disc position indication system. Associated switches located on a test panel in the reactor enclosure permit the periodic testing of the valves in accordance with the requirements of Chapter 16.

7.3.2.6.1.2.1.2 PCVR - Regulatory Guide 1.47 (1973) - Bypassed and Inoperable Status Indication for Nuclear Power Plant Safety Systems

The PCVR system is an automatic system and cannot be bypassed. Status indicating lights in the control room, provide indication of valve operability.

7.3.2.6.1.2.1.3 PCVR - Regulatory Guide 1.53 (1973) - Application of the Single Failure Criterion to Nuclear Power Plant Protection Systems

The PCVR system is an automatic system requiring only a differential pressure across the valve discs to initiate the system.

7.3.2.6.1.2.1.4 PCVR - Regulatory Guide 1.97 (1980) - Instrumentation for Light-Water-Cooled Nuclear Power Plants to Assess Plant and Environs Conditions During and Following an Accident

See Section 7.5.2.5.1.1.2 for discussion of the degree of conformance.

7.3.2.6.1.2.1.5 PCVR - Regulatory Guide 1.100 (1977) - Seismic Qualification of Electric Equipment for Nuclear Power Plants

See Section 3.10 for a discussion of Regulatory Guide 1.100 (1977).

7.3.2.6.1.2.1.6 PCVR - Regulatory Guide 1.105 (1976) - Instrument Setpoints

See Section 7.1.2.5.25 for discussion of the degree of conformance.

7.3.2.6.1.2.1.7 PCVR - Regulatory Guide 1.118 (1978) - Periodic Testing of Electric Power and Protection Systems

See Section 7.2.1.5.26 for discussion of the degree of conformance.

7.3.2.6.1.2.2 PCVR Conformance to 10CFR50, Appendix A, General Design Criteria

7.3.2.6.1.2.2.1 PCVR - GDC 1 - Quality Standards and Records

The PCVR system is designed and built in accordance with an established quality assurance program.

7.3.2.6.1.2.2.2 PCVR - GDC 2 - Design Bases for Protection Against Natural Phenomena

The PCVR system is designed to withstand the effects of natural phenomena without loss of capability to perform its safety functions.

7.3.2.6.1.2.2.3 PCVR - GDC 3 - Fire Protection

Section 7.1.2.6.3 gives compliance with GDC 3.

7.3.2.6.1.2.2.4 PCVR - GDC 4 - Environmental and Dynamic Effects Design Bases

Section 7.1.2.6.4 gives compliance with GDC 4.

7.3.2.6.1.2.2.5 PCVR - GDC 19 - Control Room

The PCVR is automatic, requiring only a differential pressure to operate. Annunciation is provided in the control room to alert the operator when any PCVR valve is not fully closed. Hand switches associated with the valves (and located on a panel in the reactor enclosure) are provided for test and containment purge purposes only.

7.3.2.6.1.2.2.6 PCVR - GDC 21 - Protection System Reliability and Testability

High functional reliability is implemented in the system design by redundant and separate PCVR valve assemblies. Each PCVR valve assembly is capable of being tested during normal plant operation.

7.3.2.6.1.2.2.7 PCVR - GDC 22 - Protection System Independence

There are four redundant PCVR valve assemblies that are physically separate. Operational tests do not affect the operation of the system in any way.

7.3.2.6.1.2.2.8 PCVR - GDC 29 - Protection Against Anticipated Operational Occurrences

No anticipated operational occurrence can prevent this equipment from performing its safety function.

7.3.2.6.1.2.3 PCVR Conformance to Industry Codes and Standards

7.3.2.6.1.2.3.1 PCVR - IEEE 279 (1971) - Criteria for Protection Systems for Nuclear Power Generating Stations

This standard is not applicable to this system because the controls for PCVR are for test purposes only. The PCVR system is a fully independent system and does not require an external power source for actuation. Other requirements such as reliability, testing, and equipment qualification requirements, have been discussed in Section 7.3.2.6.1.2.1 and Section 7.3.2.6.1.2.2. Channel bypass or removal from operation is discussed in Section 7.3.2.6.1.2.1.2.

7.3.2.6.1.2.3.2 PCVR - IEEE 308 (1974) - Criteria for Class 1E Electrical Systems for Nuclear Power Generating Stations

See Section 8.3.2.2.1.12 for a discussion of this standard.

7.3.2.6.1.2.3.3 PCVR - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1E Electric Equipment for Nuclear Power Generating Stations

See Section 7.1.2.7.4.

7.3.2.6.1.2.3.4 PCVR - IEEE 338 (1971) - Criteria for the Periodic Testing of Nuclear Power Generating Stations Protection Systems

See Section 7.1.2.7.6.

7.3.2.6.1.2.3.5 PCVR - IEEE 344 (1971) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations

See Section 7.1.2.7.7 for seismic qualification.

7.3.2.6.1.2.3.6 PCVR - IEEE 384 (1974) - Criteria for Separation of Class 1E Equipment and Circuits

This standard is not applicable as this system does not have an external power supply or wiring to safety-related equipment.

7.3.2.6.2 CAC Combustible Gas Control System - Instrumentation and Controls

7.3.2.6.2.1 CGCS General Functional Requirement Conformance

The containment hydrogen recombiner subsystem and the combustible gas analyzer subsystem both consist of two separate packages that are fully redundant and independent. If there is a LOOP, the redundant packages are powered from different divisions of Class 1E power. A single failure in either subsystem would only render the affected package unavailable, with the redundant package being fully capable of serving the intended function at full capacity. FMEAs for the containment hydrogen recombiner subsystem and the combustible gas analyzer subsystem are provided in Tables 6.2-20 and 6.2-21, respectively. See also the safety design basis identified in Section 7.1.2.1.16.1.1.

Refer to Section 6.2.5 for additional details.

7.3.2.6.2.2 CGCS Specific Regulatory Requirements Conformance

7.3.2.6.2.2.1 CGCS Conformance to Regulatory Guides

7.3.2.6.2.2.1.1 CGCS - Regulatory Guide 1.7 (1978) - Control of Combustible Gas Concentrations in Containment Following a Loss-of-Coolant Accident

See Section 6.2.5.4 for discussion of this regulatory guide.

7.3.2.6.2.2.1.2 CGCS - Regulatory Guide 1.22 (1972) – Periodic Testing of Protection System Actuation Functions (Safety Guide 22)

Actuation devices are periodically tested in accordance with the requirements of the maintenance program and the Technical Requirements Manual (TRM).

7.3.2.6.2.2.1.3 CGCS - Regulatory Guide 1.47 (1973) - Bypassed and Inoperable Status Indication for Nuclear Power Plant Safety Systems

The CGCS is manually actuated and cannot be bypassed. A light for each recombiner in the control room indicates system readiness. The light is extinguished if a recombiner is taken out-of-service.

7.3.2.6.2.2.1.4 CGCS - Regulatory Guide 1.53 (1973) - Application of the Single Failure Criterion to Nuclear Power Plant Protection Systems

Compliance with Regulatory Guide 1.53 (1973) is achieved by specifying, designing, and constructing the CGCS so that it meets the single failure criterion as described in paragraph 4.2 of IEEE 279 (1971).

7.3.2.6.2.2.1.5 CGCS - Regulatory Guide 1.62 (1973) - Manual Initiation of Protective Actions

Controls are provided in the control room to manually initiate the recombiners.

7.3.2.6.2.2.1.6 CGCS - Regulatory Guide 1.75 (1978) - Physical Independence of Electric Systems

The electrical separation criteria and degree of conformance to Regulatory Guide 1.75 (1975) are discussed in Sections 7.1.2.2.3 and 8.1.6.1.14.

7.3.2.6.2.2.1.7 CGCS - Regulatory Guide 1.97 (1980) - Instrumentation for Light-Water-Cooled Nuclear Power Plants to Assess Plant and Environs Conditions During and Following an Accident

See Section 7.5.2.5.1.1.2 for discussion of the degree of conformance.

7.3.2.6.2.2.1.8 CGCS - Regulatory Guide 1.100 (1977) - Seismic Qualification of Electric Equipment for Nuclear Power Plants

See Section 3.10.2.1.1 for a discussion of Regulatory Guide 1.100 (1977).

7.3.2.6.2.2.1.9 CGCS - Regulatory Guide 1.105 (1976) - Instrument Setpoints

See Section 7.1.2.5.25 for discussion of the degree of conformance.

7.3.2.6.2.2.1.10 CGCS - Regulatory Guide 1.118 (1978) - Periodic Testing of Electric Power and Protection Systems

See Section 7.1.2.5.26 for discussion of the degree of conformance.

7.3.2.6.2.2.2 CGCS Conformance to 10CFR50, Appendix A, General Design Criteria

7.3.2.6.2.2.2.1 CGCS - GDC 1 - Quality Standards and Records

The CGCS is designed and built in accordance with an established quality assurance program.

7.3.2.6.2.2.2.2 CGCS - GDC 2 - Design Bases for Protection Against Natural Phenomena

The CGCS can withstand an SSE and function after the SSE.

7.3.2.6.2.2.2.3 CGCS - GDC 3 - Fire Protection

The CGCS is designed to minimize the probability and effects of fire and explosions by using noncombustible and heat-resistant materials.

7.3.2.6.2.2.2.4 CGCS - GDC 4 - Environmental and Dynamic Effects Design Bases

See Section 3.11 for environmental conditions and Section 3.10 for dynamic effects.

7.3.2.6.2.2.2.5 CGCS - GDC 13 - Instrumentation and Control

Instrumentation is selected to operate within expected ranges required for the safety of the plant in all anticipated operational considerations. Controls are designed to maintain the system within expected operating ranges.

7.3.2.6.2.2.2.6 CGCS - GDC 19 - Control Room

The CGCS can be controlled from the control room. Instrumentation is provided so that the operator can be assured of correct operation.

7.3.2.6.2.2.2.7 CGCS - GDC 21 - Protection System Reliability and Testability

High functional reliability is implemented in the system design by redundant and separate recombiners. Each recombiner is capable of being tested during normal plant operation.

7.3.2.6.2.2.2.8 CGCS - GDC 22 - Protection System Independence

There are two redundant recombiners, physically and electrically separate. Operational tests, maintenance being performed, or failure of one unit does not affect the other in any way.

7.3.2.6.2.2.2.9 CGCS - GDC 23 - Protection System Failure Modes

On a loss of power, valves in the system fail as-is. The blower and heaters are deactivated, effecting a system shutdown.

7.3.2.6.2.2.2.10 CGCS - GDC 24 - Separation of Protection and Control Systems

See the discussion for GDC 22.

7.3.2.6.2.2.2.11 CGCS - GDC 29 - Protection Against Anticipated Operational Occurrences

No anticipated operational occurrence can prevent this equipment from performing its safety function.

7.3.2.6.2.2.2.12 CGCS - GDC 56 - Primary Containment Isolation

Instrument lines that penetrate containment conform to the requirements of Regulatory Guide 1.11 as discussed in Section 7.3.2.2.2.1.1.

7.3.2.6.2.2.3 CGCS Conformance to Industry Codes and Standards

7.3.2.6.2.2.3.1 CGCS - IEEE 279 (1971) - Criteria for Protection Systems for Nuclear Power Generation Systems

Compliance of the CGCS with IEEE 279 (1971) is detailed below.

7.3.2.6.2.2.3.1.1 CGCS - IEEE 279 (1971), Paragraph 4.1 - General Functional Requirement

The CGCS is manually initiated. The system safety function is adequately ensured by manual initiation.

7.3.2.6.2.2.3.1.2 CGCS - IEEE 279 (1971), Paragraph 4.2 - Single Failure Criterion

The hydrogen recombiners are fully redundant and physically and electrically separate; therefore, the system meets the single failure criterion.

7.3.2.6.2.2.3.1.3 CGCS - IEEE 279 (1971), Paragraph 4.3 - Quality of Components and Modules

All safety-related components are selected on the basis of suitability for the application. A quality assurance program is required to be implemented.

7.3.2.6.2.2.3.1.4 CGCS - IEEE 279 (1971), Paragraph 4.4 - Equipment Qualification

The CGCS safety-related controls and instrumentation have been qualified according to the requirements outlined in IEEE 323 (1971) as highlighted in Section 7.1.2.7.4. The qualifications that have been met are those identified in Sections 3.10 and 3.11. The parameters identified cover normal, abnormal, and accident environments, both inside and outside the drywell.

7.3.2.6.2.2.3.1.5 CGCS - IEEE 279 (1971), Paragraph 4.5 - Channel Integrity

The CGCS meets the channel integrity objective by using the design features described in the other paragraphs of this section.

7.3.2.6.2.2.3.1.6 CGCS - IEEE 279 (1971), Paragraph 4.6 - Channel Independence

The control, instrumentation, and power circuits to each recombiner are physically and electrically separated.

7.3.2.6.2.2.3.1.7 CGCS - IEEE 279 (1971), Paragraph 4.7 - Control and Protection System Interaction

The CGCS has no interaction with the plant control systems. Control room annunciator circuits taking input from this system are electrically isolated from the system and cannot impair its operability.

7.3.2.6.2.2.3.1.8 CGCS - IEEE 279 (1971), Paragraph 4.8 - Derivation of System Inputs

The CGCS is manually initiated.

7.3.2.6.2.2.3.1.9 CGCS - IEEE 279 (1971), Paragraph 4.9 - Capability for Sensor Checks

Sensors can be checked by cross-checking from the control room between redundant instruments. The sensors can be calibrated by introducing calibration gas to the sensors.

7.3.2.6.2.2.3.1.10 CGCS - IEEE 279 (1971), Paragraph 4.10 - Capability for Testing and Calibration

The CGCS is capable of being tested during normal plant operation to verify that the system is capable of performing its intended function.

7.3.2.6.2.2.3.1.11 CGCS - IEEE 279 (1971), Paragraph 4.11 - Channel Bypass or Removal from Operation

The two recombiners are separate electrically and physically. Removal of a component for maintenance prevents the operation of one recombiner; however, the operation of the other is unaffected. The recombiners cannot be bypassed, because they are manually initiated.

7.3.2.6.2.2.3.1.12 CGCS - IEEE 279 (1971), Paragraph 4.12 - Operating Bypasses

A light in the control room indicates the availability of each redundant package in the CGCS subsystem. The operator can manually initiate the available package. The CGCS is manually initiated and cannot be bypassed.

7.3.2.6.2.2.3.1.13 CGCS - IEEE 279 (1971), Paragraph 4.13 - Indication of Bypasses

An indicating light for each recombiner in the control room is lit if the recombiner is ready for operation. If the recombiner is removed from service for maintenance, the light goes out.

7.3.2.6.2.2.3.1.14 CGCS - IEEE 279 (1971), Paragraph 4.14 - Access to Means for Bypassing

Access to the recombiners, power cabinets, and control panels is procedurally controlled by administrative means.

7.3.2.6.2.2.3.1.15 CGCS - IEEE 279 (1971), Paragraph 4.15 - Multiple Setpoints

This paragraph is not applicable to the CGCS.

7.3.2.6.2.2.3.1.16 CGCS - IEEE 279 (1971), Paragraph 4.16 - Completion of Protective Action Once It Is Initiated

The CGCS, once initiated, operates until stopped by the operator.

7.3.2.6.2.2.3.1.17 CGCS - IEEE 279 (1971), Paragraph 4.17 - Manual Initiation

The CGCS is manually initiated.

7.3.2.6.2.2.3.1.18 CGCS - IEEE 279 (1971), Paragraph 4.18 - Access to Setpoint Adjustments, Calibration, and Test Points

Access to the recombiners, power cabinets, and control panels is procedurally controlled by administrative procedures.

7.3.2.6.2.2.3.1.19 CGCS - IEEE 279 (1971), Paragraph 4.19 - Identification of Protective Actions

The status of each recombiner is shown by indicating lights in the control room.

7.3.2.6.2.2.3.1.20 CGCS - IEEE 279 (1971), Paragraph 4.20 - Information Readout

The information readout provides information so that the operator can be assured of correct operation. Instrumentation is described in Sections 7.3.1.1.6.1.2.12.2 and 7.5.

7.3.2.6.2.2.3.1.21 CGCS - IEEE 279 (1971), Paragraph 4.21 - System Repair

The recognition and location of failed components is accomplished during periodic testing. The control logic is not complex, so that locating failed components is straightforward. The components are mounted so as to facilitate removal and replacement.

7.3.2.6.2.2.3.1.22 CGCS - IEEE 279 (1971), Paragraph 4.22 - Identification of Protection Systems

The control cabinets and power cabinets are identified with nameplates that distinctively identify them as being a safety system. Cables and cable trays are identified by a color code and tags that identify them as being a separation channel.

7.3.2.6.2.2.3.2 CGCS - IEEE 308 (1974) - Criteria for Class 1E Electrical Systems for Nuclear Power Generating Stations

See Section 8.3.2.2.1.12 for a discussion of IEEE 308 (1974).

7.3.2.6.2.2.3.3 CGCS - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1E Electric Equipment for Nuclear Power Generating Stations

See Section 7.1.2.7.4.

7.3.2.6.2.2.3.4 CGCS - IEEE 338 (1975) - Criteria for the Periodic Testing of Nuclear Power Generating Station Protection Systems

See Section 7.1.2.7.6.

7.3.2.6.2.2.3.5 CGCS - IEEE 344 (1971) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations

See Section 7.1.2.7.7 for seismic qualification.

7.3.2.6.2.2.3.6 CGCS - IEEE 379 (1972) - Guide for the Application of the Single Failure Criterion to Nuclear Power Generating Station Protection Systems

The single failure criterion of IEEE 379 (1972) is met as described in Section 7.3.2.6.2.2.3.1.2.

7.3.2.6.2.2.3.7 CGCS - IEEE 384 (1974) - Criteria for Separation of Class 1E Equipment and Circuits

Refer to section 7.1.2.7.11 for the degree of conformance.

7.3.2.6.3 CAC Additional Design Considerations Analyses

As defined in Regulatory Guide 1.70, paragraph 7.3.2, the following considerations are addressed:

a. Loss of the plant instrument air system does not prevent the CAC system from performing its protective function.

b. Loss of cooling water to any single piece of vital equipment does not prevent the CAC system from performing its protective function.

7.3.2.7 Standby Gas Treatment System – Instrumentation and Controls

7.3.2.7.1 SGTS General Functional Requirements Conformance

The SGTS is designed with sufficient capacity and redundancy so that a single active or passive electrical or control component failure does not prevent the system from performing its safety-related functions. The SGTS is automatically initiated by the REIS or RAIS. See Section 7.1.2.1.26.1 for the safety design basis and Sections 7.3.2.9 and 7.3.2.17 for additional details.

7.3.2.7.2 SGTS Specific Regulatory Requirements Conformance

7.3.2.7.2.1 SGTS Conformance to Regulatory Guides

7.3.2.7.2.1.1 SGTS - Regulatory Guide 1.22 (1972) - Periodic Testing of Protection System Actuation Functions (Safety Guide 22)

The SGTS can be manually initiated and is capable of being tested during normal plant operation. Hand switches located in the control room allow periodic testing of emergency fans in accordance with the requirements of Chapter 16.

7.3.2.7.2.1.2 SGTS - Regulatory Guide 1.29 (1978) - Seismic Design Classification

The SGTS complies with this regulatory guide as discussed in Section 3.2.

7.3.2.7.2.1.3 SGTS - Regulatory Guide 1.30 (1972) - Quality Assurance Requirements for the Installation, Inspection, and Testing of Instrumentation and Electric Equipment (Safety Guide 30)

See Section 8.1.6.1.5 and Chapter 17.

7.3.2.7.2.1.4 SGTS - Regulatory Guide 1.47 (1973) - Bypassed and Inoperable Status Indication for Nuclear Power Plant Safety Systems

The fan motor status and fan system trouble annunciator in the control room provide the required information.

7.3.2.7.2.1.5 SGTS - Regulatory Guide 1.53 (1973) - Application of the Single Failure Criterion to Nuclear Power Plant Protection Systems

Compliance with Regulatory Guide 1.53 is achieved by specifying, designing, and constructing the SGTS to meet the single failure criterion, section 4.2 of IEEE 279 (1971) and IEEE 379 (1972). Redundant sensors and wiring are separated. The logic components and wiring are separated to ensure that a failure in a sensing element or the decision logic or an actuator does not affect its redundant counterpart and prevent protective action. Separate channels are employed so that a fault affecting one channel does not prevent the redundant channel from operating properly.

7.3.2.7.2.1.6 SGTS - Regulatory Guide 1.62 (1973) - Manual Initiation of Protective Actions

Controls are provided in the main control room to manually initiate the SGTS.

7.3.2.7.2.1.7 SGTS - Regulatory Guide 1.75 (1978) - Physical Independence of Electric Systems

See Section 8.1.6.1.14 for compliance with this regulatory guide.

7.3.2.7.2.1.8 SGTS - Regulatory Guide 1.89 (1974) - Qualification of Class 1E Equipment for Nuclear Power Plants

The qualification of Class 1E equipment for the SGTS is discussed in Section 8.1.6.1.16.

7.3.2.7.2.1.9 SGTS - Regulatory Guide 1.97 (1980) - Instrumentation for Light-Water-Cooled Nuclear Power Plants to Assess Plant and Environs Conditions During and Following an Accident

Conformance is discussed in Section 7.5.2.5.1.1.2.

7.3.2.7.2.1.10 SGTS - Regulatory Guide 1.100 (1977) - Seismic Qualification of Electric Equipment for Nuclear Power Plants

Conformance with this regulatory guide is covered by Section 3.10.

7.3.2.7.2.1.11 SGTS - Regulatory Guide 1.105 (1976) - Instrument Setpoints

Instrument setpoints are selected to allow for the inaccuracy of the instrument, uncertainties in the calibration, and instrumentation drift likely to occur between calibrations to ensure initiation of the SGTS in conjunction with the isolation of the reactor enclosure or the refueling area before the uncontrolled release of airborne contaminates to the atmosphere.

7.3.2.7.2.1.12 SGTS - Regulatory Guide 1.118 (1978) - Periodic Testing of Electric Power and Protection Systems

See Section 7.1.2.5.26.

7.3.2.7.2.2 SGTS Conformance to 10CFR50, Appendix A, General Design Criteria

7.3.2.7.2.2.1 SGTS - GDC 1 - Quality Standards and Records

The SGTS is included in an established quality assurance program discussed in Section 7.1.2.6 and Chapter 17.

7.3.2.7.2.2.2 SGTS - GDC 2 - Design Bases for Protection Against Natural Phenomena

See Section 7.1.2.6.

7.3.2.7.2.2.3 SGTS - GDC 3 - Fire Protection

See Section 7.1.2.6.

7.3.2.7.2.2.4 SGTS - GDC 4 - Environmental and Dynamic Effects Design Bases

See Section 7.1.2.6.

7.3.2.7.2.2.5 SGTS - GDC 5 - Sharing of Structures, Systems, and Components

The SGTS is common to LGS Units 1 and 2. There are two independent divisions that are each capable of providing 100% exhaust requirements to maintain either Unit 1 and/or 2 reactor enclosure and/or refueling area at a negative pressure. Therefore, sharing this system does not impair its ability to perform its safety function. The SGTS maintains the reactor enclosures and/or the refueling area at a negative pressure depending on the signal received as discussed in Section 6.5.1.1.

7.3.2.7.2.2.6 SGTS - GDC 13 - Instrumentation and Control

Instrumentation for the SGTS is selected to monitor variables over anticipated ranges during normal and emergency operating conditions.

7.3.2.7.2.2.7 SGTS - GDC 20 - Protection System Functions

See Section 7.3.2.7.1.

7.3.2.7.2.2.8 SGTS - GDC 21 - Protection System Reliability and Testability

The SGTS is designed with redundancy and separation so that a single failure does not result in the loss of the protective function. The system is capable of being tested during normal plant operation.

7.3.2.7.2.2.9 SGTS - GDC 22 - Protection System Independence

The components of the SGTS are designed so that the thermal environment resulting from any potential accident in which the components are required to function does not interfere with that function. The controls for the two SGTS divisions are electrically and physically separated so that a single failure does not result in the loss of both divisions. Power for the components of each division is provided from separate Class 1E power sources.

7.3.2.7.2.2.10 SGTS - GDC 23 - Protection System Failure Modes

Each SGTS division is designed to fail in a safe state, permitting its redundant division to operate.

7.3.2.7.2.2.11 SGTS - GDC 24 - Separation of Protection and Control Systems

The control system for the SGTS does not interact with the plant control systems.

7.3.2.7.2.2.12 SGTS - GDC 29 - Protection Against Anticipated Operational Occurrences

The high functional reliability of the SGTS is achieved through system redundancy, physical and electrical independence, fail-safe design, and inservice testability and equipment suitable for normal and accident environments.

7.3.2.7.2.2.13 SGTS - GDC 60 - Control of Releases of Radioactive Materials to the Environment

The SGTS maintains the reactor enclosures and/or refueling area at a negative pressure with respect to outdoor atmospheric pressure during isolation. This prevents the uncontrolled exfiltration of air within the secondary containment to the environment.

7.3.2.7.2.3 SGTS Conformance to Industry Codes and Standards

7.3.2.7.2.3.1 SGTS - IEEE 279 (1971) - Criteria for Protection Systems for Nuclear Power Generating Stations

Compliance of the SGTS with IEEE 279 (1971) is detailed below.

7.3.2.7.2.3.1.1 SGTS - IEEE 279 (1971), Paragraph 4.1 - General Functional Requirement

The SGTS is an automatically initiated system as discussed in Section 7.3.2.7.1.

7.3.2.7.2.3.1.2 SGTS - IEEE 279 (1971), Paragraph 4.2 - Single Failure Criterion

The SGTS consists of redundant exhaust fans, filter trains, isolation valves, and independent sets of controls and power that meet the single failure criterion.

7.3.2.7.2.3.1.3 SGTS - IEEE 279 (1971), Paragraph 4.3 - Quality of Components and Modules

All safety-related components are selected on the basis of suitability for the specific application. A quality control and assurance program is required to be implemented and documented by equipment vendors, which complies with the requirements set forth in 10CFR50, Appendix B.

7.3.2.7.2.3.1.4 SGTS - IEEE 279 (1971), Paragraph 4.4 - Equipment Qualification

See Section 3.11 for a discussion of equipment qualification.

7.3.2.7.2.3.1.5 SGTS - IEEE 279 (1971), Paragraph 4.5 - Channel Integrity

The SGTS meets the channel integrity by using the design features described in the other paragraphs of this section.

7.3.2.7.2.3.1.6 SGTS - IEEE 279 (1971), Paragraph 4.6 - Channel Independence

The control and power circuits for each SGTS component are physically and electrically separated.

7.3.2.7.2.3.1.7 SGTS - IEEE 279 (1971), Paragraph 4.7 - Control and Protection System Interaction

The SGTS has no interaction with other plant control systems. Annunciator circuits using contacts at sensor and logic relays cannot impair the operability of the SGTS control because of electrical isolation.

7.3.2.7.2.3.1.8 SGTS - IEEE 279 (1971), Paragraph 4.8 - Derivation of System Inputs

Initiation of the SGTS is derived from conditions discussed in Section 7.3.2.7.1.

7.3.2.7.2.3.1.9 SGTS - IEEE 279 (1971), Paragraph 4.9 - Capability for Sensor Checks

The SGTS can be tested for operational availability as discussed in Section 7.3.1.1.7.10.

7.3.2.7.2.3.1.10 SGTS - IEEE 279 (1971), Paragraph 4.10 - Capability for Testing and Calibration

The SGTS is capable of being tested during normal plant operation to verify that the system is capable of performing its intended function.

7.3.2.7.2.3.1.11 SGTS - IEEE 279 (1971), Paragraph 4.11 - Channel Bypass or Removal from Operation

A channel bypass or removal of a component of an initiation circuit channel does not prevent the SGTS itself from complying with the single failure criterion.

7.3.2.7.2.3.1.12 SGTS - IEEE 279 (1971), Paragraph 4.12 - Operating Bypasses

SGTS bypasses are discussed in Section 7.3.1.1.7.6.

7.3.2.7.2.3.1.13 SGTS - IEEE 279 (1971), Paragraph 4.13 - Indication of Bypasses

Each of the bypasses described in Section 7.3.1.1.7.6 is automatically indicated in the control room. In addition, each of these bypasses initiates a system out-of-service annunciator.

7.3.2.7.2.3.1.14 SGTS - IEEE 279 (1971), Paragraph 4.14 - Access to Means for Bypassing

Manual bypass of initiating circuits is procedurally controlled by administrative means.

7.3.2.7.2.3.1.15 SGTS - IEEE 279 (1971), Paragraph 4.15 - Multiple Setpoints

7.3.2.7.2.3.1.16 SGTS - IEEE 279 (1971), Paragraph 4.16 - Completion of Protective Action Once It Is Initiated

Once the SGTS is initiated it continues to operate until the operator terminates system operation by manual override.

7.3.2.7.2.3.1.17 SGTS - IEEE 279 (1971), Paragraph 4.17 - Manual Initiation

A single failure in the control system of a division of the SGTS cannot disable the automatic or manual operation of the other SGTS division.

7.3.2.7.2.3.1.18 SGTS - IEEE 279 (1971), Paragraph 4.18 - Access to Setpoint Adjustments, Calibration, and Test Points

Access to pressure differential setpoints is restricted by administrative control. See Section 11.5 for access to radiation monitoring setpoints.

7.3.2.7.2.3.1.19 SGTS - IEEE 279 (1971), Paragraph 4.19 - Identification of Protective Actions

System operation is indirectly indicated and identified by high radiation and low pressure differential alarms.

7.3.2.7.2.3.1.20 SGTS - IEEE 279 (1971), Paragraph 4.20 - Information Readout

The information readout for the SGTS is described in Section 7.3.1.1.7.12.2.

7.3.2.7.2.3.1.21 SGTS - IEEE 279 (1971), Paragraph 4.21 - System Repair

The recognition and location of failed components is accomplished during periodic testing.

7.3.2.7.2.3.1.22 SGTS - IEEE 279 (1971), Paragraph 4.22 - Identification of Protection Systems

Each logic cabinet and control panel is distinctively identified with a nameplate that identifies the safety system. Cables and cable trays are identified by a color code and tags that identify them as being of a separate channel.

7.3.2.7.2.3.2 SGTS - IEEE 308 (1974) - Criteria for Class 1E Electrical Systems for Nuclear Power Generating Stations

See Section 8.3.2.2.1.12.

7.3.2.7.2.3.3 SGTS - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1E Electric Equipment for Nuclear Power Generating Stations

See Section 7.1.2.7.4.

7.3.2.7.2.3.4 SGTS - IEEE 336 (1971) - Installation, Inspection, and Testing Requirements for Instrumentation and Electric Equipment During the Construction of Nuclear Power Generating Station

The requirements of this standard have been met by the quality assurance program for construction of safety-related items.

7.3.2.7.2.3.5 SGTS - IEEE 338 (1975) - Criteria for the Periodic Testing of Nuclear Power Generating Station Protection Systems

See Section 7.1.2.7.6.

7.3.2.7.2.3.6 SGTS - IEEE 344 (1971) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations

See Section 7.1.2.7.7.

7.3.2.7.2.3.7 SGTS - IEEE 379 (1972) - Guide for the Application of the Single Failure Criterion to Nuclear Power Generating Station Protection Systems

The single failure criterion of IEEE 379 (1972) is met as described in Section 7.3.2.7.2.3.1.2.

7.3.2.7.2.3.8 SGTS - IEEE 384 (1974) - Criteria for Separation of Class 1E Equipment and Circuits

See Section 7.1.2.7.11.

7.3.2.8 Reactor Enclosure Recirculation System – Instrumentation and Controls

7.3.2.8.1 RERS General Functional Requirements Conformance

The RERS is designed with sufficient capacity and redundancy so that a single active or passive electrical or control component failure does not prevent the system from performing its safety-related functions. The RERS is automatically initiated by the REIS. See Section 7.1.2.1.25.1 for the safety design basis and Section 7.3.2.9.1 for additional details.

7.3.2.8.2 RERS Specific Regulatory Requirements Conformance

7.3.2.8.2.1 RERS Conformance to Regulatory Guides

7.3.2.8.2.1.1 RERS - Regulatory Guide 1.22 (1972) - Periodic Testing of Protection System Actuation Functions (Safety Guide 22)

The RERS can be manually initiated and is capable of being tested during normal plant operation. Hand switches located in the control room are provided for periodic testing of the recirculation fans in accordance with the requirements of Chapter 16.

7.3.2.8.2.1.2 RERS - Regulatory Guide 1.29 (1978) - Seismic Design Classification

The RERS complies with the regulatory guide as discussed in Section 3.2.

7.3.2.8.2.1.3 RERS - Regulatory Guide 1.30 (1972) - Quality Assurance Requirements for the Installation, Inspection, and Testing of Instrumentation and Electric Equipment (Safety Guide 30)

See Section 8.1.6.1.5 and Chapter 17.

7.3.2.8.2.1.4 RERS - Regulatory Guide 1.47 (1973) - Bypassed and Inoperable Status Indications for Nuclear Power Plant Safety Systems

The fan motor status and filter status information meets the intent of the regulatory guide.

7.3.2.8.2.1.5 RERS - Regulatory Guide 1.53 (1973) - Application of the Single Failure Criterion to Nuclear Power Plant Protection Systems

Compliance with Regulatory Guide 1.53 is achieved by specifying, designing, and constructing the RERS to meet the single failure criterion, section 4.2 of IEEE 279 (1971) and IEEE 379 (1972). Redundant sensors and wiring are separated. The logic components and wiring are separated to ensure that a failure in a sensing element, the decision logic, or an actuator does not affect its redundant counterpart and prevent protective action. Separate channels are employed so that a fault affecting one channel does not prevent the redundant channel from operating properly.

7.3.2.8.2.1.6 RERS - Regulatory Guide 1.62 (1973) - Manual Initiation of Protective Actions

Controls are provided in the main control room to manually initiate the RERS.

7.3.2.8.2.1.7 RERS - Regulatory Guide 1.75 (1978) - Physical Independence of Electric Systems

See Section 8.1.6.1.14 for compliance with this regulatory guide.

7.3.2.8.2.1.8 RERS - Regulatory Guide 1.89 (1974) - Qualification of Class 1E Equipment for Nuclear Power Plants

The qualification of Class 1E equipment for the RERS is discussed in Section 8.1.6.1.16.

7.3.2.8.2.1.9 RERS - Regulatory Guide 1.100 (1978) - Seismic Qualification of Electric Equipment for Nuclear Power Plants

Conformance with this regulatory guide is covered by Section 3.10.

7.3.2.8.2.1.10 RERS - Regulatory Guide 1.105 (1976) - Instrument Setpoints

The RERS response time is limited by diesel loading criteria rather than instrument error and setpoints.

7.3.2.8.2.1.11 RERS - Regulatory Guide 1.118 (1978) - Periodic Testing of Electric Power and Protection Systems

See Section 7.1.2.5.26.

7.3.2.8.2.2 RERS Conformance to 10CFR50, Appendix A, General Design Criteria

7.3.2.8.2.2.1 RERS - GDC 1 - Quality Standards and Records

The RERS is included in an established quality assurance program discussed in Section 7.1.2.6 and Chapter 17.

7.3.2.8.2.2.2 RERS - GDC 2 - Design Bases for Protection Against Natural Phenomena

See Section 7.1.2.6.

7.3.2.8.2.2.3 RERS - GDC 3 - Fire Protection

See Section 7.1.2.6.

7.3.2.8.2.2.4 RERS - GDC 4 - Environmental and Dynamic Effects Design Bases

See Section 7.1.2.6.

7.3.2.8.2.2.5 RERS - GDC 13 - Instrumentation and Control

Instrumentation for the RERS is selected to monitor variables over anticipated ranges during normal and emergency operating conditions.

7.3.2.8.2.2.6 RERS - GDC 20 - Protection System Functions

See Section 7.3.2.8.1.

7.3.2.8.2.2.7 RERS - GDC 21 - Protection System Reliability and Testability

The RERS is designed with redundancy and separation so that a single failure does not result in the loss of the protective function. The system is capable of being tested during normal plant operation.

7.3.2.8.2.2.8 RERS - GDC 22 - Protection System Independence

The components of the RERS are designed so that the thermal environment resulting from any potential accident conditions in which the components are required to function does not interfere with that function. The controls for the two RERS divisions are electrically and physically separated so that a single failure does not result in the loss of both divisions. Power for the components of each division is provided from separate Class 1E power sources.

7.3.2.8.2.2.9 RERS - GDC 23 - Protection System Failure Modes

Each RERS division is designed such that a failure in one division will not prevent the redundant division from providing the necessary recirculation and filtration.

7.3.2.8.2.2.10 RERS - GDC 24 - Separation of Protection and Control Systems

The control system for the RERS does not interact with the plant control systems.

7.3.2.8.2.2.11 RERS - GDC 29 - Protection Against Anticipated Operational Occurrences

The high functional reliability of the RERS is achieved through system redundancy, physical and electrical independence, fail-safe design, inservice testability, and equipment suitable for normal and accident environments.

7.3.2.8.2.2.12 RERS - GDC 60 - Control of Releases of Radioactive Materials to the Environment

The RERS filters and mixes the air within the reactor enclosure during isolation.

7.3.2.8.2.3 RERS Conformance to Industry Codes and Standards

7.3.2.8.2.3.1 RERS - IEEE 279 (1971) - Criteria for Protection Systems for Nuclear Power Generating Stations

Compliance of the RERS with IEEE 279 (1971) is detailed below.

7.3.2.8.2.3.1.1 RERS - IEEE 279 (1971), Paragraph 4.1 - General Functional Requirement

The RERS is an automatically initiated system as discussed in Section 7.3.2.8.1.

7.3.2.8.2.3.1.2 RERS - IEEE 279 (1971), Paragraph 4.2 - Single Failure Criterion

The RERS consists of redundant recirculation fans, filter trains, isolation valves, and independent sets of controls and power that meet the single failure criterion.

7.3.2.8.2.3.1.3 RERS - IEEE 279 (1971), Paragraph 4.3 - Quality of Components and Modules

All safety-related components are selected on the basis of suitability for the specific application. A quality control and assurance program is required to be implemented and documented by equipment vendors, which complies with the requirements set forth in 10CFR50, Appendix B.

7.3.2.8.2.3.1.4 RERS - IEEE 279 (1971), Paragraph 4.4 - Equipment Qualification

See Section 3.11 for a discussion of equipment qualification.

7.3.2.8.2.3.1.5 RERS - IEEE 279 (1971), Paragraph 4.5 - Channel Integrity

The RERS meets the channel integrity objective by using the design features described in the other paragraphs of this section.

7.3.2.8.2.3.1.6 RERS - IEEE 279 (1971), Paragraph 4.6 - Channel Independence

The control and power circuits for each RERS component are physically and electrically separated.

7.3.2.8.2.3.1.7 RERS - IEEE 279 (1971), Paragraph 4.7 - Control and Protection System Interaction

The RERS has no interaction with other plant control systems. Annunciator circuits using contacts at sensor and logic relays cannot impair the operability of the RERS control because of electrical isolation.

7.3.2.8.2.3.1.8 RERS - IEEE 279 (1971), Paragraph 4.8 - Derivation of System Inputs

Initiation of the RERS is derived from conditions discussed in Section 7.3.2.8.1.

7.3.2.8.2.3.1.9 RERS - IEEE 279 (1971), Paragraph 4.9 - Capability of Sensor Checks

The RERS can be tested for operational availability as described in Section 7.3.1.1.8.10.

7.3.2.8.2.3.1.10 RERS - IEEE 279 (1971), Paragraph 4.10 - Capability for Testing and Calibration

The RERS is capable of being tested during normal plant operation to verify that the system is capable of performing its intended function.

7.3.2.8.2.3.1.11 RERS - IEEE 279 (1971), Paragraph 4.11 - Channel Bypass or Removal from Operation

A channel bypass or removal of a component of an initiation circuit channel does not prevent the RERS itself from complying with the single failure criterion.

7.3.2.8.2.3.1.12 RERS - IEEE 279 (1971), Paragraph 4.12 - Operation Bypasses

RERS bypasses are discussed in Section 7.3.1.1.8.6.

7.3.2.8.2.3.1.13 RERS - IEEE 279 (1971), Paragraph 4.13 - Indication of Bypasses

Each of the bypasses described in Section 7.3.1.1.8.6 is automatically indicated in the control room. In addition, each of these bypasses initiates a system out-of-service annunciator.

7.3.2.8.2.3.1.14 RERS - IEEE 279 (1971) - Paragraph 4.14 - Access to Means for Bypassing

Manual bypass of initiating circuits is procedurally controlled by administrative means.

7.3.2.8.2.3.1.15 RERS - IEEE 279 (1971) - Paragraph 4.15 - Multiple Setpoints

The RERS radiation detectors are designed to allow the adjustment of trip setpoints to more stringent settings if required.

7.3.2.8.2.3.1.16 RERS - IEEE 279 (1971), Paragraph 4.16 - Completion of Protective Action Once It Is Initiated

Once the RERS is initiated, it continues to operate until the operator terminates system operation by manual override.

7.3.2.8.2.3.1.17 RERS - IEEE 279 (1971), Paragraph 4.17 - Manual Initiation

A single failure in the control system of a division of the RERS cannot disable the automatic or manual operation of the other RERS division.

7.3.2.8.2.3.1.18 RERS - IEEE 279 (1971), Paragraph 4.18 - Access to Setpoint Adjustments, Calibration, and Test Points

See Section 11.5 for access to radiation monitoring setpoints.

7.3.2.8.2.3.1.19 RERS - IEEE 279 (1971), Paragraph 4.19 - Identification of Protective Actions

System operation is indirectly indicated and identified by high radiation alarms.

7.3.2.8.2.3.1.20 RERS - IEEE 279 (1971), Paragraph 4.20 - Information Readout

The information readout for the RERS is described in Section 7.3.1.1.8.12.2.

7.3.2.8.2.3.1.21 RERS - IEEE 279 (1971), Paragraph 4.21 - System Repair

The recognition and location of failed components is accomplished during periodic testing.

7.3.2.8.2.3.1.22 RERS - IEEE 279 (1971), Paragraph 4.22 - Identification of Protection Systems

Each logic cabinet and control panel is distinctively identified with a nameplate that identifies the safety system. Cables and cable trays are identified by a color code and tags that identify them as being of a separate channel.

7.3.2.8.2.3.2 RERS - IEEE 308 (1974) - Criteria for Class 1E Electrical Systems for Nuclear Power Generating Stations

See Section 8.3.2.2.1.12.

7.3.2.8.2.3.3 RERS - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1E Electric Equipment for Nuclear Power Generating Stations

See Section 7.1.2.7.4.

7.3.2.8.2.3.4 RERS - IEEE 336 (1971) - Installation, Inspection, and Testing Requirements for Instrumentation and Electric Equipment During the Construction of Nuclear Power Generating Stations

The requirements of this standard have been met by the quality assurance program for construction for safety-related items.

7.3.2.8.2.3.5 RERS - IEEE 338 (1975) - Criteria for the Periodic Testing of Nuclear Power Generating Station Protection Systems

See Section 7.1.2.7.6.

7.3.2.8.2.3.6 RERS - IEEE 344 (1971) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations

See Section 7.1.2.7.7.

7.3.2.8.2.3.7 RERS - IEEE 379 (1972) - Guide for the Application of Single Failure Criterion to Nuclear Power Generating Station Protection Systems

The single failure criterion of IEEE 379 (1972) is met as described in Section 7.3.2.8.2.3.1.2.

7.3.2.8.2.3.8 RERS - IEEE 384 (1974) - Criteria for Separation of Class 1E Equipment and Circuits

See Section 7.1.2.7.11.

7.3.2.9 Reactor Enclosure Isolation System – Instrumentation and Controls

7.3.2.9.1 REIS General Functional Requirements Conformance

The REIS is designed with sufficient capacity and redundancy so that a single active or passive electrical or control component failure does not prevent the system from performing its safety-related functions. The REIS is automatically initiated by detection of high radiation in the reactor enclosure exhaust ducts, low pressure differential between the reactor enclosure and the atmosphere, and/or a LOCA signal. See Section 7.1.2.1.39.1 for the safety design basis and Section 11.5 for information on radiation detectors.

7.3.2.9.2 REIS Specific Regulatory Requirements Conformance

7.3.2.9.2.1 REIS Conformance to Regulatory Guides

7.3.2.9.2.1.1 REIS - Regulatory Guide 1.22 (1972) - Periodic Testing of Protection System Actuation Function (Safety Guide 22)

The REIS can be manually initiated and is capable of being tested during normal plant operation. Hand switches located in the control room allow periodic testing of the isolation valves in accordance with the requirements of Chapter 16.

7.3.2.9.2.1.2 REIS - Regulatory Guide 1.29 (1978) - Seismic Design Classification

The REIS complies with this regulatory guide as discussed in Section 3.2.

7.3.2.9.2.1.3 REIS - Regulatory Guide 1.30 (1972) - Quality Assurance Requirements for the Installation, Inspection, and Testing of Instrumentation and Electric Equipment (Safety Guide 30)

See Section 8.1.6.1.5 and Chapter 17.

7.3.2.9.2.1.4 REIS - Regulatory Guide 1.47 (1973) - Bypassed and Inoperable Status Indication for Nuclear Power Plant Safety Systems

The isolation system armed, initiation, and isolation incomplete alarms meet the intent of this regulatory guide.

7.3.2.9.2.1.5 REIS - Regulatory Guide 1.53 (1973) - Application of the Single Failure Criterion to Nuclear Power Plant Protection Systems

Compliance with Regulatory Guide 1.53 is achieved by specifying, designing, and constructing the REIS to meet the single failure criterion, section 4.2 of IEEE 279 (1971) and IEEE 379 (1972). Redundant sensors and wiring are separated. The logic components and wiring are separated to ensure that a failure in a sensing element, the decision logic, or an actuator does not affect its redundant counterpart and prevent protective action. Separate channels are employed so that a fault affecting one channel does not prevent the redundant channel from operating properly.

7.3.2.9.2.1.6 REIS - Regulatory Guide 1.62 (1973) - Manual Initiation of Protective Actions

Controls are provided in the main control room to manually initiate the REIS.

7.3.2.9.2.1.7 REIS - Regulatory Guide 1.75 (1978) - Physical Independence of Electric Systems

See Section 8.1.6.1.14 for compliance with this regulatory guide.

7.3.2.9.2.1.8 REIS - Regulatory Guide 1.89 (1974) - Qualification of Class 1E Equipment for Nuclear Power Plants

The qualification of Class 1E equipment for the REIS is discussed in Section 8.1.6.1.16.

7.3.2.9.2.1.9 REIS - Regulatory Guide 1.100 (1977) - Seismic Qualification of Electric Equipment for Nuclear Power Plants

Conformance with this regulatory guide is covered by Section 3.10.

7.3.2.9.2.1.10 REIS - Regulatory Guide 1.105 (1976) - Instrument Setpoints

To ensure initiation of the REIS in conjunction with the SGTS to prevent the uncontrolled release of airborne contaminants to the atmosphere, instrument setpoints are selected to allow for the inaccuracy of the instrument, uncertainties in the calibration, and instrumentation drift likely to occur between calibrations. Refer to Chapter 16 for safety setpoints.

7.3.2.9.2.1.11 REIS - Regulatory Guide 1.118 (1978) - Periodic Testing of Electric Power and Protection Systems

See Section 7.1.2.5.26.

7.3.2.9.2.2 REIS Conformance to 10CFR50, Appendix A, General Design Criteria

7.3.2.9.2.2.1 REIS - GDC 1 - Quality Standards and Records

The REIS is included in an established quality assurance program discussed in Section 7.1.2.6 and Chapter 17.

7.3.2.9.2.2.2 REIS - GDC 2 - Design Bases for Protection Against Natural Phenomena

See Section 7.1.2.6.

7.3.2.9.2.2.3 REIS - GDC 3 - Fire Protection

See Section 7.1.2.6.

7.3.2.9.2.2.4 REIS - GDC 4 - Environmental and Dynamic Effects Design Bases

See Section 7.1.2.6.

7.3.2.9.2.2.5 REIS - GDC 13 - Instrumentation and Control

Instrumentation for the REIS is selected to monitor variables over anticipated ranges during normal and emergency operating conditions.

7.3.2.9.2.2.6 REIS - GDC 20 - Protection System Functions

See Section 7.3.2.9.1.

7.3.2.9.2.2.7 REIS - GDC 21 - Protection System Reliability and Testability

The REIS is designed with redundancy and separation so that a single failure does not result in the loss of the protective function. The system is capable of being tested during normal plant operation.

7.3.2.9.2.2.8 REIS - GDC 22 - Protection System Independence

The components of the REIS are designed so that the thermal environment resulting from any potential accident conditions in which the components are required to function does not interfere with that function. The controls for the two REIS divisions are electrically and physically separated so that a single failure does not result in the loss of both divisions. Power for the components of each division is provided from separate Class 1E power sources.

7.3.2.9.2.2.9 REIS - GDC 23 - Protection System Failure Modes

Each REIS division is designed to fail in a safe state, permitting its redundant division to provide isolation.

7.3.2.9.2.2.10 REIS - GDC 24 - Separation of Protection and Control Systems

The control system for the REIS does not interact with the plant control systems.

7.3.2.9.2.2.11 REIS - GDC 29 - Protection Against Anticipated Operational Occurrences

The high functional reliability of the REIS is achieved through system redundancy, physical and electrical independence, fail-safe design, inservice testability, and equipment suitable for normal and accident environments.

7.3.2.9.2.2.12 REIS - GDC 60 - Control of Releases of Radioactive Materials to the Environment

The REIS isolates the reactor enclosure from the environment to prevent uncontrolled exfiltration of air to the environment.

7.3.2.9.2.3 REIS Conformance to Industry Codes and Standards

7.3.2.9.2.3.1 REIS - IEEE 279 (1971) - Criteria for Protection for Nuclear Power Generating Stations

Compliance of the REIS with IEEE 279 (1971) is detailed below.

7.3.2.9.2.3.1.1 REIS - IEEE 279 (1971), Paragraph 4.1 - General Functional Requirement

The REIS is an automatically initiated system as discussed in Section 7.3.2.9.1.

7.3.2.9.2.3.1.2 REIS - IEEE 279 (1971), Paragraph 4.2 - Single Failure Criterion

The REIS consists of redundant sets of isolation valves and independent sets of controls and power that meet the single failure criterion.

7.3.2.9.2.3.1.3 REIS - IEEE 279 (1971), Paragraph 4.3 - Quality of Components and Modules

All safety-related components are selected on the basis of suitability for the specific application. A quality control and assurance program is required to be implemented and documented by equipment vendors, which complies with the requirements set forth in 10CFR50, Appendix B.

7.3.2.9.2.3.1.4 REIS - IEEE 279 (1971), Paragraph 4.4 - Equipment Qualification

See Section 3.11 for a discussion of equipment qualification.

7.3.2.9.2.3.1.5 REIS - IEEE 279 (1971), Paragraph 4.5 - Channel Integrity

The REIS meets the channel integrity objective by using the design features described in the other paragraphs of this section.

7.3.2.9.2.3.1.6 REIS - IEEE 279 (1971), Paragraph 4.6 - Channel Independence

The control and power circuits for each REIS component are physically and electrically separated.

7.3.2.9.2.3.1.7 REIS - IEEE 279 (1971), Paragraph 4.7 - Control and Protection System Interaction

The REIS has no interaction with other plant control systems. Annunciator circuits using contact at sensor and logic relays cannot impair the operability of the REIS control because of electrical isolation.

7.3.2.9.2.3.1.8 REIS - IEEE 279 (1971), Paragraph 4.8 - Derivation of System Inputs

Initiation of the REIS is derived from conditions discussed in Section 7.3.2.9.1.

7.3.2.9.2.3.1.9 REIS - IEEE 279 (1971), Paragraph 4.9 - Capability for Sensor Checks

The REIS can be tested for operational availability as described in Section 7.3.1.1.9.10.

7.3.2.9.2.3.1.10 REIS - IEEE 279 (1971), Paragraph 4.10 - Capability for Testing and Calibration

The REIS is capable of being tested during normal plant operation to verify that the system is capable of performing its intended function.

7.3.2.9.2.3.1.11 REIS - IEEE 279 (1971), Paragraph 4.11 - Channel Bypass or Removal from Operation

A channel bypass or removal of a component of an initiation circuit channel does not prevent the REIS itself from complying with the single failure criterion.

7.3.2.9.2.3.1.12 REIS - IEEE 279 (1971), Paragraph 4.12 - Operating Bypasses

REIS bypasses are discussed in Section 7.3.1.1.9.6.

7.3.2.9.2.3.1.13 REIS - IEEE 279 (1971), Paragraph 4.13 - Indication of Bypasses

Each of the bypasses described in Section 7.3.1.1.9.6 is automatically indicated in the control room. In addition, each of these bypasses initiates a system out-of-service annunciator.

7.3.2.9.2.3.1.14 REIS - IEEE 279 (1971), Paragraph 4.14 - Access to Means for Bypassing

Manual bypass of initiating circuits is procedurally controlled by administrative means.

7.3.2.9.2.3.1.15 REIS - IEEE 279 (1971), Paragraph 4.15 - Multiple Setpoints

The REIS radiation detectors are designed to allow adjustment of trip setpoints to more stringent settings if required.

7.3.2.9.2.3.1.16 REIS - IEEE 279 (1971), Paragraph 4.16 - Completion of Protective Action Once It Is Initiated

Once the REIS is initiated, it continues to operate until the operator terminates system operation by manual override.

7.3.2.9.2.3.1.17 REIS - IEEE 279 (1971), Paragraph 4.17 - Manual Initiation

A single failure in the control system of a division of the REIS cannot disable the automatic or manual operation of the other REIS division.

7.3.2.9.2.3.1.18 REIS - IEEE 279 (1971), Paragraph 4.18 - Access to Setpoint Adjustments, Calibration, and Test Points

See Section 11.5 for access to radiation monitoring setpoints.

7.3.2.9.2.3.1.19 REIS - IEEE 279 (1971), Paragraph 4.19 - Identification of Protective Actions

System operation is indirectly indicated and identified by high radiation alarms.

7.3.2.9.2.3.1.20 REIS - IEEE 279 (1971), Paragraph 4.20 - Information Readout

The information readout for the REIS system is described in Section 7.3.1.1.9.12.2.

7.3.2.9.2.3.1.21 REIS - IEEE 279 (1971), Paragraph 4.21 - System Repair

The recognition and location of failed components is accomplished during periodic testing.

7.3.2.9.2.3.1.22 REIS - IEEE 279 (1971), Paragraph 4.22 - Identification of Protection Systems

Each logic cabinet and control panel is distinctively identified with a nameplate that identifies the safety system. Cables and cable trays are identified by a color code and tags that identify them as being of a separate channel.

7.3.2.9.2.3.2 REIS - IEEE 308 (1974) - Criteria for Class 1E Electrical Systems for Nuclear Power Generating Stations

See Section 8.3.2.2.1.12.

7.3.2.9.2.3.3 REIS - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1E Electric Equipment for Nuclear Power Generating Stations

See Section 3.11.2.

7.3.2.9.2.3.4 REIS - IEEE 336 (1971) - Installation, Inspection, and Testing Requirements for Instrumentation and Electric Equipment During the Construction of Nuclear Power Generating Stations

The requirements of this standard have been met by the quality assurance program for construction of safety-related items.

7.3.2.9.2.3.5 REIS - IEEE 338 (1975) - Criteria for the Periodic Testing of Nuclear Power Generating Station Protection Systems

See Section 7.1.2.7.6.

7.3.2.9.2.3.6 REIS - IEEE 344 (1971) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations

See Section 3.10.

7.3.2.9.2.3.7 REIS - IEEE 379 (1972) - Guide for the Application of the Single Failure Criterion to Nuclear Power Generating Station Protection Systems

The single failure criterion of IEEE 379 (1972) is met as described in Section 7.3.2.9.2.3.1.2.

7.3.2.9.2.3.8 REIS - IEEE 384 (1974) - Criteria for Separation of Class 1E Equipment and Circuits

See Section 7.1.2.7.11.

7.3.2.10 Habitability and Control Room Isolation System - Instrumentation and Controls

7.3.2.10.1 HCRIS General Functional Requirements Conformance

The HCRIS is designed with sufficient capacity and redundancy so that a single active or passive electrical or control component failure will not prevent the system from performing its safety-related functions. The HCRIS is automatically initiated by detection of radiation. See Section 7.1.2.1.14.1 for the safety design basis and Sections 9.4.1 and 6.4.1 for additional details.

7.3.2.10.2 HCRIS Specific Regulatory Requirements Conformance

7.3.2.10.2.1 HCRIS Conformance to Regulatory Guides

7.3.2.10.2.1.1 HCRIS - Regulatory Guide 1.22 (1972) - Periodic Testing of Protection System Actuation Functions (Safety Guide 22)

The HCRIS can be manually initiated and is capable of being tested during normal plant operation. Hand switches located in the control room allow periodic testing of the emergency fans in accordance with the requirements of Chapter 16.

7.3.2.10.2.1.2 HCRIS - Regulatory Guide 1.29 (1978) - Seismic Design Classification

The HCRIS complies with this regulatory guide as discussed in Section 3.2.

7.3.2.10.2.1.3 HCRIS - Regulatory Guide 1.30 (1972) - Quality Assurance Requirements for the Installation, Inspection, and Testing of Instrumentation and Electric Equipment (Safety Guide 30)

Refer to Section 8.1.6.1.5 and Chapter 17.

7.3.2.10.2.1.4 HCRIS - Regulatory Guide 1.47 (1973) - Bypassed and Inoperable Status Indications for Nuclear Power Plant Safety Systems

The isolation system armed, initiation, and isolation incomplete alarms meet the intent of this regulatory guide.

7.3.2.10.2.1.5 HCRIS - Regulatory Guide 1.53 (1973) - Application of the Single Failure Criterion to Nuclear Power Plant Protection Systems

Compliance with Regulatory Guide 1.53 is achieved by specifying, designing, and constructing the HCRIS to meet the single failure criterion, section 4.2 of IEEE 279 (1971) and IEEE 379 (1972). Redundant sensors and wiring are separated. The logic components and wiring are separated to ensure that a failure in a sensing element of the decision logic or an actuator will not affect its redundant counterpart and prevent protective action. Separate channels are employed so that a fault affecting one channel will not prevent the redundant channel from operating properly.

7.3.2.10.2.1.6 HCRIS - Regulatory Guide 1.62 (1973) - Manual Initiation of Protective Actions

Controls are provided in the main control room to manually initiate the HCRIS.

7.3.2.10.2.1.7 HCRIS - Regulatory Guide 1.75 (1978) - Physical Independence of Electric Systems

Refer to Section 8.1.6.1.14 for compliance with this regulatory guide.

7.3.2.10.2.1.8 HCRIS - Regulatory Guide 1.89 (1974) - Qualification of Class 1E Equipment for Nuclear Power Plants

The qualification of Class 1E equipment for the HCRIS is discussed in Section 8.1.6.1.16.

7.3.2.10.2.1.9 HCRIS - Regulatory Guide 1.100 (1977) - Seismic Qualification of Electric Equipment for Nuclear Power Plants

Conformance with this regulatory guide is covered by Section 3.10.

7.3.2.10.2.1.10 HCRIS - Regulatory Guide 1.105 (1976) - Instrument Setpoints

Instrument setpoints are selected to allow for the inaccuracy of the instrument, uncertainties in the calibration, and instrumentation drift likely to occur between calibrations to assure initiation of the HCRIS degradation of the control room environment. For safety setpoints, refer to Chapter 16.

7.3.2.10.2.1.11 HCRIS - Regulatory Guide 1.118 (1978) - Periodic Testing of Electric Power and Protection Systems

Refer to Section 8.1.6.1.21.

7.3.2.10.2.2 HCRIS Conformance to 10CFR50, Appendix A, General Design Criteria

7.3.2.10.2.2.1 HCRIS - GDC 1 - Quality Standards and Records

The HCRIS is included in an established quality assurance program described in Section 7.1.2.6 and Chapter 17.

7.3.2.10.2.2.2 HCRIS - GDC 2 - Design Bases for Protection Against Natural Phenomena

Refer to Section 7.1.2.6.

7.3.2.10.2.2.3 HCRIS - GDC 3 - Fire Protection

Refer to Section 7.1.2.6.

7.3.2.10.2.2.4 HCRIS - GDC 4 - Environmental and Dynamic Effects Design Bases

Refer to Section 7.1.2.6.

7.3.2.10.2.2.5 HCRIS - GDC 5 - Sharing of Structures, Systems, and Components

The HCRIS and control room structure are common to LGS Units 1 and 2. There are two independent divisions of isolation valves, emergency supply fans and filter trains, each capable of providing a safe environment within the control room for the operators to safely shutdown both reactor units. The control room as well as HCRIS components are located inside the control structure, a safety-related structure designed to remain functional during and following the most severe natural phenomena. Hence, sharing of the HCRIS will not impair its ability to perform its safety function.

7.3.2.10.2.2.6 HCRIS - GDC 13 - Instrumentation and Control

Instrumentation for the HCRIS is selected to monitor variables over anticipated ranges during normal and emergency operating conditions.

7.3.2.10.2.2.7 HCRIS - GDC 19 - Control Room

Refer to Sections 3.1 and 7.1.2.6.10.

7.3.2.10.2.2.8 HCRIS - GDC 20 - Protection System Functions

The HCRIS is automatically initiated by detection of radiation in the control room air intake duct.

7.3.2.10.2.2.9 HCRIS - GDC 21 - Protection System Reliability and Testability

The HCRIS is designed with redundancy and separation so that a single failure will not result in the loss of the protective function. The system is capable of being tested during normal plant operation.

7.3.2.10.2.2.10 HCRIS - GDC 22 - Protection System Independence

The components of the HCRIS are designed so that the thermal environment resulting from any potential accident condition, in which the components are required to function, will not interfere with that function. The controls of the two HCRIS are electrically and physically separated so that a single failure will not result in the loss of both divisions. Power for the components of each division is provided from separate Class 1E power sources.

7.3.2.10.2.2.11 HCRIS - GDC 23 - Protection System Failure Modes

Each HCRIS division is designed to fail in a safe state permitting its redundant divisions to isolate and ventilate the control room.

7.3.2.10.2.2.12 HCRIS - GDC 24 - Separation of Protection and Control Systems

The control system for the HCRIS does not interact with the plant control systems.

7.3.2.10.2.2.13 HCRIS - GDC 29 - Protection Against Anticipated Operational Occurrences

The high functional reliability of the HCRIS is achieved through system redundancy, physical and electrical independence, fail-safe design, inservice testability, and equipment suitable for normal and accident environments.

7.3.2.10.2.3 HCRIS Conformance to Industry Codes and Standards

7.3.2.10.2.3.1 HCRIS - IEEE 279 (1971) - Criteria for Protection Systems for Nuclear Power Generating Stations

Compliance of the HCRIS with IEEE 279 (1971) is detailed below.

7.3.2.10.2.3.1.1 HCRIS - IEEE 279 (1971), Paragraph 4.1 - General Functional Requirement

The HCRIS is an automatically initiated system based upon radiation detection in the control room intake duct as discussed in Section 6.4.1.

7.3.2.10.2.3.1.2 HCRIS - IEEE 279 (1971), Paragraph 4.2 - Single Failure Criterion

The HCRIS consists of redundant supply fans, filter trains, isolation valves, and independent sets of controls and power which meet the single failure criterion.

7.3.2.10.2.3.1.3 HCRIS - IEEE 279 (1971), Paragraph 4.3 - Quality of Components and Modules

All safety-related components are selected on the basis of suitability for the specific application. A quality control and assurance program is required to be implemented and documented by equipment vendors, which complies with the requirements set forth in 10CFR50, Appendix B.

7.3.2.10.2.3.1.4 HCRIS - IEEE 279 (1971), Paragraph 4.4 - Equipment Qualification

Refer to Section 3.11 for discussion of equipment qualification.

7.3.2.10.2.3.1.5 HCRIS - IEEE 279 (1971), Paragraph 4.5 - Channel Integrity

The HCRIS meets the channel integrity objective by utilizing the design features described in the other paragraphs of this section.

7.3.2.10.2.3.1.6 HCRIS - IEEE 279 (1971), Paragraph 4.6 - Channel Independence

The control and power circuits for each HCRIS component are physically and electrically separated.

7.3.2.10.2.3.1.7 HCRIS - IEEE 279 (1971), Paragraph 4.7 - Control and Protection System Interaction

The HCRIS has no interaction with other plant control systems. Annunciator circuits using contacts at sensor and logic relays cannot impair the operability of the HCRIS control because of electrical isolation.

7.3.2.10.2.3.1.8 HCRIS - IEEE 279 (1971), Paragraph 4.8 - Derivation of System Inputs

Initiation of the HCRIS is derived from high radiation signals from the control room air supply duct.

7.3.2.10.2.3.1.9 HCRIS - IEEE 279 (1971), Paragraph 4.9 - Capability for Sensor Checks

The HCRIS can be tested for operational availability as described in Section 7.3.1.1.10.10.

7.3.2.10.2.3.1.10 HCRIS - IEEE 279 (1971), Paragraph 4.10 - Capability for Testing and Calibration

The HCRIS is capable of being tested during normal plant operation to verify that the system is capable of performing its intended function.

7.3.2.10.2.3.1.11 HCRIS - IEEE 279 (1971), Paragraph 4.11 - Channel Bypass or Removal from Operation

A channel bypass or removal of a component of an initiation circuit channel will not prevent the HCRIS from isolating the control room.

7.3.2.10.2.3.1.12 HCRIS - IEEE 279 (1971), Paragraph 4.12 - Operating Bypasses

HCRIS bypasses are discussed in Section 7.3.1.1.10.6.

7.3.2.10.2.3.1.13 HCRIS - IEEE 279 (1971), Paragraph 4.13 - Indication of Bypasses

Each of the bypasses described in Section 7.3.1.1.10.6 are automatically indicated in the control room. In addition, each of these bypasses will initiate a system out-of-service annunciator.

7.3.2.10.2.3.1.14 HCRIS - IEEE 279 (1971), Paragraph 4.14 - Access to Means for Bypassing

Manual bypass of initiating circuits is procedurally controlled by administrative means.

7.3.2.10.2.3.1.15 HCRIS - IEEE 279 (1971), Paragraph 4.15 - Multiple Setpoints

The HCRIS radiation detectors have been designed to allow adjustment of trip setpoints to more stringent settings if required.

7.3.2.10.2.3.1.16 HCRIS - IEEE 279 (1971), Paragraph 4.16 - Completion of Protective Action Once It Is Initiated

Once the HCRIS is initiated, it will continue to operate until the operator terminates system operation by manual override.

7.3.2.10.2.3.1.17 HCRIS - IEEE 279 (1971), Paragraph 4.17 - Manual Initiation

A single failure in the control system of a division of the HCRIS cannot disable the automatic or manual operation of the other HCRIS divisions.

7.3.2.10.2.3.1.18 HCRIS - IEEE 279 (1971), Paragraph 4.18 - Access to Setpoint Adjustments, Calibration, and Test Points

Access to radiation monitor setpoints is restricted by lock and key.

7.3.2.10.2.3.1.19 HCRIS - IEEE 279 (1971), Paragraph 4.19 - Identification of Protective Actions

System operation is indirectly indicated and identified by high radiation, chlorine, or offsite toxic chemical concentration alarms.

7.3.2.10.2.3.1.20 HCRIS - IEEE 279 (1971), Paragraph 4.20 - Information Readout

The information readout for the HCRIS is described in Section 7.3.1.1.10.12.2.

7.3.2.10.2.3.1.21 HCRIS - IEEE 279 (1971), Paragraph 4.21 - System Repair

The recognition and location of failed components will be accomplished during periodic testing. Calibration verification of the radiation detectors can be performed at anytime by the use of built-in test circuits.

7.3.2.10.2.3.1.22 HCRIS - IEEE 279 (1971), Paragraph 4.22 - Identification of Protection Systems

Each logic cabinet and control panel is distinctively identified with a nameplate which identifies the safety system. Cables and cable trays are identified by a color code and tags which identify them as being of a separate channel.

7.3.2.10.2.3.2 HCRIS - IEEE 308 (1974) - Criteria for Class 1E Electrical Systems for Nuclear Power Generating Stations

Refer to Section 8.3.2.2.1.12.

7.3.2.10.2.3.3 HCRIS - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1E Electric Equipment for Nuclear Power Generating Stations

Refer to Section 7.1.2.7.4.

7.3.2.10.2.3.4 HCRIS - IEEE 336 (1971) - Installation, Inspection, and Testing Requirements for Instrumentation and Electric Equipment During the Construction of Nuclear Power Generating Station

The requirements of this standard have been met by the quality assurance program for construction of safety-related items.

7.3.2.10.2.3.5 HCRIS - IEEE 338 (1977) - Criteria for the Periodic Testing of Nuclear Power Generating Station Protection Systems

Refer to Section 7.1.2.7.6.

7.3.2.10.2.3.6 HCRIS - IEEE 344 (1971) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Station

Refer to Section 3.10.

7.3.2.10.2.3.7 HCRIS - IEEE 379 (1972) - Guide for the Application of the Single Failure Criterion to Nuclear Power Generating Station Protection Systems

The single failure criterion of IEEE 379 (1972) is met as described in Section 7.3.2.10.2.3.1.2.

7.3.2.10.2.3.8 HCRIS - IEEE 384 (1974) - Criteria for Separation of Class 1E Equipment and Circuits

Refer to Section 7.1.2.7.11.

7.3.2.11 Emergency Service Water System – Instrumentation and Controls

7.3.2.11.1 ESW General Functional Requirements Conformance

The ESW system is designed with sufficient capacity and redundancy so that a single active failure cannot impair the capability of the system to perform its safety-related functions. The system is common to Units 1 and 2 and consists of two independent loops, with two 50% capacity pumps per loop.

Both loops are designed to provide 100% of the ESW requirements. The ESW pumps start automatically on diesel generator operation after speed, voltage, and bus breaker conditions are met.

The ESW system is designed to supply makeup water to the spent fuel pools. The ESW system has an intertie to the spent fuel pools which can be used to supply makeup water by opening the two normally closed manual valves.

7.3.2.11.2 ESW Specific Regulatory Requirements Conformance

7.3.2.11.2.1 ESW Conformance to Regulatory Guides

7.3.2.11.2.1.1 ESW - Regulatory Guide 1.6 (1971) - Independence Between Redundant Standby (Onsite) Power Sources and Between Their Distribution Systems (Safety Guide 6)

Refer to Section 8.3.2.2.1.7.

7.3.2.11.2.1.2 ESW - Regulatory Guide 1.22 (1972) - Periodic Testing of Protection System Actuation Functions (Safety Guide 22)

ESW system actuation circuits can also be tested in conjunction with the periodic testing performed on the associated diesel generator. Testing of an ESW pump will in turn test the actuation circuits to the various loop valving. Bypass indication of the ESW control circuitry is provided in the main control room.

7.3.2.11.2.1.3 ESW - Regulatory Guide 1.29 (1978) - Seismic Design Classification

The ESW system complies with this regulatory guide as discussed in Section 3.2.

7.3.2.11.2.1.4 ESW - Regulatory Guide 1.32 (1977) - Criteria for Safety-Related Electric Power Systems for Nuclear Power Plants

Refer to Section 8.1.6.1.6.

7.3.2.11.2.1.5 ESW - Regulatory Guide 1.47 (1973) - Bypassed and Inoperable Status Indications for Nuclear Power Plant Safety Systems

The ESW system complies with this regulatory guide. See Section 7.3.1.1.11.12.2 for alarms.

7.3.2.11.2.1.6 ESW - Regulatory Guide 1.53 (1973) - Application of the Single Failure Criterion to Nuclear Power Plant Protection Systems

Compliance with Regulatory Guide 1.53 (1973) is achieved by specifying, designing, and constructing the ESW system so that it meets the single failure criterion described in paragraph 4.2 of IEEE 279 (1971). The ESW system consists of two loops which have separate and independent sets of controls and power. Each loop consists of two pumps; all four pumps and controls are assigned to separate divisions. The controls for the ESW valves are assigned to various divisions such that a single active or passive electrical or control failure cannot disable a complete ESW loop. In cases where two valves are in series to shutoff a flow path, the valves are assigned to two different divisions. Likewise, in cases where two valves are used to provide redundant flow paths in a single loop, the valves are assigned to two different divisions.

7.3.2.11.2.1.7 ESW - Regulatory Guide 1.62 (1973) - Manual Initiation of Protective Actions

Controls are provided in the main control room to manually initiate the ESW system.

7.3.2.11.2.1.8 ESW - Regulatory Guide 1.75 (1978) - Physical Independence of Electric Systems

The electrical separation criteria and degree of conformance to Regulatory Guide 1.75 (1975) are discussed in Sections 7.1.2.2.3 and 8.1.6.1.14.

7.3.2.11.2.1.9 ESW - Regulatory Guide 1.97 (1980) - Instrumentation for Light-Water-Cooled Nuclear Power Plants to Assess Plant and Environs Conditions During and Following an Accident

See Section 7.5.2.5.1.1.2 for a discussion of the degree of conformance.

7.3.2.11.2.1.10 ESW - Regulatory Guide 1.105 (1976) - Instrument Setpoints

See Section 7.1.2.5.25 for discussion of the degree of conformance.

7.3.2.11.2.1.11 ESW - Regulatory Guide 1.118 (1978) - Periodic Testing of Electric Power and Protection Systems

See Section 7.1.2.5.26 for a discussion of the degree of conformance.

7.3.2.11.2.2 ESW Conformance to 10CFR50 Appendix A, General Design Criteria

7.3.2.11.2.2.1 ESW - GDC 1 - Quality Standards and Records

The equipment for ESW and supporting systems is included in an established quality assurance program as discussed in Section 7.1.2.6 and Chapter 17.

7.3.2.11.2.2.2 ESW - GDC 2 - Design Bases for Protection Against Natural Phenomena

Refer to Section 7.1.2.6.

7.3.2.11.2.2.3 ESW - GDC 3 - Fire Protection

The ESW system is designed to minimize the probability and the effects of fire and explosions by using noncombustible and heat-resistant materials. Refer to Section 9.5.1 for a discussion of the fire protection system.

7.3.2.11.2.2.4 ESW - GDC 4 - Environmental and Dynamic Effects Design Bases

Environmental design is discussed in Section 3.11. Missile protection is discussed in Section 3.5.

7.3.2.11.2.2.5 ESW - GDC 5 - Sharing of Structures, Systems, and Components

Refer to Section 3.1 for a general discussion.

The ESW system is common to both Units 1 and 2 and consists of two independent loops, each having two 50% capacity pumps. Both the A and B loops are designed to provide 100% of the ESW requirements for either unit during a LOOP or LOCA. ESW loop A and B pumps and piping are physically separated or protected such that no single event can render both loops inoperable. Power is supplied from four independent divisions. Thus, sharing of the ESW system between Units 1 and 2 does not significantly impair the ability of the ESW system to perform its safety function.

7.3.2.11.2.2.6 ESW - GDC 13 - Instrumentation and Control

Monitoring instrumentation is provided for the ESW system as detailed in Section 7.3.1.1.11.12.2 to provide the operator with information on the operation of the system.

7.3.2.11.2.2.7 ESW - GDC 19 - Control Room

Instrumentation and controls for the ESW system are provided in the main control room. Instrumentation and controls for one pump and cooling water loop are also provided in the remote shutdown panels. In addition, two of the redundant ESW pumps that are not operable from the remote shutdown panel can be operated using local controls.

7.3.2.11.2.2.8 ESW - GDC 20 - Protection System Functions

The ESW system is automatically initiated on the starting of the diesel generators. The diesel generators are automatically started if a LOCA occurs as described in Section 8.3.

7.3.2.11.2.2.9 ESW - GDC 21 - Protection System Reliability and Testability

The ESW system is provided with redundancy and separation so that a single failure will not result in the loss of the protective function. The system is capable of being tested during normal plant operation.

7.3.2.11.2.2.10 ESW - GDC 22 - Protection System Independence

The controls for the two ESW cooling water loops are electrically and physically separated so that a single failure will not result in the loss of both cooling water loops. Power for the components of the two cooling water loops is provided by separate Class 1E power sources.

7.3.2.11.2.2.11 ESW - GDC 23 - Protection System Failure Modes

Refer to Section 9.2.2.

7.3.2.11.2.2.12 ESW - GDC 24 - Separation of Protection and Control Systems

The control system for the ESW system does not interact with the plant control systems. Annunciator circuits using contacts with sensors and logic relays cannot impair the operability of the ESW system control because of electrical isolation.

7.3.2.11.2.2.13 ESW - GDC 29 - Protection Against Anticipated Operational Occurrences

The ESW system is designed to provide cooling water to the components described in Section 9.2.2. The system will start upon the starting of the diesel generators, the diesel generators will start if a LOOP or a LOCA occurs as described in Section 8.3.

7.3.2.11.2.3 ESW Conformance to Industry Codes and Standards

7.3.2.11.2.3.1 ESW - IEEE 279 (1971) - Criteria for Protection Systems for Nuclear Power Generating Stations

Compliance of the ESW system with IEEE 279 (1971) is detailed as follows:

7.3.2.11.2.3.1.1 ESW - IEEE 279 (1971), Paragraph 4.1 - General Functional Requirement

The ESW system is an automatically initiated system based upon a change in status of the components in the diesel generator system as described in Section 7.3.1.1.11.4.

7.3.2.11.2.3.1.2 ESW - IEEE 279 (1971), Paragraph 4.2 - Single Failure Criterion

The ESW system consists of two cooling water loops which have separate and independent sets of controls and power and meet the single failure criterion.

7.3.2.11.2.3.1.3 ESW - IEEE 279 (1971), Paragraph 4.3 - Quality of Components and Modules

All safety-related components are selected on the basis of suitability for the specific application. Furthermore, a quality control and assurance program is required to be implemented and documented by equipment vendors, which complies with the requirements set forth in 10CFR50, Appendix B.

7.3.2.11.2.3.1.4 ESW - IEEE 279 (1971), Paragraph 4.4 - Equipment Qualification

The ESW system safety-related controls and instrumentation have been qualified as per the requirements outlined in IEEE 323 (1971) as highlighted in Section 7.1.2.7.4. The conditions for which the equipment has been qualified are those identified in Sections 3.10 and 3.11. The environmental parameters identified cover normal, abnormal, and accident conditions both inside and outside the drywell.

7.3.2.11.2.3.1.5 ESW - IEEE 279 (1971), Paragraph 4.5 - Channel Integrity

The ESW system meets the channel integrity objective by utilizing the design features described in the other paragraphs of this section.

7.3.2.11.2.3.1.6 ESW - IEEE 279 (1971), Paragraph 4.6 - Channel Independence

The control and power circuits for each pump and associated loop valving are physically and electrically separated. Divisional assignment is described in Section 7.3.1.1.11.4.

7.3.2.11.2.3.1.7 ESW - IEEE 279 (1971), Paragraph 4.7 - Control and Protection System Interaction

The ESW system has no interaction with other plant control systems. Annunciator circuits using contacts with sensors and logic relays cannot impair the operability of the ESW system control because of electrical isolation.

7.3.2.11.2.3.1.8 ESW - IEEE 279 (1971), Paragraph 4.8 - Derivation of System Inputs

Initiation of the ESW system is derived from the status of the diesel generator system. The diesel generators are started on receipt of a LOOP or a LOCA signal. The starting of the diesel generators will in turn start the ESW system. The ESW system is not started concurrently with the diesel generators due to bus loading considerations.

7.3.2.11.2.3.1.9 ESW - IEEE 279 (1971), Paragraph 4.9 - Capability for Sensor Checks

The ESW system has no process sensors in the initiation circuits.

7.3.2.11.2.3.1.10 ESW - IEEE 279 (1971), Paragraph 4.10 - Capability for Testing and Calibration

The ESW system is capable of being tested during normal plant operation to verify that the system is capable of performing its intended function. The pumps and loop valves can be tested in conjunction with the diesel generator tests.

7.3.2.11.2.3.1.11 ESW - IEEE 279 (1971), Paragraph 4.11 - Channel Bypass or Removed from Operation

Channel bypass or removal of a component of an initiation circuit channel will inhibit one of the four divisions of the ESW system. Removal of a component will not affect the operation of the other three divisions.

7.3.2.11.2.3.1.12 ESW - IEEE 279 (1971), Paragraph 4.12 - Operating Bypasses

ESW bypasses are described in Section 7.3.1.1.11.6.

7.3.2.11.2.3.1.13 ESW - IEEE 279 (1971), Paragraph 4.13 - Indication of Bypasses

Each of the bypasses described in Section 7.3.1.11.1.6 is automatically indicated in the control room. In addition, each of these bypasses will initiate a system out-of-service annunciator.

7.3.2.11.2.3.1.14 ESW - IEEE 279 (1971), Paragraph 4.14 - Access to Means for Bypassing

Access to the switchgear, motor control centers and relay panels is procedurally controlled by administrative means.

7.3.2.11.2.3.1.15 ESW - IEEE 279 (1971), Paragraph 4.15 - Multiple Setpoints

This paragraph is not applicable to the ESW system.

7.3.2.11.2.3.1.16 ESW - IEEE 279 (1971), Paragraph 4.16 - Completion of Protective Action Once It Is Initiated

Once the system is initiated, it will continue to operate until stopped by the operator. However, it is noted that the system could be temporarily stopped for diesel generator loading considerations as discussed in Section 7.3.1.1.11.6.

7.3.2.11.2.3.1.17 ESW - IEEE 279 (1971), Paragraph 4.17 - Manual Initiation

A single failure in the control system of a division of the ESW system cannot impair the automatic or manual operation of the other ESW divisions.

7.3.2.11.2.3.1.18 ESW - IEEE 279 (1971), Paragraph 4.18 - Access to Setpoint Adjustments, Calibration, and Test Points

ESW system controls do not contain safety-related process setpoints. Refer to Section 7.3.2.11.2.3.1.14 on access to ESW system controls.

7.3.2.11.2.3.1.19 ESW - IEEE 279 (1971), Paragraph 4.19 - Identification of Protective Actions

Protective action indication is provided by indicating lights or the status of the system components. Also, an annunciator is provided to alarm the automatic start of each of the four pumps.

7.3.2.11.2.3.1.20 ESW - IEEE 279 (1971), Paragraph 4.20 - Information Readout

The information readout for the ESW system is described in Section 7.3.1.1.11.12.2.

7.3.2.11.2.3.1.21 ESW - IEEE 279 (1971), Paragraph 4.21 - System Repair

The recognition and location of failed components can be accomplished during periodic testing. The control logic is not complex so that location of failed components should be straight forward. The components are mounted in such a manner as to facilitate removal and replacement.

7.3.2.11.2.3.1.22 ESW - IEEE 279 (1971), Paragraph 4.22 - Identification of Protection Systems

Each logic cabinet and control panel is distinctively identified with a nameplate which identifies the safety system. Cables and cable trays are identified by a color code and tags which identify them as being of a separate channel.

7.3.2.11.2.3.2 ESW - IEEE 308 (1974) - Criteria for Class 1E Electrical Systems for Nuclear Power Generating Stations

Refer to Section 8.3.2.2.1.12 for a discussion of this standard.

7.3.2.11.2.3.3 ESW - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1E Electric Equipment for Nuclear Power Generating Stations

Refer to Section 7.1.2.7.4.

7.3.2.11.2.3.4 ESW - IEEE 338 (1975) - Criteria for the Periodic Testing of Nuclear Power Generating System Protection Systems

Refer to Section 7.1.2.7.6.

7.3.2.11.2.3.5 ESW - IEEE 344 (1971) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations

Refer to Section 3.10 for seismic qualification.

7.3.2.11.2.3.6 ESW - IEEE 379 (1972) - Guide for the Application of the Single Failure Criterion to Nuclear Power Generating Station Protection Systems

The single failure criterion of IEEE 379 (1972) is described in Section 7.3.2.11.2.3.1.2.

7.3.2.11.2.3.7 ESW - IEEE 384 (1974) - Criteria for Separation of Class 1E Equipment and Circuits

See Section 7.1.2.7.11 for a discussion of the degree of conformance.

7.3.2.11.3 ESW Additional Design Considerations Analyses

As defined in Regulatory Guide 1.70, paragraph 7.3.2, the following considerations are addressed:

a. Loss of the plant instrument air system does not prevent the ESW system from performing its protective function.

b. Loss of cooling water to any single piece of vital equipment does not prevent the ESW system from performing its protective function.

7.3.2.12 RHR Service Water System - Instrumentation and Controls

7.3.2.12.1 RHRSW General Functional Requirements Conformance

The RHRSW system is designed to provide a reliable source of cooling water for all operating modes of the RHR system including heat removal under postaccident conditions, and also to provide water to flood the reactor core or to spray the primary containment after an accident, should it be necessary.

There are two RHRSW loops, each loop serving one RHR heat exchanger in each unit, to supply cooling water for plant shutdown. Each loop is isolated from the other by barriers, separate trenches, or distance to ensure that simultaneous loss of both loops cannot occur. Failure of either a MOV, a diesel generator, or a pump will not prevent the system from performing its safety

function. This arrangement ensures that the full heat removal capacity required is available after the postulated active or passive electrical or control component failure. Refer to Section 7.1.2.1.15.2.1 for the design basis and Section 9.2.3 for additional details.

7.3.2.12.2 RHRSW Specific Regulatory Requirements Conformance

7.3.2.12.2.1 RHRSW Conformance to Regulatory Guides

7.3.2.12.2.1.1 RHRSW - Regulatory Guide 1.6 (1971) - Independence Between Redundant Standby (Onsite) Power Sources and Between Their Distribution Systems (Safety Guide 6)

Refer to Section 8.1.6.1.1 and 8.3.2.2.1.7.

7.3.2.12.2.1.2 RHRSW - Regulatory Guide 1.22 (1972) - Periodic Testing of Protection System Actuation Functions (Safety Guide 22)

The RHRSW system is a manually initiated system and is capable of being tested during normal plant operation. The system is tested by the manual testing of each of the cooling water loop components. Control switches with status lights are provided in the control room for the system pumps and valves. Also, the cooling water loop flow and pressure indicators will provide an indication of proper system operation.

7.3.2.12.2.1.3 RHRSW - Regulatory Guide 1.29 (1978) - Seismic Design Classification

The RHRSW system complies with this regulatory guide as discussed in Section 3.2.

7.3.2.12.2.1.4 RHRSW - Regulatory Guide 1.32 (1977) - Criteria for Safety-Related Electric Systems for Nuclear Power Plants

Refer to Section 8.1.6.1.6.

7.3.2.12.2.1.5 RHRSW - Regulatory Guide 1.47 (1973) - Bypassed and Inoperable Status Indications for Nuclear Power Plant Safety Systems

RHRSW system conforms to this regulatory guide as a support system annunciated for status under the RHR system.

7.3.2.12.2.1.6 RHRSW - Regulatory Guide 1.53 (1973) - Application of the Single Failure Criterion to Nuclear Power Plant Protection Systems

Compliance with Regulatory Guide 1.53 (1973) is achieved by specifying, designing, and constructing the RHRSW system so that it meets the single failure criterion described in paragraph 4.2 of IEEE 279 (1971). The RHRSW system consists of two independent cooling water loops with separate and independent controls and power which are segregated by division.

7.3.2.12.2.1.7 RHRSW - Regulatory Guide 1.62 (1973) - Manual Initiation of Protective Actions

The RHRSW system is a manually initiated system. All controls necessary to operate the system are in the main control room.

7.3.2.12.2.1.8 RHRSW - Regulatory Guide 1.75 (1978) - Physical Independence of Electric Systems

The electrical separation criteria and degree of conformance to Regulatory Guide 1.75 (1975) are discussed in Sections 7.1.2.2.3 and 8.1.6.1.14.

7.3.2.12.2.1.9 RHRSW - Regulatory Guide 1.97 (1980) - Instrumentation for Light-Water-Cooled Nuclear Power Plants to Assess Plant and Environs Conditions During and Following an Accident

See Section 7.5.2.5.1.1.2 for a discussion of the degree of conformance.

7.3.2.12.2.1.10 RHRSW - Regulatory Guide 1.105 (1976) - Instrument Setpoints

See Section 7.1.2.5.25 for a discussion of the degree of conformance.

7.3.2.12.2.1.11 RHRSW - Regulatory Guide 1.118 (1978) - Periodic Testing of Electric Power and Protection Systems

See Section 7.1.2.5.26 for a discussion of the degree of conformance.

7.3.2.12.2.2 RHRSW Conformance to 10CFR50, Appendix A, General Design Criteria

7.3.2.12.2.2.1 RHRSW - GDC 1 - Quality Standards and Records

The equipment for ESF and supporting systems is included in an established quality assurance program as discussed in Section 3.1 and Chapter 17.

7.3.2.12.2.2.2 RHRSW - GDC 2 - Design Bases for Protection Against Natural Phenomena

Refer to Section 3.1.

7.3.2.12.2.2.3 RHRSW - GDC 3 - Fire Protection

The RHRSW system is designed to minimize the probability and the effects of fire and explosions by using noncombustible and heat-resistant materials. Refer to Section 9.5.1 for a discussion of the fire protection system.

7.3.2.12.2.2.4 RHRSW - GDC 4 - Environmental and Dynamic Effects Design Bases

Environmental design is discussed in Section 3.11. Missile protection design is discussed in Section 3.5.

7.3.2.12.2.2.5 RHRSW - GDC 5 - Sharing of Structures, Systems, and Components

Refer to Section 3.1 for a general discussion.

The RHRSW system is common to both Units 1 and 2 and consists of two loops. Each loop services one RHR heat exchanger in each unit and provides sufficient cooling to satisfy its safety function. Each loop has two 50% capacity pumps which are powered from separate power sources. Loss of one loop does not affect the capability of the second loop to safely shutdown either or both units during emergency conditions. Thus, sharing of the RHRSW system between Units 1 and 2 does not significantly impair the ability of the RHRSW system to perform its safety function.

7.3.2.12.2.2.6 RHRSW - GDC 13 - Instrumentation and Control

Monitoring instrumentation is provided as detailed in Section 7.3.1.1.12.12.2 to provide the operator with information on the operation of the system.

7.3.2.12.2.2.7 RHRSW - GDC 19 - Control Room

Instrumentation and controls for the RHRSW system are provided in the main control room. Instrumentation and controls for two RHRSW pumps are also provided in the remote shutdown panel. In addition, both of the two redundant RHRSW pumps that are not operable from the remote shutdown panel, can be operated using local controls.

7.3.2.12.2.2.8 RHRSW - GDC 20 - Protection System Functions

The RHRSW system is a manually initiated system. This system is not required immediately after an accident. The safety function of the system is adequately ensured by manual initiation.

7.3.2.12.2.2.9 RHRSW - GDC 21 - Protection System Reliability and Testability

The RHRSW system is provided with redundancy and separation so that a single failure will not result in the loss of the protective function. The system is capable of being tested during normal plant operation.

7.3.2.12.2.2.10 RHRSW - GDC 22 - Protection System Independence

The controls for the two RHRSW cooling water loops are electrically and physically separated so that a single failure will not result in the loss of both cooling water loops. Power for the components of the cooling water loops is provided by separate Class 1E power sources.

7.3.2.12.2.2.11 RHRSW - GDC 23 - Protection System Failure Modes

The various failure modes of the RHRSW system are described in Section 9.2.3.

7.3.2.12.2.2.12 RHRSW - GDC 24 - Separation of Protection and Control Systems

The control system for the RHRSW system does not interact with the plant control system. Annunciator circuits using contacts of sensors and logic relays cannot impair the operability of the RHRSW system control because of electrical isolation.

7.3.2.12.2.2.13 RHRSW - GDC 29 - Protection Against Anticipated Operational Occurrences

The RHRSW system is designed to provide cooling water to the components described in Section 9.2.3. The redundancy and separation of the two loops and manual initiation of the system ensure its ability to accomplish its safety function in the event of anticipated operational occurrences.

7.3.2.12.2.2.14 RHRSW - GDC 34 - Residual Heat Removal

The RHRSW system provides cooling water to the RHR heat exchangers as described in Section 9.2.3. The RHRSW system is provided with redundancy and separation so that a single failure will not result in the loss of the protective function.

7.3.2.12.2.3 RHRSW Conformance to Industry Codes and Standards

7.3.2.12.2.3.1 RHRSW - IEEE 279 (1971) - Criteria for Protection Systems for Nuclear Power Generating Stations

Compliance of the RHRSW system with IEEE 279 (1971) is detailed as follows:

7.3.2.12.2.3.1.1 RHRSW - IEEE 279 (1971), Paragraph 4.1 - General Functional Requirement

The RHRSW system is not an automatically initiated system. The system's safety function is adequately ensured by manual initiation.

7.3.2.12.2.3.1.2 RHRSW - IEEE 279 (1971), Paragraph 4.2 - Single Failure Criterion

The RHRSW system consists of two cooling water loops which have separate and independent controls and power, and therefore meets the single failure criterion.

7.3.2.12.2.3.1.3 RHRSW - IEEE 279 (1971), Paragraph 4.3 - Quality of Components and Modules

All safety-related components are selected on the basis of suitability for the application. A quality control and assurance program is required to be implemented by the equipment vendors which complies with the requirements set forth in 10CFR50, Appendix B.

7.3.2.12.2.3.1.4 RHRSW - IEEE 279 (1971), Paragraph 4.4 - Equipment Qualification

The RHRSW system safety-related controls and instrumentation have been qualified as per the requirements outlined in IEEE 323 (1971) as highlighted in Section 7.1.2.7.4. The conditions for which the equipment has been qualified are those identified in Sections 3.10 and 3.11. The identified parameters cover normal, abnormal and accident conditions both inside and outside the drywell.

7.3.2.12.2.3.1.5 RHRSW - IEEE 279 (1971), Paragraph 4.5 - Channel Integrity

The RHRSW system meets the channel integrity objective by utilizing the design features described in the other paragraphs of this Section.

7.3.2.12.2.3.1.6 RHRSW - IEEE 279 (1971), Paragraph 4.6 - Channel Independence

The control, instrumentation, and power circuits for the components of each of the RHRSW cooling water loop are physically and electrically separated. The divisional assignments of the system components are described in Section 7.3.1.1.12.9.

7.3.2.12.2.3.1.7 RHRSW - IEEE 279 (1971), Paragraph 4.7 - Control and Protection System Interaction

The RHRSW system has no interaction with the plant control systems. Annunciator circuits using contacts of circuits of sensors and logic relays cannot impair the operability of the RHRSW system control because of electrical isolation.

7.3.2.12.2.3.1.8 RHRSW - IEEE 279 (1971), Paragraph 4.8 - Derivation of System Inputs

The RHRSW system is a manually initiated system.

7.3.2.12.2.3.1.9 RHRSW - IEEE 279 (1971), Paragraph 4.9 - Capability for Sensor Checks

The RHRSW system is a manually initiated system. However, the system includes radiation instrumentation which trips components of the system as described in Section 7.3.1.1.12.5. These radiation sensors have provisions for a check source for testing this instrumentation during normal plant operation.

7.3.2.12.2.3.1.10 RHRSW - IEEE 279 (1971), Paragraph 4.10 - Capability for Testing and Calibration

RHRSW system is capable of being tested during normal plant operation to verify that the system is capable of performing its intended function.

7.3.2.12.2.3.1.11 RHRSW - IEEE 279 (1971), Paragraph 4.11 - Channel Bypass or Removal From Operation

Channel bypass or removal of a component for maintenance will inhibit the proper operation of one of the cooling water loops. However, it will not affect the proper operation of the other cooling water loop.

7.3.2.12.2.3.1.12 RHRSW - IEEE 279 (1971), Paragraph 4.12 - Operating Bypasses

RHRSW bypasses are described in Section 7.3.1.1.12.6.

7.3.2.12.2.3.1.13 RHRSW - IEEE 279 (1971), Paragraph 4.13 - Indication of Bypasses

Each of the bypasses described in Section 7.3.1.1.12.6 is automatically indicated in the control room. In addition, each of the bypasses will initiate a system annunciator if required.

7.3.2.12.2.3.1.14 RHRSW - IEEE 279 (1971), Paragraph 4.14 - Access to Means for Bypassing

Access to the switchgear and the relay panels will be procedurally controlled by administrative means.

7.3.2.12.2.3.1.15 RHRSW - IEEE 279 (1971), Paragraph 4.15 - Multiple Setpoints

This paragraph is not applicable to the RHRSW system.

7.3.2.12.2.3.1.16 RHRSW - IEEE 279 (1971), Paragraph 4.16 - Completion of Protective Action Once It Is Initiated

Once the system is started, it will continue to operate until stopped by the operator.

7.3.2.12.2.3.1.17 RHRSW - IEEE 279 (1971), Paragraph 4.17 - Manual Initiation

The RHRSW system is a manually initiated system.

7.3.2.12.2.3.1.18 RHRSW - IEEE 279 (1971), Paragraph 4.18 - Access to Setpoint Adjustments, Calibration, and Test Points

Access to the switchgear, the relay panels, and setpoint adjustments will be procedurally controlled by administrative means.

7.3.2.12.2.3.1.19 RHRSW - IEEE 279 (1971), Paragraph 4.19 - Identification of Protective Actions

The RHRSW system is manually initiated. The status of the system components is shown by indicating lights in the control room.

7.3.2.12.2.3.1.20 RHRSW - IEEE 279 (1971), Paragraph 4.20 - Information Readout

The information readout available for the RHRSW system is described in Section 7.3.1.1.12.12.2.

7.3.2.12.2.3.1.21 RHRSW - IEEE 279 (1971), Paragraph 4.21 - System Repair

The recognition and location of failed components can be accomplished during periodic testing. The control logic is not complex so that location of failed components should be straight forward. The components are mounted in such a manner as to facilitate removal and replacement.

7.3.2.12.2.3.1.22 RHRSW - IEEE 279 (1971), Paragraph 4.22 - Identification of Protection Systems

Each logic cabinet and control panel is distinctively identified with a nameplate which identifies the safety system. Cables and cable trays are identified by a color code and tags which identify them as being of separate channels.

7.3.2.12.2.3.2 RHRSW - IEEE 308 (1974) - Criteria for Class 1E Electrical Systems for Nuclear Power Generating Stations

Refer to Section 8.3.2.2.1.12 for a discussion on this standard.

7.3.2.12.2.3.3 RHRSW - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1E Electric Equipment for Nuclear Power Generating Stations

Refer to Section 7.1.2.7.4.

7.3.2.12.2.3.4 RHRSW - IEEE 338 (1975) - Criteria for the Periodic Testing of Nuclear Power Generating Station Protection Systems

Refer to discussion on Regulatory Guide 1.118 in Section 7.1.2.5.26.

7.3.2.12.2.3.5 RHRSW - IEEE 344 (1971) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations

Refer to Section 7.1.2.7.7 for seismic qualification.

7.3.2.12.2.3.6 RHRSW - IEEE 379 (1972) - Guide for the Application of the Single Failure Criterion for Nuclear Power Generating Station Protection Systems

The single failure criterion of IEEE 379 (1972) is met as described in Section 7.3.2.12.2.3.1.2.

7.3.2.12.2.3.7 RHRSW - IEEE 384 (1974) - Criteria for Separation of Class 1E Equipment and Circuits

See Section 7.1.2.7.11 for a discussion of degree of conformance.

7.3.2.12.3 RHRSW Additional Design Considerations Analyses

As defined in Regulatory Guide 1.70, paragraph 7.3.2 the following considerations are addressed:

a. Loss of the plant instrument air system does not prevent the RHRSW system from performing its protective function.

b. Loss of cooling water to any single piece of vital equipment does not prevent the RHRSW system from performing its protective function.

7.3.2.13 Control Enclosure Chilled Water System – Instrumentation and Controls

7.3.2.13.1 CECWS General Functional Requirements Conformance

The CECWS is designed with sufficient capacity and redundancy so that a single active or passive electrical or control component failure will not prevent the system from performing its safety-related functions. The CECWS is automatically initiated by operation of the control room air supply fan cabinets, the auxiliary equipment room air supply fan cabinets, the emergency switchgear and battery room air supply fan cabinets, and the SGTS room and access area unit coolers. Refer to Section 7.1.2.1.35.1 for the safety design basis.

7.3.2.13.2 CECWS Specific Regulatory Requirements Conformance

7.3.2.13.2.1 CECWS Conformance to Regulatory Guides

7.3.2.13.2.1.1 CECWS - Regulatory Guide 1.22 (1972) - Periodic Testing of Protection System Actuation Functions (Safety Guide 22)

The CECWS can be manually initiated and is capable of being tested during normal plant operation. Hand switches located in the control room allow periodic testing of the chillers and pumps in accordance with the requirements of Chapter 16.

7.3.2.13.2.1.2 CECWS - Regulatory Guide 1.29 (1978) - Seismic Design Classification

The CECWS complies with this regulatory guide as discussed in Section 3.2.

7.3.2.13.2.1.3 CECWS - Regulatory Guide 1.30 (1972) - Quality Assurance Requirements for the Installation, Inspection, and Testing of Instrumentation and Electric Equipment (Safety Guide 30)

Refer to Section 8.1.6.1.5 and Chapter 17.

7.3.2.13.2.1.4 CECWS - Regulatory Guide 1.47 (1973) - Bypassed and Inoperable Status Indication for Nuclear Power Plant Safety Systems

The CECWS by providing indication in the control room of pump and chiller status meets the intent of this regulatory guide.

7.3.2.13.2.1.5 CECWS - Regulatory Guide 1.53 (1973) - Application of the Single Failure Criterion to Nuclear Power Plant Protection Systems

Compliance with Regulatory Guide 1.53 is achieved by specifying, designing, and constructing the CECWS to meet the single failure criterion, section 4.2 of IEEE 279 (1971) and IEEE 379 (1972).

Redundant sensors and wiring are separated. The logic components and wiring are separated to ensure that a failure in a sensing element or the decision logic or an actuator will not affect its redundant counterpart and prevent protective action. Separate channels are employed so that a fault affecting one channel will not prevent the redundant channel from operating properly.

7.3.2.13.2.1.6 CECWS - Regulatory Guide 1.62 (1973) - Manual Initiation of Protective Actions

Controls are provided in the main control room to manually initiate the CECWS.

7.3.2.13.2.1.7 CECWS - Regulatory Guide 1.75 (1978) - Physical Independence of Electric Systems

Refer to Section 8.1.6.1.14 for compliance with this regulatory guide.

7.3.2.13.2.1.8 CECWS - Regulatory Guide 1.89 (1974) - Qualification of Class 1E Equipment for Nuclear Power Plants

The qualification of Class 1E equipment for the CECWS system is discussed in Section 8.1.6.1.16.

7.3.2.13.2.1.9 CECWS - Regulatory Guide 1.100 (1977) - Seismic Qualification of Electric Equipment for Nuclear Power Plants

Conformance with this regulatory guide is discussed in Section 3.10.

7.3.2.13.2.1.10 CECWS - Regulatory Guide 1.105 (1976) - Instrument Setpoints

The CECWS is automatically initiated by unit cooler operation. Refer to Section 7.3.2.15.1.2.10.

7.3.2.13.2.1.11 CECWS - Regulatory Guide 1.118 (1978) - Periodic Testing of Electric Power and Protection Systems

Refer to Section 7.1.2.5.26.

7.3.2.13.2.2 CECWS Conformance to 10CFR50, Appendix A, General Design Criteria

7.3.2.13.2.2.1 CECWS - GDC 1 - Quality Standards and Records

The CECWS is included in an established quality assurance program discussed in Section 7.1.2.6 and Chapter 17.

7.3.2.13.2.2.2 CECWS - GDC 2 - Design Bases for Protection Against Natural Phenomena

Refer to Section 7.1.2.6.

7.3.2.13.2.2.3 CECWS - GDC 3 - Fire Protection

Refer to Section 7.1.2.6.

7.3.2.13.2.2.4 CECWS - GDC 4 - Environmental and Dynamic Effects Design Bases

Refer to Section 7.1.2.6.

7.3.2.13.2.2.5 CECWS - GDC 5 - Sharing of Structures, Systems, and Components

The CECWS is common to Units 1 and 2. There are two independent divisions, each capable of providing sufficient chilled water for unit cooler operation during safe shutdown conditions. Since the CECWS is designed to remain functional during and after the most severe natural phenomena, sharing this system will not impair its ability to perform its safety function.

7.3.2.13.2.2.6 CECWS - GDC 13 - Instrumentation and Control

Instrumentation for the CECWS is selected to monitor variables over anticipated ranges during normal and emergency operating conditions.

7.3.2.13.2.3 CECWS Conformance to Industry Codes and Standards

7.3.2.13.2.3.1 CECWS - IEEE 279 (1971) - Criteria for Protection Systems for Nuclear Power Generating Stations

Compliance of the CECWS with IEEE 279 (1971) is detailed as follows:

7.3.2.13.2.3.1.1 CECWS - IEEE 279 (1971), Paragraph 4.1 - General Functional Requirement

The CECWS is automatically initiated by unit cooler operation.

7.3.2.13.2.3.1.2 CECWS - IEEE 279 (1971), Paragraph 4.2 - Single Failure Criterion

The CECWS consists of redundant chillers, pumps, piping, and independent sets of controls and power which meet the single failure criterion.

7.3.2.13.2.3.1.3 CECWS - IEEE 279 (1971), Paragraph 4.3 - Quality of Components and Modules

All safety-related components are selected on the basis of suitability for the specific application. A quality control and assurance program is required to be implemented and documented by equipment vendors, which complies with the requirements set forth in 10CFR50, Appendix B.

7.3.2.13.2.3.1.4 CECWS - IEEE 279 (1971), Paragraph 4.4 - Equipment Qualification

Refer to Section 3.11 for discussion of equipment qualification.

7.3.2.13.2.3.1.5 CECWS - IEEE 279 (1971), Paragraph 4.5 - Channel Integrity

The CECWS meets the channel integrity objective by utilizing the design features described in the other paragraphs of this section.

7.3.2.13.2.3.1.6 CECWS - IEEE 279 (1971), Paragraph 4.6 - Channel Independence

The control and power circuits for each CECWS component are physically and electrically separated.

7.3.2.13.2.3.1.7 CECWS - IEEE 279 (1971), Paragraph 4.7 - Control and Protection System Interaction

The CECWS interacts with the operation of the unit coolers as discussed in Section 7.3.2.15.1. No single event or failure of the control system can result in a condition requiring protective action and can concurrently prevent the operation of the CECWS.

7.3.2.13.2.3.1.8 CECWS - IEEE 279 (1971), Paragraph 4.8 - Derivation of System Inputs

Initiation of the CECWS is derived from operation of the control room air supply fan cabinets, the auxiliary equipment room air supply fan cabinets, the emergency switchgear and battery room air supply fan cabinets and/or the SGTS room and access area unit coolers.

7.3.2.13.2.3.1.9 CECWS - IEEE 279 (1971), Paragraph 4.9 - Capability for Sensor Checks

The CECWS can be tested for operational availability as per Section 7.3.1.1.13.10.

7.3.2.13.2.3.1.10 CECWS - IEEE 279 (1971), Paragraph 4.10 - Capability for Testing and Calibration

The CECWS is capable of being tested during normal plant operation to verify that the system is capable of performing its intended function.

7.3.2.13.2.3.1.11 CECWS - IEEE 279 (1971), Paragraph 4.11 - Channel Bypass or Removal from Operation

A channel bypass or removal of a component of an initiation circuit channel will prevent the CECWS itself from complying with the single failure criterion.

7.3.2.13.2.3.1.12 CECWS - IEEE 279 (1971), Paragraph 4.12 - Operating Bypasses

CECWS bypasses are discussed in Section 7.3.1.1.13.6.

7.3.2.13.2.3.1.13 CECWS - IEEE 279 (1971), Paragraph 4.13 - Indication of Bypasses

Each of the bypasses described in Section 7.3.1.1.13.6 are automatically indicated in the control room. In addition, each of these bypasses will initiate a system out-of-service annunciator.

7.3.2.13.2.3.1.14 CECWS - IEEE 279 (1971), Paragraph 4.14 - Access to Means for Bypassing

Manual bypass of initiating circuits will be procedurally controlled by administrative means.

7.3.2.13.2.3.1.15 CECWS - IEEE 279 (1971), Paragraph 4.15 - Multiple Setpoints

Refer to Section 7.3.2.15.1.2.3.1.15.

7.3.2.13.2.3.1.16 CECWS - IEEE 279 (1971), Paragraph 4.16 - Completion of Protective Action Once it Is Initiated

Once the CECWS is initiated, it will continue to operate until the operator terminates system operation by manual override.

7.3.2.13.2.3.1.17 CECWS - IEEE 279 (1971), Paragraph 4.17 - Manual Initiation

A single failure in the control system of a division of the CECWS cannot disable the automatic or manual operation of the other CECWS division.

7.3.2.13.2.3.1.18 CECWS - IEEE 279 (1971), Paragraph 4.18 - Access to Setpoint Adjustments, Calibration, and Test Points

Refer to Section 7.3.2.15.1.2.3.1.18.

7.3.2.13.2.3.1.19 CECWS - IEEE 279 (1971), Paragraph 4.19 - Identification of Protective Actions

System operation is indirectly indicated and identified by pump motor status and flow indication for the pumps.

7.3.2.13.2.3.1.20 CECWS - IEEE 279 (1971), Paragraph 4.20 - Information Readout

The information readout for the CECWS is described in Section 7.3.1.1.13.12.2.

7.3.2.13.2.3.1.21 CECWS - IEEE 279 (1971), Paragraph 4.21 - System Repair

The recognition and location of failed components can be accomplished during periodic testing.

7.3.2.13.2.3.1.22 CECWS - IEEE 279 (1971), Paragraph 4.22 - Identification of Protection Systems

Each logic cabinet and control panel is distinctively identified with a nameplate which identifies the safety system. Cables and cable trays are identified by a color code and tags which identify them as being of a separate channel.

7.3.2.13.2.3.2 CECWS - IEEE 308 (1974) - Criteria for Class 1E Electrical Systems for Nuclear Power Generating Stations

Refer to Section 8.3.2.2.1.12.

7.3.2.13.2.3.3 CECWS - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1E Electric Equipment for Nuclear Power Generating Stations

Refer to Section 7.1.2.7.4.

7.3.2.13.2.3.4 CECWS - IEEE 336 (1971) - Installation, Inspection, and Testing Requirements for Instrumentation and Electric Equipment During the Construction of Nuclear Power Generating Stations

The requirements of this standard have been met by the quality assurance program for construction of safety-related items.

7.3.2.13.2.3.5 CECWS - IEEE 338 (1975) - Criteria for the Periodic Testing of Nuclear Power Generating Station Protection Systems

Refer to Section 7.1.2.7.6.

7.3.2.13.2.3.6 CECWS - IEEE 344 (1971) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations

Refer to Section 3.10.

7.3.2.13.2.3.7 CECWS - IEEE 379 (1972) - Guide for the Application of the Single Failure Criterion to Nuclear Power Generating Station Protection Systems

The single failure criterion of IEEE 379 (1972) is met as described in Section 7.3.2.13.2.1.5.

7.3.2.13.2.3.8 CECWS - IEEE 384 (1974) - Criteria for Separation of Class 1E Equipment and Circuits

Refer to Section 7.1.2.7.11.

7.3.2.13.3 CECWS Additional Design Considerations Analyses

As defined in Regulatory Guide 1.70, paragraph 7.3.2, the following considerations are addressed:

a. Loss of the plant instrument air system does not prevent the CECWS from performing its protective function.

b. Loss of cooling water to any single piece of vital equipment does not prevent the CECWS from performing its protective function.

7.3.2.14 Class 1E Power Systems

For an analysis of the Class 1E power systems refer to the following:

a. Refer to Section 8.3.1.2 for an analysis of the Class 1E ac power system.

b. Refer to Section 8.3.2.2 for an analysis of the Class 1E dc power system.

7.3.2.15 Safety-Related Equipment Area Cooling Ventilation Systems

7.3.2.15.1 SGTS Filter Room and Access Area Unit Coolers - Instrumentation and Controls

7.3.2.15.1.1 SGTS-UC General Functional Requirements Conformance

The SGTS-UC are designed with sufficient capacity and redundancy so that a single or passive electrical or control component active failure will not prevent the system from performing its safety-related functions. The SGTS-UC are automatically initiated by high temperature switches. Refer to Section 7.1.2.1.33.1 for the safety design basis and Section 9.4.1.5.1 for additional details.

7.3.2.15.1.2 SGTS-UC Specific Regulatory Requirements Conformance

7.3.2.15.1.2.1 SGTS-UC Conformance to Regulatory Guides

7.3.2.15.1.2.1.1 SGTS-UC - Regulatory Guide 1.22 (1972) - Periodic Testing of Protection System Actuation Functions (Safety Guide 22)

The SGTS-UC can be manually initiated and are capable of being tested during normal plant operation. Hand switches located in the control enclosure allow periodic testing of the unit coolers in accordance with the requirements of Chapter 16.

7.3.2.15.1.2.1.2 SGTS-UC - Regulatory Guide 1.29 (1978) - Seismic Design Classification

The unit coolers comply with this regulatory guide as discussed in Section 3.2.

7.3.2.15.1.2.1.3 SGTS-UC - Regulatory Guide 1.30 (1972) - Quality Assurance Requirements for the Installation, Inspection and Testing of Instrumentation and Electric Equipment (Safety Guide 30)

Refer to Section 8.1.6.1.5 and Chapter 17.

7.3.2.15.1.2.1.4 SGTS-UC - Regulatory Guide 1.47 (1973) - Bypassed and Inoperable Status Indication for Nuclear Power Plant Safety Systems

The SGTS-UC system meets the intent of this regulatory guide through the use of a fan trouble alarm.

7.3.2.15.1.2.1.5 SGTS-UC - Regulatory Guide 1.53 (1973) - Application of the Single Failure Criterion to Nuclear Power Plant Protection Systems

Compliance with Regulatory Guide 1.53 is achieved by specifying, designing and constructing the unit coolers to meet the single failure criterion, section 4.2 of IEEE 279 (1971) and IEEE 379 (1972). Redundant sensors and wiring are separated. The logic components and wiring are separated to ensure that a failure in a sensing element or the decision logic or an actuator will not affect its redundant counterpart and prevent protective action. Separate channels are employed so that a fault affecting one channel will not prevent the redundant channel from operating properly.

7.3.2.15.1.2.1.6 SGTS-UC - Regulatory Guide 1.62 (1973) - Manual Initiation of Protective Actions

Controls are provided on the SGTS local panel to manually initiate the unit coolers.

7.3.2.15.1.2.1.7 SGTS-UC - Regulatory Guide 1.75 (1978) - Physical Independence of Electric Systems

Refer to Section 8.1.6.1.14 for compliance.

7.3.2.15.1.2.1.8 SGTS-UC - Regulatory Guide 1.89 (1974) - Qualification of Class 1E Equipment for Nuclear Power Plants

The qualification of Class 1E equipment for the SGTS-UC is discussed in Section 8.1.6.1.16.

7.3.2.15.1.2.1.9 SGTS-UC - Regulatory Guide 1.100 (1977) - Seismic Qualification of Electric Equipment for Nuclear Power Plants

Conformance is covered by Section 3.10.

7.3.2.15.1.2.1.10 SGTS-UC - Regulatory Guide 1.105 (1976) - Instrument Setpoints

Instrument setpoints are selected to allow for the inaccuracy of the instrument, uncertainties in the calibration, and instrumentation drift likely to occur between calibrations to assure initiation of the SGTS-UC prior to potential degradation of the control room environment.

7.3.2.15.1.2.1.11 SGTS-UC - Regulatory Guide 1.118 (1978) - Periodic Testing of Electric Power and Protection Systems

Refer to Section 7.1.2.5.26.

7.3.2.15.1.2.2 SGTS-UC Conformance to 10CFR50, Appendix A, General Design Criteria

7.3.2.15.1.2.2.1 SGTS-UC - GDC 1 - Quality Standards and Records

The SGTS unit coolers included in an established quality assurance program discussed in Section 3.1 and Chapter 17.

7.3.2.15.1.2.2.2 SGTS-UC - GDC 2 - Design Bases for Protection Against Natural Phenomena

Refer to Section 3.1.

7.3.2.15.1.2.2.3 SGTS-UC - GDC 3 - Fire Protection

Refer to Section 3.1.

7.3.2.15.1.2.2.4 SGTS-UC - GDC 4 - Environmental and Dynamic Effects Design Bases

Refer to Section 3.1.

7.3.2.15.1.2.2.5 SGTS-UC - GDC 5 - Sharing of Structures, Systems and Components

Refer to Section 3.1 for general discussion. The SGTS-UC are common to Units 1 and 2. There are two independent divisions, each capable of providing 100% of the cooling requirements for either unit. Therefore, sharing these unit coolers will not impair their ability to perform their safety function.

7.3.2.15.1.2.2.6 SGTS-UC - GDC 13 - Instrumentation and Control

Instrumentation for the SGTS-UC is selected to monitor variables over anticipated ranges during normal and emergency operating conditions.

7.3.2.15.1.2.3 SGTS-UC Conformance to Industry Codes and Standards

7.3.2.15.1.2.3.1 SGTS-UC - IEEE 279 (1971) - Criteria for Protection Systems for Nuclear Power Generating Stations

Compliance of the SGTS-UC with IEEE 279 (1971) is detailed as follows:

7.3.2.15.1.2.3.1.1 SGTS-UC - IEEE 279 (1971), Paragraph 4.1 - General Functional Requirement

The SGTS-UC are automatically initiated by high temperature switches.

7.3.2.15.1.2.3.1.2 SGTS-UC - IEEE 279 (1971), Paragraph 4.2 - Single Failure Criterion

The SGTS-UC consist of redundant unit coolers, and independent sets of controls and power which meet the single failure criterion.

7.3.2.15.1.2.3.1.3 SGTS-UC - IEEE 279 (1971), Paragraph 4.3 - Quality of Components and Modules

All safety-related components are selected on the basis of suitability for the specific application. A quality control and assurance program is required to be implemented and documented by equipment vendors, which complies with the requirements set forth in 10CFR50, Appendix B.

7.3.2.15.1.2.3.1.4 SGTS-UC - IEEE 279 (1971), Paragraph 4.4 - Equipment Qualification

Refer to Section 3.11 for discussion of equipment qualification.

7.3.2.15.1.2.3.1.5 SGTS-UC - IEEE 279 (1971), Paragraph 4.5 - Channel Integrity

The SGTS-UC meet the channel integrity by utilizing the design features described in the other paragraphs of this section.

7.3.2.15.1.2.3.1.6 SGTS-UC - IEEE 279 (1971), Paragraph 4.6 - Channel Independence

The control and power circuits for the unit coolers component are physically and electrically separated.

7.3.2.15.1.2.3.1.7 SGTS-UC - IEEE 279 (1971), Paragraph 4.7 - Control and Protection System Interaction

The SGTS-UC have no interaction with other plant control systems. Annunciator circuits using contacts at sensor and logic relays cannot impair the operability of the control because of electrical isolation.

7.3.2.15.1.2.3.1.8 SGTS-UC - IEEE 279 (1971), Paragraph 4.8 - Derivation of System Inputs

Initiation of the SGTS-UC is derived from high temperature signals from the control enclosure.

7.3.2.15.1.2.3.1.9 SGTS-UC - IEEE 279 (1971), Paragraph 4.9 - Capability for Sensor Checks

The SGTS-UC can be tested for operational availability per Section 7.3.1.1.15.1.10.

7.3.2.15.1.2.3.1.10 SGTS-UC - IEEE 279 (1971), Paragraph 4.10 - Capability for Testing and Calibration

The SGTS-UC are capable of being tested during normal plant operation to verify that the system is capable of performing its intended function.

7.3.2.15.1.2.3.1.11 SGTS-UC - IEEE 279 (1971), Paragraph 4.11 - Channel Bypass or Removal from Operation

A channel bypass or removal of a component of an initiation circuit channel will prevent the SGTS-UC themselves from complying with the single failure criterion.

7.3.2.15.1.2.3.1.12 SGTS-UC - IEEE 279 (1971), Paragraph 4.12 - Operating Bypasses

SGTS-UC bypasses are discussed in Section 7.3.1.1.15.1.6.

7.3.2.15.1.2.3.1.13 SGTS-UC - IEEE 279 (1971), Paragraph 4.13 - Indication of Bypasses

Each of the bypasses described in Section 7.3.1.1.15.1.6 is automatically indicated in the control room. In addition, each of these bypasses will initiate a system out-of-service annunciator.

7.3.2.15.1.2.3.1.14 SGTS-UC - IEEE 279 (1971), Paragraph 4.14 - Access to Means for Bypassing

Manual bypass of initiating circuits will be procedurally controlled by administrative means.

7.3.2.15.1.2.3.1.15 SGTS-UC - IEEE 279 (1971), Paragraph 4.15 - Multiple Setpoints

The SGTS-UC temperature switches are suitable for adjustment of trip points to more stringent settings if required.

7.3.2.15.1.2.3.1.16 SGTS-UC - IEEE 279 (1971), Paragraph 4.16 - Completion of Protective Action Once it is Initiated

Once the SGTS-UC are initiated they will continue to operate until the area temperature drops to the low temperature setting.

7.3.2.15.1.2.3.1.17 SGTS-UC - IEEE 279 (1971), Paragraph 4.17 - Manual Initiation

A single failure in the control system of a division of the SGTS-UC cannot disable the automatic or manual operation of the other SGTS-UC division.

7.3.2.15.1.2.3.1.18 SGTS-UC - IEEE 279 (1971), Paragraph 4.18 - Access to Setpoint Adjustments, Calibration and Test Points

Access to temperature switch setpoints is restricted by administrative control.

7.3.2.15.1.2.3.1.19 SGTS-UC - IEEE 279 (1971), Paragraph 4.19 - Identification of Protective Actions

System operation is indirectly indicated and identified by high temperature alarms.

7.3.2.15.1.2.3.1.20 SGTS-UC - IEEE 279 (1971), Paragraph 4.20 - Information Readout

The information readout for the SGTS-UC is described in Section 7.3.1.1.15.1.12.2.

7.3.2.15.1.2.3.1.21 SGTS-UC - IEEE 279 (1971), Paragraph 4.21 - System Repair

The recognition and location of failed components will be accomplished during periodic testing.

7.3.2.15.1.2.3.1.22 SGTS-UC - IEEE 279 (1971), Paragraph 4.22 - Identification of Protection Systems

Each logic cabinet and control panel is distinctively identified with a nameplate which identifies the safety system. Cables and cable trays are identified by a color code and tags which identify them as being of a separate channel.

7.3.2.15.1.2.3.2 SGTS-UC - IEEE 308 (1974) - Criteria for Class 1E Electrical Systems for Nuclear Power Generating Stations

Refer to Section 8.3.2.2.1.12.

7.3.2.15.1.2.3.3 SGTS-UC - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1E Electric Equipment for Nuclear Power Generating Stations

Refer to Section 7.1.2.7.4.

7.3.2.15.1.2.3.4 SGTS-UC - IEEE 336 (1971) - Installation, Inspection, and Testing Requirements for Instrumentation and Electric Equipment During the Construction of Nuclear Power Generating Stations

The requirements of this standard have been met by the quality assurance program for construction of safety-related items.

7.3.2.15.1.2.3.5 SGTS-UC - IEEE 338 (1975) - Criteria for the Periodic Testing of Nuclear Power Generating Station Protection Systems

Refer to Section 7.1.2.7.6.

7.3.2.15.1.2.3.6 SGTS-UC - IEEE 344 (1971) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Station

Refer to Section 3.10.

7.3.2.15.1.2.3.7 SGTS-UC - IEEE 379 (1972) - Guide for the Application of the Single Failure Criterion to Nuclear Power Generating Station Protection Systems

The single failure criterion of IEEE 379 (1972) is met as described in Section 7.3.2.15.1.2.3.1.2.

7.3.2.15.1.2.3.8 SGTS-UC - IEEE 384 (1974) - Criteria for Separation of Class 1E Equipment and Circuits

Refer to Section 7.1.2.7.11.

7.3.2.15.2 Diesel Generating Enclosure Ventilation System - Instrumentation and Controls

7.3.2.15.2.1 DGEVS General Functional Requirements Conformance

The DGEVS is designed with sufficient capacity and redundancy so that a single active or passive electrical or control component failure will not prevent the diesel generators from performing their safety-related functions. The DGEVS system is automatically initiated by detection of high temperature. For the safety design basis refer to Section 7.1.2.1.33.2.1 and for additional details refer to Section 9.4.6.

7.3.2.15.2.2 DGEVS Specific Regulatory Requirements Conformance

7.3.2.15.2.2.1 DGEVS Conformance to Regulatory Guides

7.3.2.15.2.2.1.1 DGEVS - Regulatory Guide 1.22 (1972) - Periodic Testing of Protection System Actuation Functions (Safety Guide 22)

The DGEVS can be manually initiated and is capable of being tested during normal plant operation. Hand switches located on the local panel allow periodic testing of the exhaust fans in accordance with the requirements of Chapter 16.

7.3.2.15.2.2.1.2 DGEVS - Regulatory Guide 1.29 (1978) - Seismic Design Classification

The DGEVS complies with this regulatory guide as discussed in Section 3.2.

7.3.2.15.2.2.1.3 DGEVS - Regulatory Guide 1.30 (1972) - Quality Assurance Requirements for Installation, Inspection, and Testing of Instrumentation and Electric Equipment (Safety Guide 30)

Refer to Section 8.1.6.1.5 and Chapter 17.

7.3.2.15.2.2.1.4 DGEVS - Regulatory Guide 1.47 (1973) - Bypassed and Inoperable Status Indication for Nuclear Power Plant Safety Systems

The DGEVS meets the intent of this regulatory guide by using a fan system trouble alarm in the control room.

7.3.2.15.2.2.1.5 DGEVS - Regulatory Guide 1.53 (1973) - Application of the Single Failure Criterion to Nuclear Power Plant Protection Systems

Compliance with Regulatory Guide 1.53 is achieved by specifying, designing, and constructing the DGEVS to meet the single failure criterion, section 4.2 of IEEE 279 (1971) and IEEE 379 (1972). Redundant sensors and wiring are separated. The logic components and wiring are separated to ensure that a failure in a sensing element or the decision logic or an actuator will not affect its redundant counterparts and prevent protective action.

The two fans for each diesel cell are on the same channel as its diesel generator.

7.3.2.15.2.2.1.6 DGEVS - Regulatory Guide 1.62 (1973) - Manual Initiation of Protective Actions

Controls are provided locally to manually initiate the DGEVS.

7.3.2.15.2.2.1.7 DGEVS - Regulatory Guide 1.75 (1978) - Physical Independence of Electric Systems

Refer to Section 8.1.6.1.14 for compliance with this regulatory guide.

7.3.2.15.2.2.1.8 DGEVS - Regulatory Guide 1.89 (1974) - Qualification of Class 1E Equipment for Nuclear Power Plants

The qualification of Class 1E equipment for the DGEVS is discussed in Section 8.1.6.1.16.

7.3.2.15.2.2.1.9 DGEVS - Regulatory Guide 1.100 (1977) - Seismic Qualification of Electric Equipment for Nuclear Power Plants

Conformance with this regulatory guide is covered by Section 3.10.

7.3.2.15.2.2.1.10 DGEVS - Regulatory Guide 1.105 (1976) - Instrument Setpoints

Instrument setpoints are selected to allow for the inaccuracy of the instrument, uncertainties in the calibration, and instrumentation drift likely to occur between calibrations to assure initiation of the DGEVS, to prevent overheating of the diesel generators. For safety setpoints refer to Chapter 16.

7.3.2.15.2.2.1.11 DGEVS - Regulatory Guide 1.118 (1978) - Periodic Testing Electric Power and Protection Systems

Refer to Section 7.1.2.5.26.

7.3.2.15.2.2.2 DGEVS Conformance to 10CFR50, Appendix A, General Design Criteria

7.3.2.15.2.2.2.1 DGEVS - GDC 1 - Quality Standards and Records

The DGEVS is included in an established quality assurance program discussed in Section 3.1 and Chapter 17.

7.3.2.15.2.2.2.2 DGEVS - GDC 2 - Design Bases for Protection Against Natural Phenomena

Refer to Section 3.1.

7.3.2.15.2.2.2.3 DGEVS - GDC 3 - Fire Protection

Refer to Section 3.1.

7.3.2.15.2.2.2.4 DGEVS - GDC 4 - Environmental and Dynamic Effects Design Bases

Refer to Section 3.1.

7.3.2.15.2.2.2.5 DGEVS - GDC 13 - Instrumentation and Control

Instrumentation for the DGEVS is selected to monitor variables over anticipated ranges during normal and emergency operating conditions.

7.3.2.15.2.2.3 DGEVS Conformance to Industry Codes and Standards

7.3.2.15.2.2.3.1 DGEVS - IEEE 279 (1971) - Criteria for Protection Systems for Nuclear Power Generating Stations

Compliance of the DGEVS with IEEE 279 (1971) is detailed as follows:

7.3.2.15.2.2.3.1.1 DGEVS - IEEE 279 (1971), Paragraph 4.1 - General Functional Requirement

The DGEVS is automatically initiated by high temperature switches.

7.3.2.15.2.2.3.1.2 DGEVS - IEEE 279 (1971), Paragraph 4.2 - Single Failure Criterion

The DGEVS consists of independent sets of exhaust fans, controls and power which meet the single failure criteria.

7.3.2.15.2.2.3.1.3 DGEVS - IEEE 279 (1971), Paragraph 4.3 - Quality of Components and Modules

All safety-related components are selected on the basis of suitability for the specific application. A quality control and assurance program is required to be implemented and documented by equipment vendors, which complies with the requirements set forth in 10CFR50, Appendix B.

7.3.2.15.2.2.3.1.4 DGEVS - IEEE 279 (1971), Paragraph 4.4 - Equipment Qualification

Refer to Section 3.11 for discussion of equipment qualification.

7.3.2.15.2.2.3.1.5 DGEVS - IEEE 279 (1971), Paragraph 4.5 - Channel Integrity

The DGEVS meets the channel integrity criterion by utilizing the design features described in the other paragraphs of this section.

7.3.2.15.2.2.3.1.6 DGEVS - IEEE 279 (1971), Paragraph 4.6 - Channel Independence

The control and power circuits for each DGEVS component are physically and electrically separated.

7.3.2.15.2.2.3.1.7 DGEVS - IEEE 279 (1971), Paragraph 4.7 - Control and Protection System Interaction

The DGEVS has no interaction with other plant control systems. Annunciator circuits using contacts at sensor and logic relays cannot impair the operability of the DGEVS control because of electrical isolation.

7.3.2.15.2.2.3.1.8 DGEVS - IEEE 279 (1971), Paragraph 4.8 - Derivation of System Inputs

Initiation of the DGEVS is derived from high temperature signals from the diesel generator enclosure.

7.3.2.15.2.2.3.1.9 DGEVS - IEEE 279 (1971), Paragraph 4.9 - Capability for Sensor Checks

The DGEVS can be tested for operational availability as per Section 7.3.1.1.15.2.10.

7.3.2.15.2.2.3.1.10 DGEVS - IEEE 279 (1971), Paragraph 4.10 - Capability for Testing and Calibration

The DGEVS is capable of being tested during normal plant operation to verify that the system is capable of performing its intended function.

7.3.2.15.2.2.3.1.11 DGEVS - IEEE 279 (1971), Paragraph 4.11 - Channel Bypass or Removal from Operation

Removal of an initiation circuit component will not prevent the DGEVS itself from complying with the single failure criterion. The two fans for each diesel cell are on the same channel as its diesel generator.

7.3.2.15.2.2.3.1.12 DGEVS - IEEE 279 (1971), Paragraph 4.12 - Operating Bypasses

DGEVS bypasses are discussed in Section 7.3.1.1.15.2.6.

7.3.2.15.2.2.3.1.13 DGEVS - IEEE 279 (1971), Paragraph 4.13 - Indication of Bypasses

Each of the bypasses described in Section 7.3.1.1.15.2.6 are automatically indicated in the control room. In addition, each of these bypasses will initiate a system out-of-service annunciator.

7.3.2.15.2.2.3.1.14 DGEVS - IEEE 279 (1971), Paragraph 4.14 - Access to Means for Bypassing

Manual bypass of initiating circuits will be procedurally controlled by administrative means.

7.3.2.15.2.2.3.1.15 DGEVS - IEEE 279 (1971), Paragraph 4.15 - Multiple Setpoints

The DGEVS temperature switches have been designed to allow adjustment of trip setpoints to more stringent settings if required.

7.3.2.15.2.2.3.1.16 DGEVS - IEEE 279 (1971), Paragraph 4.16 - Completion of Protective Action Once It Is Initiated

Once the DGEVS is initiated it will continue to operate until the diesel cell temperature drops below the low temperature setpoint.

7.3.2.15.2.2.3.1.17 DGEVS - IEEE 279 (1971), Paragraph 4.17 - Manual Initiation

A single failure in the control system of a division of the DGEVS cannot disable the automatic or manual operation of the other DGEVS divisions.

7.3.2.15.2.2.3.1.18 DGEVS - IEEE 279 (1971), Paragraph 4.18 - Access to Setpoint Adjustments, Calibration and Test Points

Access to temperature switch setpoints is restricted by administrative control.

7.3.2.15.2.2.3.1.19 DGEVS - IEEE 279 (1971), Paragraph 4.19 - Identification of Protective Actions

System operation is indirectly indicated and identified by high temperature alarms.

7.3.2.15.2.2.3.1.20 DGEVS - IEEE 279 (1971), Paragraph 4.20 - Information Readout

The information readout for the DGEVS is described in Section 7.3.1.1.15.2.12.2.

7.3.2.15.2.2.3.1.21 DGEVS - IEEE 279 (1971), Paragraph 4.21 - System Repair

The recognition and location of failed components will be accomplished during periodic testing.

7.3.2.15.2.2.3.1.22 DGEVS - IEEE 279 (1971), Paragraph 4.22 - Identification of Protection Systems

Each logic cabinet and control panel is distinctively identified with a nameplate which identifies the safety system. Cables and cable trays are identified by a color code and tags which identify them as being of a separate channel.

7.3.2.15.2.2.3.2 DGEVS - IEEE 308 (1974) - Criteria for Class 1E Electrical Systems for Nuclear Power Generating Stations

Refer to Section 8.3.2.2.1.12.

7.3.2.15.2.2.3.3 DGEVS - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1E Electric Equipment for Nuclear Power Generating Stations

Refer to Section 7.1.2.7.4.

7.3.2.15.2.2.3.4 DGEVS - IEEE 336 (1971) - Installation, Inspection, and Testing Requirements for Instrumentation and Electric Equipment During the Construction of Nuclear Power Generating Stations

The requirements of this standard have been met by the quality assurance program for construction of safety-related items.

7.3.2.15.2.2.3.5 DGEVS - IEEE 338 (1975) - Criteria for the Periodic Testing of Nuclear Power Generating Station Protection Systems

Refer to Section 7.1.2.7.6.

7.3.2.15.2.2.3.6 DGEVS - IEEE 344 (1971) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Station

Refer to Section 7.1.2.7.7.

7.3.2.15.2.2.3.7 DGEVS - IEEE 379 (1972) - Guide for the Application of the Single Failure Criterion to Nuclear Power Generating Station Protection Systems

The single failure criterion of IEEE 379 (1972) is met as described in Section 7.3.2.15.2.2.3.1.2.

7.3.2.15.2.2.3.8 DGEVS - IEEE 384 (1974) - Criteria for Separation of Class 1E Equipment and Circuits

Refer to Section 7.1.2.7.11.

7.3.2.15.3 Spray Pond Pump Structure Ventilation System - Instrumentation and Controls

7.3.2.15.3.1 SPPSVS General Functional Requirements Conformance

The SPPSVS is designed with sufficient capacity and redundancy so that a single active or passive electrical or control component failure will not prevent the system from performing its safety-related functions. For the safety design basis refer to Section 7.1.2.1.33.3 and for additional details refer to Section 9.4.7.

7.3.2.15.3.2 SPPSVS Specific Regulatory Requirements Conformance

7.3.2.15.3.2.1 SPPSVS Conformance to Regulatory Guides

7.3.2.15.3.2.1.1 SPPSVS - Regulatory Guide 1.22 (1972) - Periodic Testing of Protection System Actuation Functions (Safety Guide 22)

The SPPSVS can be manually initiated and is capable of being tested during normal plant operation. Hand switches located in the control room allow periodic testing of the fan cabinets in accordance with the requirements of Chapter 16.

7.3.2.15.3.2.1.2 SPPSVS - Regulatory Guide 1.29 (1978) - Seismic Design Classification

The SPPSVS complies with this regulatory guide as discussed in Section 3.2.

7.3.2.15.3.2.1.3 SPPSVS - Regulatory Guide 1.30 (1972) - Quality Assurance Requirements for the Installation, Inspection, and Testing of Instrumentation and Electric Equipment (Safety Guide 30)

Refer to Section 8.1.6.1.5 and Chapter 17.

7.3.2.15.3.2.1.4 SPPSVS - Regulatory Guide 1.47 (1973) - Bypassed and Inoperable Status Indication for Nuclear Power Plant Safety Systems

The SPPSVS meets the intent of this regulatory guide by using a fan system trouble alarm in the control room.

7.3.2.15.3.2.1.5 SPPSVS - Regulatory Guide 1.53 (1973) - Application of the Single Failure Criterion to Nuclear Power Plant Protection Systems

Compliance with Regulatory Guide 1.53 is achieved by specifying, designing and constructing the SPPSVS to meet the single failure criterion, section 4.2 of IEEE 279 (1971) and IEEE 379 (1972). Redundant sensors and wiring are separated. The logic components and wiring are separated to ensure that a failure in a sensing element or the decision logic or an actuator will not affect its redundant counterpart and prevent protective action. Separator channels are employed so that a fault affecting one channel will not prevent the redundant channel from operating properly.

7.3.2.15.3.2.1.6 SPPSVS - Regulatory Guide 1.62 (1973) - Manual Initiation of Protective Actions

Controls are provided in the main control room to manually initiate the SPPSVS.

7.3.2.15.3.2.1.7 SPPSVS - Regulatory Guide 1.75 (1978) - Physical Independence of Electric Systems

Refer to Section 8.1.6.1.14 for compliance with this regulatory guide.

7.3.2.15.3.2.1.8 SPPSVS - Regulatory Guide 1.89 (1974) - Qualification of Class 1E Equipment for Nuclear Power Plants

The qualification of Class 1E equipment for the SPPSVS is discussed in Section 8.1.6.1.16.

7.3.2.15.3.2.1.9 SPPSVS - Regulatory Guide 1.100 (1977) - Seismic Qualification of Electric Equipment for Nuclear Power Plants

Conformance with this regulatory guide is covered by Section 3.10.

7.3.2.15.3.2.1.10 SPPSVS - Regulatory Guide 1.105 (1976) - Instrument Setpoints

Instrument setpoints are selected to allow for the inaccuracy of the instrument, uncertainties in the calibration, and instrumentation drift likely to occur between calibrations to assure initiation of the SPPSVS to maintain the spray pond pump enclosure within specified temperature limits.

7.3.2.15.3.2.1.11 SPPSVS - Regulatory Guide 1.118 (1978) - Periodic Testing of Electric Power and Protection Systems

Refer to Section 7.1.2.5.26.

7.3.2.15.3.2.2 SPPSVS Conformance to 10CFR50, Appendix A, General Design Criteria

7.3.2.15.3.2.2.1 SPPSVS - GDC 1 - Quality Standards and Records

The SPPSVS is included in an established quality assurance program discussed in Section 3.1 and Chapter 17.

7.3.2.15.3.2.2.2 SPPSVS - GDC 2 - Design Bases for Protection Against Natural Phenomena

Refer to Section 3.1.

7.3.2.15.3.2.2.3 SPPSVS - GDC 3 - Fire Protection

Refer to Section 3.1.

7.3.2.15.3.2.2.4 SPPSVS - GDC 4 - Environmental and Dynamic Effects Design Bases

Refer to Section 3.1.

7.3.2.15.3.2.2.5 SPPSVS - GDC 5 - Sharing of Structures, Systems, and Components

The SPPSVS is common to Units 1 and 2. There are four independent divisions, any two of which can provide the required ventilation and heating requirements during and after the most severe natural phenomena to maintain a suitable environment for the other safety-related equipment in this area. Therefore, sharing this system will not impair its ability to perform its safety function.

7.3.2.15.3.2.2.6 SPPSVS - GDC 13 - Instrumentation and Control

Instrumentation for the SPPSVS is selected to monitor variables over anticipated ranges during normal and emergency operating conditions.

7.3.2.15.3.2.3 SPPSVS Conformance to Industry Codes and Standards

7.3.2.15.3.2.3.1 SPPSVS - IEEE 279 (1971) - Criteria for Protection Systems for Nuclear Power Generating Stations

Compliance of the SPPSVS with IEEE 279 (1971) is detailed as follows:

7.3.2.15.3.2.3.1.1 SPPSVS - IEEE 279 (1971), Paragraph 4.1 - General Functional Requirement

The lead SPPSVS fan will run continuously after the control switch is placed in the run position. The standby fan will automatically start if required. Temperature is controlled automatically by a temperature controller.

7.3.2.15.3.2.3.1.2 SPPSVS - IEEE 279 (1971), Paragraph 4.2 - Single Failure Criterion

The SPPSVS consists of redundant fan cabinets with electric heaters and independent sets of controls and power which meet the single failure criterion.

7.3.2.15.3.2.3.1.3 SPPSVS - IEEE 279 (1971), Paragraph 4.3 - Quality of Components and Modules

All safety-related components are selected on the basis of suitability for the specific application. A quality control and assurance program is required to be implemented and documented by equipment vendors, which complies with the requirements set forth in 10CFR50, Appendix B.

7.3.2.15.3.2.3.1.4 SPPSVS - IEEE 279 (1971), Paragraph 4.4 - Equipment Qualification

Refer to Section 3.11 for discussion of equipment qualification.

7.3.2.15.3.2.3.1.5 SPPSVS - IEEE 279 (1971), Paragraph 4.5 - Channel Integrity

The SPPSVS meets the channel integrity criterion by utilizing the design features described in the other paragraphs of this section.

7.3.2.15.3.2.3.1.6 SPPSVS - IEEE 279 (1971), Paragraph 4.6 - Channel Independence

The control and power circuits for each SPPSVS component are physically and electrically separated.

7.3.2.15.3.2.3.1.7 SPPSVS - IEEE 279 (1971), Paragraph 4.7 - Control and Protection System Interaction

The SPPSVS has no interaction with other plant control systems. Annunciator circuits using contacts at sensor and logic relays cannot impair the operability of the SPPSVS control because of electrical isolation.

7.3.2.15.3.2.3.1.8 SPPSVS - IEEE 279 (1971), Paragraph 4.8 - Derivation of System Inputs

Initiation of the SPPSVS is derived from placing the hand switch in the run position for the lead fan. The standby fan will automatically start if required. Temperature is controlled automatically by a temperature controller.

7.3.2.15.3.2.3.1.9 SPPSVS - IEEE 279 (1971), Paragraph 4.9 - Capability for Sensor Checks

The SPPSVS can be tested for operational availability per Section 7.3.1.1.15.3.10.

7.3.2.15.3.2.3.1.10 SPPSVS - IEEE 279 (1971), Paragraph 4.10 - Capability for Testing and Calibration

The SPPSVS is capable of being tested during normal plant operation to verify that the system is capable of performing its intended function.

7.3.2.15.3.2.3.1.11 SPPSVS - IEEE 279 (1971), Paragraph 4.11 - Channel Bypass or Removal from Operation

A channel bypass or removal of a component of an initiation circuit channel will not prevent the SPPSVS itself from complying with the single failure criterion.

7.3.2.15.3.2.3.1.12 SPPSVS - IEEE 279 (1971), Paragraph 4.12 - Operating Bypasses

SPPSVS bypasses are discussed in Section 7.3.1.1.15.3.6.

7.3.2.15.3.2.3.1.13 SPPSVS - IEEE 279 (1971), Paragraph 4.13 - Indication of Bypasses

The bypasses described in Section 7.3.1.1.15.3.6 are automatically indicated in the control room. In addition, each of these bypasses will initiate a system out-of-service annunciator.

7.3.2.15.3.2.3.1.14 SPPSVS - IEEE 279 (1971), Paragraph 4.14 - Access to Means for Bypassing

Manual bypass of initiating circuits will be procedurally controlled by administrative means.

7.3.2.15.3.2.3.1.15 SPPSVS - IEEE 279 (1971), Paragraph 4.15 - Multiple Setpoints

The SPPSVS high and low temperature switches have been designed to allow adjustment of trip setpoints to more stringent settings if required.

7.3.2.15.3.2.3.1.16 SPPSVS - IEEE 279 (1971), Paragraph 4.16 - Completion of Protective Action Once It Is Initiated

Once the SPPSVS is initiated, it will continue to operate until the area temperature reaches the initiating setpoint.

7.3.2.15.3.2.3.1.17 SPPSVS - IEEE 279 (1971), Paragraph 4.17 - Manual Initiation

A single failure in the control system of a division of the SPPSVS cannot disable the operation of the other SPPSVS divisions.

7.3.2.15.3.2.3.1.18 SPPSVS - IEEE 279 (1971), Paragraph 4.18 - Access to Setpoint Adjustments, Calibration and Test Points

Access to the temperature switch setpoints is restricted by administrative control.

7.3.2.15.3.2.3.1.19 SPPSVS - IEEE 279 (1971), Paragraph 4.19 - Identification of Protective Actions

System operation is indirectly indicated and identified by high temperature and fan system trouble annunciators.

7.3.2.15.3.2.3.1.20 SPPSVS - IEEE 279 (1971), Paragraph 4.20 - Information Readout

The information readout for the SPPSVS is described in Section 7.3.1.1.15.3.12.2.

7.3.2.15.3.2.3.1.21 SPPSVS - IEEE 279 (1971), Paragraph 4.21 - System Repair

The recognition and location of failed components will be accomplished during periodic testing.

7.3.2.15.3.2.3.1.22 SPPSVS - IEEE 279 (1971), Paragraph 4.22 - Identification of Protection Systems

Each logic cabinet and control panel is distinctively identified with a nameplate which identifies the safety system. Cables and cable trays are identified by a color code and tags which identify them as being of a separate channel.

7.3.2.15.3.2.3.2 SPPSVS - IEEE 308 (1974) - Criteria for Class 1E Electrical Systems for Nuclear Power Generating Stations

Refer to Section 8.3.3.2.1.12.

7.3.2.15.3.2.3.3 SPPSVS - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1E Electric Equipment for Nuclear Power Generating Stations

Refer to Section 7.1.2.7.4.

7.3.2.15.3.2.3.4 SPPSVS - IEEE 336 (1971) - Installation, Inspection, and Testing Requirements for Instrumentation and Electric Equipment During the Construction of Nuclear Power Generating Stations

The requirements of this standard have been met by the quality assurance program for construction of safety-related items.

7.3.2.15.3.2.3.5 SPPSVS - IEEE 338 (1975) - Criteria for the Periodic Testing of Nuclear Power Generating Station Protection Systems

Refer to Section 7.1.2.7.6.

7.3.2.15.3.2.3.6 SPPSVS - IEEE 344 (1971) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations

Refer to Section 7.1.2.7.7.

7.3.2.15.3.2.3.7 SPPSVS - IEEE 379 (1972) - Guide for the Application of the Single Failure Criterion to Nuclear Power Generating Station Protection Systems

The single failure criterion of IEEE 379 (1972) is met as described in Section 7.3.2.15.3.2.3.1.2.

7.3.2.15.3.2.3.8 SPPSVS - IEEE 384 (1974) - Criteria for Separation of Class 1E Equipment and Circuits

Refer to Section 7.1.2.7.11.

7.3.2.15.4 Emergency Switchgear and Battery Rooms Cooling System - Instrumentation and Controls

7.3.2.15.4.1 ESBRCS General Functional Requirements Conformance

The ESBRCS is designed with sufficient capacity and redundancy so that a single active or passive electrical or control component failure will not prevent the system from performing its safety-related functions. The ESBRCS operates continuously during normal and emergency plant operation. For the safety design basis refer to Section 7.1.2.1.33.4.1 and for additional details refer to Section 9.4.1.

7.3.2.15.4.2 ESBRCS Specific Regulatory Requirements Conformance

7.3.2.15.4.2.1 ESBRCS Conformance to Regulatory Guides

7.3.2.15.4.2.1.1 ESBRCS - Regulatory Guide 1.22 (1972) - Periodic Testing of Protection System Actuation Functions (Safety Guide 22)

The ESBRCS can be manually initiated and is capable of being tested during normal plant operation. Hand switches located on the local panel allow periodic testing of the unit coolers in accordance with the requirements of Chapter 16.

7.3.2.15.4.2.1.2 ESBRCS - Regulatory Guide 1.29 (1978) - Seismic Design Classification

The ESBRCS complies with this regulatory guide as discussed in Section 3.2.

7.3.2.15.4.2.1.3 ESBRCS - Regulatory Guide 1.30 (1972) - Quality Assurance Requirements for the Installation, Inspection, and Testing of Instrumentation and Electric Equipment (Safety Guide 30)

Refer to Section 8.1.6.1.5 and Chapter 17.

7.3.2.15.4.2.1.3A ESBRCS - Regulatory Guide 1.32 (1977) - Criteria for Safety Related Electric Power Systems for Nuclear Power Plants

Refer to Section 8.3.2.2.1.8.

7.3.2.15.4.2.1.4 ESBRCS - Regulatory Guide 1.47 (1973) - Bypassed and Inoperable Status Indication for Nuclear Power Plant Safety Systems

The ESBRCS meets the intent of this regulatory guide by using a fan system trouble alarm in the control room.

7.3.2.15.4.2.1.5 ESBRCS - Regulatory Guide 1.53 (1973) - Application of the Single Failure Criterion to Nuclear Power Protection Systems

Compliance with Regulatory Guide 1.53 is achieved by specifying, designing, and constructing the ESBRCS to meet the single failure criterion, section 4.2 of IEEE 279 (1971) and IEEE 379 (1972). Redundant sensors and wiring are separated. The logic components and wiring are separated to ensure that a failure in a sensing element or the decision logic or an actuator will not affect its redundant counterpart and prevent protective action. Separate channels are employed so that a fault affecting one channel will not prevent the redundant channel from operating properly.

7.3.2.15.4.2.1.6 ESBRCS - Regulatory Guide 1.62 (1973) - Manual Initiation of Protective Actions

Controls are provided locally to manually initiate the ESBRCS.

7.3.2.15.4.2.1.7 ESBRCS - Regulatory Guide 1.75 (1978) - Physical Independence of Electric Systems

Refer to Section 8.1.6.1.14 for compliance with this regulatory guide.

7.3.2.15.4.2.1.8 ESBRCS - Regulatory Guide 1.89 (1974) - Qualification of Class 1E Equipment for Nuclear Power Plants

The qualification of Class 1E equipment for the ESBRCS is discussed in Section 7.1.2.5.21.

7.3.2.15.4.2.1.9 ESBRCS - Regulatory Guide 1.100 (1977) - Seismic Qualification of Electric Equipment for Nuclear Power Plants

Conformance with this regulatory guide is covered by Section 3.10.

7.3.2.15.4.2.1.10 ESBRCS - Regulatory Guide 1.105 (1976) - Instrument Setpoints

Instrument setpoints are selected to allow for the inaccuracy of the instrument, uncertainties in the calibration, and instrumentation drift likely to occur between calibrations to assure initiation of the ESBRCS to maintain the associated room temperatures within the specified units.

7.3.2.15.4.2.1.11 ESBRCS - Regulatory Guide 1.118 (1978) - Periodic Testing of Electric Power and Protection System

Refer to Section 7.1.2.5.26.

7.3.2.15.4.2.2 ESBRCS Conformance to 10CFR50, Appendix A, General Design Criteria

7.3.2.15.4.2.2.1 ESBRCS - GDC 1 - Quality Standards and Records

The ESBRCS is included in an established quality assurance program discussed in Section 3.1 and Chapter 17.

7.3.2.15.4.2.2.2 ESBRCS - GDC 2 - Design Bases for Protection Against Natural Phenomena

Refer to Section 3.1.

7.3.2.15.4.2.2.3 ESBRCS - GDC 3 - Fire Protection

Refer to Section 3.1.

7.3.2.15.4.2.2.4 ESBRCS - GDC 4 - Environmental and Dynamic Effects Design Bases

Refer to Section 3.1.

7.3.2.15.4.2.2.5 ESBRCS - GDC 5 - Sharing of Structures, Systems, and Components

The ESBRCS is common to Units 1 and 2. There are two independent divisions, each capable of maintaining a suitable environment for all safety-related equipment located in the corresponding areas used for the safe shutdown of either unit. Since the ESBRCS and control structure are designed to remain functional during and after the most severe natural phenomena, sharing this system will not impair its ability to perform its safety function.

7.3.2.15.4.2.2.6 ESBRCS - GDC 13 - Instrumentation and Control

Instrumentation for the ESBRCS is selected to monitor variables over anticipated ranges during normal and emergency operating conditions.

7.3.2.15.4.2.2.7 ESBRCS - GDC 19 - Control Room

Refer to Section 3.1

7.3.2.15.4.2.3 ESBRCS Conformance to Industry Codes and Standards

7.3.2.15.4.2.3.1 ESBRCS - IEEE 279 (1971) - Criteria for Protection Systems for Nuclear Power Generating Stations

Compliance of the ESBRCS with IEEE 279 (1971) is detailed below:

7.3.2.15.4.2.3.1.1 ESBRCS - IEEE 279 (1971), Paragraph 4.1 - General Functional Requirement

Deliberate operator action after an accident is not required to initiate ESBRCS operation because it operates continuously during normal plant operation.

7.3.2.15.4.2.3.1.2 ESBRCS - IEEE 279 (1971), Paragraph 4.2 - Single Failure Criterion

The ESBRCS consists of redundant unit coolers and independent sets of controls and power which meet the single failure criterion.

7.3.2.15.4.2.3.1.3 ESBRCS - IEEE 279 (1971), Paragraph 4.3 - Quality of Components and Modules

All safety-related components are selected on the basis of suitability for the specific application. A quality control and assurance program is required to be implemented and documented by equipment vendors, which complies with the requirements set forth in 10CFR50, Appendix B.

7.3.2.15.4.2.3.1.4 ESBRCS - IEEE 279 (1971), Paragraph 4.4 - Equipment Qualification

Refer to Section 3.11 for discussion of equipment qualification.

7.3.2.15.4.2.3.1.5 ESBRCS - IEEE 279 (1971), Paragraph 4.5 - Channel Integrity

The ESBRCS meets the channel integrity criterion by utilizing the design features described in the other paragraphs of this section.

7.3.2.15.4.2.3.1.6 ESBRCS - IEEE 279 (1971), Paragraph 4.6 - Channel Independence

The control and power circuits for each ESBRCS component are physically and electrically separated.

7.3.2.15.4.2.3.1.7 ESBRCS - IEEE 279 (1971), Paragraph 4.7 - Control and Protection System Interaction

The ESBRCS has no interaction with other plant control systems. Annunciator circuits using contacts at sensor and logic relays cannot impair the operability of the ESBRCS control because of electrical isolation.

7.3.2.15.4.2.3.1.8 ESBRCS - IEEE 279 (1971), Paragraph 4.8 - Derivation of System Inputs

The ESBRCS operates continuously.

7.3.2.15.4.2.3.1.9 ESBRCS - IEEE 279 (1971), Paragraph 4.9 - Capability for Sensor Checks

The ESBRCS can be tested for operational availability as per Section 7.3.1.1.15.4.10.

7.3.2.15.4.2.3.1.10 ESBRCS - IEEE 279 (1971), Paragraph 4.10 - Capability for Testing and Calibration

The ESBRCS is capable of being tested during normal plant operation to verify that the system is capable of performing its intended function.

7.3.2.15.4.2.3.1.11 ESBRCS - IEEE 279 (1971), Paragraph 4.11 - Channel Bypass or Removal from Operation

A channel bypass or removal of a component of an initiation circuit channel will prevent the ESBRCS itself from complying with the single failure criterion.

7.3.2.15.4.2.3.1.12 ESBRCS - IEEE 279 (1971), Paragraph 4.12 - Operating Bypasses

ESBRCS bypasses are discussed in Section 7.3.1.1.15.4.6.

7.3.2.15.4.2.3.1.13 ESBRCS - IEEE 279 (1971), Paragraph 4.13 - Indication of Bypasses

Each of the bypasses described in Section 7.3.1.1.15.4.6 are automatically indicated in the control room. In addition, each of these bypasses will initiate a system out-of-service annunciator.

7.3.2.15.4.2.3.1.14 ESBRCS - IEEE 279 (1971), Paragraph 4.14 - Access to Means for Bypassing

Manual bypass of initiating circuits will be procedurally controlled by administrative means.

7.3.2.15.4.2.3.1.15 ESBRCS - IEEE 279 (1971), Paragraph 4.15 - Multiple Setpoints

The ESBRCS high temperature switches have been designed to allow adjustment of trip setpoints to more stringent settings if required.

7.3.2.15.4.2.3.1.16 ESBRCS - IEEE 279 (1971), Paragraph 4.16 - Completion of Protective Action Once It Is Initiated

Once the ESBRCS is initiated, it will continue to operate until manually terminated by the operator.

7.3.2.15.4.2.3.1.17 ESBRCS - IEEE 279 (1971), Paragraph 4.17 - Manual Initiation

A single failure in the control system of a division of the ESBRCS cannot disable the automatic or manual operation of the other ESBRCS division.

7.3.2.15.4.2.3.1.18 ESBRCS - IEEE 279 (1971), Paragraph 4.18 - Access to Setpoint Adjustments, Calibration, and Test Points

Access to the temperature switch setpoints is restricted by administrative control.

7.3.2.15.4.2.3.1.19 ESBRCS - IEEE 279 (1971), Paragraph 4.19 - Identification of Protective Actions

System operation is indirectly indicated and identified by high temperature, filter pressure differential, and low air flow alarms.

7.3.2.15.4.2.3.1.20 ESBRCS - IEEE 279 (1971), Paragraph 4.20 - Information Readout

The information readout for the ESBRCS is described in Section 7.3.1.1.15.4.12.2.

7.3.2.15.4.2.3.1.21 ESBRCS - IEEE 279 (1971), Paragraph 4.21 - System Repair

The recognition and location of failed components will be accomplished during periodic testing.

7.3.2.15.4.2.3.1.22 ESBRCS - IEEE 279 (1971), Paragraph 4.22 - Identification of Protection Systems

Each logic cabinet and control panel is distinctively identified with a nameplate which identifies the safety system. Cables and cable trays are identified by a color code and tags which identify them as being of a separate channel.

7.3.2.15.4.2.3.2 ESBRCS - IEEE 308 (1974) - Criteria for Class 1E Electrical Systems for Nuclear Power Generating Stations

Refer to Section 8.3.2.2.1.12.

7.3.2.15.4.2.3.3 ESBRCS - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1E Electric Equipment for Nuclear Power Generating Stations

Refer to Section 7.1.2.7.4.

7.3.2.15.4.2.3.4 ESBRCS - IEEE 336 (1971) - Installation, Inspection, and Testing Requirements for Instrumentation and Electric Equipment During the Construction of Nuclear Power Generating Stations

The requirements of this standard have been met by the quality assurance program for construction of safety-related items.
Refer to Section 7.1.2.7.5.

7.3.2.15.4.2.3.5 ESBRCS - IEEE 338 (1975) - Criteria for the Periodic Testing of Nuclear Power Generating Station Protection Systems

Refer to Section 7.1.2.7.6.

7.3.2.15.4.2.3.6 ESBRCS - IEEE 344 (1971) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations

Refer to Section 7.1.2.7.7.

7.3.2.15.4.2.3.7 ESBRCS - IEEE 379 (1972) - Guide for the Application of the Single Failure Criterion to Nuclear Power Generating Station Protection Systems

The single failure criterion of IEEE 379 (1972) is met as described in Section 7.3.2.15.4.2.3.1.2.

7.3.2.15.4.2.3.8 ESBRCS - IEEE 384 (1974) - Criteria for Separation of Class 1E Equipment and Circuits

Refer to Section 7.1.2.7.11.

7.3.2.15.5 Emergency Core Cooling Systems Pump Compartment Unit Coolers - Instrumentation and Controls

7.3.2.15.5.1 ECCS-UC General Functional Requirements Conformance

The ECCS-UC are designed with sufficient capacity and redundancy so that a single active or passive electrical or control component failure will not prevent the system from performing its safety-related functions. The ECCS-UC are automatically initiated by high temperature switches.

For the safety design basis refer to Section 7.1.2.1.33.5.1 and for additional details, refer to Section 9.4.2.

7.3.2.15.5.2 ECCS-UC Specific Regulatory Requirements Conformance

7.3.2.15.5.2.1 ECCS-UC Conformance to Regulatory Guides

7.3.2.15.5.2.1.1 ECCS-UC - Regulatory Guide 1.22 (1972) - Periodic Testing of Protection System Actuation Functions (Safety Guide 22)

The ECCS-UC can be manually initiated and are capable of being tested during normal plant operation. Hand switches located on local control panels allow periodic testing of the unit coolers in accordance with the requirements of Chapter 16.

7.3.2.15.5.2.1.2 ECCS-UC - Regulatory Guide 1.29 (1978) - Seismic Design Classification

The ECCS-UC comply with this regulatory guide as discussed in Section 3.2.

7.3.2.15.5.2.1.3 ECCS-UC - Regulatory Guide 1.30 (1972) - Quality Assurance Requirements for the Installation, Inspection, and Testing of Instrumentation and Electric Equipment (Safety Guide 30)

Refer to Section 8.1.6.1.5 and Chapter 17.

7.3.2.15.5.2.1.4 ECCS-UC - Regulatory Guide 1.47 (1973) - Bypassed and Inoperable Status Indication for Nuclear Power Plant Safety Systems

The ECCS-UC meets the intent of this regulatory guide by using a unit cooler system trouble alarm in the control room.

7.3.2.15.5.2.1.5 ECCS-UC - Regulatory Guide 1.53 (1973) - Application of the Single Failure Criterion to Nuclear Power Plant Protection Systems

Compliance with Regulatory Guide 1.53 is achieved by specifying, designing, and constructing the ECCS-UC to meet the single failure criterion, section 4.2 of IEEE 279 (1971) and IEEE 379 (1972). Redundant sensors and wiring are separated. The logic components and wiring are separated to ensure that a failure in a sensing element or the decision logic will not affect its redundant counterpart and prevent protective action. Separate channels are employed so that a fault affecting one channel will not prevent the redundant channel from operating properly.

7.3.2.15.5.2.1.6 ECCS-UC - Regulatory Guide 1.62 (1973) - Manual Initiation of Protective Actions

Controls are provided locally to manually initiate the unit coolers.

7.3.2.15.5.2.1.7 ECCS-UC - Regulatory Guide 1.75 (1978) - Physical Independence of Electric Systems

Refer to Section 8.1.6.1.14 for compliance with this regulatory guide.

7.3.2.15.5.2.1.8 ECCS-UC - Regulatory Guide 1.89 (1974) - Qualification of Class 1E Equipment for Nuclear Power Plants

The qualification of Class 1E equipment for the ECCS-UC is discussed in Section 8.1.6.1.16.

7.3.2.15.5.2.1.9 ECCS-UC - Regulatory Guide 1.100 (1977) - Seismic Qualification of Electric Equipment for Nuclear Power Plants

Conformance with this regulatory guide is covered by Section 3.10.

7.3.2.15.5.2.1.10 ECCS-UC - Regulatory Guide 1.105 (1976) - Instrument Setpoints

Instrument setpoints are selected to allow for the inaccuracy of the instrument, uncertainties in the calibration, and instrumentation drift likely to occur between calibrations to assure initiation of the ECCS-UC to maintain the temperature of the emergency pump rooms within the specified limits.

7.3.2.15.5.2.1.11 ECCS-UC - Regulatory Guide 1.118 (1978) - Periodic Testing of Electric Power and Protection Systems

Refer to Section 7.1.2.5.26.

7.3.2.15.5.2.2 ECCS-UC Conformance to 10CFR50, Appendix A, General Design Criteria

7.3.2.15.5.2.2.1 ECCS-UC - GDC 1 - Quality Standards and Records

The ECCS-UC are included in an established quality assurance program discussed in Section 3.1 and Chapter 17.

7.3.2.15.5.2.2.2 ECCS-UC - GDC 2 - Design Bases for Protection Against Natural Phenomena

Refer to Section 3.1.

7.3.2.15.5.2.2.3 ECCS-UC - GDC 3 - Fire Protection

Refer to Section 3.1.

7.3.2.15.5.2.2.4 ECCS-UC - GDC 4 - Environmental and Dynamic Effects Design Bases

Refer to Section 3.1.

7.3.2.15.5.2.2.5 ECCS-UC - GDC 13 - Instrumentation and Control

Instrumentation for the ECCS-UC is selected to monitor variables over anticipated ranges during normal and emergency operating conditions.

7.3.2.15.5.2.3 ECCS-UC Conformance to Industry Codes and Standards

7.3.2.15.5.2.3.1 ECCS-UC - IEEE 279 (1971) - Criteria for Protection Systems for Nuclear Power Generating Stations

Compliance of the ECCS-UC with IEEE 279 (1971) is detailed as follows:

7.3.2.15.5.2.3.1.1 ECCS-UC - IEEE 279 (1971), Paragraph 4.1 - General Functional Requirement

The ECCS-UC are automatically initiated by high temperature switches.

7.3.2.15.5.2.3.1.2 ECCS-UC - IEEE 279 (1971), Paragraph 4.2 - Single Failure Criterion

The ECCS-UC include 100% capacity redundant unit coolers and independent sets of controls and power which meet the single failure criterion.

7.3.2.15.5.2.3.1.3 ECCS-UC - IEEE 279 (1971), Paragraph 4.3 - Quality of Components and Modules

All safety-related components are selected on the basis of suitability for the specific application. A quality control and assurance program is required to be implemented and documented by equipment vendors, which complies with the requirements set forth in 10CFR50, Appendix B.

7.3.2.15.5.2.3.1.4 ECCS-UC - IEEE 279 (1971), Paragraph 4.4 - Equipment Qualification

Refer to Section 3.11 for discussion of equipment qualification.

7.3.2.15.5.2.3.1.5 ECCS-UC - IEEE 279 (1971), Paragraph 4.5 - Channel Integrity

The ECCS-UC meets the channel integrity criterion by utilizing the design features described in the other paragraphs of this section.

7.3.2.15.5.2.3.1.6 ECCS-UC - IEEE 279 (1971), Paragraph 4.6 - Channel Independence

The control and power circuits for each unit cooler are physically and electrically separated.

7.3.2.15.5.2.3.1.7 ECCS-UC - IEEE 279 (1971), Paragraph 4.7 - Control and Protection System Interaction

The ECCS-UC has no interaction with other plant control systems. Annunciator circuits using contacts at sensor and logic relays cannot impair the operability of the ECCS-UC control because of electrical isolation.

7.3.2.15.5.2.3.1.8 ECCS-UC - IEEE 279 (1971), Paragraph 4.8 - Derivation of System Inputs

Initiation of the ECCS-UC is derived from high temperature signals from the corresponding emergency pump rooms.

7.3.2.15.5.2.3.1.9 ECCS-UC - IEEE 279 (1971), Paragraph 4.9 - Capability for Sensor Checks

The ECCS-UC can be tested for operational availability per Section 7.3.1.1.15.5.10.

7.3.2.15.5.2.3.1.10 ECCS-UC - IEEE 279 (1971), Paragraph 4.10 - Capability for Testing and Calibration

The ECCS-UC is capable of being tested during normal plant operation to verify that the system is capable of performing its intended function.

7.3.2.15.5.2.3.1.11 ECCS-UC - IEEE 279 (1971), Paragraph 4.11 - Channel Bypass or Removal from Operation

A channel bypass or removal of a component of an initiation circuit channel will prevent the other ECCS-UC from complying with the single failure criterion.

7.3.2.15.5.2.3.1.12 ECCS-UC - IEEE 279 (1971), Paragraph 4.12 - Operating Bypasses

ECCS-UC bypasses are discussed in Section 7.3.1.1.15.5.6.

7.3.2.15.5.2.3.1.13 ECCS-UC - IEEE 279 (1971), Paragraph 4.13 - Indication of Bypasses

Each of the bypasses described in Section 7.3.1.1.15.5.6 are automatically indicated in the control room. In addition, each of these bypasses will initiate a system out-of-service annunciator.

7.3.2.15.5.2.3.1.14 ECCS-UC - IEEE 279 (1971), Paragraph 4.14 - Access to Means for Bypassing

Manual bypass of initiating circuits will be procedurally controlled by administrative means.

7.3.2.15.5.2.3.1.15 ECCS-UC - IEEE 279 (1971), Paragraph 4.15 - Multiple Setpoints

The ECCS-UC temperature switches have been designed to allow adjustment of trip setpoints to more stringent settings, if required.

7.3.2.15.5.2.3.1.16 ECCS-UC - IEEE 279 (1971), Paragraph 4.16 - Completion of Protective Action Once It Is Initiated

Once the ECCS-UC are initiated they will continue to operate until they are shut down by a low temperature switch.

7.3.2.15.5.2.3.1.17 ECCS-UC - IEEE 279 (1971), Paragraph 4.17 - Manual Initiation

A single failure in the control system of a division of the ECCS-UC cannot disable the automatic or manual operation of the other ECCS-UC division.

7.3.2.15.5.2.3.1.18 ECCS-UC - IEEE 279 (1971), Paragraph 4.18 - Access to Setpoint Adjustments, Calibration, and Test Points

Access to temperature switch setpoints is restricted by administrative control.

7.3.2.15.5.2.3.1.19 ECCS-UC - IEEE 279 (1971), Paragraph 4.19 - Identification of Protective Actions

System operation is indirectly indicated and identified by unit cooler trouble alarms.

7.3.2.15.5.2.3.1.20 ECCS-UC - IEEE 279 (1971), Paragraph 4.20 - Information Readout

The information readout for the ECCS-UC is described in Section 7.3.1.1.15.5.12.2.

7.3.2.15.5.2.3.1.21 ECCS-UC - IEEE 279 (1971), Paragraph 4.21 - System Repair

The recognition and location of failed components will be accomplished during periodic testing.

7.3.2.15.5.2.3.1.22 ECCS-UC - IEEE 279 (1971), Paragraph 4.22 - Identification of Protection Systems

Each logic cabinet and control panel is distinctively identified with a nameplate which identifies the safety system. Cables and cable trays are identified by a color code and tags which identify them as being of a separate channel.

7.3.2.15.5.2.3.2 ECCS-UC - IEEE 308 (1974) - Criteria for Class 1E Electrical Systems for Nuclear Power Generating Stations

Refer to Section 8.3.2.2.1.12.

7.3.2.15.5.2.3.3 ECCS-UC - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1E Electric Equipment for Nuclear Power Generating Stations

Refer to Section 7.1.2.7.4.

7.3.2.15.5.2.3.4 ECCS-UC - IEEE 336 (1971) - Installation, Inspection, and Testing Requirements for Instrumentation and Electric Equipment During the Construction of Nuclear Power Generating Stations

The requirements of this standard have been met by the quality assurance program for construction of safety-related items.

7.3.2.15.5.2.3.5 ECCS-UC - IEEE 338 (1975) - Criteria for the Periodic Testing of Nuclear Power Generating Station Protection Systems

Refer to Section 7.1.2.7.6.

7.3.2.15.5.2.3.6 ECCS-UC - IEEE 344 (1971) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations

Refer to Section 7.1.2.7.7.

7.3.2.15.5.2.3.7 ECCS-UC - IEEE 379 (1972) - Guide for the Application of the Single Failure Criterion to Nuclear Power Generating Station Protection Systems

The single failure criterion of IEEE 379 (1972) is met as described in Section 7.3.2.15.5.2.3.1.2.

7.3.2.15.5.2.3.8 ECCS-UC - IEEE 384 (1974) - Criteria for Separation of Class 1E Equipment and Circuits

Refer to Section 7.1.2.7.11.

7.3.2.15.6 Auxiliary Equipment Room Ventilation System - Instrumentation and Controls

7.3.2.15.6.1 AERVS General Functional Requirements Conformance

The AERVS is designed with sufficient capacity and redundancy so that a single active or passive electrical or control component failure will not prevent the system from performing its safety-related functions. The AERVS operates continuously during normal and emergency plant operation. For the safety design basis refer to Section 7.1.2.1.33.6.1 and for additional details refer to Section 9.4.1.

7.3.2.15.6.2 AERVS Specific Regulatory Requirements Conformance

7.3.2.15.6.2.1 AERVS Conformance to Regulatory Guides

7.3.2.15.6.2.1.1 AERVS - Regulatory Guide 1.22 (1972) - Periodic Testing of Protection System Actuation Functions (Safety Guide 22)

The AERVS can be manually initiated and is capable of being tested during normal plant operation. Hand switches located on the local panel allow periodic testing of the unit coolers in accordance with the requirements of Chapter 16.

7.3.2.15.6.2.1.2 AERVS - Regulatory Guide 1.29 (1978) - Seismic Design Classification

The AERVS complies with this regulatory guide as discussed in Section 3.2.

7.3.2.15.6.2.1.3 AERVS - Regulatory Guide 1.30 (1972) - Quality Assurance Requirements for Installation, Inspection, and Testing of Instrumentation and Electric Equipment for Nuclear Power Plants (Safety Guide 30)

Refer to Section 8.1.6.1.5 and Chapter 17.

7.3.2.15.6.2.1 3A AERVS - Regulatory Guide 1.32 (1977) - Criteria for Safety Related Electric Power Systems for Nuclear Power Plants Refer to Section 8.1.6.1.6.

7.3.2.15.6.2.1.4 AERVS - Regulatory Guide 1.47 (1973) - Bypassed and Inoperable Status Indications for Nuclear Power Plant Safety Systems

The AERVS meets the intent of this regulatory guide by using a system trouble alarm in the control room.

7.3.2.15.6.2.1.5 AERVS - Regulatory Guide 1.53 (1973) - Application of the Single Failure Criterion to Nuclear Power Plant Protection Systems

Compliance with Regulatory Guide 1.53 is achieved by specifying, designing, and constructing the AERVS to meet the single failure criterion, section 4.2 of IEEE 279 (1971), and IEEE 379 (1972). Redundant sensors and wiring are separated. The logic components and wiring are separated to ensure that a failure in a sensing element or the decision logic or an actuator does not affect its redundant counterpart and prevent protective action. Separate channels are employed so that a fault affecting one channel does not prevent the redundant channel from operating properly.

7.3.2.15.6.2.1.6 AERVS - Regulatory Guide 1.62 (1973) - Manual Initiation of Protective Actions

Controls are provided locally to manually initiate the AERVS.

7.3.2.15.6.2.1.7 AERVS - Regulatory Guide 1.75 (1978) - Physical Independence of Electric Systems

Refer to Section 8.1.6.1.14 for compliance with this regulatory guide.

7.3.2.15.6.2.1.8 AERVS - Regulatory Guide 1.89 (1974) - Qualification of Class 1E Equipment for Nuclear Power Plants

The qualification of Class 1E equipment for the AERVS is discussed in Section 8.1.6.1.16.

7.3.2.15.6.2.1.9 AERVS - Regulatory Guide 1.100 (1977) - Seismic Qualification of Electric Equipment for Nuclear Power Plants

Conformance with this regulatory guide is covered by Section 3.10.

7.3.2.15.6.2.1.10 AERVS - Regulatory Guide 1.105 (1976) - Instrument Setpoints

Instrument setpoints are selected to allow for the inaccuracy of the instrument, uncertainties in calibration, and instrument drift between calibrations to assure initiation of the AERVS to maintain the associated room temperatures within the specified limits.

7.3.2.15.6.2.1.11 AERVS - Regulatory Guide 1.118 (1978) - Periodic Testing of Electric Power and Protection Systems

Refer to Section 7.1.2.5.26.

7.3.2.15.6.2.2 AERVS Conformance to 10CFR50, Appendix A, General Design Criteria

7.3.2.15.6.2.2.1 AERVS - GDC 1 - Quality Standards and Records

The AERVS is included in an established quality assurance program discussed in Section 3.1 and Chapter 17.

7.3.2.15.6.2.2.2 AERVS - GDC 2 - Design Bases for Protection Against Natural Phenomena

Refer to Section 3.1.

7.3.2.15.6.2.2.3 AERVS - GDC 3 - Fire Protection

Refer to Section 3.1.

7.3.2.15.6.2.2.4 AERVS - GDC 4 - Environmental and Dynamic Effects Design Bases

Refer to Section 3.1.

7.3.2.15.6.2.2.5 AERVS - GDC 5 - Sharing of Structures, Systems and Components

The AERVS is common to Units 1 and 2. There are two independent divisions, each capable of maintaining a suitable environment for the safety-related equipment used for the safe shutdown of either unit. Since the AERVS and control structure are designed to remain functional during and after the most severe natural phenomena, sharing this system will not impair its ability to perform its safety function.

7.3.2.15.6.2.2.6 AERVS - GDC 13 - Instrumentation and Control

Instrumentation for the AERVS is selected to monitor variables over anticipated ranges during normal and emergency operating conditions.

7.3.2.15.6.2.2.7 AERVS - GDC 19 - Control Room

Refer to Section 3.1

7.3.2.15.6.2.3 AERVS Conformance to Industry Codes and Standards

7.3.2.15.6.2.3.1 AERVS - IEEE 279 (1971), Criteria for Protection Systems for Nuclear Power Generating Stations

Compliance of the AERVS with IEEE 279 (1971) is detailed below.

7.3.2.15.6.2.3.1.1 AERVS - IEEE 279 (1971), Paragraph 4.1 - General Functional Requirement

Deliberate operator action after an accident is not required to initiate AERVS operation because the system operates continuously during normal plant operation.

7.3.2.15.6.2.3.1.2 AERVS - IEEE 279 (1971), Paragraph 4.2 - Single Failure Criterion

The AERVS consists of redundant unit coolers and independent sets of controls and power which meet the single failure criterion.

7.3.2.15.6.2.3.1.3 AERVS - IEEE 279 (1971), Paragraph 4.3 - Quality of Components and Modules

All safety-related components are selected on the basis of suitability for the specific application. A quality control and assurance program is required to be implemented and documented by equipment vendors, which complies with the requirements set forth in 10CFR50, Appendix B.

7.3.2.15.6.2.3.1.4 AERVS - IEEE 279 (1971), Paragraph 4.4 - Equipment Qualification

Refer to Section 3.11 for discussion of equipment qualification.

7.3.2.15.6.2.3.1.5 AERVS - IEEE 279 (1971), Paragraph 4.5 - Channel Integrity

The AERVS meets the channel integrity by utilizing the design features described in the other paragraphs of this section.

7.3.2.15.6.2.3.1.6 AERVS - IEEE 279 (1971), Paragraph 4.6 - Channel Independence

The control and power circuits for each AERVS component are physically and electrically separated.

7.3.2.15.6.2.3.1.7 AERVS - IEEE 279 (1971), Paragraph 4.7 - Control and Protection System Interaction

The AERVS has no interaction with other plant control systems. Annunciator circuits using contacts at sensor and logic relays cannot impair the operability of the AERVS control because of electrical isolation.

7.3.2.15.6.2.3.1.8 AERVS - IEEE 279 (1971), Paragraph 4.8 - Derivation of System Inputs

The AERVS operates continuously.

7.3.2.15.6.2.3.1.9 AERVS - IEEE 279 (1971), Paragraph 4.9 - Capability for Sensor Checks

The AERVS can be tested for operational availability as per Section 7.3.1.1.15.6.10.

7.3.2.15.6.2.3.1.10 AERVS - IEEE 279 (1971), Paragraph 4.10 - Capability for Testing and Calibration

The AERVS is capable of being tested during normal plant operation to verify that the system is capable of performing its intended function.

7.3.2.15.6.2.3.1.11 AERVS - IEEE 279 (1971), Paragraph 4.11 - Channel Bypass or Removal from Operation

A channel bypass or removal of a component of an initiation circuit channel will prevent the AERVS itself from complying with the single failure criterion.

7.3.2.15.6.2.3.1.12 AERVS - IEEE 279 (1971), Paragraph 4.12 - Operating Bypasses

AERVS bypasses are discussed in Section 7.3.1.1.15.6.6.

7.3.2.15.6.2.3.1.13 AERVS - IEEE 279 (1971), Paragraph 4.13 - Indication of Bypasses

Each of the bypasses described in Section 7.3.1.1.15.6.6 are automatically indicated in the control room. In addition, each of these bypasses will initiate a system out-of-service annunciator.

7.3.2.15.6.2.3.1.14 AERVS - IEEE 279 (1971), Paragraph 4.14 - Access to Means for Bypassing

Manual bypass of initiating circuits will be procedurally controlled by administrative means.

7.3.2.15.6.2.3.1.15 AERVS - IEEE 279 (1971), Paragraph 4.15 - Multiple Setpoints

The AERVS high temperature switches have been designed to allow adjustment of trip setpoints to more stringent settings if required.

7.3.2.15.6.2.3.1.16 AERVS - IEEE 279 (1971), Paragraph 4.16 - Completion of Protective Action Once It Is Initiated

Once the AERVS is initiated it will continue to operate until manually terminated by the operator.

7.3.2.15.6.2.3.1.17 AERVS - IEEE 279 (1971), Paragraph 4.17 - Manual Initiation

A single failure in the control system of a division of the AERVS cannot disable the automatic or manual operation of the other AERVS division.

7.3.2.15.6.2.3.1.18 AERVS - IEEE 279 (1971), Paragraph 4.18 - Access to Setpoint Adjustments, Calibration, and Test Points

Access to the temperature switch setpoints is restricted by administrative control.

7.3.2.15.6.2.3.1.19 AERVS - IEEE 279 (1971), Paragraph 4.19 - Identification of Protective Actions

System operation is indirectly indicated and identified by high temperature, filter pressure differential, and low air flow alarms.

7.3.2.15.6.2.3.1.20 AERVS - IEEE 279 (1971), Paragraph 4.20 - Information Readout

The information readout for the AERVS is described in Section 7.3.1.1.15.6.12.2.

7.3.2.15.6.2.3.1.21 AERVS - IEEE 279 (1971), Paragraph 4.21 - System Repair

The recognition and location of failed components will be accomplished during periodic testing.

7.3.2.15.6.2.3.1.22 AERVS - IEEE 279 (1971), Paragraph 4.22 - Identification of Protection Systems

Each logic cabinet and control panel is distinctively identified with a nameplate which identifies the safety system. Cables and cable trays are identified by a color code and tags which identify them as being of a separate channel.

7.3.2.15.6.2.3.2 AERVS - IEEE 308 (1974) - Criteria for Class 1E Electrical Systems for Nuclear Power Generating Stations

Refer to Section 8.3.2.2.1.12.

7.3.2.15.6.2.3.3 AERVS - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1E Electric Equipment for Nuclear Power Generating Stations

Refer to Section 7.1.2.7.4.

7.3.2.15.6.2.3.4 AERVS - IEEE 336 (1971) - Installation, Inspection, and Testing Requirements for Instrumentation and Electric Equipment During the Construction of Nuclear Power Generating Stations

The requirements of this standard have been met by the quality assurance program for construction of safety-related items.
Refer to Section 7.1.2.7.5.

7.3.2.15.6.2.3.5 AERVS - IEEE 338 (1975) - Criteria for the Periodic Testing of Nuclear Power Generating Station Protection Systems

Refer to Section 7.1.2.7.6.

7.3.2.15.6.2.3.6 AERVS - IEEE 344 (1971) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations

Refer to Section 7.1.2.7.7.

7.3.2.15.6.2.3.7 AERVS - IEEE 379 (1972) - Guide for the Application of the Single Failure Criterion to Nuclear Power Generating Station Protection Systems

The single failure criterion of IEEE 379 (1972) is met as described in Section 7.3.2.15.6.2.3.1.2.

7.3.2.15.6.2.3.8 AERVS - IEEE 384 (1974) - Criteria for Separation of Class 1E Equipment and Circuits

Refer to Section 7.1.2.7.11.

7.3.2.15.7 Safety-Related Equipment Area Cooling Ventilation Systems Additional Design Considerations Analyses

As defined in Regulatory Guide 1.70, paragraph 7.3.2, the following considerations are addressed:

a. Loss of the plant instrument air system does not prevent the safety-related equipment area cooling ventilation systems from performing their protective function.

b. Loss of cooling water to any single piece of vital equipment does not prevent the safety-related equipment area cooling ventilation systems from performing their protective function.

7.3.2.16 Drywell Unit Coolers - Instrumentation and Controls

7.3.2.16.1 DUC General Functional Requirements Conformance

The DUC are designed with sufficient capacity and redundancy so that a single active or passive electrical or control component failure will not prevent the system from performing its safety-related function. The DUC are manually initiated and are used during normal plant operation for cooling and ventilation. During emergency conditions, they perform the safety-related function of mixing the containment atmosphere. For the safety design basis refer to Section 7.1.2.1.34.1 and for additional details refer to Section 9.4.5.

7.3.2.16.2 DUC Specific Regulatory Requirements Conformance

7.3.2.16.2.1 DUC Conformance to Regulatory Guides

7.3.2.16.2.1.1 DUC - Regulatory Guide 1.22 (1972) - Periodic Testing of Protection System Actuation Functions (Safety Guide 22)

The DUC are manually initiated and are capable of being tested during normal plant operation. Hand switches located in the control room allow periodic testing of the unit coolers in accordance with the requirements of Chapter 16.

7.3.2.16.2.1.2 DUC - Regulatory Guide 1.29 (1978) - Seismic Design Classification

The DUC comply with this regulatory guide as discussed in Section 3.2.

7.3.2.16.2.1.3 DUC - Regulatory Guide 1.30 (1972) - Quality Assurance Requirements for the Installation, Inspection, and Testing of Instrumentation and Electric Equipment (Safety Guide 30)

Refer to Section 8.1.6.1.5 and Chapter 17.

7.3.2.16.2.1.4 DUC - Regulatory Guide 1.47 (1973) - Bypassed and Inoperable Status Indication for Nuclear Power Plant Safety Systems

The DUC meets the intent of this regulatory guide by using a fan system trouble alarm in the control room.

7.3.2.16.2.1.5 DUC - Regulatory Guide 1.53 (1973) - Application of the Single Failure Criterion to Nuclear Power Plant Protection Systems

Compliance with Regulatory Guide 1.53 is achieved by specifying, designing, and constructing the DUC to meet the single failure criterion, section 4.2 of IEEE 279 (1971) and IEEE 379 (1972). The logic components and wiring are separated to ensure that a failure in a sensing element or the decision logic will not affect its redundant counterpart and prevent protective action. Separate channels are employed so that a fault affecting one channel will not prevent the redundant channel from operating properly.

7.3.2.16.2.1.6 DUC - Regulatory Guide 1.62 (1973) - Manual Initiation of Protective Action

Controls are provided in the main control room to manually initiate the DUC.

7.3.2.16.2.1.7 DUC - Regulatory Guide 1.63 (1978) - Electric Penetration Assemblies in Containment Structures for Light-Water-Cooled Nuclear Power Plants

Refer to Section 8.1.6.1.12.

7.3.2.16.2.1.8 DUC - Regulatory Guide 1.75 (1978) - Physical Independence of Electric Systems

Refer to Section 8.1.6.1.14 for compliance.

7.3.2.16.2.1.9 DUC - Regulatory Guide 1.89 (1974) - Qualification of Class 1E Equipment for Nuclear Power Plants

The qualification of Class 1E equipment for the DUC is discussed in Section 8.1.6.1.16.

7.3.2.16.2.1.10 DUC - Regulatory Guide 1.100 (1977) - Seismic Qualification of Electric Equipment for Nuclear Power Plants

Conformance is discussed in Section 3.10.

7.3.2.16.2.1.11 DUC - Regulatory Guide 1.118 (1978) - Periodic Testing of Electric Power and Protection Systems

Refer to Section 7.1.2.5.26.

7.3.2.16.2.2 DUC Conformance to 10CFR50, Appendix A, General Design Criteria

7.3.2.16.2.2.1 DUC - GDC 1 - Quality Standards and Records

The DUC are included in an established quality assurance program discussed in Section 3.1 and Chapter 17.

7.3.2.16.2.2.2 DUC - GDC 2 - Design Bases for Protection Against Natural Phenomena

Refer to Section 3.1.

7.3.2.16.2.2.3 DUC - GDC 3 - Fire Protection

Refer to Section 3.1.

7.3.2.16.2.2.4 DUC - GDC 4 - Environmental and Dynamic Effects Design Bases

Refer to Section 3.1.

7.3.2.16.2.3 DUC Conformance to Industry Codes and Standards

7.3.2.16.2.3.1 DUC - IEEE 279 (1971) - Criteria for Protection Systems for Nuclear Power Generating Stations

Compliance of the DUC with IEEE 279 (1971) is detailed as follows:

7.3.2.16.2.3.1.1 DUC - IEEE 279 (1971), Paragraph 4.1 - General Functional Requirement

Deliberate operator action after an accident is not required to initiate DUC operation because they operate continuously during normal plant operation.

7.3.2.16.2.3.1.2 DUC - IEEE 279 (1971), Paragraph 4.2 - Single Failure Criterion

The DUC consist of redundant fans within each fan cabinet and independent sets of controls and power which meet the single failure criterion.

7.3.2.16.2.3.1.3 DUC - IEEE 279 (1971), Paragraph 4.3 - Quality of Components and Modules

All safety-related components are selected on the basis of suitability for the specific application. A quality control and assurance program is required to be implemented and documented by equipment vendors which complies with the requirements set forth in 10CFR50, Appendix B.

7.3.2.16.2.3.1.4 DUC - IEEE 279 (1971), Paragraph 4.4 - Equipment Qualification

Refer to Section 3.11 for discussion of equipment qualification.

7.3.2.16.2.3.1.5 DUC - IEEE 279 (1971), Paragraph 4.5 - Channel Integrity

The DUC meet the channel integrity criterion by utilizing the design features described in the other paragraphs of this section.

7.3.2.16.2.3.1.6 DUC - IEEE 279 (1971), Paragraph 4.6 - Channel Independence

The control and power circuits for each DUC fan is physically and electrically separated.

7.3.2.16.2.3.1.7 DUC - IEEE 279 (1971), Paragraph 4.7 - Control and Protection System Interaction

No single active failure of the DUC can result in a condition requiring protective action.

7.3.2.16.2.3.1.8 DUC - IEEE 279 (1971), Paragraph 4.8 - Derivation of System Inputs

The DUC fans operate continuously during emergency conditions and are not initiated by signals from a monitored variable.

7.3.2.16.2.3.1.9 DUC - IEEE 279 (1971), Paragraph 4.9 - Capability for Sensor Checks

The DUC can be tested for operational availability as per Section 7.3.1.1.16.10.

7.3.2.16.2.3.1.10 DUC - IEEE 279 (1971), Paragraph 4.10 - Capability for Testing and Calibration

The DUC are capable of being tested during normal plant operation to verify that they are capable of performing their intended function.

7.3.2.16.2.3.1.11 DUC - IEEE 279 (1971), Paragraph 4.11 - Channel Bypass or Removal from Operation

A channel bypass or removal of a component of an initiation circuit channel will prevent the DUC themselves from complying with the single failure criterion.

7.3.2.16.2.3.1.12 DUC - IEEE 279 (1971), Paragraph 4.12 - Operating Bypasses

DUC bypasses are discussed in Section 7.3.1.1.16.6.

7.3.2.16.2.3.1.13 DUC - IEEE 279 (1971), Paragraph 4.13 - Indication of Bypasses

Each of the bypasses described in Section 7.3.1.1.16.6 is automatically indicated in the control room. In addition, each of these bypasses will initiate a system out-of-service annunciator.

7.3.2.16.2.3.1.14 DUC - IEEE 279 (1971), Paragraph 4.14 - Access to Means for Bypassing

Manual bypass of initiating circuits is procedurally controlled by administrative means.

7.3.2.16.2.3.1.15 DUC - IEEE 279 (1971), Paragraph 4.15 - Multiple Setpoints

The DUC are manually initiated. Flow switches to initiate redundant fan operation are designed to allow adjustment of trip setpoints to more stringent settings if required.

7.3.2.16.2.3.1.16 DUC - IEEE 279 (1971), Paragraph 4.16 - Completion of Protective Action Once It Is Initiated

Once the DUC are initiated, they will continue to operate until the operator terminates system operation by manual override.

7.3.2.16.2.3.1.17 DUC - IEEE 279 (1971), Paragraph 4.17 - Manual Initiation

A single failure in the control system of a division of the DUC cannot disable the automatic or manual operation of the other DUC division.

7.3.2.16.2.3.1.18 DUC - IEEE 279 (1971), Paragraph 4.18 - Access to Setpoint Adjustments, Calibration, and Test Points

The DUC are manually initiated.

7.3.2.16.2.3.1.19 DUC - IEEE 279 (1971), Paragraph 4.19 - Identification of Protective Actions

System operation is indirectly indicated and identified by fan motor status and fan system trouble annunciators.

7.3.2.16.2.3.1.20 DUC - IEEE 279 (1971), Paragraph 4.20 - Information Readout

The information readout for the DUC is described in Section 7.3.1.1.16.12.2.

7.3.2.16.2.3.1.21 DUC - IEEE 279 (1971), Paragraph 4.21 - System Repair

The recognition and location of failed components will be accomplished during periodic testing.

7.3.2.16.2.3.1.22 DUC - IEEE 279 (1971), Paragraph 4.22 - Identification of Protection Systems

Each logic cabinet and control panel is distinctively identified with a nameplate which identifies the safety system. Cables and cable trays are identified by a color code and tags which identify them as being of a separate channel.

7.3.2.16.2.3.2 DUC - IEEE 308 (1974) - Criteria for Class 1E Electrical Systems for Nuclear Power Generating Stations

Refer to Section 8.3.2.2.1.12.

7.3.2.16.2.3.3 DUC - IEEE 317 (1972) - Electric Penetration Assemblies in Containment Structures for Nuclear Power Generating Stations

Refer to Section 8.1.6.1.12.

7.3.2.16.2.3.4 DUC - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1E Electric Equipment for Nuclear Power Generating Stations

Refer to Section 3.11.

7.3.2.16.2.3.5 DUC - IEEE 336 (1971) - Installation, Inspection, and Testing Requirements for Instrumentation and Electric Equipment During the Construction of Nuclear Power Generating Stations

The requirements of this standard have been met by the quality assurance program for construction of safety-related items.

7.3.2.16.2.3.6 DUC - IEEE 338 (1975) - Criteria for the Periodic Testing of Nuclear Power Generating Station Protection Systems

Refer to Section 7.1.2.7.6.

7.3.2.16.2.3.7 DUC - IEEE 344 (1971) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations

Refer to Section 7.1.2.7.7.

7.3.2.16.2.3.8 DUC - IEEE 379 (1972) - Guide for the Application of the Single Failure Criterion to Nuclear Power Generating Station Protection Systems

The single failure criterion of IEEE 379 (1972) is met as described in Section 7.3.2.16.2.3.1.2.

7.3.2.16.2.3.9 DUC - IEEE 384 (1974) - Criteria for Separation of Class 1E Equipment and Circuits

Refer to Section 7.1.2.7.11.

7.3.2.16.3 DUC Additional Design Considerations Analyses

As defined in Regulatory Guide 1.70, paragraph 7.3.2, the following considerations are addressed:

a. Loss of the plant instrument air system does not prevent the DUC from performing their protective function.

b. Loss of cooling water to any single piece of vital equipment does not prevent the DUC from performing their protective function.

7.3.2.17 Refueling Area Isolation System – Instrumentation and Controls

7.3.2.17.1 RAIS General Functional Requirements Conformance

The RAIS is designed with sufficient capacity and redundancy so that a single active failure does not prevent the system from performing its safety-related functions. The RAIS is automatically initiated by detection of high radiation in the refueling area exhaust ducts or low pressure differential between the refueling area and the atmosphere. For the safety design basis refer to Section 7.1.2.1.42.1. Section 11.5 gives information on radiation detectors.

7.3.2.17.2 RAIS Specific Regulatory Requirements Conformance

7.3.2.17.2.1 RAIS Conformance to Regulatory Guides

7.3.2.17.2.1.1 RAIS - Regulatory Guide 1.22 (1972) - Periodic Testing of Protection System Actuation Function (Safety Guide 22)

The RAIS can be manually initiated and is capable of being tested during normal plant operation. Hand switches located in the control room allow periodic testing of the isolation valves in accordance with the requirements of Chapter 16.

7.3.2.17.2.1.2 RAIS - Regulatory Guide 1.29 (1978) - Seismic Design Classification

The RAIS complies with this regulatory guide as discussed in Section 3.2.

7.3.2.17.2.1.3 RAIS - Regulatory Guide 1.30 (1972) - Quality Assurance Requirements for the Installation, Inspection, and Testing of Instrumentation and Electrical Equipment (Safety Guide 30)

See Section 8.1.6.1.5 and Chapter 17.

7.3.2.17.2.1.4 RAIS - Regulatory Guide 1.47 (1973) - Bypassed and Inoperable Status Indication for Nuclear Power Plant Safety Systems

The RAIS isolation system armed, initiation, and isolation incomplete alarms meet the intent of this regulatory guide.

7.3.2.17.2.1.5 RAIS - Regulatory Guide 1.53 (1973) - Application of the Single Failure Criterion to Nuclear Power Plant Protection Systems

Compliance with Regulatory Guide 1.53 is achieved by specifying, designing, and constructing the RAIS to meet the single failure criterion, section 4.2 of IEEE 279 (1971) and IEEE 379 (1972). Redundant sensors and wiring are separated. The logic components and wiring are separated to ensure that a failure in a sensing element, the decision logic, or an actuator does not affect its redundant counterpart and prevent protective action. Separate channels are employed so that a fault affecting one channel does not prevent the redundant channel from operating properly.

7.3.2.17.2.1.6 RAIS - Regulatory Guide 1.62 (1973) - Manual Initiation of Protective Actions

Controls are provided in the main control room to manually initiate the RAIS.

7.3.2.17.2.1.7 RAIS - Regulatory Guide 1.75 (1978) - Physical Independence of Electric Systems

See Section 8.1.6.1.14 for compliance with this regulatory guide.

7.3.2.17.2.1.8 RAIS - Regulatory Guide 1.89 (1974) - Qualification of Class 1E Equipment for Nuclear Power Plants

The qualification of Class 1E equipment for the RAIS is discussed in Section 8.1.6.1.16.

7.3.2.17.2.1.9 RAIS - Regulatory Guide 1.100 (1977) - Seismic Qualification of Electric Equipment for Nuclear Power Plants

Conformance with this regulatory guide is covered by Section 3.10.

7.3.2.17.2.1.10 RAIS - Regulatory Guide 1.105 (1976) - Instrument Setpoints

To ensure initiation of the RAIS in conjunction with the SGTS to prevent the uncontrolled release of airborne contaminants to the atmosphere, instrument setpoints are selected to allow for the inaccuracy of the instrument, uncertainties in the calibration, and instrumentation drift likely to occur between calibrations.

Refer to Chapter 16 for safety setpoints.

7.3.2.17.2.1.11 RAIS - Regulatory Guide 1.118 (1978) - Periodic Testing of Electric Power and Protection Systems

See Section 7.1.2.5.26.

7.3.2.17.2.2 RAIS Conformance to 10CFR50, Appendix A, General Design Criteria

7.3.2.17.2.2.1 RAIS - GDC 1 - Quality Standards and Records

The RAIS is included in an established quality assurance program discussed in Section 3.1 and Chapter 17.

7.3.2.17.2.2.2 RAIS - GDC 2 - Design Bases for Protection Against Natural Phenomena

See Section 3.1.

7.3.2.17.2.2.3 RAIS - GDC 3 - Fire Protection

See Section 3.1.

7.3.2.17.2.2.4 RAIS - GDC 4 - Environmental and Dynamic Effects Design Bases

See Section 3.1.

7.3.2.17.2.2.5 RAIS - GDC 13 - Instrumentation and Control

Instrumentation for the RAIS is selected to monitor variables over anticipated ranges during normal and emergency operating conditions.

7.3.2.17.2.2.6 RAIS - GDC 20 - Protection System Functions

See Section 7.3.2.17.1.

7.3.2.17.2.2.7 RAIS - GDC 21 - Protection System Reliability and Testability

The RAIS is designed with redundancy and separation so that a single failure does not result in the loss of the protective function. The system is capable of being tested during normal plant operation.

7.3.2.17.2.2.8 RAIS - GDC 22 - Protection System Independence

The components of the RAIS are designed so that the thermal environment resulting from any potential accident conditions in which the components are required to function does not interfere with that function. The controls for the two RAIS divisions are electrically and physically separated so that a single failure does not result in the loss of both divisions. Power for the components of each division is provided from separate Class 1E power sources.

7.3.2.17.2.2.9 RAIS - GDC 23 - Protection System Failure Modes

Each RAIS division is designed to fail in a safe state, permitting its redundant division to provide isolation.

7.3.2.17.2.2.10 RAIS - GDC 24 - Separation of Protection and Control Systems

The control system for the RAIS does not interact with the plant control systems.

7.3.2.17.2.2.11 RAIS - GDC 29 - Protection Against Anticipated Operational Occurrences

The high functional reliability of the RAIS is achieved through system redundancy, physical and electrical independence, fail-safe design, inservice testability, and equipment suitable for normal and accident environments.

7.3.2.17.2.2.12 RAIS - GDC 60 - Control of Releases of Radioactive Materials to the Environment

The RAIS isolates the refueling area from the environment to prevent uncontrolled exfiltration of air to the environment.

7.3.2.17.2.3 RAIS Conformance to Industry Codes and Standards

7.3.2.17.2.3.1 RAIS - IEEE 279 (1971) - Criteria for Protection for Nuclear Power Generating Stations

Compliance of the RAIS with IEEE 279 (1971) is detailed below.

7.3.2.17.2.3.1.1 RAIS - IEEE 279 (1971), Paragraph 4.1 - General Functional Requirement

The RAIS is an automatically initiated system as discussed in Section 7.3.2.17.1.

7.3.2.17.2.3.1.2 RAIS - IEEE 279 (1971), Paragraph 4.2 - Single Failure Criterion

The RAIS consists of redundant sets of isolation valves and independent sets of controls and power that meet the single failure criterion.

7.3.2.17.2.3.1.3 RAIS - IEEE 279 (1971), Paragraph 4.3 - Quality of Components and Modules

All safety-related components are selected on the basis of suitability for the specific application. A quality control and assurance program is required to be implemented and documented by equipment vendors, which complies with the requirements set forth in 10CFR50, Appendix B.

7.3.2.17.2.3.1.4 RAIS - IEEE 279 (1971), Paragraph 4.4 - Equipment Qualification

See Section 3.11 for a discussion of equipment qualification.

7.3.2.17.2.3.1.5 RAIS - IEEE 279 (1971), Paragraph 4.5 - Channel Integrity

The RAIS meets the channel integrity objective by using the design features described in the other paragraphs of this section.

7.3.2.17.2.3.1.6 RAIS - IEEE 279 (1971), Paragraph 4.6 - Channel Independence

The control and power circuits for each RAIS component are physically and electrically separated.

7.3.2.17.2.3.1.7 RAIS - IEEE 279 (1971), Paragraph 4.7 - Control and Protection System Interaction

The RAIS has no interaction with other plant control systems. Annunciator circuits using contact at sensor and logic relays cannot impair the operability of the RAIS control because of electrical isolation.

7.3.2.17.2.3.1.8 RAIS - IEEE 279 (1971), Paragraph 4.8 - Derivation of System Inputs

Initiation of the RAIS is derived from conditions discussed in Section 7.3.2.17.1.1.

7.3.2.17.2.3.1.9 RAIS - IEEE 279 (1971), Paragraph 4.9 - Capability for Sensor Checks

The RAIS can be tested for operational availability as described in Section 7.3.1.1.17.10.

7.3.2.17.2.3.1.10 RAIS - IEEE 279 (1971), Paragraph 4.10 - Capability of Testing and Calibration

The RAIS is capable of being tested during normal plant operation to verify that the system is capable of performing its intended function.

7.3.2.17.2.3.1.11 RAIS - IEEE 279 (1971), Paragraph 4.11 - Channel Bypass or Removal from Operation

A channel bypass or removal of a component of an initiation circuit channel does not prevent the RAIS itself from complying with the single failure criterion.

7.3.2.17.2.3.1.12 RAIS - IEEE 279 (1971), Paragraph 4.12 - Operating Bypasses

RAIS bypasses are discussed in Section 7.3.1.1.17.6.

7.3.2.17.2.3.1.13 RAIS - IEEE 279 (1971), Paragraph 4.13 - Indication of Bypasses

Each of the bypasses described in Section 7.3.1.1.17.6 is automatically indicated in the control room. In addition, each of these bypasses initiates a system out-of-service annunciator.

7.3.2.17.2.3.1.14 RAIS - IEEE 279 (1971), Paragraph 4.14 - Access to Means for Bypassing

Manual bypass of initiating circuits is procedurally controlled by administrative means.

7.3.2.17.2.3.1.15 RAIS - IEEE 279 (1971), Paragraph 4.15 - Multiple Setpoints

The RAIS radiation detectors are designed to allow adjustment of trip setpoints to more stringent settings if required.

7.3.2.17.2.3.1.16 RAIS - IEEE 279 (1971), Paragraph 4.16 - Completion of Protective Action Once It Is Initiated

Once the RAIS is initiated, it continues to operate until the operator terminates system operation by manual override.

7.3.2.17.2.3.1.17 RAIS - IEEE 279 (1971), Paragraph 4.17 - Manual Initiation

A single failure in the control system of a division of the RAIS cannot disable the automatic or manual operation of the other RAIS division.

7.3.2.17.2.3.1.18 RAIS - IEEE 279 (1971), Paragraph 4.18 - Access to Setpoint Adjustments, Calibration, and Test Points

See Section 11.5 for access to radiation monitoring setpoints.

7.3.2.17.2.3.1.19 RAIS - IEEE 279 (1971), Paragraph 4.19 - Identification of Protective Actions

System operation is indirectly indicated and identified by high radiation alarms.

7.3.2.17.2.3.1.20 RAIS - IEEE 279 (1971), Paragraph 4.20 - Information Readout

The information readout for the RAIS system is described in Section 7.3.1.1.17.12.2.

7.3.2.17.2.3.1.21 RAIS - IEEE 279 (1971), Paragraph 4.21 - System Repair

The recognition and location of failed components is accomplished during periodic testing.

7.3.2.17.2.3.1.22 RAIS - IEEE 279 (1971), Paragraph 4.22 - Identification of Protection Systems

Each logic cabinet and control panel is distinctively identified with a nameplate that identifies the safety system. Cables and cable trays are identified by a color code and tags that identify them as being of a separate channel.

7.3.2.17.2.3.2 RAIS - IEEE 308 (1974) - Criteria for Class 1E Electrical Systems for Nuclear Power Generating Stations

See Section 8.3.2.2.1.12.

7.3.2.17.2.3.3 RAIS - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1E Electric Equipment for Nuclear Power Generating Stations

See Section 7.1.2.7.4.

7.3.2.17.2.3.4 RAIS - IEEE 336 (1971) - Installation, Inspection, and Testing Requirements for Instrumentation and Electric Equipment During the Construction of Nuclear Power Generating Stations

The requirements of this standard have been met by the quality assurance program for construction of safety-related items.

7.3.2.17.2.3.5 RAIS - IEEE 338 (1975) - Criteria for the Periodic Testing of Nuclear Power Generating Station Protection Systems

See Section 7.1.2.7.6.

7.3.2.17.2.3.6 RAIS - IEEE 344 (1971) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations

See Section 3.10.

7.3.2.17.2.3.7 RAIS - IEEE 379 (1972) - Guide for the Application of the Single Failure Criterion to Nuclear Power Generating Station Protection Systems

The single failure criterion of IEEE 379 (1972) is met as described in Section 7.3.2.17.2.3.1.2.

7.3.2.17.2.3.8 RAIS - IEEE 384 (1974) - Criteria for Separation of Class 1E Equipment and Circuits

See Section 7.1.2.7.11.

Table 7.3-1

HIGH PRESSURE COOLANT INJECTION SYSTEM
INSTRUMENT SPECIFICATIONS[2]

HPCI FUNCTION	INSTRUMENT	RANGE
Reactor vessel high water level turbine trip	Level sensor	-150/0/+60 inches[1]
Turbine exhaust high pressure	Pressure sensor	0-200 psi
HPCI system pump high/low suction pressure	Pressure sensor	0-100 psi 0-25 psi
Reactor vessel low water level	Level sensor	-150/0/+60 inches[1]
Primary containment (drywell) high pressure	Pressure sensor	0-10 psig
Pump minimum flow	Flow sensor	0-700 gpm
HPCI system steam supply low pressure	Pressure sensor	0-200 psig
Pump discharge pressure	Pressure sensor	0-1500 psi
CST low level	Level sensor	-12/0/+45 inches
Suppression pool high water level	Level sensor	23 feet - 25 feet
Turbine overspeed	Centrifugal device	[3]

(1) Instrument zero equal to 527.5 inches above vessel zero.
(2) For instrument accuracy and setpoints, see the Technical Specifications.
(3) Instrument range does not apply to this device.

Table 7.3-2

AUTOMATIC DEPRESSURIZATION SYSTEM
INSTRUMENT SPECIFICATIONS

ADS FUNCTION	INSTRUMENT	INSTRUMENT RANGE	ACCURACY
Reactor vessel low water level Level 1	Level sensor	-150/0/+60	±6 inches inches[1]
Reactor vessel low water level Level 3	Level sensor	0-60 inches	±1.5 inches
Primary containment high pressure	Pressure sensor	0-10 psig	±0.05 psi
LPCI permissive	Pressure sensor	0-500 psi	±2.5 psi
Core Spray permissive	Pressure sensor	0-500 psi	±2.5 psi
Automatic depressurization time delay	Timer	0-180 sec	±18 sec.

(1) Instrument zero equal to 527.5 inches above vessel zero.

Table 7.3-3

CORE SPRAY SYSTEM INSTRUMENT SPECIFICATIONS[2]

CORE SPRAY FUNCTION	INSTRUMENT	RANGE
Reactor vessel low water	Level sensor	-150/0/+60 inches [1]
Primary containment high pressure	Pressure sensor	0-10 psig
Reactor vessel low pressure	Pressure sensor	0-1200 psi
Core spray sparger high differential pressure	Differential pressure sensor	-10/0/+10 psid
Pump discharge flow	Flow sensor	0-8,800 gpm
Pump suction Pressure	Pressure sensor	-30" Hg to 60 psig
Pump discharge pressure	Pressure sensor	0-500 psig

(1) Instrument zero equal to 527.5 inches above vessel zero.

(2) For allowable value of applicable core spray function see technical specifications.

Table 7.3-4

LOW PRESSURE COOLANT INJECTION INSTRUMENT SPECIFICATIONS[2]

LPCI FUNCTION	INSTRUMENT	RANGE
Reactor vessel low water level (LPCI initiation)	Level sensor	-150/0/+60 inches[1]
Drywell high pressure (LPCI initiation)	Pressure sensor	0-10 psig
LPCI pump delay (on loss of normal auxiliary power)	Timer	1.5-15 sec
Injection valve Differential pressure	Differential pressure switch	-200/0/+800 psid
Pump minimum flow bypass	Flow sensor	0-2500 gpm
Pump discharge pressure (signal to ADS)	Pressure sensor	0-500 psig
RHR injection line high differential pressure	Differential pressure sensor	-10/0/10 psi

(1) Instrument zero equal to 527.5 inches above vessel zero.
(2) For instrument accuracy and setpoints, see the Technical Specifications.

Table 7.3-5

PRIMARY CONTAINMENT AND REACTOR VESSEL ISOLATION CONTROL SYSTEM INSTRUMENT SPECIFICATIONS

ISOLATION FUNCTION	SENSOR	RANGE
Reactor vessel low water level (isolation of primary system valves except main steam line valves) Level 3	Level sensor	0-60 inches(1)
Reactor vessel low water level Level 2	Level sensor	-150/0/+60 inches(1)
Reactor vessel low water level (isolates main steam line valves) Level 1	Level sensor	-150/0/+60 inches(1)
Reactor vessel low water level Level 1	Level sensor	-150/0/+60 inches(1)
Main steam line high flow	Differential pressure sensor	0-150 psid
Main turbine inlet low pressure	Pressure sensor	0-1200 psi
Drywell high pressure	Pressure sensor	0-10 psig
RCIC turbine steam line space high temperature	Differential temperature & ambient temperature sensors	0°F-150°F(3) 50°F-350°F
RCIC turbine steam line high flow	Differential pressure sensor	-500/0/+500 inches

Table 7.3-5 (Cont'd)

ISOLATION FUNCTION	SENSOR	RANGE
RCIC turbine steam line low pressure	Pressure sensor	0-200 psi
HPCI turbine steam line space high temperature	Differential temperature & ambient temperature sensors	0°F-150°F(3) 50°F-350°F
HPCI turbine steam line high flow	Differential pressure sensor	-1000/0/+1000 inches
HPCI turbine line low pressure	Pressure sensor	0-200 psi
Reactor enclosure Ventilation exhaust high radiation	Radiation monitor	0.01-100 mr/hr
Refueling floor Ventilation exhaust high radiation	Radiation monitor	0.01-100 mr/hr
RWCU space high Temperature	Differential temperature & ambient temperature sensors	0°F-150°F(3) 50°F-350°F
Main Steam Line Outboard MSIV room high temperature	Ambient temperature sensor	50°F-350°F
RWCU high Differential flow	Differential flow	0-100 gpm(3)

(1) Instrument zero equal to 527.5 inches above vessel zero.
(2) For instrument accuracy and setpoints, see the Technical Specifications.
(3) The range shown is for the instrument channel trip switch which processes multiple sensor inputs to monitor the differential value between the inputs.

7.4 SYSTEMS REQUIRED FOR SAFE SHUTDOWN

7.4.1 DESCRIPTION

The following systems are provided for safe shutdown of the reactor:

a. Reactor core isolation cooling system

b. Standby liquid control system

c. Reactor shutdown cooling mode of the RHR system

d. Remote shutdown system

The following are supporting systems for safe shutdown of the reactor:

a. Emergency service water system

b. Residual heat removal service water system

c. Class 1E power systems

d. Shutdown ventilation systems:

1. RCIC system pump compartment unit coolers

2. RHR system pump compartment unit coolers

3. RSS (remote shutdown panels) ventilation system

7.4.1.1 Reactor Core Isolation Cooling System – Instrumentation and Controls

7.4.1.1.1 RCIC System Identification

7.4.1.1.1.1 RCIC Function

The RCIC system consists of a turbine, pump, piping, valves, accessories, and instrumentation designed to ensure that sufficient reactor water inventory is maintained in the reactor vessel, thus ensuring continuity of core cooling. Reactor vessel water is maintained or supplemented by the RCIC during the following conditions:

a. When the reactor vessel is isolated and maintained in the hot standby condition

b. When the reactor vessel is isolated and accompanied by a loss of normal coolant flow from the reactor feedwater system

c. When a complete plant shutdown under condition of loss of normal feedwater system flow is started before the reactor is depressurized to a level where the reactor shutdown cooling mode of the RHR system can be put into operation

7.4.1.1.1.2 RCIC Classification

Electrical components for the RCIC system are classified as Safety Class 2, seismic Category I, and Class 1E.

7.4.1.1.2 RCIC Power Sources

The RCIC system is provided with Class 1E power source. RCIC logic and outboard RCIC isolation valve logic are powered from 125 V dc bus A. Inboard RCIC isolation valve logic is powered from 125 V dc bus C. The system is capable of initiation and operation independent of ac power.

7.4.1.1.3 RCIC Equipment Design

7.4.1.1.3.1 RCIC General

When actuated, the RCIC system pumps water from either the CST or the suppression pool to the reactor vessel. The RCIC system includes a turbine-driven pump, a barometric condenser, a dc vacuum pump, a dc condensate pump, valves, controls, and sensors. The arrangement of equipment and controls is shown in drawings M-49 and M-50. The entire system is operable manually from the control room.

Pressure and level switches used in the RCIC system are located on instrument panels outside the drywell. The only operating component of the RCIC system that is located inside the drywell is the inboard steam line isolation valve.

A design flow functional test of the RCIC system may be performed during normal plant operation by drawing suction from the CST and discharging through a full flow test return line to the CST. The discharge valve to the feedwater line remains closed during the test, and reactor operation remains undisturbed. All components of the RCIC system are capable of individual functional testing during normal plant operation.

The control system provides automatic return from test to normal operating mode if system initiation is required, except for the following situations:

a. The RCIC flow controller AUTO/MANUAL feature in MANUAL mode maintains RCIC flow rate at set value; the operator can switch back to AUTO if required. This feature is required for operational flexibility during system test. This mode is annunciated by the manual out-of-service alarm.

b. Steam inboard/outboard isolation valves closed. Closure of either or both of these valves requires operator action to properly sequence their opening. An alarm sounds when either of these valves leaves the fully open position.

c. RCIC test switch in F012 or F013 position and test plug J1 inserted results in RCIC system being inoperable. Depending on whether test switch is in F012 or F013 position, one of the two series discharge valves are interlocked closed preventing reactor core isolation cooling. RCIC DIV 1 TEST STATUS alarm light in control room illuminates.

7.4.1.1.3.2 RCIC Initiating Circuits

Reactor vessel low water level is monitored by four indicating-type level sensors that sense the difference in pressure between a constant reference leg of water and the pressure that is due to the actual height of water in the vessel. The sensing lines for the RCIC sensors are physically separated and tap off the reactor water vessel at widely separated points.

The RCIC system is initiated only by low water level using a one-out-of-two-twice logic.

The RCIC system is initiated automatically after the receipt of a reactor vessel low water signal (level 2) and produces the design flow rate within 55 seconds. The system then functions to provide makeup water flow to the reactor vessel until level 8 is reached at which time the RCIC system automatically shuts down. The system will automatically restart if the level returns to the low level trip point. The controls are arranged to allow remote manual startup, operation, and shutdown.

The RCIC turbine is functionally controlled as shown in drawings E51-1030-F-004, E51-1030-F-005, E51-1030-F-006, E51-1030-F-007, E51-1030-F-008, and E51-1030-F-009. The turbine governor controls turbine speed and adjusts the turbine steam control valve so that demand pump discharge flow rate is obtained. The flow signal used for automatic control of the turbine is derived from a differential pressure measurement across a flow element in the RCIC system pump discharge line.

The turbine is automatically shut down by closing the turbine stop (trip throttle) valve if any of the following conditions are detected:

a. Mechanical turbine overspeed trip (one-out-of-one logic trip)

b. High turbine exhaust pressure trip (one-out-of-two logic trip)

c. RCIC turbine excessive moisture protective flow reduction at reactor vessel water level 8 (one-out-of-two-twice logic trip)

d. Low pump suction pressure trip (one-out-of-one logic trip)

e. RCIC isolation trip (one-out-of-two logic for turbine trip, for isolation one channel closes the inboard valve and one channel closes the outboard valve).

f. Remote manual trip

g. Local manual trip

Each of the isolation logics consists of the following:

a. Steam supply line high flow (one-out-of-two trip logic)

b. High turbine diaphragm exhaust pressure (two-out-of-two trip logic)

c. High area temperature (one-out-of-seven trip logic for Unit 1, one-out-of-six trip logic for Unit 2)

d. Low steam line pressure (two-out-of-two trip logic)

Precautions taken to preclude a spurious RCIC turbine shutdown or system isolation are as follows:

a. Use of coincident isolation trip logic circuits.

b. Use of time delay in logic of trip circuits (See NUREG-0737, Item II.K.3.15).

c. Use of safety-grade seismically qualified instrumentation and control components.

d. Use of trip settings far enough from normal operating values to reduce spurious trips, yet protect equipment from damage.

The series RCIC test return valve F022 and the HPCI test return to CST valve F011 are closed, unless opened by the operator for the RCIC flow test. If during flow test a low reactor water level condition occurs, RCIC initiates and F022 closes. Also, if either RCIC pump suction valves F029 or F031 is fully open, RCIC valve F022 and HPCI valve F011 will automatically close.

Turbine overspeed indicates a malfunction of the turbine control mechanism. High turbine exhaust pressure indicates a condition that threatens the physical integrity of the exhaust line. Low pump suction pressure warns that cavitation and lack of cooling can cause damage to the pump that could place it out of service. A turbine trip is initiated for these conditions so that if the causes of the abnormal conditions can be found and corrected, the system can be quickly restored to service. The trip settings are selected far enough from normal values so that a spurious turbine trip is unlikely, but not so far that damage occurs before the turbine is shut down. Turbine overspeed is detected by a standard turbine overspeed mechanical device.

Two pressure sensors are used to detect high turbine exhaust pressure. The logic for either sensor will initiate turbine shutdown. One pressure sensor is used to detect low RCIC system pump suction pressure.

Low steam line pressure in the supply line to the turbine indicates loss of motive force for the turbine, therefore the isolation valves are closed to shut down the turbine.

Pressure sensors monitor the pressure produced in the supply line to the turbine. Trip conditions signals are sent to the Leak Detection System (LDS) isolation logic to shut off the steam line.

High water level in the reactor vessel (level 8) indicates that the RCIC system has performed satisfactorily in providing makeup water to the reactor vessel. A further increase in level could damage the RCIC system turbine as a result of gross carryover of moisture. Four level sensors that sense differential pressure are arranged in a one-out-of-two-twice logic configuration to initiate closure of the F045 valve.

7.4.1.1.3.3 RCIC Logic and Sequencing

The scheme used for initiating the RCIC system is shown in drawings E51-1030-F-004, E51-1030-F-005, E51-1030-F-006, E51-1030-F-007, E51-1030-F-008, and E51-1030-F-009. The instrument settings for the RCIC system controls and instrumentation are listed in Chapter 16.

To prevent the pump from overheating at reduced flow, a pump discharge minimum flow line is provided to route the water from the pump back to the suppression pool.

The minimum flow line is controlled by an automatic dc MOV F019 whose control scheme is shown in drawings E51-1030-F-004, E51-1030-F-005, E51-1030-F-006, E51-1030-F-007, E51-1030-F-008, and E51-1030-F-009. At RCIC high flow, the valve is closed; conversely, at low flow with high pump discharge pressure, the valve is opened. The signals come from a sensor actuated by the pressure difference across a flow element in the RCIC pump discharge pipeline.

To prevent the RCIC steam supply pipeline from filling up with water and cooling the steam line excessively, a condensate drain pot, steam line drain, and appropriate valves are provided in a drain pipeline arrangement just upstream of the turbine supply valve. The control scheme is shown in drawings E51-1030-F-004, E51-1030-F-005, E51-1030-F-006, E51-1030-F-007, E51-1030-F-008, and E51-1030-F-009. The controls position valves F025 and F026 so that during normal plant operation steam line drainage is routed to the main condenser. The water level in the steam line drain condensate pot is controlled by a level switch and a direct-acting solenoid valve that energizes to allow condensate to flow out of the drain pot. After receiving an RCIC initiation signal, the drainage path is isolated.

The level in the drain pot is controlled primarily by a flow orifice (Unit 1) and steam trap (Unit 2); the level switch and trap bypass valve F054 are backups to the primary control.

Upon reduction in steam line pressure to the low pressure setpoint the isolation valves are closed to shutdown the system.

7.4.1.1.3.4 RCIC Bypasses and Interlocks

During test operation, the RCIC pump discharge is routed to the CST. A dc MOV F022 is installed in the pump discharge to the CST pipeline. The piping arrangement is shown in drawing M-49. The control scheme for the valves is shown in drawings E51-1030-F-004, E51-1030-F-005, E51-1030-F-006, E51-1030-F-007, E51-1030-F-008, and E51-1030-F-009. Upon receipt of an RCIC initiation signal, the valve closes and remains closed. A redundant valve (HPCI F011) on the same line is closed on HPCI initiation. The RCIC pump suction F010, RCIC pump discharge F022, and HPCI pump discharge F011 to CST valves are interlocked closed if the suppression pool suction valves F029 and F031 for RCIC are fully open.

7.4.1.1.3.5 RCIC Redundancy and Diversity

On a network basis, the RCIC is redundant to HPCI for the safe shutdown function. Therefore, RCIC as a system by itself is not required to be redundant.

Redundancy and diversity of initiating signals is a requirement stipulated only for the RPS and ESF. Therefore, diversity of initiating circuits is not a requirement for the RCIC system.

The RCIC is actuated by reactor low water level. Four level sensors in a one-out-of-two-twice circuit supply this signal.

7.4.1.1.3.6 RCIC Actuated Devices

All automatic valves in the RCIC are equipped with remote manual capability so that the entire system can be operated from the control room. MOVs are equipped with the appropriate limit and/or torque switches to turn off the motors when the fully open or fully closed positions are reached. Overload protection is provided to valve motors in accordance with Section 8.1.6.1.19. All MOVs and AOVs provide control room indication of valve position. The system is capable of initiation and operation independent of ac power.

To ensure that the RCIC can be brought to design flow rate within 55 seconds after receiving the initiation signal, the following maximum operating times for essential RCIC valves are provided by the valve operation mechanisms:

a. RCIC turbine steam supply valve (F045) 20 seconds

b. RCIC pump discharge valves (F012, F013) 23 seconds

c. RCIC pump minimum flow bypass valve (F019) 5 seconds

The operating time is the time required for the valve to travel from the fully closed to the fully open position, or vice-versa. The two RCIC steam supply line isolation valves F007 and F008 are normally open, and they are designed to isolate the RCIC steam line if there is a break in that line. A normally closed dc MOV F045 is located in the turbine steam supply pipeline just upstream of the turbine stop valve. After receiving an RCIC initiation signal (Level 2), this valve (F045) opens partially. The partial opening of the valve is to permit the turbine to attain an idle speed after which the ramp generator is turned on and the valve opens all the way. F045 remains open until either a predetermined high level (Level 8) is reached when the valve will automatically close or until manually closed by operator action from the control room.

The RCIC steam supply line isolation valves and steam line warm-up isolation valves automatically close on receipt of an RCIC automatic isolation signal. Detailed discussion is found in Section 7.6.1.3.3.3.

Two isolation valves are provided in the steam supply line to the turbine. The valves, one inside (F007) and one outside (F008) the primary containment, are normally open. They automatically close after receiving an RCIC isolation signal. These valves are operated by ac motors powered from different ac sources. The outboard isolation valve has a bypass line with an automatic remotely controlled valve (F076) in it. The bypass line is used to equalize and preheat the steam line.

The instrumentation for isolation consists of the following:

a. Outboard RCIC Turbine Isolation Valve (F008)

1. Differential temperature switches - RCIC equipment ventilation air inlet and outlet high differential temperature

2. Ambient temperature switches - RCIC equipment area high temperature

3. Ambient temperature switches - RCIC emergency area cooler high temperature

4. Differential pressure switches - RCIC steam line high flow or instrument line break

5. Two pressure switches - RCIC turbine exhaust diaphragm high pressure. Both sensors must activate to isolate.

6. Two pressure switches - RCIC steam supply pressure low. Indicates loss of the motive force for the turbine, therefore, the isolation valves are closed to shut down the turbine. Both sensors must activate to isolate.

7. Manual isolation if the system has been initiated

b. Inboard RCIC Turbine Isolation Valve (F007)

A similar set of instrumentation causes the inboard valve to isolate except for the manual isolation feature.

Three pump suction valves are provided in the RCIC system. One valve (F010) lines up pump suction from the CST; the other two (F029, F031) do so from the suppression pool. The CST is the preferred source. All valves are operated by dc motors. The control arrangement is shown in drawings E51-1030-F-004, E51-1030-F-005, E51-1030-F-006, E51-1030-F-007, E51-1030-F-008, and E51-1030-F-009. After receiving an RCIC initiation signal, the CST suction valve automatically opens. If the water level in the CST falls below a predetermined level, the RCIC pump suction is automatically transferred to the suppression pool. Redundant level sensors are used to detect the CST low water level condition. Either sensor can cause the suppression pool suction valve to open. When the suppression pool suction valves are opened, the CST suction valve automatically closes. Two dc motor-operated RCIC pump discharge valves in the pump discharge pipeline are provided. The control scheme for these valves is shown in drawings E51-1030-F-004, E51-1030-F-005, E51-1030-F-006, E51-1030-F-007, E51-1030-F-008, and E51-1030-F-009. They are arranged to open after receiving the RCIC initiation signal. The inboard valve closes automatically upon receipt of a turbine trip valve closure signal or steam supply valve closure signal.

7.4.1.1.3.7 RCIC Separation

As in the ECCS, the RCIC system is separated into two independent divisions designated 1 and 3. The RCIC system is a Division 1 system, but all inboard valves are Division 3. Division 1 logic is powered by the 125 V dc Division 1 bus A, and the Division 3 logic is powered by the 125 V dc Division 3 bus C. To maintain the required separation, the RCIC logic relays, cabling, instruments, and manual controls are mounted so that physical separation of Division 1 and Division 3 is maintained. The HPCI system is divisionalized in Divisions 2 and 4 and is therefore separated from RCIC.

The auxiliary systems that support the RCIC system are the barometric condenser system, which prevents turbine leakage, and the lube oil cooling water system. An initiation signal starts the condenser vacuum pump and opens the cooling water valve that initiates the barometric condenser and oil cooling action. The systems remain on until manually turned off, or tripped off by one of the parameters described in 7.4.1.1.3.2. The condensate pump starts when high level is sensed in the vacuum tank and automatically stops when tank level drops below the low level setpoint.

A complete description of the complete independence between divisions is given in Section 7.1.2.2.

7.4.1.1.3.8 RCIC Testability

The RCIC instrumentation and control system is capable of being tested during normal unit operation to verify the operability of each system component. Testing of the initiation sensors located outside the drywell is accomplished by valving out each sensor, one at a time, and applying a test pressure source.

This verifies the operability of the sensor. Trip units located in the auxiliary equipment room are calibrated individually by a calibration source with verification of setpoint by a digital readout located on the calibration module.

a. Calibration and test controls for the sensors are located in the reactor enclosure. Calibration and test controls for the trip units are located in the auxiliary equipment room. To gain access to the calibration points of each sensor, a cover plate must be removed. The control room operator is responsible for granting access to the calibration points. Only properly qualified plant personnel are granted access for testing or calibration adjustments.

   In addition to the above tests, operability of the sensors can be verified by cross-checking instrument readouts in the auxiliary equipment room at any time during operation.

b. Test jacks are provided to test the logic. Annunciation is provided in the control room whenever a test lug is inserted in a jack to indicate to the control room operator that the RCIC system is in the test status. Operation of the test plug switches initiates the RCIC system. Injection into the reactor is prevented by an interlock, actuated only when the test plug is inserted, which prevents the opening of one of the RCIC discharge valves. The test can be repeated with the other discharge valve interlock closed. The manual initiation switch can also be tested at this time. This sequence of tests ensures that all components are tested. A logic test of the RCIC does not interfere with the operation of any ECCS equipment if required by an initiation signal.

c. The functional performance of the RCIC system can be verified by pumping water from the CST, through the full flow test lines, and back to the CST. If initiation were to occur during this mode of operation, the valve line-up would automatically be changed so that water can be pumped to the reactor.

During the above testing, the operation of the RCIC system can be observed in the control room by panel lamps, indicators, recorders, annunciators, and computer printout.

7.4.1.1.4 RCIC Environmental Considerations

The control mechanisms for the inboard isolation valve are the only RCIC control components located inside the drywell that must remain functional in the post-LOCA environment. The RCIC control and instrumentation equipment located outside the drywell is selected in consideration of the environments in which it must operate. Selected safety-related RCIC instrumentation, such as

RCIC LDS instrumentation is qualified as described in Sections 3.10 and 3.11. However, the RCIC turbine instrumentation is not environmentally qualified because it is not required to operate in a potentially harsh environment per 10CFR50.49.

7.4.1.1.5 RCIC Operational Considerations

7.4.1.1.5.1 RCIC General Information

Normal core cooling is required if, during normal operation, the reactor becomes isolated from the main condenser by a closure of the MSIVs. Cooling is necessary because of the core fission product decay heat. Steam is vented through the pressure relief/safety valves to the suppression pool. The RCIC system maintains reactor water level by providing the makeup water. Initiation and control are automatic.

7.4.1.1.5.2 RCIC Reactor Operator Information

The following items are located in the control room for operator information:

a. Analog Indication

   1. RCIC steam supply pressure
   2. RCIC pump suction pressure
   3. RCIC pump discharge pressure
   4. RCIC pump discharge flow
   5. RCIC turbine speed
   6. RCIC turbine exhaust line pressure

b. Indicating Lamps

   1. Position of all MOVs
   2. Position of all solenoid-operated valves
   3. Turbine trip solenoid energized or de-energized
   4. All sealed-in circuits
   5. Pump status

c. Annunciators

   Annunciators are provided as shown in the RCIC FCD (drawings E51-1030-F-004, E51-1030-F-005, E51-1030-F-006, E51-1030-F-007, E51-1030-F-008, and E51-1030-F-009) and the RCIC system P&ID (M-49 and M-50).

7.4.1.1.5.3 RCIC Setpoints

Instrument settings for the RCIC system controls and instrumentation are listed in Chapter 16.

The reactor vessel low water level setting for RCIC system initiation is selected high enough above the active fuel to start the RCIC system before the low pressure ECCS is needed. The water level setting is far enough below normal levels that spurious RCIC system startups are avoided.

The low steam line pressure setpoint is established to terminate system function where there is insufficient motive force for the turbine.

7.4.1.1.6 RCIC - IEEE 279 - Design Basis

The following information is documented herein and as such satisfies the requirements of IEEE 279:

a. The generating station conditions that require protective action are identified in Chapter 15.

b. The generating station variables that must be monitored to provide protective actions are identified in Section 7.4.1.1.3.2 and in Chapter 16.

c. The minimum number and location of the sensors required to adequately monitor, for protective function purposes, those variables listed in Section 7.4.1.1.3.2 that have a spatial dependence do not exist for this system.

d. Prudent operational limits for each variable listed in Section 7.4.1.1.3.2 in each applicable reactor operation mode are identified in Chapter 16.

e. The margin, with appropriate interpretive information, between each operational limit and the level considered to mark the onset of unsafe conditions is included in the values developed in Chapter 16.

f. The levels that, when reached, will require protective action are identified in Chapter 16.

g. The range of transient and steady-state conditions of the energy supply are contained in Chapter 8.

h. The malfunctions, accidents, or other unusual events that could physically damage protection system components or could cause environmental changes leading to functional degradation of system performance, and for which provisions must be incorporated to retain necessary protective action, are identified in IEEE 279, paragraph 4.1 (Section 7.4.2.1.2.3.1.1).

i. Minimum performance requirements include the following:

    1. System response times

    2. System accuracies

3. Ranges (normal, abnormal, and accident conditions) of the magnitudes and rates of change of sensed variables to be accommodated until proper conclusion of the protective action is ensured have been considered and included in Chapter 15 and Chapter 16.

7.4.1.2 Standby Liquid Control System - Instrumentation and Controls

7.4.1.2.1 SLCS System Identification

7.4.1.2.1.1 SLCS Function

The instrumentation and controls for the SLCS are designed to initiate and continue injection of a liquid neutron absorber into the reactor when manually initiated or automatically initiated by the RRCS. This equipment also provides the necessary controls to maintain this liquid chemical solution well above saturation temperature in readiness for injection.

The instrumentation and controls are also designed to provide sufficient sodium pentaborate to the reactor vessel to maintain suppression pool pH at 7.0 or greater following a LOCA when manually initiated.

7.4.1.2.1.2 SLCS Classification

The SLCS is a backup method of shutting down the reactor to cold subcritical conditions by independent means other than the normal method using the control rods. Thus, the system is considered a "safe shutdown system." The standby liquid control process equipment and controls essential for injection of the neutron absorber solution into the reactor are designed to seismic Category I criteria. In addition, these controls are Class 1E, meeting the quality requirements of 10CFR50.

The SLCS process equipment and controls essential for post LOCA pH control in accordance with Regulatory Guide 1.183 (AST) are designed to Seismic Category I criteria and controls are Class 1E.

Nondirect process equipment, instrumentation, and controls of the system are not required to meet seismic Category I requirements; however, the local and control room mounted equipment is located in seismically qualified panels.

7.4.1.2.2 SLCS Power Sources

The SLCS pumps, valves, heaters, and associated controls are powered from Class 1E power supplies. The power supply to the explosive operated injection valves and injection pumps are from separate emergency buses. The power supply to both the control room bench board indicator lights and the level and pressure sensors is powered from an emergency instrument bus.

7.4.1.2.3 SLCS Equipment Design

7.4.1.2.3.1 SLCS General

The SLCS is a special "plant capability" event system. No single active component failure of any plant system or component would necessitate the operational function of the SLCS. It is included for two special cases:

a. Plant capability to shut down the reactor without control rods from normal operation (Section 15.9)

b. Plant capability to shut down the reactor without control rods from a transient incident (Sections 15.8 and 15.9)

c. Plant capability to maintain suppression pool water inventory at a pH of 7.0 or greater post LOCA in accordance with Regulatory Guide 1.183, Alternative Source Terms.

Although this system has been designed to a high degree of reliability with many safety system features, it is not required to meet the safety design basis requirements of the safety systems.

7.4.1.2.3.2 SLCS Initiating Circuits

The SLCS is manually initiated in the control room, when the operator determines that normal reactivity control systems have not shutdown the reactor as required, by turning the key-lock switch to the run position for either one or both of the two in-service pumps. Indicator lights located near each key-lock switch apprise the operator of the selected system initiation.

Two loops of the SLCS can also be automatically initiated by the RRCS after a time delay, provided that APRM power is not downscale and the key-lock switch is in the center normal position. This automatic initiation overrides the manual initiation signal; however, the manual shutoff signal overrides the automatic initiation signals. Section 7.6.1.8.3.4 describes the RRCS automatic initiation of the SLCS.

7.4.1.2.3.3 SLCS Logic and Sequencing

When a SLCS pump is started (manually or automatically), both squibs on its explosive- operated valve fire. Firing of either or both of the two squibs installed on each valve will open the valve. The SLCS is manually initiated in the control room by turning the key-locked switch for either one of both of the two in-service pumps to the run position. Only two SLCS pumps are started to prevent lifting the pressure relief valves(s) on high discharge header pressure with three SLCS pump operation.

SLCS operates automatically when both channels A and B of either RRCS division are tripped. Normally only SLCS pumps A and B are aligned to receive the start signal (key-lock switches in the normal position) with SLCS pump C automatic start signal blocked (key-lock switch in the stop position and the key removed). However, when either the A or B SLCS pump is out-of-service, then the C SLCS pump can be aligned to receive the automatic start signal (key-lock switch positioned to normal).

For automatic operation, both squibs on each injection valve fire, all three SLCS pumps receive a start signal when both channels A and B of either RRCS division are tripped.

The SLCS is provided with instrumentation and control to automatically shut off the SLCS pumps when the solution level in the storage tank is below the low level limit. This low level pump shutoff signal is provided by two-out-of-two logic. Three sets of storage tank level monitoring devices are provided to automatically shut off the SLCS pumps. Each set consists of two independent transmitters and trip units. There is a separate external line for each set of transmitters; this prevents a single instrument line problem from affecting all three SLCS pumps.

7.4.1.2.3.4 SLCS Bypasses and Interlocks

Initiation of SLCS pump A or C will close the inboard isolation valve of the RWCU system. Initiation of SLCS pump B will close the RWCU outboard isolation valve.

7.4.1.2.3.5 SLCS Redundancy and Diversity

Under special shutdown conditions, the SLCS is functionally redundant to the control rods in achieving and maintaining the reactor subcritical. Therefore, the SLCS as a system by itself is not required to be redundant. The power buses, pumps and explosive-operated injection valves are redundant so that a single component may be removed from service for maintenance during plant operation.

Diversity of initiating signals is a requirement only for RPS and ESF. Therefore, diversity of initiating circuits is not used in the SLCS design.

7.4.1.2.3.6 SLCS Actuated Devices

When the SLCS is initiated to inject a liquid neutron absorber into the reactor, the following devices are actuated:

a. Explosive valves are fired.

b. Injection pumps are started.

c. The pressure sensing equipment indicates that the SLCS is pumping liquid into the reactor.

d. The RWCU system inboard isolation valve closes on initiation of SLCS pumps A and C and the outboard isolation valve closes on initiation of SLCS pump B.

7.4.1.2.3.7 SLCS Separation

The SLCS is separated both physically and electrically from the CRD system. The SLCS instrument channels are separated in accordance with the requirements of IEEE 279 (1971).

7.4.1.2.3.8 SLCS Testability

The instrumentation and control system of the SLCS is tested when the system test is performed as outlined in Section 9.3.5.

7.4.1.2.4 SLCS Environmental Considerations

The environmental considerations for the instrument and control portions of the SLCS are discussed in Section 3.11. The instrument and control portions of the SLCS are seismically qualified not to fail during, and to remain functional following, an SSE. See Section 3.10 for seismic qualification aspects.

7.4.1.2.5 SLCS Operational Considerations

7.4.1.2.5.1 SLCS General Information

The control scheme for the SLCS is shown in drawings C41-1030-F-002, C41-1030-F-003 and C41-1030-F-004. The SLCS is automatically initiated by the RRCS or manually initiated by key-locked switches located in the control room. The SLCS pumps will automatically stop on SLCS storage tank low level or they may be stopped manually from the key-locked switches after an automatic initiation.

7.4.1.2.5.2 SLCS Reactor Operator Information

After the SLCS is initiated, the operator has several indicators and alarms to determine proper system operation. Indicator lights show which system was initiated, explosive valve continuity, isolation valve position, and inboard maintenance valve position. The control room annunciators indicate:

a. Isolation valve not fully open

b. Loss of continuity to the squib valves

c. SLCS storage tank Hi/Lo temperature

d. SLCS storage tank Hi/Lo level

e. SLCS A, B or C pump motor overload or loss of power.

Analog information is also available for the storage tank level and for pump pressures. At the local panel, additional operator information is available, such as storage tank level, system pressure, and storage tank temperature.

7.4.1.2.5.3 SLCS Setpoints

The SLCS has setpoints for the various instruments as follows:

a. The loss of continuity meter is set to activate the annunciator just below the trickle current that is observed when the primers of the explosive valves are new.

b. The SLCS storage tank temperature switch is set to activate an annunciator at high and low temperatures.

c. The SLCS storage tank level switch is set to activate an annunciator when the level is either high or low.

d. A thermostatically controlled heater maintains the temperature of the SLCS solution to prevent precipitation.

7.4.1.2.6 SLCS - IEEE 279 - Design Basis

SLCS is not a protection system, but it is designed to meet IEEE 279. The following information is documented herein and as such satisfies the requirements of IEEE 279:

a. The plant conditions that require protective action are identified in Chapter 15.

b. The generating station variables that must be monitored to provide protective actions are identified in Sections 7.4.1.2.3.2 and 7.6.1.8.3.4, and in Chapter 16.

c. The minimum number and location of the sensors required to adequately monitor, for protective function purposes, those variables listed in Section 7.4.1.2.3.2 that have a spatial dependence do not exist for this system.

d. Prudent operational limits for each variable listed in Section 7.4.1.2.3.2 in each applicable reactor operation mode are identified in Chapter 16.

e. The margin, with appropriate interpretive information, between each operational limit and the level considered to mark the onset of unsafe conditions is included in the values developed in Chapter 16.

f. The levels that, when reached, will require protective action are identified in Chapter 16.

g. The range of transient and steady-state conditions of both the energy supply and the environment during normal, abnormal, and accident circumstances throughout which the system must perform are contained in Chapter 8 for the energy supply, and Sections 3.10 and 3.11 for the environmental parameters.

h. The malfunctions, accidents, or other unusual events that could physically damage protection system components or could cause environmental changes leading to functional degradation of system performance, and for which provisions must be incorporated to retain necessary protective action, are identified in IEEE 279, paragraph 4.1 (Section 7.4.2.2.2.3.1.1).

i. Minimum performance requirements include the following:

    1. System response times

    2. System accuracies

    3. Ranges (normal, abnormal, and accident conditions) of the magnitudes and rates of change of sensed variables to be accommodated until proper conclusion of the protective action is ensured have been considered and included in Chapter 15 and Chapter 16.

7.4.1.3 Reactor Shutdown Cooling Mode of the RHR System -Instrumentation and Controls

7.4.1.3.1 RHR-SCM System Identification

7.4.1.3.1.1 Function

The RHR-SCM used during a normal reactor shutdown and cooldown performs a safe shutdown function.

The initial phase of a normal nuclear system cooldown is accomplished by routing steam from the reactor vessel to the main condenser, which serves as the heat sink.

The RHR-SCM consists of a set of pumps, valves, heat exchangers, and instrumentation designed to provide decay heat removal capability from the core. The system specifically accomplishes the following:

a. The RHR-SCM is capable of providing cooling for the reactor during shutdown operation after the vessel pressure is reduced to approximately 75 psig.

b. The system is capable of cooling the reactor water to a temperature at which reactor refueling and servicing can be accomplished.

The system can use a preferred method to accomplish its design objectives by directly extracting reactor vessel water from the reactor vessel via the recirculation loop and routing it to a heat exchanger and back to the vessel. An alternate method is to indirectly extract the water via relief valve discharge lines to the suppression pool and route the suppression pool water to the heat exchanger and back to the vessel.

7.4.1.3.1.2 RHR-SCM Classification

Electrical components for the RHR-SCM are classified as Safety Class 3, seismic Category I, and Class 1E.

7.4.1.3.2 RHR-SCM Power Sources

This system uses the safeguard 4 kV, 440 V ac, 120 V ac divisional instrument buses, and divisional 125 V dc sources.

7.4.1.3.3 RHR-SCM Equipment Design

7.4.1.3.3.1 RHR-SCM General

The reactor water is cooled by taking suction from one recirculation loop and pumping the water through the system heat exchangers back to the reactor vessel via both recirculation loops. If it is necessary to discharge a complete core load of reactor fuel to the spent fuel pool, a means is provided for making an intertie between the spent fuel pool and the RHR heat exchangers when required. This intertie increases the cooling capacity for cooling the spent fuel pool to handle the heat load for this situation. See drawing M-51 for the RHR system P&ID.

7.4.1.3.3.2 RHR-SCM Initiating Circuits

The operator manually initiates the RHR-SCM; automatic control is not necessary.

7.4.1.3.3.3 RHR-SCM Logic and Sequencing

The RHR-SCM is manually operated.

7.4.1.3.3.4 RHR-SCM Bypasses and Interlocks

To prevent the reactor shutdown cooling valves from opening except under proper conditions, the interlocks are provided as shown in Table 7.4-2.

The two RHR pumps (A and B) normally aligned for shutdown cooling are interlocked to trip if the reactor shutdown cooling valves and suction valves from the suppression pool are not properly positioned. Operation of the C and D RHR pumps in the shutdown cooling mode is controlled administratively.

7.4.1.3.3.5 RHR-SCM Redundancy and Diversity

The RHR-SCM contains two heat exchanger loops with each heat exchanger alignable to one of two RHR pumps. Either loop is enough to satisfy the cooling requirements for shutdown cooling. However, both loops share a common suction line with two suction valves in series. If one of the suction valves fails closed causing shutdown cooling to be lost, an alternate shutdown cooling flowpath may be established by manually switching to take suction water from the suppression pool and manually opening the ADS valves to allow reactor water to flow down to the suppression pool. The ADS valves may be actuated by either Division 1 or Division 3 power, thus providing redundancy if there is a divisional power failure.

If this failure occurs, an alternative flow path exists: water can be discharged from the reactor through the SRVs to the suppression pool, and then pumped to the reactor through an operable heat exchanger and associated LPCI injection valve.

During cold shutdown and refueling operation conditions, four subsystems of shutdown cooling exist, comprised of the A heat exchanger with the A RHR pump, A heat exchanger with the C RHR pump, B heat exchanger with the B RHR pump, and B heat exchanger with D RHR pump. If two required operable shutdown cooling subsystems are associated with the same heat exchanger, a failure of the shutdown cooling discharge valve or check valve associated with that heat exchanger will result in manual actions to effect valve repair, and if unsuccessful, may require cooling water flow to be returned through the LPCI line as described above.

Refer to Section 15.9 for a system level examination of the above operation.

Although instrumentation diversity is not required for the RHR-SCM, the design basis objective is achieved by two diverse shutdown cooling heat exchanger loops.

7.4.1.3.3.6 RHR-SCM Actuated Devices

All valves and pumps required for the RHR-SCM are equipped with remote manual switches in the control room, with the exception of alignment of the LPCI dedicated (C and D) RHR pumps for RHR-SCM operation which is performed locally. Further discussion of the general operation of the RHR system, including its other modes of operation, can be found in Section 7.3.1.1.

7.4.1.3.3.7 RHR-SCM Separation

Because various modes of operation of the RHR system perform safety-related functions (LPCI and containment cooling), any of the system's equipment performing safety-related functions satisfies the appropriate safety separation criteria (Section 7.3.1.1). The shutdown cooling mode of operation can use two diverse techniques. The separation between components used in these approaches satisfies separation criteria.

7.4.1.3.3.8 RHR-SCM Testability

The RHR pumps used for the RHR-SCM may be tested to full capacity during normal plant operation. All valves except those isolated by the reactor pressure interlock in the system may be tested during normal plant operation using the remote manual switches in the control room.

7.4.1.3.4 RHR-SCM Environmental Considerations

RHR control equipment is classified and seismically and environmentally qualified as discussed in Sections 3.2, 3.10, and 3.11.

7.4.1.3.5 RHR-SCM Operational Considerations

The RHR-SCM is used for normal shutdown.

7.4.1.3.5.1 RHR-SCM General Information

All controls for the RHR-SCM are located in the control room, with the exception of alignment of the LPCI dedicated (C and D) RHR pumps for RHR-SCM operation which is performed locally. Reactor operator information is provided as described in the RHR discussion of the LPCI mode in Section 7.3.1.1.

7.4.1.3.5.2 RHR-SCM Reactor Operator Information

See Section 7.3.1.1 for reactor operator information associated with the RHR in general. In addition, position indication on shutdown cooling maintenance valves 51-F060A and 51-F060B is provided.

7.4.1.3.5.3 RHR-SCM Setpoints

There are no safety-related setpoints involved in the operation of the RHR-SCM, except that reactor pressure and water level setpoints must be satisfied, and no isolation signal is present before the operator can begin this mode.

7.4.1.3.6 RHR-SCM - IEEE 279 - Design Basis

The following information is documented herein and as such satisfies the requirements of IEEE 279:

a. The generating station conditions which require protective action are identified in Chapter 15.

b. The generating station variables that must be monitored to provide protective actions are identified in Section 7.4.1.3.3.2 and in Chapter 16.

c. The minimum number and location of the sensors required to adequately monitor, for protective function purposes, those variables listed in Section 7.4.1.3.3.2 that have a spatial dependence do not exist for this system.

d. Prudent operational limits for each variable listed in Section 7.4.1.3.3.2 in each applicable reactor operation mode are identified in Chapter 16.

e. The margin, with appropriate interpretive information, between each operational limit and the level considered to mark the onset of unsafe conditions is included in the values developed in Chapter 16.

f. The levels that, when reached, will require protective action are identified in Chapter 16.

g. The range of transient and steady-state conditions of both the energy supply and the environment during normal, abnormal, and accident circumstances throughout which the system must perform are contained in Chapter 8 for the energy supply, and Sections 3.10 and 3.11 for the environmental parameters.

h. The malfunctions, accidents, or other unusual events that could physically damage protection system components or could cause environmental changes leading to functional degradation of system performance, and for which provisions must be incorporated to retain necessary protective action, are identified in IEEE 279, paragraph 4.1 (Section 7.4.2.3.2.3.1).

i. Minimum performance requirements include the following:
   1. System response times
   2. System accuracies
   3. Ranges (normal, abnormal, and accident conditions) of the magnitudes and rates of change of sensed variables to be accommodated until proper conclusion of the protective action is ensured have been considered and included in Chapter 15 and Chapter 16.

7.4.1.4 Remote Shutdown System

7.4.1.4.1 RSS Identification

7.4.1.4.1.1 RSS General

It is possible to carry out the reactor shutdown functions from outside the control room and bring the reactor to cold conditions in a safe and orderly fashion.

7.4.1.4.1.2 Postulated Conditions Assumed to Exist when the Control Room Becomes Inaccessible (RSS)

a. The plant is operating initially at, or less than, design power.

b. The plant is not experiencing any transient situations. Even though the loss of offsite ac power is considered unlikely, the essential controls and instrumentation on the remote shutdown panel or facilities are powered from a Class 1E power system bus. Manual controls of the diesel generator are available in the diesel generator enclosure.

c. The plant is not experiencing any accident situations. No DBA, including a LOCA, is assumed, so that complete control of ESF systems from outside the control room is not required.

d. All plant personnel have evacuated the control room.

e. The control room continues to be inaccessible for several hours.

f. The initial event that causes the control room to become inaccessible permits the reactor operator to manually scram the reactor before leaving the control room. If it is not possible to do so, the capability of opening the output breakers of the RPS logic from outside the control room can be used as a backup means to achieve initial reactor reactivity shutdown.

g. The main turbine pressure regulators may control reactor pressure via the bypass valves. However, to demonstrate that the plant can accommodate even loss of the turbine controls, it is assumed that this turbine-generator control panel function is also lost. Therefore, main steam line isolation is assumed to occur at a specified low turbine inlet pressure, and reactor pressure is relieved through the relief valves to the suppression pool.

h. The reactor feedwater system that is normally available is also assumed to be inoperable. Reactor water is made up by the RCIC system.

i. Power services are expected to be supplied for each essential system or equipment item in the remote shutdown system.

The above initial conditions and associated assumptions are very severe and conservatively bound any similarly postulated situation.

7.4.1.4.2 RSS Description

a. The system described provides remote control for reactor systems needed to carry out the shutdown function from outside the control room and bring the reactor to a cold condition in an orderly fashion.

b. The RSS provides a variation to the normal system used in the control room, permitting the shutdown of the reactor when feedwater is unavailable and the normal heat sinks (turbine and condenser) are lost.

c. Activation of relief valves and the RCIC system brings the reactor to a hot shutdown condition after scram and isolation are achieved by removing RPS power. During

this phase of shutdown, the suppression pool is cooled by operating the RHR system in the suppression pool cooling mode. Reactor pressure is controlled and core decay and sensible heat are rejected to the suppression pool by relieving steam pressure through the relief valves. Reactor water inventory is maintained by the RCIC system.

d. Manual operation of the relief valves cools the reactor and reduces its pressure at a controlled rate until reactor pressure becomes so low that the RCIC system discontinues operation.

e. The RHR system is then operated in the shutdown cooling mode using the RHR system heat exchanger to bring the reactor to the cold shutdown condition.

f. The RHRSW system is operated during operation of the RHR system in both the suppression pool cooling and shutdown cooling modes to provide cooling water to the RHR heat exchangers. A selector switch on the remote shutdown panel is used to operate either the spray pond or the cooling tower to cool the RHRSW. Additionally, spray or bypass can be selected when using the spray pond for cooling.

g. A redundant remote shutdown capability is provided as discussed in Sections 7.4.1.4.4, 7.4.1.4.5 and 7.4.2.4.2.2.1.

7.4.1.4.3 RSS Procedure

a. If evacuation becomes necessary, the operator scrams the reactor by depressing the scram switches at the control room panel.

b. Under normal conditions, the main turbine pressure regulator controls the reactor pressure while rejecting heat (steam) through the turbine bypass valves, and the feedwater control system controls water level.

c. The output breakers on feeders from RPS buses A and B to the RPS trip systems A and B, respectively, are opened as a backup means of scramming the reactor and closing the PCRVICS valves. The controls for this function are located on the RPS power distribution panel.

d. The remainder of the procedure assumes that the automatic pressure regulator is not available from time zero and the MSIVs are closed.

e. Transfer switches are operated to transfer control to the remote shutdown panel.

f. Relief valves not used in the remote shutdown system may open automatically and cycle to control reactor pressure. The reactor level starts to drop at a rate that depends on prior power level and elapsed time from scram.

g. The operator starts the RCIC system manually and maintains reactor level with RCIC. The level starts to rise as a result of RCIC system flow.

h. Reactor pressure is maintained by manually actuating the relief valves as necessary. While these relief valves are actuated, reactor water level, reactor pressure, and suppression pool temperature are observed.

i. The RHR system is used with one pump and heat exchanger and the associated RHRSW loop to cool the suppression pool.

j. If depressurization is required, reactor pressure is reduced by manually actuating the relief valves as necessary. While these relief valves are being activated, the reactor water level, reactor pressure, and suppression pool temperature are observed. The reactor cooldown rate is controlled so that it does not exceed 100°F per hour, as determined by observing the reactor pressure.

k. Reactor pressure is reduced to the shutdown cooling conditions. The RHR system is placed in the shutdown cooling mode. Cooldown is continued until the reactor is in the cold shutdown condition.

l. Reactor water level is held normal.

7.4.1.4.4 RSS Controls and Instrumentation - Equipment, Panels, and Displays

7.4.1.4.4.1 Control Room - RSS Interconnection Design Considerations

Some of the existing systems used for normal reactor shutdown operation are also used in the RSS to shut down the reactor from outside the control room. The RSS is designed to control the required shutdown systems from outside the control room irrespective of shorts, opens, or grounds in the control room control circuit that may have resulted from an event causing an evacuation. The functions needed for remote shutdown control are provided with manual transfer devices on the remote shutdown panel that override controls from the control room and transfer them to the RSS.

After transfer of control from the control room to the remote panel, all wiring and devices in the control room are isolated and cannot affect the operation of the transferred circuits. This is accomplished by running the control wiring from the equipment through the remote panel transfer switches to the control room.

All necessary power supplies are also transferred. Remote shutdown control is not possible without actuation of the transfer devices. Operation of the transfer devices causes an alarm in the control room. The remote shutdown panel is located in the remote shutdown room, which is in the control structure directly above the control room. Access to the panels is administratively controlled.

Adequate environmental control capability is provided at the location of these panels. The remote shutdown room and the control room are serviced by separate HVAC systems as described in Section 9.4.

In the remote shutdown room, transceivers for the plant public address system, the telephone system, and the distributed antenna system are provided.

Sections 7.4.1.4.2 and 7.4.1.4.3 describe steps for ensuring cold shutdown from departure of the control room through cold shutdown.

The following systems are required for safe remote shutdown:

a. RCIC system to maintain reactor water level

b. Relief valves and nuclear boiler system to reduce and monitor reactor vessel pressure, respectively

c. RHR system to control suppression pool water temperature and for reactor shutdown cooling mode

d. RHRSW system to supply cooling water to the RHR heat exchanger

e. ESW system to supply cooling water to RCIC and RHR room coolers, RHR motor oil and seal coolers, and the diesel generator

f. Containment and suppression pool system monitoring instrumentation

Table 7.4-3 is a listing of control and indicating devices on the remote shutdown panels.

7.4.1.4.5 RSS - IEEE 279 - Design Basis

The following information is documented herein and as such satisfies the requirements of IEEE 279:

a. The generating station conditions that require protective action are identified in Chapter 15.

b. The generating station variables that must be monitored to provide protective actions during RSS operation are identified in Table 7.4-3 and in Chapter 16.

c. The minimum number and location of the sensors required to adequately monitor, for protective function purposes, those variables listed in Table 7.4-3 that have a spatial dependence do not exist for this system.

d. Prudent operational limits for each variable listed in Table 7.4-3 in each applicable reactor operation mode are identified in Chapter 16.

e. The margin, with appropriate interpretive information, between each operational limit and the level considered to mark the onset of unsafe conditions is included in the values developed in Chapter 16.

f. The levels that, when reached, will require protective action are identified in Chapter 16.

g. The range of transient and steady-state conditions of both the energy supply and the environment during normal, abnormal, and accident conditions throughout

which the system must perform are contained in Chapter 8 for the energy supply, and Sections 3.10 and 3.11 for the environmental parameters.

h. The malfunctions, accidents, or other unusual events that could physically damage protection system components or could cause environmental changes leading to functional degradation of system performance, and for which provisions must be incorporated to retain necessary protective action, are identified in IEEE 279, paragraph 4.1 (Section 7.4.2.4.2.3.1).

i. Minimum performance requirements include the following:
   1. System response times
   2. System accuracies
   3. Ranges (normal, abnormal, and accident conditions) of the magnitudes and rates of change of sensed variables to be accommodated until proper conclusion of the protective action is ensured have been considered and included in Chapter 15 and Chapter 16.

j. As required by the Technical Specifications the remote shutdown monitoring instrumentation will be checked monthly and calibrated once per refueling cycle.

7.4.1.5 Emergency Service Water System - Instrumentation and Controls

For a description of the ESW system, see Section 7.3.1.1.11.

7.4.1.6 Residual Heat Removal Service Water System - Instrumentation and Controls

For a description of the RHRSW system, see Section 7.3.1.1.12.

7.4.1.7 Class 1E Power Systems

Descriptions of the standby power system can be found in the following:

a. Section 8.3.1 describes the onsite Class 1E ac power system.

b. Section 8.3.2 describes the onsite Class 1E dc power system.

7.4.1.8 Shutdown Ventilation Systems

7.4.1.8.1 RCIC System Pump Compartment Unit Coolers - Instrumentation and Controls

7.4.1.8.1.1 RCIC-UC System Identification

7.4.1.8.1.1.1 RCIC-UC Function

The RCIC-UC provides cooling to the RCIC pump-room during pump operation. For description and operation, see Section 9.4.2.

7.4.1.8.1.1.2 RCIC-UC Classification

Electrical components for the RCIC-UC are classified as seismic category I and Class 1E.

7.4.1.8.1.2 RCIC-UC Power Sources

Power for the instruments and controls associated with the RCIC-UC is supplied from the Class 1E 120 V ac system. See Chapter 8 for a description of the electrical system.

7.4.1.8.1.3 RCIC-UC Equipment Design

Equipment design is described in Section 9.4.2.

7.4.1.8.1.3.1 RCIC-UC Initiating Circuits

Each of the fans may be initiated in a protective function mode as follows:

a. A unit cooler may be manually started from the local control panel.

b. A fan may be started by initiating a high temperature switch.

7.4.1.8.1.3.2 RCIC-UC Logic and Sequencing

See drawing M-76FD for the control logic diagram.

Each pair of unit coolers is set up in a lead-lag mode. Automatic start is initiated under the following conditions:

a. When the area temperature exceeds the high temperature switch setting, the lead fan starts.

b. When the area temperature exceeds the high-high temperature switch, the standby fan starts.

The starting of a fan automatically opens a valve in the ESW system to supply cooling water to the unit.

The fan shuts down when the area temperatures drop below the low temperature switch setting.

7.4.1.8.1.3.3 RCIC-UC Bypasses and Interlocks

The hand switch of each fan, when in the off position, provides input to a local panel alarm that is relayed to the control room.

7.4.1.8.1.3.4 RCIC-UC Redundancy and Diversity

To maintain the redundancy of the mechanical equipment, controls and instrumentation are provided on a one-to-one basis with the mechanical equipment they serve. Diversity is not applicable.

7.4.1.8.1.3.5 RCIC-UC Actuated Devices

No additional devices or systems are actuated by the RCIC-UC.

7.4.1.8.1.3.6 RCIC-UC Separation

The controls, instrumentation, and power supplies are physically and electrically separated for each of the RCIC-UC. See Section 8.1.6.1 for a discussion of electrical separation.

7.4.1.8.1.3.7 RCIC-UC Testability

Operability of initiation circuits may be verified when the applicable pumps are operationally tested. The units may be manually tested by hand switches located on local control cabinets.

7.4.1.8.1.4 RCIC-UC Environmental Considerations

The controls for the subject equipment are located in the reactor enclosure. The environmental considerations for this area are provided in Section 3.11. Qualification information is also identified in Section 3.11.

7.4.1.8.1.5 RCIC-UC Operational Considerations

7.4.1.8.1.5.1 RCIC-UC General Information

The RCIC-UC are not required for normal cooling when the RCIC pumps are not operating.

7.4.1.8.1.5.2 RCIC-UC Reactor Operator Information

The operator is provided with a unit cooler system trouble alarm.

7.4.1.8.1.5.3 RCIC-UC Setpoints

For setpoints, see Chapter 16.

7.4.1.8.2 RHR System Pump Compartment Unit Coolers

7.4.1.8.2.1 RHR-UC System Identification

7.4.1.8.2.1.1 RHR-UC Function

The RHR-UC operation is the same during the RHR reactor shutdown cooling mode as for emergency RHR operation. See Section 7.3.1.1.15.5 for a description.

7.4.1.8.3 Remote Shutdown System Ventilation System

7.4.1.8.3.1 RSSV System Identification

7.4.1.8.3.1.1 RSSV System Function

The remote shutdown panels are located in the auxiliary equipment area of the control structure. See Section 7.3.1.1.15.5 for a description of the auxiliary equipment room ventilation system.

7.4.2 ANALYSIS

7.4.2.1 Reactor Core Isolation Cooling System - Instrumentation and Controls

7.4.2.1.1 RCIC General Functional Requirements Conformance

a. RCIC Safety Design Basis 7.1.2.1.17.1(a)

For events other than pipe breaks, the RCIC system has enough makeup capacity to prevent the reactor vessel water level from decreasing to the level where the core is uncovered.

b. RCIC Safety Design Basis 7.1.2.1.17.1(b)

The RCIC system is automatically initiated after receipt of a reactor vessel low water level signal as detailed in Section 7.4.1.1.3.2. The operator controls of the system are arranged to allow manual and remote manual operation.

c. RCIC Safety Design Basis 7.1.2.1.17.1(c)

The electrical control components of the RCIC system satisfy seismic Category I design requirements.

d. RCIC Safety Design Basis 7.1.2.1.17.1(d)

To provide a high degree of assurance that the RCIC system operates when necessary and in time to provide adequate inventory makeup, the power supply for the system is taken from highly reliable energy sources that are immediately available. Evaluation of instrumentation reliability for the RCIC system shows that a failure of a single initiating sensor does not prevent or falsely start the system.

e. RCIC Safety Design Basis 7.1.2.1.17.1(e)

The system is tested during plant operation using a series of overlapping tests, one of which is the design flow functional test. This test takes suction from the demineralized water in the CST and discharges through the full flow test return line back to the CST. During the test, the discharge valve to the reactor vessel remains closed and reactor operation is not disturbed. Control system design provides automatic return from the test mode to the operating mode if system initiation is required during testing, except for the conditions described in Section 7.4.1.1.3.1.

Chapter 15 examines the system level aspects of this system in-plant operation and consider its function under various plant transient events.

7.4.2.1.2 RCIC Specific Regulatory Requirements Conformance

Conformance of the transmitter/trip unit system, used for RCIC instrumentation, is discussed in Licensing Topical Report NEDO-21617-A, "Analog Transmitter/Trip Unit System for Engineered

Safeguard Sensor Inputs." Conformance of the other features with the regulatory requirements is discussed in the following sections.

7.4.2.1.2.1 RCIC Conformance To Regulatory Guides

7.4.2.1.2.1.1 RCIC - Regulatory Guide 1.6 (1971) - Independence Between Redundant Standby (Onsite) Power Sources and Between Their Distribution Systems (Safety Guide 6)

See Section 8.1.6.1.

Because it is not necessary for RCIC alone to meet the single failure criteria, redundant power sources are not required.

7.4.2.1.2.1.2 RCIC - Regulatory Guide 1.11 (1971) - Instrument Lines Penetrating Primary Reactor Containment (Safety Guide 11)

All RCIC instrument lines penetrating or connected to containment meet the guidelines of regulatory position C.1 of Regulatory Guide 1.11.

7.4.2.1.2.1.3 RCIC - Regulatory Guide 1.22 (1972) - Periodic Testing of Protection System Actuation Functions (Safety Guide 22)

The RCIC is fully testable from initiating sensors to actuated devices during full power operation.

7.4.2.1.2.1.4 RCIC - Regulatory Guide 1.29 (1978) - Seismic Design Classification

The safety-related portion of RCIC instrumentation and control is classified as seismic Category I and is qualified to remain functional during and following an SSE.

7.4.2.1.2.1.5 RCIC - Regulatory Guide 1.30 (1972) - Quality Assurance Requirements for the Installation, Inspection, and Testing of Instrumentation and Electric Equipment (Safety Guide 30)

Conformance to Regulatory Guide 1.30 is discussed in Section 8.1.6.1.

7.4.2.1.2.1.6 RCIC - Regulatory Guide 1.32 (1977) - Criteria for Safety-Related Electric Power Systems for Nuclear Power Plants

Conformance to Regulatory Guide 1.32, as discussed in Section 8.1, applies to RCIC safety-related control instrumentation.

7.4.2.1.2.1.7 RCIC - Regulatory Guide 1.47 (1973) - Bypassed and Inoperable Status Indication for Nuclear Power Plant Safety Systems

Automatic indication is provided in the control room to inform the operator that the RCIC is inoperable. Annunciation is provided to indicate that the system or part of the system is inoperable. The RCIC has test bypasses generated by inserting test jacks. Any test bypass annunciates at the system level (i.e., RCIC out-of-service). Bypasses of certain infrequently used pieces of equipment, such as manual locked open valves, are not automatically annunciated in the control room; however, capability for manual activation of the system level bypass annunciator is provided in the

control room for those systems that have these infrequently used bypasses. An administratively controlled switch is used for this manual activation. Further examples of automatic indication of inoperability are shown in drawings E51-1030-F-004, E51-1030-F-005, E51-1030-F-006, E51-1030-F-007, E51-1030-F-008, and E51-1030-F-009.

The annunciator can be tested by depressing the appropriate annunciator test switch on the control room bench boards.

Individual indicators are arranged and grouped together on the control room panel to indicate which function of the system is out-of-service, bypassed, or otherwise inoperable. Indication of pressures, temperatures, and other system variables that are a result of system operation are not included with the bypass inoperability indicators.

As a result of design, preoperational testing, and startup testing, no erroneous bypass indication is anticipated.

The bypass inoperability indications supplement administrative controls and aid the operator in assessing the availability of component and system level protective actions. This indication does not perform a safety function.

Each indicator that can be periodically tested is provided with dual lamps.

7.4.2.1.2.1.8 RCIC - Regulatory Guide 1.53 (1973) - Application of the Single Failure Criterion to Nuclear Power Plant Protection Systems

The RCIC meets the single failure criteria on a network basis in conjunction with HPCI. It is not necessary for the RCIC alone to meet the single failure criteria, because its function is duplicated by the HPCI.

7.4.2.1.2.1.9 RCIC - Regulatory Guide 1.62 (1973) - Manual Initiation of Protective Actions

The RCIC may be automatically and manually initiated inside the control room as well as at the remote shutdown facility outside the control room.

7.4.2.1.2.1.10 RCIC - Regulatory Guide 1.75 (1978) - Physical Independence of Electric Systems

RCIC conformance to Regulatory Guide 1.75 is discussed in Section 7.1.2.5.19.

7.4.2.1.2.1.11 RCIC - Regulatory Guide 1.89 (1974) - Qualification of Class 1E Equipment for Nuclear Power Plants

RCIC conformance to Regulatory Guide 1.89 is discussed in Section 3.11.2.

7.4.2.1.2.1.12 RCIC - Regulatory Guide 1.97 (1980) - Instrumentation for Light-Water-Cooled Nuclear Power Plants to Assess Plant and Environs Conditions During and Following an Accident

Conformance is discussed in Section 7.5.2.5.1.1.2.

7.4.2.1.2.1.13 RCIC - Regulatory Guide 1.100 (1977) - Seismic Qualification of Electric Equipment for Nuclear Power Plants

RCIC conformance to Regulatory Guide 1.100 is discussed in Section 3.10.

7.4.2.1.2.1.14 RCIC - Regulatory Guide 1.105 (1976) - Instrument Setpoints

RCIC conformance to this guide is discussed in Section 7.1.2.5.25.

7.4.2.1.2.1.15 RCIC - Regulatory Guide 1.118 (1978) - Periodic Testing of Electric Power and Protection Systems

RCIC conformance to this guide is discussed in Section 7.1.2.5.26.

7.4.2.1.2.2 RCIC Conformance to 10CFR50, Appendix A - General Design Criteria

7.4.2.1.2.2.1 RCIC - GDC 1 - Quality Standards and Records

See Section 7.1.2.6.

7.4.2.1.2.2.2 RCIC - GDC 2 - Design Bases for Protection Against Natural Phenomena

See Section 7.1.2.6 for RCIC conformance.

7.4.2.1.2.2.3 RCIC - GDC 3 - Fire Protection

See Section 7.1.2.6 for RCIC conformance.

7.4.2.1.2.2.4 RCIC - GDC 4 - Environmental and Dynamic Effects Design

See Section 7.1.2.6 for RCIC conformance.

7.4.2.1.2.2.5 RCIC - GDC 10 - Reactor Design

See Section 7.1.2.6 for RCIC conformance.

7.4.2.1.2.2.6 RCIC - GDC 13 - Instrumentation and Control

The reactor vessel water level, RCIC pump discharge pressure, and RCIC flow rate are monitored and displayed in the control room.

7.4.2.1.2.2.7 RCIC - GDC 20 - Protection System Functions

The RCIC system constantly monitors the water level in the reactor vessel and is automatically initiated when the level drops below the pre-established setpoint.

7.4.2.1.2.2.8 RCIC - GDC 21 - Protection System Reliability and Testability

The RCIC is fully testable from sensor to actuated device during normal operation.

7.4.2.1.2.2.9 RCIC - GDC 22 - Protection System Independence

The RCIC system is independent of the HPCI system to ensure that the safe shutdown function can be accomplished.

7.4.2.1.2.2.10 RCIC - GDC 29 - Protection Against Anticipated Operational Occurrences

The RCIC maintains the reactor vessel water level by providing makeup water if the reactor becomes isolated from the main condenser during normal operation.

7.4.2.1.2.3 RCIC Conformance to Industry Codes and Standards

Conformance of the transmitter/trip unit system, used for RCIC instrumentation, is discussed in Licensing Topical Report NEDO-21617-A, "Analog Transmitter/Trip Unit System for Engineered Safeguard Sensor Inputs." Conformance of the other features with industry standards is discussed in the following sections.

7.4.2.1.2.3.1 RCIC - IEEE 279 (1971) - Criteria for Protection Systems for Nuclear Power Generating Stations

7.4.2.1.2.3.1.1 RCIC - IEEE 279 (1971), Paragraph 4.1 - General Functional Requirement

The system is automatically initiated to perform the appropriate protective action with precision and reliability under the adverse conditions defined below:

a. Power supply voltage and frequency - Since the RCIC system is backed up by the independent HPCI system, the design provides tolerance to power supply failure in one motive power system or one control power system.

b. Temperature - The RCIC system is designed to operate properly in the high temperature environment expected during the events requiring system operation.

c. Humidity - The system is designed to function properly in the high humidity (steam) environment expected during the events requiring system operation.

d. Pressure - The system is designed to function properly in the full range of pressures expected during the events requiring system operation.

e. Vibration - Tolerance to environmentally induced vibration (earthquake, wind) is discussed in Section 3.10.

f. Accidents - The system tolerates any event requiring system operation.

g. Fire - Since the RCIC system is backed up by the independent HPCI system, the design provides tolerance to a fire in a single division raceway or enclosure.

h. Explosions - Explosions are not defined in the design basis.

i. Missiles - Since the RCIC system is backed up by the independent HPCI system, the design provides tolerance to any single missile destroying no more than one pipe, raceway, or electrical enclosure.

j. Lightning - Since the RCIC system is backed up by the independent HPCI system, the design provides tolerance to lightning damage to one auxiliary ac bus.

k. Flood - All instrumentation and controls are located above flood level or are protected from flood damage.

l. Earthquake - All control equipment is housed in a seismic Category I structure. Tolerance to earthquake damage is discussed in Section 3.10.

m. Wind and tornado - The structures containing RCIC components have been designed to withstand the meteorological events described in Section 3.3.2.

n. System response time and system accuracies - System response time and accuracy are covered in Chapter 16.

o. Ranges of monitored parameters - Instrument sensors and processing equipment are capable of displaying the full ranges of parameters expected during events requiring system operation.

7.4.2.1.2.3.1.2 RCIC - IEEE 279 (1971), Paragraph 4.2 - Single Failure Criteria

The RCIC system alone is not required to meet the single failure criteria. The control logic circuits for RCIC initiation and control are housed in a single relay cabinet, and the power supply for the control logic and other RCIC equipment is from a single dc power source.

The RCIC system meets the single failure criteria on a network basis in conjunction with HPCI. It is not necessary for the RCIC alone to meet the single failure criteria in itself, because its function is duplicated or backed up by HPCI.

7.4.2.1.2.3.1.3 RCIC - IEEE 279 (1971), Paragraph 4.3 - Quality of Components and Modules

The components of the RCIC instrumentation and control are of the same high quality as the ECCS systems.

7.4.2.1.2.3.1.4 RCIC - IEEE 279 (1971), Paragraph 4.4 - Equipment Qualification

The RCIC safety-related controls and instrumentation have been qualified according to the requirements outlined in IEEE 323 (1971), as highlighted in Section 7.1.2.7.1. The conditions for which the equipment has been qualified are those identified in Sections 3.10 and 3.11. The conditions identified cover normal, abnormal, and accident environments both inside and outside the drywell.

7.4.2.1.2.3.1.5 RCIC - IEEE 279 (1971), Paragraph 4.5 - Channel Integrity

The RCIC system instrument initiation channels satisfy the channel integrity objective.

7.4.2.1.2.3.1.6 RCIC - IEEE 279 (1971), Paragraph 4.6 - Channel Independence

Channel independence for initiation sensors is not provided for the RCIC. Independence of HPCI and RCIC sensors is provided by electrical and mechanical separation. HPCI sensors are Division 2, and RCIC sensors are Division 1.

Disabling the sensors does not disable the control for both RCIC and HPCI initiation.

7.4.2.1.2.3.1.7 RCIC - IEEE 279 (1971), Paragraph 4.7 - Control and Protection System Interaction

The RCIC system has no interaction with plant control systems. Annunciator circuits using contacts of sensors and logic relays cannot impair the operability of the RCIC system control because of electrical isolation.

7.4.2.1.2.3.1.8 RCIC - IEEE 279 (1971), Paragraph 4.8 - Derivation of System Inputs

The RCIC system uses a direct measure of the need for coolant inventory makeup, e.g., reactor vessel low water level.

7.4.2.1.2.3.1.9 RCIC - IEEE 279 (1971), Paragraph 4.9 - Capability for Sensor Checks

All sensors are installed with calibration taps and instrument valves to permit testing during normal plant operation or during shutdown. An example of sensor calibration is shown in section 6 of NEDO-21617-A, "Analog Transmitter/Trip Unit System for Engineered Safeguard Sensor Trip Inputs."

7.4.2.1.2.3.1.10 RCIC - IEEE 279 (1971), Paragraph 4.10 - Capability for Testing and Calibration

The RCIC control system can be completely tested during normal plant operation to verify that each element of the system, whether active or passive, is capable of performing its intended function.

As part of this test, the turbine and RCIC pump are started in the test mode with the pump discharging into the CST. In this test mode, all major components except the isolation valves are tested. Valve operability tests complete the major system component testing.

7.4.2.1.2.3.1.11 RCIC - IEEE 279 (1971), Paragraph 4.11 - Channel Bypass or Removal from Operation

Calibrating a sensor that introduces a single instrument channel trip does not cause a protective function without the coincident trip of a second channel. There are no instrument channel bypasses. Removing a sensor from operation during calibration does not prevent the redundant instrument channel from functioning. An instrument channel is only briefly removed from service during calibration.

7.4.2.1.2.3.1.12 RCIC - IEEE 279 (1971), Paragraph 4.12 - Operating Bypasses

There are no operating bypasses in the RCIC system.

7.4.2.1.2.3.1.13 RCIC - IEEE 279 (1971), Paragraph 4.13 - Indication of Bypasses

Bypasses are automatically indicated by individual lights that designate which function of the system is out-of-service, bypassed, or otherwise inoperative. In addition, each of the indicated bypasses also activates a system out-of-service annunciator. A manual system out-of-service switch is provided for operator use for items that are only under administrative control.

7.4.2.1.2.3.1.14 RCIC - IEEE 279 (1971), Paragraph 4.14 - Access to Means for Bypassing

The access to means for bypassing is controlled by administrative procedures.

7.4.2.1.2.3.1.15 RCIC - IEEE 279 (1971), Paragraph 4.15 - Multiple Setpoints

This is not applicable because there are no multiple setpoints for the RCIC system.

7.4.2.1.2.3.1.16 RCIC - IEEE 279 (1971), Paragraph 4.16 - Completion of Protective Action Once It is Initiated

The final control elements for the RCIC system are essentially bistable, i.e., MOVs stay open or closed once they have reached their desired position, even though their starter may drop out. In the case of pump starters, the automatic initiation signal is electrically sealed in.

Thus, once protective action is initiated (i.e., flow established), it will go to completion until terminated by deliberate operator action or automatically stopped by high vessel water level or system malfunction trip signals.

7.4.2.1.2.3.1.17 RCIC - IEEE 279 (1971), Paragraph 4.17 - Manual Initiation

Each piece of RCIC actuation equipment required to operate (pumps and valves) is capable of manual initiation from the control room.

Failure of logic circuitry to initiate the RCIC system does not prevent manual initiation. However, failures of active components or control circuits that produce a RCIC turbine trip may disable the manual actuation of the RCIC system. Failures of this type are continuously monitored by alarms.

Because the RCIC system is independent of the HPCI system, the protective function can be accomplished even in the presence of a single failure within the manual, automatic, or common portions of the RCIC system. Manual initiation depends on the operation of a minimum of equipment.

7.4.2.1.2.3.1.18 RCIC - IEEE 279 (1971), Paragraph 4.18 - Access to Setpoint Adjustments, Calibration, and Test Points

See Licensing Topical Report NEDO-21617-A for the compliance of the trip unit.

7.4.2.1.2.3.1.19 RCIC - IEEE 279 (1971), Paragraph 4.19 - Identification of Protective Actions

Protective actions are directly indicated and identified by annunciator operation or a trip unit light with an identification tag that permits convenient visible verification of instrument channel status.

The combination of annunciation and trip unit observation is considered to fulfill the requirements of this criterion.

7.4.2.1.2.3.1.20 RCIC - IEEE 279 (1971), Paragraph 4.20 - Information Readout

The RCIC control system is designed to provide the operator with accurate and timely information pertinent to its status. It does not introduce signals into other systems that could cause confusing anomalous indications. Information is provided continuously so that the operator can have a high degree of confidence that the RCIC function is available and/or operating properly.

7.4.2.1.2.3.1.21 RCIC - IEEE 279 (1971), Paragraph 4.21 - System Repair

The RCIC control system is designed to permit repair or replacement of components.

Recognition and location of a failed component is accomplished during periodic testing. The simplicity of the logic provides ease in detection and location of the problem, and components are mounted in such a way that they can be conveniently replaced in a short time.

7.4.2.1.2.3.1.22 RCIC - IEEE 279 (1971), Paragraph 4.22 - Identification of Protection Systems

Control room devices are identified by tags on the panels, that indicate the function of the device.

7.4.2.1.2.3.2 RCIC - IEEE 308 (1974) - Criteria for Class 1E Electrical Systems for Nuclear Power Generating Stations

Conformance to IEEE 308 is as described in Section 8.3.1 for ac power supply and Section 8.3.2 for dc power supply to the safety-related instrumentation and controls.

7.4.2.1.2.3.3 RCIC - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1 Electric Equipment for Nuclear Power Generating Stations

Specific conformance to the requirements of IEEE 323 is covered in Sections 7.1.2.7.4 and 3.11.

7.4.2.1.2.3.4 RCIC - IEEE 336 (1971) - Installation, Inspection, and Testing Requirements for Instrumentation and Electric Equipment During the Construction of Nuclear Power Generating Stations

See Section 8.1.6.1 for RCIC conformance.

7.4.2.1.2.3.5 RCIC - IEEE 338 (1971) - Criteria for the Periodic Testing of Nuclear Power Generating Station Protection Systems

The RCIC system is tested as described in Section 7.4.1.1.3.8.

7.4.2.1.2.3.6 RCIC - IEEE 344 (1971) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations

Conformance to the requirements of IEEE 344 (1971) is detailed in Section 3.10.

7.4.2.1.2.3.7 RCIC - IEEE 379 (1972) - Guide for the Application of the Single Failure Criterion to Nuclear Power Generating Station Protection Systems

See Section 7.4.2.1.2.3.1.2 for RCIC conformance.

7.4.2.1.2.3.8 RCIC - IEEE 384 (1974) - Criteria for Separation of Class 1E Equipment and Circuits

See Section 7.1.2.7.11 for RCIC conformance.

7.4.2.2 Standby Liquid Control System - Instrumentation andControls

7.4.2.2.1 SLCS General Functional Requirements Conformance

The injection of the sodium pentaborate solution into the reactor is sufficient to shut down the reactor from full power to cold shutdown and maintain the reactor in a subcritical state.

Injection of sodium pentaborate solution into the reactor is also sufficient to maintain the suppression pool at a pH of 7.0 or higher following a LOCA.

Redundant, positive displacement pumps, explosive valves, and control circuits for the SLCS components are provided as described in Section 7.4.1.2. These constitute all of the active equipment required for injection of the sodium pentaborate solution. Continuity relays monitor the explosive valves, and indicator lights indicate system status on the reactor control console. Testability and redundant power sources are described in Sections 14.2, 7.4.1.2.2, and 7.4.1.2.3.8. The safety design basis is discussed in Section 7.1.2.1.18.1.

The SLCS can be automatically initiated by the RRCS. This initiation will override the manual start signal, but can be overridden by the manual stop signal. The SLCS will be automatically shut off by the low level in the SLCS storage tank.

Chapter 15 examines the system level aspects of the subject system under applicable plant events.

7.4.2.2.2 SLCS Specific Regulatory Requirements Conformance

7.4.2.2.2.1 SLCS Conformance to Regulatory Guides

7.4.2.2.2.1.1 SLCS - Regulatory Guide 1.22 (1972) - Periodic Testing of Protection System Actuation Functions (Safety Guide 22)

The SLCS is capable of testing from initiation to actuated devices, except squib valves, during normal operation. The system design uses squib valves for positive rapid operation, which cannot be tested during operation without injecting the sodium pentaborate. In the test mode, demineralized water rather than sodium pentaborate is circulated in the SLCS loops. The explosive valves may be tested when the plant is shut down. Otherwise, continuity in the explosive valve initiation circuits is continuously monitored and indicated in the control room during plant operation to ensure that the dual squibs in each valve are available.

7.4.2.2.2.1.2 SLCS - Regulatory Guide 1.29 (1978) - Seismic Design Classification

The control instrumentation required for injection of the SLCS is classified as seismic Category I and is qualified to remain functional during and following an SSE.

7.4.2.2.2.1.3 SLCS - Regulatory Guide 1.30 (1972) - Quality Assurance Requirements for the Installation, Inspection, and Testing of Instrumentation and Electric Equipment (Safety Guide 30)

SLCS conformance to Regulatory Guide 1.30 is discussed in Section 8.1.6.1.

7.4.2.2.2.1.4 SLCS - Regulatory Guide 1.32 - Criteria for Safety-Related Electric Power Systems for Nuclear Power Plants

SLCS conformance to IEEE 308 as discussed in Section 8.1 is applicable to SLCS control instrumentation.

7.4.2.2.2.1.5 SLCS - Regulatory Guide 1.53 (1973) - Application of the Single Failure Criterion to Nuclear Power Plant Protection Systems

The SLCS serves as a backup reactivity control system to the control rods. It is not necessary for the SLCS to meet the single failure criteria. The discharge pumps, pump motors, and explosive valves are redundant so that a single failure in these components does not prevent initiation of the SLCS.

7.4.2.2.2.1.6 SLCS - Regulatory Guide 1.63 (1978) - Electric Penetration Assemblies in Containment Structures for Light-Water-Cooled Nuclear Power Plants

SLCS conformance to Regulatory Guide 1.63 is discussed in Section 8.1.

7.4.2.2.2.1.7 SLCS - Regulatory Guide 1.75 (1978) - Physical Independence of Electric Systems

SLCS conformance to Regulatory Guide 1.75 is discussed in Section 7.1.2.5.19.

7.4.2.2.2.1.8 SLCS - Regulatory Guide 1.89 (1974) - Qualification of Class 1E Equipment for Nuclear Power Plants

SLCS conformance to Regulatory Guide 1.89 is discussed in Section 3.11.

7.4.2.2.2.1.9 SLCS - Regulatory Guide 1.97 (1980) - Instrumentation for Light-Water-Cooled Nuclear Power Plants to Assess Plant and Environs Conditions During and Following an Accident

Conformance is discussed in Section 7.5.2.5.1.1.2.

7.4.2.2.2.1.10 SLCS - Regulatory Guide 1.100 (1977) - Seismic Qualification of Electric Equipment for Nuclear Power Plants

SLCS conformance to Regulatory Guide 1.100 is discussed in Section 3.10.

7.4.2.2.2.1.11 SLCS - Regulatory Guide 1.105 (1976) - Instrument Setpoints

SLCS conformance to this guide is discussed in Section 7.1.2.5.25.

7.4.2.2.2.1.12 SLCS - Regulatory Guide 1.118 (1978) - Periodic Testing of Electric Power and Protection Systems

SLCS conformance to this guide is discussed in Section 7.1.2.5.26.

7.4.2.2.2.2 SLCS Conformance to 10CFR50, Appendix A, General Design Criteria

7.4.2.2.2.2.1 SLCS - GDC 1 - Quality Standards and Records

See Section 7.1.2.6 for SLCS conformance.

7.4.2.2.2.2.2 SLCS - GDC 2 - Design Bases for Protection Against Natural Phenomena

See Section 7.1.2.6 for SLCS conformance.

7.4.2.2.2.2.3 SLCS - GDC 3 - Fire Protection

See Section 7.1.2.6 for SLCS conformance.

7.4.2.2.2.2.4 SLCS - GDC 4 - Environmental and Dynamic Effects Design Bases

See Section 7.1.2.6 for SLCS conformance.

7.4.2.2.2.2.5 SLCS - GDC 10 - Reactor Design

The SLCS is a backup method of manually shutting down the reactor to cold subcritical conditions by independent means other than the normal method, i.e., the control rod system.

7.4.2.2.2.2.6 SLCS - GDC 13 - Instrumentation and Control

The sodium pentaborate tank temperature and level and the explosive valves controlling circuit continuity are monitored and annunciated.

7.4.2.2.2.2.7 SLCS - GDC 26 - Reactivity Control System Redundancy and Capability

The SLCS provides the backup reactivity control system to the control rods.

7.4.2.2.2.3 SLCS Conformance to Industry Codes and Standards

7.4.2.2.2.3.1 SLCS - IEEE 279 (1971) - Criteria for Protection Systems for Nuclear Power Generating Stations

7.4.2.2.2.3.1.1 SLCS - IEEE 279 (1971), Paragraph 4.1 - General Functional Requirement

RRCS will automatically initiate SLCS in the event of an ATWS condition. Also, the operator may manually initiate the SLCS. Display instrumentation in the control room provides the operator with information on neutron flux level, control rod position, and scram valve status so the operator can determine if SLCS initiation is required.

7.4.2.2.2.3.1.2 SLCS - IEEE 279 (1971), Paragraph 4.2 - Single Failure Criteria

The SLCS serves as backup to the control rod scram in controlling reactivity. It is not necessary for the SLCS to meet the single failure criteria. However, the pumps and the explosive valves are redundant so that a single active failure in these components does not prevent initiation of SLCS.

7.4.2.2.2.3.1.3 SLCS - IEEE 279 (1971), Paragraph 4.3 - Quality of Components and Modules

The components of the SLCS system instrumentation and controls are of the same high quality as the ECCS system.

7.4.2.2.2.3.1.4 SLCS - IEEE 279 (1971), Paragraph 4.4 - Equipment Qualification

No active components of the SLCS are required to operate in the drywell environment. A maintenance valve, test taps and drain line are the only components located inside the drywell. The maintenance valve is a normally locked open valve. The test taps and drain line are normally locked closed. Other SLCS equipment is located in the reactor enclosure or containment and is capable of operation during and following an SSE (Section 3.10).

7.4.2.2.2.3.1.5 SLCS - IEEE 279 (1971), Paragraph 4.5 - Channel Integrity

The SLCS is not required to operate during a DBA. It is designed to remain functional during and following an SSE.

7.4.2.2.2.3.1.6 SLCS - IEEE 279 (1971), Paragraph 4.6 - Channel Independence

The SLCS serves as backup to the control rods in controlling reactivity. The channels are independent of each other, so that failure in one channel does not prevent operation of another channel.

7.4.2.2.2.3.1.7 SLCS - IEEE 279 (1971), Paragraph 4.7 - Control and Protection System Interaction

The SLCS has no interaction with plant control systems. It has no function during normal plant operation and is completely independent of control systems.

7.4.2.2.2.3.1.8 SLCS - IEEE 279 (1971), Paragraph 4.8 - Derivation of System Inputs

Display instrumentation in the control room provides the operator with information on neutron flux level, control rod position, and scram valve status. Using this information, the operator may manually initiate the SLCS.

7.4.2.2.2.3.1.9 SLCS - IEEE 279 (1971), Paragraph 4.9 - Capability for Sensor Checks

The explosive valve control circuit continuity is continuously monitored, and loss of continuity is annunciated in the control room. See also Section 7.4.2.2.2.1.1.

The testability of the sensors that provide information on neutron flux is discussed in Sections 7.2 and 7.7.

The testability of the rod position, because the RPIS is not safety-related, is limited to a sequential interrogation of the individual rod position information while stationary or during rod movement.

The scram valves can be tested during full power operation by individually scramming each valve from local test switches.

7.4.2.2.2.3.1.10 SLCS - IEEE 279 (1971), Paragraph 4.10 - Capability for Testing and Calibration

The explosive valves may be tested during plant shutdown. The explosive valve control circuits are continuously monitored, and loss of continuity is annunciated in the control room. The remainder of the SLCS may be tested during normal plant operation to verify that each element is capable of performing its intended function. In the test mode, demineralized water rather than sodium pentaborate solution is circulated from and back to the test tank. See also Section 7.4.2.2.2.1.1. During testing of explosive valves demineralized water is injected to the vessel.

7.4.2.2.2.3.1.11 SLCS - IEEE 279 (1971), Paragraph 4.11 - Channel Bypass or Removal from Operation

The pumps, pump motors, and associated controls are redundant so that one pump may be removed from service during normal plant operation.

7.4.2.2.2.3.1.12 SLCS - IEEE 279 (1971), Paragraph 4.12 - Operating Bypasses

There are no operating bypasses in the SLCS.

7.4.2.2.2.3.1.13 SLCS - IEEE 279 (1971), Paragraph 4.13 - Indication of Bypasses

The removal of components from service is automatically or manually annunciated in the control room.

7.4.2.2.2.3.1.14 SLCS - IEEE 279 (1971), Paragraph 4.14 - Access to Means for Bypassing

Removal of components from service during normal plant operation is under administrative control.

7.4.2.2.2.3.1.15 SLCS - IEEE 279 (1971), Paragraph 4.15 - Multiple Setpoints

There are no multiple setpoints in the SLCS.

7.4.2.2.2.3.1.16 SLCS - IEEE 279 (1971), Paragraph 4.16 - Completion of Protective Action Once It Is Initiated

The explosive valves remain open, once fired, and the pump motor operation, once initiated, does not stop unless terminated by operator action, or automatic low level shut off of the SLCS pumps is initiated.

7.4.2.2.2.3.1.17 SLCS - IEEE 279 (1971), Paragraph 4.17 - Manual Initiation

The SLCS can be manually initiated.

7.4.2.2.2.3.1.18 SLCS - IEEE 279 (1971), Paragraph 4.18 - Access to Setpoint Adjustments, Calibration, and Test Points

Setpoint adjustments, module calibration adjustments, and test setpoints are under administrative control.

7.4.2.2.2.3.1.19 SLCS - IEEE 279 (1971), Paragraph 4.19 - Identification of Protective Actions

The explosive valve status, is continuously indicated in the control room. Pump motor status is also indicated in the control room.

7.4.2.2.2.3.1.20 SLCS - IEEE 279 (1971), Paragraph 4.20 - Information Readout

See Section 7.4.1.2.5.2 for a complete listing of operator information. The information readouts supplied minimize conditions that could cause meters, annunciators, and indicating lights to give anomalous information that might confuse the operator.

7.4.2.2.2.3.1.21 SLCS - IEEE 279 (1971), Paragraph 4.21 - System Repair

The control circuits, pumps, and pump motors may be repaired or replaced during normal plant operation.

7.4.2.2.2.3.1.22 SLCS - IEEE 279 (1971), Paragraph 4.22 - Identification of Protection Systems

All control room controls and instrumentation are located in one control room panel and are clearly identified by nameplates.

The name of each system logic cabinet and the particular redundant portion is identified distinctively as being in the protective system. Cabling outside the cabinets is identified for safety classification. An identification scheme is used to distinguish between redundant cables and raceways. Details of this identification scheme are given in Section 8.1.6.1. Redundant racks are identified by the identification marker plates of instruments on the racks. Control room devices are identified by tags on the panels. These tags indicate the function of the devices.

7.4.2.2.2.3.2 SLCS - IEEE 308 (1971) - Criteria for Class 1E Electrical Systems for Nuclear Power Generating Stations

The SLCS pumps, pump motors, and associated controls are physically separated and electrically isolated into independent load groups so that safety action provided by redundant counterparts is not compromised.

7.4.2.2.2.3.3 SLCS - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1 Electric Equipment for Nuclear Power Generating Stations

The requirements are satisfied through qualification testing as described in Sections 3.10 and 3.11, which contain further discussion on the degree of conformance.

7.4.2.2.2.3.4 SLCS - IEEE 338 (1971) - Criteria for the Periodic Testing of Nuclear Power Generating Station Protection System

See Section 7.4.2.2.2.3.1.10 for SLCS conformance.

7.4.2.2.2.3.5 SLCS - IEEE 344 (1971) Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations

The control instrumentation of the SLCS required for injection is classified as seismic Category I and remains functional during and following an SSE. The qualification and documentation procedures used for seismic Category I equipment are discussed in Section 3.10.

7.4.2.3 Reactor Shutdown Cooling Mode of the RHR System - Instrumentation and Controls

7.4.2.3.1 RHR-SCM General Functional Requirements Conformance

The design of the RHR-SCM meets the general functional requirements as follows:

a. Control Room

1. Instrumentation and controls are provided that enable residual heat to be removed from the reactor vessel during normal shutdown.

2. Manual controls for reactor shutdown cooling are provided in the control room and on the remote shutdown panel.

3. The instrumentation used to monitor the performance of the system is also provided in the control room and the remote shutdown panel.

b. Valves

Manual control and position indication is provided. A single failure in the system does not cause a loss of capability to perform reactor shutdown cooling.

c. Instrumentation

Instrumentation is provided for shutdown cooling flow, heat exchanger shutdown cooling water, and RHRSW temperatures.

d. Annunciation

Annunciation of valve motor overload, heat exchanger cooling water outlet high temperature, heat exchanger cooling water inlet high temperature, shutdown suction header high pressure, and pump motor overload is provided in the control room.

e. Pumps

Manual controls and stop and start indicators are provided.

Section 15.9 examines the protective sequences relative to the above events and equipment. Chapter 15 considers the operation and the system level qualitative and NSOA aspects of this system.

Loss of plant instrument air or cooling water does not, by itself, prevent reactor shutdown cooling capability.

7.4.2.3.2 RHR-SCM Specific Regulatory Requirements Conformance

7.4.2.3.2.1 RHR-SCM Conformance to Regulatory Guides

Conformance of the ECCS portions of the RHR-SCM to regulatory guides is discussed in Section 7.3.2.

7.4.2.3.2.1.1 RHR-SCM - Regulatory Guide 1.22 (1972) - Periodic Testing of Protection System Activation Functions (Safety Guide 22)

See Section 7.4.1.3.3.8 for RHR-SCM conformance.

7.4.2.3.2.1.2 RHR-SCM - Regulatory Guide 1.29 (1978) - Seismic Design Classification

See Section 3.10 for RHR-SCM conformance.

7.4.2.3.2.1.3 RHR-SCM - Regulatory Guide 1.30 (1972) - Quality Assurance Requirements for the Installation, Inspection, and Testing of Instrumentation and Electric Equipment (Safety Guide 30)

See Section 8.1.6.1 for RHR-SCM conformance.

7.4.2.3.2.1.4 RHR-SCM - Regulatory Guide 1.32 (1977) - Use of IEEE 308 (1971)

See Section 8.1 for RHR-SCM conformance.

7.4.2.3.2.1.5 RHR-SCM - Regulatory Guide 1.47 (1973) - Bypassed and Inoperable Status Indication for Nuclear Power Plant Safety Systems

See Section 7.4.1.3.5.2 for RHR-SCM conformance.

7.4.2.3.2.1.6 RHR-SCM - Regulatory Guide 1.53 (1973) - Application of the Single Failure Criterion to Nuclear Power Plant Protection Systems

RHR-SCM controls and instrumentation are configured to satisfy the single failure criteria. Single failure susceptibility has been identified and resolved by designating alternate flow paths through the SRVs and suppression pool as backup for the single suction line, and through the LPCI injection valves as backup for the loss of outboard injection isolation valves and the shutdown cooling suction valves.

7.4.2.3.2.1.7 RHR-SCM - Regulatory Guide 1.62 (1973) - Manual Initiation of Protective Actions

See Section 7.4.2.3.1 for RHR-SCM conformance.

7.4.2.3.2.1.8 RHR-SCM - Regulatory Guide 1.73 (1974) - Qualification Tests of Electric Valve Operators Installed Inside the Containment of Nuclear Power Plants

See Section 7.1.2.5.18 for RHR-SCM conformance.

7.4.2.3.2.1.9 RHR-SCM - Regulatory Guide 1.75 (1978) - Physical Independence of Electric Systems

The RHR-SCM system used during a normal reactor shutdown and cooldown performs a safe shutdown function. See Section 7.3.1.1.4.3 for a discussion of the degree of conformance of the safety-related portions of the RHR. Also see Section 7.1.2.5.19.

7.4.2.3.2.1.10 RHR-SCM - Regulatory Guide 1.89 (1974) - Qualification of Class 1E Equipment for Nuclear Power Plants

See Section 3.11 for RHR-SCM conformance.

7.4.2.3.2.1.11 RHR-SCM - Regulatory Guide 1.97 (1980) - Instrumentation for Light-Water-Cooled Nuclear Power Plants to Assess Plant and Environs Conditions During and Following an Accident

Section 7.5.2.5.1.1.2 contains a discussion of the degree of conformance.

7.4.2.3.2.1.12 RHR-SCM - Regulatory Guide 1.100 (1977) - Seismic Qualification of Electric Equipment for Nuclear Power Plants

See Section 3.10 for RHR-SCM conformance.

7.4.2.3.2.2 RHR-SCM Conformance to 10CFR50, Appendix A, General Design Criteria

7.4.2.3.2.2.1 RHR-SCM - GDC 1 - Quality Standards and Records

See Section 7.1.2.6 for RHR-SCM conformance.

7.4.2.3.2.2.2 RHR-SCM - GDC 2 - Design Bases for Protection Against Natural Phenomena

See Section 7.1.2.6 for RHR-SCM conformance.

7.4.2.3.2.2.3 RHR-SCM - GDC 3 - Fire Protection

See Section 7.1.2.6 for RHR-SCM conformance.

7.4.2.3.2.2.4 RHR-SCM - GDC 4 - Environmental and Dynamic Effects Design Bases

See Section 7.1.2.6 for RHR-SCM conformance.

7.4.2.3.2.2.5 RHR-SCM - GDC 10 - Reactor Design

The RHR-SCM is designed with sufficient margin to maintain the fuel and RCPB within design limits using quality components and instrumentation to monitor its variables over their anticipated ranges for normal operation and anticipated operational occurrences of this RHR mode.

7.4.2.3.2.2.6 RHR-SCM - GDC 13 - Instrumentation and Control

The RHR-SCM is designed with sufficient margin to maintain the fuel and RCPB within design limits using quality components and instrumentation to monitor its variables over their anticipated ranges for normal operation and anticipated operational occurrences of this RHR mode.

7.4.2.3.2.2.7 RHR-SCM - GDC 15 - Reactor Coolant System Design

The RHR-SCM is designed with sufficient margin to maintain the fuel and RCPB within design limits using quality components and instrumentation to monitor its variables over their anticipated ranges for normal operation and anticipated operational occurrences of this RHR mode.

7.4.2.3.2.2.8 RHR-SCM - GDC 19 - Control Room

The RHR-SCM controls and instrumentation are provided in the main control room and the remote shutdown panel. The control functions do not compromise the separation design of the safety-related positions of the RHR system (Section 7.3.2.1.2.2).

7.4.2.3.2.2.9 RHR-SCM - GDC 20 - Protection System Functions

The RHR-SCM controls and instrumentation are provided in the main control room and the remote shutdown panel. The control functions do not compromise the separation design of the safety-related positions of the RHR system (Section 7.3.2.1.2.2).

7.4.2.3.2.2.10 RHR-SCM - GDC 21 - Protection System Reliability and Testability

The RHR-SCM controls and instrumentation are provided in the main control room and the remote shutdown panel. The control functions do not compromise the separation design of the safety-related positions of the RHR system (Section 7.3.2.1.2.2).

7.4.2.3.2.2.11 RHR-SCM - GDC 22 - Protection System Independence

The RHR-SCM controls and instrumentation are provided in the main control room and the remote shutdown panel. The control functions do not compromise the separation design of the safety-related positions of the RHR system (Section 7.3.2.1.2.2).

7.4.2.3.2.2.12 RHR-SCM - GDC 23 - Protection System Failure Modes

The RHR-SCM controls and instrumentation are provided in the main control room and the remote shutdown panel. The control functions do not compromise the separation design of the safety-related positions of the RHR system (Section 7.3.2.1.2.2).

7.4.2.3.2.2.13 RHR-SCM - GDC 24 - Separation of Protection and Control Systems

The RHR-SCM controls and instrumentation are provided in the main control room and the remote shutdown panel. The control functions do not compromise the separation design of the safety-related positions of the RHR system (Section 7.3.2.1.2.2).

7.4.2.3.2.2.14 RHR-SCM - GDC 34 - Residual Heat Removal

The RHR-SCM removes residual heat from the reactor when it is shut down and the main steam lines are isolated to maintain the fuel and RCPB within design limits. Redundant channels are provided to ensure performance even with a single failure. Onsite and offsite power are provided in case either source is not available when shutdown cooling is needed. Section 3.1 provides a discussion of RHR system compliance with GDC 34. Section 5.2.5 provides a discussion of the leak detection system and its application to the RHR system. Section 5.4 discusses a backup method for disposing of residual heat if the normal shutdown line becomes unavailable during shutdown.

7.4.2.3.2.3 RHR-SCM Conformance to Industry Codes and Standards

7.4.2.3.2.3.1 RHR-SCM - IEEE 279 (1971) - Criteria for Protection Systems for Nuclear Power Generating Stations

IEEE 279 does not apply to the RHR-SCM because it is not a safety system function; however, the degree of conformance of the safety portions of the RHR system is discussed in Sections 7.3.2.1.2.3.1, 7.3.2.4.2.3.1, and 7.3.2.6.2.2.3.1.

7.4.2.3.2.3.2 RHR-SCM - IEEE 308 (1971) - Criteria for Class 1E Electrical Systems for Nuclear Power Generating Stations

RHR-SCM conformance to IEEE 308 is as discussed in Section 8.3.1 for the ac power supply to the RHR system of safety-related instrumentation and controls.

7.4.2.3.2.3.3 RHR-SCM - IEEE 317 (1972) - Electric Penetration Assemblies in Containment Structures for Nuclear Power Generating Stations

See Section 7.1.2.7.3.

7.4.2.3.2.3.4 RHR-SCM - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1 Electric Equipment for Nuclear Power Generating Stations

See Section 7.1.2.7.4.

7.4.2.3.2.3.5 RHR-SCM - IEEE 336 (1971) - Installation, Inspection, and Testing Requirements for Instrumentation and Electric Equipment During the Construction of Nuclear Power Generating Stations

See Section 8.1.6.1.

7.4.2.3.2.3.6 RHR-SCM - IEEE 344 (1971) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations

See Sections 3.10 and 7.1.2.7.7.

7.4.2.3.2.3.7 RHR-SCM - IEEE 379 (1972) - Guide for the Application of the Single Failure Criterion to Nuclear Power Generating Station Protection Systems

See Section 7.4.2.3.2.1.8.

7.4.2.3.2.3.8 RHR-SCM - IEEE 384 (1974) - Criteria for Separation of Class 1E Equipment

See Section 7.1.2.7.11.

7.4.2.4 Remote Shutdown System - Instrumentation and Controls

7.4.2.4.1 RSS General Functional Requirements Conformance

For remote shutdown operation, no off-normal operation is assumed. Because the remote shutdown capability, by itself, does not perform any safety-related or protective function, it does not fall within the criteria set by IEEE 279. This system interfaces with safety-related systems, such as RHR and RCIC, and during normal operation becomes part of, and meets the design criteria for, these systems.

a. RSS Safety Design Basis 7.1.2.1.34.1(a)

   The reactor can be brought from full power operation to cold shutdown using controls located outside the control room. Section 7.4.1.4.1.2 details the systems that are used in this process. The design criteria for the RSS are addressed in the respective design requirements section.

b. RSS Safety Design Basis 7.1.2.1.34.1(b)

   Suitable procedures are provided for the operator to take the reactor to the cold shutdown condition.

Section 15.9 examines the protective sequences relative to the above requirements and equipment. Chapter 15 considers the operation and the system level qualitative NSOA aspects of this plant capability.

7.4.2.4.2 RSS Specific Regulatory Requirements Conformance

7.4.2.4.2.1 RSS Conformance to Regulatory Guides

7.4.2.4.2.1.1 RSS - Regulatory Guide 1.29 (1978) - Seismic Design Classification

The RSS is classified as seismic Category I and is qualified to remain functional during and following an SSE.

7.4.2.4.2.1.2 RSS - Regulatory Guide 1.75 (1978) - Physical Independence of Electric Systems

Those RSS components that interface with safety-related systems maintain the integrity and channel separation of those systems. The separation criteria as defined in Section 8.1.6.1.14 is followed. Inside the remote shutdown panel, physical barriers between redundant divisions and between safety-related and nonsafety-related equipment are provided. Also see Section 7.1.2.5.19.

7.4.2.4.2.1.3 RSS - Regulatory Guide 1.89 (1974) - Qualification of Class 1E Equipment for Nuclear Power Plants

See Section 3.11 for a discussion of the degree of conformance of RSS.

7.4.2.4.2.1.4 RSS - Regulatory Guide 1.100 (1977) - Seismic Qualification of Electric Equipment for Nuclear Power Plant

See Section 3.10 for RSS compliance with Regulatory Guide 1.100.

7.4.2.4.2.2 RSS Conformance to 10CFR50, Appendix A, General Design Criteria

7.4.2.4.2.2.1 RSS - GDC 19 - Control Room

The RSS consists of equipment at appropriate locations outside the control room that is sufficient to provide and ensure prompt hot shutdown of the reactor and to maintain safe conditions during hot shutdown. The equipment also provides the capability for subsequent cold shutdown of the reactor.

The LGS remote shutdown system provides control of safety-related equipment at a panel in the remote shutdown room to bring the reactor to a cold shutdown condition if the control room should become uninhabitable. This capability is backed up by control of redundant equipment from local panels. The equipment qualification envelopes the service conditions expected to occur during shutdown conditions. The remote shutdown panel and transfer switches are seismically qualified. The instrumentation on this remote panel is single channel but is backed up by indications of the same parameters on other panels located in the auxiliary equipment room. The system is designed to achieve cold shutdown with the LOOP.

Operation of the transfer switches on the remote shutdown panel disables only the automatic actuation signal to a single division of the ESF equipment. This equipment can be manually placed in service from the remote panel.

Administrative procedures control access to the remote shutdown panel and its function. Additional remote shutdown procedures also control the operation of equipment from local panels including any information required to place this equipment in service.

7.4.2.4.2.3 RSS Conformance to Industry Codes and Standards

7.4.2.4.2.3.1 RSS - IEEE 279 (1971) - Criteria for Protection Systems for Nuclear Power Generating Stations

These criteria are not applicable to the RSS by itself. During normal plant operation the RSS interfaces with and becomes part of the RCIC and RHR systems, which can be controlled remotely from the control room. During this time, the interfacing RSS instrumentation and controls maintain channel independence as required by IEEE 279 (1971), paragraph 4.6, and discussed in sections covering the compliance of each individual system with these criteria.

7.4.2.4.2.3.2 RSS - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1 Electric Equipment for Nuclear Power Generating Stations

Specific RSS conformance to requirements of IEEE 323 (1971) is covered in Sections 7.1.2.7.4 and 3.11.

7.4.2.4.2.3.3 RSS - IEEE 344 (1971) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations

RSS conformance to the requirement of IEEE 344 (1971) is detailed in Section 3.10.

7.4.2.5 Emergency Service Water System – Instrumentation and Controls

For analysis of the ESW system, see Section 7.3.1.1.11.

7.4.2.6 Residual Heat Removal Service Water System - Instrumentation and Controls

For an analysis of the RHRSW system, see Section 7.3.1.1.12.

7.4.2.7 Class 1E Power Systems

For an analysis of the Class 1E power systems, see the following:

a. Section 8.3.1.2 for an analysis of the Class 1E ac power system

b. Section 8.3.2.2 for an analysis of the Class 1E dc power system

7.4.2.8 Shutdown Ventilation Systems

7.4.2.8.1 RCIC System Pump Compartment Unit Coolers - Instrumentation and Controls

7.4.2.8.1.1 RCIC-UC - General Functional Requirements Conformance

The RCIC-UC are designed with sufficient capacity and redundancy so that a single active failure does not prevent the system from performing its safety-related functions. They are automatically initiated by high temperature switches. For safety design basis refer to Section 7.1.2.1.14.1 and for additional details, refer to Section 9.4.

7.4.2.8.1.2 RCIC-UC to Specific Regulatory Requirements Conformance

7.4.2.8.1.2.1 RCIC-UC Conformance to Regulatory Guides

7.4.2.8.1.2.1.1 RCIC-UC - Regulatory Guide 1.22 (1972) - Periodic Testing of Protection System Actuation Functions (Safety Guide 22)

The RCIC-UC can be manually initiated and can be tested during normal plant operation. The RCIC-UC actuation functions are periodically tested.

7.4.2.8.1.2.1.2 RCIC-UC - Regulatory Guide 1.29 (1978) - Seismic Design Classification

The RCIC-UC comply with this regulatory guide as discussed in Section 3.2.

7.4.2.8.1.2.1.3 RCIC-UC - Regulatory Guide 1.30 (1972) - Quality Assurance Requirements for the Installation, Inspection, and Testing of Instrumentation and Electric Equipment (Safety Guide 30)

See Section 8.1.6.1.5 and Chapter 17 for RCIC-UC conformance.

7.4.2.8.1.2.1.4 RCIC-UC - Regulatory Guide 1.53 (1973) - Application of the Single Failure Criterion to Nuclear Power Plant Protection Systems

Compliance with Regulatory Guide 1.53 is achieved by specifying, designing, and constructing the HCRIS to meet the single failure criterion, section 4.2 of IEEE 279 (1971) and IEEE 379 (1972). Redundant sensors and wiring are separated to ensure that a failure in a sensing element, the decision logic, or an actuator does not affect its redundant counterpart and prevent protective action. Separate channels are employed so that a fault affecting one channel does not prevent the redundant channel from operating properly.

7.4.2.8.1.2.1.5 RCIC-UC - Regulatory Guide 1.62 (1973) - Manual Initiation of Protective Actions

Compliance with Regulatory Guide 1.62 is achieved at the system level by the Control Room RCIC Manual Initiation circuitry which starts the unit coolers. In addition, controls are provided locally to manually initiate the unit coolers.

7.4.2.8.1.2.1.6 RCIC-UC - Regulatory Guide 1.75 (1978) - Physical Independence of Electric Systems

See Section 8.1.6.1 for RCIC-UC compliance with this regulatory guide.

7.4.2.8.1.2.1.7 RCIC-UC - Regulatory Guide 1.89 (1974) - Qualification of Class 1E Equipment for Nuclear Power Plants

The qualification of Class 1E equipment for the RCIC-UC is discussed in Section 3.11.2.

7.4.2.8.1.2.1.8 RCIC-UC - Regulatory Guide 1.100 (1977) - Seismic Qualification of Electric Equipment for Nuclear Power Plants

RCIC-UC conformance with this regulatory guide is covered by Section 3.10.

7.4.2.8.1.2.1.9 RCIC-UC - Regulatory Guide 1.105 (1976) - Instrument Setpoints

To ensure initiation of the unit coolers to maintain the temperature of the RCIC pump compartment within the specified limits, instrument setpoints are selected to allow for the inaccuracy of the instrument, uncertainties in the calibration, and instrumentation drift likely to occur between calibrations.

7.4.2.8.1.2.1.10 RCIC-UC - Regulatory Guide 1.118 (1978) - Periodic Testing of Electric Power and Protection Systems

See Section 8.1.6.1.21. for RCIC-UC conformance.

7.4.2.8.1.2.2 RCIC-UC Conformance to 10CFR50, Appendix A, General Design Criteria

7.4.2.8.1.2.2.1 RCIC-UC - GDC 1 - Quality Standards and Records

The RCIC-UC are included in an established quality assurance program described in Section 3.1 and Chapter 17.

7.4.2.8.1.2.2.2 RCIC-UC - GDC 2 - Design Bases for Protection Against Natural Phenomena

See Section 7.1.2.6.

7.4.2.8.1.2.2.3 RCIC-UC - GDC 3 - Fire Protection

See Section 7.1.2.6.

7.4.2.8.1.2.2.4 RCIC-UC - GDC 4 - Environmental and Dynamic Effects Design Bases

See Section 7.1.2.6.

7.4.2.8.1.2.2.5 RCIC-UC - GDC 13 - Instrumentation and Control

Instrumentation for the RCIC-UC is selected to monitor variables over anticipated ranges during normal and emergency operating conditions.

7.4.2.8.1.2.3 RCIC-UC Conformance to Industry Codes Standards

7.4.2.8.1.2.3.1 RCIC-UC - IEEE 279 (1971) - Criteria for Protection Systems for Nuclear Power Generating Stations

Conformance of the RCIC-UC with IEEE 279 (1971) is detailed below.

7.4.2.8.1.2.3.1.1 RCIC-UC - IEEE 279 (1971), Paragraph 4.1 - General Functional Requirement

The unit coolers are automatically initiated by high temperature switches.

7.4.2.8.1.2.3.1.2 RCIC-UC - IEEE 279 (1971), Paragraph 4.2 - Single Failure Criterion

The ventilation system includes 100% capacity redundant unit coolers and independent sets of controls and power that meet the single failure criteria.

7.4.2.8.1.2.3.1.3 RCIC-UC - IEEE 279 (1971), Paragraph 4.3 - Quality of Components and Modules

All safety-related components are selected on the basis of suitability for the specific application. A quality control and assurance program is required to be implemented and documented by equipment vendors, which complies with the requirements set forth in 10CFR50, Appendix B.

7.4.2.8.1.2.3.1.4 RCIC-UC - IEEE 279 (1971), Paragraph 4.4 - Equipment Qualification

See Section 3.11 for a discussion of equipment qualification.

7.4.2.8.1.2.3.1.5 RCIC-UC - IEEE 279 (1971), Paragraph 4.5 - Channel Integrity

The unit coolers meet channel integrity by using the design features described in the other paragraphs of this section.

7.4.2.8.1.2.3.1.6 RCIC-UC - IEEE 279 (1971), Paragraph 4.6 - Channel Independence

The control and power circuits for each unit cooler are physically and electrically separated.

7.4.2.8.1.2.3.1.7 RCIC-UC - IEEE 279 (1971), Paragraph 4.7 - Control and Protection System Interaction

The unit coolers have no interaction with other plant control systems. Annunciator circuits using contacts at sensor and logic relays cannot impair the operability of the unit cooler control because of electrical isolation.

7.4.2.8.1.2.3.1.8 RCIC-UC - IEEE 279 (1971), Paragraph 4.8 - Derivation of System Inputs

Initiation of the unit coolers is derived from high temperature signals from the corresponding pump-room.

7.4.2.8.1.2.3.1.9 RCIC-UC - IEEE 279 (1971), Paragraph 4.9 - Capability for Sensor Checks

The unit coolers can be tested for operational availability as described in Section 7.4.1.8.1.3.7.

7.4.2.8.1.2.3.1.10 RCIC-UC - IEEE 279 (1971), Paragraph 4.10 - Capability for Testing and Calibration

The unit coolers can be tested during normal plant operation to verify that the system is capable of performing its intended function.

7.4.2.8.1.2.3.1.11 RCIC-UC - IEEE 279 (1971), Paragraph 4.11 - Channel Bypass or Removal from Operation

A channel bypass or removal of a component from an initiation circuit channel prevents the unit cooler from complying with the single failure criterion.

7.4.2.8.1.2.3.1.12 RCIC-UC - IEEE 279 (1971), Paragraph 4.12- Operating Bypasses

The unit cooler bypasses are discussed in Section 7.4.1.8.1.3.3.

7.4.2.8.1.2.3.1.13 RCIC-UC - IEEE 279 (1971), Paragraph 4.13- Indication of Bypasses

Each of the bypasses described in Section 7.4.1.8.1.3.3 is automatically indicated in the control room. In addition, each of these bypasses initiates a system out-of-service annunciator.

7.4.2.8.1.2.3.1.14 RCIC-UC - IEEE 279 (1971), Paragraph 4.14- Access to Means for Bypassing

Manual bypass of initiating circuits is procedurally controlled by administrative means.

7.4.2.8.1.2.3.1.15 RCIC-UC - IEEE 279 (1971), Paragraph 4.15 - Multiple Setpoints

The temperature switches are designed to allow trip setpoints to be adjusted to more stringent settings if required.

7.4.2.8.1.2.3.1.16 RCIC-UC - IEEE 279 (1971), Paragraph 4.16 - Completion of Protective Action Once It Is Initiated

Once the unit coolers are initiated they continue to operate until the room temperature drops below the low temperature switch setpoint.

7.4.2.8.1.2.3.1.17 RCIC-UC - IEEE 279 (1971), Paragraph 4.17 - Manual Initiation

A single failure in the control system of a unit cooler cannot disable the automatic or manual operation of the other unit cooler.

7.4.2.8.1.2.3.1.18 RCIC-UC - IEEE 279 (1971), Paragraph 4.18 - Access to Setpoint Adjustments, Calibration, and Test Points

Access to temperature switch setpoints is restricted by administrative control.

7.4.2.8.1.2.3.1.19 RCIC-UC - IEEE 279 (1971), Paragraph 4.19 - Identification of Protective Actions

System operation is indirectly indicated and identified by unit cooler trouble alarms.

7.4.2.8.1.2.3.1.20 RCIC-UC - IEEE 279 (1971), Paragraph 4.20 - Information Readout

The information readout for each unit cooler is described in Section 7.4.1.8.1.5.2.

7.4.2.8.1.2.3.1.21 RCIC-UC - IEEE 279 (1971), Paragraph 4.21 - System Repair

The recognition and location of failed components is accomplished during periodic testing.

7.4.2.8.1.2.3.1.22 RCIC-UC - IEEE 279 (1971), Paragraph 4.22 - Identification of Protection Systems

Each logic cabinet and control panel is distinctively identified with a nameplate that identifies the safety system. Cables and cable trays are identified by a color code and tags that identify them as being of a separate channel.

7.4.2.8.1.2.3.2 RCIC-UC - IEEE 308 (1974) - Criteria for Class 1E Electrical Systems for Nuclear Power Generating Stations

See Section 8.1 for RCIC-UC conformance.

7.4.2.8.1.2.3.3 RCIC-UC - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1 Electric Equipment for Nuclear Power Generating Stations

See Section 3.11.2. for RCIC-UC conformance.

7.4.2.8.1.2.3.4 RCIC-UC - IEEE 336 (1971) - Installation, Inspection, and Testing Requirements for Instrumentation and Electric Equipment During the Construction of Nuclear Power Generating Stations

The requirements of this standard have been met by the quality assurance program for construction of safety-related items.

7.4.2.8.1.2.3.5 RCIC-UC - IEEE 338 (1977) - Criteria for the Periodic Testing of Nuclear Power Generating Station Protection Systems

See Section 8.1.6.1.21 for RCIC-UC conformance.

7.4.2.8.1.2.3.6 RCIC-UC - IEEE 344 (1971) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations

See Section 3.10 for RCIC-UC conformance.

7.4.2.8.1.2.3.7 RCIC-UC - IEEE 379 (1972) - Guide for the Application of the Single Failure Criterion to Nuclear Power Generating Station Protection Systems

The single failure criteria of IEEE 379 (1972) is met as described in Section 7.4.2.8.1.2.1.4.

7.4.2.8.1.2.3.8 RCIC-UC - IEEE 384 (1974) - Criteria for Separation of Class 1E Equipment and Circuits

See Section 8.1.6.1.14 for RCIC-UC conformance.

7.4.2.8.2 RHR System Pump Compartment Unit Coolers

See Section 7.3.2.15.5 for an analysis of RHR-UC.

7.4.2.8.3 Remote Shutdown System Ventilation System

See Section 7.3.2.15.6 for an analysis of the auxiliary equipment room ventilation system.

7.4.2.9 Additional Design Consideration Analyses

7.4.2.9.1 Loss of Plant Instrument Air

Loss of plant instrument air does not affect the capability of the plant to be safely shut down.

7.4.2.9.2 Loss of Cooling Water to Vital Equipment

Equipment vital to safe shutdown of the plant is cooled by the ESW system. A single failure in the ESW system does not prevent a safe shutdown of the reactor (Section 9.2.2).

7.4.2.9.3 Plant Load Rejection

Generator load rejection results in a turbine control valve fast closure that in turn initiates a reactor scram via the RPS. The RPS is described in Section 7.2.

7.4.2.9.4 Turbine Trip

Turbine trip closes a main stop valve, which in turn initiates a reactor scram via the RPS. The RPS is described in Section 7.2.

Table 7.4-1

REACTOR CORE ISOLATION COOLING INSTRUMENT SPECIFICATIONS

REACTOR FUNCTION	INSTRUMENT	RANGE
Reactor vessel high water level turbine trip (level 8)	Level sensor	-150/0/+60 inches[1]
Turbine exhaust high Pressure	Pressure sensor	0-30 psi
RCIC system pump high/low suction pressure	Pressure sensor	100 psig 30" Hg Vac
Reactor vessel low water level (level 2)	Level sensor	-150/0/+60 inches[1]
RCIC system steam supply low pressure	Pressure sensor	0-200 psig
Turbine overspeed	Centrifugal device	

(1) Instrument zero equal to 527.5 inches above vessel zero.

(1) Indicating lights are provided for these valves as well as the following: turbine tripped, turbine bearing oil pressure low, and turbine bearing oil temperature high.

(2) Indicating lights are provided for these valves as well as the RHRSW loop A return to spray pond high radiation.

(3) Indicating lights are provided for these breakers.

7.5 INFORMATION SYSTEMS IMPORTANT TO SAFETY

7.5.1 DESCRIPTION

7.5.1.1 General

This section describes the instrumentation that provides information that enables the operator to monitor transient reactor plant behavior to verify proper safety system performance following an accident and to perform required safety functions.

The SRDI is listed in Table 7.5-1. This table tabulates equipment illustrated in the various system P&IDs, IEDs, and FCDs referenced in Sections 7.2, 7.3, 7.4, and 7.6.

The instrumentation and ranges shown in Table 7.5-1 are selected based on their ability to provide the reactor operator with the information needed to perform normal plant maneuvers, and their capability to track process variables pertinent to safety during expected operational perturbations.

Table 7.5-3 identifies Regulatory Guide 1.97 variables applicable to LGS. Table 7.5-3 lists the instrumentation from Table 7.5-1 that provides indication of Regulatory Guide 1.97 variables.

Table 7.5-2 summarizes the LGS design and qualification criteria for the Regulatory Guide 1.97 display instrumentation and systems. Conformance with Regulatory Guide 1.97 is discussed in Section 7.5.2.5.1.1.2. Sections 7.5.1.4.2 and 7.5.1.4.3 describe the display instrumentation for indication of Regulatory Guide 1.97 variables. References are made to other sections for descriptions of the instrumentation systems.

The separation of redundant display instrumentation and electrical isolation of redundant sensors and channels is shown in elementary diagrams and in Table 7.1-6. The P&IDs, IEDs, FCDs, and elementary diagrams adequately illustrate the redundancy of monitored variables and component sensors and channels.

The arrangement of the control room and the auxiliary equipment room is shown in drawings M-602 and M-603, respectively.

7.5.1.2 Normal Operation

The information channel ranges and indicators are selected on the basis of giving the reactor operator the information needed to perform all normal plant startup, steady-state maneuvers, and to monitor all the process variables pertinent to safety during expected operational perturbations.

7.5.1.3 Transient Occurrences

The ranges of indicators and recorders provided are capable of covering the extremes of process variables and providing adequate information for all transient events.

7.5.1.4 Accident Conditions

Information readouts are designed to accommodate all credible accidents from the standpoint of operator action, information, and event monitoring requirements.

7.5.1.4.1 Initial Accident Event

The design basis of all ESFs is to mitigate the consequences of an accident without operator action or assistance for the first 10 minutes of the event. This requirement, therefore, makes it mandatory that all protective action necessary in the first 10 minutes be automatic. Therefore, although continuous monitoring of process variables is available, no operator action based on them is required.

7.5.1.4.2 Postaccident Monitoring

No operator action is required for at least 10 minutes following an accident, although the various monitoring devices are continuously tracking and indicating important parameter information and displaying it to the operator as well as recording appropriate data.

The DBA-LOCA serves as the envelope accident sequence event to provide and demonstrate the plant's postaccident monitoring capabilities. All other accidents have less severe requirements.

7.5.1.4.2.1 Reactor Monitoring

The following process instrumentation which monitor reactor conditions provides information to the operator after a design basis LOCA.

7.5.1.4.2.1.1 Reactor Water Level

a. Two wide range water level signals are transmitted from two independent differential pressure transmitters and recorded on two recorders. One channel records the wide range level and the other channel records the reactor pressure as stated in Section 7.5.1.4.2.1.2. The differential pressure transmitters have one side connected to a condensing chamber reference leg and the other side connected directly to a vessel nozzle for the variable leg. The range of the recorded level is from the top of the feedwater control range (just above the high level turbine trip point) to a point near the top of the active fuel. Each independent instrumentation channel is powered from separate Class 1E buses.

b. The fuel zone water level signals are transmitted from two differential pressure transmitters. The level signals are electronically compensated for variation in reactor water and steam density with respect to pressure. One signal goes to a fuel zone water level indicator and the other water level signal goes to a fuel zone water level recorder. The differential pressure transmitters have one side connected to a condensing chamber for the reference leg and the other side connected directly to the bottom tap of a calibrated jet pump for the variable leg. The fuel zone level transmitters are calibrated for saturated conditions for a reactor pressure of 0 psig. The level range is from over the top of the active fuel to near the bottom of the active fuel. The ranges of the wide range level and the fuel zone level overlap. Power is fed from two independent Class 1E power sources.

c. A continuous backfill system is connected to each condensing chamber reference leg. The backfill system provides a continuous flow of water from the Control Rod Drive (CRD) System to the reference leg. This flow of water will continuously purge the reference leg and preclude the build-up of noncondensable gas in the reference leg.

7.5.1.4.2.1.2 Reactor Pressure

Two reactor pressure signals are transmitted from two independent pressure transmitters and are recorded on two recorders. One channel records pressure and the other channel records the wide range level. The range of recorded pressure is from 0-1500 psig. Power is fed from two independent Class 1E power sources.

7.5.1.4.2.1.3 Primary Containment Pressure

Wide range primary containment signals are transmitted from two pressure transmitters. One signal is displayed in a recorder in the control room while the other signal is displayed on an indicator located in the control room. The range of both instruments is from -5 psig to 165 psig. Power is supplied from two independent Class 1E power sources.

One narrow range primary containment signal is transmitted from a pressure transmitter and is indicated in the control room. The range of the indicated pressure is from -5 to +5 psig. Power is supplied from a Class 1E power source.

7.5.1.4.2.1.4 Primary Containment Gas Analyzers

Two redundant analyzer packages, each containing a hydrogen sensor and an oxygen sensor, monitor primary containment hydrogen and oxygen. These analyzers are part of the CAC system (Section 6.2.5.2.2). The hydrogen sensor has a range of 0% to 10% (by volume) and the oxygen sensor has a range of 0% to 25% (by volume). Each analyzer is calibrated with a high (7%) and a low (2%) oxygen and hydrogen supply. The hydrogen and oxygen concentrations are indicated in the control room.

Power is supplied from two independent Class 1E power sources.

7.5.1.4.2.1.5 Primary Containment Radiation Monitors

Four ion chamber sensors measure the gross radioactivity present in the containment atmosphere and transmit their signals to radiation recorders located in the control room. (Section 7.6.1.1.6). The range of recorded radiation is from $1\text{-}10^8$ rads per hour. Power is supplied from two independent Class 1E power sources.

7.5.1.4.2.1.6 Suppression Chamber Pressure

One suppression chamber pressure signal is transmitted from a pressure transmitter and is recorded in the control room. This signal is displayed on a pressure recorder located in the control room. The range of recorded pressure is from -5 psig to 165 psig.

Power is supplied from a Class 1E power source.

7.5.1.4.2.1.7 Suppression Pool Temperature

Two independent divisionalized recorders are located in the control room to monitor temperatures from 16 independent temperature sensors located in the suppression pool. Eight temperature sensors are dedicated to each recorder. Power is supplied from two independent Class 1E power sources. Each recorder has a digital display with which the operator can select the sensor to be

displayed. Normally the display indicates the average temperature of the eight temperature sensor inputs. A control room alarm is generated when the average temperature increases to 95°F, 105°F, 110°F, and 120°F. In addition, an alarm will be provided when any temperature loop malfunctions.

The SPTMS is described in Appendix 3A.15.

7.5.1.4.2.1.8 Suppression Pool Water Level

Two suppression pool water level signals are transmitted from two independent level transmitters. Each signal is transmitted to an indicator, located in the control room.

Power is supplied from two independent Class 1E sources (Table 7.5-3).

7.5.1.4.2.2 Reactor Shutdown, Isolation, and Core Cooling Indication

7.5.1.4.2.2.1 Reactor Operator Information and Observations

The following information furnished to the control room operator permits him to assess reactor shutdown, isolation, and availability of emergency core cooling following the postulated accident.

a. Operator verification that reactor shutdown has occurred is made by observing the following indications:

    1. Control rod status lamps indicate each rod to be fully inserted; the power source is one of the instrument ac buses.

    2. Control rod scram pilot valve status lamps indicate open valves; the power source is an instrument ac bus.

    3. Neutron monitoring power range channels and recorders downscale; the power source is a dedicated UPS system.

    4. Annunciators for RPS variables and trip logic in the tripped state. The power source is dc from a plant battery. The function of the annunciators is to supply information to the operator. They are not protective systems as they do not provide trip signals.

    5. The plant process computer (Section 7.7) provides thermal-hydraulic information to the operator that is used to determine plant operating conditions.

b. The reactor operator verifies reactor isolation by observing one or more of the following indications:

    1. Isolation valve position lamps indicate valve closure; the power source is the same as for the associated motor, solenoid, operator and solenoid for AOVs.

2. Annunciators for the containment and reactor vessel isolation system variables, and trip logic in the tripped state. The power source is dc from the plant battery system.

c. Operation of the ECCS following the accident is verified by observing the following indicators:

1. Annunciators for HPCI, core spray, RHR, and ADS, sensor initiation logic trips. The power source is dc from a plant battery.

2. There are flow and pressure indications for each ECCS. The power sources are independent and are from the same Class 1E buses as the driven equipment.

3. Injection valve position lights indicating either open or closed valves. The power source is the same as for the valve motor.

4. Relief valve position lights indicate valve open or closed status through acoustical sensors located on piping directly downstream of the relief valves. Power is supplied from UPS.

5. Relief valve discharge pipe temperature monitors. The power source is instrument ac from one of the instrument ac buses.

6. Operation of the containment systems following the accident is verified by observing the following indications:

(a) Annunciators for containment high oxygen and high hydrogen. The power source is dc from the plant battery system.

(b) Indication and recording (by virtue of the non-safety related ERFDS/PMS computer) of containment oxygen and hydrogen concentrations (Table 7.5-1).

7. Operation of the auxiliary supporting systems following the accident is verified by observing the following indicators:

(a) Control room emergency ventilation: Recording and annunciation of radiation monitoring of the CREFAS intake and charcoal filter discharge duct (Table 7.5-1).

(b) Service water systems: RHRSW system flow and temperature (Table 7.5-3).

(c) SGTS, RERS, and REIS: Indication of flow for SGTS; indication of temperatures for SGTS and RERS charcoal filters; and reactor enclosure and refueling area differential pressure for REIS (Table 7.5-1).

7.5.1.4.2.2.2 System Operation Information Display Equipment

The following information furnished to the control room operator permits the operator to assess the operation of the safety-related systems:

a. HPCI: Three indicators, one displaying HPCI discharge flow rate, one displaying HPCI pump discharge pressure, and one displaying HPCI turbine steam pressure, are located in the control room.

b. CS: Two indicators each displaying CS flow rate for one of the two CS loops are located in the control room.

c. RHR: Four indicators, each displaying RHR flow rate for each loop, two indicators each displaying RHRSW flow rate for each RHR heat exchanger; two indicators each displaying RHR coolant outlet temperature for each RHR heat exchanger and two indicators, each displaying service water inlet temperature for each RHR heat exchanger, located in the control room.

d. RCIC: One indicator displaying RCIC flow rate, located in the control room.

e. ESW: Two indicators, each displaying ESW flow rate for each ESW loop and two indicators, each displaying ESW temperature for each ESW loop, located in the control room.

f. Drywell atmosphere temperature: One 2-pen recorder displaying drywell atmosphere temperature and suppression pool air space temperature, located in the control room.

g. Drywell sump level (floor drain and equipment drain tanks): A level indication for each tank, provided in the control room.

h. Equipment drain collection tank level: One indicator displaying high radioactive equipment drain collection tank level, located in the radwaste control room.

i. Floor drain collection tank level: One indicator displaying high radioactive floor drain collection tank level, located in the radwaste control room.

j. Chemical waste collection tank level: One indicator displaying high radioactive chemical waste tank level, located in the radwaste control room.

k. SLCS storage tank level: A CRT tank level readout for the SLCS storage tank, available in the control room through the ERFDS.

l. PCIG pressure: Two indicators, each displaying PCIG pressure, located in the control room.

m. CRD hydraulic charging water pressure: One indicator displaying CRD hydraulic charging pressure, located in the control room.

n. Reactor recirculation pump flow: One 2-channel recorder displaying reactor recirculation pump flow, located in the control room.

o. Deleted

p. Miscellaneous: In addition to the above displays, the following also provide information to enable the reactor operator in the control room to perform postaccident functions:

1. Control rod status lamps (Section 7.5.1.4.2.2.1.a.1)

2. Scram pilot valve status lamps (Section 7.5.1.4.2.2.1.a.2)

3. Neutron flux level meters (Section 7.5.1.4.2.2.1.a.3)

4. Main feedwater flow: Three indicators, each displaying feedwater flow for each feedwater line, located in the control room. Signals transmitted to these indicators are totalized and displayed as total main feedwater flow on a recorder located in the control room.

5. CST level: One recorder displaying CST level, located in the control room.

6. Condenser hotwell level: One recorder displaying condenser hotwell level, located in the control room.

7. Condenser pressure: condenser vacuum for each condenser shell is displayed on the HMI workstations located in the control room.

8. Main steam bypass valve position: Each main steam bypass valve open and close position is displayed on HMI workstations in the control room.

9. Circulating water pump discharge pressure: Four indicators, each displaying discharge pressure for each circulating water pump, located in the control room.

7.5.1.4.2.2.3 System Operation Information Display Equipment Qualification

The safety-related reactor shutdown information equipment up to the display is of the same high quality as the safety system's instrumentation.

The postaccident monitoring instrumentation is of a quality that is consistent with minimum maintenance requirements and low failure rates. The safety-related equipment and indication equipment that have seismic and environmental qualifications are discussed in Sections 7.5.2.5.1.3.2 and 7.5.2.5.1.3.3.

7.5.1.4.2.3 Plant Electrical System

Display instrumentation for the status of the 4.16 kV safeguard and battery buses is provided in the control room. Each 4.16 kV safeguard bus is monitored for voltage and frequency, and each battery bus is monitored for voltage and amperage. Eight indicators (two indicators per bus) are provided in the control room to monitor each of the 4.16 kV safeguard buses for voltage and

frequency. Eight indicators (two indicators per bus) are provided in the control room to monitor each of the battery buses for voltage and amperage.

7.5.1.4.2.4 Bypass Indication System

There are bypass indications through either administrative control or automatic systems level indications. These bypass capabilities are discussed independently for each safety system (Section 7.3).

7.5.1.4.3 Additional Instrumentation for Regulatory Guide 1.97 Variables

The following instrumentation provides postaccident indication in accordance with Regulatory Guide 1.97.

7.5.1.4.3.1 Radioactivity Concentration in Primary Coolant

Indication of radiation levels in primary coolant is provided by two methods are discussed in Section 7.5.2.5.1.1.2.4.4: (1) by means of the MSL-RMS and the AEO-RMS when the NSSS is not isolated; and (2) by means of the PASS when the NSSS is isolated.

a. MSL-RMS - Four redundant radiation detectors provide signals via rate meters to one 2-pen recorder in the control room. The 2-pen recorder allows the output of any two selected detector channels to be displayed. This system is described in Sections 7.6.1.1.1 and 11.5.2.1.1.

b. AEO-RMS - A radiation monitor designed to sense changes in the off- gas gross fission product concentration transmits signals to a recorder in the control room. This system is described in Section 11.5.2.2.8.

c. PASS - Grab samples of both the primary containment atmosphere and the reactor coolant are provided by the PASS. Analysis of these samples provides information for detection of a breach in the fuel cladding when the NSSS is isolated. This system is described in Section 11.5.5.

7.5.1.4.3.2 Radiation Exposure Rate in Areas Requiring Personnel Access Postaccident

As discussed in Section 7.5.2.5.1.1.2.4.11, area radiation monitors are provided in areas outside the reactor enclosure where access is needed after an accident. Signals from these monitors are available on a CRT display in the control room through the ERFDS or through a multipoint recorder. These monitors are listed in Table 7.5-3. Because these monitors are also used during normal operation, they are described in Section 12.3.4.1.

7.5.1.4.3.3 Airborne Radioactive Materials Released from Plant

In the event of an accident, the secondary containment is isolated and all exhaust from it is processed through the SGTS as described in Sections 6.2.3, 6.5.1.1, and 9.4.2. After a LOCA, any drywell purge from the CAC system is processed through the SGTS (Section 9.4.5.1). Because the SGTS exhausts into the north stack, the wide range accident monitor (Sections 7.6.1.1.8 and 11.5.2.2.1) of the north stack effluent radiation monitoring system is used to provide indication of airborne radioactive material releases postaccident.

Noble gas radioactivity concentration signals are transmitted from the wide range accident monitor to a 3-pen recorder that displays the entire range of the monitor, 10^{-7} μCi/cc to 10^{+5} μCi/cc in three overlapping scales. Indication of north stack flow rate is provided from a transmitter and displayed via a digital display/control module in the control room.

The system also provides grab sampling capability for particulates and halogens.

7.5.2 ANALYSIS

7.5.2.1 General

The SRDI provides adequate information to enable the operator to monitor transient reactor plant behavior and to verify proper safety system performance following an accident.

All protective actions required under accident conditions during the first 10 minutes are automatic and redundant so that immediate operator intervention is unnecessary.

The information provided, in addition to the performance of the emergency system, supplies sufficient time for the operator to make reasoned judgments and take action when required.

7.5.2.2 Normal Operation

Instrumentation ranges for normal, transient, or accident, conditions are selected to maintain the accuracy requirements for all conditions. The accuracy of SRDI is shown in Table 7.5-1.

7.5.2.3 Transient Occurrences

These occurrences are not limiting from the point of view of instrument ranges and functional capability (Section 7.5.2.2).

7.5.2.4 Accident Conditions

The DBA LOCA is the most extreme operational event. Information readouts are designed to accommodate this event from the standpoint of operator actions, information, and event tracking requirements.

7.5.2.4.1 Initial Accident Event

The design basis of all ESFs, to mitigate accident event conditions, takes into consideration that no operator action or assistance is required or recommended for the first 10 minutes of the event. This requirement therefore makes it mandatory that all protective action necessary in the first 10 minutes be automatic. Therefore, although continuous tracking of variables is available, no operator action based on them is intended within the first 10 minutes.

7.5.2.4.2 Postaccident Monitoring

The following process instrumentation provides information to the operator after a DBA LOCA for use in monitoring reactor conditions:

a. Reactor Water Level and Pressure:

Vessel water level and pressure sensor instrumentation described in Section 7.5.1.4.2.1 is redundant, electrically independent, and is qualified to be operable during and after a LOCA in conjunction with a SSE. Power is from two independent Class 1E instrument buses supplied from two of the divisional ac buses. This instrumentation complies with the independence and redundancy requirements of IEEE 279 (1971) and provides recorded outputs. The equipment performs its required functions during and after a seismic event, except that the recorders and indicators are not functional during the seismic event.

The reactor water level and pressure transmitters are mounted on two independent local racks. The transmitters and recorders are designed to operate during normal operation and postaccident environmental conditions. The design criteria that the instruments must meet are discussed in Section 7.1.2.1.7. There are two complete and independent channels of wide range reactor water level and reactor vessel pressure with each channel having its readout in the control room on a separate recorder.

Two recorders are furnished, each monitoring one channel of pressure and one channel of reactor water level.

An evaluation was conducted of the effects of high temperature on the reference legs of the water level measuring instruments resulting from the exposure to HELBs.

HELBs are breaks occurring in a fluid system whose normal plant conditions are either in operation or maintained pressurized under conditions where either or both of the following are met:

1. Maximum operating temperature exceeds 200°F.

2. Maximum operating pressure exceeds 275 psig.

These HELBs can be categorized into three sizes: a) large, b) intermediate, and c) small. Each break has its own temperature and pressure effects on the vessel drywell and suppression pool. However, the small HELB imposes the most severe temperature conditions on the drywell and is more likely to affect the vessel level instrumentation reference legs.

The LGS reactor vessel level instrumentation design consists of four divisions of cold reference leg, differential pressure, level indications. The design includes parallel reference and variable legs with an approximate 12 foot vertical drop in the drywell. This design minimizes the error in level indication caused by elevated drywell temperatures. Reference leg temperature and drywell temperature are monitored by the ERFDS. The LGS design also includes redundant, safety-grade, wide range and fuel zone reactor water level indication in the control room.

Under a small break accident condition, the maximum temperature in the drywell could approach 340°F. Given this elevated drywell temperature and the gradual depressurization of the reactor vessel, a potential boil-off condition could occur

when the reactor vessel pressure falls below 118 psia (corresponding to a 340°F saturation temperature). However, the EOPs have been written to prevent the boil-off conditions from occurring.

For purposes of illustration, the following sequence of events is assumed to occur. With the reactor and containment at the maximum normal conditions, a small HELB occurs that allows blowdown of reactor steam to the drywell. The resulting pressure increase in the drywell leads to a high drywell pressure signal that scrams the reactor, initiates high pressure ECCS, and activates the containment isolation system. Drywell temperature would increase rapidly and approach 340°F. However, reactor vessel pressure and level would tend to decrease at a slow rate due to the small size of the break. The ADS will not initiate until low RPV level and high drywell pressure signals have been received. In instruments with cold reference legs, the reference leg temperature could increase to the drywell ambient temperature, which will not exceed 340°F. Thus, under the least favorable possible conditions, a cold reference leg will not boil until the system pressure falls to 118 psia (T_{sat} at 340°F). Thus pressure maintained above about 100 psig is an assurance that boiling of the cold reference column has not occurred, even under the worst possible drywell temperature conditions. Given this information, the following scenarios show the accident conditions and operator actions.

The reactor operator is alerted to the incident by the drywell high pressure and temperature alarms and by the reactor scrams. At this point, the operator will start to follow the EOPs. The operator will be aware of the elevated drywell temperature and pressure and is required to monitor and control these parameters as well as suppression pool temperature and pressures. The operator will also be continuously monitoring RPV pressure and reference leg temperature and comparing these parameters against a curve to determine the potential for reference leg boiling.

The EOPs require the operator to control drywell pressure and temperature. The main concern, as it pertains to RPV level instrumentation, is drywell temperature. If the reactor pressure is maintained high enough, the saturation temperature will be higher than the drywell temperature and a boil-off condition will never occur. If, however, the drywell temperature cannot be controlled, the operator is required to shut down the drywell cooling system and initiate drywell sprays in accordance with the restrictions of the drywell spray initiation limit curve. The sprays will lower drywell temperature and prevent the boiling condition from occurring. Drywell sprays are also used to reduce drywell pressure in the event that the pressure cannot be controlled.

As previously mentioned, the operator is sensitive to the reference leg temperature versus reactor pressure curve. If at any time the existing conditions fall into the unsafe area above the curve, the operator will assess the ability to determine RPV water level. If RPV water level cannot be determined, a contingency EOP which addresses the inability to determine RPV level will be performed concurrently with the EOP being executed at that time. The operator would be aware of a boil-off condition by the occurrence of erratic level indications caused by the flashing fluid as it is forced out through the instrument line. The first action is to blowdown the vessel, then, flood the RPV to the elevation of the main steam lines using available

low pressure makeup systems until RPV level indication can be determined. The RPV will remain flooded to the elevation of the main steam lines until RPV level indication is available. Flooding the vessel also ensures that adequate core cooling is accomplished.

Therefore, the existing LGS design coupled with the required operator actions as prescribed by the EOPs are sufficient to prevent or mitigate any detrimental effects on the water level indication that may be caused by a small HELB.

b. Suppression Pool Water Level:

This instrumentation complies with the requirements of IEEE 279 (1971) and provides indicated outputs. Power is from two independent Class 1E independent buses. The equipment performs its required function during and after the seismic event, except that the indicators are not functional during the seismic event. The indicators are selected from equipment that meets the design specification in effect at the time of the plant design. This parameter is recorded in the ERFDS data base.

c. Containment Pressure:

This instrumentation is redundant, electrically independent, and is qualified to be operable during and after a LOCA. Power is from two independent Class 1E buses, and the instrumentation complies with the requirements of IEEE 279 (1971) and provides a recorded output. The equipment will perform its required function during and after a seismic event, except that the recorder and indicators are not functional during the seismic event.

d. Emergency Core Cooling Systems:

Performance of ECCS following an accident can be verified by observing redundant and independent indications as described in Section 7.5.1.4.2.2.1.c, and fully satisfies the need for operator verification of the system's operation.

Redundancy of instrumentation within the individual ECCS is not provided; however, redundancy is provided within the combination of ECCS. Each ECCS is provided with system flow-measuring indication and isolation valve status indication, thereby allowing the operator to assess the operating conditions. The indicators and recorders are selected from equipment that meets the design specifications in effect at the time of the plant design.

e. Control Room Habitability:

Performance of the control room habitability is verified by observing the redundant and independent indication listed in Table 7.5-1 which satisfies the need for operator verification of the system operation.

f. Service Water Availability:

The operation of the ESW and the RHRSW systems is verified by observing the indications described in Sections 7.3.1.1.11.12.2 and 7.3.1.1.12.12.2, respectively, and satisfies the need for operator verification of the operation of the system.

g. Containment Atmospheric Control:

The operation of the CAC system is verified by observing the indications described in Sections 7.5.1.4.2.2.1.c.6 and 7.3.1.1.6.1.2.12.2, and satisfies the need for operator verification of the system operation.

h. Primary Containment Post-LOCA Radiation

The rate of buildup/decay of radioactivity inside the primary containment is verified by observing the indications described in Section 7.5.1.4.2.1.5, and satisfies the need for operator verification that safety functions are being accomplished.

i. SGTS, RERS, and REIS:

Performance of the SGTS, RERS, and REIS is verified by observing indication as described in Section 7.5.1.4.2.2, and satisfies the need for operator verification of the operation of the systems.

7.5.2.4.3 Safe Shutdown Displays

The safe shutdown display instrumentation in Section 7.5.1 consists of the control rod status lamps, scram pilot valve status lamps, and neutron monitoring instrumentation. These displays are expected to remain operable following an accident to indicate the occurrence of safe and orderly shutdown.

The displays provide diversity in that they are in three separate systems. The neutron monitoring outputs are recorded. The indicators and recorders are selected from equipment that meets the design specification in effect at the time of the plant design.

Sufficient instrumentation is provided for the operator to verify proper cooling water flow for the various shutdown cooling systems and modes. Proper shutdown cooling mode operation is indicated by RHR pump running indication, position indication for MOVs, cooling water flow indication, and RHRSW flow indication. Annunciators are provided to indicate RHR pump trip, abnormal pump discharge pressure, and loss of RHR system integrity. Proper RCIC operation is indicated by RCIC pump discharge and suction pressure and valve position indication. Annunciators are provided to indicate abnormal turbine operating parameters, low RCIC pump flow, and high turbine steam flow.

The safe shutdown display instrumentation conforms to the power generation design basis in that:

a. Abnormal conditions requiring operator action are indicated or annunciated in the control room.

b. Sufficient instrumentation is provided for the operator to verify proper cooling water flow and cooling system piping integrity.

7.5.2.5 General Functional Requirements Conformance

Conformance of the transmitter/trip unit system, used for safe shutdown display, is discussed in the Licensing Topical Report NEDO-21617, Revision A, "Analog Transmitter/Trip Unit System for Engineered Safeguard Sensor Inputs". Conformance of the other features with the regulatory and industry standards is discussed in the following sections.

7.5.2.5.1 Specific Regulatory Requirements Conformance

7.5.2.5.1.1 Conformance to Regulatory Guides

7.5.2.5.1.1.1 Regulatory Guide 1.47 (1973) - Bypassed and Inoperable Status Indication for Nuclear Power Plant Safety Systems

The SRDI is designed to operate continuously, and there is no requirement for bypass provisions. Removal of instrumentation for servicing during plant operation is administratively controlled. Refer to the individual safety system analysis discussions of Regulatory Guide 1.47 contained in Sections 7.2, 7.3, 7.4 and 7.6.

7.5.2.5.1.1.2 Regulatory Guide 1.97 (1980) - Instrumentation for Light-Water-Cooled Nuclear Power Plants to Assess Plant and Environs Conditions During and Following an Accident

LGS conforms with the intent of the regulatory guide, which is to ensure that instrumentation systems be provided to assess equipment and plant conditions during and following an accident as required by GDC 13, GDC 19 and GDC 64. In general, the regulatory guide requirements are implemented except where deviations from the guide are justified technically and can be implemented without disrupting the general intent of the guide. In assessing Regulatory Guide 1.97, LGS has drawn on information in ANSI/ANS 4.5 and on data derived from other analyses and studies.

7.5.2.5.1.1.2.1 Design and Qualification Criteria

LGS conformance with the design and qualification criteria defined in the regulatory positions of Regulatory Guide 1.97 is summarized in Table 7.5-2 and discussed below (the paragraph numbers cited correspond to those in Regulatory Guide 1.97).

a. Paragraph 1.3: Instruments used for accident monitoring to meet the provisions of Regulatory Guide 1.97 have the proper sensitivity, range, transient response, and accuracy to ensure that the control room operator is able to perform the role of bringing the plant to, and maintaining it in, a safe shutdown condition and in assessing actual or possible releases of radioactive material following an accident.

   Accident monitoring instruments that are required to be environmentally qualified are qualified to the requirement of NUREG-0588 (Section 3.11.1). The seismic qualification of instruments, where required, is in accordance with Regulatory Guide 1.100 (Section 3.10).

   The LGS quality assurance program is used to comply with the quality assurance requirements (Section 8.1.6.1 and Chapter 17).

Periodic checking, testing, calibrating, and calibration verification of accident monitoring instrument channels (Regulatory Guide 1.118) are in accordance with the LGS Technical Specifications.

b. Paragraph 1.4: Instruments designated as Categories 1 and 2 for variable Types A, B, and C are identified in such a manner as to optimize the human factors engineering and presentation of information to the control room operator. This position is taken to clarify the intent of Regulatory Guide 1.97, which specified that these instruments be easily discerned for use during accident conditions.

c. Paragraph 1.6: It is LGS's position that Table 1 of Regulatory Guide 1.97 does not represent the minimum number of variables, correct ranges, or instrumentation categories for accident monitoring at a BWR facility. The LGS list of accident monitoring variables and classification of instrumentation as Category 1, 2 or 3 is in compliance with the intent and method used in Regulatory Guide 1.97. The LGS position on implementation of each variable is presented in Section 7.5.2.5.1.1.2.3.

d. Paragraph 2: Conformance with Paragraph 1.3 described above is applicable to the Type D and E variables of Regulatory Guide 1.97.

7.5.2.5.1.1.2.2 Analysis for Type A Variables

Regulatory Guide 1.97 (Rev 2) designates all Type A variables as plant specific, thereby defining none in particular. Type A variables for LGS have been selected in conformance with the definition in Regulatory Guide 1.97. Variables associated with contingency actions that will be identified in written procedures are excluded. The following is a list of Type A variables specific to LGS. Detailed description of each Type A variable is given in Section 7.5.1.4.2.1. The variables listed here are also included in Section 7.5.2.5.1.1.2.3.

a. Variable A1 - Oxygen and Hydrogen Concentration:

Operator action: If containment atmosphere approaches the combustible limits, initiate CGCS.

Safety function: Prevent combustible concentrations and thus preserve containment integrity.

b. Variable A2 - RPV Pressure:

Operator action: (1) Depressurize RPV and maintain safe cooldown rate by any of several systems, such as main turbine bypass valves, HPCI, RCIC, and RWCU; or (2) manually open one SRV to reduce pressure to below SRV setpoint if an SRV is cycling.

Safety function: (1) Core cooling; (2) maintain RCS integrity.

c. Variable A3 - RPV Water Level:

Operator action: Restore and maintain RPV water level.

Safety function: Core cooling

d. Variable A4 - Suppression Pool Water Temperature:

Operator action: (1) Operate available suppression pool cooling system when pool temperature exceeds normal operating limits; (2) scram reactor if temperature reaches limit for scram; (3) if suppression pool temperature cannot be maintained below the heat capacity temperature limit, maintain RPV pressure below the corresponding limit; and (4) close any SORV.

Safety function: (1) Maintain containment integrity and (2) maintain RCS integrity.

e. Variable A5 - Suppression Pool Water Level:

Operator action: Maintain suppression pool water level within normal operating limits: (1) transfer RCIC suction from the CST to the suppression pool in the event of high suppression pool level; and (2) if suppression pool water level cannot be maintained below the suppression pool load limit, maintain RPV pressure below corresponding limit.

Safety function: Maintain containment integrity.

f. Variable A6 - Drywell Pressure:

Operator action: Control primary containment pressure by any of several systems, such as containment pressure control systems, SGTS, suppression pool sprays, drywell sprays.

Safety function: (1) Maintain containment integrity and (2) maintain RCS integrity.

7.5.2.5.1.1.2.3 Plant Variables for Accident Monitoring

LGS's implementation of the variables listed in table 1 of Regulatory Guide 1.97 and the fulfillment of design criteria and assignment of qualification categories for the instrumentation proposed for their measurement are summarized in Table 7.5-5.

Measurement of the five variable types provides the following kinds of information to plant operators during and after an accident:

a. Type A - plant pressure, barrier and heat sink information, on the basis of which operators can take specified manual control actions

b. Type B - information about the accomplishment of plant safety functions

c. Type C - plant information about the breaching of barriers to fission product release

d. Type D - information about the operation of individual safety systems

e. Type E - information about the magnitude of the release of radioactive materials.

The categories are also related (in Regulatory Guide 1.97) to "key variables." Key variables are defined differently for the different variable types. For Type B and Type C variables, the key variables are those variables that most directly indicate the accomplishment of a safety function; instrumentation for these key variables is designated Category 1.

Key variables that are Type D variables are defined as those variables that most directly indicate the operation of an emergency safety system; instrumentation for these key variables is usually Category 2. Key variables that are Type E variables are defined as those variables that most directly indicate the release of radioactive material; instrumentation for these key variables is also usually Category 2.

The variables are listed in Table 7.5-5 in the same sequence as in table 1 of Regulatory Guide 1.97; however, for convenience in cross-referencing entries and supporting data, the variables are designated by letter and number. For example, the sixth B-type variable listed in Regulatory Guide 1.97 is denoted in Table 7.5-5 as variable B6.

The LGS position is shown for each variable. In general, there are three kinds of responses, the variable and instrumentation are: (1) implemented to meet the regulatory guide criteria; (2) implemented with qualifying exceptions or (3) not implemented.

As necessary, the positions are elaborated or substantiated in the supplementary analyses in Section 7.5.2.5.1.1.2.4. References to these analyses are made in the tabulation by citing the appropriate UFSAR section.

7.5.2.5.1.1.2.4 Regulatory Guide 1.97 Project Position

The issues used to substantiate deviation of the LGS system from the Regulatory Guide 1.97 criteria are presented below.

7.5.2.5.1.1.2.4.1 Variable B1 - Neutron Flux

Issue Definition

The measurement of neutron flux is specified as the key variable in monitoring the status of reactivity. Neutron flux is classified as a Type B variable, Category 1. The specified range is 10^{-6}% to 100% full power (SRM, APRM). The stated purpose is "Function detection; accomplishment of mitigation."

Discussion

The lower end of the specified range, 10^{-6}% full power, is intended to allow detection of an approach to criticality by some undefined and noncontrolled mechanism after shutdown.

In attempting to analyze the performance of the neutron flux monitoring systems, a scenario was postulated to obtain the required approach to criticality. Basically, it assumes an increase in reactivity from loss of boron in the reactor water after SLCS actuation.

The accident scenario incorporates the following factors:

a. The control rods fail (completely or partially) to insert, and the operator actuates the SLCS.

b. The SLCS shuts down the reactor.

c. A slow leak in the primary system results in an outgo of borated water and its replacement by water that contains no boron.

d. A range of leak rates up to 20 gpm was considered (Table 7.5-4).

Calculations were made to evaluate the rise in neutron population as a function of different leak rates. The calculations were made for a shutdown neutron level of $5x10^{-8}$% of full power. The choice of $5x10^{-8}$% was based on measurements at two BWR plants. The shutdown level was assumed to have a negative reactivity of 10 dollars, an assumption that is representative of a shutdown with all rods inserted. The results of the calculations are presented in Table 7.5-4. The numbers in the table refer to the time in hours required to increase the flux by 1 decade. For example, with a leak of 5 gpm, it takes 100 hr to increase the power from $5x10^{-8}$% to a $5x10^{-7}$%, and 10 hr to increase it from $5x10^{-7}$% to $5x10^{-6}$%.

The reactor is subcritical and the neutron level is given by:

$$\text{Neutron level} = S \cdot M, \qquad \text{(EQ. 7.5-1)}$$

where:

S = the source strength

M = the multiplication, which is given by:

$$M = 1/(1-k) \qquad \text{(EQ. 7.5-2)}$$

For k = 0.9, M is 10; for k = 0.99, M is 100 and so forth. For criticality, the denominator approaches 0, as (k) approaches 1.0. Thus, the above equation was used to calculate relative neutron flux levels for a subcritical reactor until the reactor was near critical; then the critical equation of power with excess reactivity was used. Reactor power is directly proportional to neutron level.

The increase in reactivity toward criticality can be turned around by actuating the SLCS. A second actuation of the SLCS would cause a decrease in reactivity because of the high concentration of boron in the injected SLCS fluid relative to that in the leaking fluid (nominally 400 ppm). The sensitivity of the detector must allow adequate time for the operator to act. For a scaling evaluation, 10 minutes was considered sufficient time for operator action for accident prevention and mitigation.

Table 7.5-4 shows that the detector sensitivity (i.e., lower range) requirement is a function of leak rate and therefore of reactivity addition rate. On the basis of a 20 gpm leak rate, Table 7.5-4 shows that a detector that is one scale (i.e., about 10^{-5}) within 3 decades of the shutdown power (10^{-8}) would allow 0.18 hr (10.8 minutes) for operator action before reactor power increased another decade. A total of 0.36 hr (21.6 minutes) would be available for operator action from the time the indicator comes on scale to the time reactor power reaches 0.5% of full power. An alarm would be provided to warn the operator when the neutron flux reaches some plant specific setpoint.

The 20 gpm leak rate, which was assumed to continue for 27.75 hr, was used to define the sensitivity of the detector. It should be noted that the assumed leak rate, extended over the 27.75 hr period, would result in a loss of inventory so large that it could not in reality go undetected by the operator. Moreover, reactivity addition caused by this gradual boron depletion is unlikely because boron concentration is sampled and measured periodically. Again, the improbable 20 gpm leak rate was used only to obtain a mechanistic and conservative approach for selection of instrument sensitivity.

An absolute criterion for the lower range must include consideration of the neutron source level. The use of the neutron level 100 days after shutdown is conservative. There is high probability that conditions would be stable and controllable 2 days after the emergency shutdown, for the core decay heat is at a low level and the boron monitoring system should be functioning by that time. The actual neutron level will vary with fuel design, fuel history, and shutdown control strength. Measurements of shutdown neutron flux (with all rods inserted) at two BWR reactors show readings of 30-80 counts/sec (1000 counts/sec corresponds to 10^{-8} of full power). Measurements on other BWR reactors and for different fuel histories would show some variation, but those variations would be small compared with a criterion that is concerned with units of decades.

Neutron flux is the key variable for measuring reactivity control. The degree to which this variable is important to safety is another consideration. The large number of detectors (i.e., SRMs and IRMs) that are driven into the core soon after shutdown makes it highly probable that one or more of the existing NMS detectors will be inserted. On the other hand, there is little probability that there would be, simultaneously, a need for this measurement (in terms of operator action to be taken) and an accident environment in which the NMS would be rendered inoperable. Further, the operator can always actuate the SLCS on loss of instrumentation.

Conclusion

The existing NMS is adequate to meet the requirement of neutron flux measurement with some upgrading to improve system reliability. The upgrade of the existing system consists of powering the safety-related portion of the system from an UPS as described in Section 7.6.1.4.5. A rigorous Category 1 requirement is not justified relative to the criterion of "importance to safety." A Category 2 classification of this measurement fully meets the intent of Regulatory Guide 1.97 for neutron flux indication.

7.5.2.5.1.1.2.4.2 Variable B4 - Coolant Level in Reactor

7.5.2.5.1.1.2.4.2.1 Reactor Level Monitoring

LGS used overlapping ranges to monitor coolant level in the reactor as discussed in Section 7.5.1.4.2.1.1.

The reference leg of the wide range water level transmitter is 5 feet lower than the Regulatory Guide 1.97 required tap, i.e., centerline of the main steam lines. It was necessary to use this range to eliminate long runs of exposed sensing line tubing that contribute to erratic indication. The variable leg of the fuel zone water level is below the bottom of the core support plate. These two level monitors cover the range specified by Regulatory 1.97 except as mentioned above.

7.5.2.5.1.1.2.4.2.2 Trend Recording

Issue Definition

The purpose of addressing this issue is to determine which variables set forth in Regulatory Guide 1.97 need trend recording.

Discussion

Regulatory Guide 1.97, paragraph 1.3.2(f), states the general requirements for trend recording as follows: "Where direct and immediate trend or transient information is essential for operator information or action, the recording should be continuously available from dedicated recorders." Using the BWROG EPGs as a basis, the only trended variables required for operator action are reactor water level and reactor vessel pressure.

Conclusions

For LGS, only reactor water level (variable B4) and reactor vessel pressure (variable B6) require trend recording.

7.5.2.5.1.1.2.4.3 Variables B8 and C6 - Drywell Sump Level (B8) and Drywell Drain Sumps Level (C6)

Issue Definition

Regulatory Guide 1.97 specifies Category 1 instrumentation to monitor drywell sump level (variable B8) and drywell drain sumps level (variable C6). These designations refer to the drywell equipment drain tank and floor drain tank levels. Category 1 instrumentation indicates that the variable being monitored is a key variable. In Regulatory Guide 1.97, a key variable is defined as "... that single variable (or minimum number of variables) that most directly indicates the accomplishment of a safety function ..." The following discussion supports the BWROG alternative position that drywell sump level and drywell drain sumps levels should be qualified to Category 3 instrumentation requirements.

Discussion

The LGS drywell has two drain sumps. One drain is the equipment drain sump, which collects identified leakage; the other is the floor drain sump, which collects unidentified leakage.

Although the level of the drain sumps can be a direct indication of breach of the RCS pressure boundary, the indication is not unambiguous because there can be water in those sumps during normal operation. Other instrumentation specified in Regulatory Guide 1.97 that would also indicate leakage in the drywell are identified below:

a. Drywell pressure - variable B7, Category 1

b. Drywell temperature - variable D7, Category 2

c. Primary containment area radiation - variable C5, Category 1.

The drywell sump levels signal neither automatically initiates safety-related systems nor alerts the operator to take safety-related actions. Both sumps have level detectors that provide only the following nonsafety indications:

a. Continuous volume indication

b. High level alarm

c. Low level alarm

d. Average sump leak rate

e. Sump leak rate increase alarm

Regulatory Guide 1.97 specifies instrumentation to function during and after an accident. The drywell sump systems are deliberately isolated at the primary containment penetration on receipt of an accident signal to establish containment integrity. This fact renders the drywell sump level signal irrelevant.

Therefore, by design drywell level instrumentation serves no useful accident monitoring function.

The EOPs use the RPV level and the drywell pressure as entry conditions for the RPV Control Procedure. A small line break will cause the drywell pressure to increase before a noticeable increase in the sump level. Therefore, the drywell sumps will provide a "lagging" versus "early" indication of a leak.

Conclusions

Based on the above, LGS believes that Category 3, "high quality off-the-shelf instrumentation" is appropriate for drywell sump level and drywell drain sumps level instrumentation.

7.5.2.5.1.1.2.4.4 Variable C1 - Radioactivity Concentration or Radiation Level in Circulating Primary Coolant

Issue Definition

Regulatory Guide 1.97 specifies that the status of the fuel cladding be monitored. The specified variable is C1 (radioactivity concentration or radiation level in circulating primary coolant). The range is given as "½ technical specification limit to 100 times technical specification limit (R/hr)". Instrumentation for measuring variable C1 is designated as Category 1. The purpose for monitoring this variable is given as "detection of breach", referring, in this case, to breach of fuel cladding.

Discussion

The critical actions that must be taken to prevent and mitigate a gross breach of fuel cladding in a BWR are (1) shut down the reactor and (2) maintain water level. Monitoring variable C1, as directed in Regulatory Guide 1.97, will have no influence on either of these actions. Any usefulness from this monitored variable falls into the category of "information that the barriers to release of radioactive material are being challenged" and "identification of degraded conditions

and their magnitude, so the operator can take actions that are available to mitigate the consequences." There are no additional operator actions to mitigate the consequences of fuel barriers being challenged, other than those based on Type A and B variables.

Although the subject of concern in the Regulatory Guide 1.97 requirement is assumed to be an isolated NSSS, LGS has given consideration to events that do not isolate the NSSS. The PASS provides a means of obtaining samples of reactor coolant and primary containment atmosphere. Analyses of these samples provide information on the status of fuel cladding integrity when the plant is isolated. Radiation monitors in the SJAE and main steam lines provide information on the status of fuel cladding when the plant is not isolated.

Conclusion

Instrumentation for measuring variable C1 is implemented as Category 3 because no planned operator actions are identified and no operator actions are anticipated based on this variable serving as the key variable.

7.5.2.5.1.1.2.4.5 Variable C14 - Radiation Exposure Rate

Issue Definition

Variable C14 is defined in table 1 of Regulatory Guide 1.97 as follows: "Radiation exposure rate (inside buildings or areas which are in direct contact with primary containment where penetrations and hatches are located)." The reason for monitoring variable C14 is given as "Indication of breach".

Discussion

The use of local radiation exposure rate monitors to detect breach or leakage through primary containment penetrations is impractical. In general, radiation exposure rate in the secondary containment will be largely a function of radioactivity in primary containment and in the fluids flowing in ECCS piping, which will cause direct radiation shine on the areas of concern where radioactive fluids are piped. Because of the amount of piping and the number of electrical penetrations and hatches and their widely scattered locations, local radiation exposure rate monitors could give ambiguous indications. Breach of containment is more appropriately assessed by using the noble gas effluent monitor provided to monitor variable E4 (Section 7.5.2.1.1.2.4.10).

Conclusion

LGS is not implementing this parameter. Other means of breach detection that are better suited to this function (as described above), are available. Radiation exposure rate monitors as described in Section 12.3.4.1 are provided in these buildings for indication of habitability only.

7.5.2.5.1.1.2.4.6 Variables D3 and D8 - Suppression Spray Flow (D3) and Drywell Spray Flow (D8)

Issue Definition

Regulatory Guide 1.97 specifies flow measurements of suppression chamber spray (variable D3) and drywell spray (variable D8) for monitoring the operation of the primary containment related systems. Instrumentation for measuring these variables is designated Category 2, with a range of 0% to 110% of design flow. These flows relate to spray flow for controlling pressure and temperature of the drywell and suppression chamber.

Discussion

The drywell sprays can be used to control the pressure and temperature of the drywell. The RHR system flow element is used for measuring drywell flow.

The pressure-suppression chamber sprays can be used to control the pressure and temperature in the suppression chamber. From the control room, the operator controls pressure and temperature by adjusting suppression chamber spray flow. The RHR system flow element is used for flow indication. The suppression chamber spray operates in parallel with the drywell spray and is regulated with a throttling valve. The flow is determined by RHR flow indication. The effectiveness of spray flow can be verified by pressure and temperature changes of the drywell and the suppression chamber as indicated in the control room.

Conclusions

The current plant equipment, in conjunction with operating practice, meets performance requirements of accuracy and reliability for measurement of spray flows into the drywell and suppression chamber.

7.5.2.5.1.1.2.4.7 Variables D13 through D17 - RCIC Flow (D13), HPCI Flow (D14), Core Spray System Flow (D15), LPCI System Flow (D16) and SLCS Flow (D17)

Issue Definition

Regulatory Guide 1.97 specifies flow measurements of the following systems: RCIC (variable D13), HPCI (variable D14), core spray (variable D15), LPCI (variable D16), and SLCS (variable D17). The purpose is for monitoring the operation of individual safety systems. Instrumentation for measuring these variables is designated as Category 2; the range is specified as 0% to 110% of design flow. These variables are related to flow into the RPV.

Discussion

The RCIC, HPCI, and CS systems each have one branch line (the test line) downstream of the flow-measuring element. The test line is provided with a MOV that is normally closed (two valves in series in the case of the HPCI). In addition, the valve in the test line closes automatically when the emergency system is actuated, thereby ensuring that indicated flow is not being diverted by the test line. Proper valve position can be verified by a direct indication of valve position.

Although the LPCI has several branch lines located downstream of each flow-measuring element, each of those lines is either normally closed or automatically aligned. On initiation of the LPCI, the valves in the system automatically line up for proper operation and prevent flow diversion by branch lines. Proper valve position can be verified by a direct indication of valve position.

For all of the above systems, there are valid primary indicators other than flow measurement to verify the performance of the emergency system; for example, vessel water level. With respect to SLCS, flow-measuring devices were not provided for this system. The pump discharge header pressure, which is indicated in the control room, will indicate SLCS pump operation. Besides the discharge header pressure observation, the operator can verify the proper functioning of the SLCS by monitoring the following:

a. Decrease in the level of the boric acid storage tank

b. Reactivity change in the reactor as measured by neutron flux and concentration of boron

c. Motor contactor indicating lights (or motor current); the use of these indications is believed to be a valid alternative to SLCS flow indication (some plants have indicators for open/close positions of check valves)

d. Squib valve continuity indicating lights

Conclusion

The flow measurement schemes for the RCIC, HPCI, CS, and LPCI are adequate in that they meet the requirements of Regulatory Guide 1.97. Monitoring the SLCS can be adequately done by measuring variables other than the flow.

7.5.2.5.1.1.2.4.8 Variable D18 - SLCS Storage Tank Level

Issue Definition

Regulatory Guide 1.97 lists SLCS storage tank level as a Type D variable with Category 2 design and qualification criteria.

Discussion

Regarding the instrumentation category requirement for variable D18, Regulatory Guide 1.97 indicates that it is a key variable in monitoring SLCS operation. Regulatory Guide 1.97 also states that, in general, key Type D variables be designed and qualified to Category 2 requirements.

In applying these requirements of the regulatory guide to this instrumentation, the following are noted:

a. The current design basis for the SLCS assumes a need for an alternative method of reactivity control without a concurrent LOCA or HELB. The environment in which the SLCS instrumentation must work is therefore a mild environment for qualification purposes.

b. The current design basis for the SLCS is recognized as considerably less than the importance to safety of the RPS and the engineered safeguards systems. Therefore, in accordance with the graded approach to quality assurance specified in Regulatory Guide 1.97, it is unnecessary to apply a full quality assurance program to this instrumentation.

Conclusion

SLCS storage tank level instrumentation will meet Category 3 design and qualification criteria as required by Regulatory Guide 1.97.

7.5.2.5.1.1.2.4.9 Variables D26 through D30 - Main Steam Bypass Valve Position (D26), Condenser Hotwell Level (D27), Condenser Pressure (D28), Circulating Water Pump Discharge Pressure (D29) and Reactor Recirculation Pump Flow (D30)

Issue Definition

Regulatory Guide 1.97 states that "The plant designer should select variables and information display channels required by his design to enable the control room personnel to ascertain the operating status of each individual safety system and other systems important to safety to that extent necessary to determine if each system is operating or can be placed in operation..." The purpose of this analysis was to determine whether certain other D-type variables should be added to table 1, Regulatory Guide 1.97.

Discussion

Regulatory Guide 1.97 addressed safety systems and systems important to safety to mitigate consequences of an accident. Another list of variables has been compiled for the BWR in NUREG/CR-2100. That report and a companion report, NUREG/CR-1440, address plant systems not important to safety, as well as systems that are important to safety. In particular, these reports consider the potential role of the turbine plant in mitigating certain accidents. These two reports were reviewed in determining whether the listed variables (D26 through D30) should be added to the Regulatory Guide 1.97 list.

The NUREG evaluations used a systematic approach to derive a variables list. The basic approach of the analysis was to focus on those accident conditions under which the operator is most likely to be confronted with "and/or" accident conditions that result in the most serious consequences if the operator should fail to accomplish his required tasks. This is a probabilistic event tree type of study, and the reports used the sequences of the Reactor Safety Study (WASH-1440), and similar studies. The events in each sequence that involved operator action were identified; also, events were added to the event tree to include additional operator actions that could mitigate the accident. The event tree defines a series of key plant states that could evolve as the accident progresses and as the operator attempts to respond. Thus the operator's informational needs are linked to these plant states.

NUREG/CR-2100 is a BWR evaluation undertaken to address appropriate operator actions, the information needed to take those actions, and the instrumentation necessary to provide the required information.

The sequences evaluated were:

a. Anticipated transient followed by loss of decay heat removal

b. Anticipated transients without scram

c. Anticipated transient together with failure of HPCI, RCIC, and low pressure ECCS

d. Large LOCA with failure of ECCS

e. Small LOCA with failure of ECCS

The Regulatory Guide 1.97 list is based on accidents that result in an isolated NSSS. The NUREG documents considered accidents that could be prevented or mitigated by using water inventory and the heat sink in the turbine plant.

Conclusion

Five of the 15 variables identified in the NUREG, but not in Regulatory Guide 1.97, are included as Type D, Category 3 additions to the Regulatory Guide 1.97 list. Four of these variables are in the turbine plant: the main steam bypass valve position, condenser hotwell level, condenser pressure, and circulating water pump discharge pressure. These variables provide a primary measure of the status of a heat sink or water inventory in the turbine plant. The turbine plant systems are not to be classed as "safety systems" or as systems important to safety. The reactor recirculation pump flow is also added to the Regulatory Guide 1.97 list.

7.5.2.5.1.1.2.4.10 Variable E2 - Reactor Building or Secondary Containment Radiation

Issue Definition

Regulatory Guide 1.97 specifies that reactor building or secondary containment area radiation (variable E2) should be monitored over the range of 10^{-1} R/h to 10^{4} R/h for Mark II containments. The classification for Mark II is Category 2.

Discussion

As discussed in the variable C14 analysis (Section 7.5.2.5.1.1.2.4.5), secondary containment area radiation is not an appropriate parameter to use to detect or assess primary containment leakage.

Conclusion

The specified reactor enclosure area radiation monitors are not required for the LGS secondary containment.

7.5.2.5.1.1.2.4.11 Variable E3 - Radiation Exposure Rate

Issue Definition

Regulatory Guide 1.97 specifies in table 1, variable E3, that radiation exposure rate (inside buildings or areas where access is required to service equipment important to safety) be monitored

over the range of 10^{-1} R/hr to 10^{4} R/hr for detection of significant releases, for release assessment, and for long-term surveillance.

Discussion

In general, access is not required to any area of the secondary containment to service equipment important to safety in a postaccident situation. If and when accessibility is re-established in the long-term, it will be done by a combination of portable radiation survey instruments and postaccident sampling of the secondary containment atmosphere. Lower range area radiation monitors (typically 3 decades lower than the Regulatory Guide 1.97 range) are provided for use only in those instances in which radiation levels are very mild.

There are areas outside secondary containment where access is needed postaccident for specific sampling, monitoring or analysis tasks. Dose rates greater than 10 R/hr are not expected in these areas. In the event that these areas experience dose rates greater than 10 R/hr, access could result in excessive operator exposure.

Conclusion

The LGS design does not require access to a harsh environment area to service safety-related equipment during an accident; portable radiation monitors will be provided to re-establish accessibility. Lower range area monitors are implemented as Category 3 for areas outside secondary containment where postaccident access is needed.

7.5.2.5.1.1.2.4.12 Variable E8 - Plant and Environs Radiation

Issue Definition

Regulatory Guide 1.97 specifies that plant and environs radiation (variable E8) should be monitored over the range of 10^{-3} R/hr to 10^{4} R/hr, photons and 10^{-3} Rad/hr to 10^{4} Rad/hr, beta radiations and low energy photons. The classification is Category 3.

Discussion

The plant inventory of portable radiation survey instrumentation described in Section 12.5.2.2.3 will be supplemented with additional equipment to enhance postaccident monitoring capabilities. This additional equipment will be comprised of low range, medium range, and high range portable ion chambers (1 mR/hr to 20,000 R/hr gamma and 20,000 Rad/hr beta), open window alpha scintillation probes, pancake GM probes, energy compensated beta/gamma GM probes (for low energy photons), and portable beta/gamma geiger counters. Audio speakers, alarming count rate meters, and extension arms will be provided for attachments to the survey instruments. Airborne radioactivity levels will be determined from laboratory analysis of particulate filters and iodine cartridge samples obtained with high and low volume samplers. Portable instruments and equipment reserved for emergency use will be located at an assembly area remote from the main plant.

Conclusion

A range of monitoring of 10^{4} R/hr would not enhance plant and environs radiation monitoring. LGS meets the intention and the purpose of the regulatory guide criteria.

7.5.2.5.1.1.2.4.13 Variable E13 - Primary Coolant and Sump

Issue Definition

Regulatory Guide 1.97 requires installation of the capability for obtaining grab samples (variable E13) of the containment sump, ECCS pump-room sumps, and other similar auxiliary building sumps for the purpose of release assessment, verification, and analysis.

Discussion

The need for sampling a particular sump must take into account its location and the sump design. For all accidents in which radioactive material would be in the primary containment sump, it will be isolated and will overflow to the suppression pool. A suppression pool sample can be obtained through the PASS as described in Section 11.5.5 and this can therefore be used as a valid alternative to a containment sump sample.

The analysis of ECCS pump-room sumps and other similar auxiliary building sump liquid samples can be used for release assessment, as suggested in Regulatory Guide 1.97 only if potentially radioactive water can be pumped out of a controlled area to an area such as radwaste. If the design does not allow sump pump-out on a high radiation signal, a sump sample does not contribute to release assessment. The use of the subject sump samples for verification and analysis is of little value; a sample of the suppression pool and reactor water, as required by other portions of Regulatory Guide 1.97, provides a better measurement for these purposes.

Conclusion

A suppression pool sample will be used as an alternative to a primary containment sump sample. The analysis of ECCS pump-room sumps and other similar auxiliary building sumps is a consideration only if the water is pumped out of the reactor enclosure (e.g., pumped to radwaste). LGS design does not allow sump pump-out on receipt of high radiation signal. The capability for sampling and analysis of ECCS pump-room and auxiliary building sumps is therefore not provided.

7.5.2.5.1.1.2.4.14 Variables C5 and E1 - Primary Containment Post-LOCA Radiation Monitoring System

Issue Definition

Regulatory Guide 1.97 requires that containment radiation after an event be measured to within a factor of two.

Discussion

The primary containment post-LOCA radiation monitoring system installed at Limerick Generating Station meets this requirement except under extreme conditions of high drywell temperature and low radiation levels.

The licensee was notified by the system vendor in February 1987 that under high drywell temperature conditions, Insulation Resistance (IR) leakage current may cause a system error.

Because the instrument signal at low radiation levels is very weak, high temperature IR leakage current significantly affects the accuracy of the indicated readings up to a maximum of 112.5 Rad/hr at the maximum design drywell temperature of 340°F. As a result, the indicated readings below 112.5 Rad/hr may not be within the factor of two accuracy recommendation of Regulatory Guide 1.97 Rev.2. The induced error decreases exponentially with drywell temperature and becomes insignificant below 230°F. This induced error is significant only under low radiation conditions coincident with high drywell temperatures, whereas the system will operate to perform its principal function under normal and varying temperature conditions during and following an accident.

Conclusion

Since this failure is apparent only under low radiation conditions coincident with high drywell temperature, whereas the principal function of the system is to monitor high radiation postaccident conditions, continued operation without replacing the cable is justified. As drywell temperature is reduced with time, the error will also be reduced.

7.5.2.5.1.2 Conformance to 10CFR50, Appendix B

The SRDIs, except the displays, are of the same type, and are subject to the same qualification testing, quality control, and documentation, in accordance with the recommendation of 10CFR50, Appendix B as the safety systems' instrumentation. The displays are of a high quality consistent with the rest of the SRDIs, and are proven through industrial usage. The displays' qualification testing, quality assurance program, and documentation are provided and maintained by the vendor. For further information, refer to Chapter 17.

7.5.2.5.1.3 Conformance to Industry Codes and Standards

7.5.2.5.1.3.1 IEEE 279 (1971) - Criteria for Protection Systems for Nuclear Power Generating Stations

A discussion of the degree of conformance to IEEE 279 (1971) is not appropriate for application to SRDI. Most Regulatory Guide 1.97 Category 1 instrumentation meets the requirements of IEEE 279 (1971). Refer to the individual safety system discussion to find the degree of system conformance, for each parameter with a safety-related display instrumentation output.

7.5.2.5.1.3.2 IEEE 323 (1974) - IEEE Standard for Qualifying Class 1E Equipment for Nuclear Power Generating Stations

Safety-related display instrumentation equipment, where required (Table 7.5-2), meets the requirement of IEEE 323 (1974). Refer to Section 3.11 for a discussion of the degree of conformance of the environment qualified for the SRDI equipment.

7.5.2.5.1.3.3 IEEE 344 (1975) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations

SRDI equipment, where required (Table 7.5-2), meets the requirements of IEEE 344 (1975). Refer to Section 3.10 for a discussion of the degree of conformance for the seismic capacity of the qualified SRDI equipment.

Table 7.5-1

SAFETY-RELATED DISPLAY INSTRUMENTATION

PARAMETER MEASURED	INSTRUMENT NO.	NUMBER OF CHANNNELS[5]	RANGE	ACCURACY
Reactor vessel pressure	XR42-1R623A/B	2	0-1500 psig	0.5% FS[1]
Reactor vessel water level	XR42-1R623A/B LR42-1R615 LI42-1R610	2 1 1	-150" to +60"[3] -350" to -100"H_2O[4] -350" to -100"H_2O[4]	0.5% FS
HPCI flow	FI55-1R600-1	1	0-6000 gpm	±2% FS
HPCI discharge pressure	PI55-1R601	1	0-1500 psig	±2% FS
HPCI turbine steam pressure	PI55-1R602	1	0-1500 psig	±2% FS
CS flow	FI52-1R601A/B	2	0-8,800 gpm	±2% FS
RHR flow (LPCI and shutdown cooling)	FI51-1R603A/B/C/D	4	0-12,000 gpm	±2% FS

Control room airborne activity	RIX26-007A/B/C/D (outside air intake)	4	10^{-6} to 10^{-1} Ci/cc	±25%
	RIX26-068C/D (emergency fresh air filter discharge)	2	10^{-6} to 10^{-1} Ci/cc	±25%

[1] FS = Full Scale
[2] Per steam line
[3] Instrument zero equal to 527.5 in above vessel zero
[4] Top active fuel indicated in red
[5] Electrical divisions
[6] The value listed in the column is the manufacturers stated accuracies for the device. These values are “FOR INFORMATION ONLY” the actual calibration requirements for the instrumentation systems are contained within the IISCP Program.

Table 7.5-2

DESIGN AND QUALIFICATION REQUIREMENTS FOR POSTACCIDENT MONITORING INSTRUMENTATION

REGULATORY GUIDE 1.97 CATEGORY/REQUIREMENT	1	2	3
Seismic Qualification (Regulatory Guide 1.100 (Rev 1)	Yes(1)	Yes(2)	No
Single Failure Criterion	Yes	No	No
Environmental Qualification (Regulatory Guide 1.89 (1974) & NUREG-0588 (Rev 1)	Yes(1)	Yes(1)	No
Power Supply	Class 1E	Class 1E or UPS	Instrument ac
Out-of-Service Interval	Continuous(7)	System Technical Specification	None(3)
Display Type	Continuous or On Demand	Continuous or On Demand	On Demand
Display Method	Indication(4)	Indication(5)(6)	Indication(5)(6)

(1) Where the signal is to be displayed by a non-Class 1E computer-based system, qualification includes the sensor and the computer input isolation device.

(2) Seismic qualification is needed, provided that the instrumentation is part of a safety-related system. Where the signal is to be displayed by a non-Class 1E computer-based system, seismic qualification includes the sensor and the computer input isolation device.

(3) Not necessary to include in the safety and environmental technical specifications unless specified by other requirements.

(4) Where direct and immediate trend or transient information is essential for operator information or action, recording is provided on dedicated recorders. Otherwise, it is available on demand.

(5) Dial, digital, CRT, or strip-chart recorder indication.

(6) Recording required for effluent radioactivity monitors, area radiation monitors, and meteorology monitors. Where direct and immediate trend or transient information is essential for operator information or action, the recording is provided on dedicated recorders. Otherwise, it is available on demand.

(7) Continuous service is achieved through redundant instrument channels.

Estimation of Atmospheric Stability	E12	3	Recorder	2	-10°F to 20°F	XR-MS-091 or XR-MS-092	Control room

(1) For definitions, refer to Section 7.5.2.5.1.1.2.3.

(2) Above instrument zero.

(3) 61 inches above top of active fuel with same instrument zero as the wide range level monitor.

(4) This variable is provided with non-Class 1E power.

(5) For emergency ventilation damper position, ERFDS monitoring is also provided aside from the position indicating lights.

(6) Grab samples of RCS soluble boron can be obtained from the postaccident monitoring system (Section 11.5.5).

(7) Valves HV-57-262, HV-57-263, HV-1(2)64, HV-57-269 are administratively controlled such that these valves are treated as seal closed barriers. These valves are electrically deactivated and, therefore, do not provide indication in the Control Room.

Table 7.5-4

RELATIVE NEUTRON FLUX VERSUS TIME[1]

Percent of power	Leakage rate, gpm (ramp rate, c/min)[2] 1(0.03)		5(0.15)		20(0.60)	
	Σ	Δ	Σ	Δ	Σ	Δ
$5x10^{-8}$	-555	500	-111	100	-27.75	25
$5x10^{-7}$	-55	50	-11	10	-2.75	2.5
$5x10^{-6}$	-5	5	-1	1	-0.25	0.25
$5x10^{-5}$	0		0		0	
$5x10^{-4}$	0.8	0.8	0.36	0.36	0.18	0.18
$5x10^{-3}$	1.33	0.53	0.51	0.15	0.25	0.07
$5x10^{-2}$	1.59	0.26	0.62	0.11	0.31	0.06
$5x10^{-1}$	1.80	0.21	0.72	0.10	0.36	0.05
$5x10^{0}$	1.89	0.09	0.80	0.08	0.40	0.04

(1) Shutdown flux = $5x10^{-8}$% of power.

(2) Σ = total number of hours; Δ = hours for neutron flux to increase by one decade.

Table 7.5-5

PLANT VARIABLES FOR ACCIDENT MONITORING

Type A Variables	Position
A1 Oxygen and Hydrogen Concentration	LGS meets regulatory guide criteria for all Type A variables.
A2 RPV Pressure	
A3 RPV Water Level	Criteria met for overlapping range of -350" - +60" (Section 7.5.2.5.1.1.2.4.2)
A4 Suppression Pool Water Temperature	
A5 Suppression Pool Water Level	
A6 Drywell Pressure	
Type B Variables	
B1 Neutron Flux	Classified as Category 2 (Section 7.5.2.5.1.1.2.4.1)
B2 Control Rod Position	Criteria met
B3 RCS soluble boron concentration (Grab sample)	Criteria met
B4 Coolant level in reactor	Criteria met for overlapping range of -350" - +60" (Section 7.5.2.5.1.1.2.4.2)
B5 BWR core thermocouples	Not implemented. Reactor level instrumentation adequate with EPGs
B6 RCS pressure	Criteria met (Section 7.5.2.5.1.1.2.4.2)
B7 Drywell pressure	Criteria met

Table 7.5-5 (Cont'd)

Type B Variables (Cont'd)	
B8 Drywell sump level	Criteria for Category 3 met (Section 7.5.2.5.1.1.2.4.3)
B9 Primary Containment Pressure	Criteria met
B10 Primary Containment Isolation Valve Position	Criteria met, redundant indication is not required on redundant isolation valves. Exclude check valves.
Type C Variables	
C1 Radioactivity concentration or radiation level in circulating primary coolant	Implemented as Category 3 (Section 7.5.2.5.1.1.2.4.4)
C2 Analysis of primary coolant (gamma spectrum)	Criteria met
C3 BWR core thermocouples	Will not implement (See B5)
C4 RCS pressure	Criteria met
C5 Primary containment area Radiation	Criteria met except at extreme drywell temperature (See E1 and Section 7.5.2.5.1.1.2.4.14)
C6 Drywell drain sumps level	Criteria met for Category 3 (Section 7.5.2.5.1.1.2.4.3)
C7 Suppression pool water level	Criteria met
C8 Drywell pressure	Criteria met
C9 RCS pressure	Criteria met
C10 Primary containment pressure	Criteria met
C11 Containment and drywell H_2 concentration	Criteria met
C12 Containment and drywell O_2 concentration	Criteria met
C13 Containment effluent radioactivity - noble gases (from identified release points including SGTS vent)	Criteria met (See E4)

Table 7.5-5 (Cont'd)

Type C Variables (Cont'd)	
C14 Radiation exposure rate (inside buildings or areas in direct contact with primary containment where penetrations are located)	Not implemented (See E2, E3 and Section 7.5.2.5.1.1.2.4.5)
C15 Effluent radioactivity - noble gases (from buildings as indicated above)	Criteria met (See E4)
Type D Variables	
D1 Main feedwater flow	Criteria met
D2 CST level	Criteria met
D3 Suppression spray flow	Current design is adequate (Section 7.5.2.5.1.1.2.4.6)
D4 Drywell pressure	Criteria met
D5 Suppression pool water level	Criteria met
D6 Suppression pool water temperature	Criteria met
D7 Drywell atmosphere temperature	Criteria met
D8 Drywell spray flow	Current design is adequate (Section 7.5.2.5.1.1.2.4.6)
D9	Deleted
D10 SRV position	Criteria met
D11 Isolation condenser system shell-side water level	N/A
D12 Isolation condenser system valve position	N/A
D13 RCIC flow	Criteria met (Section 7.5.2.5.1.1.2.4.7)

Table 7.5-5 (Cont'd)

Type D Variables (Cont'd)	
D14 HPCI flow	Criteria met (Section 7.5.2.5.1.1.2.4.7)
D15 Core spray system flow	Criteria met (Section 7.5.2.5.1.1.2.4.7)
D16 LPCI system flow	Criteria met (Section 7.5.2.5.1.1.2.4.7)
D17 SLCS flow	Alternate criteria met for Category 3 (Section 7.5.2.5.1.1.2.4.7)
D18 SLCS storage tank level	Criteria met for category 3 (Section 7.5.2.5.1.1.2.4.8)
D19 RHR system flow	Criteria met
D20 RHR heat exchanger outlet temperature	Criteria met
D21 Cooling water temperature to ESF components	Criteria met for main system flow
D22 Cooling water flow to ESF Components	Criteria met for main system flow
D23 High radioactivity liquid tank level	Criteria met
D24 Emergency ventilation damper position	Criteria met for damper actuated under accident conditions whose failure could result in radioactive release.
D25 Status of standby power and other energy sources	Criteria met, onsite sources only
D26 Main steam bypass valve position	Added to Regulatory Guide 1.97 list (Section 7.5.2.5.1.1.2.4.9)
D27 Condenser hotwell level	Added to Regulatory Guide 1.97 list (Section 7.5.2.5.1.1.2.4.9)
D28 Condenser pressure	Added to Regulatory Guide 1.97 list (Section 7.5.2.5.1.1.2.4.9)
D29 Circulating water pump discharge pressure	Added to Regulatory Guide 1.97 list (Section 7.5.2.5.1.1.2.4.9)

Table 7.5-5 (Cont'd)

Type D Variables (Cont'd)	
D30 Reactor recirculation pump Flow	Added to Regulatory Guide 1.97 list (Section 7.5.2.5.1.1.2.4.9)
Type E Variables	
E1 Primary containment area radiation - high range	Criteria met except at extreme drywell temperature (See C5 and Section 7.5.2.5.1.1.2.4.14)
E2 Reactor building or secondary containment area radiation	Not implemented (See C14, E3 and Section 7.5.2.5.1.1.2.4.10)
E3 Radiation exposure rate (inside buildings or areas where access is required to service equipment important to safety)	Implemented as Category 3 (See C14, E2 and Section 7.5.2.5.1.1.2.4.11)
E4 Noble gases and vent flow rate	Criteria met
E5 Particulates and halogens	Criteria met
E6 Radiation exposure meters	Deleted per NRC errata July 1981
E7 Airborne radiohalogens and particulates	Criteria met
E8 Plant and environs radiation	Criteria met (Section 7.5.2.5.1.1.2.4.12)
E9 Plant and environs radioactivity (MCA)	Criteria met
E10 Wind direction	Criteria met
E11 Wind speed	Criteria met
E12 Estimation of atmospheric stability	Criteria met
E13 Primary coolant and sump (grab sample)	Criteria met for primary coolant and suppression pool (Section 7.5.2.5.1.1.2.4.13)
E14 Containment air sample	Criteria met

7.6 ALL OTHER INSTRUMENTATION SYSTEMS REQUIRED FOR SAFETY

7.6.1 DESCRIPTION

This section examines and discusses the instrumentation and control aspects of the safety-related portions of the following plant systems:

a. Process radiation monitoring systems

   1. Main steam line radiation monitoring system
   2. Reactor enclosure ventilation exhaust radiation monitoring system
   3. Refueling area ventilation exhaust radiation monitoring system
   4. Control room ventilation radiation monitoring system
   5. Control room emergency fresh air radiation monitoring system
   6. Primary containment post-LOCA radiation monitoring system
   7. RHRSW radiation monitoring system
   8. North stack effluent radiation monitoring system

b. High pressure/low pressure systems interlocks

c. Leak detection systems

   1. Main steam line leak detection system
   2. RCIC system leak detection system
   3. RWCU system leak detection system
   4. HPCI system leak detection system

d. Neutron monitoring system

   1. Intermediate range monitor system
   2. Local power range monitor system
   3. Average power range monitor system

e. Safety/relief valve position indication system

f. Containment instrument gas system - ADS control

g. Safeguard piping fill system

h. Redundant reactivity control system

Systems not related to safety, and nonsafety-related portions of the above systems, are discussed in Section 7.7.

7.6.1.1 Process Radiation Monitoring Systems – Instrumentation and Controls

Radiation monitoring systems are provided on process liquid and gas lines that serve as discharge routes for radioactive materials. These include the following safety-related systems. (Nonsafety-related systems are described in Section 7.7.1.9.)

This system classification is provided in Table 3.2-1. The locations of radiation monitoring sensors identified in Section 7.6 are provided in Table 7.6-6. Additional discussion of the process radiation monitors is provided in Section 7.3.2.2.2.3.

7.6.1.1.1 Main Steam Line Radiation Monitoring System - Instrumentation and Controls

7.6.1.1.1.1 MSL-RMS Identification

High radiation in the vicinity of the main steam lines indicates a gross release of fission products from the fuel.

The high radiation alarm setting is selected high enough above background radiation levels to avoid spurious alarms, yet low enough to promptly detect a gross release of fission products from the fuel.

The objective of the MSL-RMS is to monitor for the gross release of fission products from the fuel and, upon indication of such release, to initiate appropriate alarms.

7.6.1.1.1.2 MSL-RMS Power Sources

The 120 V ac RPS buses A and B are the power sources for the MSL-RMS. Two channels are powered from one RPS bus, and the other two channels are powered from the other RPS bus.

7.6.1.1.1.3 MSL-RMS Initiating Circuits

Four gamma-sensitive instrument channels monitor the gross gamma radiation from the main steam lines. The detectors are physically located near the main steam lines just downstream of the outboard MSIVs. The detectors are geometrically arranged to detect significant increases in radiation level with any number of main steam lines in operation. Their location along the main steam lines allows the earliest practicable detection of a gross fuel failure.

Each monitoring channel consists of a gamma-sensitive ion chamber and a log radiation monitor, as shown in drawings M-26 and M-41. Capabilities of the monitoring channel are listed in Table 11.5-1. Each log radiation monitor has four trip circuits: one upscale high-high trip and one inoperative trip, either of which results in an alarm and a trip of the mechanical vacuum pump and its suction valve; one upscale high trip and one downscale trip, either of which results in an alarm only. The output from each log radiation monitor is displayed on a meter in the control enclosure.

7.6.1.1.1.4 MSL-RMS Logic and Sequencing

When a significant increase in the main steam line radiation level is detected (high-high condition), an alarm is given in the control room. At the same time, a trip signal is issued to stop the Mechanical Vacuum Pump and close its input line. This function is not safety related. The logic of pump trip is 1-out-of-2. Failure of one monitoring channel will not prevent a Mechanical Vacuum Pump trip; however, a failure in one monitoring channel in the high-high direction will cause an inadvertent MVP trip.

7.6.1.1.1.5 MSL-RMS Bypasses and Interlocks

No operational bypasses are provided with this system; however, the individual log radiation monitors may be bypassed for maintenance or calibration by the use of test switches on each monitor. The main steam line radiation monitors provide trip signals to operate the mechanical vacuum pump and close the vacuum pump line isolation valve.

7.6.1.1.1.6 MSL-RMS Redundancy and Diversity

The number of monitoring channels in this system provides the required redundancy and is verified in the circuit description.

The single failure criterion is met in the design by providing redundant sensors, logic channels, and trip systems that are seismically and environmentally qualified. The failure of a single component does not prevent the system from functioning in the event that protective action is required.

There is no diversity of monitoring variables.

7.6.1.1.1.7 MSL-RMS Testability

A built-in source of adjustable current is provided to simulate sensor input to each log radiation monitor for test purposes. The operability of each monitoring channel can be routinely verified by comparing the outputs of the channels during power operation.

7.6.1.1.1.8 MSL-RMS Environmental Considerations

This system is designed, and has been qualified, to meet the environmental conditions indicated in Section 3.11. In addition, this system is seismically qualified as described in Section 3.10.

7.6.1.1.1.9 MSL-RMS Operational Considerations

In the event of a high or low radiation condition detected within any of the channels, the system automatically activates the appropriate alarm annunciator in the control room. Radiation level indication is provided in the auxiliary equipment room. A continuous radiation record for any two selected channels is provided in a 2-pen recorder in the control room.

The panels in the control room, associated with the PCRVICS, are identified by tags that indicate the panel function and identification of the contained logic channels.

The only direct support required for the MSL-RMS is the electrical power system, which is provided from 120 V ac RPS buses A and B as described in Section 7.3.1.1.2.2 and Chapter 8.

7.6.1.1.2 Reactor Enclosure Ventilation Exhaust Radiation Monitoring System - Instrumentation and Controls

7.6.1.1.2.1 REVE-RMS Identification

The purpose of this system is to indicate when excessive amounts of radioactivity exist in the reactor enclosure ventilation exhaust and to provide signals for initiation of appropriate action so that the release of radioactive gases to the environs is limited to levels below guidelines of published regulations. The radiation monitoring system is shown in drawing M-26. Instrument characteristics are given in Table 7.6-1. The system consists of four independent channels monitoring the reactor zone.

Refer to Section 7.3.1.1.9 for a description of the isolation function for this system.

7.6.1.1.2.2 REVE-RMS Power Sources

The 120 V ac RPS buses A and B are the power sources for these systems. Two channels receive power from one RPS bus, and the other two channels receive power from the other RPS bus.

7.6.1.1.2.3 REVE-RMS Initiating Circuits

Each channel includes a GM-type of detector and an indicator and trip unit. Two channels share a 2-pen strip-chart recorder. All equipment except the detectors is located in the control room and the auxiliary equipment room. The detectors are located in the reactor enclosure HVAC discharge ducts.

7.6.1.1.2.4 REVE-RMS Logic and Sequencing

Each channel has an upscale trip as described in Section 11.5.2.

The four upscale trips are arranged into two trip systems, A and B. When both channels of either A or B are tripped, the resultant output of the trip system is an isolation signal that trips fans, closes valves to the vent exhaust system, and initiates the SGTS. The isolation signal also initiates isolation of the following primary containment lines: purge, vent, atmosphere sample containment, and instrument gas suction and discharge lines. There are two isolation valves in each of the above lines. Each trip system operates one or the other of these valves. The two valves in each line are redundant, and one is sufficient to provide isolation.

7.6.1.1.2.5 REVE-RMS Bypasses and Interlocks

No operational bypasses are provided, but the trip units for each sensor channel may be bypassed for maintenance or testing. Bypassing the trip unit causes a downscale alarm and actuates the upscale trip for the channel.

7.6.1.1.2.6 REVE-RMS Redundancy and Diversity

As discussed in Section 7.6.1.1.2.4, the reactor enclosure ventilation exhaust radiation monitoring system consists of four independent sensors and trip units, sensing a common variable. This

independence provides sufficient redundancy to ensure that a high radiation condition will be detected and protective action initiated.

No diversity of trip variables is provided.

7.6.1.1.2.7 REVE-RMS Testability

The monitors are readily accessible for inspection, calibration, and testing. Operability of the detectors can be verified through use of a portable gamma source.

7.6.1.1.2.8 REVE-RMS Environmental Considerations

The environmental considerations are given in Section 3.11.

In addition, this system is seismically qualified for conditions of an SSE as indicated in Section 3.10.

7.6.1.1.2.9 REVE-RMS Operational Considerations

7.6.1.1.2.9.1 REVE-RMS General Information

The reactor enclosure ventilation exhaust radiation monitoring system is required to prevent release of radioactive materials to the environs. The isolation function is performed automatically and provides annunciation in the control room to alert operating personnel of the condition.

7.6.1.1.2.9.2 REVE-RMS Reactor Operator Information

REVE-RMS and RAVE-RMS radiation alarms are combined in the control room. REVE-RMS and RAVE-RMS channels A/B and C/D share high-high/downscale alarms in the control room. There is an additional upscale alarm shared by all channels of the RAVE-RMS and REVE-RMS. Refer to Table 7.3-5 for system characteristics and display ranges.

7.6.1.1.2.9.3 REVE-RMS Setpoints

Refer to the Technical Specifications.

7.6.1.1.3 Refueling Area Ventilation Exhaust Radiation Monitoring System - Instrumentation and Controls

7.6.1.1.3.1 RAVE-RMS Identification

The purpose of this system is to indicate when excessive amounts of radioactivity exist in the refueling area ventilation exhaust, and to provide signals for initiation of appropriate action so that the release of radioactive gases to the environs is limited to levels below guidelines of published regulations. The radiation monitoring system is shown in drawing M-26 and its specifications are given in Table 7.3-5. The system consists of four independent channels.

Refer to Section 7.3.1.1.17 for a description of the isolation function.

7.6.1.1.3.2 RAVE-RMS Power Sources

The 120 V ac RPS buses A and B are the power sources for these systems. Two channels receive power from one RPS bus, and the other two channels receive power from the other RPS bus.

7.6.1.1.3.3 RAVE-RMS Initiating Circuits

Each channel includes a GM-type detector and an indicator and trip unit. Two channels share a 2-pen strip-chart recorder. All equipment except the detectors are located in the control room and auxiliary equipment room.

7.6.1.1.3.4 RAVE-RMS Logic and Sequencing

Each channel has an upscale trip as described in Section 11.5.2.

The four upscale trips are arranged into two trip systems, A and B. When both channels of either A or B are tripped, the resultant output of the trip system is an isolation signal that trips fans, closes valves to the vent exhaust system, and initiates SGTS. The isolation signal also initiates isolation of the following primary containment lines: purge, vent, atmosphere sample containment, instrument gas suction and discharge lines. There are two isolation valves in each of the above lines. Each trip system operates one of the valves. The two valves in each line are redundant, and one is sufficient to provide isolation.

7.6.1.1.3.5 RAVE-RMS Bypasses and Interlocks

No operational bypasses are provided, but the trip units for each sensor channel can be bypassed for maintenance or testing. Bypassing the trip unit causes a downscale alarm and actuates the upscale trip for the channel.

7.6.1.1.3.6 RAVE-RMS Redundancy and Diversity

As discussed in Section 7.6.1.1.3 the RAVE-RMS consists of four independent sensors and trip units, sensing a common variable. This independence provides sufficient redundancy to ensure that a high radiation condition is detected and protective action initiated.

No diversity of trip variables is provided.

7.6.1.1.3.7 RAVE-RMS Testability

The monitors are readily accessible for inspection, calibration, and testing. Operability of the detectors can be verified through use of a portable gamma source.

7.6.1.1.3.8 RAVE-RMS Environmental Considerations

The environmental considerations are given in Section 3.11.

In addition, this system is seismically qualified for conditions of an SSE as indicated in Section 3.10.

7.6.1.1.3.9 RAVE-RMS Operational Considerations

7.6.1.1.3.9.1 RAVE-RMS General Information

The RAVE-RMS is required to prevent release of radioactive materials to the environs. The isolation function is performed automatically and provides annunciation in the control room to alert operating personnel of the condition.

7.6.1.1.3.9.2 RAVE-RMS Reactor Operator Information

REVE-RMS and RAVE-RMS radiation alarms are combined in the control room. REVE-RMS and RAVE-RMS channels A/B and C/D share high-high/ downscale alarms in the control room. There is an additional upscale alarm shared by all channels of the RAVE-RMS and REVE-RMS. Refer to Table 7.3-5 for system characteristics and display ranges.

7.6.1.1.3.9.3 RAVE-RMS Setpoints

Refer to the Technical Specifications.

7.6.1.1.4 Control Room Ventilation Radiation Monitoring System - Instrumentation and Controls

7.6.1.1.4.1 CRV-RMS Identification

In the event of an accident in which a significant quantity of radioactive material escapes from the plant, there is a risk that a hazardous quantity of this material could be introduced into the control room and auxiliary equipment room via the intake louvers. In this eventuality, these rooms could become uninhabitable, and the capability of plant shutdown under accident conditions could be curtailed.

The CRV-RMS detects the presence of radioactivity in the intake louvers leading to the control room and auxiliary equipment room. Trip setting is selected at such a level as to close the air intake dampers before the radioactivity level in these rooms reaches a unacceptable level. The emergency fresh air system is also actuated by this trip.

7.6.1.1.4.2 CRV-RMS Power Supplies

Power to this monitoring system is supplied from four 120 V ac Class 1E buses, Divisions I, II, III, and IV.

7.6.1.1.4.3 CRV-RMS Initiating Circuits

The system initiating circuits are described in Sections 6.4, 7.3.1.1.10, and 9.4.1.

7.6.1.1.4.4 CRV-RMS Logic and Sequencing

Four independent sensors and isolation logic channels are provided to ensure protective action when required and to prevent inadvertent isolation resulting from instrumentation malfunctions. When a predetermined increase in radioactivity above normal background is detected, trip signals are transmitted to the control room dampers and emergency fresh air system. The output trip signal of each radiation detector initiates a logic division trip. The output trip signals are combined

in a one-out-of-two-twice logic. Logic A or C and B or D are required to initiate control room isolation. Failure of any one channel does not result in an inadvertent isolation action.

7.6.1.1.4.5 CRV-RMS Redundancy and Diversity

Redundancy of trip initiation signals for high radioactivity is provided by four independent detectors. Each radiation signal is associated with one of four logics with different power sources. Diversity of trip initiation signals is neither required nor provided.

7.6.1.1.4.6 CRV-RMS Testability

A built-in source for simulating a midrange radioactivity level is provided to simulate sensor input to each radiation detector for test purposes. The operability of each monitoring channel can be routinely verified by comparing the outputs of the channels during power operation.

7.6.1.1.4.7 CRV-RMS Environmental Considerations

This system is designed and qualified to meet the environmental conditions under all plant operating conditions. In addition, this system is seismically qualified as described in Section 3.10.

7.6.1.1.4.8 CRV-RMS Operational Conditions

Both control trip and annunciation capabilities are provided for by this system.

7.6.1.1.5 Control Room Emergency Fresh Air Radiation Monitoring System - Instrumentation and Controls

7.6.1.1.5.1 CREFA-RMS Identification

The CREFA-RMS is subordinated to the control room ventilation monitoring system. If the concentration of radioactive material entering the control room ducts reaches an unacceptable level, the control room radiation monitors trip, close the ventilation dampers, and start up the emergency fresh air system. In this eventuality, the control room radiation monitors are no longer functional, and the CREFA-RMS takes over the function of monitoring the control room ventilation air supply. Most of the noble gases present in the ventilation air pass through the HEPA charcoal filters, where the radioactive particulates and iodines are filtered out. Thus, the CREFA-RMS located downstream of the HEPA charcoal filters, continues to alarm as long as the unacceptable condition persists. If the control room operator judges that the concentration of noble gases entering the control room is unacceptable, the operator shuts off the ventilation system completely. The CREFA-RMS also provides information as to when the unacceptable condition has ended.

7.6.1.1.5.2 CREFA-RMS Power Supplies

Power to this monitoring system is supplied from two 120 V ac Class 1E buses, Divisions III and IV.

7.6.1.1.5.3 CREFA-RMS Initiating Circuits

The CREFA-RMS does not initiate any controls.

7.6.1.1.5.4 CREFA-RMS Logic and Sequencing

The CREFA-RMS is comprised of two independent and redundant channels. The trip circuits do not provide any control functions. Alarms annunciate in response to high, high-high, and downscale trips. Failure of either channel does not prevent the alarms or readouts from functioning.

7.6.1.1.5.5 CREFA-RMS Redundancy and Diversity

Redundancy of trip signals for high radioactivity is provided by two independent detectors. Each detector is supplied by a separate power source.

7.6.1.1.5.6 CREFA-RMS Testability

A built-in source for simulating a midrange radioactivity level is provided to simulate sensor input to each radiation detector for test purposes. The operability of each monitoring channel can be routinely verified by comparing the outputs of the channels during power operation.

7.6.1.1.5.7 CREFA-RMS Environmental Considerations

This system is designed and qualified to meet the environmental conditions under all plant operating conditions. In addition, this system is seismically qualified as described in Section 3.10.

7.6.1.1.5.8 Operational Considerations

The CREFA-RMS provides only alarm annunciation capability and readouts in the control room. No control functions are involved.

7.6.1.1.6 Primary Containment Post-LOCA Radiation Monitoring System - Instrumentation and Controls

7.6.1.1.6.1 PCPL-RMS Identification

The objective of the PCPL-RMS is to monitor the total intensity of gross radioactivity present inside the containment. In correlation with other points of consideration this information provides a basis for making postaccident decisions.

The PCPL-RMS is shown in drawing M-26and specifications are given in Table 7.6-1.

7.6.1.1.6.2 PCPL-RMS Power Sources

Power to this monitoring system is supplied from two 120 V ac Class 1E power buses.

7.6.1.1.6.3 PCPL-RMS Redundancy and Diversity

Four physically separated sensors, two in each of two electrical separation channels, provide the required redundancy.

7.6.1.1.6.4 PCPL-RMS Testability

A built-in source of adjustable current is provided to simulate sensor input to each radiation monitor for test purposes. The operability of each monitoring channel can be routinely verified by comparing the outputs of the channels during power operation.

7.6.1.1.6.5 PCPL-RMS Environmental Considerations

This system is designed and qualified to meet the environmental conditions under post accident considerations. In addition, this system is seismically qualified as described in Section 3.10.

Under high drywell temperature conditions, Insulation Resistance (IR) leakage current will cause a system error. Because the instrument signal at low radiation levels is very weak, high temperature IR leakage current significantly affects the accuracy of the indicated readings up to a maximum of 112.5 Rad/hr at the maximum design drywell temperature of 340°F. As a result, the indicated readings below 112.5 Rad/hr may not be within the factor of two accuracy recommendation of Regulatory Guide 1.97 Rev. 2. The induced error decreases exponentially with drywell temperature and becomes insignificant below 230°F. This induced error is significant only under low radiation conditions coincident with high drywell temperatures, whereas the system will operate to perform its principal function under normal and varying temperature conditions during and following an accident.

7.6.1.1.6.6 PCPL-RMS Operational Considerations

Continuous radiation levels are recorded on dedicated Class 1E recorders in the control room. Trip and annunciation capabilities are described in Section 11.5.2.3.1.

7.6.1.1.7 Residual Heat Removal Service Water Radiation Monitoring System - Instrumentation and Controls

7.6.1.1.7.1 RHRSW-RMS System Identification

The purpose of the RHRSW-RMS is to indicate to operations personnel when the radioactivity of a liquid stream being released to the environs exceeds pre-established limits.

7.6.1.1.7.2 RHRSW-RMS Power Sources

The 120 V ac uninterruptible buses are the power sources for this system.

7.6.1.1.7.3 RHRSW-RMS Equipment Design

Design of this system is described in Section 11.5. This system is classified as a safety system in order to ensure that it will be functional after an SSE or LOCA in accordance with GDC 64.

7.6.1.1.7.4 RHRSW-RMS Circuit Description

The RHRSW-RMS is shown in drawing M-26. Specifications are given in Table 7.6-1. Two channels monitor the common RHRSW discharges from Units 1 and 2 to the cooling pond.

Each channel has a scintillation detector and a radiation monitor. Each detector monitors a sample of the process liquid for gamma activity. The sample is drawn from the process system, flows through the shielded sample chamber where it is monitored, and then is returned to the process system.

Indication is provided in the control room.

The RHRSW system provides cooling water for the RHR heat exchangers, which may contain radioactive water from leakage in the heat exchangers. Leaks that could contaminate the service water are detected by the two monitors for the service water effluent. A high radiation signal trips the RHRSW pumps.

7.6.1.1.7.5 RHRSW-RMS Logic and Sequencing

The logic is provided in a single high signal. The trip signal shuts off the RHRSW pumps.

7.6.1.1.7.6 RHRSW-RMS Bypass and Interlocks

None are provided.

7.6.1.1.7.7 RHRSW-RMS Redundancy and Diversity

A single monitor is provided for each of the common RHRSW discharge lines. The loss of monitor operability is annunciated in the Main Control Room. Periodic grab sampling is used following a monitor failure.

7.6.1.1.7.8 RHRSW-RMS Actuated Devices

The RHRSW pumps are subject to shutoff.

7.6.1.1.7.9 RHRSW-RMS Separation

The channels associated with the common discharge lines are separated in accordance with IEEE 279, paragraph 4.6.

7.6.1.1.7.10 RHRSW-RMS Setpoints

Setpoints are such that the instrument will trip the control room annunciator and the RHRSW pump when the radioactive concentration of the RHRSW equals or exceeds ten-times the 10CFR20, Appendix B, Table 2 activity limits (post-1994).

7.6.1.1.8 North Stack Effluent Radiation Monitoring System - Instrumentation and Controls

7.6.1.1.8.1 NSE-RMS System Identification

Under an accident condition, the south stack is isolated, but the north stack continues to emit effluents received from the SGTS and other sources. Radioactivity levels in these effluents are monitored continually by means of the north stack monitoring system.

Two independent subsystems, the normal range subsystem and the wide range accident monitoring subsystem, are provided as described in Sections 7.6.2.1.8 and 11.5.2.2.1.

7.6.1.1.8.2 NSE-RMS Power Sources

Power to the wide range accident monitoring system is provided by one 120 V ac Class 1E bus.

7.6.1.1.8.3 NSE-RMS Redundancy and Diversity

Although no redundancy is required, two independent radiation monitors are provided as part of the normal range subsystem. The wide range subsystem provides an extended measuring range designed to function during an accident and to follow decreasing concentrations of noble gases following an accident.

7.6.1.1.8.4 NSE-RMS Testability

Built-in radioactive check sources for simulating midrange radiation levels are provided for each channel for test purposes. Remote controlled purge and check source capabilities are provided. The operability of each monitoring channel can be routinely verified by comparing the outputs of the two monitoring systems during power operation.

7.6.1.1.8.5 NSE-RMS Environmental Considerations

The wide range accident monitor has been designed and qualified to meet environmental conditions under all modes of plant operation, including accidents. The normal range monitor is designed to withstand the normal service environment.

7.6.1.1.8.6 NSE-RMS Operational Considerations

Annunciation, computation, and recording capabilities are provided for this system. The equipment is located in an area where the radiation environment is sufficiently low to afford personnel access over the range of plant operating conditions. However, the instrumentation is designed for remote operation and control as well as data retrieval.

7.6.1.2 High Pressure/Low Pressure Systems Interlocks - Instrumentation and Controls

7.6.1.2.1 HPLPSI Function Identification

The low pressure systems that interface with the RCPB, and the instrumentation that protects them from overpressurization, are discussed in this section.

7.6.1.2.2 HPLPSI Power Sources

The power for the interlocks is provided from the essential power supplies for the associated systems.

7.6.1.2.3 HPLPSI Equipment Design

At least two isolation valves are provided in series in each line.

As discussed in Section 5.4.7.1.1.5, all components which make up the steam condensing mode of the RHR system have either been abandoned in place or physically removed from the plant. Therefore, this mode is no longer required.

A list of high pressure/low pressure interlock equipment is provided in Table 7.6-7.

The interlocked valves of the HPLPSI meet BTP ICSB 3 in accordance with the following:

Two MOVs in Series (ICSB 3, paragraph 2)

E11-F008 and E11-F009 (RHR shutdown cooling suction outboard and inboard valves, respectively) are two manually activated MOVs in series. Both valves are inhibited from opening and close automatically if primary system pressure is above setpoint. Reactor pressure is also indicated in the control room. The logic components for both valves are independent. Each valve control circuit requires two reactor low pressure permissives before valves can open; this results in a four-out-of-four logic to open the suction line. Removal of one signal (one-out-of-four logic) isolates the line. The pressure permissive components rely on the transmitter trip unit combination which is testable from the control room.

Reactor pressure instrumentation used by the operator (via plant procedures) to initiate shutdown cooling is independent of the interlocks. Procedural controls ensure that the manually initiated shutdown cooling mode is not begun until the reactor pressure is below approximately 75 psig; A safety factor is maintained since the piping in the pump discharge has ratings that vary from 350-500 psig and the suction piping is rated at 190 psig.

Because of the foregoing additional safety design features, diversity of interlocks as suggested by ICSB 3, paragraph 2, has not been implemented for LGS. This is consistent with all other BWR testability (transmitter trip unit) enhanced plants such as Grand Gulf.

MOVs in Series with (Testable) Check Valves (ICSB 3, paragraph 3)

E11-F015A and E11-F015B (RHR shutdown cooling injection outboard valves) are manually activated MOVs in series with E11-F050A and E11-F050B (testable check AOVs),respectively. These MOVs (loop A and B) are inhibited from opening and close automatically if primary system pressure is above setpoint. Both valves use the same valve control circuit, which requires two reactor low pressure permissives before the valves can open. Removal of one pressure permissive signal will close the valves.

The remaining HPLPSI valves in this discussion are required for ECCS operation. The recommendation of ICSB 3 was followed in evaluating ECCS high pressure/low pressure interlocks on an individual case basis.

Paired MOVs and Air-Operated Check Valves

The valves listed below are paired MOVs and air-operated check valves, which isolate low pressure ECCS from higher pressure primary system.

E11-F017A, B, C, and D LPCI injection MOVs are interlocked to prevent opening when differential pressure across the valves exceeds the setpoint. This interlock applies to manual or automatic opening. The ΔP is indicated by a permissive alarm in the control room. The normally closed core spray inboard injection valves (E21-F005 and E21-F037) and the normally open outboard injection

valves (E21-F004A and E21-F004B) are interlocked by high reactor pressure (one-out-of-two-twice logic) to prevent their receiving an opening signal on automatic system initiation. The inboard injection valve is interlocked by limit switch with outboard injection valve position to permit testing, such that it may be opened manually only if the outboard valve is closed. The outboard valve is interlocked so that during an automatic CS system initiation, the outboard valve close circuit will be disabled.

7.6.1.2.3.1 HPLPSI Circuit Description

The RHR shutdown cooling suction valves from the recirculation line have independent interlocks to prevent the valves from opening when the reactor pressure is above the RHR system design pressure. These valves also receive a signal to close when reactor pressure is above the RHR system pressure.

The RHR shutdown cooling suction valve F008 is provided with an additional interlock which prevents a fire-induced open signal from causing it to open simultaneously with valve F009 when the reactor pressure is greater than the design capabilities of the RHR low-pressure piping.

The RHR system shutdown cooling discharge valves have two reactor pressure interlocks. Both of these low pressure permissives must be satisfied in order to open the valves. Each line has a remote testable check valve downstream of the discharge valve.

The RHR system LPCI injection valves open when differential pressure across the valves is low. There is a remote testable check valve downstream of the injection valve in each loop.

The CS system injection valves open when reactor pressure decreases below the system design pressure. There is a remote testable check valve downstream of each injection valve. There is an additional check valve downstream of the injection valve on loop B.

7.6.1.2.3.2 HPLPSI Logic and Sequencing

The RHR shutdown cooling valves are interlocked by reactor pressure in two-out-of-two logic. In all other cases, the sensor inputs operate the interlocks without logic combination.

7.6.1.2.3.3 HPLPSI Bypasses and Interlocks

There are no bypasses or interlocks in the high pressure/low pressure interlocks.

7.6.1.2.3.4 HPLPSI Redundancy

Each process line has two valves in series that are redundant in ensuring the interlock. The RHR shutdown cooling suction valves have independent interlocks to prevent the valves from opening when the reactor pressure is above the system design pressure.

The RHR shutdown cooling suction valve F008 is provided with an additional interlock which prevents a fire-induced open signal from causing it to open simultaneously with valve F009 when the reactor pressure is greater than the design capabilities of the RGR low-pressure piping.

7.6.1.2.3.5 HPLPSI Actuated Devices

The MOVs listed in Section 7.6.1.2.3 and Table 7.6-7 are the actuated devices.

7.6.1.2.3.6 HPLPSI Separation

Separation is maintained between redundant portions of the high pressure/low pressure interlocks by assigning the signals for the redundant electrically controlled valves to separate electrical divisions (Section 7.1.2.2.).

The redundant high pressure interlocked valves are powered by separate essential electrical power. The relay logic, which performs the function of preventing valve opening unless pressure is below setpoint, is the same essential power as that of the associated interlocked valve. The interlocked valves of the HPLPSI are provided in Table 7.6-8.

The sensors that actuate the interlock logic (on pressure below setpoint) are on separate instrument lines and power such that no single failure can prevent core cooling. The electrical separation of the HPLPSI is consistent with the systems of which they comprise a part and represent no deviation from the intent of Regulatory Guide 1.75 as discussed in Section 8.1.6.1.14.

7.6.1.2.3.7 HPLPSI Testability

The actuated devices (except those valves kept closed by reactor pressure interlocks) can be tested during reactor operation. The sensors are tested during reactor operation in the same manner that ESF sensors are tested. Refer to Section 7.3.1 for a discussion of testing ESF sensors.

7.6.1.2.4 HPLPSI Environmental Considerations

The instrumentation and controls for the high pressure/low pressure interlocks are qualified as Class 1E equipment. The sensors are mounted on local instrument panels and the control circuitry is housed in panels in the auxiliary equipment room and the control room. Refer to Sections 3.10 and 3.11 for details of the qualification testing.

7.6.1.2.5 HPLPSI Operational Considerations

7.6.1.2.5.1 HPLPSI General Information

The high pressure/low pressure interlocks are strictly automatic. There is no manual actuation capability. If the operator initiates a low pressure system, the interlocks prevent exposure of the low pressure piping to high pressure.

7.6.1.2.5.2 HPLPSI Reactor Operator Information

The status of each valve providing the high pressure/low pressure boundary is indicated in the control room. The state of the reactor pressure and RHR injection valve differential pressure sensors is indicated in the control room.

7.6.1.2.5.3 HPLPSI Setpoints

The setpoints for HPLPSI are contained in Chapter 16.

7.6.1.3 Leak Detection System - Instrumentation and Controls

The LDS consists of the following safety-related subsystems:

a. Main steam line leak detection system

b. RCIC leak detection system

c. RWCU leak detection system

d. HPCI leak detection system

7.6.1.3.1 LDS Identification

This section discusses the instrumentation and controls associated with the safety-related portion of the leak detection system. The nonsafety-related portion is described in Section 7.7.1.16. The LDS itself is discussed in Section 5.2.5.

The purpose of the leak detection system instrumentation and controls is to detect and provide the signals necessary to isolate leakage from the RCPB before predetermined limits are exceeded. Environmental conditions and qualification for the leak detection system are discussed in Sections 3.10 and 3.11. Seismic qualification of the main steam line break detection subsystem is discussed in Section 7.3.2.2.2.3.1.5.

7.6.1.3.2 LDS Power Sources

Separation requirements are applicable to leak detection signals that are associated with the PCRVICS. Four power sources are used to comply with separation criteria. The normal 120 V ac power feed to the equipment associated with Division 1, Division 2, Division 3 and Division 4 is from the safeguard DC/AC Inverters E21-K601A, B, C and D respectively. The alternate 120 V ac power source to the equipment is from safeguard instrument buses A, B, C and D respectively also.

7.6.1.3.3 LDS Equipment Design

7.6.1.3.3.1 LDS General

The systems or parts of systems that contain water or steam coming from the reactor vessel or supply water to the reactor vessel, and which are in direct communication with the reactor vessel, are provided with leakage detection systems.

Outside the primary containment, the piping within each system monitored for leakage is in compartments or rooms separate from other systems wherever feasible, so that leakage may be detected by sump pump monitoring outside of containment, ambient and differential area temperature indications, high process flow, high process differential flow, level alarms, or area radiation indication.

7.6.1.3.3.2 Main Steam Line Leak Detection System - Instrumentation and Controls

7.6.1.3.3.2.1 MSL-LDS Identification

The main steam lines are constantly monitored for leaks by the LDS. Steam line leaks cause changes in at least one of the following monitored operating variables: area ambient and differential temperature, flow rate, or low water level in the reactor vessel. If a leak is detected, the detection system responds by triggering an annunciator and initiating a steam line isolation trip logic signal. An isolation trip logic signal will not initiate on TE MSL Tunnel High Temperature, it will only trigger an annunciator.

The MSL-LDS consists of four types of monitoring circuits:

a. The first two of these circuits monitor the ambient and differential area temperature in the vicinity of the MSIVs and cause an alarm to be initiated when an observed temperature rises above a preset maximum. The ambient area temperature monitors will initiate an Outboard MSIV room main steam line isolation when the observed temperature rises above a preset maximum. The ambient temperature monitors are located along the entire steam line.

b. The third type of circuit monitors the volumetric rate and initiates an alarm and closure of isolation valves when the monitored flow rate exceeds a preset maximum.

c. The fourth type of circuit monitors reactor vessel water level and sends a trip signal to the isolation valve logic when the level decreases below a preselected setpoint.

The MSL-LDS has no manual bypass switch because the MSIV isolation logic is A or C and B or D. This permits testing of a single channel without affecting the isolation function or causing inadvertent isolation. Annunciation of "Reactor isolation system out-of-service inboard" and "Reactor isolation system out-of- service outboard" is manually provided by individual "NORM-INOP" switches. Each MSL-LDS temperature monitor point has bypass capabilities, but this function is not used.

7.6.1.3.3.2.2 Main Steam Line Temperature in Outboard MSIV Room and Turbine Enclosure Main Steam Tunnel Monitoring Subsystem - Instrumentation and Controls

7.6.1.3.3.2.2.1 Identification

High ambient temperature in the areas in which the main steam lines are located outside of the primary containment could indicate a leak in a main steam line. Each main steam line isolation logic channel is tripped by high ambient temperature in the outboard MSIV room. The automatic closure of various valves prevents the excessive loss of reactor coolant and the release of a significant amount of radioactive material from the RCPB.

High temperature in the vicinity of the main steam lines is detected by dual element thermocouples located above the main steam lines between the primary containment wall and the turbine. The detectors are located or shielded so that they are sensitive to air temperature and not the radiated heat from hot equipment.

The temperature sensors give an input to temperature indicating switches.

The temperature detection system is designed to detect steam leaks equivalent to 5 gpm. A total of 4 main steam line high ambient temperature channels are provided in the outboard MSIV room

and 32 are provided on the main steam line in the turbine enclosure. Each main steam line isolation logic channel is tripped by high ambient temperature in the outboard MSIV room.

Refer to Section 7.3 for a description of the isolation function.

7.6.1.3.3.2.2.2 Power Supplies

Power supplies are discussed in Section 7.3.1.1.2.

7.6.1.3.3.2.2.3 Initiating Circuits

Four ambient temperature sensing circuits monitor the outboard MSIV room, and thirty-two monitor the turbine enclosure. The temperature elements are connected to four separate instrumentation channels. The 36 ambient temperature elements are physically located near the main steam lines in the outboard MSIV room and the turbine enclosure. The locations of the temperature elements provide the earliest practicable detection of a main steam line leak.

7.6.1.3.3.2.2.4 Logic and Sequencing

When a predetermined increase in ambient temperature is detected, trip signals are transmitted to the PCRVICS. The PCRVICS initiates closure of all main steam line isolation and drain valves.

Four instrumentation channels are provided to ensure protective action when needed and to prevent inadvertent isolation resulting from instrumentation malfunctions.

The output trip signal of each logic channel initiates a trip logic division trip. The output trip signals of the trip logic divisions are combined in one-out-of-two-twice for the MSIVs or two-out-of-two logics for the main steam line drains. Logic channels A or C and B or D are required to initiate main steam line isolation. Logic channels A and B or C and D are required to initiate main steam line drain isolation. Thus, failure of any one division does not result in inadvertent action.

7.6.1.3.3.2.2.5 Redundancy and Diversity

Redundancy of alarm initiation signals for high ambient temperature is provided by 16 thermocouples installed at different locations within the main steam line tunnel. The temperature indicating switches associated with each thermocouple provides an input to one of four logic channels. Ambient temperature indicating switches A, B, C and D are normally powered by 120 V ac from the safeguard DC/AC Inverters E21-K601A, B, C and D respectively. The alternate power source to these switches is from the 120 V ac safeguard instrument buses A, B, C and D respectively also.

Diversity of trip initiation signals for a main steam line leak is provided by main steam line Outboard MSIV room ambient temperature, main steam line high flow, and steam line low pressure instrumentation. An increase in ambient temperature for Outboard MSIV room only, main steam line flow, or a decrease in pressure initiates main steam line and main steam line drain valve isolation.

7.6.1.3.3.2.2.6 Bypasses and Interlocks

There are no bypasses associated with this system or interlocks to other systems from a main steam line tunnel high temperature alarm. Each MSL-LDS temperature monitor point has bypass capabilities, but this function is not used.

7.6.1.3.3.2.2.7 Testability

Testability is the same as discussed in Section 7.3.1.1.2.11.

7.6.1.3.3.2.2.8 Environmental Considerations

This system is designed and qualified to meet the environmental conditions indicated in Section 3.11. This subsystem, except for the sensors located in the reactor enclosure, is installed in the turbine enclosure. Seismic qualification of the subsystem is discussed in Section 7.3.2.2.2.3.1.5.

7.6.1.3.3.2.3 Main Steam Line High Flow Monitoring Subsystem - Instrumentation and Controls

7.6.1.3.3.2.3.1 Identification

Main steam line high flow could indicate a breach in a main steam line. Automatic closure of isolation valves prevents excessive loss of reactor coolant and release of significant amounts of radioactive material from the RCPB.

The main steam line high flow trip setting is high enough to permit isolation of one main steam line for test at rated power without causing an automatic isolation of the other steam lines, yet low enough to permit early detection of a steam line break.

High flow in each main steam line is sensed by four indicating differential pressure sensors that sense the pressure difference across the flow element in each line.

Refer to Section 7.3.1 for a description of the isolation function.

7.6.1.3.3.2.3.2 Power Supplies

Refer to Figures 7.3-1 and 7.3-2.

7.6.1.3.3.2.3.3 Initiating Circuits

Sixteen differential pressure indicating switches, four for each main steam line, monitor the main steam line flow. Four differential pressure indicating sensors are installed on each main steam line and provide the earliest practicable detection of a main steam line break. One differential pressure circuit for each main steam line is associated with each of four logics.

7.6.1.3.3.2.3.4 Logic and Sequencing

When a significant increase in main steam line flow is detected, trip signals are transmitted to the PCRVICS. The PCRVICS initiates closure of all main steam line isolation and drain valves on any significant main steam line break.

Four instrumentation logics are provided to ensure protective action when required and to prevent inadvertent isolation resulting from instrumentation malfunctions. The output trip signal of each

instrumentation channel initiates a division logic trip. The output trip signals of the logic divisions are combined in one-out-of-two-twice and two-out-of-two logics is shown in Figures 7.3-1 and 7.3-2. Logic divisions A or C and B or D are required to initiate main steam line isolation. Logic divisions A and B or C and D are required to initiate main steam line drain isolation. Failure of any one logic does not result in inadvertent action.

7.6.1.3.3.2.3.5 Redundancy and Diversity

Redundancy of trip initiation signals for high flow is provided by two groups of redundant differential pressure sensors for each main steam line. Each differential pressure sensor for each main steam line is associated with one of four logic divisions. Two differential pressure trip channels for each main steam line are supplied from 120 V ac RPS bus A, and two are supplied from 120 V ac RPS bus B.

Diversity of the trip initiation signals for a main steam line break is provided by main steam line high flow, main steam line tunnel ambient temperature and main steam low pressure. An increase in main steam line flow, ambient temperature or a decrease in pressure initiates main steam line drain valve isolation.

7.6.1.3.3.2.3.6 Bypasses and Interlocks

There are no bypasses associated with this system or interlocks to other systems from main steam line high flow trip signals.

7.6.1.3.3.2.3.7 Testability

Testability is discussed in Section 7.3.1.1.2.11.

7.6.1.3.3.2.3.8 Environmental Considerations

This system is designed and qualified to meet the environmental conditions indicated in Section 3.11. In addition, this subsystem is seismically qualified as described in Section 3.10.

The main steam line leak detection containment isolation function is discussed in Section 7.3.1.

7.6.1.3.3.3 RCIC Leak Detection System - Instrumentation and Controls

7.6.1.3.3.3.1 RCIC-LDS Identification

The steam lines of the RCIC system are constantly monitored for leaks and breaks by the following types of monitoring circuits:

a. Equipment area and pipe chase area ambient and differential temperature monitoring (leaks)

b. RCIC steam flow rate monitoring (pipe break)

c. RCIC steam line pressure monitoring (pipe break)

d. RCIC turbine exhaust diaphragm pressure monitoring (pipe break)

Setpoints are predetermined which indicate a possible leak. If the setpoint is reached, an RCIC autoisolation signal is initiated and an annunciator activated in the control room.

7.6.1.3.3.3.2 RCIC-LDS Power Sources

Refer to Sections 7.4.1.1.2 and 7.6.1.3.2.

7.6.1.3.3.3.3 RCIC Equipment Area and Pipe Chase Area Ambient and Differential Temperature Monitoring Subsystem - Instrumentation and Controls

7.6.1.3.3.3.3.1 Circuit Description

RCIC area temperatures are monitored by instrumentation of the LDS. Monitored temperatures include the following:

a. RCIC pipe chase area temperatures

b. RCIC compartment ambient temperature

c. RCIC area ventilation air differential temperature

7.6.1.3.3.3.3.2 Initiating Circuits

For Unit 1, ten ambient temperature elements are installed in the RCIC pipe chase areas. Five sensors are associated with each autoisolation logic division. For Unit 2, eight ambient temperature elements are installed in the RCIC pipe chase areas. Four sensors are associated with each autoisolation logic division. Seven temperature elements are installed in the RCIC equipment compartment. Four of these elements form two differential temperature pairs which monitor high ventilation air differential temperature. One pair is associated with one logic division and the other pair is associated with the other logic division. The other three temperature elements monitor the RCIC pump compartment ambient temperature. One ambient temperature element is associated with one logic division and the other two ambient temperature elements are associated with the other logic division.

7.6.1.3.3.3.3.3 Logic and Sequencing

When any one monitored temperature reaches its setpoint, an RCIC autoisolation signal is initiated and an annunciator activated in the control room.

Closure of the outboard RCIC steam supply isolation valve and steam line warm-up isolation valve is controlled by one logic division and the inboard steam supply isolation valve by the other logic division.

Two instrumentation channels are provided to ensure protective action when required.

In order to close both the inboard and outboard isolation valves, both logic divisions must trip. Protection against inadvertent isolation due to instrumentation malfunction is not required or provided.

The manual bypass switch bypasses the temperature leak detection signal from the RCIC isolation logic. The RCIC isolation is arranged such that a trip of any one of the temperature indicating

switches results in RCIC isolation and RCIC turbine trip. The bypass switch allows testing without isolating the RCIC system. Administrative control is provided by a two-position key-lock bypass switch, with the key removable in the normal position. Separate switches are provided for each of the redundant divisions.

Each RCIC-LDS temperature monitor point has bypass capabilities, but this function is not used.

Divisional level of bypass is indicated automatically in the control room when the respective divisional switch is placed in bypass position. System level annunciation of "RCIC system out-of-service" is automatically annunciated in the control room when either of the bypass switches is placed in the bypass position.

The RCIC isolation function will still be available from the redundant logic. Manual capability to actuate system level annunciation of "RCIC system out-of-service" is provided by separate NORMAL-INOP switches for the redundant divisions. Annunciation will occur when either of the divisional switches is placed in the INOP position. The RCIC bypass switch and the RCIC system is in conformance to Regulatory Guide 1.47. The HPCI leak detection system has a bypass switch that serves the same capacity as the RCIC bypass switch. All of the comments made for the RCIC system are applicable to the HPCI system. The HPCI system conforms to all of the requirements of Regulatory Guide 1.47.

7.6.1.3.3.3.4 RCIC Steam Flow Rate Monitoring Subsystem - Instrumentation and Controls

7.6.1.3.3.3.4.1 Circuit Description

The RCIC steam line connecting the nuclear boiler and the RCIC turbine is monitored by differential pressure sensors which signal a high steam flow rate condition.

7.6.1.3.3.3.4.2 Initiating Circuits

Two differential pressure sensors are installed on separate taps of a venturi flow element inside the primary containment. Steam flow rate in excess of a predetermined setpoint indicates a possible steam line break and initiates a sensor trip signal.

Spurious system isolations are precluded by a time delay that prevents short-term flow peaks from initiating system isolation. At the end of the timing period, system isolation will occur only if the initiating signal remains above the trip setpoint. Time delay will reset each time signal drops below setpoint.

7.6.1.3.3.3.4.3 Logic and Sequencing

The autoisolation logic utilizes one-out-of-two logic. Closure of the outboard RCIC steam supply isolation valve and steam line warm-up isolation valve is controlled by one logic division and the inboard steam supply isolation valve by the other logic division.

7.6.1.3.3.3.5 RCIC Steam Line Pressure Monitoring Subsystem - Instrumentation and Controls

7.6.1.3.3.3.5.1 Circuit Description

The RCIC steam line connecting the nuclear boiler and the RCIC turbine is monitored by four pressure sensors which signal a low steam supply pressure condition.

7.6.1.3.3.3.5.2 Initiating Circuits

Four pressure sensors are installed on the steam pipe. Steam pressure below a predetermined setpoint indicates a possible line break and initiates a sensor trip signal.

7.6.1.3.3.3.5.3 Logic and Sequencing

The autoisolation logic utilizes two-out-of-two logic in each logic division. Closure of the outboard RCIC steam supply isolation valve and steam line warm-up isolation valve is controlled by one logic division and the inboard steam supply isolation valve by the other logic division.

7.6.1.3.3.3.6 RCIC Turbine Exhaust Diaphragm Pressure Monitoring Subsystem - Instrumentation and Controls

7.6.1.3.3.3.6.1 Circuit Description

The RCIC turbine exhaust diaphragm is monitored by pressure sensors which signal a high pressure condition.

7.6.1.3.3.3.6.2 Initiating Circuits

Four pressure sensors monitor the turbine exhaust diaphragm. If monitored pressure exceeds a predetermined setpoint, indicating a possible diaphragm rupture, a sensor trip signal occurs.

7.6.1.3.3.3.6.3 Logic and Sequencing

The autoisolation logic utilizes two-out-of-two logic in each logic division. Closure of the outboard RCIC steam supply isolation valve and steam line warm-up isolation valve is controlled by one logic division, and the inboard steam supply isolation valve by the other logic division.

7.6.1.3.3.3.7 RCIC-LDS Bypasses and Interlocks

Each RCIC-LDS temperature monitor point has bypass capabilities, but this function is not used.

The trip signals from the leak detection area temperature monitors can be bypassed by a manual bypass switch. This switch permits testing of the temperature monitors without initiating system isolation. Bypassing the temperature trip signals in one logic division will not prevent proper operation of the other division. No other bypasses or interlocks are provided.

7.6.1.3.3.3.8 RCIC-LDS Redundancy and Diversity

For Unit 1, redundancy of trip initiation for high ambient temperature is provided by 10 ambient temperature elements installed in RCIC pipe chase areas. Five temperature sensors are associated with each logic division.

For Unit 2, redundancy of trip initiation for high ambient temperature is provided by 8 ambient temperature elements installed in RCIC pipe chase areas. Four temperature sensors are associated with each logic division.

Redundancy of trip initiation signals for high ventilation air differential temperature and RCIC area high ambient temperature is provided by seven temperature elements. Four of these elements

form two differential temperature pairs which monitor high ventilation air differential temperature. One pair is associated with one logic division and the other pair is associated with the other logic division. The other three temperature elements monitor the RCIC pump compartment ambient temperature. One ambient temperature element is associated with one logic division and the other two ambient temperature elements are associated with the other logic division.

Redundancy of steam flow monitoring is provided by two differential pressure sensors, each associated with different logic divisions. Redundancy of RCIC steam supply low pressure monitoring is provided by two pairs of sensors in the RCIC steam supply line, each pair of sensors associated with different logic divisions. Turbine exhaust diaphragm pressure monitoring is provided by two pairs of sensors, each pair associated with different logic divisions.

Diversity of leak detection is provided by monitoring equipment area and pipe chase area ambient and differential temperature monitoring, steam flow rate monitoring, steam line pressure monitoring, and turbine exhaust diaphragm pressure monitoring.

7.6.1.3.3.3.9 RCIC-LDS System Testability

Testability is discussed in Sections 7.3.1.1.2.11.

7.6.1.3.3.3.10 RCIC-LDS Environmental Considerations

This system is designed and has been qualified to meet the environmental conditions indicated in Section 3.11. In addition, this system is seismically qualified as described in Section 3.10.

7.6.1.3.3.4 Reactor Water Cleanup Leak Detection System - Instrumentation and Controls

7.6.1.3.3.4.1 RWCU-LDS Identification

The purpose of this part of the leak detection system is to monitor the RWCU system components and isolate the system should a leak of sufficient magnitude occur.

The RWCU-LDS consists of the following two subsystems:

a. RWCU system high differential flow (Leakage monitoring by the flow comparison of RWCU system water inlet and outlet flow rate)

b. RWCU system area high temperature and differential temperature

The RWCU-LDS uses no manual bypass switch. Annunciation of RWCU isolation system out-of-service is by manual switches. The logic used results in isolation if the flow sensor or if any of the temperature sensors trip. Testing can cause isolation of the RWCU system. This does not present a problem because isolation of the RWCU system does not prevent any safety function.

7.6.1.3.3.4.2 RWCU System High Differential Flow Monitoring Subsystem

7.6.1.3.3.4.2.1 Circuit Description

The RWCU system inlet flow is compared to RWCU outlet flow. A flow element, flow transmitter, and square root converter for each of these three lines provide signals to a common flow summer

that trips two differential flow alarm units on a high differential flow condition. Each flow alarm unit starts a timer that, after a time delay to avoid spurious trips, activates an alarm and isolation. Flow and differential flow indications are provided in the control room.

7.6.1.3.3.4.2.2 Logic and Sequencing

Using one-out-of-two logic, the RWCU flow comparison monitoring circuit initiates an RWCU system isolation signal after a time delay from the time the flow rate difference exceeds a preset limit.

7.6.1.3.3.4.2.3 Bypasses and Interlocks

Each time a high differential flow condition exists, the alarm unit initiates a 45 second time delay to delay the alarm and isolation signal during the normal operation system surge, i.e., pump startup, valving changes, etc; if the high differential flow condition still exists upon timer expiration, then alarm and isolation are initiated. The RWCU system high differential flow monitoring subsystem has no bypass capabilities.

7.6.1.3.3.4.2.4 Redundancy and Diversity

RWCU system isolation redundancy is accomplished by independent actuation of the inboard and outboard isolation valves from their respective logic channels. Actuation signals to the inboard and outboard isolation valves are derived from two separate logic channels using individual trip units.

Diversity is accomplished through isolation by the following monitored variables: high differential flow, and ambient and differential temperature.

7.6.1.3.3.4.3 RWCU Area High Temperature and Differential Temperature Monitoring Subsystem

7.6.1.3.3.4.3.1 Identification

High temperature in the equipment room areas of the RWCU system could indicate a breach of the RCPB portion of the RWCU system. High ambient temperature and high differential temperature in the equipment area ventilation system initiates isolation of the RWCU system.

Refer to Section 7.3.1.1.2 for a description of isolation function of this system.

7.6.1.3.3.4.3.2 Power Supplies

Trip logic channels for the inboard and outboard valves are supplied from RPS 120 V ac bus A and B, respectively.

7.6.1.3.3.4.3.3 Initiating Circuits

Twelve ambient temperature and 12 differential temperature sensing circuits monitor the RWCU system area temperatures. Six ambient and 6 differential temperature circuits are associated with each of two instrumentation channels. Six ambient temperature elements are located in the pump-room and the heat exchanger room. Six pairs of temperature elements are located in the ventilation supply and exhaust areas of the above locations. The locations of the temperature elements provide the earliest practicable detection of any RWCU system high temperature leak.

7.6.1.3.3.4.3.4 Logic and Sequencing

When a significant increase in RWCU system area ambient or differential temperature is detected, trip signals are transmitted to the PCRVICS. The PCRVICS initiates closure of all RWCU system isolation valves.

Two independent instrumentation trip channels are provided to ensure protective action when required. The output trip signal of each instrumentation channel initiates a logic channel and closure of either the inboard or outboard RWCU system isolation valve. In order to close both the inboard and outboard isolation valves, both logic channels must trip. Protection against inadvertent isolation due to instrumentation malfunction is neither required nor provided.

7.6.1.3.3.4.3.5 Redundancy and Diversity

Redundancy of trip initiation signals for high ambient temperature is provided by two ambient temperature elements and associated temperature indicating switches installed in each RWCU system area, with each associated with a different logic channel.

Redundancy of trip initiation signals for high differential temperature is provided by two pairs of differential temperature elements and associated temperature indicating switches in each RWCU system area. Each pair of temperature elements and its temperature indicating switch are associated with one of two logic channels.

Diversity is discussed in Section 7.6.1.3.3.4.2.4.

7.6.1.3.3.4.3.6 Bypasses and Interlocks

RWCU system high ambient and differential temperature trips have no automatic bypasses.

There are no interlocks to other systems from the RWCU system ambient and differential temperature trip signals.

Each RWCU-LDS temperature monitor point has bypass capabilities, but this function is not used.

7.6.1.3.3.4.3.7 Testability

Testability is discussed in Section 7.3.1.1.2.11.

7.6.1.3.3.4.3.8 Environmental Considerations

This subsystem is designed and qualified to meet the environmental conditions indicated in Section 3.11. In addition, this subsystem is seismically qualified as described in Section 3.10.

7.6.1.3.3.5 HPCI System Leak Detection System - Instrumentation and Controls

7.6.1.3.3.5.1 HPCI-LDS Identification

The steam line of the HPCI system is constantly monitored for leaks and breaks by the following types of monitoring circuits:

a. Equipment area and pipe chase area ambient and differential temperature monitoring (leaks)

b. HPCI steam flow rate monitoring (pipe break)

c. HPCI steam line pressure monitoring (pipe break)

d. HPCI turbine exhaust diaphragm pressure monitoring (pipe break)

Setpoints are predetermined which indicate a possible leak. If a setpoint is attained, an HPCI autoisolation signal is initiated and an annunciator is activated in the control room.

7.6.1.3.3.5.2 HPCI-LDS Power Sources

Refer to Section 7.6.1.3.2.

7.6.1.3.3.5.3 HPCI Equipment Area and Pipe Chase Area Temperature Monitoring Subsystem - Instrumentation and Controls

7.6.1.3.3.5.3.1 Circuit Description

HPCI area monitored temperatures include the following:

a. HPCI pipe chase area ambient temperatures

b. HPCI compartment ambient temperature

c. HPCI area ventilation air differential temperature

7.6.1.3.3.5.3.2 Initiating Circuits

Eight ambient temperature elements are installed in the HPCI pipe chase areas. Four sensors are associated with each autoisolation logic division. Seven temperature elements are installed in the HPCI equipment compartment. Four of these elements form two differential temperature pairs which monitor high ventilation air differential temperature. One pair is associated with one logic division and the other pair is associated with the other logic division. The other three temperature elements monitor the HPCI pump compartment ambient temperature. One ambient temperature element is associated with one logic division and the other two ambient temperature elements are associated with the other logic division.

7.6.1.3.3.5.3.3 Logic and Sequencing

When any one monitored temperature reaches its setpoint, an HPCI autoisolation signal is initiated and an annunciator activated in the control room.

Closure of the outboard HPCI steam supply isolation valve and the steam line warm-up isolation valve is controlled by one logic division and the inboard steam supply isolation valve by the other logic division.

Two instrumentation channels are provided to assure protective action when required.

In order to close both the inboard and outboard isolation valves, both logic divisions must trip. Protection against inadvertent isolation due to instrumentation malfunction is not required or provided.

HPCI-LDS is also described in Section 7.6.1.3.3.3.3.3.

7.6.1.3.3.5.4 HPCI Steam Flow Rate Monitoring Subsystem - Instrumentation and Controls

7.6.1.3.3.5.4.1 Circuit Description

The HPCI steam line connecting the nuclear boiler and the HPCI turbine is monitored by differential pressure sensors which signal a high steam flow rate condition.

7.6.1.3.3.5.4.2 Initiating Circuits

Two differential pressure sensors are installed on separate taps of a venturi flow element inside the primary containment. Steam flow rate in excess of a predetermined setpoint indicates a possible steam line leak and initiates a sensor trip signal.

Spurious system isolations are precluded by a time delay that prevents short-term flow peaks from initiating system isolation. At the end of the timing period, system isolation will occur only if the initiating signal remains above the trip setpoint. Time delay will reset each time signal drops below setpoint.

7.6.1.3.3.5.4.3 Logic and Sequencing

The autoisolation logic utilizes one-out-of-two logic to isolate the HPCI steam line. Closure of the outboard HPCI steam supply isolation valve and steam line warm-up isolation valve are controlled by one logic division and the inboard steam supply isolation valve is controlled by a different logic division. Each logic division requires a two-out-of-two pressure signal to isolate the valves.

7.6.1.3.3.5.5 HPCI Steam Line Pressure Monitoring Subsystem - Instrumentation and Controls

7.6.1.3.3.5.5.1 Circuit Description

The HPCI steam line connecting the nuclear boiler and the HPCI turbine is monitored by four pressure sensors which signal a low steam supply pressure condition.

7.6.1.3.3.5.5.2 Initiating Circuits

Four pressure sensors are installed on the steam pipe. Steam pressure below a predetermined setpoint indicates a possible line break and initiates a sensor trip signal.

7.6.1.3.3.5.5.3 Logic and Sequencing

The autoisolation logic utilizes two-out-of-two logic in each logic division. Closure of the outboard HPCI steam supply isolation valve and steam line warm-up isolation valve is controlled by one logic division and the inboard steam supply isolation valve by the other logic division.

7.6.1.3.3.5.6 HPCI Turbine Exhaust Diaphragm Pressure Monitoring Subsystem - Instrumentation and Control

7.6.1.3.3.5.6.1 Circuit Description

The HPCI turbine exhaust diaphragm is monitored by pressure sensors which signal a high pressure condition.

7.6.1.3.3.5.6.2 Initiating Circuits

Four pressure sensors monitor the HPCI turbine exhaust diaphragm. If monitored pressure exceeds a predetermined setpoint, indicating a possible diaphragm rupture, a sensor trip signal occurs.

7.6.1.3.3.5.6.3 Logic and Sequencing

The autoisolation logic utilizes two-out-of-two logic in each logic division. Closure of the outboard HPCI steam supply isolation valve and steam line warm-up isolation valve are controlled by one logic division and the inboard steam supply isolation valve is controlled by the other logic division.

7.6.1.3.3.5.7 HPCI-LDS Bypasses and Interlocks

Each HPCI-LDS temperature monitor point has bypass capabilities, but this function is not used. The trip signals from the leak detection area temperature monitors can be bypassed by a manual bypass switch. This switch permits testing of the temperature monitors without initiating system isolation. Bypassing the temperature trip signals in one division will not prevent proper operation of the other division. No other bypasses or interlocks are provided.

7.6.1.3.3.5.8 HPCI-LDS Redundancy and Diversity

Redundancy of trip initiation for high ambient temperature is provided by 8 ambient temperature elements installed in the HPCI pipe chase areas. Four temperature sensors are associated with each logic division.

Redundancy of trip initiation signals for ventilation air high differential temperature and HPCI area high ambient temperature is provided by seven temperature elements. Four of these elements form two differential temperature pairs which monitor high ventilation air differential temperature. One pair is associated with one logic division and the other pair is associated with the other logic division. The other three temperature elements monitor the HPCI pump compartment ambient temperature. One ambient temperature element is associated with one logic division and the other two ambient temperature elements are associated with the other logic division.

Redundancy of steam flow monitoring is provided by two differential pressure sensors, each associated with different logic divisions. Redundancy of HPCI steam supply low pressure monitoring is provided by two pairs of sensors in the HPCI steam supply line, each pair of sensors associated with different logic divisions. Redundancy of turbine exhaust diaphragm pressure monitoring is provided by two pairs of sensors, each pair associated with different logic divisions.

Diversity of leak detection is provided by monitoring equipment area and pipe chase area ambient and differential temperature monitoring, steam flow rate monitoring, steam line pressure monitoring, and turbine exhaust diaphragm pressure monitoring.

7.6.1.3.3.5.9 HPCI-LDS Testability

Testability is discussed in Sections 7.3.1.1.2.11.

7.6.1.3.3.5.10 HPCI-LDS Environmental Considerations

This system is designed and has been qualified to meet the environmental conditions indicated in Section 3.11. In addition, this system is seismically qualified as described in Section 3.10.

7.6.1.4 Neutron Monitoring System - Instrumentation and Controls

The NMS consists of the following safety- related systems:

a. IRM system

b. LPRM system

c. APRM system

The nonsafety-related portion is described in Section 7.7.1.6.

The NMS FCD is shown in Figure 7.6-4, and the ranges of the systems are shown in Figure 7.6-8.

7.6.1.4.1 NMS Identification

The purpose of this system is to monitor power generation in the core and provide signals to the RPS, the RRCS, and the rod block portion of the RMCS. It also provides information for operation and control of the reactor.

The IRM and APRM systems provide a safety function and are designed to meet particular requirements established by the NRC. The LPRM system is designed to provide a sufficient number of LPRM inputs to the APRM system to meet the APRM requirements. All other portions of the NMS have no safety function. The system is classified as shown in Table 3.2-1. The safety-related systems are seismically and environmentally qualified as described in Sections 3.10 and 3.11 (Section 7.2.1).

7.6.1.4.2 NMS Power Sources

The power sources for each system are discussed in the individual circuit descriptions that follow.

7.6.1.4.3 Intermediate Range Monitor System

7.6.1.4.3.1 IRM Equipment Design

7.6.1.4.3.1.1 IRM Circuit Description

The IRM monitors neutron flux from the upper portion of the SRM range to the lower portion of the APRM range. The IRM system has eight IRM channels, each of which includes one detector that can be positioned in the core by remote control. The detectors are inserted into the core for a reactor startup and are withdrawn after the reactor mode selector switch is turned to RUN.

a. Power supply

Power is supplied separately from the two 120 V ac RPS sources. The channels are arranged so that loss of a power supply results in the loss of only one trip system of the RPS.

b. Physical arrangement

Each detector assembly consists of a miniature fission chamber attached to a low loss, quartz/fiber insulated transmission cable. When coupled to the signal conditioning equipment, the detector produces a reading of full-scale on the most sensitive range with a neutron flux of $4x10^8$ nv. The detector cable is connected underneath the reactor vessel to a triple-shielded cable that carries the pulses generated in the fission chamber to the preamplifier.

The detector and cable are located in the drywell. They are movable in the same manner as the SRM detectors and use the same type of mechanical arrangement (Figures 7.6-2 and 7.6-3).

c. Signal conditioning

A voltage amplifier unit located outside the drywell serves as a preamplifier. This unit converts the current pulses to voltage pulses, modifies the voltage signal, and provides impedance matching. The preamplifier output signal is coupled by a cable to the IRM signal conditioning electronics (Figure 7.6-5).

Each IRM channel receives its input signal from the preamplifier and operates on it with various combinations of preamplification gain and amplifier attenuation ratios. The amplification and attenuation ratios of the IRM and preamplifier are selected by a remote range switch that provides 10 ranges of increasing attenuation (the first six called low range and the last four called high range) acting on the signal from the fission chamber. As the neutron flux of the reactor core increases from $1x10^8$ nv to $1.5x10^{13}$ nv, the signal from the fission chamber is attenuated to keep the input signal to the inverter in the same range. The output signal, which is proportional to neutron flux at the detector, is amplified and supplied to a locally mounted meter. Outputs are also provided for a remote meter and recorder.

d. Trip functions

The IRM scram trip functions are discussed in Section 7.2. The IRM trips are shown in Table 7.6-2. The IRM rod block trip functions are discussed in Section 7.7.

7.6.1.4.3.1.1.1 IRM Bypasses and Interlocks

The arrangement of IRM channels allows one IRM channel in each group of four channels (A, C, E, and G, and B, D, F, and H) to be bypassed without compromising intermediate range neutron monitoring.

7.6.1.4.3.1.1.2 IRM Redundancy

The IRM system consists of eight IRM channels, four of which are connected to one RPS trip system and the other four are connected to the other RPS trip system. The redundancy and single failure requirements are met because any single failure with the IRM system cannot prevent needed safety action of the RPS (Section 7.2.1.1.4.1).

7.6.1.4.3.1.1.3 IRM Testability

Each IRM channel is tested and calibrated using written procedures. The IRM detector drive mechanisms and the IRM rod blocking functions are checked in the same manner as the SRM channels. Each IRM channel can be checked to ensure that the IRM high flux scram function is operable.

7.6.1.4.3.1.2 IRM Environmental Considerations

The wiring, cables, and connectors located in the drywell are designed for the same environmental conditions as the SRMs.

The IRM preamplifier, located in the reactor enclosure, and the monitor, located in the control room, are designed to operate under all expected environmental conditions in those areas. These IRM system components are designed to operate during and after design basis events, including earthquakes, and anticipated operational occurrences (Sections 3.10 and 3.11).

7.6.1.4.3.1.3 IRM Operational Considerations

The IRM range switches are upranged or downranged to follow increases and decreases in power within the range of the IRM to prevent either a scram or a rod block. The IRM detectors are inserted into the core whenever these channels are needed, and withdrawn from the core, when permitted, to prevent their burnup. The identification scheme for the IRM system is given in Section 7.2.

7.6.1.4.4 Local Power Range Monitor System

7.6.1.4.4.1 LPRM Equipment Design

7.6.1.4.4.1.1 LPRM Circuit Description

The LPRM consists of fission chamber detectors, signal conditioning equipment, and trip circuits. The LPRM provides outputs to the APRM, the RBM, and the process computer. The LPRM signal processing is performed by the same electronic equipment that performs the APRM functions.

a. Power supply

   Power for the LPRM, associated APRM channel, and channelized RBMs is provided by two independent 120 V ac buses, each of which is supplied by a UPS. Detector polarizing voltage for the LPRMs is supplied by eight pairs of redundant

LPRM detector DC power supplies, adjustable from 75 to 200 VDC. Each LPRM detector DC power supply pair powers approximately one-eighth of the LPRMs. Power for the LPRM detector DC power supplies comes redundantly from the two 120 Vac buses via intervening DC power supplies.

The LPRM detector DC power supplies are located in the electronic chassis that houses the LPRM signal processing equipment. Each electronic chassis houses one pair of LPRM detector DC power supplies and the electronics for processing approximately one-eight of the total LPRM detector signals (or approximately one-half of the 43 detectors per APRM/LPRM channel).

The intervening DC supplies are located in a separate power supply chassis. Each power supply chassis contains up to 4 Low Voltage DC Power Supplies (LVPSs). One of the 120 Vac busses provides input power to 2 of the LVPSs in the power supply chassis while the second 120 Vac bus provides input power to the other two LVPSs in the power supply chassis. Two of the LVPSs in the power supply chassis, one operating from each of the two 120 Vac busses, supply “auctioned” low voltage power to the electronic chassis. If either of the two 120 Vac power busses is lost, or if either of the two LVPSs fail, the remaining LVPS will continue to supply low voltage power to the electronic chassis.

The auctioned low voltage power input to the electronic chassis provides power to each of the pair of LPRM detector DC power supplies in the electronic chassis, and the LPRM (and APRM) signal processing hardware in the chassis. The LPRM detector polarizing voltage for all of the detectors processed by the electronic chassis (21 in one chassis and 22 in the other) is normally provided by one of the two LPRM detector DC power supplies in the electronic chassis. If that one DC power supply fails, the second LPRM detector DC power supply is automatically switched in to supply LPRM detector polarizing voltage.

The 75 - 200 Vdc LPRM detector DC power supplies can supply up to 3 milliamperes for each LPRM detector which ensures that the chambers can be operated in the saturated region at the maximum specified neutron fluxes. The voltage applied to the detectors varies no more than 2 Vdc over the maximum variation of electrical input and environmental parameters.

b. Physical arrangement

The LPRM includes 43 LPRM detector assemblies having detectors located at different axial heights in the core. Each detector assembly contains 4 fission chambers. These assemblies are distributed to monitor four horizontal planes throughout the core. Figure 7.6-6 shows the LPRM detector radial layout scheme that provides a detector assembly at every fourth intersection not containing control crosses of the water channels around the fuel bundles. Thus, the uncontrolled water gap has either an actual detector assembly or a symmetrically equivalent assembly in some other quadrant. The LPRM assembly consists of 4 neutron detectors permanently installed in a housing (Figure 7.6-6). The assemblies are installed and removed through the top of the vessel (when the head is removed). The upper end of the assembly is held to the top of the fuel guide by a spring-loaded plunger. A permanently installed sleeve (incore guide tube and incore housing) locates and constrains the assembly below the lower core plate and provides a sealing surface under the reactor vessel. Special sealing caps are

placed over the connection end of the assembly and over the penetration at the bottom of the vessel during installation or removal of an assembly. This prevents loss of reactor coolant water on removal of an assembly and also prevents the connection end of the assembly from being immersed in the water during installation or removal.

Each LPRM detector assembly contains 4 miniature ion chambers with an associated solid sheath cable. The chambers are vertically spaced in the LPRM detector assemblies in a way that gives adequate axial coverage of the core, complementing the radial coverage given by the horizontal arrangement of the LPRM detector assemblies. Each ion chamber produces a current that is coupled with the LPRM signal conditioning equipment to provide the desired scale indications.

Each miniature chamber consists of 2 concentric cylinders that act as electrodes. The inner cylinder (the collector) is mounted on insulators and is separated from the outer cylinder by a small gap. The gas between the electrodes is ionized by the charged particles produced as a result of neutron fissioning of the uranium-coated outer electrode. The chamber is operated at a polarizing potential of approximately 100 V dc. The negative ions produced in the gas are accelerated to the collector by the potential difference maintained between the electrodes. In a given neutron flux, all the ions produced in the ion chamber can be collected if the polarizing voltage is high enough. When this situation exists, the ion chamber is considered to be saturated. Output current is then independent of operating voltage.

Each assembly also contains a calibration tube for a TIP. The enclosing tube around the entire assembly contains holes that allow circulation of the reactor coolant water to cool the ion chambers. Numerous tests have been performed on the chamber assemblies, including tests of linearity, lifetime, gamma sensitivity, and cable effects. These tests and experience in operating reactors provide confidence in the ability of the LPRM system to monitor neutron flux to the design accuracy throughout the design lifetime.

c. Signal conditioning

The current signal from the LPRM detectors are transmitted to LPRM amplifiers located on LPRM Input Modules in the APRM/LPRM electronic chassis in the Auxiliary Equipment Room. Each LPRM Input Module provides amplification for up to 5 LPRM detector signals. The current signal from a chamber is transmitted directly to its amplifier through coaxial cable. The amplifier is a linear current amplifier whose voltage output is proportional to the current input and therefore proportional to the magnitude of the neutron flux. The amplifier output is “read” by the digital processing electronics. The digital electronics applies hardware gain corrections, performs filtering, and applies the LPRM gain factors. The digital electronics provide suitable output signals for the computer, recorders, annunciators, etc. The LPRM amplifiers also isolate the detector signals from the rest of the processing so that individual faults in one LPRM signal path will not affect other LPRM signals.

The LPRM signals can be read by the operator on the reactor console on either the APRM ODAs or the RBM ODAs. LPRM readings can be read on the APRM ODAs

by selecting summary LPRM displays. When a control rod is selected for movement, LPRM readings can be read on the RBM ODAs for the 16 LPRM detectors nearest to the selected rod (see Figure 7.7-14).

d. Trip functions

The trip functions for the LPRM provide trip signals to activate annunciators and displays on ODAs. Table 7.6-3 indicates the trips.

The trip levels can be adjusted to within ±0.1% of full-scale deflection and are accurate to ±1% of full- scale deflection in the normal operating environment.

7.6.1.4.4.1.1.1 LPRM Bypasses and Interlocks

Each LPRM channel may be individually bypassed. When the maximum number of bypassed LPRMs associated with any APRM channel has been exceeded, an APRM trouble alarm is generated by that APRM.

7.6.1.4.4.1.1.2 LPRM Redundancy

The LPRMs are divided into four groups for separation purposes. The LPRMs are separated so that in the event of a single failure under permissible APRM bypass conditions, a scram signal can be generated in the RPS when required.

7.6.1.4.4.1.1.3 LPRM Testability

LPRM channels are calibrated using data from previous full power runs and TIP data and can be tested with written procedures. The update uncertainty assigned to the LPRMs is twice the update uncertainty value specified in GE topical licensing report NEDC-32694P-A, "Power Distribution Uncertainties for Safety Limit MCPR Minimum Critical Ratio Evaluations, dated August 1999.

7.6.1.4.4.1.2 LPRM Environmental Considerations

Each individual chamber of the assembly is a moisture-proof, pressure-sealed unit. The chambers are designed to operate up to 600°F and 1250 psig. The wiring, cables, and connectors located within the drywell are designed for continuous-duty up to 150°F at 90% relative humidity and a single exposure to a peak temperature of 340°F at 100% relative humidity. The LPRMs are capable of functioning during and after design basis events such as earthquakes and anticipated operational occurrences (Sections 3.10 and 3.11).

7.6.1.4.4.1.3 LPRM Operational Considerations

The LPRM is a monitoring system with no special operating considerations.

7.6.1.4.5 Average Power Range Monitor System

(References 7.6-1 through 7.6-4 and Reference 7.6-6.)

7.6.1.4.5.1 APRM Equipment Design

7.6.1.4.5.1.1 APRM Circuit Description

The APRM System has four APRM channels. Each APRM uses input signals from 43 LPRM detectors. Each of the four APRM channels provides input to four 2-out-of-4 voter channels. Two of the voter channels are associated with each of the trip systems of the Reactor Protection System.

a. Power supply

Power for the LPRM, associated APRM channel, and channelized RBMs is provided by two independent 120 Vac buses, each of which is supplied by a UPS. Each APRM 2-out-of-4 voter channel receives power from one of the two 120 Vac busses with each bus supplying power to two of the voter channels. The APRM, LPRM and RBM functions will continue to operate as long as either of the two 120 Vac busses is still available. However, if one of the two 120 Vac busses is lost, the two Voter Channels supplied by that bus will go to the tripped state resulting in a RPS half scram.

b. Signal conditioning

The APRM channel uses digital electronic equipment which averages the output signals from a selected set of LPRMs, generates trip outputs via the 2-out-of-4 voter channels (see Section 7.6.1.4.5.1.1.c), and provides signals to readout equipment.

Each APRM channel can average the output signals from up to 43 LPRM channels. Assignment of LPRM channels to an APRM is shown in Table 1A and 1B on Figure 7.6-1 (Sheets 2 and 4) with the distribution through the core shown in Figure 7.2-9. The letters at the detector locations in Figure 7.6-1 refer to the axial positions of the detectors in the LPRM detector assembly. Position A is the bottom position, positions B and C are above position A, and position D is the top most LPRM detector position. The pattern provides LPRM signals from all four core axial LPRM detector positions throughout the core. Some LPRM detectors may be bypassed, but the averaging logic automatically corrects for these by removing them from the average.

The APRM flux value is developed by averaging the LPRM signals and then adjusting the average by a digitally entered factor to allow calibration of the APRM to be APRM power. The APRM power is processed through a first order filter with a six second time constant to calculate simulated thermal power. The APRM simulated thermal power upscale rod block and scram trip setpoints are varied as a function of reactor recirculation flow. The slope of the upscale rod block and scram trip response curves is set to track the required trip setpoint with recirculation flow changes. These calculations are all performed by the digital processor and result in a digital representation of APRM and simulated thermal power, and of the flow-biased rod block and scram setpoints.

Each APRM channel calculates a flow signal which is used to determine the APRM's flow-biased rod block and scram setpoints (see Figure 7.6-1). Each signal is determined by summing the flow signals from the two recirculation loops. These signals are sensed from two flow elements, one in each recirculation loop. The differential pressure from each flow element is routed to four differential pressure

transducers (eight total). The signals from two differential pressure transducers, one from each flow element, are routed to two inputs to each APRM digital electronics.

Each APRM also includes an OPRM Upscale Function. For this function, LPRMs are assigned to up to four OPRM cells with each cell including 4 LPRMs (see Figure 7.2-17). The OPRM function combines the signals from each LPRM in an OPRM cell and evaluates that combined cell signal using the OPRM algorithms to detect thermal-hydraulic instabilities.

All APRM channels are powered redundantly, via intervening low voltage DC power supplies, from both of the two APRM 120 Vac UPS power busses. The LPRM signal processing equipment is powered by the same sources as their associated APRM channels.

c. Trip function

The APRM trip functions are performed by digital comparisons with APRM electronics. For each RPS trip and rod block alarm, the APRM power of simulated thermal power, as applicable, is compared to the setpoint. If the power value exceeds the setpoint, the applicable trip is issued. Trip signals from each APRM channel are provided, via APRM interface hardware directly to the Reactor Manual Control System and via the APRM 2-out-of-4 voter channels to the Reactor Protection System (RPS). Table 7.6-4 lists the APRM trip functions and trip settings.

An OPRM upscale trip output is generated from an APRM channel when the period based detection algorithm in that channel detects oscillatory changes in the neutron flux indicated by the combined signals for the LPRM detectors in a cell with the period confirmations and relative cell amplitude exceeding specific setpoints. One or more cells in a channel exceeding the trip conditions will result in a channel trip. An OPRM upscale trip is also issued from any APRM channel if either the growth rate or amplitude based algorithms detect growing oscillatory changes in the neutron flux from one or more cells in that channel. The OPRM upscale trip output is automatically enabled (not-bypassed) when the combined APRM STP is equal to or above the OPRM auto-enable power setpoint and recirculation flow is below the OPRM auto-enable flow setpoint. The OPRM upscale trip output is automatically bypassed when STP and/or recirculation flow are not within the OPRM trip enabled region. The OPRM upscale trip is active only when the reactor mode switch is in the RUN position.

At least two unbypassed APRM channels must be in the APRM upscale trip or inoperative trip state to cause an APRM/Inop RPS trip output from the APRM 2-out-of-4 voter channels (see Figure 7.6-7). Similarly, at least two unbypassed APRM channels must be in the OPRM upscale trip state to cause an OPRM RPS trip output from the APRM 2-out-of-4 voter channels. The APRM/Inop and OPRM trips are voted independently. In either of these conditions, all four voter channels will provide a RPS trip output, two to each RPS trip system. If only one unbypassed APRM channel is providing a trip output, each of the four APRM 2-out-of-4 voter channels will have a half-trip, but no trip signals will be sent to the RPS. Trip

outputs to the RPS are transmitted by removing voltage to a relay coil, so loss of power results in actuating the RPS trips. A simplified APRM/RPS interface circuit arrangement is shown in Figure 7.2-6.

Any one unbypassed APRM can initiate a rod block. Subsection 7.7, "Reactor Manual Control System," describes in more detail the APRM rod block functions.

In the startup mode of operation, the APRM "fixed" upscale trip setpoint is set down to a low level. This trip function is provided in addition to the existing IRM upscale trip in the startup mode.

The trips from one APRM can be bypassed by operator action in the control room, which bypasses both the APRM/Inop and OPRM trips from that APRM channel.

d. RRCS interface

APRM signal levels are sent to the RRCS to enable the initiation of the logic if additional reactivity control is necessary following an ATWS event. The use of this signal is discussed in Section 7.6.1.8.

7.6.1.4.5.1.1.1 APRM Bypasses and Interlocks

One of the four APRM channels can be bypassed at any time. None of the APRM 2-out-of-4 voter channels can be bypassed. An interlock circuit provides an APRM trouble alarm whenever the number of LPRM inputs to an APRM is less than the required minimum.

7.6.1.4.5.1.1.2 APRM Redundancy

Four independent channels of APRMs monitor neutron flux and each channel provides inputs to all four independent APRM 2-out-of-4 voter channels. A trip condition in any one APRM channel does not cause the APRM 2-out-of-4 voters to initiate a trip in any RPS trip system. The APRM 2-out-of-4 voter must recieve a trip signal from at least two unbypassed APRM channels in order to initiate a trip in any RPS trip system.

7.6.1.4.5.1.1.3 APRM Testability

APRM channels are calibrated using data from previous full power runs and are tested by written procedures. Each APRM channel can be tested individually for the operability of the APRM scram and rod blocking functions by introducing test signals.

7.6.1.4.5.2 APRM Environmental Considerations

All APRM equipment is installed in the control structure and operated in the environment as described in Section 3.11. The APRM system is capable of functioning during and after the design basis events, including earthquakes and anticipated operational occurrences (Sections 3.10 and 3.11).

7.6.1.4.5.3 APRM Operational Considerations

The APRM system is a monitoring system that has no special operational considerations.

7.6.1.5 Safety/Relief Valve Positions Indication System - Instrumentation and Controls

7.6.1.5.1 SRVPI System Identification

A positive and reliable OPEN/NOT OPEN indication of the SRVs alerts the operator to abnormal valve position which could cause release of reactor coolant.

The SRVPI system provides an indication and alarm of SRV position through the use of acoustic sensors. Accelerometers, two per valve, are mounted on piping downstream of the SRV. When an SRV is actuated, the accelerometer produces a signal proportional to the flow noise through the valve. This signal is then amplified and transmitted to a signal conditioning unit.

Each SRV is instrumented with two channels (active and passive) of in-containment equipment, consisting of accelerometers and connecting cables. The signals from both channels are routed to the SRVPI preamplifier where the active signal is amplified and routed to the SRVPI cabinet in the control room and used for alarm and indication, while the passive signal is available if needed.

7.6.1.5.2 SRVPI Power Supplies

The SRVPI system is powered from a 120 V ac UPS.

7.6.1.5.3 SRVPI Initiating Circuits

The SRVPI system senses steam flow through the valve and indicates OPEN/NOT OPEN status of the SRVs. It does not interface with, or provide actuation for any other system.

7.6.1.5.4 SRVPI Logic and Sequencing

Logic and sequencing do not apply to the SRVPI system.

7.6.1.5.5 SRVPI Bypasses and Interlocks

There are no bypasses or interlocks associated with this system.

7.6.1.5.6 SRVPI Redundancy and Diversity

Each SRV is provided with an active and a passive instrumentation channel. Each channel consists of an accelerometer and associated cables. The active and passive channel signals are routed to the preamplifier. The active channel signal is amplified, routed to the SRVPI cabinet in the control room and used for alarm and indication.

The passive channel signal is available for use at the preamplifier outside containment if a component of the active channel should fail. The SRV temperature monitoring system (Section 7.7.1.16.7) provides a backup for the SRVPI system. It senses valve opening through a diverse means. Another diverse means of valve position indication is provided by the redundant safety-grade suppression pool temperature monitoring system, powered from a Class 1E power source.

7.6.1.5.7 SRVPI Testability

Proper operation of each SRVPI channel can be checked during plant operations.

7.6.1.5.8 SRVPI Environmental Considerations

The SRVPI system is designed to operate under both environmental and seismic conditions as outlined in Sections 3.11 and 3.2.

7.6.1.5.9 SRVPI Operational Considerations

7.6.1.5.9.1 General Information

The SRVPI system uses acoustic sensors (accelerometers) to monitor steam flow through the SRV. When the signal generated from the sensor reaches a predetermined level, alarms in the control will actuate to alert the operator of an open SRV.

7.6.1.5.9.2 SRVPI Reactor Operator Information

The OPEN/NOT OPEN/WAS OPENED status of each SRV is provided for the operator in the control room, as well as a common annunciator indicating an open SRV.

7.6.1.5.9.3 SRVPI Setpoints

The setpoints for SRVPI are determined individually for each SRV using information obtained during system installation and initial plant testing. Cross-talk measurements are conducted to ensure that an alarming SRV will not cause another SRV to alarm.

7.6.1.6 Containment Instrument Gas System – Automatic Depressurization System Control - Instrumentation and Controls

7.6.1.6.1 CIGS-ADS Description

The CIGS-ADS consists of nitrogen bottles, pressure controls, and instrumentation and associated piping which tie into the two instrument gas supply headers to the ADS valves as shown in Section 9.3.1.3 and drawing M-59.

In the event that the nonsafety-related CIGS header is unable to supply gas to its ADS valves for use during long-term shutdown cooling or vessel venting, the gas supply for that header is automatically switched to its CIGS-ADS gas bottles. The CIGS-ADS gas bottles must be connected at all times during normal operation. Each CIGS-ADS header supplies instrument gas to its respective ADS valves. One set of ADS valves and its gas supply will meet the requirements for the backup long-term shutdown cooling path.

7.6.1.6.2 CIGS-ADS Initiating Circuits

The CIGS-ADS is initiated by a pressure switch which senses low pressure in the respective ADS gas supply header. The system can also be initiated manually.

7.6.1.6.3 CIGS-ADS Logic

In the event that low pressure is sensed in an ADS gas supply header, a pressure switch causes a solenoid-operated valve in the supply line from the CIGS to close and a solenoid-operated valve in

the CIGS-ADS supply to that header to open. Those actions may be controlled manually from the control room.

7.6.1.6.4 CIGS-ADS Bypasses

There are no bypasses in the CIGS-ADS.

7.6.1.6.5 CIGS-ADS Interlocks

The CIGS-ADS is interlocked with the nonsafety-related CIGS so that only one system at a time will provide instrument gas to the ADS valves.

7.6.1.6.6 CIGS-ADS Redundancy and Diversity

Diversity is not required for the CIGS-ADS. The CIGS-ADS is redundant in that each header is supplied by its own gas supply and separate divisional safeguard power.

7.6.1.6.7 CIGS-ADS Actuated Devices

The solenoid-operated shutoff valves in the CIGS supply line and the solenoid-operated shutoff valves in the CIGS-ADS supply line are actuated by this system.

7.6.1.7 Safeguard Piping Fill System - Instrumentation and Controls

7.6.1.7.1 SPFS Description

The SPFS pumps take suction from the suppression pool by way of the core spray suction line and discharge into the ECCS pump discharge lines to maintain these lines in a full condition. In this capacity, they are a backup to the condensate transfer system, which is the primary water source for keeping the ECCS discharge lines full. The SPFS pumps also discharge into the feedwater lines to provide a water seal in the event of any line break other than a feedwater line break inside containment. The SPFS is a supporting system to the ECCS.

7.6.1.7.2 SPFS Initiating Circuits

The SPFS is manually operated.

7.6.1.7.3 SPFS Logic

The SPFS pumps are started and stopped manually from the main control room. The shutoff valves to the feedwater lines are manually operated from the main control room. Refer to drawing M-52FD for logic diagram.

7.6.1.7.4 SPFS Bypasses and Interlocks

There are no bypasses or interlocks in the SPFS.

7.6.1.7.5 SPFS Redundancy and Diversity

There are two pumps powered from separate Class 1E buses in different divisions. Distribution of fill water from each pump is in accordance with redundancy of the ECCS (i.e., the A SPFS pump delivers fill water to RCIC, RHR loops A & C, etc.).

Each pump can provide seal water to either or both of the feedwater lines. There is a shutoff valve to each feedwater line from each pump. The shutoff valves from each pump are in the same division as their associated pump.

No diversity is provided for this system.

7.6.1.7.6 SPFS Actuated Devices

There are no actuated devices in this system.

7.6.1.8 Redundant Reactivity Control System – Instrumentation and Controls

7.6.1.8.1 RRCS System Identification

The RRCS is designed to mitigate the potential consequences of an ATWS event. The system consists of control panels, their associated ATWS detection and actuation logic, and the necessary interface logic to the recirculation system, the feedwater system, the SLCS, and the ARI components of the CRD system required to perform specific functions in response to an ATWS event.

7.6.1.8.2 RRCS Power Sources

RRCS Division 1, channels A and B are powered by the 125 V dc Bus A (Division 1), and RRCS Division 2, channels A & B are powered from 125 V dc Bus B (Division 2). The power supplies to the RRCS functions are available during all potential ATWS initiating events, including those events involving loss of normal power supplies.

7.6.1.8.3 RRCS Equipment Design

The RRCS consists of vessel pressure and level sensors, solid-state logic, control room cabinets and indications, and interfaces with several systems actuated to mitigate an ATWS event (Figure 7.6-10). The solid-state logic is divided into Divisions 1 and 2, each of which is subdivided into channels A and B. The logic is energized to trip, and both channels A and B of either division must be tripped to initiate the RRCS protective actions. The system can be manually initiated by depressing two push buttons (tripping both channels A and B) in the same division. This manual initiation function is designed so that no single operator action can result in an inadvertent initiation. The push button collar must be rotated to arm the switch before depressing will trip the logic. The manual initiation push buttons are located in the control room near the RPS manual scram push buttons. There are four RRCS manual initiation push buttons.

The RRCS logic monitors reactor dome pressure and water level. The logic will cause the immediate energization of the ARI valves when either the reactor high pressure trip setpoint or low water level 2 setpoint is reached, or the manual push buttons are armed and depressed (Table 7.6-5). Energization of the RRCS ARI valves depressurizes the scram air header independent of the logic and vent valves of the RPS system (Figure 7.6-11). The valves are sized to allow insertion of all control rods to begin within 15 seconds. Additional immediate RRCS response to the initiation signals include recirculation system pump motor breaker trip immediately if reactor

high pressure is received or 9 seconds after a low water level 2 signal is received. The high pressure initiation signal will initiate a feedwater runback after 25 seconds whether the feed pumps are in automatic or manual if the APRM not downscale trip signal is present. If power is not downscale after a 118 second time delay from the beginning of the ATWS event, the RWCU system will be isolated and the SLCS will be automatically initiated. Ten minutes after the SLCS initiation, the RRCS can be reset, provided that RRCS actuation parameters have reset and the RRCS manual reset push buttons are depressed.

The RRCS is continually checked by a solid-state microprocessor based self-test system. This self-test system checks the RRCS sensors, logic, and protective devices and itself.

7.6.1.8.3.1 RRCS Alternate Rod Insertion

The RRCS signal to insert the control rods is generated in either of two separate divisions (two-out-of-two logic in a given division) and results in the energization of eight valves. Two of these, F160A and B, vent the scram air supply line downstream of the F110A and B backup scram valves (Figure 7.6-11). These RRCS valves also act to block the supply of air to the scram header. Check valves F161A and B provide an air flow path around the F160 valves in the event one or more of the valves fails. Four additional RRCS valves (F162A, B, C, and D) vent the A and B scram header to the atmosphere. As the header depressurizes, the scram valves at each HCU will spring open, scramming the rods. Two RRCS valves (F163A and B) vent the scram air header to the SDV drain and vent valves, closing these valves and isolating the SDV. All eight RRCS ARI valves are normally de-energized. Positive position of the ARI solenoid valves is shown by voltage and plant air indications.

The ARI signal can be reset after a 30 second time delay, provided that the high reactor pressure, low water level 2, and manual initiation signals no longer exist.

7.6.1.8.3.2 RRCS Recirculation System Trips

The ATWS RPT contributes to the mitigation of the consequences of an ATWS event by tripping the recirculation pumps early in the event, reducing core flow and thereby reducing the core power generation.

Low water level 2 or high reactor pressure RRCS signals cause a trip of the recirculation pump drive motor breakers 3A, 3B, 4A, and 4B. There are two separate divisions of instrumentation with divisional power sources, each one with two pressure sensors and two level sensors. A reactor vessel high dome pressure signal from either division will immediately trip both recirculation pump motors. A reactor vessel low water level signal from either division will trip both recirculation pump motors after a 10 second delay. This reduction in core flow protects the vessel and fuel during the ATWS event by limiting core power during the time required for the scram air header to depressurize sufficiently to open the scram valves.

Both sensors in either division (i.e., two level sensors in one division or two pressure sensors in one division) are required to generate a trip signal. The ATWS RPT pump breakers are the same ones used in the EOC RPT. There are two breakers in series in each pump motor feed; the control logic of each breaker is assigned to a separate safety division.

Manual initiation of RRCS without reactor high pressure or reactor low level 2 does not trip the recirculation pump drive motor breaker; however, after manual initiation of RRCS, the breaker trip will occur if either reactor high pressure or low level 2 occur.

The ATWS RPT trip circuitry is separate from and independent of the EOC RPT trip circuitry. Separate trip coils are used in each breaker (one for ATWS RPT and one for EOC RPT). The trip coils are fed from RPS power supplies.

The trip circuits, including the sensors and the pump breakers, are Class 1E. The entire trip circuits may be tested during plant operation, except for opening of the pump breakers. ATWS RPT circuitry is separated from non-Class 1E circuitry in accordance with the LGS separation criteria.

Indicators and annunciators in the control room provide the status of the trip coils and the mechanical position of the pump circuit breakers. Actuation of the ATWS-RPT is recorded in the control room.

7.6.1.8.3.3 RRCS Feedwater Runback

The feedwater runback function mitigates the consequences of an ATWS event by stopping feedwater flow into the vessel, which reduces the core subcooling, thereby reducing the core power generation.

Reactor high pressure combined with a 25 second time delay and APRM power not downscale will initiate a feedwater runback. Feedwater flow will be reduced to 0% within 15 seconds. The logic to initiate feedwater runback is energized to trip and can be manually overridden 30 seconds after runback initiation. The runback reduces the input of cooler water flowing to the vessel. As average core coolant temperature increases, voids increase, reactivity decreases, and power is reduced.

The RRCS feedwater runback will occur whether the feed pumps are in automatic or in manual mode of control. The normal loss of signal interlock that prohibits changes in feedwater pump output during loss of signal conditions is disabled during ATWS.

7.6.1.8.3.4 Standby Liquid Control System Initiation

Low water level 2, reactor high pressure, or manual initiation of the RRCS immediately starts a timer. A signal will be sent to initiate the SLCS if, at the expiration of a 118 second time delay, the core power is not downscale as measured by the APRM system. Initiation of the SLCS requires start signals from both channels A and B of either division of RRCS. Receipt of these signals starts the two in-service pumps and causes the associated squibs to fire, opening the explosive valves. Both pumps will inject borated water into the vessel until the storage tank low level sensors, arranged in two-out-of-two logic, trip the pumps.

The SLCS pump control switches can be used to manually stop SLCS pump injection.

7.6.1.8.3.5 RRCS Impact on Other Systems

7.6.1.8.3.5.1 Reactor Water Cleanup System Isolation

When the SLCS is initiated to inject the neutron absorber into the reactor, the inboard isolation valve of the RWCU system is automatically closed from the SLCS Division 1 or 3 logic and the outboard valve is closed from the SLCS Division 2 logic. This RWCU isolation prevents removal and dilution of the neutron absorber.

7.6.1.8.3.5.2 Nuclear Boiler Instrumentation

Nuclear boiler system instrumentation is provided to monitor the reactor parameters required for ATWS mitigation and to provide signals that are indicative of a potential ATWS event. The instrumentation is provided to monitor reactor vessel high dome pressure and low vessel water level. The sensors, transducers, and trip units are Class 1E, independent from the RPS, and environmentally qualified to perform their protective function during ATWS events.

7.6.1.8.3.5.3 Neutron Monitoring System

The APRMs through the APRM interface hardware, provide a not downscale trip signal to the RRCS permissive logic. This signal is Class 1E and contains all available channels of input. APRM signals from NMS Divisions 1 and 2 are routed to RRCS Division 1 through isolators, and APRM signals from NMS Divisions 3 and 4 are sent to RRCS Division 2 through isolators. Loss of power to an APRM channel or an APRM INOP condition will result in an RRCS permissive signal. Bypassing an APRM channel will prevent the bypassed APRMs not downscale or INOP trip from supplying a permissive. Only one APRM at a time can be bypassed.

7.6.1.8.3.6 RRCS Reset

Each RRCS channel can be manually reset by depressing the RRCS reset push buttons (four, one for each tripped channel), provided that a specified time delay has elapsed since RWCU isolation and SLCS initiation. When the RRCS is reset, the following seal-in signals are broken:

a. RWCU isolation

b. Low water level 2

c. Manual initiation

d. High reactor pressure

e. Feedwater runback signal

f. SLCS initiation

The RRCS ARI function is reset by the RRCS ARI reset push buttons. This second set of four push buttons (one for each channel) will enable the reset of the ARI logic 30 seconds after initiation of ARI, provided that initiating signals have cleared. This 30 second time delay before the ARI reset permissive appears is designed to ensure that the RRCS ARI scram goes to completion.

7.6.1.8.3.7 RRCS Bypass

There is no RRCS bypass or operating bypass.

7.6.1.8.3.8 Separation

The RRCS is a two-divisional system. Separation is maintained between the redundant divisions of the system to ensure compliance with the separation and single failure criteria. This separation is done to satisfy the single failure criterion. The two divisions of RRCS logic are designed so that either can cause ARI, recirculation pump motor trip, feedwater runback, RWCU isolation, and SLCS injection when a sufficient power reduction has not occurred. The RRCS meets IEEE 279 (1971) and Regulatory Guide 1.75 (Rev 1).

7.6.2 ANALYSIS

7.6.2.1 Process Radiation Monitoring Systems – Instrumentation and Controls

7.6.2.1.1 Main Steam Line Radiation Monitoring System

The analysis for this system is discussed in Section 11.5.4.

7.6.2.1.2 Reactor Enclosure Ventilation Exhaust Radiation Monitoring System

The analysis for this system is discussed in Section 7.3.2.2.2.3.1.

7.6.2.1.3 Refueling Area Ventilation Exhaust Radiation Monitoring System

The analysis for this system is discussed in Section 7.3.2.2.2.3.1.

7.6.2.1.4 Control Room Ventilation Radiation Monitoring System

7.6.2.1.4.1 CRV-RMS General Functional Requirements Conformance

The control room ventilation system is provided with instrumentation and controls to ensure that it remains habitable in order to ensure the capability of plant shutdown under accident conditions. Instrumentation and controls for this purpose are safety-graded and selected to be operable under worst case environmental and seismic conditions at their respective locations.

The use of different divisional power for the redundant radiation monitoring system ensures that the system will be operational upon loss of a single divisional power source.

7.6.2.1.4.2 CRV-RMS Specific Regulatory Requirements Conformance

7.6.2.1.4.2.1 CRV-RMS Conformance to Regulatory Guides

7.6.2.1.4.2.1.1 CRV-RMS - Regulatory Guide 1.22 (1972) - Periodic Testing of Protection System Actuation Functions (Safety Guide 22)

The system is designed for periodic testing in accordance with IEEE 279.

7.6.2.1.4.2.1.2 CRV-RMS - Regulatory Guide 1.29 (1978) - Seismic Design Classification

The radiation monitoring system is qualified to seismic Category I criteria, in accordance with IEEE 344. Refer to Section 3.10.

7.6.2.1.4.2.1.3 CRV-RMS - Regulatory Guide 1.89 (1974) - Qualification of Class 1E Equipment for Nuclear Power Plants

The radiation monitoring system is qualified in accordance with IEEE 323 (1974).

7.6.2.1.4.2.1.4 CRV-RMS - Regulatory Guide 1.97 (1980) - Instrumentation for Light-Water-Cooled Nuclear Power Plants to Assess Plant and Environs Conditions During and Following an Accident

Section 7.5.2.5.1.1.2 contains a discussion of the degree of conformance.

7.6.2.1.4.2.1.5 CRV-RMS - Regulatory Guide 1.100 (1977) - Seismic Qualification of Electrical Equipment for Nuclear Power Plants

See Section 3.10 for a discussion of the degree of conformance.

7.6.2.1.4.2.1.6 CRV-RMS - Regulatory Guide 1.105 (1976) - Instrument Setpoints

See Section 7.1.2.5.25 for a discussion of the degree of conformance.

7.6.2.1.4.2.1.7 CRV-RMS - Regulatory Guide 1.118 (1978) - Periodic Testing of Electric Power and Protection Systems

See Section 7.1.2.5.26 for a discussion of the degree of conformance.

7.6.2.1.4.2.2 CRV-RMS Conformance to 10CFR50, Appendix A, General Design Criteria

7.6.2.1.4.2.2.1 CRV-RMS - GDC 1 - Quality Standards and Records

The radiation monitoring system is constructed in accordance with a documented quality assurance program.

7.6.2.1.4.2.2.2 CRV-RMS - GDC 2 - Design Bases for Protection Against Natural Phenomena

The system is designed to survive SSEs.

7.6.2.1.4.2.2.3 CRV-RMS - GDC 3 - Fire Protection

The system is designed to be fire resistant.

7.6.2.1.4.2.2.4 CRV-RMS - GDC 4 - Environmental and Dynamic Effects Design Bases

Redundancy of the system affords protection against missile damage.

7.6.2.1.4.2.2.5 CRV-RMS - GDC 5 - Sharing of Structures, Systems, and Components

Control room monitoring is common to both units of the plant, but a malfunction in either unit does not inhibit the function of this system.

7.6.2.1.4.2.2.6 CRV-RMS - GDC 13 - Instrumentation and Control

Instrumentation and controls are provided to monitor the control room atmosphere over the anticipated range of radiation levels for normal and accident conditions.

7.6.2.1.4.2.2.7 CRV-RMS - GDC 19 - Control Room

This system ensures the habitability of the control room under accident conditions.

7.6.2.1.4.2.2.8 CRV-RMS - GDC 20 - Protection System Functions

This system is designed to automatically initiate the control room protection controls in response to accident conditions.

7.6.2.1.4.2.2.9 CRV-RMS - GDC 21 - Protection System Reliability and Testability

This system is designed to incorporate adequate reliability and testability so that no single failure results in the loss of its protective function.

7.6.2.1.4.2.2.10 CRV-RMS - GDC 22 - Protection System Independence

The four channels are independent so that bypassing any one channel does not result in the loss of the system's protective function.

7.6.2.1.4.2.2.11 CRV-RMS - GDC 23 - Protection System Failure Modes

Redundancy ensures that failure of one channel does not prevent the system from carrying out its trip function. The system is designed to fail-safe on loss of power to the CRV-RMS.

7.6.2.1.4.2.2.12 CRV-RMS - GDC 24 - Separation of Protection and Control Systems

Protection and control systems are separated so that the loss of any one channel does not prevent a safety-related function.

7.6.2.1.4.2.2.13 CRV-RMS - GDC 29 - Protection Against Anticipated Operational Occurrences

The system is protected against anticipated operational occurrences.

7.6.2.1.4.2.2.14 CRV-RMS - GDC 64 - Monitoring Radioactivity Releases

This system provides an indirect method of monitoring the plant environs in that the radioactivity level of incoming air from the plant environment is continually measured during all operational occurrences including accidents.

7.6.2.1.4.2.3 CRV-RMS - Conformance to Industry Codes and Standards

7.6.2.1.4.2.3.1 CRV-RMS - IEEE 279 (1971) - Criteria for Protection Systems for Nuclear Power Generating Stations

7.6.2.1.4.2.3.1.1 CRV-RMS - IEEE 279 (1971), Paragraph 4.2 - Single Failure Criterion

The radiation monitoring system consists of four independent channels. The failure of any one of these channels does not prevent this system from carrying out its safety-related functions of isolation and alarming.

7.6.2.1.4.2.3.1.2 CRV-RMS - IEEE 279 (1971), Paragraph 4.3 - Quality of Components and Modules

Components of the radiation monitoring system are carefully selected on the basis of suitability for the specific application. A quality control and assurance program is implemented and documented by the equipment vendor with the intent of complying with the requirements set forth in 10CFR50, Appendix B.

7.6.2.1.4.2.3.1.3 CRV-RMS - IEEE 279 (1971), Paragraph 4.4 - Equipment Qualification

See Section 7.6.2.1.4.2.2.

7.6.2.1.4.2.3.1.4 CRV-RMS - IEEE 279 (1971), Paragraph 4.5 - Channel Integrity

The radiation monitoring system is designed to maintain its functional capability under the environmental conditions and malfunctions that may occur in the design basis LOCA.

7.6.2.1.4.2.3.1.5 CRV-RMS - IEEE 279 (1971), Paragraph 4.6 - Channel Independence

Channel independence of sensors is provided by electrical and mechanical separation. Physical separation is maintained between each of the four channels.

7.6.2.1.4.2.3.1.6 CRV-RMS - IEEE 279 (1971), Paragraph 4.7 - Control and Protection System Interaction

The four channels are independent, so that a single failure does not prevent the system from carrying out its safety-related function.

7.6.2.1.4.2.3.1.7 CRV-RMS - IEEE 279 (1971), Paragraph 4.9 - Capability for Sensor Checks

The detectors used in the radiation monitoring system are equipped with check sources and can be checked one at a time during normal plant operation.

7.6.2.1.4.2.3.1.8 CRV-RMS - IEEE 279 (1971), Paragraph 4.10 - Capability for Testing and Calibration

Testing is achieved by check sources. There are no valves or moving parts in the radiation monitoring system requiring periodic testing. Instrument setpoints are tested by simulated signals to verify that the setpoints are within limits. Calibration sources are provided for periodic calibration.

7.6.2.1.4.2.3.1.9 CRV-RMS - IEEE 279 (1971), Paragraph 4.11 - Channel Bypass or Removal from Operation

The system design of four redundant and independent channels permits the removal from operation of one channel for testing, calibration, or maintenance without preventing the remaining three channels from being operated to perform their protective function.

7.6.2.1.4.2.3.1.10 CRV-RMS - IEEE 279 (1971), Paragraph 4.13 - Indication of Bypasses

A downscale alarm annunciates in the control room when a channel is bypassed.

7.6.2.1.4.2.3.1.11 CRV-RMS - IEEE 279 (1971), Paragraph 4.14 - Access to Means for Bypassing

The control module in the control room requires a key for bypassing its function. This key is controlled by Operations.

7.6.2.1.4.2.3.1.12 CRV-RMS - IEEE 279 (1971), Paragraph 4.15 - Multiple Setpoints

Setpoints of the monitoring system may be changed only by the control room operator by use of both his key and a code number to activate the microprocessor.

7.6.2.1.4.2.3.1.13 CRV-RMS - IEEE 279 (1971), Paragraph 4.18 - Access to Setpoint Adjustments, Calibration, and Test Points

Access to setpoint adjustments, calibration points, and test setpoints is available to qualified plant personnel by means of the access key and code number.

7.6.2.1.4.2.3.1.14 CRV-RMS - IEEE 279 (1971), Paragraph 4.19 - Identification of Protective Actions

Initiation of shutoff of the control room ventilation system and startup of the emergency fresh air system is indicated in the control room.

7.6.2.1.4.2.3.1.15 CRV-RMS - IEEE 279 (1971), Paragraph 4.20 - Information Readout

Meters located in the control room provide indications of radiation levels in the ventilation ducting. Indicator lights actuated when setpoints are exceeded provide information on alarm conditions. Trending is available on demand at the RMDS display consoles (Section 11.5.6) in the control room.

7.6.2.1.4.2.3.1.16 CRV-RMS - IEEE 279 (1971), Paragraph 4.21 - System Repair

The system is designed to provide quick recognition of malfunction through check procedures. Accessibility is provided for the detectors and controls to facilitate repairs or adjustment. Malfunctioning components can easily be replaced.

7.6.2.1.4.2.3.1.17 CRV-RMS - IEEE 279 (1971), Paragraph 4.22 - Identification of Protection Systems

Nameplates identify each module and instrument panel of the radiation monitoring system.

7.6.2.1.4.2.3.2 CRV-RMS - IEEE 308 (1974) - Criteria for Class 1E Electrical Systems for Nuclear Power Generating Stations

Refer to Section 7.1.2.7.2.

7.6.2.1.4.2.3.3 CRV-RMS - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1 Electric Equipment for Nuclear Power Generating Stations

The Class 1E equipment qualification is demonstrated by the vendor by the type-tests on actual equipment in accordance with the purchase specification. Qualification documentation is maintained.

Refer to Section 3.10.

7.6.2.1.4.2.3.4 CRV-RMS - IEEE 336 (1971) - Installation, Inspection, and Testing Requirements for Instrumentation and Electric Equipment During the Construction of Nuclear Power Generating Stations

Installation, inspection, and testing provisions are in accordance with Class 1E requirements.

7.6.2.1.4.2.3.5 CRV-RMS - IEEE 338 (1975) - Criteria for the Periodic Testing of Nuclear Power Generating Station Protection Systems

Provisions are made for the periodic testing of this system in accordance with IEEE Class 1E requirements.

7.6.2.1.4.2.3.6 CRV-RMS - IEEE 344 (1971) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations

Capability of the instruments and controls to meet seismic requirements is demonstrated by the vendor. Documentation is maintained to verify that the equipment is seismically qualified.

Refer to Section 3.10.

7.6.2.1.4.2.3.7 CRV-RMS - IEEE 379 (1972) - Guide for the Application of the Single Failure Criterion to Nuclear Power Generating Station Protection Systems

This system is designed in accordance with the single failure criterion for safety-related equipment.

7.6.2.1.4.2.3.8 CRV-RMS - IEEE 384 (1974) - Criteria for Separation of Class 1E Equipment and Circuits

Channel separation and electrical wiring separation are designed in accordance with IEEE 279 requirements.

7.6.2.1.4.3 CRV-RMS Preoperational Checkout

Preoperational tests are conducted prior to initial startup. The tests ensure functioning of all controls and active components. System reference characteristics such as setpoints are documented during preoperational testing and used as base points for measurements obtained during subsequent calibrations.

7.6.2.1.4.4 CRV-RMS Operational Tests

During plant operation, components of this system can be inspected at any time. Test frequency is consistent with the requirements of the plant Technical Specifications.

7.6.2.1.5 Control Room Emergency Fresh Air Radiation Monitoring System

7.6.2.1.5.1 CREFA-RMS General Functional Requirements Conformance

The CREFAS provides for the habitability of the control room when the main control room ventilation system is shut down. Radiation monitors in the normal control room ventilation system are not functional in this circumstance, so the CREFA-RMS provides for continued surveillance of the control room atmosphere.

7.6.2.1.5.2 CREFA-RMS Specific Regulatory Requirements Conformance

7.6.2.1.5.2.1 CREFA-RMS Conformance to Regulatory Guides

7.6.2.1.5.2.1.1 CREFA-RMS - Regulatory Guide 1.22 (1972) - Periodic Testing of Protection System Actuation Functions (Safety Guide 22)

The system is designed for periodic testing in accordance with IEEE 279.

7.6.2.1.5.2.1.2 CREFA-RMS - Regulatory Guide 1.29 (1978) - Seismic Design Classification

The CREFA-RMS is qualified to seismic Category I criteria, in accordance with IEEE 344. Refer to Section 3.10.

7.6.2.1.5.2.1.3 CREFA-RMS - Regulatory Guide 1.89 (1974) - Qualification of Class 1E Equipment for Nuclear Power Plants

The CREFA-RMS is qualified in accordance with IEEE 323 (1974).

7.6.2.1.5.2.1.4 CREFA-RMS - Regulatory Guide 1.97 (1980) - Instrumentation for Light-Water-Cooled Nuclear Power Plants to Assess Plant and Environs Conditions During and Following an Accident

Conformance is discussed in Section 7.5.2.5.1.1.2.

7.6.2.1.5.2.1.5 CREFA-RMS - Regulatory Guide 1.100 (1977) - Seismic Qualification of Electric Equipment for Nuclear Power Plants

See Section 3.10 for a discussion of the degree of conformance.

7.6.2.1.5.2.1.6 CREFA-RMS - Regulatory Guide 1.105 (1976) - Instrument Setpoints

See Section 7.1.2.5.25 for a discussion of the degree of conformance.

7.6.2.1.5.2.1.7 CREFA-RMS - Regulatory Guide 1.118 (1978) - Periodic Testing of Electric Power and Protection Systems

See Section 7.1.2.5.26 for a discussion of the degree of conformance.

7.6.2.1.5.2.2 CREFA-RMS Conformance to 10CFR50, Appendix A, General Design Criteria

7.6.2.1.5.2.2.1 CREFA-RMS - GDC 1 - Quality Standards and Records

The radiation monitoring system is constructed in accordance with a documented quality assurance program.

7.6.2.1.5.2.2.2 CREFA-RMS - GDC 2 - Design Bases for Protection Against Natural Phenomena

The system is designed to survive SSEs.

7.6.2.1.5.2.2.3 CREFA-RMS - GDC 3 - Fire Protection

The system is designed to be fire resistant.

7.6.2.1.5.2.2.4 CREFA-RMS - GDC 4 - Environmental and Dynamic Effects Design Bases

Redundancy of the system affords protection against missile damage.

7.6.2.1.5.2.2.5 CREFA-RMS - GDC 5 - Sharing of Structures, Systems, and Components

Control room monitoring is common to both units of the plant, but a malfunction in either unit does not inhibit the function of this system.

7.6.2.1.5.2.2.6 CREFA-RMS - GDC 13 - Instrumentation and Control

Instrumentation and controls are provided to monitor the control room atmosphere over the anticipated range of radiation levels for normal and accident conditions.

7.6.2.1.5.2.2.7 CREFA-RMS - GDC 19 - Control Room

This system ensures habitability of the control room under accident conditions.

7.6.2.1.5.2.2.8 CREFA-RMS - GDC 21 - Protection System Reliability and Testability

This system is designed to incorporate adequate reliability and testability so that no single failure results in the loss of its monitoring function.

7.6.2.1.5.2.2.9 CREFA-RMS - GDC 22 - Protection System Independence

The two channels are independent so that bypass of either channel does not affect the other channel.

7.6.2.1.5.2.2.10 CREFA-RMS - GDC 23 - Protection System Failure Modes

Failure of either channel does not inhibit the function of the other.

7.6.2.1.5.2.2.11 CREFA-RMS - GDC 29 - Protection Against Anticipated Operational Occurrences

The system is protected against anticipated operational occurrences.

7.6.2.1.5.2.2.12 CREFA-RMS - GDC 64 - Monitoring Radioactivity Releases

This system provides an indirect method of monitoring the plant environs in that the radioactivity level of incoming air from the plant environment is measured while the emergency fresh air system is functioning during accident conditions.

7.6.2.1.5.2.3 CREFA-RMS Conformance to Industry Codes and Standards

7.6.2.1.5.2.3.1 CREFA-RMS - IEEE 279 (1971) - Criteria for Protection Systems for Nuclear Power Generating Stations

7.6.2.1.5.2.3.1.1 CREFA-RMS - IEEE 279 (1971), Paragraph 4.2 - Single Failure Criterion

The CREFA-RMS consists of two independent channels. The failure of either of these channels does not prevent this system from carrying out its functions of readout and alarming.

7.6.2.1.5.2.3.1.2 CREFA-RMS - IEEE 279 (1971), Paragraph 4.3 - Quality of Components and Modules

Components of the radiation monitoring system are carefully selected on the basis of suitability for the specific application. A quality control and assurance program is implemented and documented by the equipment vendor with the intent of complying with the requirements set forth in 10CFR50, Appendix B.

7.6.2.1.5.2.3.1.3 CREFA-RMS - IEEE 279 (1971), Paragraph 4.4 - Equipment Qualification

The equipment is qualified to meet the standards of IEEE 323 (1974).

7.6.2.1.5.2.3.1.4 CREFA-RMS - IEEE 279 (1971), Paragraph 4.5 - Channel Integrity

The radiation monitoring system is designed to maintain its functional capability under the environmental conditions and malfunctions that may occur in the design basis LOCA.

7.6.2.1.5.2.3.1.5 CREFA-RMS - IEEE 279 (1971), Paragraph 4.6 - Channel Independence

Channel independence of sensors is provided by electrical and mechanical separation. Physical separation is maintained between the two channels.

7.6.2.1.5.2.3.1.6 CREFA-RMS - IEEE 279 (1971), Paragraph 4.9 - Capability for Sensor Checks

The detectors used in the CREFA-RMS are equipped with check sources, and can be checked one at a time during normal plant operation.

7.6.2.1.5.2.3.1.7 CREFA-RMS - IEEE 279 (1971), Paragraph 4.10 - Capability for Testing and Calibration

Testing is achieved by check sources. There are no valves or moving parts in the CREFA-RMS requiring periodic testing. Instrument setpoints are tested by simulated signals to verify that the setpoints are within limits. Calibration sources are provided for periodic calibration.

7.6.2.1.5.2.3.1.8 CREFA-RMS - IEEE 279 (1971), Paragraph 4.11 - Channel Bypass or Removal from Operation

The system design of two redundant and independent channels permits the removal from operation of one channel for testing, calibration, or maintenance without preventing the remaining channel from operating normally.

7.6.2.1.5.2.3.1.9 CREFA-RMS - IEEE 279 (1971), Paragraph 4.13 - Indication of Bypasses

Indication of bypass is provided by the extinguishing of the normal operation light when a channel is inoperative for test, calibration, or maintenance. The downscale alarm annunciates in the control room under this condition.

7.6.2.1.5.2.3.1.10 CREFA-RMS - IEEE 279 (1971), Paragraph 4.14 - Access to Means for Bypassing

The control module in the control room requires a key for the bypassing of its function. This key is controlled by Operations.

7.6.2.1.5.2.3.1.11 CREFA-RMS - IEEE 279 (1971), Paragraph 4.15 - Multiple Setpoints

Setpoints of the CREFA-RMS is controlled by the control room operator by use of both the key and a code number to activate the microprocessor.

7.6.2.1.5.2.3.1.12 CREFA-RMS - IEEE 279 (1971), Paragraph 4.18 - Access to Setpoint Adjustments, Calibration, and Test Points

Access to setpoint adjustment, calibration points, and test setpoints is limited to qualified plant personnel by means of control of the access key and code number.

7.6.2.1.5.2.3.1.13 CREFA-RMS - IEEE 279 (1971), Paragraph 4.20 - Information Readout

Meters located in the control room provide indications of radiation levels in the ducting. Indicator lights actuated by setpoints provide information on alarm conditions. Trending is available on demand at the RMDS display consoles (Section 11.5.6) in the control room.

7.6.2.1.5.2.3.1.14 CREFA-RMS - IEEE 279 (1971), Paragraph 4.21 - System Repair

The CREFA-RMS is designed to provide quick recognition of malfunction through check procedures. Accessibility is provided for the detectors and controls to facilitate repairs or adjustments. Malfunctioning components can readily be replaced.

7.6.2.1.5.2.3.1.15 CREFA-RMS - IEEE 279 (1971), Paragraph 4.22 - Identification of Protection Systems

Nameplates identify each module and instrument panel of the CREFA-RMS.

7.6.2.1.5.2.3.2 CREFA-RMS - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1 Electric Equipment for Nuclear Power Generating Stations

Class 1E equipment qualification is demonstrated by the vendor by type-tests on actual equipment in accordance with the purchase specification. Qualification documentation is maintained.

7.6.2.1.5.2.3.3 CREFA-RMS - IEEE 336 (1971) - Installation, Inspection, and Testing Requirements for Instrumentation and Electric Equipment During the Construction of Nuclear Power Generating Stations

Installation, inspection, and testing provisions are in accordance with IEEE Class 1E requirements.

7.6.2.1.5.2.3.4 CREFA-RMS - IEEE 338 (1975) - Criteria for the Periodic Testing of Nuclear Power Generating Station Protection Systems

Provisions are made for the periodic testing of this system in accordance with IEEE Class 1E requirements.

7.6.2.1.5.2.3.5 CREFA-RMS - IEEE 344 (1971) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations

Capability of the instruments and controls to meet seismic requirements is demonstrated by the vendor. Documentation is maintained to verify that the equipment is seismically qualified.
Refer to Section 3.10.

7.6.2.1.5.2.3.6 CREFA-RMS - IEEE 379 (1972) - Guide for the Application of the Single Failure Criterion to Nuclear Power Generating Station Protection Systems

This system is designed in accordance with the single failure criterion for safety-related equipment.

7.6.2.1.5.2.3.7 CREFA-RMS - IEEE 384 (1974) - Criteria for Separation of Class 1E Equipment and Circuits

Channel separation and electrical wiring separation are designed in accordance with IEEE 279 requirements.

7.6.2.1.5.3 CREFA-RMS Preoperational Checkout

Preoperational tests are conducted prior to initial startup. The tests ensure functioning of all components and controls. System reference characteristics such as setpoints are documented during preoperational testing and used as base points for measurements obtained during subsequent calibrations.

7.6.2.1.5.4 CREFA-RMS Operational Tests

During plant operation, components of the CREFA-RMS can be operationally tested at any time. Test frequency intervals are established by plant staff.

7.6.2.1.6 Primary Containment Post-LOCA Radiation Monitoring System

7.6.2.1.6.1 PCPL-RMS General Functional Requirements Conformance

The primary containment is provided with gamma-sensitive radiation monitors to maintain continuing surveillance of the containment atmosphere under postaccident conditions.

The description in Section 11.5.2.3.1 demonstrates how the PCPL- RMS meets the safety design bases identified in Section 7.1.2.1.11.6.

7.6.2.1.6.2 PCPL-RMS Specific Regulatory Requirements Conformance

7.6.2.1.6.2.1 PCPL-RMS Conformance to Regulatory Guide

7.6.2.1.6.2.1.1 PCPL-RMS - Regulatory Guide 1.22 (1972) - Periodic Testing of Protection System Actuation Functions (Safety Guide 22)

The system is designed for periodic testing in accordance with IEEE 279.

7.6.2.1.6.2.1.2 PCPL-RMS - Regulatory Guide 1.29 (1978) - Seismic Design Classification

The radiation monitoring system is qualified to seismic Category I criteria, in accordance with IEEE 344. Refer to Section 3.10.

7.6.2.1.6.2.1.3 PCPL-RMS - Regulatory Guide 1.89 (1974) - Qualification of Class 1E Equipment for Nuclear Power Plants

The radiation monitoring system is qualified in accordance with IEEE 323 (1974).

7.6.2.1.6.2.1.4 PCPL-RMS - Regulatory Guide 1.97 (1980) - Instrumentation for Light-Water-Cooled Nuclear Power Plants to Assess Plant and Environs Conditions During and Following an Accident

Conformance is discussed in Section 7.5.2.5.1.1.2.

7.6.2.1.6.2.1.5 PCPL-RMS - Regulatory Guide 1.100 (1977) - Seismic Qualification of Electric Equipment for Nuclear Power Plants

Conformance is discussed in Section 3.10.

7.6.2.1.6.2.1.6 PCPL-RMS - Regulatory Guide 1.105 (1976) - Instrument Setpoints

See Section 7.1.2.5.25 for a discussion of the degree of conformance.

7.6.2.1.6.2.1.7 PCPL-RMS - Regulatory Guide 1.118 (1978) - Periodic Testing of Electric Power and Protection Systems

See Section 7.1.2.5.26 for a discussion of the degree of conformance.

7.6.2.1.6.2.2 PCPL-RMS Conformance to 10CFR50, Appendix A, General Design Criteria

This system is designed to conform to the following criteria of 10CFR50, Appendix A:

7.6.2.1.6.2.2.1 PCPL-RMS - GDC 1 - Quality Standards and Records

A quality assurance program is established for the design and production of this system.

7.6.2.1.6.2.2.2 PCPL-RMS - GDC 2 - Design Bases for Protection Against Natural Phenomena

This system is designed and tested to meet seismic Category I requirements.

7.6.2.1.6.2.2.3 PCPL-RMS - GDC 3 - Fire Protection

Fire resistant components are used throughout.

7.6.2.1.6.2.2.4 PCPL-RMS - GDC 4 - Environmental and Dynamic Effects Design Bases

Redundancy of the system provides for missile damage.

7.6.2.1.6.2.2.5 PCPL-RMS - GDC 5 - Sharing of Structures, Systems, and Components

No components are shared between the unitized systems.

7.6.2.1.6.2.2.6 PCPL-RMS - GDC 13 - Instrumentation and Control

Operating ranges of the instrumentation are compatible with anticipated accident conditions.

7.6.2.1.6.2.2.7 PCPL-RMS - GDC 21 - Protection System Reliability and Testability

The system is designed for high functional reliability and inservice testability.

7.6.2.1.6.2.2.8 PCPL-RMS - GDC 22 - Protection System Independence

System redundancy and separation of channels provides for protection system independence.

7.6.2.1.6.2.2.9 PCPL-RMS - GDC 23 - Protection System Failure Modes

Loss of either channel in this system does not impair the function of the other.

7.6.2.1.6.2.2.10 PCPL-RMS - GDC 24 - Separation of Protection and Control Systems

The two channels are separated in accordance with IEEE 279 (1971).

7.6.2.1.6.2.2.11 PCPL-RMS - GDC 29 - Protection Against Anticipated Operational Occurrences

The system is designed to ensure functional reliability in the event of an anticipated operational occurrence.

7.6.2.1.6.2.2.12 PCPL-RMS - GDC 64 - Monitoring Radioactivity Releases

The requirement for the monitoring of the containment atmosphere is fulfilled.

7.6.2.1.6.2.3 PCPL-RMS Conformance to Industry Codes and Standards

7.6.2.1.6.2.3.1 PCPL-RMS - IEEE 279 (1971) - Criteria for Protection Systems for Nuclear Power Generating Stations

7.6.2.1.6.2.3.1.2 PCPL-RMS - IEEE 279 (1971), Paragraph 4.2 - Single Failure Criterion

The design based on two electrical separation channels, each containing two monitoring channels, does not meet the single failure criterion. However, only two monitoring channels are required in accordance with Section 1.13.

7.6.2.1.6.2.3.1.3 PCPL-RMS - IEEE 279 (1971), Paragraph 4.3 - Quality of Components and Modules

A quality assurance program is adhered to in the production of this system.

7.6.2.1.6.2.3.1.4 PCPL-RMS - IEEE 279 (1971), Paragraph 4.4 - Equipment Qualification

The system is qualified in accordance with IEEE 323 (1974).

7.6.2.1.6.2.3.1.5 PCPL-RMS - IEEE 279 (1971), Paragraph 4.5 - Channel Integrity

The system is designed to meet the most extreme environmental conditions anticipated.

7.6.2.1.6.2.3.1.6 PCPL-RMS - IEEE 279 (1971), Paragraph 4.6 - Channel Independence

The two redundant channels are independent and separate.

7.6.2.1.6.2.3.1.7 PCPL-RMS - IEEE 279 (1971), Paragraph 4.7 - Control and Protection System Interaction

The system serves no control function. However, the separation and independence of the two channels satisfies the remaining requirements of this section.

7.6.2.1.6.2.3.1.8 PCPL-RMS - IEEE 279 (1971), Paragraph 4.8 - Derivation of System Inputs

System inputs are derived from radioactivity measurements inside the containment.

7.6.2.1.6.2.3.1.9 PCPL-RMS - IEEE 279 (1971), Paragraph 4.9 - Capability for Sensor Checks

Check signals are provided for the detectors. However, no check sources are provided.

7.6.2.1.6.2.3.1.10 PCPL-RMS - IEEE 279 (1971), Paragraph 4.10 - Capability for Testing and Calibration

The check signal provides capability for testing during power operation. Calibration capabilities are discussed in Section 11.5.2.3.1.

7.6.2.1.6.2.3.1.11 PCPL-RMS - IEEE 279 (1971), Paragraph 4.11 - Channel Bypass or Removal from Operation

Either channel can be bypassed for checking or servicing without impairing the functions of the other channel.

7.6.2.1.6.2.3.1.12 PCPL-RMS - IEEE 279 (1971), Paragraph 4.13 - Indication of Bypasses

The bypassing of a channel results in downscale alarm in the control room.

7.6.2.1.6.2.3.1.13 PCPL-RMS - IEEE 279 (1971), Paragraph 4.14 - Access to Means for Bypassing

Administrative controls are provided as the means to remove a channel from service.

7.6.2.1.6.2.3.1.14 PCPL-RMS - IEEE 279 (1971), Paragraph 4.15 - Multiple Setpoints

This requirement is not applicable.

7.6.2.1.6.2.3.1.15 PCPL-RMS - IEEE 279 (1971), Paragraph 4.18 - Access to Setpoint Adjustments, Calibration, and Test Points

Access to setpoints is available in the control module. However, to change a setpoint necessitates the use of a supervisory key to prevent unauthorized adjustments.

7.6.2.1.6.2.3.1.16 PCPL-RMS - IEEE 279 (1971), Paragraph 4.20 - Information Readout

Readouts are provided in the control room. Indication of the variable and monitor status are provided.

7.6.2.1.6.2.3.1.17 PCPL-RMS - IEEE 279 (1971), Paragraph 4.21 - System Repair

The system is modular to facilitate quick repair or component replacement.

7.6.2.1.6.2.3.1.18 PCPL-RMS - IEEE 279 (1971), Paragraph 4.22 - Identification of Protection Systems

Suitable system and component identification is provided.

7.6.2.1.6.2.3.2 PCPL-RMS - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1 Electric Equipment for Nuclear Power Generating Stations

The Class 1E equipment qualification is demonstrated by the type- tests on actual equipment. Qualification documentation is maintained.

7.6.2.1.6.2.3.3 PCPL-RMS - IEEE 336 (1971) - Installation, Inspection, and Testing Requirements for Instrumentation and Electric Equipment During the Construction of Nuclear Power Generating Stations

Installation, inspection, and testing provisions are in accordance with Class 1E requirements.

7.6.2.1.6.2.3.4 PCPL-RMS - IEEE 338 (1975) - Criteria for the Periodic Testing of Nuclear Power Generating Station Protection Systems

Provisions are made for the periodic testing of this system in accordance with IEEE Class 1E requirements.

7.6.2.1.6.2.3.5 PCPL-RMS - IEEE 379 (1972) - Guide for the Application of the Single Failure Criterion to Nuclear Power Generating Station Protection Systems

Refer to Section 7.6.2.1.6.2.3.1.2.

7.6.2.1.6.2.3.6 PCPL-RMS - IEEE 384 (1974) - Criteria for Separation of Class 1E Equipment and Circuits

Channel separation and electrical wiring separation are designed in accordance with IEEE 384 requirements.

7.6.2.1.6.3 PCPL-RMS Preoperational Checkout

Preoperational tests are conducted prior to initial startup. The tests ensure functioning of all components and controls. System reference characteristics such as setpoints are documented during preoperational testing and used as base points for measurements obtained during subsequent calibrations.

7.6.2.1.6.4 PCPL-RMS Operational Tests

During plant operation, components of the PCPL-RMS can be operationally tested at any time. Test frequency is consistent with the requirements of plant Technical Specifications.

7.6.2.1.7 RHR Service Water Radiation Monitoring System

7.6.2.1.7.1 RHRSW-RMS General Functional Requirements Conformance

Service water piping from the RHR heat exchangers is provided with radiation monitors for detecting evidence of leakage through the interface between the service water and the RHR system. If significant radioactivity is detected in the service water, the radiation monitors provide signals to trip the RHRSW pumps. Alarm signals are annunciated in the control room.

7.6.2.1.7.2 RHRSW-RMS Specific Regulatory Requirements Conformance

7.6.2.1.7.2.1 RHRSW-RMS Conformance to Regulatory Guides

7.6.2.1.7.2.1.1 RHRSW-RMS - Regulatory Guide 1.21 (1974) - Measuring, Evaluating, and Reporting Radioactivity in Solid Wastes and Releases of Radioactive Materials in Liquid and Gaseous Effluents from Light-Water-Cooled Nuclear Power Plants

The RHRSW monitor is designed to keep an ongoing record should any radioactive material be released via the RHRSW system.

7.6.2.1.7.2.1.2 RHRSW-RMS - Regulatory Guide 1.22 (1972) - Periodic Testing of Protection System Actuation Functions (Safety Guide 22)

The system is designed to be periodically tested in accordance with IEEE 279.

7.6.2.1.7.2.1.3 RHRSW-RMS - Regulatory Guide 1.100 (1977) - Seismic Qualification of Electric Equipment for Nuclear Power Plants

See Section 3.10 for a discussion of the degree of conformance.

7.6.2.1.7.2.1.4 RHRSW-RMS - Regulatory Guide 1.105 (1976) - Instrument Setpoints

See Section 7.1.2.5.25 for a discussion of the degree of conformance.

7.6.2.1.7.2.1.5 RHRSW-RMS - Regulatory Guide 1.118 (1978) - Periodic Testing of Electric Power and Protection Systems

See Section 7.1.2.5.26 for a discussion of the degree of conformance.

7.6.2.1.7.2.2 RHRSW-RMS Conformance to 10CFR50, Appendix A, General Design Criteria

7.6.2.1.7.2.2.1 RHRSW-RMS - GDC 1 - Quality Standards and Records

Quality standards and records are maintained for this system.

7.6.2.1.7.2.2.2 RHRSW-RMS - GDC 2 - Design Bases for Protection Against Natural Phenomena

The system is designed to seismic Category I criteria.

7.6.2.1.7.2.2.3 RHRSW-RMS - GDC 3 - Fire Protection

The system is designed to be fireproof.

7.6.2.1.7.2.2.4 RHRSW-RMS - GDC 4 - Environmental and Dynamic Effects Design Bases

Redundancy and component separation of this system provide protection against missile damage.

7.6.2.1.7.2.2.5 RHRSW-RMS - GDC 5 - Sharing of Structures, Systems, and Components

One monitoring channel is dedicated to each of the two common return lines of the RHRSW system. The two monitoring channels are shared by both units. However, this does not impair the function of the monitoring system because of the separation and independence of the two channels.

7.6.2.1.7.2.2.6 RHRSW-RMS - GDC 13 - Instrumentation and Control

The instrumentation is designed to cover the anticipated range of abnormal conditions.

7.6.2.1.7.2.2.7 RHRSW-RMS - GDC 20 - Protection System Functions

The system is designed to sense abnormal occurrences and to initiate operation of components important to safety.

7.6.2.1.7.2.2.8 RHRSW-RMS - GDC 21 - Protection System Reliability and Testability

The system is designed for high functional reliability and testability.

7.6.2.1.7.2.2.9 RHRSW-RMS - GDC 22 - Protection System Independence

The system provides independence of function.

7.6.2.1.7.2.2.10 RHRSW-RMS - GDC 23 - Protection System Failure Modes

Failure of one channel does not prevent the system from carrying out its protective function.

7.6.2.1.7.2.2.11 RHRSW-RMS - GDC 24 - Separation of Protection and Control Systems

Redundancy ensures that the failure of one channel does not prevent the system from carrying out its trip function.

7.6.2.1.7.2.2.12 RHRSW-RMS - GDC 29 - Protection Against Anticipated Operational Occurrences

The system is designed to ensure the high probability of carrying out its safety functions in the event of anticipated operational occurrences.

7.6.2.1.7.2.2.13 RHRSW-RMS - GDC 30 - Quality of Reactor Coolant Pressure Boundary

The system provides a means of detecting and identifying a source of reactor coolant leakage.

7.6.2.1.7.2.2.14 RHRSW-RMS - GDC 34 - Residual Heat Removal

The system provides leak detection of the RHR system.

7.6.2.1.7.2.2.15 RHRSW-RMS - GDC 38 - Containment Heat Removal

The system provides a means of leak detection and isolation of the RHR system.

7.6.2.1.7.2.2.16 RHRSW-RMS - GDC 40 - Testing of Containment Heat Removal System

The system provides one of the means for testing the integrity of the RHR system.

7.6.2.1.7.2.2.17 RHRSW-RMS - GDC 60 - Control of Releases of Radioactive Materials to the Environment

This system provides a means for controlling releases of radioactive materials to the environment.

7.6.2.1.7.2.2.18 RHRSW-RMS - GDC 64 - Monitoring Radioactivity Releases

This system monitors radioactivity releases from normal operations, operational occurrences, and from postulated accidents.

7.6.2.1.7.2.3 RHRSW-RMS Conformance to Industry Codes and Standards

7.6.2.1.7.2.3.1 RHRSW-RMS - IEEE 279 (1971) - Criteria for Protection Systems for Nuclear Power Generating Stations

7.6.2.1.7.2.3.1.1 RHR-RMS - IEEE 279 (1971), Paragraph 4.1 - General Functional Requirement

The RHRSW-RMS automatically alarms and trips the appropriate RHRSW pumps whenever the effluent radiation levels exceed a preset level.

7.6.2.1.7.2.3.1.2 RHRSW-RMS - IEEE 279 (1971), Paragraph 4.2 - Single Failure Criterion

The monitoring system consists of one monitor dedicated to each of the common service water return lines. The failure of either channel is alarmed in the Main Control Room. Following the failure of a channel, grab sampling is performed on a periodic basis. Should a high radiation level be detected, the RHRSW pumps may be tripped and the appropriate RHR heat exchangers isolated by manual operator actions. Thus, the safety related function of detection and isolation are maintained.

7.6.2.1.7.2.3.1.3 RHRSW-RMS - IEEE 279 (1971), Paragraph 4.3 - Quality of Components and Modules

Components of the radiation monitoring system are carefully selected on the basis of suitability for the specific application. A quality control and assurance program is implemented and documented by the equipment vendor with the intent of complying with the requirements set forth in 10CFR50, Appendix B.

7.6.2.1.7.2.3.1.4 RHRSW-RMS - IEEE 279 (1971), Paragraph 4.4 - Equipment Qualification

The equipment is qualified in accordance with IEEE 323, except that no aging test conditions have been imposed.

7.6.2.1.7.2.3.1.5 RHRSW-RMS - IEEE 279 (1971), Paragraph 4.5 - Channel Integrity

The radiation monitoring system is designed to maintain its functional capability under the environmental conditions and malfunctions that occur in the design basis LOCA.

7.6.2.1.7.2.3.1.6 RHRSW-RMS - IEEE 279 (1971), Paragraph 4.6 - Channel Independence

Channel independence of detectors is provided by electrical and mechanical separation. Physical separation is maintained between each of the two channels (both units).

7.6.2.1.7.2.3.1.7 RHRSW-RMS - IEEE 279 (1971), Paragraph 4.7 - Control and Protection System Interaction

The two channels (both units) are independent, so that a single failure does not prevent the system from carrying out its safety- related function.

7.6.2.1.7.2.3.1.8 RHRSW-RMS - IEEE 279 (1971), Paragraph 4.8 - Derivation of System Inputs

Trip control signals are derived from measurement of activity levels in the RHRSW. Trip logic is not necessary.

7.6.2.1.7.2.3.1.9 RHRSW-RMS - IEEE 279 (1971), Paragraph 4.9 - Capability for Sensor Checks

The detectors used in the radiation monitoring system are equipped with check sources and can be checked one at a time during normal plant operation.

7.6.2.1.7.2.3.1.10 RHRSW-RMS - IEEE 279 (1971), Paragraph 4.10 - Capability for Testing and Calibration

Testing and calibration are achieved by means of check sources.

7.6.2.1.7.2.3.1.11 RHRSW-RMS - IEEE 279 (1971), Paragraph 4.11 - Channel Bypass or Removal from Operation

The system permits removal from operation of one channel for calibration, testing, or maintenance. With a channel bypass, the protective function is performed by periodic grab sampling of the service water.

7.6.2.1.7.2.3.1.12 RHRSW-RMS - IEEE 279 (1971), Paragraph 4.13 - Indication of Bypasses

A downscale alarm annunciates in the control room when a channel is bypassed.

7.6.2.1.7.2.3.1.13 RHRSW-RMS - IEEE 279 (1971), Paragraph 4.14 - Access to Means for Bypassing

Means for channel bypass is limited to the control module in the auxiliary equipment room.

7.6.2.1.7.2.3.1.14 RHRSW-RMS - IEEE 279 (1971), Paragraph 4.15 - Multiple Setpoints

Setpoints of each monitoring channel may be changed in the control module located in the auxiliary equipment room.

7.6.2.1.7.2.3.1.15 RHRSW-RMS - IEEE 279 (1971), Paragraph 4.18 - Access to Setpoint Adjustments, Calibration, and Test Points

Access to setpoint adjustments is limited to control room personnel who have access to the rear of the control module in the auxiliary equipment room.

7.6.2.1.7.2.3.1.16 RHRSW-RMS - IEEE 279 (1971), Paragraph 4.19 - Initiation of Protective Actions

Initiation of shutoff of the RHRSW pumps is indicated in the control room.

7.6.2.1.7.2.3.1.17 RHRSW-RMS - IEEE 279 (1971), Paragraph 4.20 - Information Readout

Rate meters located in the auxiliary equipment room and recorders located in the control room provide indications of activity levels in the RHRSW. Indicator lights actuated when setpoints are exceeded provide information on alarm conditions.

7.6.2.1.7.2.3.1.18 RHRSW-RMS - IEEE 279 (1971), Paragraph 4.21 - System Repair

The system is designed for quick recognition of malfunction through check procedures. Accessibility to the monitoring racks and controls is provided to facilitate repair or adjustment.

7.6.2.1.7.2.3.1.19 RHRSW-RMS - IEEE 279 (1971), Paragraph 4.22 - Identification of Protection Systems

Nameplates identify each module and instrument panel of the radiation monitoring system.

7.6.2.1.7.2.3.2 RHRSW-RMS - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1 Electric Equipment for Nuclear Power Generating Stations

Aging test requirements in IEEE 323 (1971) were not complied with because this equipment was procured before the effective date of Regulatory Guide 1.89. Qualification documentation is maintained.

7.6.2.1.7.2.3.3 RHRSW-RMS - IEEE 336 (1971) - Installation, Inspection, and Testing Requirements for Instrumentation and Electric Equipment During the Construction of Nuclear Power Generating Stations

Provisions are made for the installation, inspection, and testing of this system in accordance with Class 1E requirements.

7.6.2.1.7.2.3.4 RHRSW-RMS - IEEE 338 (1975) - Criteria for the Periodic Testing of Nuclear Power Generating Station Protection Systems

The system is periodically tested in accordance with a standard recalibration and functional test program.

7.6.2.1.7.2.3.5 RHRSW-RMS - IEEE 344 (1971) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations

Capability of the instruments and controls to meet seismic requirements is demonstrated by the vendor. Documentation is maintained to verify that the equipment is qualified. Refer to Section 3.10.

7.6.2.1.7.2.3.6 RHRSW-RMS - IEEE 379 (1972) - Guide for the Application of the Single Failure Criterion to Nuclear Power Generating Station Protection Systems

Redundancy of the system ensures that a single failure does not prevent the system from carrying out its safety-related function.

7.6.2.1.7.2.3.7 RHRSW-RMS - IEEE 384 (1974) - Criteria for Separation of Class 1E Equipment and Circuits

The channels of this system are separated in accordance with IEEE 279.

7.6.2.1.7.3 RHRSW-RMS Preoperational Checkout

Preoperational tests are conducted before initial startup. These tests ensure functioning of all controls and active components. System reference characteristics such as setpoints are documented during preoperational testing and are used as base points for measurements obtained during subsequent calibrations.

7.6.2.1.7.4 RHRSW-RMS Operational Tests

During plant operation, components of this system can be inspected at any time. Test frequency is consistent with the requirements of plant Technical Specifications.

7.6.2.1.8 North Stack Effluent Radiation Monitoring System

7.6.2.1.8.1 NSE-RMS General Functional Requirements Conformance

Two independent monitoring subsystems are provided:

a. Normal range plant subsystem

b. Wide range accident monitoring subsystem

Subsystem (a) is designed to monitor the north stack effluents under normal plant operating conditions. Subsystem (b) is designed to monitor the north stack effluents under normal plant operation, accident, and postaccident condition. Section 11.5.2.2.1 describes the system and shows how the design bases identified in Section 7.1.2.1.11.6.1 are met.

7.6.2.1.8.2 NSE-RMS Specific Regulatory Requirements

7.6.2.1.8.2.1 NSE-RMS Conformance to Regulatory Guides

7.6.2.1.8.2.1.1 NSE-RMS - Regulatory Guide 1.21 (1974) - Measuring, Evaluating, and Reporting Radioactivity in Solid Wastes and Releases of Radioactive Materials in Liquid or Gaseous Effluents from Light-Water-Cooled Nuclear Power Plants

Ongoing inventories of radiation particulates, iodines, and noble gases are provided for the preparation of Regulatory Guide 1.21, Appendix B reports.

7.6.2.1.8.2.1.2 NSE-RMS - Regulatory Guide 1.22 (1972) - Periodic Testing of Protection System Actuation Functions (Safety Guide 22)

The system will be periodically tested in accordance with IEEE 279 (1971).

7.6.2.1.8.2.1.3 NSE-RMS - Regulatory Guide 1.29 (1978) - Seismic Design Classification

Subsystem (b), the wide range accident monitor is qualified to seismic Category I criteria to ensure the integrity of its Class 1E power source. The sampling nozzles and lines of the wide range accident monitor are designed to seismic Category II. Subsystem (a), the normal plant operation monitor, is designed to meet seismic Category II requirements.

7.6.2.1.8.2.1.4 NSE-RMS - Regulatory Guide 1.89 (1974) - Qualification of Class 1E Equipment for Nuclear Power Plants

To ensure its functionability during and after an accident, Subsystem (b) is qualified to meet IEEE 323 (1974) requirements.

7.6.2.1.8.2.1.5 NSE-RMS - Regulatory Guide 1.97 (1980) - Instrumentation for Light-Water-Cooled Nuclear Power Plants to Access Plant and Environs Conditions During and Following an Accident

Refer Section 7.5.2.5.1.1.2 for degree of compliance.

7.6.2.1.8.2.1.6 NSE-RMS - Regulatory Guide 1.100 (1977) - Seismic Qualification of Electric Equipment for Nuclear Power Plants

See Section 3.10 for a discussion of the degree of conformance.

7.6.2.1.8.2.1.7 NSE-RMS - Regulatory Guide 1.105 (1976) - Instrument Setpoints

See Section 7.1.2.5.25 for a discussion of the degree of conformance.

7.6.2.1.8.2.1.8 NSE-RMS Regulatory Guide 1.118 (1978) - Periodic Testing of Electric Power and Protection Systems

See Section 7.1.2.5.26 for a discussion of the degree of conformance.

7.6.2.1.8.2.2 NSE-RMS Conformance to 10CFR50, Appendix A, General Design Criteria

7.6.2.1.8.2.2.1 NSE-RMS - GDC 1 - Quality Standards and Records

Quality assurance has been provided for the wide range accident monitor commensurate with its importance to safety in accordance with the guidelines of Regulatory Guide 1.97 (1980).

7.6.2.1.8.2.2.2 NSE-RMS - GDC 2 - Design Bases for Protection Against Natural Phenomena

The wide range accident monitor is designed to meet seismic Category I requirements as discussed in Section 7.6.2.1.8.2.1.3.

7.6.2.1.8.2.2.3 NSE-RMS - GDC 3 - Fire Protection

Fire resistant components are used throughout.

7.6.2.1.8.2.2.4 NSE-RMS - GDC 4 - Environmental and Dynamic Effects Design Bases

No provision is made for protection against missiles.

7.6.2.1.8.2.2.5 NSE-RMS - GDC 5 - Sharing of Structures, Systems, and Components

The wide range accident radiation monitoring subsystem is shared by both units of the plant. The system is designed to perform its safety function in the event of an accident in one unit and during the orderly shutdown and cooldown of the other unit.

7.6.2.1.8.2.2.6 NSE-RMS - GDC 13 - Instrumentation and Control

Operating ranges of the instrumentation cover normal plant operations, accident conditions, and postaccident conditions.

7.6.2.1.8.2.2.7 NSE-RMS - GDC 21 - Protection System Reliability and Testability

This system is designed for high functional reliability and inservice testability.

7.6.2.1.8.2.2.8 NSE-RMS - GDC 22 - Protection System Failure Modes

Two independent systems are provided. Within their operating ranges, redundancy and channel separation are provided, however only one system is provided for high range accident and postaccident conditions.

7.6.2.1.8.2.2.9 NSE-RMS - GDC 60 - Control of Releases of Radioactive Materials to the Environment

Surveillance is maintained of release of radioactive materials to the environment; however, remedial action is initiated by control room personnel.

7.6.2.1.8.2.2.10 NSE-RMS - GDC 64 - Monitoring Radioactive Releases

The requirement for monitoring radioactive releases from normal operations, anticipated operational occurrences, and from postulated accident is fulfilled.

7.6.2.1.8.2.3 NSE-RMS Conformance to 10CFR50, Appendix I

This system is equipped with instruments capable of state-of-the- art sensitivity to provide control room personnel with real-time information needed for restricting release of radioactive materials to limits as-low-as-practicable.

7.6.2.1.8.3 NSE-RMS Conformance to Industry Codes and Standards

7.6.2.1.8.3.1 NSE-RMS - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1 Electric Equipment for Nuclear Power Generating Stations

The wide range accident monitor is qualified to IEEE 323 (1974).

7.6.2.1.8.3.2 NSE-RMS - IEEE 344 (1971) - Guide for Seismic Qualifications of Class 1 Electric Equipment for Nuclear Power Generating Stations

The wide range accident monitor is qualified for seismic Category I as discussed in Section 7.6.2.1.8.2.1.3. Refer to Section 3.10.

7.6.2.1.8.3.3 NSE-RMS - IEEE 384 (1974) - Criteria for Separation of Class 1E Equipment and Circuits

The wide range accident monitor is designed in accordance with IEEE 384 (1974).

7.6.2.1.8.4 NSE-RMS Preoperational Checkout

Preoperational tests are conducted prior to initial startup. The tests ensure functioning of all components and controls. System reference characteristics such as setpoints are documented during preoperational testing and used as base points for measurements obtained during subsequent calibrations.

7.6.2.1.8.5 NSE-RMS Operational Tests

During plant operation, components of the NSE-RMS can be operationally tested at any time. Test frequency is consistent with the requirements of plant Technical Specifications.

7.6.2.2 High Pressure/Low Pressure Systems Interlocks - Instrumentation and Controls

7.6.2.2.1 HPLPSI General Functional Requirements Conformance

For conformance discussion, refer to Sections 7.3.2.1, 7.3.2.4, and 7.4.2.3.

7.6.2.2.2 HPLPSI Specific Regulatory Requirements Conformance

7.6.2.2.2.1 HPLPSI Conformance to Regulatory Guides

7.6.2.2.2.1.1 HPLPSI - Regulatory Guide 1.22 (1972) - Periodic Testing of Protection System Actuation Functions (Safety Guide 22)

Refer to Section 7.1.

7.6.2.2.2.1.2 HPLPSI - Regulatory Guide 1.29 (1978) - Seismic Design Classification

For compliance to Regulatory Guide 1.29, see Section 7.1.2.5.6.

7.6.2.2.2.1.3 HPLPSI - Regulatory Guide 1.30 (1972) - Quality Assurance Requirements for the Installation, Inspection, and Testing of Instrumentation and Electric Equipment (Safety Guide 30)

For compliance to Regulatory Guide 1.30, see Section 8.1.6.1.5.

See Section 7.6.2.2.2.3.3 on conformance to IEEE 338 (1971).

7.6.2.2.2.1.4 HPLPSI - Regulatory Guide 1.47 (1973) - Bypassed and Inoperable Status Indication for Nuclear Power Plant Safety Systems

Refer to Section 7.1.2.5.11.

7.6.2.2.2.1.5 HPLPSI - Regulatory Guide 1.53 (1973) - Application of the Single Failure Criterion to Nuclear Power Plant Protection Systems

See Section 7.6.2.2.2.3.4 on conformance to IEEE 379 (1972).

7.6.2.2.2.1.6 HPLPSI - Regulatory Guide 1.68 (1978) - Preoperational and Initial Startup Test Programs for Water-Cooled Power Reactors

Conformance is discussed in Section 14.2.

7.6.2.2.2.1.7 HPLPSI - Regulatory Guide 1.75 (1978) - Physical Independence of Electric Systems

See Section 7.1.2.5.19 on conformance to Regulatory Guide 1.75.

7.6.2.2.2.1.8 HPLPSI - Regulatory Guide 1.100 (1977) - Seismic Qualification of Electric Equipment for Nuclear Power Plants

See Section 3.10 for conformance to Regulatory Guide 1.100.

7.6.2.2.2.1.9 HPLPSI Regulatory Guide General Conformance Statement

Refer to Section 7.1.2.5 for a general conformance statement for Regulatory Guides 1.11, 1.45, 1.89, 1.105, and 1.118.

7.6.2.2.2.2 HPLPSI Conformance to 10CFR50, Appendix A, General Design Criteria

There are no general design criteria that apply to HPLPSI.

7.6.2.2.2.3 HPLPSI Conformance to Industry Codes and Standards

7.6.2.2.2.3.1 HPLPSI - IEEE 279 (1971) - Criteria for Protection Systems for Nuclear Power Generating Stations

The interlocks are designed in accordance with the single failure criterion, redundancy requirements, and testability criteria.

7.6.2.2.2.3.2 HPLPSI - IEEE 336 (1971) - Installation, Inspection, and Testing Requirements for Instrumentation and Electrical Equipment During the Construction of Nuclear Power Generating Stations

Conformance is discussed in Section 7.1.2.7.5.

7.6.2.2.2.3.3 HPLPSI - IEEE 338 (1971) - Criteria for the Periodic Testing of Nuclear Power Generating Station Protection Systems

The design of the interlocks is such that they can be tested during reactor operation except for the actuated devices (valves). The valves can be tested during startup and shutdown.

7.6.2.2.2.3.4 HPLPSI - IEEE 379 (1972) - Guide for the Application of the Single Failure Criterion to Nuclear Power Generating Station Protection Systems

The low pressure process lines are protected as defined in Section 7.6.1.2.3. Where two redundant MOVs are used, the valves are interlocked with independent pressure transmitters and trip units so that not more than one redundant interlock is disabled by a single failure. The RHR shutdown cooling suction valve F008 is provided with an additional interlock which prevents a fire-induced open signal from causing it to open simultaneously with valve F009 when the reactor pressure is greater than the design capabilities of the RHR low-pressure piping. When only one MOV is used, a check valve is used in series with the MOV. The check valve will not open until reactor pressure has decreased to a value less than the low pressure process line design value.

7.6.2.2.2.3.5 HPLPSI IEEE General Conformance Statement

Refer to Section 7.1.2.7 for a general conformance statement for IEEE 308 (1974), 323 (1971), 344 (1971), and 384 (1974).

7.6.2.3 Leak Detection System - Instrumentation and Controls

7.6.2.3.1 LDS General Functional Requirements Conformance

The safety-related portions of the leak detection system are part of the PCRVICS, and conform to the design basis requirements for the PCRVICS as described in Section 7.3.1.1.2.1.

7.6.2.3.2 LDS Specific Regulatory Requirements Conformance

7.6.2.3.2.1 LDS Conformance to Regulatory Guides

7.6.2.3.2.1.1 LDS - Regulatory Guide 1.22 (1972) - Periodic Testing of Protection System Actuation Functions (Safety Guide 22)

The portion of the LDS that provides outputs to the system isolation logic is designed so that complete periodic testing of the isolation system actuation function is possible. This is accomplished by tripping the leak detection system one channel at a time from the leak detection panel in the control room. An indicator lamp is provided to show that the particular channel is tripped.

7.6.2.3.2.1.2 LDS - Regulatory Guide 1.29 (1978) - Seismic Design Classification

All equipment that performs an isolation function is qualified to seismic Category I criteria (Section 3.10). The application of this equipment in the turbine enclosure is discussed in Section 7.3.2.2.2.3.1.5.

7.6.2.3.2.1.3 LDS - Regulatory Guide 1.30 (1972) - Quality Assurance Requirements for the Installation, Inspection, and Testing of Instrumentation and Electric Equipment (Safety Guide 30)

For conformance discussion refer to Section 7.1.2.5.7.

7.6.2.3.2.1.4 LDS - Regulatory Guide 1.47 (1973) - Bypassed and Inoperable Status Indication for Nuclear Power Plant Safety Systems

The LDS annunciates all bypass conditions.

7.6.2.3.2.1.5 LDS - Regulatory Guide 1.53 (1973) - Application of the Single Failure Criterion to Nuclear Power Plant Protection Systems

The portions of the LDS that provide outputs to system isolation logic comply with this guide. Discussion is provided in Section 7.1.2.5.12 under Regulatory Guide 1.53.

7.6.2.3.2.1.6 LDS - Regulatory Guide 1.68 (1978) - Preoperational and Initial Startup Test Programs for Water-Cooled Reactor Power Reactors

The degree of conformance is discussed in Section 7.1.2.5.

7.6.2.3.2.1.7 LDS - Regulatory Guide 1.75 (1978) - Physical Independence of Electric Equipment

For a conformance discussion see Section 7.1.2.5.19.

7.6.2.3.2.1.8 LDS - Regulatory Guide 1.89 (1974) - Qualification of Class 1E Equipment for Nuclear Power Plants

The degree of conformance is discussed in Section 7.1.2.5.

7.6.2.3.2.1.9 LDS - Regulatory Guide 1.100 (1977) - Seismic Qualification of Electric Equipment for Nuclear Power Plants

See Section 3.10 for discussion of the degree of conformance.

7.6.2.3.2.1.10 LDS - Regulatory Guide 1.105 (1976) - Instrument Setpoints

See Section 7.1.2.5.25 for a discussion of the degree of conformance.

7.6.2.3.2.1.11 LDS - Regulatory Guide 1.118 (1978) - Periodic Testing of Electric Power and Protection Systems

See Section 7.1.2.5.26 for the discussion of the degree of conformance.

7.6.2.3.2.2 LDS Conformance to 10CFR50, Appendix A, General Design Criteria

7.6.2.3.2.2.1 LDS - GDC 1 - Quality Standards and Records

A quality assurance program for the LDS is established and implemented in order to provide adequate assurance that the system will satisfactorily perform its safety functions.

7.6.2.3.2.2.2 LDS - GDC 2 - Design Bases for Protection Against Natural Phenomena

For a conformance discussion, refer to Section 7.1.2.6.2.

7.6.2.3.2.2.3 LDS - GDC 3 - Fire Protection

For a conformance discussion, refer to Section 7.1.2.6.3.

7.6.2.3.2.2.4 LDS - GDC 4 - Environmental and Dynamic Effects Design Bases

For a conformance discussion, refer to Section 7.1.2.6.4.

7.6.2.3.2.2.5 LDS - GDC 10 - Reactor Design

The LDS is designed with an appropriate margin to monitor leakage from the RCPB.

7.6.2.3.2.2.6 LDS - GDC 13 - Instrumentation and Control

The leak detection sensors and associated electronics are designed to monitor the reactor coolant leakage over all expected ranges required for the safety of the plant.

Automatic initiation of the system isolation action, reliability, testability, independence, and separation are factored into leak detection design as required for isolation systems.

7.6.2.3.2.2.7 LDS - GDC 19 - Control Room

Controls and instrumentation are provided in the control room.

7.6.2.3.2.2.8 LDS - GDC 20 - Protection System Functions

Leak detection equipment senses accident conditions and initiates the PCRVICS when appropriate.

7.6.2.3.2.2.9 LDS - GDC 21 - Protection System Reliability and Testability

Protection-related equipment is arranged in two redundant divisions and maintained separately. Testing is covered in the conformance discussion for Regulatory Guide 1.22.

7.6.2.3.2.2.10 LDS - GDC 22 - Protection System Independence

Protection-related equipment is arranged in two redundant divisions so that no single failure can prevent isolation. Diversity of sensed variables is utilized.

7.6.2.3.2.2.11 LDS - GDC 23 - Protection System Failure Modes

Signals provided are such that isolation logic is fail-safe.

7.6.2.3.2.2.12 LDS - GDC 24 - Separation of Protection and Control Systems

The system has no control functions.

7.6.2.3.2.2.13 LDS - GDC 29 - Protection Against Anticipated Operational Occurrences

No anticipated operational occurrence can prevent an isolation.

7.6.2.3.2.2.14 LDS - GDC 30 - Quality of Reactor Coolant Pressure Boundary

The system provides means for the detection and general location of the source of reactor coolant leakage.

7.6.2.3.2.2.15 LDS - GDC 34 - Residual Heat Removal

Leak detection is provided for RHR lines penetrating the drywell.

7.6.2.3.2.2.16 LDS - GDC 35 - Emergency Core Cooling

ECCS leak detection is augmented by the sump monitoring system portion of the leak detection system. ECCS leaks can be identified by operator correlation of various flow, pressure, and reactor vessel level signals transmitted to the control room.

7.6.2.3.2.2.17 LDS - GDC 54 - Piping Systems Penetrating Containment

Leak detection is provided for main steam, RCIC, and RWCU lines penetrating the containment.

7.6.2.3.2.3 LDS Conformance to Industry Codes and Standards

7.6.2.3.2.3.1 LDS - IEEE 279 (1971) and 379 (1972) - Guide for the Application of the Single Failure Criterion

LDS isolation functions compliance with IEEE 279 (1971) and 379 (1972), is included in the IEEE 279 and 379 compliance discussions of the PCRVICS Section 7.3.2.2.3.1, for which this system provides logic trip signals.

7.6.2.3.2.3.2 LDS - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1 Electric Equipment for Nuclear Power Generating Stations

Leak detection compliance is shown in Section 7.1.2.7.4.

7.6.2.3.2.3.3 LDS - IEEE 336 (1971) - Installation, Inspection, and Testing Requirements for Instrumentation and Electric Equipment During the Construction of Nuclear Power Generating Stations

For a conformance discussion, refer to Section 7.1.2.7.5.

7.6.2.3.2.3.4 LDS - IEEE 338 (1971) - Criteria for the Periodic Testing of Nuclear Power Generating Station Protection Systems

Leak detection complies with IEEE 338 (1971). All active components of the LDS associated with the isolation signal can be tested during plant operation.

7.6.2.3.2.3.5 LDS - IEEE 344 (1971) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations

Leak detection system compliance is shown in Section 3.10.

7.6.2.3.2.3.6 LDS - IEEE 379 (1972) - Guide for the Application of the Single Failure Criterion to Nuclear Power Generation Station Protection Systems

The degree of conformance is discussed in Section 7.1.2.7.8.

7.6.2.3.2.3.7 LDS - IEEE 384 (1977) - Criteria for Separation of Class 1E Equipment and Circuits

For an assessment, refer to Section 7.1.2.7.11.

7.6.2.4 Neutron Monitoring System - Instrumentation and Controls

7.6.2.4.1 Intermediate Range Monitor System

7.6.2.4.1.1 IRM General Functional Requirements Conformance

The analysis for the RPS trip inputs from the IRM system are discussed in Section 7.2.2.

7.6.2.4.1.2 IRM Power Generation Design Basis

The IRM is the primary source of information as the reactor approaches the power range. Its linear steps (approximately a half decade) and the rod blocking features on both high flux level and low flux level require that all the IRMs be on the correct range as core power is increased. The SRM overlaps the IRM. The sensitivity of the IRM is such that the IRM is on scale on the least sensitive (highest) range with approximately 15% reactor power.

The number and locations of the IRM detectors provide sufficient intermediate range neutron flux level information under the worst permitted bypass conditions. To ensure that each IRM is on the correct range, a rod block is initiated any time the IRM is both downscale and not on the most sensitive (lowest) scale. A rod block is initiated if the IRM detectors are not fully inserted in the core, unless the reactor mode switch is in the RUN position.

The IRM scram trips and the IRM rod block trips are automatically bypassed when the reactor mode switch is in the RUN position.

The IRM detectors and electronics have been tested under operating conditions and verified to have the operational characteristics described. They provide the level of precision and reliability required by the RPS safety design bases.

7.6.2.4.1.3 IRM Specific Regulatory Requirements Conformance

7.6.2.4.1.3.1 IRM Conformance with Regulatory Guides

7.6.2.4.1.3.1.1 IRM - Regulatory Guide 1.22 (1972) - Periodic Testing of Protection System Actuation Functions (Safety Guide 22)

The portion of the IRM system that provides outputs to the RPS is designed to allow complete periodic testing of protection system actuation function as desired. The provision is accomplished by initiating an output trip of one IRM channel at any given time, which results in tripping one of the two RPS trip systems. Details are provided in the discussion of IEEE 279 (Section 7.2.2.1.2.3.1).

Indication of IRM bypass to operators is provided by indicator lamps.

7.6.2.4.1.3.1.2 IRM - Regulatory Guide 1.29 (1978) - Seismic Design Classification

All devices and circuitry from sensor to trip output are classified Category I (Section 7.1.2.5.6).

7.6.2.4.1.3.1.3 IRM - Regulatory Guide 1.30 (1972) - Quality Assurance Requirements for the Installation, Inspection, and Testing of Instrumentation and Electric Equipment (Safety Guide 30)

For compliance with Regulatory Guide 1.30, see Section 8.1.6.1.

7.6.2.4.1.3.1.4 IRM - Regulatory Guide 1.47 (1973) - Bypassed and Inoperable Status Indication for Nuclear Power Plant Safety Systems

The IRM complies with this guide. Discussion is provided in Section 7.2.2.1.2.

7.6.2.4.1.3.1.5 IRM - Regulatory Guide 1.53 (1973) - Application of the Single Failure Criterion to Nuclear Power Plant Protection Systems

The IRM complies with this guide. Discussion is provided in Section 7.2.2.1.2.1.8 under Regulatory Guide 1.53.

7.6.2.4.1.3.1.6 IRM - Regulatory Guide 1.68 (1978) - Preoperational and Initial Startup Test Programs for Water-Cooled Power Reactors

For conformance discussion refer to Section 7.1.2.5.16.

7.6.2.4.1.3.1.7 IRM - Regulatory Guide 1.75 (1978) - Physical Independence of Electric Systems

For conformance discussion refer to Section 7.1.2.5.19.

7.6.2.4.1.3.1.8 IRM - Regulatory Guide 1.89 (1974) - Qualification of Class 1E Equipment for Nuclear Power Plants

The IRM complies with this guide. Discussion is provided in Section 7.2.2.1.2.

7.6.2.4.1.3.1.9 IRM - Regulatory Guide 1.100 (1977) - Seismic Qualification of Electric Equipment for Nuclear Power Plants

The IRM complies with this guide. Discussion is provided in Section 7.2.2.1.2.

7.6.2.4.1.3.1.10 IRM - Regulatory Guide 1.105 (1976) - Instrument Setpoints

The IRM complies with this guide. Discussion is provided in Section 7.2.2.1.2.

7.6.2.4.1.3.1.11 IRM - Regulatory Guide 1.118 (1978) - Periodic Testing of Electric Power and Protection Systems

The IRM complies with this guide. Discussion is provided in Section 7.2.2.1.2.

7.6.2.4.1.3.2 IRM Conformance with 10CFR50, Appendix A, General Design Criteria

7.6.2.4.1.3.2.1 IRM - GDC 1 - Quality Standards and Records

The IRM, as an input to the RPS, complies with these criteria as discussed in Section 7.2.2.1.2.2.1.

7.6.2.4.1.3.2.2 IRM - GDC 2 - Design Bases for Protection Against Natural Phenomena

The IRM, as an input to the RPS, complies with these criteria as discussed in Section 7.2.2.1.2.2.2.

7.6.2.4.1.3.2.3 IRM - GDC 3 - Fire Protection

The IRM, as an input to the RPS, complies with these criteria as discussed in Section 7.2.2.1.2.2.3.

7.6.2.4.1.3.2.4 IRM - GDC 4 - Environmental and Dynamic Effects Design Bases

The IRM, as an input to the RPS, complies with these criteria as discussed in Section 7.2.2.1.2.2.4.

7.6.2.4.1.3.2.5 IRM - GDC 10 - Reactor Design

The IRM, as an input to the RPS, complies with these criteria as discussed in Section 7.2.2.1.2.2.5.

7.6.2.4.1.3.2.6 IRM - GDC 12 - Suppression of Reactor Power Oscillations

The IRM, as an input to the RPS, complies with these criteria as discussed in Section 7.2.2.1.2.2.6.

7.6.2.4.1.3.2.7 IRM - GDC 13 - Instrumentation and Control

The IRM detectors and associated electronics are designed to monitor the incore flux over all expected ranges required for the safety of the plant.

7.6.2.4.1.3.2.8 IRM - GDC 19 - Control Room

The IRM detectors and associated electronics are designed to monitor the incore flux over all expected ranges required for the safety of the plant.

7.6.2.4.1.3.2.9 IRM - GDC 20 - Protection System Functions

The IRM detectors and associated electronics are designed to monitor the incore flux over all expected ranges required for the safety of the plant.

7.6.2.4.1.3.2.10 IRM - GDC 21 - Protection System Reliability and Testability

Automatic initiation of protection system action, reliability, testability, independence, and separation are factored into the IRM design as required for protection systems.

7.6.2.4.1.3.2.11 IRM - GDC 22 - Protection System Independence

Automatic initiation of protection system action, reliability, testability, independence, and separation are factored into the IRM design as required for protection systems.

7.6.2.4.1.3.2.12 IRM - GDC 23 - Protection System Failure Modes

Automatic initiation of protection system action, reliability, testability, independence, and separation are factored into the IRM design as required for protection systems.

7.6.2.4.1.3.2.13 IRM - GDC 24 - Separation of Protection and Control Systems

Automatic initiation of protection system action, reliability, testability, independence, and separation are factored into the IRM design as required for protection systems.

7.6.2.4.1.3.2.14 IRM - GDC 25 - Protection System Requirements for Reactivity Control Malfunctions

Automatic initiation of protection system action, reliability, testability, independence, and separation are factored into the IRM design as required for protection systems.

7.6.2.4.1.3.2.15 IRM - GDC 29 - Protection Against Anticipated Operational Occurrences

Automatic initiation of protection system action, reliability, testability, independence, and separation are factored into the IRM design as required for protection systems.

7.6.2.4.1.3.3 IRM Conformance to Industry Codes and Standards

7.6.2.4.1.3.3.1 IRM - IEEE 279 (1971) - Criteria for Protection Systems for Nuclear Power Generating Stations

The IRM design is shown to comply with the design requirements of IEEE 279 in Section 7.2.2.1.2.3.1.

7.6.2.4.1.3.3.2 IRM - IEEE 317 (1972) - Electric Penetration Assemblies in Containment Structures for Nuclear Power Generating Stations

IRM conformance with IEEE 317 (1972) is endorsed by Regulatory Guide 1.63 (1978). For compliance to Regulatory Guide 1.63, see Section 8.1.6.1.

7.6.2.4.1.3.3.3 IRM - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1 Electric Equipment for Nuclear Power Generating Stations

Written procedures and responsibilities are developed for the design and qualification of all Class 1E equipment. This includes preparation of specifications, qualification procedures, and documentation. Whenever possible, qualification testing or analysis is accomplished prior to release of the engineering design for production. Standards manuals are maintained and contain specifications, practices, and procedures for implementing qualification requirements; an auditable file of qualification documents is available for review.

7.6.2.4.1.3.3.4 IRM - IEEE 336 (1971) - Installation, Inspection, and Testing Requirements for Instrumentation and Electric Equipment During the Construction of Nuclear Power Generating Stations

IEEE 336 (1971) is endorsed by Regulatory Guide 1.30 (1972). For compliance to Regulatory Guide 1.30, see Section 8.1.6.1.

7.6.2.4.1.3.3.5 IRM - IEEE 338 (1971) - Criteria for the Periodic Testing of Nuclear Power Generating Station Protection Systems

IRM compliance with IEEE 338 is provided in Section 7.2.2.1.2.3.1 under IEEE 279, Paragraphs 4.9 and 4.10.

7.6.2.4.1.3.3.6 IRM - IEEE 344 (1971) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations

The IRMs are qualified for seismic events. Compliance is further shown in Section 3.10.

7.6.2.4.1.3.3.7 IRM - IEEE 379 (1972) - Guide for the Application of the Single Failure Criterion to Nuclear Power Generating Station Protection Systems

IRM signal separation, cabinet separation, use of isolation circuitry, and number of channels per trip system are methods used to meet the single failure criterion. Convenient tests and calibration circuits permit frequent checks for undetected failures.

7.6.2.4.1.3.3.8 IRM - IEEE 384 (1977) - Criteria for Separation of Class 1E Equipment and Circuits

For conformance discussion refer to Section 7.3.2

7.6.2.4.2 Local Power Range Monitor System

7.6.2.4.2.1 LPRM General Functional Requirement Conformance

The LPRM provides detailed information about neutron flux throughout the reactor core. The number of LPRM assemblies and their distribution is determined by extensive calculational and

experimental procedures. The division of the LPRM into various groups for ac power supply allows operation with one ac power supply failed or out-of-service without limiting reactor operation. Individual failed chambers can be bypassed. Neutron flux information for a failed chamber location can be interpolated from nearby chambers. A substitute reading for a failed chamber can be derived from an octant-symmetric chamber, or an actual flux indication can be obtained by inserting a TIP to the failed chamber position. Each output is electrically isolated so that an event (grounding the signal or applying a stray voltage) on the reception end does not destroy the validity of other LPRM signals. Tests and experience attest to the ability of the detector to respond proportionally to the local neutron flux changes.

The LPRM design conforms with the provisions of the safety design basis in that there are sufficient LPRM detectors to ensure that under worst case LPRM bypass conditions the APRM is capable of generating a trip signal to prevent fuel damage. The LPRM system utilizes 43 detector assemblies, each assembly monitoring all four axial planes in the core. Sufficient LPRM channels are assigned to each APRM channel to provide a valid signal for average core flux, even with the maximum number of channels bypassed. When more than the maximum allowable number of LPRM channels associated with an APRM channel are bypassed, an APRM trouble alarm occurs.

The LPRM design conforms to the provisions of the power generation design basis as follows:

a. The LPRM signals are proportional to the local neutron flux at various locations in the core. The LPRM subsystem utilizes 43 detector assemblies, each assembly consisting of four fission chambers located in different axial positions. The detector output characteristic is linear with neutron flux in the power range.

b. The LPRM system has trips for LPRM downscale and upscale. The trips are annunciated in the control room.

c. The LPRM provides signals to the process computer system which, utilizing additional inputs, computes local power densities for each fuel assembly, core power distribution, core thermal limits, and fuel exposure.

d. The LPRM provides signals to the RBM for the rod block trip function. When the averaged LPRM signal exceeds the rod block setpoint, control rod withdrawal is inhibited.

7.6.2.4.2.2 LPRM Specific Regulatory Requirements Conformance

7.6.2.4.2.2.1 LPRM Conformance to Regulatory Guides

7.6.2.4.2.2.1.1 LPRM - Regulatory Guide 1.22 (1972) - Periodic Testing of Protection System Actuation Functions (Safety Guide 22)

Refer to Section 7.1.2.5.5b for a general conformance statement for Regulatory Guide 1.22.

7.6.2.4.2.2.1.2 LPRM - Regulatory Guide 1.30 (1972) - Quality Assurance Requirements for the Installation, Inspection, and Testing of Instrumentation and Electric Equipment (Safety Guide 30)

For compliance to Regulatory Guide 1.30, see Section 8.1.6.1.

7.6.2.4.2.2.1.3 LPRM - Regulatory Guide 1.66 (1973) - Nondestructive Testing of Nuclear Products

This regulatory guide has been withdrawn by the NRC. The LPRM assembly dry tube was nondestructively examined in accordance with ASTM and ASME requirements; however, it was exempt from the requirements of Regulatory Guide 1.66 under note 3 of section C.

7.6.2.4.2.2.1.4 LPRM - Regulatory Guide 1.89 (1974) - Qualification of Class 1E Equipment for Nuclear Power Plants

Refer to Section 7.1.2.5.21 for a general conformance statement for Regulatory Guide 1.89.

7.6.2.4.2.2.2 LPRM Conformance to Industry Codes and Standards

7.6.2.4.2.2.2.1 LPRM - IEEE 279 (1971) - Criteria for Protection Systems for Nuclear Power Generating Stations

7.6.2.4.2.2.2.1.1 LPRM - IEEE 279 (1971), Paragraph 4.1 - General Functional Requirement

The LPRMs continuously supply flux level signals to the assigned APRM channel, which will automatically initiate the appropriate protective action whenever the core average flux reaches the trip setpoint.

7.6.2.4.2.2.2.1.2 LPRM - IEEE 279 (1971), Paragraph 4.2 - Single Failure Criterion

The LPRM is divided into four separate groups such that even in the event of a single failure under permissible APRM bypass conditions a scram signal can be generated in the RPS. Physical panel barriers and electrical isolation provides independence between groups. Redundant wiring and trip logic is physically separated to prevent a single failure from impairing a protective action.

7.6.2.4.2.2.2.1.3 LPRM - IEEE 279 (1971), Paragraph 4.3 - Quality of Components and Modules

LPRM signals are processed by modules and components used on previous GE BWR plants which have exhibited high quality and reliability.

The detectors and related drive equipment as well as the trip logic circuitry are also of high quality and reliability.

7.6.2.4.2.2.2.1.4 LPRM - IEEE 279 (1971), Paragraph 4.4 - Equipment Qualification

Qualification tests of LPRM equipment are conducted to confirm their adequacy for service. Environmental qualification is discussed in detail in Section 3.11.

7.6.2.4.2.2.2.1.5 LPRM - IEEE 279 (1971) Paragraph 4.5 - Channel Integrity

All components of LPRM are designed to operate under abnormal conditions of environment, power supply, and accidents.

7.6.2.4.2.2.2.1.6 LPRM - IEEE 279 (1971), Paragraph 4.6 - Channel Independence

The redundant channels of LPRM monitoring circuitry are physically separated from one another in conformance with this requirement.

7.6.2.4.2.2.2.1.7 LPRM - IEEE 279 (1971), Paragraph 4.7 - Control and Protective System Interaction

The LPRM output signals to the APRM are isolated from the output to the RBM. A failure in the RBM circuitry will not affect the output signal necessary for proper functioning of the APRM or RPS. Furthermore the APRM is designed such that a fault in any single LPRM output will not affect any other LPRMs supplying inputs to the same APRM channel.

7.6.2.4.2.2.2.1.8 LPRM - IEEE 279 (1971), Paragraph 4.8 - Deviation of System Inputs

The LPRM detector directly measures local neutron flux, which is a direct measure of local core power density.

7.6.2.4.2.2.2.1.9 LPRM - IEEE 279 (1971), Paragraph 4.9 - Capability for Sensor Checks

Proper detector operation can be verified during normal power operation by comparing detector response with TIP system response.

7.6.2.4.2.2.2.1.10 LPRM - IEEE 279 (1971), Paragraph 4.10 - Capability for Testing and Calibration

The gain adjustments for LPRMs are determined from process computer computations based on TIP flux measurements and reactor heat balance data.

7.6.2.4.2.2.2.1.11 LPRM - IEEE 279 (1971), Paragraph 4.11 - Channel Bypass or Removal from Operation

Each LPRM channel can be individually bypassed. When more than the permissible number of LPRM channels associated with an APRM channel is bypassed, an APRM trouble alarm is generated by that APRM.

7.6.2.4.2.2.2.1.12 LPRM - IEEE 279 (1971), Paragraph 4.12 - Operating Bypasses

There are no operating bypass circuits provided for the LPRM or the APRM systems.

7.6.2.4.2.2.2.1.13 LPRM - IEEE 279 (1971), Paragraph 4.13 - Indication of Bypasses

ODAs in the control room indicate bypassed LPRM channels.

7.6.2.4.2.2.2.1.14 LPRM - IEEE 279 (1971), Paragraph 4.14 - Access to Means for Bypassing

Manual bypassing of LPRM channels is accomplished by manual entry of settings in the NUMAC electronics, which are under the administrative control of the operator.

7.6.2.4.2.2.2.1.15 LPRM - IEEE 279 (1971), Paragraph 4.15 - Multiple Setpoints

The LPRM has no varying or multiple setpoints.

7.6.2.4.2.2.2.1.16 LPRM - IEEE 279 (1971), Paragraph 4.16 - Completion of Protective Action Once It Is Initiated

See Section 7.2.2.1.2.3.1.16.

7.6.2.4.2.2.2.1.17 LPRM - IEEE 279 (1971), Paragraph 4.17 - Manual Initiation

See Section 7.2.2.1.2.3.1.17.

7.6.2.4.2.2.2.1.18 LPRM - IEEE 279 (1971), Paragraph 4.18 - Access to Setpoint Adjustments, Calibration, and Test Points

Access to LPRM setpoint adjustments, calibration controls, and test setpoints is under the administrative control of plant supervisors.

7.6.2.4.2.2.2.1.19 LPRM - IEEE 279 (1971), Paragraph 4.19 - Identification of Protective Actions

See Section 7.2.2.1.2.3.1.19.

7.6.2.4.2.2.2.1.20 LPRM - IEEE 279 (1971), Paragraph 4.20 - Information Readout

The LPRM provides signals to the APRM for display of neutron flux level. Signals are also provided to the process computer, which, utilizing additional inputs, computes local power densities for each fuel assembly, core power distribution, core thermal units, and fuel exposure. LPRM upscale, downscale, and inoperative signals are annunciated in the control room.

7.6.2.4.2.2.2.1.21 LPRM - IEEE 279 (1971), Paragraph 4.21 - System Repair

Replacement of LPRM detectors must be accomplished during plant shutdown. Repair of the LPRM circuitry can be accomplished during plant operation by bypassing the affected channel. The design of the system facilitates rapid diagnosis and repair.

7.6.2.4.2.2.2.1.22 LPRM - IEEE 279 (1971), Paragraph 4.22 - Identification of Protective Systems

Each system cabinet is marked and the particular division is indicated on a marker plate. Cabling outside the cabinet is distinctively marked as are cable trays and racks.

7.6.2.4.2.2.2.2 LPRM - IEEE 317 (1972) - Electric Penetration Assemblies for Containment Structures for Nuclear Power Generating Stations

IEEE 317 (1972) is endorsed by Regulatory Guide 1.63 (1978). For compliance to Regulatory Guide 1.63, see Section 8.1.6.1.

7.6.2.4.2.2.2.3 LPRM - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1 Electric Equipment for Nuclear Power Generating Stations

The LPRM equipment is qualified per the requirements of the standard.

7.6.2.4.2.2.2.4 LPRM - IEEE 336 (1971) - Installation, Inspection, and Testing Requirements for Instrumentation and Electric Equipment During the Construction of Nuclear Power Generating Stations

IEEE 336 (1971) is endorsed by Regulatory Guide 1.30 (1972). For conformance to Regulatory Guide 1.30, see Section 8.1.6.1.5.

7.6.2.4.2.2.2.5 LPRM - IEEE 338 (1971) - Criteria for the Periodic Testing of Nuclear Power Generating Station Protection Systems

LPRM equipment is designed so that individual channels can be taken out-of-service for test or calibration without affecting the remaining channels.

7.6.2.4.2.2.2.6 LPRM - IEEE 344 (1971) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations

The LPRM equipment is designed and qualified to function during and after an SSE. Refer to Section 3.10.

7.6.2.4.2.2.2.7 LPRM - IEEE 379 (1972) - Guide for the Application of the Single Failure Criterion to Nuclear Power Generating Station Protection Systems

The LPRM equipment is designed so that a single failure does not prevent needed safety functions.

7.6.2.4.2.2.2.8 LPRM - IEEE 384 (1974) - Criteria for Separation of Class 1E Equipment and Circuits

Refer to Section 7.1.2.7.11.

7.6.2.4.2.2.2.9 LPRM Conformance to 10CFR50, Appendix A, General Design Criteria

The degree of conformance is discussed in Section 7.6.2.4.3.2.2.

7.6.2.4.3 Average Power Range Monitor System

7.6.2.4.3.1 APRM General Functional Requirements Conformance

Each APRM derives its signal from LPRM information. The assignment, power separation, cabinet separation, and LPRM signal isolation are in accord with the safety design bases of the RPS. There are four APRM channels with the Reactor Protection System trip outputs from each routed to each of four APRM 2-out-of-4 voter channels. Two voter channels are associated with each Reactor Protection System trip system. This configuration allows one APRM channel to be bypassed plus one failure while still meeting the Reactor Protection System safety design basis.

Above a plant power level defined by Technical Specifications, the APRM power (and simulated thermal power) is adjusted periodically based on heat balance. This adjustment is made regularly at a rate sufficient to compensate for LPRM burnup and the related change in APRM values. However, coolant flow changes, control rod movements, and failed or bypassed LPRM inputs can also affect the relationship between APRM measured flux and reactor power. These predictable APRM variations are included in the analysis performed to determine minimum number of LPRM inputs required to be operable in order for the APRM channel to be operable. The analysis is performed, considering worst case combinations of failed LPRM inputs, at rate conditions by

assuming both continuous withdrawal of the maximum worth control rod and reduction of recirculation flow to 40% of rated flow. The minimum number of LPRM inputs for an APRM is determined such that the average of the remaining operable LPRM inputs still allows the APRM to track power excursions within the acceptance criteria assumed in plant safety analysis. If the number of operable LPRMs is less than required minimum, the APRM channel is declared inoperable.

There is also a minimum cells requirement applied to the OPRM upscale function. The minimum number of OPRM cells per APRM channel is established to ensure that thermal-hydraulic instabilities can be detected within the limits of the OPRM licensing methodology. If the number of cells is less than the required minimum, an OPRM/APRM trouble alarm is provided and the channel is declared inoperable.

The flow-referenced APRM scram setpoint is adequate to prevent fuel damage during an abnormal operational transient, as demonstrated in Chapter 15.

The APRM design conforms with the provision of the safety design bases in that under worst case LPRM bypass conditions the APRM is capable of generating a trip signal to prevent fuel damage. The APRM logic circuitry which interfaces with the RPS is discussed in Sections 7.2.1.1.4.2, 7.2.2.1.2.3.1.2, and 7.2.2.1.2.3.1.6.

The APRM design conforms to the provisions of the power generation design basis as follows:

a. Continuous indication of average reactor power is provided for the range of neutron flux from 0% to 125%.

b. An APRM upscale condition, or inoperative condition, or an APRM downscale condition, or a recirculation flow upscale condition, or less than the minimum number of LPRMs initiates a rod block. The rod block inhibits erroneous control rod motion to prevent circumstances that require a RPS protective action, and inhibits rod withdrawal when an APRM channel is disabled or unable to monitor core response.

c. Neutron flux level data are utilized by the process computer to compute power distribution and fuel exposure.

d. One primary APRM channel and one alternate APRM channel provide the reference reactor power signal for each RBM.

7.6.2.4.3.2 APRM Specific Regulatory Requirements Conformance

7.6.2.4.3.2.1 APRM Conformance to Regulatory Guides

7.6.2.4.3.2.1.1 APRM - Regulatory Guide 1.22 (1972) - Periodic Testing of Protection System Actuation Functions (Safety Guide 22)

The portion of the APRM system that provides output to the RPS, the APRM 2-out-of-4 voters, is designed to allow complete periodic testing of protection system actuation functions. This provision is accomplished by initiating an output trip of one APRM 2-out-of-4 voter channel at any given time, which results in tripping one of the two RPS trip systems. Details are provided in Section 7.2.2.1.2.3.1 under IEEE 279 (1971).

Indication of APRM bypass to operators is provided by indicator lamps and ODA displays.

7.6.2.4.3.2.1.2 APRM - Regulatory Guide 1.29 (1978) - Seismic Design Classification

For conformance discussion refer to Section 3.1.2.

7.6.2.4.3.2.1.3 APRM - Regulatory Guide 1.30 (1972) - Quality Assurance Requirements for the Installation, Inspection, and Testing of Instrumentation and Electric Equipment (Safety Guide 30)

For compliance to Regulatory Guide 1.30, see Section 8.1.6.1.

7.6.2.4.3.2.1.4 APRM - Regulatory Guide 1.47 (1973) - Bypassed and Inoperable Status Indication for Nuclear Power Plant Safety Systems

The APRM complies with these guides. Discussion is provided in Section 7.2.2.1.2.1.7 under Regulatory Guide 1.47.

7.6.2.4.3.2.1.5 APRM - Regulatory Guide 1.53 (1973) - Application of the Single Failure Criterion to Nuclear Power Plant Protection Systems

For conformance discussion refer to Section 7.1.2.5.12.

7.6.2.4.3.2.1.6 APRM - Regulatory Guide 1.68 (1978) - Preoperational and Initial Startup Test Programs for Water-Cooled Power Reactors

For conformance discussion refer to Section 7.1.2.5.16.

7.6.2.4.3.2.1.7 APRM - Regulatory Guide 1.75 (1978) - Physical Independence of Electric Systems

For conformance discussion refer to Section 7.1.2.5.19.

7.6.2.4.3.2.1.8 APRM - Regulatory Guide 1.89 (1974) - Qualification of Class 1E Equipment for Nuclear Power Plants

Refer to Section 7.1.2.5.21.

7.6.2.4.3.2.1.9 APRM Regulatory Guide 1.97 (1980) - Instrumentation for Light-Water-Cooled Nuclear Power Plants to Assess Plant and Environs Conditions During and Following an Accident

Section 7.5.2.5.1.1.2 contains a discussion of the degree of conformance.

7.6.2.4.3.2.1.10 APRM - Regulatory Guide 1.100 (1977) - Seismic Qualification of Electric Equipment for Nuclear Power Plants

See Section 3.10 for conformance.

7.6.2.4.3.2.1.11 APRM - Regulatory Guide 1.105 (1976) - Instrument Setpoints

For conformance discussion refer to Section 7.1.2.5.25.

7.6.2.4.3.2.1.12 APRM - Regulatory Guide 1.118 (1978) - Periodic Testing of Electric Power and Protection Systems

For conformance discussion refer to Section 7.1.2.5.26.

7.6.2.4.3.2.2 APRM Conformance to 10CFR50, Appendix A, General Design Criteria

7.6.2.4.3.2.2.1 APRM - GDC 1 - Quality Standards and Records

For conformance discussion see Section 7.1.2.6.1.

7.6.2.4.3.2.2.2 APRM - GDC 2 - Design Bases for Protection Against Natural Phenomena

For conformance discussion see Section 7.1.2.6.2.

7.6.2.4.3.2.2.3 APRM - GDC 3 - Fire Protection

For conformance discussion see Section 7.1.2.6.3.

7.6.2.4.3.2.2.4 APRM - GDC 4 - Environmental and Dynamic Effects Design Bases

For conformance discussion see Section 7.1.2.6.4.

7.6.2.4.3.2.2.5 APRM - GDC 10 - Reactor Design

For conformance discussion refer to Section 7.1.2.6.6 and 7.2.2.1.2.2.5.

The APRM detection system and associated electronics are designed to monitor the incore flux over all expected ranges required for safety of the plant.

Automatic initiation of protection system action, reliability, testability, independence, and separation are factored into the APRM design as required for protection systems.

7.6.2.4.3.2.2.6 APRM - GDC 12 - Suppression of Reactor Power Oscillations

Refer to Section 7.1.2.6.7 and 7.2.2.1.2.2.6.

7.6.2.4.3.2.2.7 APRM - GDC 13 - Instrumentation and Control

The APRM detection system and associated electronics are designed to monitor the incore flux over all expected ranges required for safety of the plant.

Automatic initiation of protection system action, reliability, testability, independence, and separation are factored into the APRM design as required for protection systems.

7.6.2.4.3.2.2.8 APRM - GDC 19 - Control Room

The APRM detection system and associated electronics are designed to monitor the incore flux over all expected ranges required for safety of the plant.

Automatic initiation of protection system action, reliability, testability, independence, and separation are factored into the APRM design as required for protection systems.

7.6.2.4.3.2.2.9 APRM - GDC 20 - Protection System Functions

The APRM detection system and associated electronics are designed to monitor the incore flux over all expected ranges required for safety of the plant.

Automatic initiation of protection system action, reliability, testability, independence, and separation are factored into the APRM design as required for protection systems.

7.6.2.4.3.2.2.10 APRM - GDC 21 - Protection System Reliability and Testability

Refer to Section 7.1.2.6.12.

The APRM detection system and associated electronics are designed to monitor the incore flux over all expected ranges required for safety of the plant.

Automatic initiation of protection system action, reliability, testability, independence, and separation are factored into the APRM design as required for protection systems.

7.6.2.4.3.2.2.11 APRM - GDC 22 - Protection System Independence

The APRM detection system and associated electronics are designed to monitor the incore flux over all expected ranges required for safety of the plant.

Automatic initiation of protection system action, reliability, testability, independence, and separation are factored into the APRM design as required for protection systems.

7.6.2.4.3.2.2.12 APRM - GDC 23 - Protection System Failure Modes

The APRM detection system and associated electronics are designed to monitor the incore flux over all expected ranges required for safety of the plant.

Automatic initiation of protection system action, reliability, testability, independence, and separation are factored into the APRM design as required for protection systems.

7.6.2.4.3.2.2.13 APRM - GDC 24 - Separation of Protection and Control Systems

The APRM detection system and associated electronics are designed to monitor the incore flux over all expected ranges required for safety of the plant.

Automatic initiation of protection system action, reliability, testability, independence, and separation are factored into the APRM design as required for protection systems.

7.6.2.4.3.2.2.14 APRM - GDC 25 - Protection System Requirements for Reactivity Control Malfunctions

For conformance discussion refer to Section 7.1.2.6.16.

The APRM detection system and associated electronics are designed to monitor the incore flux over all expected ranges required for safety of the plant.

Automatic initiation of protection system action, reliability, testability, independence, and separation are factored into the APRM design as required for protection systems.

7.6.2.4.3.2.2.15 APRM - GDC 29 - Protection Against Anticipated Operational Occurrences

Refer to Section 7.1.2.6.

The APRM detection system and associated electronics are designed to monitor the incore flux over all expected ranges required for safety of the plant.

Automatic initiation of protection system action, reliability, testability, independence, and separation are factored into the APRM design as required for protection systems.

7.6.2.4.3.2.3 APRM Conformance to Industry Codes and Standards

7.6.2.4.3.2.3.1 APRM - IEEE 279 (1971) - Criteria for Protection Systems for Nuclear Power Generating Stations

The APRM design is shown to comply with the design requirements of IEEE 279 in Section 7.2.2.1.2.3.1 and Subsection 4.4.1.1 of NEDC-32410P-A.

7.6.2.4.3.2.3.2 APRM - IEEE 317 (1972) - Electric Penetration Assemblies in Containment Structures for Nuclear Power Generating Stations

IEEE 317 (1972) is endorsed by Regulatory Guide 1.63 (1978). For compliance to Regulatory Guide 1.63, see Section 8.1.6.1.

7.6.2.4.3.2.3.3 APRM - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1 Electric Equipment for Nuclear Power Generating Stations

APRM compliance is discussed in Section 7.1.2.7.4.

7.6.2.4.3.2.3.4 APRM - IEEE 336 (1971) - Installation, Inspection, and Testing Requirements for Instrumentation and Electric Equipment During the Construction of Nuclear Power Generating Stations

IEEE 336 (1971) is endorsed by Regulatory Guide 1.30. For compliance to Regulatory Guide 1.30, see Section 8.1.6.1.

7.6.2.4.3.2.3.5 APRM - IEEE 338 (1971) - Criteria for the Periodic Testing of Nuclear Power Generating Station Protection Systems

APRM compliance with IEEE 338 is shown in Section 7.2.2.1.2.3.1 under IEEE 279, Paragraphs 4.9 and 4.10.

7.6.2.4.3.2.3.6 APRM - IEEE 344 (1971) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations

APRM compliance is as shown in Section 7.1.2.7.7.

7.6.2.4.3.2.3.7 APRM - IEEE 379 (1972) - Guide for the Application of the Single Failure Criterion to Nuclear Power Generating Station Protection Systems

APRM signal separation, cabinet separation, use of isolation circuitry, and number of channels per trip system are methods used to meet the single failure criterion. Convenient test and calibration circuits permit regular checks for undetected failures.

7.6.2.4.3.2.3.8 APRM - IEEE 384 (1977) - Criteria for Separation of Class 1E Equipment and Circuits

For conformance discussion refer to Section 7.1.2.7.11.

7.6.2.5 Safety/Relief Valve Position Indication System - Instrumentation and Controls

7.6.2.5.1 SRVPI General Functional Requirements Conformance

The system provides alarm and indication of SRV position in the control room and provides a means to test the monitoring channels during system operation.

7.6.2.5.2 SRVPI Specific Regulatory Requirements Conformance

7.6.2.5.2.1 SRVPI Conformance to Regulatory Guides

7.6.2.5.2.1.1 SRVPI - Regulatory Guide 1.29 (1978) - Seismic Design Classification

Conformance is discussed in Section 7.6.2.5.2.1.5.

7.6.2.5.2.1.2 SRVPI - Regulatory Guide 1.30 (1972) - Quality Assurance Requirements for the Installation, Inspection, and Testing of Instrumentation and Electric Equipment (Safety Guide 30)

Conformance is discussed in Section 8.1.6.1.

7.6.2.5.2.1.3 SRVPI - Regulatory Guide 1.89 (1974) - Qualification of Class 1E Equipment for Nuclear Power Plants

The SRVPI equipment is qualified for the environment expected during SRV discharge to the suppression pool and for 12 hours after a LOCA.

7.6.2.5.2.1.4 SRVPI - Regulatory Guide 1.97 (1980) - Instrumentation for Light-Water-Cooled Nuclear Power Plants to Assess Plant and Environs Conditions During and Following an Accident

Conformance is discussed in Section 7.5.2.5.1.1.2.

7.6.2.5.2.1.5 SRVPI - Regulatory Guide 1.100 (1977) - Seismic Qualification of Electric Equipment for Nuclear Power Plants

The SRVPI instrument is qualified to seismic Category I criteria in accordance with IEEE 344 (1975) and is mounted on seismic Category I equipment. The signal and power raceways for the system are routed through seismic Category I structures and are designated seismic Category IIA. Refer to Section 3.10.

7.6.2.5.2.2 SRVPI Conformance to 10CFR50, Appendix A, General Design Criteria

7.6.2.5.2.2.1 SRVPI - GDC 1 - Quality Standards and Records

The SRVPI is a nonsafety-related system designed and manufactured in accordance with approved documented procedures. A documented quality assurances program which complies with the pertinent quality assurance requirements of 10CFR50, Appendix B, is followed for installation of the instrumentation.

7.6.2.5.2.2.2 SRVPI - GDC 2 - Design Bases for Protection Against Natural Phenomena

Conformance is discussed in Section 7.6.2.5.2.1.5.

7.6.2.5.2.2.3 SRVPI - GDC 3 - Fire Protection

Fire resistant components are used throughout the SRVPI system.

7.6.2.5.2.2.4 SRVPI - GDC 4 - Environmental and Dynamic Effects Design Bases

Conformance is discussed in Section 7.1.2.6.4.

7.6.2.5.2.2.5 SRVPI - GDC 13 - Instrumentation and Control

The SRVPI system components are designed to provide indication during normal and accident conditions.

7.6.2.5.2.3 SRVPI Conformance to Industry Codes and Standards

7.6.2.5.2.3.1 SRVPI - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1 Electric Equipment for Nuclear Power Generating Stations

Conformance is discussed in Section 7.6.2.5.2.1.3.

7.6.2.5.2.3.2 SRVPI - IEEE 338 (1977) - Criteria for the Periodic Testing of Nuclear Power Generating Station Protection Systems

Provisions are made for the periodic testing of this system in accordance with IEEE Class 1E requirements.

7.6.2.5.2.3.3 SRVPI - IEEE 344 (1975) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations

Conformance is discussed in Section 7.6.2.5.2.1.5.

7.6.2.6 Containment Instrument Gas System - ADS Control - Instrumentation and Controls

7.6.2.6.1 CIGS-ADS General Functional Requirements Conformance

The following analysis demonstrates how the CIGS-ADS meets the safety design bases identified in Section 7.1.2.1.29.

The CIGS-ADS provides a backup supply of instrument gas to the ADS valves in the event that the non-safety-related CIGS equipment is not available. This function is safety-related. The ADS valves must be available for long-term operation. The ADS valves require a safety-related, seismic gas supply. The remainder of CIGS is non-safety-related, non-seismic.

7.6.2.6.2 CIGS-ADS Specific Regulatory Requirements Conformance

7.6.2.6.2.1 CIGS-ADS Conformance to Regulatory Guides

7.6.2.6.2.1.1 CIGS-ADS - Regulatory Guide 1.29 (1978) - Seismic Design Classification

All controls for the CIGS-ADS are seismic Category 1.

7.6.2.6.2.1.2 CIGS-ADS - Regulatory Guide 1.30 (1972) - Quality Assurance Requirements for the Installation, Inspection, and Testing of Instrumentation and Electric Equipment (Safety Guide 30)

See Section 8.1.6.1.

7.6.2.6.2.1.3 CIGS-ADS - Regulatory Guide 1.47 (1973) - Bypassed and Inoperable Status Indication for Nuclear Power Plant Safety Systems

A low pressure alarm in the control room alerts the operator to low pressure in either set of nitrogen bottles.

7.6.2.6.2.1.4 CIGS-ADS - Regulatory Guide 1.53 (1973) - Application of the Single Failure Criterion to Nuclear Power Plant Protection Systems

Compliance is discussed in Section 7.1.2.5.12.

7.6.2.6.2.1.5 CIGS-ADS - Regulatory Guide 1.89 (1974) - Qualification of Class 1E Equipment for Nuclear Power Plants

Compliance is discussed in Section 8.1.6.1.

7.6.2.6.2.1.6 CIGS-ADS - Regulatory Guide 1.97 (1980) - Instrumentation for Light-Water-Cooled Nuclear Power Plants to Assess Plant and Environs Conditions During and Following an Accident

Section 7.5.2.5.1.1.2 contains a discussion of the degree of conformance.

7.6.2.6.2.1.7 CIGS-ADS - Regulatory Guide 1.100 (1977) - Seismic Qualification of Electric Equipment for Nuclear Power Plants

See Section 3.10.

7.6.2.6.2.2 CIGS-ADS Conformance to 10CFR50, Appendix A, General Design Criteria

7.6.2.6.2.2.1 CIGS-ADS - GDC 1 - Quality Standards and Records

This system is built in accordance with an established quality assurance program.

7.6.2.6.2.2.2 CIGS-ADS - GDC 2 - Design Bases for Protection Against Natural Phenomena

Compliance is discussed in Section 7.1.2.6.2.

7.6.2.6.2.2.3 CIGS-ADS - GDC 3 - Fire Protection

Compliance is discussed in Section 7.1.2.6.3.

7.6.2.6.2.2.4 CIGS-ADS - GDC 4 - Environmental and Dynamic Effects Design Bases

Compliance is discussed in Section 7.1.2.6.4.

7.6.2.6.2.2.5 CIGS-ADS - GDC 20 - Protection System Functions

The transfer from the instrument gas compressors (CIGS) to the CIGS-ADS as the gas source for the ADS valves is initiated automatically by a low pressure sensor in the respective header.

7.6.2.6.2.2.6 CIGS-ADS - GDC 21 - Protection System Reliability and Testability

The system is redundant on a system level; i.e., each gas source supplies sufficient ADS valves to accomplish the safety function. Testing during normal operation is possible without disrupting operation of the CIGS.

7.6.2.6.2.2.7 CIGS-ADS - GDC 22 - Protection System Independence

Diversity is not required for this system.

7.6.2.6.2.2.8 CIGS-ADS - GDC 23 - Protection System Failure Modes

On loss of instrument air or electric power, the system fails into an alignment that supplies nitrogen to the ADS valves.

7.6.2.6.2.2.9 CIGS-ADS - GDC 24 - Separation of Protection and Control Systems

The CIGS-ADS has no plant control functions.

7.6.2.6.2.2.10 CIGS-ADS - GDC 29 - Protection Against Anticipated Operational Occurrences

The CIGS-ADS is designed to withstand anticipated operational occurrences by seismic and environmental qualification as described in Sections 3.10 and 3.11.

7.6.2.6.2.3 CIGS-ADS Conformance to Industry Codes and Standards

7.6.2.6.2.3.1 CIGS-ADS - IEEE 279 (1971) - Criteria for Protection Systems for Nuclear Power Generating Stations

7.6.2.6.2.3.1.1 CIGS-ADS - IEEE 279 (1971), Paragraph 4.1 - General Functional Requirement

On low supply pressure from the CIGS receivers, automatic transfer is effected to the CIGS-ADS gas bottles. The system is effective over the range of environmental conditions cited below:

a. Power supply voltages - Equipment is designed to operate within the range of voltages specified in Section 8.3.1.

b. Power supply frequency - Equipment is designed to operate within the range of power supply frequencies specified in Section 8.3.1.

c. Temperature - The system is operable at all temperatures that can result from a design basis LOCA.

d. Humidity - The system is operable at all humidities, including steam, that can result from a LOCA.

e. Pressure - The system is operable at all pressures resulting from a LOCA.

f. Radiation - The system is operable at all radiation levels expected for any design basis LOCA.

g. Vibration - The system will tolerate the conditions stated in Section 3.10.

h. Malfunction - The system will tolerate a single failure proof at the system level.

i. Accidents - The system will continue to operate during and following any DBA.

j. Fire - The system will tolerate raceway fires in a single division.

k. Explosions - Explosions are not defined in design bases.

l. Missiles - The system will tolerate any single missile destroying raceway, cabinet, or equipment in one division.

m. Lightning - Lightning damage to the electrical division powering the outboard isolation will render the system inoperative if the valve is closed on loss of power.

n. Floods - The plant is not subject to flooding, as discussed in Section 3.4.

o. Earthquake - The system will tolerate conditions stated in Section 3.10.

p. Wind and Tornado - All control equipment is located in a seismic Category 1 structure. See Section 3.3 for wind loadings.

q. System response times - The system response times are within the need to initiate alternate gas supply to the ADS valves.

r. System accuracies - Accuracies are within those needed for correct action.

s. Abnormal ranges of Sensed variables - Sensors are designed for the expected ranges and rates of change of variables.

7.6.2.6.2.3.1.2 CIGS-ADS - IEEE 279 (1971), Paragraph 4.2 - Single Failure Criterion

A single active or passive electrical or control failure will not prevent the CIGS-ADS from performing its design safety function.

7.6.2.6.2.3.1.3 CIGS-ADS - IEEE 279 (1971), Paragraph 4.3 - Quality of Components and Modules

All safety-related components are selected on the basis of suitability for the application. A quality assurance program is implemented.

7.6.2.6.2.3.1.4 CIGS-ADS - IEEE 279 (1971), Paragraph 4.4 - Equipment Qualification

The CIGS-ADS safety-related controls and instrumentation are qualified according to the requirements outlined in IEEE 323 (1971) as highlighted in Section 7.1.2.7.4. The qualifications criteria are identified in Sections 3.10 and 3.11. The parameters identified cover normal, abnormal, and accident environments.

7.6.2.6.2.3.1.5 CIGS-ADS - IEEE 279 (1971), Paragraph 4.5 - Channel Integrity

The CIGS-ADS meets the channel integrity objective by using the design features described in the other paragraphs of this section.

7.6.2.6.2.3.1.6 CIGS-ADS - IEEE 279 (1971), Paragraph 4.6 - Channel Independence

The CIGS-ADS is a two train system. The control, instrumentation, and power circuits to each train of the system are physically and electrically separate from electrical channels in another division.

7.6.2.6.2.3.1.7 CIGS-ADS - IEEE 279 (1971), Paragraph 4.7 - Control and Protection System Interaction

The CIGS-ADS has no interaction with the plant control systems. Control room annunciator circuits taking input from this system are electrically isolated from the system and cannot impair its operability.

7.6.2.6.2.3.1.8 CIGS-ADS - IEEE 279 (1971), Paragraph 4.8 - Derivation of System Inputs

The CIGS-ADS is initiated by low pressure in the normal ADS gas supply header, from a pressure switch in each header.

7.6.2.6.2.3.1.9 CIGS-ADS - IEEE 279 (1971), Paragraph 4.9 - Capability for Sensor Checks

The pressure sensors for the CIGS-ADS can be checked by introducing a substitute input and observing system initiation.

7.6.2.6.2.3.1.10 CIGS-ADS - IEEE 279 (1971), Paragraph 4.10 - Capability for Testing and Calibration

The pressure sensors used for system initiation can be tested and calibrated during power operation.

7.6.2.6.2.3.1.11 CIGS-ADS - IEEE 279 (1971), Paragraph 4.11 - Channel Bypass or Removal from Operation

The two CIGS-ADS trains are separate electrically and physically. Removal of a component for maintenance prevents the operation of one train; however, operation of the other train is unaffected. The CIGS-ADS cannot be bypassed because all control is manual.

7.6.2.6.2.3.1.12 CIGS-ADS - IEEE 179 (1971), Paragraph 4.12 - Operating Bypasses

There are no operating bypasses.

7.6.2.6.2.3.1.13 CIGS-ADS - IEEE 279 (1971), Paragraph 4.13 - Indication of Bypasses

A system out-of-service annunciator will be manually brought up by administrative procedures whenever system tests are performed.

7.6.2.6.2.3.1.14 CIGS-ADS - IEEE 279 (1971), Paragraph 4.14 - Access to Means for Bypassing

Access to components of the CIGS-ADS is controlled by administrative procedures.

7.6.2.6.2.3.1.15 CIGS-ADS - IEEE 279 (1971), Paragraph 4.15 - Multiple Setpoints

This paragraph is not applicable.

7.6.2.6.2.3.1.16 CIGS-ADS - IEEE 279 (1971), Paragraph 4.16 - Completion of Protective Action Once It Is Initiated

The CIGS-ADS, once initiated, will perform its protective action to completion. The operator must reset the system to normal status.

7.6.2.6.2.3.1.17 CIGS-ADS - IEEE 279 (1971), Paragraph 4.17 - Manual Initiation

The CIGS-ADS can be manually initiated.

7.6.2.6.2.3.1.18 CIGS-ADS - IEEE 279 (1971), Paragraph 4.18 - Access to Setpoint Adjustments, Calibration and Test Points

Access is controlled by administrative procedures.

7.6.2.6.2.3.1.19 CIGS-ADS - IEEE 279 (1971), Paragraph 4.19 - Identification of Protective Actions

The positions of valves in the CIGS-ADS is indicated in the control room. Low gas supply header pressure is alarmed.

7.6.2.6.2.3.1.20 CIGS-ADS - IEEE 279 (1971), Paragraph 4.20 - Information Readout

Valve position and low gas supply header pressure provides information to assure the operator of correct operation.

7.6.2.6.2.3.1.21 CIGS-ADS - IEEE 279 (1971), Paragraph 4.21 - System Repair

Malfunctioning components will be identified during periodic testing. The control logic is not complex, therefore location of a failed component is straightforward. The components are mounted to facilitate removal and replacement.

7.6.2.6.2.3.1.22 CIGS-ADS - IEEE 279 (1971), Paragraph 4.22 - Identification of Protection Systems

Controls for the CIGS-ADS are located in control panels distinctively identified with nameplates that identifies them as having safety-related equipment. Cables and cable trays are color coded and tagged to identify them as being a separate channel.

7.6.2.6.2.3.2 CIGS-ADS - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1 Electric Equipment for Nuclear Power Generating Stations See Section 3.11.

7.6.2.6.2.3.3 CIGS-ADS - IEEE 336 (1971) - Installation, Inspection, and Testing Requirements for Instrumentation and Electric Equipment During the Construction of Nuclear Power Generating Stations

See Section 8.1.6.1 in the discussion of conformance to Regulatory Guide 1.30, which endorses/modifies this IEEE standard.

7.6.2.6.2.3.4 CIGS-ADS - IEEE 338 (1975) - Criteria for the Periodic Testing of Nuclear Power Generating Station Protection System

The operability of the CIGS-ADS can be verified and failures are detectable through testing during normal plant operation. The input sensor and setpoint are checked by the application of simulated signals.

7.6.2.6.2.3.5 CIGS-ADS - IEEE 344 (1971) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations

See Section 3.10.

7.6.2.6.2.3.6 CIGS-ADS - IEEE 379 (1972) - Guide for the Application of the Single Failure Criterion to Nuclear Power Generating Station Protection Systems

This system is not required to meet the single failure criterion.

7.6.2.6.2.3.7 CIGS-ADS - IEEE 384 (1974) - Criteria for Separation of Class 1E Equipment and Circuits

This standard is not applicable to CIGS-ADS.

7.6.2.6.2.4 CIGS-ADS Additional Design Considerations Analysis

As identified in Regulatory Guide 1.70 (1978), paragraph 7.6.2, the following accidents are addressed:

a. Cold water slug injections - CIGS-ADS has no function in preventing or mitigating the consequences of this accident.

b. Refueling accidents - CIGS-ADS has no function in preventing or mitigating the consequences of these accidents.

c. Over-pressurization of low pressure systems - CIGS-ADS has no function in preventing or mitigating the consequences of this accident.

d. Fire - CIGS-ADS has no function in preventing or mitigating the consequences of fires.

7.6.2.7 Safeguard Piping Fill System - Instrumentation and Controls

7.6.2.7.1 SPFS General Functional Requirements Conformance

The following analysis shows how the SPFS meets the safety design bases identified in Section 7.1.2.1.41.1.

The SPFS provides water to the discharge lines of the ECCS pumps to maintain these lines in a full condition. The SPFS is normally on standby (not operating) and provides a safety-related backup to the condensate transfer system, which keeps the ECCS lines full during normal plant operation, through different piping connections. If the water level in the ECCS lines starts to drop, level instrumentation on the high point vents will annunciate an alarm in the control room, and the operator can start the SPFS pumps. The SPFS also provides water to the feedwater lines to maintain a water seal against discharge of containment atmosphere into the reactor enclosure in the event of any line break other than a feedwater line break inside containment. The SPFS is a supporting system to the ECCS. Once the fill system pumps are started, they operate continuously until they are turned off by the operator.

The SPFS is designed with redundancy as described in Section 7.6.1.7.5 so that no single active or passive electrical or control failure will prevent the SPFS from meeting its safety-related objective.

7.6.2.7.2 SPFS Specific Regulatory Requirements Conformance

7.6.2.7.2.1 SPFS Conformance to Regulatory Guides

7.6.2.7.2.1.1 SPFS - Regulatory Guide 1.22 (1972) - Periodic Testing of Protection System Actuation Functions (Safety Guide 22)

The SPFS pumps can be functionally tested during normal plant operation. The fill-water supply to feedwater line shutoff valves can be opened from the control room to verify operability.

7.6.2.7.2.1.2 SPFS - Regulatory Guide 1.29 (1978) - Seismic Design Classification

The SPFS is qualified to seismic Category I criteria, in accordance with IEEE 344. Refer to Section 3.10.

7.6.2.7.2.1.3 SPFS - Regulatory Guide 1.30 (1972) - Quality Assurance Requirements for the Installation, Inspection, and Testing of Instrumentation and Electric Equipment (Safety Guide 30)

See Section 8.1.6.1.

7.6.2.7.2.1.4 SPFS - Regulatory Guide 1.53 (1973) - Application of the Single Failure Criterion to Nuclear Power Plant Protection Systems

A single failure within the SPFS will not prevent the SPFS from performing its safety function.

7.6.2.7.2.1.5 SPFS - Regulatory Guide 1.89 (1974) - Qualification of Class 1E Equipment for Nuclear Power Plants

The SPFS is qualified to meet Class 1E requirements.

7.6.2.7.2.1.6 SPFS - Regulatory Guide 1.100 (1977) - Seismic Qualification of Electric Equipment for Nuclear Power Plants

Conformance with this regulatory guide is discussed in Section 3.10.

7.6.2.7.2.2 SPFS Conformance to 10CFR50, Appendix A, General Design Criteria

7.6.2.7.2.2.1 SPFS - GDC 1 - Quality Standards and Records

See Section 7.1.2.6.1.

7.6.2.7.2.2.2 SPFS - GDC 2 - Design Bases for Protection Against Natural Phenomena

See Section 3.1.

7.6.2.7.2.2.3 SPFS - GDC 3 - Fire Protection

See Section 3.1.

7.6.2.7.2.2.4 SPFS - GDC 4 - Environmental and Dynamic Effects Design Bases

See Section 3.1.

7.6.2.7.2.2.5 SPFS - GDC 5 - Sharing of Structures, Systems, and Components

No portions of the SPFS are shared between units.

7.6.2.7.2.2.6 SPFS - GDC 13 - Instrumentation and Control

Indicating lights are provided in the main control room to indicate operation of the SPFS pumps and to indicate the positions of the shutoff valves to the feedwater lines. Low pressure in the pump discharge lines is annunciated. The fill pumps are manually started and stopped from the control room. Low level in the ECCS pump discharge lines is annunciated in the control room by level instrumentation that is located on the vents at the high points of the lines. Feedwater line pressure is indicated in the control room so that the operator can determine if there has been a feedwater line break inside containment. If so, the operator can isolate the fill system from the broken line and still provide fill system water to the other (intact) feedwater line.

7.6.2.7.2.2.7 SPFS - GDC 20 - Protection System Functions

The SPFS is manually initiated.

7.6.2.7.2.2.8 SPFS - GDC 21 - Protection System Reliability and Testability

The components used in the SPFS are selected to ensure high functional reliability. The system can be tested and failures determined during normal plant operation.

7.6.2.7.2.2.9 SPFS - GDC 22 - Protection System Independence

The two SPFS trains are independent and physically separated with separate instruments to provide assurance that the protective function is not lost.

7.6.2.7.2.2.10 SPFS - GDC 23 - Protection System Failure Modes

The system is designed to tolerate a single active or passive electrical or control failure.

7.6.2.7.2.2.11 SPFS - GDC 29 - Protection Against Anticipated Operational Occurrences

The SPFS is designed to remain functional during anticipated operating occurrences.

7.6.2.7.2.3 SPFS Conformance to Industry Codes and Standards

7.6.2.7.2.3.1 SPFS - IEEE 279 (1971) - Criteria for Protection Systems for Nuclear Power Generating Stations

7.6.2.7.2.3.1.1 SPFS - IEEE 279 (1971), Paragraph 4.1 - General Functional Requirement

The SPFS is manually initiated. It is effective over the full range of environmental conditions cited below:

a. Power supply voltages - Equipment is designed to operate within the range of voltages specified in Section 8.3.1.

b. Power supply frequency - Equipment is designed to within the range of power supply frequency specified in Section 8.3.1.

c. Temperature - The system is operable at all temperatures that can result from a design basis LOCA.

d. Humidity - The system is operable at all humidities, including steam, that can result from a LOCA.

e. Pressure - The system is operable at all pressures resulting from a LOCA.

f. Radiation - The system is operable at all radiation levels expected for any design basis LOCA.

g. Vibration - The system will tolerate the conditions stated in Section 3.10.

h. Malfunction - The system will tolerate any single component failure.

i. Accidents - The system will operate during and following any DBA.

j. Fire - The system will tolerate raceway fires in a single division.

k. Explosion - Explosions are not defined in design bases.

l. Missiles - The system will tolerate any single missile destroying raceway, cabinet, or equipment in one division.

m. Lightning - The system will tolerate lightning damage to one electrical division.

n. Flood - The plant is not subject to flooding as discussed in Section 3.4.

o. Earthquake - The system will tolerate conditions stated in Section 3.10.

p. Wind and Tornado - All control equipment is located in seismic Category 1 structure. See Section 3.3 for wind loadings.

q. System response times - The system is manually initiated.

r. System accuracies - Accuracies are within those needed for correct action.

s. Abnormal range of sensed variables - No variables are sensed.

7.6.2.7.2.3.1.2 SPFS - IEEE 279 (1971), Paragraph 4.2 - Single Failure Criterion

A single active or passive electrical or control failure will not prevent the SPFS from meeting its safety-related objective.

7.6.2.7.2.3.1.3 SPFS - IEEE 279 (1971), Paragraph 4.3 - Quality of Components and Modules

All safety-related components are selected on the basis of suitability for the application. A quality assurance program is implemented.

7.6.2.7.2.3.1.4 SPFS - IEEE 279 (1971), Paragraph 4.4 - Equipment Qualification

The SPFS safety-related controls and instrumentation have been qualified according to the requirements outlined in IEEE 323 (1971) as highlighted in Section 7.1.2.7.4, identified in Sections 3.10 and 3.11. The parameters identified cover normal, abnormal, and accident environments.

7.6.2.7.2.3.1.5 SPFS - IEEE 279 (1971), Paragraph 4.5 - Channel Integrity

The SPFS meets the channel integrity objective by using the design features described in the other paragraphs of this section.

7.6.2.7.2.3.1.6 SPFS - IEEE 279 (1971), Paragraph 4.6 - Channel Independence

The control, instrumentation, and power circuits to each SPFS pump and its associated feedwater shutoff valves are physically and electrically separated from the other pump and associated valves.

7.6.2.7.2.3.1.7 SPFS - IEEE 279 (1971), Paragraph 4.7 - Control and Protection System Interaction

The SPFS has no interaction with the plant control systems. Control room annunciator circuits taking input from this system are electrically isolated from the system and cannot impair its operability.

7.6.2.7.2.3.1.8 SPFS - IEEE 279 (1971), Paragraph 4.8 - Derivation of System Inputs

There are no system inputs.

7.6.2.7.2.3.1.9 SPFS - IEEE 279 (1971), Paragraph 4.9 - Capability for Sensor Checks

There are no sensed inputs to the SPFS.

7.6.2.7.2.3.1.10 SPFS - IEEE 279 (1971), Paragraph 4.10 - Capability for Testing and Calibration

The SPFS pumps and feedwater shutoff valves can be tested during normal plant operation.

7.6.2.7.2.3.1.11 SPFS - IEEE 279 (1971), Paragraph 4.11 - Channel Bypass or Removal from Operation

The two SPFS trains are separate electrically and physically. Removal of a component for maintenance prevents the operation of one train; however, operation of the other train is unaffected. The SPFS cannot be bypassed because all control is manual.

7.6.2.7.2.3.1.12 SPFS - IEEE 279 (1971), Paragraph 4.12 - Operating Bypasses

All control for the SPFS is manual.

7.6.2.7.2.3.1.13 SPFS - IEEE 279 (1971), Paragraph 4.13 - Indication of Bypasses

A common annunciator is provided in the control room to indicate low pump discharge pressure in either train of the SPFS, which may be a consequence of pump stoppage, whether by deliberate action or other reasons.

7.6.2.7.2.3.1.14 SPFS - IEEE 279 (1971), Paragraph 4.14 - Access to Means for Bypassing

Access to components of the SPFS is procedurally controlled by administrative means.

7.6.2.7.2.3.1.15 SPFS - IEEE 279 (1971), Paragraph 4.15 - Multiple Setpoints

This paragraph is not applicable to the SPFS.

7.6.2.7.2.3.1.16 SPFS - IEEE 279 (1971), Paragraph 4.16 - Completion of Protective Action Once It Is Initiated

The SPFS operates continuously once started by the operator and until stopped by the operator.

7.6.2.7.2.3.1.17 SPFS - IEEE 279 (1971), Paragraph 4.17 - Manual Initiation

The SPFS is manually initiated.

7.6.2.7.2.3.1.18 SPFS - IEEE 279 (1971), Paragraph 4.18 - Access to Setpoint Adjustments, Calibration, and Test Points

This paragraph is not applicable to the SPFS.

7.6.2.7.2.3.1.19 SPFS - IEEE 279 (1971), Paragraph 4.19 - Identification of Protective Actions

The status of SPFS pumps and feedwater shutoff valves is shown by indicating lights on the control room panels.

7.6.2.7.2.3.1.20 SPFS - IEEE 279 (1971), Paragraph 4.20 - Information Readout

The SPFS pumps status and feedwater valve position provides information to assure the operator of correct operation.

7.6.2.7.2.3.1.21 SPFS - IEEE 279 (1971), Paragraph 4.21 - System Repair

Recognition of failed components is accomplished during testing of the system. During system operation, low discharge pressure is indicative of a failed pump. The control logic is not complex, therefore, location of a failed component is straightforward. The components are mounted to facilitate removal and replacement.

7.6.2.7.2.3.1.22 SPFS - IEEE 279 (1971), Paragraph 4.22 - Identification of Protection Systems

Controls for the SPFS are located in control panels distinctively identified with nameplates that identifies them as being a safety system. Cables and cable trays are color coded and tagged to identify them as being a separation channel.

7.6.2.7.2.3.2 SPFS - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1 Electric Equipment for Nuclear Power Generating Stations

See Section 3.11.

7.6.2.7.2.3.3 SPFS - IEEE 336 (1971) - Installation, Inspection, and Testing Requirements for Instrumentation and Electric Equipment During the Construction of Nuclear Power Generating Stations

See Section 8.1.6.1 for a discussion of conformance with Regulatory Guide 1.30, which endorses/modifies this IEEE standard.

7.6.2.7.2.3.4 SPFS - IEEE 344 (1971) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations

See Section 3.10.

7.6.2.7.2.3.5 SPFS - IEEE 379 (1972) - Guide for the Application of the Single Failure Criterion to Nuclear Power Generating Station Protection Systems

A single failure within the SPFS will not prevent the SPFS from performing its safety function.

7.6.2.7.2.3.6 SPFS - IEEE 384 (1974) - Criteria for Separation of Class 1E Equipment and Circuits

See Section 7.1.2.7.11.

7.6.2.7.2.3.7 SPFS - IEEE 338 (1975) - Criteria for the Periodic Testing of Nuclear Power Generating Station Protection Systems

The SPFS pumps and feedwater shutoff valves can be tested during normal plant operation. A failure of one valve during testing does not prevent the other valve from functioning.

7.6.2.7.2.4 SPFS Additional Design Considerations Analysis

As identified in Regulatory Guide 1.70 (1978), paragraph 7.6.2, the following accidents are addressed:

a. Cold water slug injection - SPFS has no function in preventing or mitigating the consequences of this accident.

b. Refueling accidents - SPFS has no function in preventing or mitigating the consequences of these accidents.

c. Overpressurization of low pressure systems - The SPFS has no function in preventing or mitigating the consequences of this accident.

d. Fires - SPFS has no function in preventing or mitigating the consequences of fires.

7.6.2.8 Redundant Reactivity Control System – Instrumentation and Controls

7.6.2.8.1 RRCS General Functional Requirements Conformance

The sensors, transmitters, trip units, and other assigned associated logic for the RRCS are Class 1E, separate and independent from the RPS, and environmentally qualified to expected ATWS conditions.

The RRCS is diverse from the RPS. No credible common mode failure can prevent both normal scram and ATWS prevention or mitigation functions. The RRCS is designed to independently monitor reactor pressure and water level and to shut down the nuclear chain reaction if these variables reach their respective trip setpoint. This shutdown is accomplished in the first few seconds after the trip by signals that cause rapid recirculation flow reduction and simultaneously open the ARI valves venting the air supply holding the scram valves shut.

Twenty-five seconds after the RRCS trip, additional core reactivity reduction is provided by a rapid termination (runback to 0%) of feedwater flow if the initiating signals include high pressure and core power is not downscale. Reactor high pressure is a symptom of loss of primary heat sink and is indicative of vessel isolation. The RRCS recirculation trips and feedwater runback serve to reduce core power below the steam flow capability of the SRVs.

7.6.2.8.2 RRCS Specific Regulatory Requirements Conformance

General exceptions to and positions taken on the regulatory guides, and the revision to the guide that is followed, are discussed in Sections 1.8 and 7.1.2.5. Specific applications of selected guides to the RRCS instrumentation and controls are discussed in this section.

7.6.2.8.2.1 RRCS Conformance to Regulatory Guides

7.6.2.8.2.1.1 RRCS - Regulatory Guide 1.6 (1971) - Independence Between Redundant Standby (Onsite) Power Sources and Between Their Distribution System (Safety Guide 6)

The RRCS electrically powered safety loads are separated into load groups such that loss of any one group will not prevent the minimum safety functions from being performed. Division I RRCS logic is powered by 125 V dc from Bus A Division I. Division II logic is powered by 125 V dc from Bus B Division II.

7.6.2.8.2.1.2 RRCS - Regulatory Guide 1.22 (1972) – Periodic Testing of Protection System Actuation Functions (Safety Guide 22)

The RRCS equipment is designed so that integrated system testing can be performed to verify overall system performance.

7.6.2.8.2.1.3 RRCS - Regulatory Guide 1.29 (1978) - Seismic Design Classification

The sensors, transmitters, trip units and associated logic for the RRCS are classified as seismic Category I. The feedwater pump trip contacts are high quality but not necessarily safety-grade.

7.6.2.8.2.1.4 RRCS - Regulatory Guide 1.30 (1972) - Quality Assurance Requirements for the Installation, Inspection, and Testing of Instrumentation and Electric Equipment (Safety Guide 30)

See Sections 1.8 and 7.1.2.5.

7.6.2.8.2.1.5 RRCS - Regulatory Guide 1.32 (1977) - Criteria for Safety-Related Electric Power and Protection Systems for Nuclear Power Plants

See Sections 1.8 and 7.1.2.5.

7.6.2.8.2.1.6 RRCS - Regulatory Guide 1.47 (1973) - Bypassed and Inoperable Status Indication for Nuclear Power Plant Safety Systems

There is no RRCS bypass or operating bypass.

The following annunciators are provided to communicate system status to the operating personnel in the control room.

a. RRCS MANUAL INITIATION ARMED Division I/II

b. RRCS POTENTIAL ATWS Division I/II (receipt of high pressure or low water level 2)

c. 1A RECIRC PUMP MOTOR ATWS TRIP CIRCUIT POWER FAILURE
1B RECIRC PUMP MOTOR ATWS TRIP CIRCUIT POWER FAILURE

d. 1A RECIRC PUMP MOTOR TRIP
1B RECIRC PUMP MOTOR TRIP

e. RWCU ISOLATED

f. RRCS OUT OF SERVICE Division I (test fault, ATM calibration or gross failure)
RRCS OUT OF SERVICE Division II (test fault, ATM calibration or gross failure)

g. RRCS CONFIRMED ATWS Division I/II (timer has timed out and APRM power is not downscale, SLCS injection initiation signal is present)

h. RRCS CHANNEL ACTIVATED Division I/II

i. RRCS MANUAL INITIATION Division I/II

Additional operator interface with RRCS is provided by the following status lights. Each status light consists of a pair of bulbs for redundancy and an individual lamp test switch for each pair. These status lamps are repeated for Division II. All lamps are amber.

RRCS ARI INITIATION Division I
RRCS MANUAL INITIATION Division I
RRCS ARI READY FOR RESET Division I
RRCS READY FOR RESET Division I
RRCS TEST FAULT Division I
RRCS LOSS OF DC POWER Division I Channel A
RRCS LOSS OF DC POWER Division I Channel B
RRCS FEEDWATER RUNBACK INITIATED Division I
RRCS MANUAL INITIATION ARMED Division I
HIGH DOME PRESSURE Division I Channel A
HIGH DOME PRESSURE Division I Channel B

LOW WATER LEVEL 2 TRIP Division I Channel A
LOW WATER LEVEL 2 TRIP Division I Channel B
RRCS POTENTIAL ATWS Division I
RRCS RWCU ISOLATED Division I
RRCS CONFIRMED ATWS Division I
RRCS ATM CALIBRATION OR GROSS FAILURE Division I
RRCS TROUBLE Division I
RRCS RECIRCULATION PUMPS TRIPPED Division I

7.6.2.8.2.1.7 RRCS - Regulatory Guide 1.53 (1973) - Application of the Single Failure Criterion to Nuclear Power Plant Protection Systems

The RRCS meets the requirements of IEEE 279 (1971) and IEEE 379 (1972) (Section 7.6.2.8.2.3.1.2 and Section 7.6.2.8.2.3.6).

7.6.2.8.2.1.8 RRCS - Regulatory Guide 1.62 (1973) - Manual Initiation of Protective Actions

Means are provided for manual initiation of the RRCS protective actions. The RRCS ARI function and, after time delays, the SLCS are initiated upon depression of the RRCS manual initiation push button. The RRCS RPT and feedwater runback are not initiated by manual initiation of RRCS. These may be manually initiated at the respective system control panels using system breaker control switches.

7.6.2.8.2.1.9 RRCS - Regulatory Guide 1.68 (1978) - Preoperational and Initial Startup Test Programs for Water-Cooled Power Reactors

The RRCS meets Regulatory Guide 1.68 and will undergo preoperational and initial startup tests as described in Section 14.2.

7.6.2.8.2.1.10 RRCS - Regulatory Guide 1.75 (1978) - Physical Independence of Electric Systems

The RRCS meets Regulatory Guide 1.75. Methods for compliance with conditions involving the physical independence of electrical systems are discussed in Section 8.1.6.1.

7.6.2.8.2.1.11 RRCS - Regulatory Guide 1.89 (1974) - Qualification of Class 1E Equipment for Nuclear Power Plants

The RRCS equipment is qualified to meet IEEE 323 (1974), IEEE 344 (1975) and Regulatory Guide 1.89.

7.6.2.8.2.1.12 RRCS - Regulatory Guide 1.100 (1977) - Seismic Qualification of Electric Equipment for Nuclear Power Generating Stations

The RRCS equipment is qualified to meet IEEE 344 (1975) and Regulatory Guide 1.100. Refer to Section 3.10.

7.6.2.8.2.1.13 RRCS - Regulatory Guide 1.105 (1976) - Instrument Setpoints

Instrument setpoints (accuracy, margin, and drift) for reactor power, water level, and pressure are described in the plant Technical Specifications.

7.6.2.8.2.1.14 RRCS - Regulatory Guide 1.118 (1978) - Periodic Testing of Electric Power and Protection Systems

The RRCS is continually checked by a solid-state microprocessor based self-test system that is part of the analog trip units. This system checks the RRCS sensors, logic, protective devices, and itself.

7.6.2.8.2.2 RRCS Conformance to 10CFR50, Appendix A, General Design Criteria

GDC that are generally applicable to all safety-related systems, are discussed in Section 3.1. Those with specific impact on the RRCS are described in this section.

7.6.2.8.2.2.1 RRCS - GDC 1 - Quality Standards and Records

See Section 7.1.2.2.

7.6.2.8.2.2.2 RRCS - GDC 2 - Design Bases for Protection Against Natural Phenomena

See Section 7.1.2.2.

7.6.2.8.2.2.3 RRCS - GDC 3 - Fire Protection

See Section 7.1.2.2.

7.6.2.8.2.2.4 RRCS - GDC 4 - Environmental and Dynamic Effects Design Bases

See Section 7.1.2.2.

7.6.2.8.2.2.5 RRCS - GDC 19 - Control Room

See Section 7.1.2.2.

7.6.2.8.2.2.6 RRCS - GDC 10 - Protection System Functions

The RRCS is completely automatic.

7.6.2.8.2.2.7 RRCS - GDC 21 - Protection System Reliability and Testability

The RRCS is designed for high functional reliability, and its logic can be tested for the safety functions to be performed. No single failure in this two divisional, four-channel protection system will result in the loss of the protective functions.

7.6.2.8.2.2.8 RRCS - GDC 22 - Protection System Independence

The RRCS is a two division Class 1E system separate and diverse from the RPS. It has functional diversity via ARI, RPT, and feedwater runback.

7.6.2.8.2.2.9 RRCS - GDC 24 - Separation of Protection and Control Systems

The RRCS protection system interfaces with control systems through isolation devices. Specifically, the RRCS signals to the recirculation system pump and the signal to the feedwater system to initiate runback both pass through isolators. This ensures that electrical failures in the control systems cannot propagate back into the RRCS system and therefore cannot prevent other channels in the RRCS divisions from performing their protective functions.

7.6.2.8.2.2.10 RRCS - GDC 29 - Protection Against Anticipated Operational Occurrences

The RRCS is highly reliable because it is redundant, Class 1E, functionally diverse and has continuous self-test capability.

7.6.2.8.2.3 RRCS Conformance to Industry Codes and Standards

7.6.2.8.2.3.1 RRCS - IEEE Standard 279 (1971) - Criteria for Protection Systems for Nuclear Power Generating Stations

7.6.2.8.2.3.1.1 RRCS - IEEE Standard 279 (1971), Paragraph 4.1 - General Functional Requirement

The RRCS will automatically initiate the appropriate protective actions whenever reactor high pressure or low water level 2 are received. These actions include tripping of the recirculation pump motor breakers, initiating a feedwater runback and RWCU system isolation.

7.6.2.8.2.3.1.2 RRCS - IEEE Standard 279 (1971), Paragraph 4.2 - Single Failure Criterion

The RRCS is two divisional with two channels (A and B) in each division. The RRCS protective action will be initiated when both channel A and channel B in either division are tripped. Different water level and pressure sensors feed each of the four channels of trip logic. Trip signals to trip the recirculation pump act on independent breakers. The feedwater runback and RWCU system isolation are capable of being initiated from either division. In this manner, any single failure within RRCS cannot prevent the protective actions at the system level from taking place.

7.6.2.8.2.3.1.3 RRCS - IEEE Standard 279 (1971), Paragraph 4.3 - Quality of Components and Modules

RRCS components and modules, and equipment in non-Class 1E systems supporting the RRCS (such as the recirculation system pump motor breaker ATWS trip coils), are Class 1E electrical, suitable for and consistent with the low failure rates required for nuclear power station safety-related equipment, except as noted below. High quality, although not necessarily safety-grade equipment shall be used to meet the feedwater control runback ATWS reliability requirements.

7.6.2.8.2.3.1.4 RRCS - IEEE Standard 279 (1971), Paragraph 4.4 - Equipment Qualification

Type test data or reasonable engineering extrapolation based on test data is available to verify that the RRCS can meet its performance requirements on a continuing basis.

7.6.2.8.2.3.1.5 RRCS - IEEE Standard 279 (1971), Paragraph 4.5 - Channel Integrity

RRCS channels and components meet the necessary functional requirements of the environmental conditions for components listed in the tables in Section 3.11.

7.6.2.8.2.3.1.6 RRCS - IEEE Standard 279 (1971), Paragraph 4.6 - Channel Independence

Each channel, A and B, of each division of logic is independent and physically separated from the other channel. Separate sensors provide signals of reactor pressure and water level for each channel of each division. Signals are routed through separate cabling to separate ATMs and RRCS logic. Actuation signals also travel to the trip-actuated devices via divisionally separated cabling. This design effectively decouples the effects of unsafe environmental factors, electrical transients, and physical accident consequences.

7.6.2.8.2.3.1.7 RRCS - IEEE Standard 279 (1971), Paragraph 4.7 - Control and Protection System Interaction

The transmission of signals from RRCS protection system equipment for control system use is accomplished through isolation devices that are classified as part of the protection system and meet all the requirements of this standard. No credible failure at these isolators will prevent the associated protection system channel from meeting its design requirements.

7.6.2.8.2.3.1.8 RRCS - IEEE Standard 279 (1971), Paragraph 4.8 - Derivation of System Inputs

The RRCS system inputs, reactor pressure, and water level are derived from pressure and level transmitters that produce signals that are to the extent, feasible and practical, direct measures of these desired variables.

7.6.2.8.2.3.1.9 RRCS - IEEE Standard 279 (1971), Paragraph 4.9 - Capability for Sensor Checks

The RRCS self-test unit automatically checks the RRCS level and pressure sensors. The automatic check determines if the sensor output is downscale, within normal operating bounds, or too high. If the sensor output is found to be abnormal, an alarm is sounded. The sensor output can be observed and compared at the middle bay of the RRCS cabinet where the ATM diagnostic display is mounted.

7.6.2.8.2.3.1.10 RRCS - IEEE 279 (1971), Paragraph 4.10 - Capability for Testing and Calibration

Each RRCS sensor provides input to an analog trip module. The ATM electrically monitors the incoming sensor signal level and provides the appropriate output to the RRCS logic if that sensor signal level goes beyond its trip setpoints. Sensor signal level can be read at the ATM and compared to the known characteristics of the transmitter. Trip setpoint can be adjusted at the ATM, and the operability of this trip module is checked repeatedly by the RRCS self-test unit. RRCS sensors, logic, timers, and actuated devices are continuously checked by the RRCS self-test unit, thus meeting paragraph 4.10.

7.6.2.8.2.3.1.11 RRCS - IEEE 279 (1971), Paragraph 4.11 - Channel Bypass or Removal from Operation

The RRCS is designed such that portions may be removed from service for maintenance or testing without initiating the RRCS protective actions at the system level. Removal of portions of the RRCS for service will not result in protective actions because the system is normally de-energized.

7.6.2.8.2.3.1.12 RRCS - IEEE 279 (1971), Paragraph 4.12 - Operating Bypasses

There is no operating bypass affecting the RRCS.

7.6.2.8.2.3.1.13 RRCS - IEEE 279 (1971), Paragraph 4.13 - Indication of Bypasses

There is no manual bypass of the RRCS.

7.6.2.8.2.3.1.14 RRCS - IEEE 279 (1971), Paragraph 4.14 - Access to Means for Bypassing

The RRCS cannot be manually bypassed.

7.6.2.8.2.3.1.15 RRCS - IEEE 279 (1971), Paragraph 4.15 - Multiple Setpoints

There are no multiple setpoints applicable to the RRCS.

7.6.2.8.2.3.1.16 RRCS - IEEE 279 (1971), Paragraph 4.16 - Completion of Protective Action Once It Is Initiated

The RRCS protective actions are sealed in by the solid-state logic. The RRCS ARI function cannot be reset for 30 seconds after its initiation. This ensures that the scram will go to completion because the ARI valves are designed to vent the scram air header to cause all rods to begin scramming within 15 seconds. All other RRCS protective actions cannot be reset for at least 10 minutes. Operator control of the feedwater system can be regained 30 seconds after initiation of the RRCS feedwater runback. Because the runback is designed to bring feedwater flow to 0% within 15 seconds, this protective function will also go to completion.

7.6.2.8.2.3.1.17 RRCS - IEEE 279 (1971), Paragraph 4.17 - Manual Initiation

The RRCS can be manually initiated by depressing the manual initiation push buttons. The manual initiation signal is immediately sealed into the RRCS ARI logic.

7.6.2.8.2.3.1.18 RRCS - IEEE 279 (1971), Paragraph 4.18 - Access to Setpoint Adjustments, Calibration, and Test Points

The design of RRCS permits the administrative control of access to all setpoint adjustments, module calibration adjustments, and test setpoints via enclosing the ATMs and logic in key-locked cabinets.

7.6.2.8.2.3.1.19 RRCS - IEEE 279 (1971), Paragraph 4.19 - Identification of Protective Actions

RRCS protective actions are indicated and identified down to the channel level by status lights and annunciators.

7.6.2.8.2.3.1.20 RRCS - IEEE 279 (1971), Paragraph 4.20 - Information Readout

The RRCS provides the operator with pertinent information as to its condition via status lights and annunciators. This includes indication of the various stages of the RRCS logic actuation such as RPT, feedwater runback, and both potential and confirmed ATWS. An RRCS trouble annunciator is provided to signal a test fault, ATM in calibration or gross failure. Loss of power to RRCS is signaled by the RRCS trouble annunciator.

7.6.2.8.2.3.1.21 RRCS - IEEE 279 (1971), Paragraph 4.21 - System Repair

The RRCS system is designed to facilitate the recognition, location, replacement, repair, or adjustment of malfunctioning components or modules. The use of the analog trip module facilitates the calibration, adjustment, or repair of the trip system. The modules are plug-in units that can be easily replaced. RRCS logic is separated by division and channel onto individual cards that can be easily replaced by spares.

7.6.2.8.2.3.1.22 RRCS - IEEE 279 (1971), Paragraph 4.22 - Identification of Protection Systems

The RRCS protection system equipment is identified distinctively as being in the protection system, and its equipment is marked to clearly indicate divisional separation. Panels are labeled with distinctive marker plates.

7.6.2.8.2.3.2 RRCS - IEEE 308 (1974) - Criteria for Class 1E Electrical Systems for Nuclear Power Generating Stations

The RRCS meets IEEE 308. The logic is in two divisions. Each division has separate Class 1E power. RRCS components are energized to trip, therefore loss of power to one division will not affect protective actions of the RRCS.

7.6.2.8.2.3.3 RRCS - IEEE 323 (1971) - IEEE Trial Use Standard: General Guide for Qualifying Class 1 Electric Equipment for Nuclear Power Generating Stations

The RRCS is in conformance with IEEE 323 as shown in Section 3.11.

7.6.2.8.2.3.4 RRCS - IEEE 338 (1975) - Criteria for the Periodic Testing of Nuclear Power Generating Station Protection Systems

RRCS compliance with IEEE 338 is demonstrated in Section 7.6.1.8.2, ATM self-test capability and in 7.6.2.8.2.3.1, paragraphs 4.9 and 4.10.

7.6.2.8.2.3.5 RRCS - IEEE 344 (1975) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations

The RRCS is qualified for seismic events shown in Section 3.10.

7.6.2.8.2.3.6 RRCS - IEEE 379 (1972) - Guide for the Application of the Single Failure Criterion to Nuclear Power Generating Station Protection Systems

RRCS signal separation, cabinet separation, use of isolation circuitry, and number of channels per trip system are methods used to meet the single failure criterion. The RRCS self-test system eliminates nondetectable failures by continually checking RRCS sensors, logic, and trip devices.

7.6.2.8.2.3.7 RRCS - IEEE 384 (1974) - Criteria for Separation of Class 1E Equipment and Circuits

The RRCS meets IEEE 384 as discussed in Section 7.1.2.7.11. The RRCS meets Regulatory Guide 1.75 as discussed in Section 7.6.1.8.2. Physical independence of electrical systems is discussed in Section 8.3.1.4.

7.6.2.9 Additional Design Considerations Analyses

7.6.2.9.1 General Plant Safety Analyses

The examination of the subject safety systems at the plant safety analyses level is presented in Chapter 15.

7.6.2.9.2 Cold Water Slug Injection

Refer to Section 15.5.1.

7.6.2.9.3 Refueling Accidents

Refer to Section 15.7.4.

7.6.2.9.4 Overpressurization of Low Pressure System

Refer to Section 7.6.1.2.

7.7 CONTROL SYSTEMS NOT REQUIRED FOR SAFETY

7.7.1 DESCRIPTION

This section discusses instrumentation and controls of systems whose functions are not essential to the safety of the plant. The systems include:

a. Reactor vessel instrumentation

b. Reactor manual control system

c. Recirculation flow control system

d. Feedwater control system

e. Pressure regulator and turbine-generator system

f. Neutron monitoring system - instrumentation and controls

1. Source range monitor system

2. Rod block monitor system

3. Traversing incore probe system

g. DELETED

h. Reactor water cleanup system

i. Process radiation monitoring systems

1. South stack effluent radiation monitoring system

2. Radwaste equipment rooms ventilation exhaust radiation monitoring system

3. Charcoal treatment system process exhaust radiation monitoring system

4. Recombiner rooms and hydrogen analyzer compartments exhaust radiation monitoring system

5. Steam exhauster discharge and vacuum pump exhaust radiation monitoring system

6. Radwaste enclosure and chem. lab ventilation exhaust radiation monitoring system

7. Air ejector offgas effluent radiation monitoring system

8. Primary containment leak detection radiation monitoring system

9. Hot maintenance shop ventilation exhaust radiation monitoring system

10. Liquid radwaste discharge radiation monitoring system

11. Service water radiation monitoring system

12. Reactor enclosure cooling water radiation monitoring system

j. Area radiation monitoring system

k. Gaseous radwaste system

l. Liquid radwaste system

m. Solid radwaste system

n. Fuel pool cooling and cleanup system

o. Refueling interlocks

p. Leak detection system

q. Emergency Response Facility Data System

r. Containment instrument gas system

s. Fire protection and suppression system

t. Nonsafety-related equipment area cooling ventilation systems

u. Rod worth minimizer

v. Plant monitoring system

w. Hydrogen water chemistry system

7.7.1.1 Reactor Vessel Instrumentation

Drawings M-41, M-43 and M-44 show the instrument numbers, arrangements of sensors, and sensing equipment used to monitor the reactor vessel conditions. Because the reactor vessel sensors used for safety-related systems are described and evaluated in other portions of this document, only the sensors not required for safety are described in this section.

7.7.1.1.1 RVI Identification

7.7.1.1.1.1 RVI General

The purpose of the reactor vessel instrumentation is to monitor the key reactor vessel operating variables during plant operation.

These instruments and systems are used to provide the operator with information during normal plant operation, startup, and shutdown. They are monitoring devices and provide no active power control or safety functions.

7.7.1.1.1.2 RVI Classification

The systems and instruments discussed in this section are designed to operate under normal and peak operating conditions of system and ambient pressures and temperatures, and are classified as not related to safety.

7.7.1.1.1.3 RVI Reference Design

Table 7.1-2 lists the reference design information. The RVI is an operational system and has no safety function. Therefore, there are no safety design differences between this system and those of the referenced design facilities. This system is functionally identical to the referenced system, except for RPV level instrumentation used during refueling.

7.7.1.1.2 RVI Power Sources

Nonsafeguard instrumentation is powered from a non-Class 1E 120 V ac 60 Hz instrument bus. Safeguard pressure, differential pressure, and level transmitter and trip unit channels are powered from divisional 24 V dc buses that are energized by Class 1E 120 V ac / 24 V dc power supplies. Some of these power supplies are energized from the appropriate Class 1E 120 V ac divisional instrument bus, and the others are energized from the Class 1E 125 V dc instrument bus for the division via a 125 V dc/120 V ac inverter. See Sections 7.2, 7.3, and 7.4 for more discussion of the Class 1E safeguard (divisional) power sources.

7.7.1.1.3 RVI Equipment Design

For safeguard and nonsafeguard sensing instruments located below the process tap, the sensing lines slope downward from the process tap to the instrument about ½ in/ft (the design minimum is ¼ in/ft, which is allowed for those lines that cannot be sloped a minimum ½ in/ft because of obstructions) so that air traps are not formed.

Where it is impractical to locate the instruments below the process tap, the sensing lines ascend vertically for at least 36 inches of process connection up to a high point vent located at an accessible elevation above the instrument, before sloping a minimum of ¼ in/ft to the instrument. The purpose of this is to prevent entrapment of a noncondensable gas in the sensing line.

7.7.1.1.3.1 RVI Circuit Description

7.7.1.1.3.1.1 RVI Jet Pump Flow

Chapter 5 gives a description of the reactor jet pump flow controls.

7.7.1.1.3.1.2 RVI Temperature

The reactor vessel temperature is indicated by several thermocouples placed at selected locations on the vessel shell and flange, as well as one on the vessel bottom head drain line as shown in

drawing M-41. These thermocouple temperatures are recorded at a local panel in the reactor enclosure and some selected thermocouples are input into the plant and ERFDS computers.

The reactor vessel temperature can also be determined on the basis of reactor coolant temperature. Temperatures needed for operation and compliance with the Technical Specification operating limits are obtained from one of several sources, depending on the operating condition. During normal operation, either reactor pressure (Section 7.7.1.1.3.1.5) or the inlet temperature of the coolant in the recirculation loops (drawing M-43) can be used to determine the vessel temperature. Below the operating span of the resistance temperature detectors in the recirculation loop, and above 212°F, the vessel pressure is used to determine the temperature. Below 212°F, the vessel coolant, and thus the vessel temperature, is shown by the RWCU system inlet temperature (drawing M-44). These three sources of input are available from the process computer and from indicators or recorders in the control room. During normal operation, vessel thermal transients are limited by operational constraints on parameters other than temperature.

7.7.1.1.3.1.3 RVI Water Level

Figure 7.7-1 shows the water level ranges and the vessel penetration for each range. The instruments that sense water level are differential pressure devices calibrated to be accurate at a specific vessel pressure and liquid temperature condition. Additional gauge pressure devices are used during refueling. Water level instrument line failure is addressed in Section 7.7.1.1.6. The following is a description of each water level range shown in Figure 7.7-1:

a. Shutdown water level range:

   This range is used to monitor the reactor water level during the shutdown condition when the reactor system is flooded for maintenance and head removal. The water level measurement design is of the condensate reference chamber-type when the vessel head is in place. The vessel temperature and pressure conditions used for the calibration are 0 psig and 120°F water in the vessel. The zero of the instrument is the bottom of the dryer skirt. The two vessel instrument penetrations used for this water level measurement are located at the top of the RPV head and just below the bottom of the dryer skirt. When the vessel head is removed for refueling, the condensate reference chamber and associated wet leg is not functional, and a gauge pressure transmitter is switched in, to measure shutdown range level. One indicator is provided in the control room to indicate reactor water level in the shutdown range.

b. Upset water level range:

   This range is used to monitor the reactor water when the level of the water goes off the narrow range scale on the high side. The upset range is also used during refueling to provide redundant level indication in the control room. The design and vessel taps are the same as outlined above. The vessel pressure and temperature condition for accurate indication are at the normal operating point, except for the gauge pressure transmitter used during refueling, which is calibrated to the same conditions as for the shutdown range instrumentation. The upset water level is continuously indicated by a recorder in the control room. The upset range recorder and narrow range indicators are located in close proximity to each other. The upset range upper limit is higher than the narrow range upper limit. Therefore, when the

indication goes off scale in the upscale direction on the narrow range indicator, water level indication can be read immediately from the upset range recorder.

c. Narrow water level range:

This range uses RPV taps at an elevation near the top of the dryer skirt and taps at an elevation near the bottom of the dryer skirt. The zero of the instrument is the bottom of the dryer skirt and the instruments are calibrated to be accurate at the normal operating point. The water level measurement design is of the condensate reference chamber-type and uses differential pressure devices as the primary elements. The feedwater control system uses this range for its water level control and indication inputs. For more information about the range, trip points, number of channels, and control room indication, see the discussion on the feedwater control system in Section 7.7.1.4.

d. Wide water level range:

This range uses RPV taps at an elevation near the top of the dryer skirt and taps at an elevation near the top of the active fuel. The zero of the instrument is the bottom of the dryer skirt and the instruments are calibrated to be accurate at the normal power operating point. The water level measurement design is of the condensate reference chamber-type, and uses differential pressure devices as the primary elements. Control room indication in the wide range is used for normal and accident conditions. See Section 7.5 for a description of the number of channels, type of indication, and ranges.

e. Fuel zone water level range:

This range uses RPV taps at an elevation near the top of the dryer skirt and taps at the jet pump diffuser skirt. The zero of the instrument is the bottom of the dryer skirt and the instruments are calibrated to be accurate at 0 psig and saturated condition. The fuel zone level transmitters output signals are electronically compensated for variation in reactor water and steam density with respect to pressure. The water level design is of the condensate reference chamber-type, and uses differential pressure devices as the primary elements. One recorder and one indicator are provided in the control room to indicate reactor water level in the fuel zone range. The top of the active fuel will be indicated in red.

The condensate reference chamber for the narrow range, wide range, and fuel zone water level range is common, as shown in drawing M-42. A continuous backfill system is connected to each condensing chamber reference leg. The backfill system provides a continuous flow of water from the Control Rod Drive (CRD) System to the reference leg. This flow of water will continuously purge the reference leg and preclude the build up of noncondensable gas in the reference leg.

7.7.1.1.3.1.4 RVI Reactor Core Hydraulics

A differential pressure transmitter indicates the core plate pressure drop by measuring the pressure difference between the core inlet plenum and the space just above the core support assembly (core plate and fuel supports). The instrument sensing line used to determine differential pressure is a pipe within a pipe arrangement attached to the reactor vessel tap initially designed to provide differential pressure taps and inject the liquid from the SLCS. Now SLCS is injected through the B Core Spray sparger and the differential pressure sensing line only taps the pressure above and below the core support assembly. The differential pressure of the core plate is recorded in the control room.

7.7.1.1.3.1.5 RVI Pressure

Pressure sensors/transducers, indicators, and transmitters detect reactor vessel internal pressure from the same instrument lines used to measure reactor vessel water level. The only nonsafety-related pressure measuring instruments provided are discussed in Section 7.7.1.4.

7.7.1.1.3.1.6 RVI Head Seal Leak Detection

Pressure between the inner and outer reactor vessel head seal ring is sensed by a local pressure indicator and a pressure switch that alarms in the control room. If the inner seal fails, the pressure at the pressure sensors increases to the vessel pressure. The plant continues to operate with the outer seal as a backup, and the inner seal can be repaired at the next outage when the head is removed. If both the inner and outer head seals fail, the leak is detected by an increase in drywell temperature and pressure.

7.7.1.1.3.1.7 RVI/SRV Leak Detection

Thermocouples are located in the discharge exhaust pipe of the SRV. The temperature signal goes to a multipoint recorder with an alarm and is activated by any temperature in excess of a set temperature, signaling that one of the SRV seals or pilot valves has started to leak (drawing M-41). The temperature signals can also be used as a means to determine SRV position, hence this instrumentation is a diverse backup to the SRVPI system (Section 7.6.1.5).

7.7.1.1.3.1.8 RVI Other Instruments

a. Steam temperature is measured and transmitted to the control room.

b. Feedwater temperature is measured and transmitted to the control room.

c. Feedwater conductivity is monitored and recorded locally. An instrument trouble alarm is provided in the control room (drawing M-23).

7.7.1.1.3.2 RVI Testability

There are no testability requirements for the RVI described in this section because the instruments are nonsafety-related and are not required for any postulated DBA or for safe shutdown. The instruments located outside the drywell can be tested during plant operation, while those that are inaccessible during plant operation can be tested during plant shutdown. Plant test procedures will establish methodology and frequency.

7.7.1.1.4 RVI Environmental Considerations

There are no special environmental considerations for the instruments described in this section.

7.7.1.1.5 RVI Operational Considerations

7.7.1.1.5.1 RVI General Information

The RVI discussed in this section is designed to augment the existing information from the safety-related systems so that the operator can start up, operate at power, shut down, and service

the reactor vessel in an efficient manner. None of this instrumentation is required to initiate any safety-related system.

7.7.1.1.5.2 RVI Operator Information

The following is the information that the operator has at his disposal from the instrumentation discussed in this section:

a. The temperature of the reactor coolant in the recirculation loops is recorded in the control room.

b. The RWCU inlet temperature is indicated in the control room.

c. Water level in the shutdown range is indicated in the control room.

d. Water level in the upset range is recorded in the control room.

e. Water level in the fuel zone range is indicated and recorded in the control room.

f. The core plate differential pressure and total core flow are recorded in the control room.

g. The reactor pressure is indicated and recorded in the control room.

h. The reactor head seal leak detection turns on an annunciator when the inner reactor head seal fails.

i. The discharge temperatures of all the SRVs are shown on a multipoint recorder in the control room. Any temperature point that exceeds the trip setting turns on an annunciator indicating that a SRV seal or pilot valve has started to leak.

j. Feedwater conductivity is recorded in the control room. The recorder turns on an annunciator in the control room on a high signal.

7.7.1.1.5.3 RVI Setpoints

The annunciator alarm setpoints for the reactor head seal leak detection, and SRV seal and pilot valve leak detection are set so that the sensitivity to the variable being measured provides adequate information.

Figure 7.7-1 includes a chart showing the relative indicated water levels at which various alarms are initiated.

Level trips to initiate various alarms and trip the main turbine and the feed pumps are discussed in Section 7.7.1.4.

7.7.1.1.6 Water Level Instrument Line Failure

An analysis has been performed to verify that there is sufficient redundancy in the water level instrumentation to prevent a sensing line failure (i.e., break, blockage or leak) concurrent with a

random single electrical failure from defeating an automatic RPS or ESF actuation. This analysis was conducted based on the methodology provided in Table 7.7-6.

The instrument reference lines common to feedwater control and to protective system sensors are identified in Table 7.7-7. An evaluation was performed to determine the consequences of failures in such reference lines concurrent with additional single failures in protective channels not dependent on the failed sensing line.

In the highly unlikely scenario, the most severe reference line was assumed to fail such that all attached level instruments erroneously indicated high levels. Then, additional worse case single failures were postulated in the circuits connected to the remaining reference line. The criteria for selection of the potential worst case combinations of reference line failure plus additional single failure was to determine those combinations, if any, which preclude automatic operation of a RPS and/or ESF system(s), and which may require manual action by the operator to bring the reactor to a safe condition. Worst case single division power supply loss was considered for ECCS and RCIC, but this is independent from other single failures which could affect RPS or MSIV closure, etc. (i.e., a power bus failure in RPS would fail "safe" causing a trip of that channel).

A review of the various failure combinations resulted in the identification of two cases which would represent the worst postulated failure paths. These are described as follows:

Case 1 was found to be failure of the Division 2 instrument reference line (i.e., connected to condensing chamber B21-D004B) combined with a failure "high" of the B21-N091D or H level transmitter. The worst case also assumes that the FCS level soft majority selector fails to perform its designed function of removing the failed transmitter signal from the level control signal. The feedwater controller responds to the high level error signal by reducing the feedwater flow. Following the loss of feedwater, water level will decrease to level 4, initiating a low water level alarm. Reactor scram will be initiated when water level decreases to the low water level 3 scram setpoint. The low water level 3 signal will result in the initiation of a second low water level alarm. As water level decreases to low water level 2, a third low water level alarm will initiate, the RCIC system will automatically start, and both recirculation pumps will trip. The HPCI system is unavailable due to the assumed failure. This scenario is identical to the sizing basis of the RCIC. The RCIC will provide sufficient water inventory makeup to prevent the water level from dropping below low water level 1, thus avoiding initiation of the ADS and the low pressure ECCS systems. The core remains covered at all times and no fuel failure would occur.

All other scenarios identified were less severe than the two cases just described. Those that involve failures which do not affect the level 3 scram are accompanied by either HPCI or HPCI + RCIC automatic initiation by low reactor water level 2 signals. Other scenarios which involve failures in the level 3 scram circuits are accompanied by scram due to ARI at level 2 and automatic initiation of both HPCI and RCIC.

The results of this assessment can be summarized as follows:

a. The LGS reactor system can withstand any reactor vessel level reference line break coupled with an additional worst single failure in a protective channel not dependent on the failed sensing line without compromising safety. This is assured by the following evaluations:

1. No part of the active fuel is uncovered at any time. This assures no fuel damage and no degradation of the CPR or reactivity release.

2. Both the vessel and the containment remain structurally sound throughout the postulated event. This provides secondary assurance that no reactivity can be released to the public.

3. The scenario postulated is a highly unlikely event (instrument line breakage with coincident random failure) and compounds it with worst case conditions through the event. Though no credit is taken in the scenarios identified, it is highly probable that the operator would recover feedwater immediately by switching the controller to the alternate instrument line because of the alarms that call his attention to level indication mismatch and the numerous low water level alarms. In addition, if the failed instrument reference line is either the Division 3 or 4 instrument line (i.e., connected to condensing chamber B21-D004C or D) no feedwater controller error would occur and there would be no reduction in feedwater flow.

LGS has the capability of providing automatic protection under all postulated scenarios. This is due to its four instrumentation divisions, which provide sufficient redundancy for automatic initiation of protection systems and eliminates the need for manual corrective action by the operator to prevent compromising plant safety.

b. There are no failure combinations that result in failure of both HPCI and RCIC. One of the two systems is always available.

c. Failure combinations which result in failure of the reactor to scram at low reactor water level 3 are always accompanied by reactor scram (due to ARI) and either HPCI or RCIC automatic initiation due to low reactor water level 2 signals.

It is concluded from this assessment of a break in a vessel level sensing line common to control and protective systems plus an additional worst single failure in a protective channel not dependent on the failed sensing line that the resulting accident is less severe and bounded by the DBAs already analyzed in Chapter 15.

7.7.1.2 Reactor Manual Control System - Instrumentation and Controls

7.7.1.2.1 RMCS Identification

7.7.1.2.1.1 RMCS General

The objective of the RMCS is to provide the operator with the means to make changes in nuclear reactivity so that reactor power level and power distribution can be controlled. The system allows the operator to manipulate control rods.

The RMCS instrumentation and controls consist of the electrical circuitry, switches, indicators, and alarm devices provided for operational manipulation of the control rods and surveillance of associated equipment.

This system includes the interlocks that inhibit rod movement (rod block) under certain conditions. The RMCS does not include any of the circuitry or devices used to automatically or manually scram the reactor (Section 7.2).

In addition, the mechanical devices of the CRDs and the CRD hydraulic system are not included in the RMCS. The latter mechanical components are described in Section 4.1.3.

7.7.1.2.1.2 RMCS Classification

This system is a power generation system and is classified as not related to safety.

7.7.1.2.1.3 RMCS Reference Design

Table 7.1-2 lists reference design information. The RMCS is an operational system and has no safety function. Therefore, there are no safety design differences between this system and those of the reference design facilities. This system is functionally identical to the referenced system.

7.7.1.2.2 RMCS Power Sources

a. Normal: The reactor manual control system receives its power from the 120 V ac instrumentation buses. Each of these buses receives its normal power supply from the appropriate 440 V ac standby power system.

b. Alternate: On loss of normal auxiliary power, the station diesel generators provide backup power to the 440 V standby ac power systems.

7.7.1.2.3 RMCS Equipment Design

7.7.1.2.3.1 RMCS General

The following discussions examine the control rod movement instrumentation and control aspects of the subject system, and the control rod position information system. The control descriptions include the following:

a. Control rod drive - control system

b. Control rod drive - hydraulic system

c. Rod block interlocks

The position descriptions include the following:

a. Rod position probes

b. Display electronics

Drawings M-46 and M-47 show the CRD hydraulic system. Drawings C11-1030-F-008, C11-1030-F-009, C11-1030-F-010, C11-1030-F-011, C11-1030-F-012, C11-1030-F-013, and C11-1030-F-014 show the FCD for the CRD hydraulic system.

Although they also show the arrangement of scram devices, these devices are not part of the RMCS. Control rods are moved by admitting water under pressure from the CRD water pump into the appropriate end of the CRD cylinder. The pressurized water forces

the piston, which is attached by a connecting rod to the control rod, to move. Three modes of control rod operation are used: insert, withdraw, and settle. Four solenoid-operated valves are associated with each control rod to accomplish the actions required for the operational modes. The valves control the path that the CRD water takes to the cylinder.

7.7.1.2.3.2 Rod Movement Controls

7.7.1.2.3.2.1 CRD Control System

7.7.1.2.3.2.1.1 Introduction

When the operator selects a control rod for motion and operates the rod insertion control switch, identical messages are formulated in the A and B portions of the rod drive control system as shown in Figure 7.7-3. A comparison test is made of these two messages, and if identical messages are confirmed, a serial message in the form of results is produced; then a serial message in the form of electrical pulses is transmitted to all HCUs. The message contains two portions: the identity or "address" of the selected HCU, and the operation data on the action to be executed. Only the selected HCU responds to this transmission and proceeds to execute the rod action commands. Hence, the drive water and exhaust valves for the selected rod open and allow the CRD water to follow a path that results in the desired control rod movement.

On receipt of the transmitted signal as shown in Figure 7.7-3, the responding HCU transmits three portions of an acknowledge message back to the auxiliary equipment room panel for comparison with the original message:

a. Its own hard-wire identity "address"

b. Its own operations currently being executed

c. Status indications of valve positions, accumulator conditions, and test switch positions.

In either rod motion direction, the A and B messages are formulated and compared each millisecond; if they agree, the message is transmitted to the HCU selected by the operator. Continued rod motion depends on receipt of a train of sequential messages because the HCU insert, withdraw, and settle valve control circuits are ac-coupled. The system must operate in a dynamic manner to effect rod motion. Postulated failures within the RMCS generally result in a static condition within the system, which prevents further rod motion.

Any disagreement between the A and B formulated messages or the C acknowledge message prevents further rod motion. However, electrical noise disruptions only momentarily affect the system in proportion to the duration of the offending source. Correct operation of the system resumes when the noise source ceases. In Figure 7.7-4, three action loops of the solid-state RMCS are depicted:

a. The high speed loop (a nominal 0.0002 second duration) services the control rod selected by the operator to transmit action commands and receive status indications.

b. The medium speed loop (a nominal 0.045 second duration) monitors the other control rods in the reactor, one at a time, to update their status display.

c. The low speed loop (on the order of 20 second to 100 second duration) exercises one HCU at a time to ensure correct execution of actions commanded. This provides for a continuous, periodic self-test of the entire RMCS.

The rod selection circuitry is arranged so that a rod selection is sustained until either another rod is selected, or separate action is taken to revert the selection circuitry to a no-rod-selected condition. Initiating movement of the selected rod prevents the selection of any other rod until the movement cycle of the selected rod has been completed. Reversion to the no-rod-selected condition is not possible (except for loss of control circuitry power) until any moving rod has completed its movement cycle.

The direction in which the selected rod moves is determined by the position of four switches located on the reactor control panel. These four switches, INSERT, WITHDRAW, CONTINUOUS INSERT and CONTINUOUS WITHDRAW, are push buttons that return to an off position by spring action.

7.7.1.2.3.2.1.2 CRD Insert Cycle

A description of the detailed operation of the RMCS during an insert cycle follows. The cycle is described in terms of the insert, withdraw, and settle commands emanating from the RMCS. The response of a selected rod to the various commands transmitted has been explained previously. Drawings C11-1030-F-008, C11-1030-F-009, C11-1030-F-010, C11-1030-F-011, C11-1030-F-012, C11-1030-F-013, and C11-1030-F-014 can be used to follow the sequence of an insert cycle.

With a control rod selected for movement, depressing the INSERT switch and then releasing it energizes the insert command for a specific time. Just as the insert command is removed, the settle command is automatically energized and remains energized for a specific time. The insert command time setting and the rate of drive water flow provided by the CRD hydraulic system determine the distance traveled by a rod. The time setting results in a one notch (6 inch) insertion of the selected rod for each momentary application of a rod-in signal from the rod movement switch. Continuous insertion of a selected control rod is possible by holding the INSERT switch down, as long as rod movement is within pattern restraints.

A second switch can be used to effect insertion of a selected control rod. This switch is the CONTINUOUS INSERT switch. By holding this switch in, the unit maintains the insert command in a continuous, energized state to cause continuous insertion of the selected control rod. When released, the timers are no longer bypassed and normal insert and settle cycles are initiated to stop the drive.

7.7.1.2.3.2.1.3 CRD Withdraw Cycle

A description of the detailed operation of the RMCS during a withdraw cycle follows. The cycle is described in terms of the insert, withdraw, and settle commands. The response of a selected rod to

the various commands transmitted has been explained previously. Drawings C11-1030-F-008, C11-1030-F-009, C11-1030-F-010, C11-1030-F-011, C11-1030-F-012, C11-1030-F-013, and C11-1030-F-014 can be used to follow the sequence of a withdrawal cycle.

With a control rod selected for movement, depressing the WITHDRAW switch energizes the insert valves for a short time. Energizing the insert valves at the beginning of the withdrawal cycle is necessary to allow the collet fingers to disengage the index tube. When the insert valves are de-energized, the withdraw and settle valves are energized for a controlled period of time. The withdraw valve is de-energized before movement is completed. The drive then settles until the collet fingers engage. The settle valve is then de-energized, completing the withdraw cycle . This withdrawal cycle is the same whether the withdrawal switch is held down continuously or momentarily depressed. The timers that control the withdrawal cycle are set so that the rod travels one notch (6-inches) per cycle. Provisions are included to prevent further control rod motion in the event of timer failure.

At high power levels when RWM is not operable, a selected control rod can be continuously withdrawn if the WITHDRAWAL switch is held in the depressed position at the same time that the CONTINUOUS WITHDRAWAL switch is held in the depressed position. With both switches held in these positions, the withdraw and settle commands are continuously energized. When released, the normal settle period completes the withdrawal cycle.

7.7.1.2.3.2.2 CRD Hydraulic System

One motor-operated pressure control valve, two air-operated flow control valves, and four solenoid-operated stabilizer valves are included in the CRD hydraulic system to maintain smooth and regulated system operation. These devices are shown in drawing M-46. The motor-operated pressure control valve is positioned by manipulating a switch in the control room. The switch for this valve is located close to the pressure indicator, which responds to the pressure changes caused by the movement of the valve. Only one flow control valve is in service at a time. The air-operated flow control valves are automatically positioned in response to signals from an upstream flow-measuring device. Only two stabilizer valves are in service at a time. The stabilizer valves are automatically controlled by the energization of the insert and withdraw commands. The control scheme is shown in drawings C71-1010-F-002, C71-1010-F-003, C71-1010-F-004, and C71-1010-F-005. Two drive water pumps are controlled by switches in the control room. Each pump automatically trips on indication of low suction pressure.

7.7.1.2.3.2.3 Rod Block Interlocks

7.7.1.2.3.2.3.1 RBI Trip System

A portion of the RMCS, upon receipt of input signals from other systems and subsystems, inhibits movement or selection of control rods.

7.7.1.2.3.2.3.2 RBI Grouping of Channels

The same grouping of neutron monitoring system equipment (SRM, IRM, APRM, and RBM) that is used in the RPS is also used in the rod block circuitry (Section 7.6.1.4).

Half of the total monitors (SRM, IRM, APRM, and RBM) provides inputs to one of the RMCS rod block logic circuits and the remaining half provides inputs to the other RMCS rod block logic circuit. Two APRM channels provide recirculation flow upscale rod blocks to one logic circuit; the other two

APRM channels provide recirculation flow upscale rod block signals to the other logic circuit. SDV high water level signals are provided as inputs into both of the rod block logic circuits. Both rod block logic circuits sense when the high water level scram trip for the SDV is bypassed.

The rod withdrawal block from the RWM trip prevents both notch insertion and continuous insertion. The rod insert block from the RWM functions prevents both notch insertion and continuous insertion.

The APRM rod block settings are varied as a function of recirculation flow and core thermal power, and the RBM rod block settings are varied as a function of core thermal power. Analyses show that the selected settings are sufficient to avoid both RPS action and local fuel damage as a result of a single control rod withdrawal error. Mechanical switches in the SRM and IRM detector drive systems provide the position signals used to indicate that a detector is not fully inserted. Additional detailed information on all the NMS trip channels is available in Section 7.6.1.4. The rod block from SDV high water level uses two nonindicating float switches installed on the scram discharge volume. Two additional float switches provide a control room annunciation of increasing level below the level at which a rod block occurs.

7.7.1.2.3.2.3.3 RBI Functions

The following discussion describes the various rod block functions and explains the intent of each function. The instruments used to sense the conditions for which a rod block is provided are discussed later. The rod block functions provided specifically for refueling situations are described in Section 7.7.1.15.

a. With the mode switch in the SHUTDOWN position, no control rod can be withdrawn. This enforces compliance with the intent of the shutdown mode.

b. The circuitry is arranged to initiate a rod block regardless of the position of the mode switch for the following conditions:

    1. Any APRM Simulated Thermal Power upscale rod block alarm - The purpose of this rod block function is to avoid conditions that would require RPS action if allowed to proceed. The APRM upscale rod block alarm setting is selected to initiate a rod block before the APRM high neutron flux or Simulated Thermal Power scram setting is reached.

    2. Any APRM inoperative alarm - This ensures that no control rod is withdrawn unless the average power range neutron monitoring channels are either in service or correctly bypassed.

    3. Any APRM LPRM low count alarm - This ensures that no control rod is withdrawn unless the average power range neutron monitoring channels have the required number of LPRM inputs to be considered operable.

    4. SDV high water level - This ensures that no control rod is withdrawn unless enough capacity is available in the SDV to accommodate a scram. The setting is selected to initiate a rod block earlier than the scram that is initiated on SDV high water level.

5. SDV high water level scram trip bypassed - This ensures that no control rod is withdrawn while the SDV high water level scram function is out-of-service.

6. The RWM can initiate a rod insert and a rod withdrawal block. The purpose of these functions is to reinforce procedural controls that limit the reactivity worth of control rods under low power conditions. The rod block trip settings are based on the allowable control rod worth limits established for the design basis rod-drop accident. Adherence to prescribed control rod patterns is the normal method by which this reactivity restriction is observed. Additional information on the RWM function is available in Section 7.7.1.21.

7. RPIS malfunction - This ensures that no control rod is withdrawn unless the RPIS is in service.

8. Either RBM upscale alarm - This function is provided to stop the erroneous withdrawal of a control rod so that local fuel damage does not result, although local fuel damage poses no significant threat in terms of radioactive material released from the nuclear system.

9. Either RBM inoperative alarm - This ensures that no control rod is withdrawn unless the RBM channels are in service or correctly bypassed.

c. With the reactor mode switch in the RUN position, any of the following conditions initiates a rod block:

1. Any APRM downscale alarm - This ensures that no control rod is withdrawn during power range operation unless the average power range neutron monitoring channels are operating correctly or are correctly bypassed. All unbypassed APRMs must be on scale during reactor operations in the RUN mode.

2. Either RBM downscale alarm - This ensures that no control rod is withdrawn during power range operation unless the RBM channels are operating correctly or are correctly bypassed. Unbypassed RBMs must be on scale during reactor operations in the RUN mode.

3. Any APRM recirculation flow upscale alarm - This ensures that the no control rod is withdrawn unless the APRM recirculation flow signals are operable and the flow rate in not unusually high.

d. With the mode switch in the STARTUP or REFUEL position, any of the following conditions initiates a rod block:

1. Any SRM detector not fully inserted into the core when the SRM count level is below the retract permit level and any IRM range switch is on either of the two lowest ranges - This ensures that no control rod is withdrawn unless all SRM detectors are correctly inserted, because they must be relied on to provide the operator with neutron flux level information.

2. An SRM upscale level alarm - This ensures that no control rod is withdrawn unless the SRM detectors are correctly retracted during a reactor startup. The block setting is selected at the upper end of the range over which the SRM is designed to detect and measure neutron flux.

3. Any SRM downscale alarm - This ensures that no control rod is withdrawn unless the SRM count rate is above the minimum prescribed for low neutron flux level monitoring.

4. Any SRM inoperative alarm - This ensures that no control rod is withdrawn during low neutron flux level operations unless neutron monitoring capability is available because all SRM channels are in service or correctly bypassed.

5. Any IRM detector not fully inserted into the core -This ensures that no control rod is withdrawn during low neutron flux level operations unless proper neutron monitoring capability is available because all IRM detectors are correctly located.

6. Any IRM upscale alarm - This ensures that no control rod is withdrawn unless the intermediate range neutron monitoring equipment is correctly upranged during a reactor startup. This rod block also provides a means to stop rod withdrawal in time to avoid conditions requiring RPS action (scram) in the event that a rod withdrawal error is made during low neutron flux level operations.

7. Any IRM downscale alarm except when the range switch is on the lowest range - This ensures that no control rod is withdrawn during low neutron flux level operations unless the neutron flux is being correctly monitored. This rod block prevents the continuation of a reactor startup if the operator upranges the IRM too far for the existing flux level. Thus, the rod block ensures that the IRM is on scale if control rods are to be withdrawn.

8. Any IRM inoperative alarm - This ensures that no control rod is withdrawn during low neutron flux level operations unless neutron monitoring capability is available because all IRM channels are in service or are correctly bypassed.

7.7.1.2.3.2.3.4 RBI Bypasses

To permit continued power operation during repair or calibration of equipment for selected functions that provide rod block interlocks, a limited number of manual bypasses are permitted as follows:

a. One SRM channel

b. Two IRM channels (one on either Bus A or Bus B)

c. One APRM channel

d. One RBM channel

The permissible IRM bypasses are arranged as two groups of equal numbers of channels. One manual bypass is allowed in each group. The groups are chosen so that adequate monitoring of the core is maintained with one channel bypassed in each group. The arrangement allows the bypassing of one IRM in each rod block logic circuit.

One of the four APRM channels can be bypassed at any time. The assignment of LPRMs to APRM channels is chosen so that adequate monitoring of the core is maintained with an APRM channel bypassed.

These bypasses are effected by positioning switches in the control room. A light in the control room indicates the bypassed condition.

An automatic bypass of the SRM detector position rod block is effected as the neutron flux increases beyond a preset low level on the SRM instrumentation. The bypass allows the detectors to be partially or completely withdrawn as a reactor startup is continued.

An automatic bypass of the RBM rod block occurs when the power level is below the preselected level or when a peripheral control rod is selected. Either condition indicates that local fuel damage is not threatened and that RBM action is not required.

The RWM system rod block functions are automatically bypassed when reactor power is above a preselected value in the power range. The RWM can be manually bypassed for maintenance at any time.

7.7.1.2.3.2.3.5 RBI Interface

Tables 7.7-4 and 7.7-5 detail the rod block interlocks used in the RMCS, as well as the rod blocking functions that originate in the neutron monitoring system.

7.7.1.2.3.2.3.6 RBI Redundancy

To achieve an operationally desirable performance objective where most failures of individual components would either be easily detectable or would not disable the rod movement inhibiting functions, the rod block logic circuitry is arranged as two redundant logic circuits. Each logic circuit receives input trip signals from a number of trip channels and each logic circuit can provide a separate rod block signal to inhibit rod withdrawal.

The output of each logic circuit is coupled to a comparator by electro-optical devices in the rod drive control cabinet. The formulated A and B signals are compared and rod blocks applied when either an A or B trip is present. Rod withdrawal is permitted only if the two signals agree at all times and no rod block signals are present. Because the transmitted signals are dynamic and vary with time, any RMCS failure that interrupts the dynamic signals transmitted to the HCUs prevents further control rod motion. Hence, failures consisting of short circuits, open circuits, loss of circuit continuity, or loss of power inhibit manual rod movement.

The rod block circuitry is effective in preventing rod withdrawal, if required, during both normal (notch) withdrawal and continuous withdrawal. If a rod block signal is received during a rod withdrawal, the control rod is automatically stopped at the next notch position, even during a continuous rod withdrawal.

The components used to initiate rod blocks in combination with refueling operations provide rod block trip signals to these same rod block circuits. These refueling rod blocks are described in Section 7.7.1.15.

7.7.1.2.3.2.3.7 RBI On-Line Testability

On-line testability of the systems and indication of bypassed or inoperable status of the system are provided.

7.7.1.2.3.2.3.8 RBI Environmental Considerations

The equipment is mounted in the control structure. Environmental conditions in the control structure are listed in Section 3.11.

7.7.1.2.3.2.3.9 RBI Operational Considerations

The rod block trips prevent an operator from withdrawing rods if the associated equipment is not capable of monitoring core response or, if unchecked, the withdrawals might require a RPS action (scram). There are no special operational considerations.

7.7.1.2.3.2.4 RBI Testability

In addition to the periodic self-test mode of system operation, the RMCS circuitry can be routinely checked for correct operation by manipulating control rods using the various methods of control. Detailed testing and calibration can be performed by using standard test and calibration procedures for the various components of the RMCS circuitry.

7.7.1.2.3.3 Rod Position Information System

This system includes the rod position probes and the electronic hardware that processes the probe signals and provides the data described above.

7.7.1.2.3.3.1 RPIS Position Probes

The position probe is a long cylindrical assembly that fits inside the CRD. It includes 53 magnetically operated reed switches located along the length of the probe and operated by a permanent magnet fixed to the moving part of the hydraulic drive mechanism. As the drive, and with it the control rod blade, moves along its length, the magnet causes reed switches to close as it passes over the switch locations. The particular closed switch then indicates where the CRD, and hence the rod itself, is positioned.

The switches are located as follows: one at each of 25 notch (even) positions; one at each of 24 midnotch (odd) positions; two at the fully inserted position (approximately the same location as the "00" notch); one at the fully withdrawn position (approximately the same location as the "48" notch); and one at the "overtravel," or decoupled, position.

All of the midnotch, or odd, switches are wired in parallel and treated as one switch (for purposes of external connections), and the two fully inserted switches are wired in parallel and treated as one switch. These and the remaining switches are wired in a 5x6 array (the switches short the

intersections) and are routed out in an 11 wire cable to the processing electronics (the probe also includes a thermocouple that is wired out separately from the 5x6 array) (Figure 7.7-5).

7.7.1.2.3.3.2 RPIS Electronics

The electronics consist of a set of "probe multiplexer cards" (one per four-rod group), a set of "file control cards" (one per 11-probe multiplexer cards), and one set of master control and processing cards serving the whole system. All probe multiplexer cards are the same except that each has a pair of plug-in "daughter cards" containing the identity code of one four-rod group (the probes for the corresponding four rods are connected to the probed multiplexer card).

7.7.1.2.3.3.3 RPIS Operation

The system operates on a continuous scanning basis with a complete cycle every 45 milliseconds. The operation is as follows: The control logic generates the identity code of one rod in the set, and transmits it using time multiplexing to all of the file control cards. These in turn transmit the identity with timing signals to all of the probe multiplexer cards. The one multiplexer card with the matching rod identity responds and transmits its identity (locally generated) plus the raw probe data for that rod back through the file control card to the master control and processing logic. The processing logic does several checks on the returning data. First, a check is made to verify that an answer was received. Next, the identity of the answering data is checked against that which was sent. Finally, the format of the data is checked for legitimacy. Only a single even position, or full-in plus position "00," or full-out plus position "48," or odd, or overtravel, or blank [no switch closed] are legitimate. Any other combination of switches is flagged as a fault.)

If the data passes all of these tests, it is decoded and transmitted in multiplexed form to the displays in the main control panel and is then loaded into a memory to be read by the computer as required.

As soon as one rod's data are processed, the next rod's identity is generated, processed, and repeated for all of the rods. When data for all rods have been gathered, the cycle repeats.

7.7.1.2.4 RMCS Environmental Considerations

The RMCS (control and position indication circuitry) is not required for any plant safety function nor is it required to operate in any associated design basis events or transient occurrences. The reactor manual control circuitry is required to operate only in the normal plant environments during normal power generation operations.

The CRD HCUs are located outside the drywell in the reactor enclosure. The logic, control units, and readout instrumentation are located in the control structure.

The CRDs' position detectors are located beneath the reactor vessel in the drywell. The normal design environments encountered in these areas are given in Section 3.11.

7.7.1.2.5 RMCS Operational Considerations

7.7.1.2.5.1 RMCS General Information

The RMCS is totally operable from the control room. Manual operation of individual control rods is possible with switches to effect control rod insertion, withdrawal, or settle. Rod position indicators provide the necessary information to ascertain the operating state and position of all control rods. Conditions that prohibit control rod insertion are alarmed with the rod block annunciator.

7.7.1.2.5.2 RMCS Reactor Operator Information

Table 7.7-1 gives information on the process instruments for the CRD hydraulic system. A large rod information display on the rod status display panel is patterned after a top view of the reactor core. The display allows the operator to acquire information rapidly by scanning.

Colored windows provide an overall indication of rod pattern and allow the operator to quickly identify an abnormal indication. The following information for each control rod is presented in the display:

a. Rod fully inserted (green)

b. Rod fully withdrawn (red)

c. Selected rod identification (coordinate position, white)

d. Accumulator trouble (amber)

e. Rod scram (blue)

f. Rod drift (red)

A separate, smaller display (the four-rod display) is located on the control console. This display shows the positions of the control rod selected for movement and the other rods in the rod group. For display purposes, the control rods are considered in groups of four adjacent rods (a four-rod group) centered around a common core volume monitored by four LPRM strings. Rod groups at the periphery of the core can have less than four rods. The four-rod display shows the positions, in digital form, of the rods in the group to which the selected rod belongs. A lighted background on the digital display indicates which of the four rods is selected for movement.

The four-rod display allows the operator to better focus his attention on the portion of the core experiencing rod motion. A full core rod position display would tend to be confusing and difficult to read. In addition, on demand by the operator, the Plant Monitoring System can provide a printout of all rod positions.

During startup or shutdown, rods of a given sequence which are either fully withdrawn or fully inserted are indicated on the full core display with the full-in or full-out lights. In addition to the whole core display, a drifting rod is indicated by an alarm and red light in the control room. The Plant Monitoring System also monitors the rod drift condition.

An indication is also provided for rod travel beyond the limits of normal rod movement. If the rod drive piston moves to the OVERTRAVEL position, an alarm is sounded in the control room. The overtravel alarm provides a means to verify that the drive-to-rod coupling is intact because, with the

coupling in its normal condition, the drive cannot be physically withdrawn to the overtravel position. Coupling integrity can be checked by attempting to withdraw the drive to the overtravel position.

For the displays above, the selected rod identification, accumulator trouble, and rod scram indicators are provided to the displays by the rod drive control system. The remaining information to the displays and the position information for the Plant Monitoring System are provided by the RPIS.

The following control room lights are provided to allow the operator to know the conditions of the CRD hydraulic system and the control circuitry:

a. Stabilizer valve selector switch position

b. Insert command energized

c. Withdraw command energized

d. Settle command energized

e. Withdrawal not permitted

f. Continuous withdrawal

g. Pressure control valve position

h. Flow control valve position

i. Drive water pump low suction pressure (alarm and pump trip)

j. Pump suction filter high differential (alarm only)

k. Charging water (to accumulator) low pressure (alarm only)

l. CRD temperature (alarm only)

m. SDV not drained (alarm only)

n. Scram valve pilot air header high/low pressure (alarm only)

o. System flow

p. SDV vent and drain valve position

q. Accumulator trouble alarm

r. Drive water filter differential pressure (alarm only)

7.7.1.2.5.3 RMCS Setpoints

The subject system has no safety setpoints.

7.7.1.3 Recirculation Flow Control System - Instrumentation and Controls

7.7.1.3.1 RFCS Identification

7.7.1.3.1.1 RFCS General

The objective of the RFCS is to control reactor power level, over a limited range, by controlling the flow rate of the reactor recirculating water (Figure 7.7-7).

The control valves varying the speed of the recirculation pumps by changing the voltage and frequency of the ac supply to each pump motor. The ac supply to each pump motor is provided by an Adjustable Speed Drive (ASD). The ASD consists of a transformer section coupled to a solid state power cell electronics section. Microprocessor controllers modulate the output of the power cells to convert the input 13.2 kV into the variable frequency MV output.

7.7.1.3.1.2 RFCS Classification

This system is a power generation system and not safety-related.

7.7.1.3.1.3 RFCS Reference Design

Table 7.1-2 lists reference design information. The RFCS is an operational system and has no safety function; therefore, there are no safety differences between this system and those of the above-referenced facilities. This system is functionally identical to the referenced system.

7.7.1.3.2 RFCS Power Sources

7.7.1.3.2.1 Normal/Alternate

a. Normal: ASD l20 Vac control power is derived from one of two dedicated UPS's (auctioneered) powered from their respective 480 Vac sources. Each UPS is capable of powering the control system for both ASD trains A and B, but normally only one UPS is dedicated to each drive.

b. Alternate: On loss of the normally aligned UPS or its 480 Vac source, the backup UPS automatically provides power to the ASD drive via the diode auctioneered circuit.

7.7.1.3.2.2 Deleted.

7.7.1.3.3 RFCS Equipment Design

7.7.1.3.3.1 RFCS General

Reactor recirculation flow is changed by adjusting the speed of the two reactor recirculating pumps. This is accomplished by adjusting the frequency and voltage of the electrical power supplied to the recirculation pump motor (Figure 7.7-7). Control of pump speed, and thus core flow, is such that at various control rod patterns, different power level changes can be accommodated. For a full power rod pattern, power change control down to approximately 65% of full power is possible using flow variation. Power control is possible over a range of approximately 35% of the maximum operating power level for that rod pattern.

An increase in recirculation flow temporarily reduces the void content of the moderator by increasing the flow of coolant through the core. The additional neutron moderation increases the reactivity of the core, which causes the reactor power level to increase. The increased steam generation rate increases the steam volume in the core with a consequent negative reactivity effect, and a new steady-state power level is established. When recirculation flow is reduced, the power level is reduced in the reverse manner.

7.7.1.3.3.2 RFCS Pump Drive Motor

7.7.1.3.3.2.1 RFCS Pump Drive Motor Control

Each recirculation pump motor has its own ASD for a power supply. The ASD uses digital controllers and solid state power electronics to vary the frequency and voltage supplied to the pump motor to give the desired pump speed.

7.7.1.3.3.2.2 RFCS Pump Drive Motor Trip

Two dual trip coil circuit breakers are placed in series in the power feed to each recirculation pump motor. The RPT feature uses one trip coil of each breaker to trip the recirculation pump motors when either a turbine stop valve closure or turbine control valve fast closure occurs. The RPT subsystem consists of sensors for EHC oil pressure, valve position, and turbine pressure, relays, switches and indications arranged in two separate divisions of logic, either one of which will generate a trip signal.

Turbine stop valve closure is detected by monitoring stop valve position. Turbine control valve fast closure is detected by monitoring control valve oil pressure. Closure of the A and B stop valves or fast closure of the A and B control valves will initiate the Division I RPT logic. Closure of the C and D stop valves or fast closure of the C and D control valves will initiate the Division II RPT logic. RPT is bypassed when reactor power is 29.5% as detected by turbine first stage pressure.

The recirculation pump motor breakers are also tripped by signals generated in the RRCS (Section 7.6.1.8) and by overcurrent relays monitoring the pump motor feeds (Section 8.1.6.1.12.a). The RRCS trip signal is connected to one trip coil; the RPT and overcurrent trip signals are connected to the other trip coil.

7.7.1.3.3.3 RFCS Variable-Frequency Drive

7.7.1.3.3.3.1 RFCS Adjustable Speed Drive

The two ASD trains and their associated controls are identical. The ASD can continuously supply power to the pump motor at any speed to approximately 99.2% of pump rated speed. The ASD is capable of starting the pump and accelerating it from a standstill to a desired operating speed when the pump motor thrust bearing is fully loaded by reactor pressure acting on the pump shaft. The main components of the ASD are MV input and output termination cabinets, input transformer cabinet, power electronic cell cabinets, control cabinet, relay cabinet and cooling cabinet.

a. Input and Output Termination Cabinets - where the 13.2kV supply and 4kV pump motor feed MV cables are terminated.

b. Transformer Cabinet - the transformer coverts the input 13.2 kV on the primary side down 750 Vac on the secondary side which is then connected directly to the power electronics cells. The ASD can operate under electrical supply variations of +/- 10% of rated voltage.

c. Power Electronics Cell Cabinets - there are three cabinets, each with four power cells connected in series per phase. They convert the input 750 Vac to the variable frequency / voltage proportional output which is fed directly to the pump motor. The power cells are composed mainly of a diode bridge, filtering capacitors, and an insulated gate bipolar transistor (IGBT). The lGBT is a semiconductor field effect transistor that fires a bipolar transistor to provide reliable high speed switching with high-power capabilities.

d. Control Cabinet - this cabinet houses the main controllers which control all the essential elements of the ASD and the PLCs which provide most of the interface between the main controllers and the plant. It also contains the pre-charge circuitry used to start the ASD.

The primary functions of the redundant main controllers include:

- regulate the firing of the power cells to produce the Pulse Width Modulated (PWM) output signal fed to the pump motor
- communicate to I/O and PLC for status information
- execute the plant specific System Operational Program (SOP)
- monitor drive and process parameters for alarm output

Only one of the two controllers is actively controlling all the power cells under all conditions. Typically, the “A” controller is active with the “B” controller in stand-by to take control should the “A” controller detect failure.

The primary functions of the redundant PLCs include:

- interface plant parameters and drive status between the plant and the main controller via I/O
- perform alarm checking of certain drive parameters
- the stand-by PLC monitors communications of the active PLC for failure detection
- actuates alarm and output status information

The pre-charge circuitry performs a controlled slow charge of the power cells capacitors to extend capacitor life.

e. Relay Cabinet – this cabinet houses protective relays for pump motor protection and over-frequency protection. These relays are arranged in a two-out-of-three logic and tied into the supply 13.2 kV breaker trip device. They provide backup equipment protection in the event of malfunction of failure of the ASD controllers.

f. Coolant Cabinet – this cabinet houses the coolant pumps, piping, valves and controls for supplying closed loop demineralized cooling water throughout the input transformer, power cells and cabinets. The coolant is routed to a heat exchanger dedicated to each ASD train which is cooled by service water. A third swing heat exchanger is kept in reserve to be

aligned to either ASD train as a backup, should the dedicated heat exchanger need to be taken OOS.

7.7.1.3.3.3.2 Deleted.

7.7.1.3.3.4 RFCS Speed Control Components

7.7.1.3.3.4.1 RFCS Speed Control Components for ASD

The ASD speed control system controls the firing of the power cells for both ASD trains. Each ASO train is individually controlled manually from either the MCR or locally at the ASD control cabinet. The speed control system Human Machine lnterface (HMI) is different for each location.

On MCR console *0-C602, it consists of two columns of three pushbuttons, one column dedicated for raising speed and the other for lowering speed. Speed can be raised or lowered at fixed step changes of 1, 5 or 10 rpm (raising) or 1, 5 or 30 rpm (lowering). All six pushbuttons are “one-shot” in that only one digital speed change command is read by the ASD for each press and release. Extending speed changes beyond the available increments requires repeat press/release of the appropriate pushbutton. The rate of change in speed of the pump is fixed at 2.5% / second for all commanded speed changes. The MCR controls interface with two redundant Remote I/O (RIO) cabinets per train. The RlOs convert each discrete analog speed change command to a digital signal for communication to the main speed controller. The speed change command must be received by both RlOs in order for the command to be acted upon by the ASD; otherwise a single speed change command to only one of the two RlOs will be ignored. This prevents uncontrolled speed changes from spurious invalid signals.

At the local control panel, it consists of a touch screen display HMI which graphically mimics the MCR console speed controls with the same functionality. The local HMI communicates directly to the main controller as a digital input. Transfer of control to the local HMI is via the keylock switch (controlled by SSV)) mounted on the control panel.

7.7.1.3.3.4.2 Deleted.

7.7.1.3.3.4.3 RFCS Manual Control Station

There is no manual control station. Instead, six discrete pushbuttons, each corresponding to a fixed speed change increment and direction, are used on the MCR console or on the local touch screen HMI.

7.7.1.3.3.4.4 RFCS Speed Controller

The ASD speed controller is a microprocessor based multi-card rack module device mounted inside the ASD control cabinet. It accepts the speed change command signals from the MCR console via the redundant RIOs and PLCs over redundant communication channels. It also receives speed change commands from the local touch screen HMI when it is enabled.

7.7.1.3.3.4.5 RFCS Signal Failure Alarm

The speed change command must be received simultaneously by both redundant RIOs for each ASD train to be acted upon by the controller. Invalid spurious signals are ignored. An algorithm

within the ASD controller selects which signal is valid and ignores the malfunctioning redundant channel. The algorithm also determines when the ignored channel signal is again valid. Loss of either one or both communication channels for all inputs between the ASO and each RIO results in a MCR alarm.

7.7.1.3.3.4.6 RFCS Startup Signal Generator

There is no discrete startup signal generator module within the ASD control system. Once the ASD is ready to run, startup control of the pump motor resides in the internal System Operating Program (SOP) code and eagle code of the speed controller.

7.7.1.3.3.4.7 RFCS Speed Limiter

The speed limiters for each ASD train are adjustable high speed limiter setpoints which reside in the speed controller System Operating Procedure (SOP) code.

The speed controller setpoint signal is automatically limited by the speed limiters to approximately 28% of rated speed if the recirculation pump main discharge valve is not fully open, if the feedwater flow is less than 20% of rated flow, or if the reactor level is less than level 3. The setpoint is limited to a speed corresponding to approximately 75% of rated core flow if the reactor level is low and any feedwater pump flow is low or if a condensate pump trips when feedwater flow is greater than 85% of Nuclear Boiler rated flow. If the discharge valve is closed and the pump is at high speed, the pump may overheat. If feedwater flow is less than 20% of rated flow, there is not enough subcooling of the downcomer water to provide the net positive suction head needed by the jet pumps and recirculating pumps to operate at flow rates greater than approximately 30%, this functionality is performed by the ASD internal controller.

7.7.1.3.3.4.8 RFCS Recirculation Loop Starting Sequence

Each recirculation loop is independently put into operation by operating the controls of each loop as follows:

a. The operator can not start the recirc pump unitl the “Ready to Precharge” light on MCR console *0-C602 is lit. This light indicates when all external plant and all internal ASD permissives required for pump start are met.

b. Anytime after the “Ready to Pre-charge” light is lit (no time limit) the operator can start the pump by taking the MV input breaker control switch to "Start." This initiates the Pre-charge/Start cycle.

c. During the Pre-charge/Start cycle the 480 Vac Pre-charge breaker closes which charges up the capacitors on the power cells.

d. Once the ASD power cell capacitors are fully charged and all permissives are still met, the ASD automatically closes the MV input breaker.

e. Once the MV is sensed at the ASD input, the ASD automatically ramps up the recirc pump motor from 0 to 20% speed at 5% / second, and then from 20% to 28% at 2.5% / second with no operator action.

f. Once at or above 28% speed, the operator can incrementally raise or lower speed while staying above 28%.

7.7.1.3.3.5 RFCS Testability

The ASD and associated speed controllers, are functioning during normal power operation. Any abnormal operation of these components can be detected during operation. The components that do not continually function during normal operation can be tested and inspected for calibration and operability during scheduled plant shutdowns. All the recirculation flow control system components can be tested and inspected during scheduled shutdowns.

7.7.1.3.4 RFCS Environmental Considerations

The RFCS is not required for safety purposes, nor is it required to operate after a DBA. The system is required to operate in the normal plant environment for power generation purposes only.

The only part of the recirculation flow control equipment in the drywell is the pump motor. It is subject to the design conditions environment specified in Section 3.11.

The logic control units and instrumentation are located in the control structure and are subject to that environment (Section 3.11).

7.7.1.3.5 RFCS Operational Considerations

7.7.1.3.5.1 RFCS General Information

The ASD system includes self-test, failure detection, indications and alarms to keep the operator informed of the status of the system and equipment, and to permit the operator to quickly determine the location of malfunctioning equipment. Temperature of the equipment is monitored and alarmed if safe levels are exceeded. A recorder for each loop displays the closed loop cooling temperature into the cabinets and out of the transformer and power cells. Each recorder also shows ASD output parameters of voltage, current power, frequency, and frequency demand. Indicators are provided to show recirculation loop flow and valve positions. MCR alarms alert the operator to approximately 256 drive and process alarm conditions which are individually displayed for quick diagnosis on the ASD touch screen display HMI on MCR panel 10-C602 and local control panel.

7.7.1.3.5.2 RFCS Reactor Operator Information

Indication and alarms are provided to keep the operator informed of the status of the systems and equipment, and to allow the operator to quickly determine the location of malfunctioning equipment.

The visual display consists of recirculation loop flow, valve position, speed demand, ASD cooling loop temperatures and ASD output parameters of volts, current, frequency and power. Alarms are provided to alert the operator to various ASD and process alarm conditions such as: malfunctioning equipment, loss of ASD communications, ASD cabinet and components high temperatures, cooling loop conductivity, temperature and level, high or low level runback initiation or bypass, speed hold, etc.

7.7.1.3.5.3 RFCS Setpoints

The subject system has no safety setpoints. However, signals from the RRCS can cause a trip of the recirculation pump motor breakers in the event of an ATWS (Section 7.6.1.8).

7.7.1.4 Feedwater Control System - Instrumentation and Controls

7.7.1.4.1 FCS Identification

7.7.1.4.1.1 FCS General

The FCS controls the flow of feedwater into the RPV to maintain the water in the vessel within predetermined levels during all plant operating modes. The predetermined range of water level is based on the requirements of the steam separators (this includes limiting carry-over, which affects turbine performance, and carry-under, which affects recirculation pump operation). The feedwater control system employs water level, steam flow, and feedwater flow as a three-element control.

Single-element control is also available based on water level only. Normally, the signal from the feedwater flow is equal to the steam flow signal; thus, if a change in the steam flow occurs, the feedwater flow follows. The steam flow signal anticipates the change in water level that results from a change in load. The level signal corrects any mismatch between the steam and feedwater flow that causes the level of the water in the reactor vessel to rise or fall accordingly.

7.7.1.4.1.2 FCS Classification

This system is a power generation system and is classified as not related to safety.

7.7.1.4.1.3 FCS Reference Design

Table 7.1-2 lists reference design information. The FCS is an operational system and has no safety function. Therefore, there are no safety differences between this system and those of the above-referenced facilities. The subject system is functionally identical to the referenced system.

7.7.1.4.2 FCS Power Sources

The FCS power is supplied by three independent sources so that no single power failure can incapacitate more than one of the three level sensing elements used for narrow range indication. Power for two of the three narrow range level sensing and indicating channels is supplied from the 120 V ac instrumentation buses and the other channel is powered from a plant 125 V dc battery and an inverter. The 120 V ac instrumentation bus feeds are each powered through a separate uninterruptible power supply. The FCS panel inserts are supplied with independent 120VAC power feeds. In all cases, each AC feed powers a separate power supply and is UPS backed. The configuration allows continuous operation upon loss of any power feed or power supply unit.

High Level 8 channels A and B level transmitters and corresponding equipment for High Level 8 trip logic are single fed by two independent 120VAC feeds. High Level 8 channel C and D transmitters and corresponding equipment for High Level 8 trip logic are powered by the same 125VDC power source. High Level 8 channel D is also powered by an AC source.

7.7.1.4.3 FCS Equipment Design

7.7.1.4.3.1 FCS General

During normal plant operation, the feedwater control system automatically regulates feedwater flow into the reactor vessel. The system can be manually operated.

The feedwater flow control instrumentation measures the water level in the reactor vessel, the feedwater flow rate into the reactor vessel, and the steam flow rate from the reactor vessel. During automatic operation, these three measurements are used to control feedwater flow.

The optimum reactor vessel water level is determined by the requirements of the steam separators. The separators limit water carry-over in the steam going to the turbines and limit steam carry-under in water returning to the core. The water level in the reactor vessel is maintained within ±2 inches of the setpoint value during normal steady-state operation and within the high and low level trip setpoints during normal plant maneuvering transients.

This control capability is achieved during plant load changes by balancing the mass flow rate of feedwater to the reactor vessel with the steam flow from the reactor vessel. The feedwater flow is regulated by controlling the speed of the turbine-driven feedwater pumps to deliver the required flow to the reactor vessel.

The RRCS can initiate a feedwater runback, reducing flow to 0% within 15 seconds. This runback is independent of the feedwater control operating mode and overrides the loss of signal interlock that prohibits change of feed pump output under loss of control signal conditions. Control of the feedwater system can be regained by the operator 30 seconds after the runback begins. This runback is discussed in Section 7.6.1.8.3.3. ATWS alarm lights are provided on the front of the feedwater control panel. The feedwater system trip contacts associated with the RRCS ATWS runback are required to be high quality but not necessarily safety-grade.

7.7.1.4.3.2 FCS Reactor Vessel Water Level Measurement

Reactor vessel narrow range water level is measured by four identical, independent sensing systems. For each channel, a differential pressure transmitter senses the difference between the pressure caused by a constant reference column of water and the pressure caused by the variable height of water in the reactor vessel. The differential pressure transmitters are installed on lines that serve other systems (Section 7.7.1.1). All four narrow range differential pressure transmitters are used as input to the digital FCS. The FCS system performs error checking and soft majority selection (SMS) on the four transmitters to ensure the final level control signal is accurate. This produces a highly reliable and fault tolerant system, reducing the likelihood of a transmitter failure causing a transient or SCRAM. Three narrow range differential pressure transmitters are used for MCR panel indication. All four narrow range differential pressure signals are displayed on the FCS operator workstation and are arranged to provide failure-tolerant trips of the main turbine and feed pump prime movers. A fifth level sensing system (upset range) provides level indication beyond the span of the narrow range devices.

The SMS water level and upset range water level are continually recorded in the control room.

7.7.1.4.3.3 FCS Steam Flow Measurement

Steam flow is sensed at each main steam line flow restrictor by a differential pressure transmitter. The signals from the four transmitters are sent to the FCS where it is manipulated to produce the true mass flow rate for each line. The FCS than transmits the flow rate of each line to indicators in the control room. The four steam line flow signals are also connected to a SMS within the FCS; the SMS selects the mid-value of its inputs. Total steam flow is calculated as this mid-value

multiplied by the number of valid steam flow signals. The total steam flow is recorded in the control room. All four differential pressure transmitter signals and the SMS flow signal are displayed on the FCS operator work station.

7.7.1.4.3.4 FCS Feedwater Flow Measurement

Feedwater flow is sensed at a flow element in each feedwater line by differential pressure transmitters. One transmitter is designated the primary feed flow measurement and the other is designated as the secondary feed flow measurement. In addition, a calculation of the feed flow is performed for each pump based on pump speeds, and on suction and discharge pressures, with miniflow measurement subtracted. The primary and secondary measurements are compared to each other and to the calculated measurement, to validate the values.

The signals from the transmitters are sent to the FCS where they are manipulated to produce a true mass flow rate for each line. The FCS then transmits the flow rate of each line to indicators in the control room. The total feedwater flow rate is sent to a recorder in the control room. The calculated feedwater flow rate is sent to the plant computer. All differential pressure transmitters, total feedwater flow, and calculated feedwater flow are displayed on the FCS operator workstation.

Feedwater flow is also sensed by a second flow measurement system based on ultrasonic flow measurement. The system includes spool pieces integrated into each feedwater line, where each spool piece contains ultrasonic transducers, a pressure trap for measuring fluid pressure, and a thermowell to measure fluid temperature. The ultrasonic transducers measure fluid velocity, while the pressure transmitters measure the feedwater pressure. Measurements from this system are combined to produce volumetric flow, mass flow, and temperature of the feedwater fluid so that the values can be utilized as inputs to core thermal power computations. Outputs from the system are received by the plant process computer.

7.7.1.4.3.5 FCS Feedwater/Level Control

The FCS has one manual mode and two modes of automatic operation. The manual mode operates the RFPs in parallel. The two automatic modes are single-element and three-element control. The FCS can automatically transfer from single-element to three-element control and vice versa. Single-element control utilizes only the reactor water level to determine the need for increasing or decreasing feedwater flow. Single-element control is normally used when reactor power is less than 20%. Three-element control receives input from three different parameters: reactor water level, total steam flow and total feedwater flow. When reactor power is above 20%, an automatic transfer to three-element control is performed. Automatic transfer can be blocked by the operator selecting forced single-element control before the setpoint is reached.

The FCS has a level controller in the control room. The level controller serves three functions: setting the level setpoint, transfer between single-element and three-element control and indication. Level setpoint is increased or decreased by pushbuttons. Transfer between single-element and three-element is performed by lighted pushbuttons. The level and feedwater flow controllers are balanced to allow bumpless transfer from single-element to three-element control.

During three-element control the reactor water level is compared to reactor water level setpoint and level controller. The level controller output signal is then summed together with the total steam flow to create a feedwater flow demand signal. The total feedwater flow is compared to the feedwater flow demand signal and is passed to the feedwater flow controller. The feedwater flow controller

output is then sent to the RFPs. Upon loss of condensate pump the feedwater flow is automatically limited to nominally 88% of rated feedwater flow.

To improve level control after a SCRAM, a predefined feedwater flow setpoint profile is used. The profile predicts the steam production after a scram and controls the feedwater flow in order to minimize flow and reactor level transients. The profile is also designed to meet the relative runback in the reactor recirculation flow, minimizing thermal stress on the reactor internals caused by non-preheated feedwater.

The scram profile can only be used if three-element control is possible. If the FCS is not in three-element control, then the FCS will automatically switch to three-element control. If the FCS cannot switch to three-element control, then single-element control continues to be active.

Once the scram profile reset logic has been satisfied, the post scram flow profile signals automatically reset and automatic bumpless transfer to single-element control occurs. The scram profile can only be active for a predefined period of time before it is forced to reset.

7.7.1.4.3.6 FCS Interlocks

The level control system also provides interlocks and control functions to other systems. When one of the reactor feed pumps is lost and coincident or subsequent low water level exists, or a condensate pump trips when feedwater flow is greater than 80% of Nuclear Boiler rated flow, recirculation flow is reduced to within the power capabilities of the remaining reactor feed pumps. This reduction helps avoid a low level scram by reducing the steaming rate. Reactor recirculation flow is also reduced on sustained low feedwater flow to ensure that adequate NPSH is provided for the recirculation system.

An interlock from total steam flow is used to initiate insertion of the RWM block. An alarm on low steam flow indicates that the above RWM insertion interlock setpoint is being approached. Alarms are also provided for high and low water level, and for reactor high pressure. Interlocks trip the plant turbine and feedwater pumps if there is reactor high water level. Interlocks trip the reactor recirculation pumps upon loss of the main generator coolant system if feedwater flow exceeds 44% of Nuclear Boiler rated flow.

7.7.1.4.3.7 FCS Turbine-Driven Feedwater Pump Control

Feedwater is delivered to the reactor vessel through turbine-driven feedwater pumps arranged in parallel. The turbines are driven by steam from the reactor vessel during normal operation, or from the auxiliary boilers during startup. The feedwater control signal from the level controller is fed to the turbine speed control systems, which adjust the speed of their associated turbine so that feedwater flow is proportional to the feedwater demand signal. Each turbine can be controlled by its manual/automatic transfer station. The M/A stations are located in the control room and their function is as follows: Manual fast or slow control of the RFP, transfer between Automatic and Manual mode Bias control, and Indication. In manual mode, pushbuttons are used to increase or decrease the M/A station output. Transfer between manual and automatic is performed by lighted pushbuttons. When two or more RFPs are in automatic mode, it is possible to bias the common control output between them. The bias adjustment is performed by the lower/raise pushbuttons on the M/A stations. The bias is maintained as long as all RFPs are in automatic mode. If two or more RFPs are transferred to manual mode, the M/A station output is balanced to actual control output value. The bias value is automatically adjusted to

zero for the RFP still in automatic mode. Each feedwater pump has a minimum flow valve. The minflow valve can be controlled in manual or automatic mode. Manual mode control is performed from M/A stations in the control room. In automatic mode, the minflow valve positions are controlled in an open loop to avoid the situation where the minflow control and the FCS "fight" each other. If the feedwater control signal to the turbine signal is lost, a digital output in the feedwater control circuit causes the turbine speed control system to lock the turbine speed "as is" and initiates an alarm in the control room. The level controller and the manual/automatic transfer stations associated with each turbine speed controller are the "bumpless transfer" type.

7.7.1.4.3.8 FCS Testability

All feedwater flow control system components can be tested and inspected before plant operation and during scheduled shutdowns. Reactor vessel water level indications from the three water level sensing systems can be compared during normal operation to detect instrument malfunctions. Steam mass flow rate and feedwater mass flow rate can be compared during constant load operation to detect inconsistencies in their signals. The FCS has a built in process model and disturbance tool. The process model is used during outages for testing and verification of parameter and control algorithm modifications. The process model simulates the final control elements. The disturbance tool allows operators to introduce disturbances at predefined locations in the control algorithm. The predefined locations are as follows: reactor water level setpoint, flow demand signal, total steam flow, total feedwater flow, and demand output of each final control element.

7.7.1.4.4 FCS Environmental Considerations

The feedwater control system is not required for safety purposes, nor is it required to operate after a DBA. This system is required to operate in the normal plant environment for power generation only. The reactor feed pumps in the turbine enclosure experience the normal design environments listed in Section 3.11.

7.7.1.4.5 FCS Operational Considerations

7.7.1.4.5.1 FCS General Information

The level controller is located in the control room where, at the operator's discretion, the system can be operated either manually or automatically.

Manual control of the individual turbine-driven feedwater pumps is available to the operator in the control room. This includes control of the low flow feedwater bypass valve that can be used for startup.

If there is a loss of feedwater and reactor vessel water level falls below the low level setpoint, the RPS causes plant shutdown, thus preventing any further lowering of the reactor vessel water level.

7.7.1.4.5.2 FCS Reactor Operator Information

Indicators and alarms, provided to keep the operator informed of the status of the system, are as noted in previous sections. The Operator Station provides an interface through which the Operator

can observe and interact with plant processes. The Operator can enter commands using the mouse or keyboard. Process alarms and events are time-tagged and presented in a list.

7.7.1.4.5.3 FCS Setpoints

The subject system has no safety setpoints.

7.7.1.5 Pressure Regulator and Turbine-Generator System - Instrumentation and Controls

7.7.1.5.1 PRTGS Identification

7.7.1.5.1.1 PRTGS General

One of the features of direct cycle BWRs is the direct passage of the nuclear boiler generated steam through the turbine and regenerative system. In this system the turbine is slaved to the reactor in that all steam generated by the reactor is normally accepted by the turbine. The operation of the reactor requires a pressure regulator to maintain a constant (within the range of the regulator controller proportional band setting) turbine inlet pressure.

The turbine pressure regulator normally controls the turbine control valves to maintain constant (within the range of the regulator controller proportional band setting) turbine inlet pressure. In addition, the pressure regulator also operates the steam bypass valves so that a portion of nuclear boiler rated flow can be bypassed when operating at steam flow loads above those that can be accepted by the turbine, as well as during the startup and shutdown phases.

The overall turbine-generator and pressure control system accomplishes the following:

a. Controls turbine speed and turbine acceleration

b. Operates the steam bypass system to keep reactor pressure within limits and avoid large power transients

c. Controls main turbine inlet pressure within the proportional band setting of the pressure regulator

7.7.1.5.1.2 PRTGS Classification

The PRTGS is classified as a primary power generation system. That is, it is not a safety system, but its operation is essential to the power production cycle.

7.7.1.5.1.3 PRTGS Reference Design

Table 7.1-2 lists reference design information. The subject instrumentation and control system is an operational system and has no safety function. Therefore, there are no safety design differences between this system and those of the reference design facilities. This system is functionally identical to the referenced systems.

7.7.1.5.2 PRTGS Power Sources

A. The DEHC electrical power is supplied by redundant 120Vac UPS Distribution Panels. Failure of either power supply source will not affected the operation of the PRTGS control functions.

7.7.1.5.3 PRTGS Equipment Design

7.7.1.5.3.1 PRTGS General

BWR pressure is controlled by regulating the main steam pressure through modulation of the turbine control or steam bypass valves. Command signals to these valves are generated by redundant control elements using the sensed turbine inlet pressure signals as the feedback, as shown in Figure 7.7-9. For normal operation, the turbine control valves regulate steam pressure; however, whenever the total steam flow demand from the pressure regulator exceeds the capacity of the turbine control valves, the pressure control system sends the excess steam flow directly to the main condenser through the steam bypass valves. The plant's ability to follow grid system load demands is determined by adjusting reactor power level, manually varying reactor recirculation flow, or manually moving control rods. In response to the resulting steam production changes, the pressure control system adjusts the turbine control valves to accept the steam output change, thereby regulating steam pressure.

7.7.1.5.3.2 PRTGS Steam Pressure Control

During normal plant operation, steam pressure is controlled by the main turbine control valves, positioned in response to the pressure regulation demand signal (Figure 7.7-9). The steam bypass valves are normally closed.

Two essentially redundant regulators are provided so that the one is the primary controller and the backup controller is in standby tracking the same steam flow demand signal to ensure, if required, an automatic bumpless transfer to the backup regulator. Each regulator accesses the pressure signal that is validated based upon the turbine inlet (throttle) pressure signals.

The turbine control valve (steam flow) demand signal is limited, after passage through the low value gate (Figure 7.7-9), to the signal required to fully open the main control valves. Thus, if the pressure control system requires that additional steam flow be released from the reactor when the control valves reach wide open, the control signal error to the bypass valves increases and causes bypass actuation.

7.7.1.5.3.3 PRTGS Steam Bypass System

The steam bypass system is designed to control steam pressure when reactor steam generation exceeds turbine requirements during startup (pressure, speed ramping, and synchronizing), sudden load reduction, and cooldown.

The bypass capacity of the system is 24.3% of the rated steam flow; sudden load reductions within the capacity of the steam bypass can be accommodated without reactor scram.

Normally, the bypass valves are closed and the pressure regulator controls the turbine control valves, directing all steam flow to the turbine. If the speed governor or the load limiter restricts steam flow to the turbine, the regulator controls system pressure by opening the bypass valves. If

the capacity of the bypass valves is exceeded while the turbine cannot accept an increase in steam flow, the system pressure rises and RPS action causes the reactor to shutdown.

The bypass valves are an automatically operated, regulating-type that are proportionally controlled by the turbine pressure regulator and control system.

The turbine control system provides a signal to the bypass valves that corresponds to both the "error" between the turbine control valve opening required by the controlling pressure regulator and the turbine control valve position demanded by the output of the low value gate circuit (Figure 7.7-9). An adjustable bias signal is provided to keep the bypass valves closed during momentary differences that occur during normal operational transients.

Bypass valves and controls are designed so that bypass steam flow is shut off upon loss of control system electrical power, hydraulic pressure, or low condenser vacuum.

7.7.1.5.3.4 PRTGS Turbine Speed-Load Control Systems

7.7.1.5.3.4.1 Normal Operation

During base load plant operation, the turbine load reference is held above the desired load, so that the pressure regulation demand governs the turbine control valves.

7.7.1.5.3.4.2 PRTGS Behavior of Turbine Outside of Normal Operation

a. Turbine startup

   Prior to turbine startup, sufficient reactor steam flow is generated to permit the steam bypass valves to maintain reactor pressure control while the turbine is brought up to speed and synchronized under its speed-load control.

b. Partial load rejection

   During partial load rejection transients, which appear to the reactor as a reduction in turbine load demand resulting from an increase in generator (or grid) frequency, the turbine pressure control scheme allows the reduced turbine speed-load demand to override the pressure regulation demand and thereby directly regulate the turbine control valves. The pressure controller modulates the bypass valves to maintain reactor pressure.

c. Turbine shutdown or turbine-generator trip

   During turbine shutdown or turbine-generator trip conditions, the main turbine stop valves and control valves are closed. Reactor steam flow is then passed through the steam bypass valves under steam pressure control and through the reactor SRVs, as needed.

d. Steam bypass operation

   Fast opening of the steam bypass valves during turbine trips or generator load rejections requires coordinated action with the turbine control system. When the turbine control valves are under pressure control, no bypass steam flow is demanded; conversely, when the turbine speed-load demand falls below the

pressure regulation demand, a net bypass flow demand is computed. During turbine or generator trip events resulting in fast closure of the turbine stop or control valves, the turbine control valve demand is immediately reduced to zero, causing the bypass steam flow demand to equal the initial pressure regulation demand.

e. Loss of turbine control system power

Turbine controls and valves are designed so that the turbine stop and control valves close upon loss of control system power or hydraulic pressure.

7.7.1.5.3.5 PRTGS Turbine-Generator to RPS Interface

The RPS initiates reactor scram when any monitored plant condition requires it. Two such conditions are: turbine stop valve closure and turbine control valve fast closure when reactor power is above 29.5% of rated power. The turbine stop valve closure signal is generated before the turbine stop valves have closed more than 5%. This signal originates from position switches that sense stop valve motion away from fully open. A limit switch is provided on each of the four turbine stop valves. The switches are closed when the stop valves are fully open, and open within 10 milliseconds after the setpoint is reached. The switches are electrically isolated from each other and from other turbine plant equipment.

The control valve fast closure signal is generated by four hydraulic oil pressure sensors that are distributed equally among the control valves and that sense hydraulic oil pressure decay as an indication of fast control valve closure. The switches are closed when the valves are open, and open within 30 milliseconds after the control valves start to close in a fast closure mode.

To avoid reactor scram due to stop valve closure or control valve fast closure when power is below 29.5% of rated power, two independent sensing lines are provided from pressure taps located in the turbine steam supply lines upstream of the high pressure turbine first stage and are connected to pressure switches to supply power level signals to the RPS. The pressure taps are located to provide a pressure signal proportional to turbine steam flow. The pressure taps are shared with other instrumentation sensors. All sensors have individual shutoff valves.

7.7.1.5.3.6 PRTGS Turbine-Generator to Main Steam Isolation System Interface

Four independent main condenser vacuum sensors provide an isolation signal to the NSSS MSIVs. Condenser vacuum transmitters and trip units are discussed in Section 7.3.1.1.2.

7.7.1.5.3.7 PRTGS Testability

Controls are provided to test the turbine valve RPS interface signal switches in the following ways:

a. Actuate each stop valve individually to the 10% closed point with no interaction with other valves

b. Actuate the following pairs of stop valves to the 10% closed point, one pair at a time: 1 and 2; 3 and 4; 1 and 3; 2 and 4

c. Actuate one control valve fast closure hydraulic oil pressure switch at a time by individually closing the control test mode

d. Individually test each main condenser low vacuum instrument channel

7.7.1.5.4 PRTGS Environmental Considerations

The turbine-generator control system is required to operate in the normal plant environment for power generation purposes only.

Instruments and controls on the turbine experience the turbine building normal design environment as listed in Section 3.11. The logic, remote control units, and instrument terminals located in the control structure experience the environment listed in Section 3.11.

7.7.1.5.5 PRTGS Operational Considerations

7.7.1.5.5.1 PRTGS General Information

Process variables controlled by the pressure regulator and speed/ load control system are displayed in the control room on the turbine-generator section of the control boards. Manual and automatic control modes for the various turbine-generator operational modes (such as startup, normal operation, and shutdown) are available to the operator from the control room. Automatic HMI display indication is provided to inform the operator as to the operating mode of the turbine-generator unit. The pressure control is active during all modes of operation and cannot be selected or deselected. The default mode allows the operator to select speed reference and rate, start up the turbine, close the bypass valves, and set the turbine in Turbine-Follow-Reactor mode.

Two pressure control channels, operating redundantly, receive inputs from validated pressure signals from the two pressure transducers in the main steam line upstream of the main steam stop valves and from the pressure reference function. Main steam pressure indications and pressure setpoint adjustments/indications are located on the HMI workstation of the turbine control panel. Minor and Major Trouble Pressure Control annunciation is provided in the control room.

7.7.1.5.5.2 PRTGS Reactor Operator Information

The NSSS pressure regulator has the following controls and information displayed in the control room:

a. Main steam pressure transducer output

b. Main steam pressure transducer output

c. Main steam pressure regulator setpoint A

d. Main steam pressure regulator setpoint B

e. Individual bypass valve position

f. Individual bypass valve demand control signal

g. Bypass valve test controls

h. Pressure regulator selection control

i. Individual control valve position

j. Individual control valve demand control signal

7.7.1.5.5.3 PRTGS Setpoints

There are no safety setpoints associated with this system.

7.7.1.6 Neutron Monitoring System - Instrumentation and Controls

The NMS consists of the following nonsafety-related systems:

a. Source range monitor system

b. Rod block monitor system

c. Traversing incore probe system

The safety-related portion is described in Section 7.6.1.4.

7.7.1.6.1 Source Range Monitor System

7.7.1.6.1.1 SRM Equipment Design

7.7.1.6.1.1.1 SRM Circuit Description

The SRM provides neutron flux information during reactor startup and low flux level operations. There are four SRM channels. Each includes one detector that can be physically positioned in the core from the control room (Figure 7.6-2).

The detectors are inserted into the core for reactor startup. They can be withdrawn if the indicated count rate is between preset limits or if the IRM is on the third range or above (Figure 7.6-3).

During initial startup, neutron flux is monitored by source range neutron monitoring channels, providing a scram signal when the preset flux level of any channel has been reached. This logic is removed from the scram circuitry after completion of initial startup.

a. Power Supply - The power for the monitors is supplied from the two 120 V ac RPS buses. Two monitors are powered from each bus.

b. Physical Arrangement - Each detector assembly consists of a miniature fission chamber and a low-noise, quartz fiber insulated transmission cable. The sensitivity of the detector is 1.2×10^{-3} cps/nv nominal, 5.0×10^{-4} cps/nv minimum, and 2.5×10^{-3} cps/nv maximum. The detector cable is connected underneath the reactor vessel to the multiple shielded coaxial cable. This shielded cable carries the pulses to a pulse current preamplifier located outside the drywell.

The detector and cable are located inside the reactor vessel in a dry tube sealed against reactor vessel pressure. A remote controlled detector drive system

moves the detector along the dry tube. The active length of fuel is positioned vertically up to 30 inches below the reactor fuel region (Figure 7.6-2). When a detector arrives at a travel end point, detector motion is automatically stopped. SRM drive control arrangement and logic are presented in Figure 7.6-3. The electronics for the SRM, their trips, and their bypasses are located in four cabinets. Source range signal conditioning equipment is designed so that it can also be used for open vessel experiments.

c. Signal Conditioning - A current pulse preamplifier provides amplification and impedance matching for the signal conditioning electronics (Figure 7.7-13).

The signal conditioning equipment converts the current pulses to analog dc currents that correspond to the logarithm of the count rate. The equipment also derives the period. The output is displayed on front panel meters and is provided to remote meters and recorders. The logarithm of the count rate meter displays the rate of occurrence of the input current pulses. The period meter displays the time in seconds for the count rate to change by a factor of 2.7. In addition, the equipment contains integral test and calibration circuits, trip circuits, power supplies, and selector circuits.

d. Trip Functions - The trip outputs of the SRM operate in the fail-safe mode. Loss of power to the SRM causes the associated outputs to become tripped.

The SRM provides signals indicating SRM upscale, downscale, inoperative, and incorrect detector position to the RMCS to block rod withdrawal under certain conditions. Any SRM channel can initiate a rod block. These rod blocking functions are discussed in Section 7.7.1.6.2. Appropriate lights and annunciators are also actuated to indicate the existence of these conditions. Refer to Table 7.7-4 for a description of the trip functions.

7.7.1.6.1.1.2 SRM Bypasses and Interlocks

One of the four SRM channels can be bypassed at any one time by a switch on the operator's control panel.

7.7.1.6.1.1.3 SRM Redundancy and Diversity

SRM channels are not redundant because SRM detectors are spatially dependent and do not serve as a backup to other detectors.

7.7.1.6.1.1.4 SRM Testability

Each SRM channel can be fully tested and calibrated using written procedures. Inspection and testing are performed as required on the SRM detector drive mechanism; the mechanism can be checked for full insertion and retraction capability. The various combinations of SRM trips can be introduced to ensure the operability of the rod blocking functions.

7.7.1.6.1.2 SRM Environmental Considerations

The wiring, cables, and connectors located within the drywell are designed for continuous-duty in the conditions described in Section 3.11. The above SRM system components are designed to operate during and after certain design basis events such as earthquakes and anticipated operational occurrences.

7.7.1.6.1.3 SRM Operational Considerations

The SRM system provides information to the operator. It is operated by inserting the SRM detectors into the core whenever these channels are needed, and withdrawing them, when permitted, to reduce their burnup.

7.7.1.6.2 Rod Block Monitor System

7.7.1.6.2.1 RBM Equipment Design

7.7.1.6.2.1.1 RBM Circuit Description

The RBM has two channels (Figure 7.6-4). Each channel uses input signals from a number of LPRM channels. A trip signal from either RBM channel initiates a rod block. One RBM channel can be bypassed without loss of system function. The minimum number of LPRM inputs required for each RBM channel to prevent an instrument inoperative alarm is four when using four LPRM assemblies, three when using three LPRM assemblies, and two when using two LPRM assemblies.

a. Power Supply - The RBM power is received from two independent 120 V ac buses, each of which is supplied by an UPS. Each RBM is supplied by two redundant DC power supplies. Each DC power supply is supplied by one of the two 120 Vac buses.

b. Signal Conditioning - The RBM signal is generated by averaging a set of LPRM signals. The LPRM signals used depend on the control rod selected. Upon selection of a rod for withdrawal or insertion, the conditioned signals from the LPRMs around that rod will be automatically selected by the two RBM channels (Figure 7.7-14 shows examples of the four possible LPRM/selected rod assignment combinations). For typical non-edge rod, each RBM channel averages LPRM inputs from two of the four B-level and D-level detectors, and all four of the C-level detectors (see Figure 7.7-14). A-level LPRM detectors are not included in the RBM averages, but are displayed to the operator. When a rod near, but not at, the edge of the core is selected, where there are fewer than four but at least two LPRM strings around the rod, the number of detectors used by the RBM channels is either six of four depending on how many LPRM strings are available. If a detector has been bypassed in the LPRM system, that detector is automatically deleted from the RBM processing and the averaging logic is adjusted to average only the remaining detectors.

   After selection of a control rod, each RBM channel calculates the average of the related LPRM detectors and calculates a gain factor that will adjust the average to 100. Thereafter, until another rod is selected, the gain factor is applied to the LPRM average to obtain the RBM signal value. The RBM signal value is compared to RBM trip setpoints.

When a peripheral rod is selected or the RBMs associated reference APRM power signal is below the automatic bypass level, the RBM function is automatically bypassed, the rod block outputs are set to “permissive”, and the RBM average is set to zero.

In the operating range, the RBM signal is accurate to approximately 1% of full-scale.

7.7.1.6.2.1.2 RBM Trip Function

The RBM is designed to prohibit erroneous withdrawal of a control rod during operation at core high power levels. This prevents local fuel damage under permitted bypass and/or LPRM detector chamber failure conditions and prevents local fuel damage during a single rod withdrawal error. Local fuel damage poses no significant threat relative to radioactive release from the plant.

The RBM supplies a trip signal to the RMCS to inhibit control rod withdrawal. The trip is initiated when RBM output exceeds the rod block setpoint. The RBM has three upscale trip levels and one downscale trip level. Figure 7.7-17 illustrates the trip setpoints. Below 30 percent rated power, fuel damage cannot occur for any single control rod withdrawal; hence, the RBM system is automatically bypassed. The low trip setpoint (LTSP) is enforced between 30 percent and 65 percent rated power, the intermediate trip setpoint (ITSP) is enforced between 65 percent and 85 percent rated power, and the high trip setpoint (HTSP) is enforced between 85 percent and 100 percent rated power. The percent rated power input used to automatically select the applicable RBM trip is provided by the APRM. The RBM system is automatically bypassed if the control rod has one or more adjacent fuel bundles comprising the outer boundary of the core. The operator can bypass one of the two RBM channels at any time. Either RBM channel can inhibit control rod withdrawal.

7.7.1.6.2.1.3 RBM Bypasses

The operator can bypass one of the two RBM channels at any time. Both RBM channels can be bypassed provided the following conditions are met:

for power $\geq$30% and <90%, MCPR $\geq$1.70
for power $\geq$90%, MCPR $\geq$1.40

7.7.1.6.2.1.4 RBM Redundancy

Although the RBM does not perform a safety-related function, in the interest of plant economics and availability, it is designed to meet certain salient design principles of a safety system. These include the following:

a. Redundant, separate, and isolated RBM channels.

b. Redundant, separate, isolated rod selection information.

c. Independent, isolated RBM level readouts and status displays from the RBM channels.

d. A mechanical barrier between channels A and B of the manual bypass switch.

e. Multiple manual RBM channel bypass is prohibited by switch design.

f. Fail-safe design; loss of power initiates a rod block.

g. A trip of either RBM channel initiates a rod block.

h. Redundant APRM simulated thermal power reference signals provided to each RBM for trip level information

i. Each RBM channel has a backup reference APRM

7.7.1.6.2.1.5 RBM Testability

The RBM channels are tested and calibrated with written procedures. The RBMs are functionally tested by introducing test signals into the RBM channels.

7.7.1.6.2.2 RBM Operational Considerations

Trip setpoint automatically changes to the next higher rod block setpoint line.

The RBM interfaces with the following safety-related systems:

a. LPRM: Separate, isolated LPRM flux level is provided to each RBM channel.

b. APRM: Independent, separate, isolated APRM simulator thermal power reference signals are supplied to each RBM channel for trip reference.

7.7.1.6.3 Traversing Incore Probe System

7.7.1.6.3.1 TIP System Identification

7.7.1.6.3.1.1 TIP General

Flux readings along the axial length of the core are obtained by fully inserting the traversing probe into one of the calibration guide tubes, then taking data as the probe is withdrawn. The analog data are available for display on a recorder or for use by the process computer. One traversing probe and its associated drive mechanism is provided for each of five groups of nine or ten incore guide tubes.

7.7.1.6.3.1.2 TIP Classification

This system is a power generation system and is not related to safety.

7.7.1.6.3.1.3 TIP Reference Design

Table 7.1-2 lists reference design information. The subject instrumentation and controls system is an operational system and has no safety function. Therefore, there are no safety design

differences between this system and those of the referenced design facilities. This system is functionally similar to the referenced system.

7.7.1.6.3.2 TIP Power Source

The power for the subject system is supplied from an instrument ac power source.

7.7.1.6.3.3 TIP Equipment Design

7.7.1.6.3.3.1 TIP General

There are five TIP machines as shown in Figure 7.6-1. The TIP machines have the following components:

a. One TIP

b. One drive mechanism

c. One indexing mechanism

d. Up to 10 incore guide tubes

The system allows calibration of LPRM signals by correlating TIP signals to LPRM signals as the TIP is positioned in various radial and axial locations in the core. The guide tubes inside the reactor are divided into groups. Each group has its own associated TIP machine.

7.7.1.6.3.3.2 TIP Equipment Arrangement

A TIP drive mechanism uses a gamma sensitive probe assembly attached to a flexible drive cable (Figure 7.7-10). The cable is driven from outside the drywell by a gearbox assembly. The flexible cable is contained by guide tubes that penetrate the reactor core. The guide tubes are a part of the LPRM detector assembly. The indexing mechanism allows the use of a single detector in any one of 10 different tube paths. The 10th tube is used for TIP cross calibration with the other TIP machines. The control system provides for both manual and semi-automatic operation. The electronics in the TIP panel in the control room amplifies and displays the TIP signal. Core position versus gamma flux may be plotted on an X-Y recorder in the control room, and is also provided to the Plant Monitoring System. A block diagram of the drive system is shown in Figure 7.6-3.

7.7.1.6.3.3.3 TIP Testability

The TIP equipment is tested and calibrated with written procedures.

7.7.1.6.3.4 TIP Environmental Considerations

The equipment and cabling located in the drywell are designed for continuous-duty up to 150°F and 100% relative humidity.

7.7.1.6.3.5 TIP Operational Considerations

The TIP can be operated during reactor operation to calibrate the LPRM channels. This system has no safety setpoints.

7.7.1.7 Deleted

7.7.1.8 Reactor Water Cleanup System - Instrumentation and Controls

7.7.1.8.1 RWCU System Identification

7.7.1.8.1.1 RWCU General

The purpose of the RWCU system is to provide for removal of soluble and insoluble waterborne impurities to reduce the secondary source of β and γ radiation.

7.7.1.8.1.2 RWCU Classification

This is a power generation system and is classified as not related to safety.

7.7.1.8.1.3 RWCU Reference Design

Table 7.1-2 lists reference design information. This control system is an operational system and has no safety function.

7.7.1.8.2 RWCU Power Sources

The RWCU system is powered from the plant instrumentation bus, with the exception of the Noble Metals Monitoring System Data Acquisition System, which is powered from a lighting panel power supply. No backup power source is necessary since the RWCU system is not a safety-related system. Adequate fuse protection is provided so that a short circuit within the system has only a local effect that can be easily corrected without interrupting reactor operation.

7.7.1.8.3 RWCU Equipment Design

7.7.1.8.3.1 RWCU General

The RWCU system is described in Section 5.4.8.

7.7.1.8.3.2 RWCU Circuit Description

The cleanup system is protected against overpressurization by relief valves. The ion exchange resin is protected from high temperature by temperature switches upstream of the filter/ demineralizer unit. One switch activates an alarm while a second switch closes the outboard isolation valve, which subsequently trips the cleanup pumps. The isolation valves also close automatically on a reactor low water level signal, when the SLCS is actuated, and on a "leak signal" from the leak detection system. See Section 7.3 for a detailed description of the isolation function.

A high differential pressure across the filter/demineralizer or its discharge strainer automatically isolates the units and sounds an alarm. The holding pump starts whenever there is a low flow through a filter/demineralizer.

A sampling station is provided to obtain reactor water samples from the inlet and outlet of both filter/demineralizers.

Flow, pressure, temperature, and conductivity are recorded or indicated on a panel in the control room. Instrumentation and controls for backwashing and precoating the filter/demineralizers are on a local panel outside the drywell. Alarms are sounded in the control room to alert the operator to abnormal conditions.

7.7.1.8.3.3 RWCU Testability

Because the RWCU system is usually in service during plant operation, satisfactory performance is demonstrated without the need for any special inspection or testing beyond that specified in the manufacturer's instructions.

7.7.1.8.4 RWCU Environmental Considerations

The RWCU system is not required for safety purposes nor is it required to operate after the DBA. The RWCU system is required to operate in the normal plant environment for power generation purposes only.

RWCU instrumentation and controls located in the RWCU equipment area are subject to the environment described in Section 3.11.

7.7.1.8.5 RWCU Operational Considerations

7.7.1.8.5.1 General Information

The RWCU system instrumentation and controls are not required for safe operation of the plant. They provide a means of monitoring parameters of the system and protecting the system.

7.7.1.8.5.2 RWCU Reactor Operator Information

See drawing M-44.

7.7.1.8.5.3 RWCU Setpoints

No safety-related setpoints are associated with the RWCU system.

7.7.1.9 Process Radiation Monitoring Systems – Instrumentation and Controls

7.7.1.9.1 South Stack Effluent Radiation Monitoring System

7.7.1.9.1.1 SSE-RMS Identification

The objective of the SSE-RMS is to monitor the quantity of radioactive gases, particulates, and iodines emitted from the south stack. Inasmuch as the south stack is a main point of potential escape of radioactive material to the environment, these data are used for the generation of Regulatory Guide 1.21 reports.

7.7.1.9.1.2 SSE-RMS Classification

This system is a power generation system and is classified as not related to safety. Inasmuch as the south stack will be isolated if there is an accident, the capability to monitor accident and postaccident conditions is not required.

7.7.1.9.1.3 SSE-RMS Reference Design

Table 7.1-2 lists reference design information. The SSE-RMS is an operational monitoring system and has no safety function.

7.7.1.9.1.4 SSE-RMS Power Sources

Power is provided by the 120 V ac instrument bus. Safety-related power is not required for this application.

7.7.1.9.1.5 SSE-RMS Equipment Design

7.7.1.9.1.5.1 SSE-RMS General

The south stack consists of two discrete ducts for the two units. Two isokinetic, representative samples of air are drawn from each duct in accordance with Regulatory Guide 1.21 and ANSI N13.1. Consequently, four independent radiation monitoring subsystems are provided. Each of these subsystems is provided with three channels for monitoring radioactive particulates, iodines, and noble gases in the stack effluents.

Each subsystem consists of three detectors, a microprocessor, and a local control and readout module. All subsystems are provided with high, high-high, and downscale alarm outputs.

7.7.1.9.1.5.2 SSE-RMS Circuit Description

Each monitoring subsystem has two upscale trips for high and high-high radiation and a downscale trip that indicates instrument trouble. These trips are actuated by the above conditions in any of the subsystem channels. These trips annunciate, but provide no control action. The trip circuits are set so that loss of power causes an alarm. The range of each channel is six decades and is selected to cover both normal and possible maximum radiation levels in the south stack effluents.

The monitors are located on the roof of the reactor enclosure, where the background radiation environment is minimal. These monitors are interfaced to the RMMS (Section 11.5.6) to allow indication, trending, and remote control at RMDS display consoles in the control room. Remote controls are provided for purging the noble gas chamber. Controls are also provided for remotely resetting the alarm setpoints and for checking detector operability.

7.7.1.9.1.5.3 SSE-RMS Testability

Check sources are provided for each detector to verify operability of each channel. Access to the controls and setpoints is restricted by the operator's key and coded input signals.

7.7.1.9.1.6 SSE-RMS Environmental Considerations

The monitoring racks, microprocessors, and isokinetic sampling systems are designed to meet the environmental conditions on the reactor enclosure roof. These systems are protected by a room

provided with ventilation, heating, and cooling. Radiation background in this location is minimal. See Section 3.11 for the environmental conditions of the equipment locations.

7.7.1.9.1.7 SSE-RMS Operational Considerations

7.7.1.9.1.7.1 SSE-RMS General Information

Annunciator outputs in the control room are shared for all subsystems. Redundancy and independence ensure continuous monitoring during periods of equipment checking, servicing, and shutdown. Fixed filters provide for continuous accumulation of radioactive samples that can be analyzed in the counting room. Digitized outputs of all three channels, as well as flow measurements, are provided as input data to the RMMS for the generation of Regulatory Guide 1.21 reports.

7.7.1.9.1.7.2 SSE-RMS Reactor Operator Information

Processed inputs to the control room provide the reactor operator with early warnings of anomalous changes in radioactive effluents. This information can be used as a guide for remedial action.

7.7.1.9.2 Radwaste Equipment Rooms Ventilation Exhaust Radiation Monitoring System

7.7.1.9.2.1 RERV-RMS Identification

The RERV-RMS is an off-line process radiation monitoring system that measures the concentration of radioactive material in the ventilation duct from the charcoal offgas treatment compartment. The purpose of this monitoring system is to detect leakage of radioactive noble gases from the charcoal beds. Such leakage could escape to the north stack.

7.7.1.9.2.2 RERV-RMS Classification

The RERV-RMS is a power generation system and is not related to safety.

7.7.1.9.2.3 RERV-RMS Reference Design

Table 7.1-2 lists reference design information. The RERV-RMS is designed to alarm in response to excessive concentrations of noble gases in the effluents released to the north stack, indicating leakage from the charcoal offgas treatment system.

7.7.1.9.2.4 RERV-RMS Power Sources

Power is supplied to the monitor by the 120 V ac uninterruptible bus B. The pumps and solenoid valves are supplied from the 120 V ac local power. The recorder and purge controls are supplied from the 120 V ac instrument bus.

7.7.1.9.2.5 RERV-RMS Equipment Design

7.7.1.9.2.5.1 RERV-RMS General

The RERV-RMS is a standard off-line process radiation monitoring system. It draws an air sample from a ventilation duct, passes this sample through a chamber containing a radiation detector, and then returns the sample to the duct.

7.7.1.9.2.5.2 RERV-RMS Circuit Description

The RERV-RMS is provided with a gamma-sensitive detector and converter that transmits its signal to a rate meter located in the auxiliary equipment room. This rate meter indicates the concentration of radioactivity in the air sample and transmits both a signal to a recorder in the control room and upscale/downscale alarm signals to annunciators in the control room. No control trip capabilities are provided. A flow indicator trips an annunciator if there is a malfunction of the sampling pump.

7.7.1.9.2.6 RERV-RMS Testability

Test signals are fed into the monitor via the control module in the auxiliary equipment room. A check source is provided for secondary calibration. Purge controls are also provided.

7.7.1.9.2.7 RERV-RMS Environmental Considerations

The monitoring rack is designed to meet the environmental conditions in the radwaste enclosure. The control module and recorder are in the environment of the auxiliary equipment room and control room. See Section 3.11 for the environmental conditions of the equipment locations.

7.7.1.9.2.8 RERV-RMS Operational Considerations

7.7.1.9.2.8.1 RERV-RMS General

Annunciator outputs of the RERV-RMS alarm signals are provided in the control room. Fixed filters for particulates and iodines provide for continuous accumulation of radioactive materials that can be analyzed in the counting room. However, very few, if any, particulates or iodines are expected in this application.

7.7.1.9.2.8.2 RERV-RMS Reactor Operator Information

Inputs to the control room provide the operator with an indication of leakage from the charcoal beds. If there is such an indication, remedial action can be taken.

7.7.1.9.3 Charcoal Treatment System Process Exhaust Radiation Monitoring System

7.7.1.9.3.1 CTSP-RMS Identification

The CTSP-RMS is identical with the system discussed in Section 7.7.1.9.2, except that the monitored sample is drawn from the charcoal offgas treatment system effluent pipe. The purpose of this monitoring system is to provide ongoing records and alarm capability for indicating unacceptable concentrations of noble gases in the effluents being released to the north stack.

7.7.1.9.3.2 CTSP-RMS Classification

The CTSP-RMS is a power generation system and is not related to safety.

7.7.1.9.3.3 CTSP-RMS Reference Design

Table 7.1-2 lists reference design information. The CTSP-RMS is designed to alarm in response to excessive concentrations of noble gases in effluents from the charcoal offgas treatment system.

7.7.1.9.3.4 CTSP-RMS Power Sources

Power is supplied to the monitors by the 120 V ac uninterruptible bus A. The pumps and solenoid valves are supplied from the 120 V ac local power. The recorder and purge controls are supplied from the 120 V ac instrument bus.

7.7.1.9.3.5 CTSP-RMS Equipment Design

7.7.1.9.3.5.1 CTSP-RMS General

The CTSP-RMS is a standard off-line process radiation monitoring system. It draws a gas sample from a process pipe, passes the sample through a chamber containing a radiation detector, and then returns the sample to the pipe.

7.7.1.9.3.5.2 CTSP-RMS Circuit Description

The CTSP-RMS is provided with a gamma-sensitive detector and converter that transmits its signal to a rate meter located in the auxiliary equipment room. This rate meter indicates the concentration of radioactive material in the gas sample and transmits both a signal to a recorder in the control room and upscale/downscale alarm signals to annunciators in the control room. No control trip capabilities are provided. A flow indicator trips an annunciator if the sampling pump malfunctions.

7.7.1.9.3.6 CTSP-RMS Testability

Test signals are fed into the monitor via the control module in the auxiliary equipment room. A check source is provided for secondary calibration. Purge controls are also provided.

7.7.1.9.3.7 Environmental Considerations

The monitoring rack is designed to meet the environmental conditions in the radwaste enclosure. The control module and recorder are in the environment of the auxiliary equipment room and control room. See Section 3.11 for the environmental conditions of the equipment locations.

7.7.1.9.3.8 CTSP-RMS Operational Considerations

7.7.1.9.3.8.1 CTSP-RMS General

Annunciator outputs of the CTSP-RMS alarm signals are provided in the control room. Fixed filters for particulates and iodines provide for continuous accumulation of radioactive materials that can be analyzed in the counting room. However, very few, if any, particulates or iodines are expected in this application.

7.7.1.9.3.8.2 CTSP-RMS Reactor Operator Information

Inputs to the control room provide the operator with an indication of the effectiveness of the charcoal offgas treatment system in arresting releases of radioactivity to the north stack. If there are unacceptable inputs, remedial action can be taken.

7.7.1.9.4 Recombiner Rooms and Hydrogen Analyzer Compartments Exhaust Radiation Monitoring System

7.7.1.9.4.1 RRHAC-RMS Identification

This off-line process radiation monitoring system detects the presence of radioactive material escaping to the north stack from the recombiner compartments, hydrogen analyzer compartments, and equipment drain sump vent. If there is a high radiation alarm, the manifolded sample line leading from the main ducts can be isolated, and each branch of this line can be checked separately to determine the exact source of leakage.

7.7.1.9.4.2 RRHAC-RMS Classification

This monitoring system is a power generation system and is not related to safety.

7.7.1.9.4.3 RRHAC-RMS Reference Design

Table 7.1-2 lists reference design information. This system is designed to alarm in response to significant concentrations of gross radioactivity in the duct effluents from the recombiner compartments, hydrogen analyzer compartments, or equipment drain sump vent. Capability is provided to locate the source of this radioactivity.

7.7.1.9.4.4 RRHAC-RMS Power Source

Power is supplied to the monitor by the 120 V ac uninterruptible bus B. The pumps and solenoid valves are supplied from the 120 V ac local power. The recorder and purge controls are supplied from the 120 V ac instrument bus.

7.7.1.9.4.5 RRHAC-RMS Equipment Design

7.7.1.9.4.5.1 RRHAC-RMS General

This standard off-line radiation monitoring system draws samples from two exhaust ventilation ducts, combines them, passes the samples through a chamber containing a radiation detector, and then returns the sample to the exhaust duct. The operator can select the branch sample line he chooses to check using a set of solenoid valves. In this way, seven discrete sources of radioactivity can be monitored with a single instrument system.

7.7.1.9.4.5.2 RRHAC-RMS Circuit Description

This monitoring system is provided with a gamma-sensitive detector and converter that transmits its signal to a rate meter located in the auxiliary equipment room. This rate meter indicates radioactivity in the air sample and transmits both a signal to a recorder in the control room and upscale/downscale alarm signals to an annunciator in the control room. No control trip capability is provided. A flow indicator trips an annunciator if there is a malfunction of the sampling pump. A

hand selector switch in the control room provides for determination of which of the following sources to monitor:

a. Main exhaust ducting

b. Recombiner compartment A

c. Recombiner compartment B

d. Hydrogen analyzer 1A, Hydrogen analyzer 2A

e. Hydrogen analyzer 1B, Hydrogen analyzer 2B

f. Hydrogen analyzer 1C, Hydrogen analyzer 2C

g. Equipment drain sump

The hand selector switch is normally set for the main exhaust duct.

7.7.1.9.4.6 RRHAC-RMS Testability

Test signals are fed into the monitor via the control module in the auxiliary equipment room. A check source is provided for secondary calibration. Purge controls are also provided.

7.7.1.9.4.7 RRHAC-RMS Environmental Considerations

The monitoring rack is designed to meet the environmental conditions in the control structure. The control module and recorder are in the environment of the auxiliary equipment room and control room. See Section 3.11 for the environmental conditions of the equipment locations.

7.7.1.9.4.8 RRHAC-RMS Operational Considerations

7.7.1.9.4.8.1 RRHAC-RMS General

Annunciator outputs of alarms from this monitoring system are provided in the control room. Fixed filters for particulates and iodines provide for continuous accumulation of radioactive materials that can be analyzed in the counting room. However, very few, if any, particulates or iodines are expected in this application.

7.7.1.9.4.8.2 RRHAC-RMS Reactor Operator Information

Inputs to the control room provide the operator with an indication of any evidence of leakage from the sources tabulated above. When such evidence is perceived, remedial action can be taken.

7.7.1.9.5 Steam Exhauster Discharge and Vacuum Pump Exhaust Radiation Monitoring System

7.7.1.9.5.1 SEDVP-RMS Identification

The SEDVP-RMS is an off-line radiation monitoring system that detects the presence of short half-life radioactive isotopes (mostly N-16) leaking from the steam seals of the turbine. The purpose of this system is to indicate the existence of such leakage. The monitor also provides the capability to sample the mechanical vacuum pump exhaust when this equipment is operated.

7.7.1.9.5.2 SEDVP-RMS Classification

The SEDVP-RMS is a power generation system and is not related to safety.

7.7.1.9.5.3 SEDVP-RMS Reference Design

Table 7.1-2 lists reference design information. The SEDVP-RMS is designed to alarm in response to significant evidence of radioactive isotopes escaping from the steam seals of the turbine or the mechanical vacuum pump exhaust.

7.7.1.9.5.4 SEDVP-RMS Power Source

Power is supplied to the monitors by the 120 V ac uninterruptible bus A. The pumps and solenoid valves are supplied from the 120 V ac local power. The recorder and purge controls and supplied from the 120 V ac instrument bus.

7.7.1.9.5.5 SEDVP-RMS Equipment Design

7.7.1.9.5.5.1 SEDVP-RMS General

The SEDVP-RMS is a standard off-line process radiation monitoring system. It draws a combined gas sample from the exhaust line leading from the steam packing exhaust condenser and mechanical vacuum pump exhaust, passes the sample through a chamber containing a radiation detector, and then returns the sample to the exhaust line. The source of detected radioactivity can be identified by manually isolating one of the sample lines.

7.7.1.9.5.5.2 SEDVP-RMS Circuit Description

The SEDVP-RMS is provided with a gamma-sensitive detector and converter that transmits its signal to a rate meter in the auxiliary equipment room. This rate meter indicates radioactivity in the gas sample and transmits a signal to a recorder in the control room. No control trip capabilities are provided.

7.7.1.9.5.5.3 SEDVP-RMS Testability

Test signals are fed into the monitor via the control module in the auxiliary equipment room. A check source is provided for secondary calibration. Purge controls are also provided.

7.7.1.9.5.5.4 SEDVP-RMS Environmental Considerations

The monitoring rack is designed to meet the environmental conditions in the turbine enclosure. The control module and recorder are in the environmental conditions of the auxiliary equipment room and control room. See Section 3.11 for the environmental conditions of the equipment locations.

7.7.1.9.5.5.5 SEDVP-RMS Operational Considerations

7.7.1.9.5.5.5.1 SEDVP-RMS General

Fixed filters for particulates and iodines continuously accumulate radioactive solids that can then be analyzed in the counting room. However, very few, if any, particulates or iodines are expected

in this application. A cooler and moisture separator are provided in the sample line to prevent damage to the detector as a result of excessive sample temperature.

7.7.1.9.5.5.5.2 SEDVP-RMS Reactor Operator Information

A recorder provides the operator with an indication of defectiveness of the turbine steam seals or excessive radiation in the vacuum pump exhaust.

7.7.1.9.6 Radwaste Enclosure and Chem. Lab. Expansion Ventilation Exhaust Radiation Monitoring System

7.7.1.9.6.1 REV-RMS Identification

The REV-RMS is an off-line instrument system that measures the concentration of gross radioactive effluents in the ventilation exhaust duct leading from the radwaste enclosure and chem. lab. expansion to the north stack. The purpose of the system is to provide ongoing records and alarm capability for gaseous radioactivity in effluents released to the north stack from the radwaste enclosure.

7.7.1.9.6.2 REV-RMS Classification

The REV-RMS is a power generation system and is not related to safety.

7.7.1.9.6.3 REV-RMS Reference Design

Table 7.1-2 lists reference design information. The REV-RMS is designed to alarm in response to excessive concentrations of gross radioactivity in the ventilation exhaust from the radwaste enclosure.

7.7.1.9.6.4 REV-RMS Power Sources

Power is supplied to the monitors by the 120 V ac uninterruptible bus A. The pumps and solenoid valves are supplied from the 120 V ac local power. The recorder and purge controls are supplied from the 120 V ac instrument bus.

7.7.1.9.6.5 REV-RMS Equipment Design

7.7.1.9.6.5.1 REV-RMS General

The REV-RMS is a standard off-line process radiation monitoring system. It draws an air sample from a ventilation duct, passes the sample through a chamber containing a radiation detector, and then returns the sample to the duct.

7.7.1.9.6.5.2 REV-RMS Circuit Description

The REV-RMS is provided with a gamma-sensitive detector and converter that transmits its signal to a rate meter in the auxiliary equipment room. This rate meter indicates radioactivity in the air sample and transmits both a signal to a recorder in the control room and upscale/downscale alarm signals to an annunciator in the control room. No control trip capabilities are provided. A flow indicator trips an annunciator if the sampling pump malfunctions.

7.7.1.9.6.6 REV-RMS Testability

Test signals are fed into the monitor via the control module in the auxiliary equipment room. A check source is provided for secondary calibration. Purge controls are also provided.

7.7.1.9.6.7 REV-RMS Environmental Considerations

The monitoring rack is designed to meet the environmental conditions in the control structure. The control module and recorder are in the environment of the auxiliary equipment room and control room. See Section 3.11 for the environmental conditions of the equipment locations.

7.7.1.9.6.8 REV-RMS Operational Considerations

7.7.1.9.6.8.1 REV-RMS General

Annunciator outputs of the REV-RMS alarm signals are provided in the control room. Fixed filters for particulates and iodines continuously accumulate radioactive solids that can be analyzed in the counting room. However, an insignificant quantity of particulates and iodines is expected.

7.7.1.9.6.8.2 REV-RMS Reactor Operator Information

Inputs to the control room provide the operator with evidence of the escape of airborne radioactive material from the radwaste enclosure. This can be used as a basis for diagnostic investigation.

7.7.1.9.7 Air Ejector Offgas Effluent Radiation Monitoring System

7.7.1.9.7.1 AEO-RMS Identification

The AEO-RMS measures the concentration of gross radioactivity in effluents from the steam jet air ejector downstream of the recombiner.

7.7.1.9.7.2 AEO-RMS Classification

This monitoring system is a power generation system and is not related to safety.

7.7.1.9.7.3 AEO-RMS Reference Design

Table 7.1-2 lists reference design information. This system serves the following functions:

a. It provides an ongoing record and indication of concentrations of radioactivity in air ejector offgas.

b. It provides the capability to detect fuel element contamination in the air ejector offgas.

c. It provides alarm annunciation capability.

d. It provides a grab sampling capability for detailed analysis in the counting room.

7.7.1.9.7.4 AEO-RMS Power Sources

Power is supplied to the two log monitors by the 120 V ac uninterruptible buses A and B. The linear monitor is supplied from a 20 V dc bus which is supplied from the 120 V ac uninterruptible Bus A. The pump and solenoid valves for grab sampling are supplied from 120 V ac local power. The recorder and purge controls are supplied from the 120 V ac instrument bus.

7.7.1.9.7.5 AEO-RMS Equipment Design

7.7.1.9.7.5.1 AEO-RMS General

This monitoring system is designed to provide indication and alarm if there are excessive discharges of radioactivity and to detect fuel element contamination in the air ejector effluents. It also provides grab sampling equipment for diagnostic purposes.

7.7.1.9.7.5.2 AEO-RMS Circuit Description

Two ionization chamber-type detectors with sensitivity ranges 1 mR/hr to 10^6 mR/hr are used to detect gross radioactive concentration in the air ejector effluents. In addition, a linear response channel is provided as an expanded scale device to aid in detecting fuel element contamination. The three channels provide outputs to recorders in the control room. A flow indicating switch provides annunciation if there is a high or low flow condition. By means of a local hand-selector switch, sampling pump controls, and solenoid valves controls, grab samples can be taken. The three rate meters are located in the auxiliary equipment room. Outputs from the log rate meters are fed to annunciators in the control room. Monitor purge controls are located in the control room.

7.7.1.9.7.6 AEO-RMS Testability

A built-in source of adjustable current is provided to simulate sensor input to each radiation monitor for test purposes.

7.7.1.9.7.7 AEO-RMS Environmental Considerations

The monitoring rack is designed to meet the environmental conditions in the control structure. The control module and recorders are in the environment of the auxiliary equipment and control rooms. See Section 3.11 for the environmental conditions of the equipment locations.

7.7.1.9.7.8 AEO-RMS Operational Considerations

7.7.1.9.7.8.1 AEO-RMS General

Annunciator outputs and control trip outputs are provided by this monitoring system. Controls are both local and located in the auxiliary equipment room or control room. Gross radioactivity readings can be further diagnosed using grab samples.

7.7.1.9.7.8.2 AEO-RMS Reactor Operator Information

Inputs to the control room apprise the operator of concentrations of radioactivity in the air ejector effluents, including indications of fuel element deterioration. Diagnostic capability is available.

7.7.1.9.8 Primary Containment Leak Detector Radiation Monitor

7.7.1.9.8.1 PCLD-RMS Identification

The objective of the PCLD-RMS is to indicate and record radiation levels of the primary containment atmosphere. The instrument provides alarm capability in response to a rapid increase in this radiation level. Alarm setpoints are discussed in Section 5.2.5.2.1.5.3.

7.7.1.9.8.2 PCLD-RMS Classification

The PCLD-RMS is a power generation system and is not related to safety.

7.7.1.9.8.3 PCLD-RMS Reference Design

Table 7.1-2 lists reference design information. The PCLD-RMS does not have a safety function.

7.7.1.9.8.4 PCLD-RMS Power Sources

Power is supplied to the monitor and recorder by a 120 V ac uninterruptible bus A. The pumps and solenoid valves are supplied from the 120 V ac local power. The purge control circuit is supplied from the 120 V ac instrument bus.

7.7.1.9.8.5 PCLD-RMS Equipment Design

7.7.1.9.8.5.1 PCLD-RMS General

A gas sample is drawn from the primary containment and is passed through the PCLD-RMS to measure the concentration of noble gases. Alarm capability is provided. Outputs are transmitted to a control module in the auxiliary equipment room, and to a recorder in the control room.

7.7.1.9.8.5.2 PCLD-RMS Circuit Description

The monitor channel has an upscale trip that indicates a rate of increase of radioactivity in the primary containment. A downscale trip is also provided to indicate instrument trouble. These trips annunciate, but provide no control action. The trip circuits are set so that loss of power causes an alarm. The five decade range is selected to cover both normal and maximum radiation levels (short of an accident resulting in shutdown) in the primary containment. If an accident occurs, the PCLD-RMS will be isolated, and its functions will cease.

The PCLD-RMS monitoring rack is adjacent to the primary containment. Outputs of this instrument are transmitted to the auxiliary equipment room and the control room. Remote controls purge the noble gas chamber, reset the alarm setpoints, and check the calibrations.

7.7.1.9.8.5.3 PCLD-RMS Testability

Test signals are fed into the monitor via the control module in the auxiliary equipment room. Check sources are provided for secondary calibration of each channel.

7.7.1.9.8.6 PCLD-RMS Environmental Considerations

The monitoring rack is designed to be suitable for the environmental conditions adjacent to the primary containment. Control modules and recorders are subjected to the environment of the

auxiliary equipment room and control room. See Section 3.11 for the environmental conditions of the equipment locations.

7.7.1.9.9 Hot Maintenance Shop Ventilation Exhaust Radiation Monitoring System

7.7.1.9.9.1 HMS-RMS Identification

The objective of the HMS-RMS is to indicate and record the quantity of radioactive material that escapes from the hot maintenance shop ventilation exhaust duct. Filters are provided in this duct, and sample air is drawn from a station downstream of the filters. Consequently, the quantity of radioactive material in the sample is normally negligible.

7.7.1.9.9.2 HMS-RMS Classification

This system is a power generation system and is not related to safety.

7.7.1.9.9.3 HMS-RMS Reference Design

Table 7.1-2 lists reference design information.

7.7.1.9.9.4 HMS-RMS Power Sources

The power source of the HMS-RMS is the 120 V ac lighting power.

7.7.1.9.9.5 HMS-RMS Equipment Design

7.7.1.9.9.5.1 HMS-RMS General

The system consists of two channels: one for monitoring particulate effluents, and the other for monitoring iodine effluents. Radioactive material in the gas sample is accumulated on filters where it is sensed by scintillator-type detectors. Output signals are transmitted to a microprocessor and then retransmitted to the RMMS (Section 11.5.6) for the purpose of insertion into Regulatory Guide 1.21 reports.

7.7.1.9.9.5.2 HMS-RMS Circuit Description

Each channel has two upscale trips that indicate high and high-high radiation and a downscale trip that indicates instrument trouble. These trips sound local alarms, but cause no control action. There are three trip indicating lights per channel on the control module. The range of each channel is six decades and is selected to cover both normal and possible maximum levels at the monitoring location. The system is self-contained, and all outputs are indicated on the local control module and RMMS.

7.7.1.9.9.5.3 HMS-RMS Testability

Check sources are provided to verify operability of each channel.

7.7.1.9.9.5.4 HMS-RMS Environmental Considerations

The system is designed to function within the environmental range of hot shop conditions.

7.7.1.9.10 Liquid Radwaste Discharge Radiation Monitoring System

7.7.1.9.10.1 LRD-RMS Identification

The LRD-RMS is an off-line process radiation monitoring system that measures the concentration of radioactive material in the liquid radwaste discharge to the cooling tower blowdown line. This liquid radwaste discharge includes discharges from the laundry drain, chemical wastes, floor drains, and oily waste treatment water sump. If unacceptable radioactive concentrations are detected in these discharges, valves in the discharge line automatically close, isolating the radwaste discharge system for the cooling tower blowdown line.

7.7.1.9.10.2 LRD-RMS Classification

The LRD-RMS is a power generation system and is not related to safety. However, control trip capability is provided to prevent the release of radioactive contamination to the environment.

7.7.1.9.10.3 LRD-RMS Reference Design

Table 7.1-2 lists reference design information. The LRD-RMS is designed to trip the isolation valves in the radwaste discharge line and to annunciate an alarm in the control room if there is an unacceptable concentration of radioactivity in the radwaste discharge. Data are also transmitted to a recorder in the radwaste control room.

7.7.1.9.10.4 LRD-RMS Power Sources

Power is supplied to the LRD-RMS from the 120 V ac uninterruptible bus A. Recorder power is supplied by the instrument bus in the radwaste control room. Power to the sample pump is supplied from the 120 V ac local bus.

7.7.1.9.10.5 LRD-RMS Equipment Design

7.7.1.9.10.5.1 LRD-RMS General

The LRD-RMS is a standard off-line process radiation monitoring system for liquids. It draws a sample from the radwaste discharge pipe, passes the sample through a chamber containing a radiation detector, and then returns the sample to the pipe.

7.7.1.9.10.5.2 LRD-RMS Circuit Description

The LRD-RMS has a gamma-sensitive detector and converter that transmits its signal to a rate meter located in the auxiliary equipment room. This rate meter indicates the concentration of radioactivity in the liquid sample and transmits a signal to a recorder in the radwaste control room and an upscale/downscale trip signal to the annunciator in the main control room. The upscale trip signal also actuates the trip relays to the radwaste discharge valves. A flow indicator switch trips an annunciator if the sample pump malfunctions.

7.7.1.9.10.6 LRD-RMS Testability

Test signals are fed into the monitor via the control module in the auxiliary equipment room. A check source is provided for secondary calibration.

7.7.1.9.10.7 LRD-RMS Environmental Considerations

Off-line monitoring was selected for this application in preference to in-line monitoring because of the problems involved in removing crud buildup and in decontamination. The monitoring rack is designed to meet the environmental conditions in the radwaste enclosure. The control module is in the environment of the auxiliary equipment room, and the recorder is in the environment of the radwaste control room. See Section 3.11 for the environmental conditions of the equipment locations.

7.7.1.9.10.8 LRD-RMS Operational Considerations

7.7.1.9.10.8.1 LRD-RMS General

Control trip signals close the radwaste discharge valves and alarm in the control room. Operation of the system is automatic, requiring minimum attention.

7.7.1.9.10.8.2 LRD-RMS Reactor Operator Information

Inputs to the radwaste control room and main control room provide the operators with an indication of excessive release of radioactive material via the radwaste liquids. Such releases are terminated automatically, after which remedial action can be taken.

7.7.1.9.11 Service Water Radiation Monitoring System

7.7.1.9.11.1 SW-RMS Identification

The SW-RMS is an off-line process radiation monitoring system that measures the concentration of radioactive material in the plant service water. The SW-RMS draws a sample from the main discharge pipe to the cooling tower. Plant service water is used to cool such normally nonradioactive areas as air compressors, turbine auxiliary systems, and pump bearings. It also cools the containment enclosure closed cooling water system through a heat exchanger. An increase in the radiation level of the service water stream may indicate a leak into the system from a contaminated stream.

7.7.1.9.11.2 SW-RMS Classification

The SW-RMS is a power generation system and is not related to safety.

7.7.1.9.11.3 SW-RMS Reference Design

Table 7.1-2 lists reference design information. The SW-RMS is designed to provide an alarm annunciation in the control room when a significant concentration of radioactive contamination is detected in the service water. Data are also transmitted to a control room recorder.

7.7.1.9.11.4 SW-RMS Power Sources

Power is supplied to the SW-RMS from the 120 V ac uninterruptible bus B. Power is supplied to the recorder from the 120 V ac instrument bus. The sample pump is powered by the 120 V ac local bus.

7.7.1.9.11.5 SW-RMS Equipment Design

7.7.1.9.11.5.1 SW-RMS General

The SW-RMS is a standard off-line process radiation monitoring system for liquids. It draws a sample from the service water discharge pipe, passes the sample through a shielded chamber containing a radiation detector, and then returns the sample to the pipe.

7.7.1.9.11.5.2 SW-RMS Circuit Description

The SW-RMS has a gamma-sensitive detector and converter that transmits a signal to a rate meter in the auxiliary equipment room. This rate meter indicates the concentration of radioactivity in the water sample and transmits upscale/downscale signals to the control room annunciator. It also transmits data to the control room recorder. A flow indicator switch trips an annunciator if the sample pump malfunctions.

7.7.1.9.11.6 SW-RMS Testability

Test signals are fed into the monitor via the control module in the auxiliary equipment room. A check source is provided for secondary calibration.

7.7.1.9.11.7 SW-RMS Environmental Considerations

The monitoring rack is designed to meet the environmental conditions of the turbine enclosure. The control module is in the environment of the auxiliary equipment room, and the recorder is in the environment of the control room. See Section 3.11 for the environmental conditions of the equipment locations.

7.7.1.9.11.8 SW-RMS Operational Considerations

7.7.1.9.11.8.1 SW-RMS General

Upscale/downscale trip signals actuate the annunciator in the control room. The monitoring system does not have a control trip function. Radiation data are continuously recorded in the control room.

7.7.1.9.11.8.2 SW-RMS Reactor Operator Information

The SW-RMS provides the operator with information on the concentration of radioactivity in the service water leaving the plant. If this concentration is unacceptable, remedial action can be taken.

7.7.1.9.12 Reactor Enclosure Cooling Water Radiation Monitoring System

7.7.1.9.12.1 RECW-RMS Identification

The RECW-RMS is an off-line process radiation monitoring system that measures the concentration of radioactive material in the RECW system. The RECW-RMS draws a sample from the pipe downstream of the cleanup nonregenerative heat exchangers, the reactor recirculation pump seal, and motor oil coolers. This cooling system constitutes a closed circuit and, consequently, no radioactive material in this circuit could be discharged to the environment. The reactor enclosure closed cooling water system cools potentially contaminated areas such as the nonregenerative heat exchanger, recirculation pumps, and various sample coolers. Radioactivity detected in this system indicates leakage in one or more of the heat exchangers.

7.7.1.9.12.2 RECW-RMS Classification

The RECW-RMS is a power generation system and is not related to safety.

7.7.1.9.12.3 RECW-RMS Reference Design

Table 7.1-2 lists reference design information. The RECW-RMS is designed to provide an alarm annunciation in the control room when a significant concentration of radioactive contamination is detected in the cooling water. Data are also transmitted to a recorder in the control room.

7.7.1.9.12.4 RECW-RMS Power Sources

Power is supplied to the RECW-RMS from the 120 V ac uninterruptible bus B. Power is supplied to the recorder from the 120 V ac instrument bus. The sample pump is powered by the 120 V ac local bus.

7.7.1.9.12.5 RECW-RMS Equipment Design

7.7.1.9.12.5.1 RECW-RMS General

The RECW-RMS is a standard off-line process radiation monitoring system for liquids. It draws a sample from the cooling system pipe, passes the sample through a shielded chamber containing a radiation detector, and then returns the sample to the pipe.

7.7.1.9.12.5.2 RECW-RMS Circuit Description

The RECW-RMS has a gamma-sensitive detector and converter that transmits a signal to a rate meter in the auxiliary equipment room. This rate meter indicates radioactivity in the water sample and transmits signals to the recorder and annunciator in the control room. A flow indicator switch trips an annunciator if the sample pump malfunctions.

7.7.1.9.12.6 RECW-RMS Testability

Test signals are fed into the monitor via the control module in the auxiliary equipment room. A check source is provided for secondary calibration.

7.7.1.9.12.7 RECW-RMS Environmental Considerations

The monitoring rack is designed to meet the environmental conditions of the reactor enclosure. The control module is in the environment of the auxiliary equipment room, and the recorder is in

the environment of the control room. See Section 3.11 for the environmental conditions of the equipment locations.

7.7.1.9.12.8 RECW-RMS Operational Considerations

7.7.1.9.12.8.1 RECW-RMS General

Upscale/downscale trip signals actuate the annunciator in the control room. The monitoring system provides no control trip function. Radiation data are continuously recorded in the control room.

7.7.1.9.12.8.2 RECW-RMS Reactor Operator Information

The RECW-RMS provides a backup for the service water radiation monitor. The RECW-RMS detects radiation only if radiation is present in the service water and if leaks occur between the service water system and the RECW system.

7.7.1.10 Area Radiation Monitoring System - Instrumentation and Controls

7.7.1.10.1 ARMS Identification

7.7.1.10.1.1 ARMS General

The ARMS indicates and records gamma radiation levels in areas where radioactive material is present, stored, handled, or inadvertently introduced.

7.7.1.10.1.2 ARMS Classification

This is a power generation system and is classified as not related to safety.

7.7.1.10.1.3 ARMS Reference Design

Table 7.1-2 lists reference design information. The ARMS instrumentation and control system is an operational monitoring system and has no safety function.

7.7.1.10.2 ARMS Power Sources

The power source for the ARMS is the 120 V ac instrument bus.

7.7.1.10.3 ARMS Equipment Design

7.7.1.10.3.1 ARMS General

The ARMS is described in Section 12.3.4. Each channel consists of a combined sensor and converter unit; a combined indicator and trip unit; a shared power supply; and a shared multipoint recorder. Each channel also has a local audio alarm auxiliary unit.

7.7.1.10.3.2 ARMS Circuit Description

Each monitor has an upscale trip that indicates high radiation, and a downscale unit that can indicate instrument trouble. These trips sound alarms but cause no control action. The trip circuits are set so that loss of power causes an alarm. There are two trip indicating lights in the front face of an indicator and trip unit. The range of the channel is six decades and is selected to cover both normal and possible maximum radiation levels at the monitoring location.

The monitors are located (Table 12.3-7) at various places in the containment, auxiliary/reactor enclosure, radwaste facility, turbine enclosure, control room, and other areas where radiation monitoring is desired, based on the following objectives:

a. To monitor the radioactivity level in areas where personnel may be required to work.

b. To provide a record of the radioactivity as a function of time at key locations throughout the plant.

Ranges and sensitivities are selected for each location based on the anticipated radioactivity level as provided by experimental measurements of levels in similar plants and shielding calculations. Local alarming and indication is provided at those remote sensor locations where a substantial increase in radiation levels might be immediately important to personnel in the area. This system does not have any bypass or interlock interfaces, however each channel can be bypassed.

7.7.1.10.3.3 ARMS Testability

An internal trip test circuit, adjustable over the full range of the trip circuit, is provided. The test signal is fed into the indicator and trip unit input so that a meter reading is provided in addition to a real trip. All trip circuits are of the latching-type and must be manually reset at the front panel.

A facility for calibrating these monitor units is provided. This is a test unit designed for use in the adjustment procedure for the area radiation monitor sensor and converter unit. It provides several gamma radiation levels between approximately 4 mR/hr to 300 MR/hr. The calibration unit source is an approved source.

A cavity in the calibration unit receives the sensor and converter unit. A window through which radiation from the source emanates is located on the back wall of the cylindrical lower half of the cavity. A chart on each unit indicates the radiation levels available from the unit for the various control settings.

7.7.1.10.4 ARMS Environmental Considerations

The sensor, converter, and local audio alarm auxiliary unit are designed to operate under the environmental conditions at the monitoring locations. The indicator/trip unit and the power supply are designed to operate under auxiliary equipment room environmental conditions and power source fluctuations to guarantee successful operation of the system. See Section 3.11 for the equipment location environmental conditions.

7.7.1.10.5 ARMS Operational Considerations

7.7.1.10.5.1 ARMS General Information

An annunciator window is provided for each operational area, such as the turbine building area or the auxiliary/reactor enclosure area, although there are a number of ARMS channels in the area, and any one of them can trip the annunciator.

7.7.1.10.5.2 ARMS Reactor Operator Information

An operator is able to identify the channel that causes the annunciation by checking the indicating lights of the indicator/trip units.

7.7.1.11 Gaseous Radwaste System - Instrumentation and Controls

7.7.1.11.1 GRS Identification

7.7.1.11.1.1 GRS General

The objective of the GRS is to process and control the release of gaseous radioactive wastes to the site environs so that the total radiation exposure to persons outside the controlled area is as-low-as-practicable and does not exceed applicable regulations.

7.7.1.11.1.2 GRS Classification

This system is required for power generation only and is classified as not related to safety.

7.7.1.11.1.3 GRS Reference Design

Table 7.1-2 lists reference design information. The subject instrumentation and control system is an operational system and has no safety function. Therefore, there are no safety design differences between this system and those of the reference design facilities. This system is functionally identical to the referenced system.

See drawings M-69 and M-70 for the system P&IDs.

7.7.1.11.1.4 GRS Power Source

The 120 V ac instrument bus provides power for the GRS instrumentation.

7.7.1.11.2 GRS Equipment Design

7.7.1.11.2.1 GRS General

This system is monitored by flow, temperature, pressure, conductivity, and hydrogen analyzers to ensure correct operation and control. Drawings M-69 and M-70 show the process parameters that are instrumented to alarm in the control room. They also indicate whether the parameters are recorded or just indicated. The reactor operator is in control of the system at all times.

The air ejector holdup pipe discharge radiation monitor continuously monitors radioactive effluents to the offgas charcoal treatment system. This monitor provides an alarm in response to high radiation in the offgas. A radiation monitor downstream of the charcoal offgas treatment system continuously monitors radioactive effluents from the charcoal beds. Thus, the radioactivity of the gas entering and leaving the charcoal offgas treatment system is continuously monitored, so that

the performance of this system is known to the operator at all times. Provisions are also made for the periodic extraction and analysis of grab samples of the influent and effluent gases for determining their compositions.

7.7.1.11.2.2 GRS Recombiner Instrumentation

Recombiner vessel temperatures are monitored by inlet and outlet thermocouples. Inlet process gas is monitored for temperature and annunciated in the main control room if its temperatures are high or low. Outlet gas temperature is measured and high temperature is annunciated in the main control room. In addition, gas outlet hydrogen concentration is recorded and alarmed (high) in the control room (drawing M-69). Recombiner inlet hydrogen can also be measured if required.

7.7.1.11.2.3 GRS Offgas Aftercondenser Condensate High and Low Level

The offgas aftercondenser condensate high and low levels are annunciated in the main control room. The level switches also control the aftercondenser drain valve. A control board mounted level controller provides remote/manual control of this valve.

7.7.1.11.2.4 GRS Offgas System Inlet Gas Measurements

The gas inlet to the offgas components is monitored for temperature, pressure, and moisture content on local panels and in the control room. These parameters are annunciated to alert the operator that corrective action is required.

7.7.1.11.2.5 GRS Hydrogen and Oxygen Analyzer Measurement System

Two oxygen analyzers are used to measure the oxygen content of the offgas process stream at the discharge of the aftercondenser. The system is designed to ensure that there is sufficient oxygen available to combine with the hydrogen and yet ensure that the oxygen level does not get too high so as to impose an increased fire hazard for the offgas charcoal beds. Oxygen concentration % output from the analyzer is displayed in the control room.

Three parallel independent hydrogen analyzers are used to measure the hydrogen content of the offgas process steam downstream of the offgas aftercondenser. One analyzer can be selected to measure hydrogen level upstream of the recombiner. The hydrogen concentration percentage output from the analyzers is recorded in the control room along with independent alarm annunciation for a high hydrogen concentration. Each hydrogen analyzer continuously withdraws a sample of the process offgas, analyzes the hydrogen content, and returns the sample gas to the main condenser. During normal plant operation, the main condenser vacuum provides the pumping force to withdraw the sample gas from the hydrogen analyzer system. Hydrogen percentage calibration checks are made by closing off the line to the offgas process line and admitting a hydrogen calibration gas or a hydrogen free gas; this test is periodically performed. The specified analyzer element is a thermal conductivity cell type of unit, and is designed to prevent hydrogen ignition. An auxiliary vacuum pump is provided to withdraw sample gases in the absence of sufficient main condenser vacuum.

7.7.1.11.2.6 Moisture Measurement

One independent moisture detector is placed upstream of the charcoal beds. The moisture content is indicated on a local panel and in the control room, and a high or above moisture content point alarms and annunciates on a local panel and in the control room to notify the operator of the possibility that corrective action may have to be taken.

7.7.1.11.2.7 GRS Charcoal Vessel Temperature Monitoring

The temperature of each charcoal vessel is monitored and indicated on a local panel and recorded in the control room. This parameter is also annunciated at both locations.

7.7.1.11.2.8 GRS Differential Pressure Measurements

Differential pressure is measured across the filter located downstream of the charcoal beds. High differential pressure is alarmed on a local panel and in the control room, and local differential pressure indication is provided.

7.7.1.11.2.9 GRS Testability

Because this is a process on-line monitoring, the cross-correlation of the data provides sufficient confirmation of the system's correct operation.

7.7.1.11.3 GRS Environmental Considerations

7.7.1.11.3.1 GRS General

The GRS is not required for safety purposes or required to operate after the DBA. The control system is required to operate in the normal plant environment for power generation purposes only. Radwaste controls and instrumentation located in the offgas equipment area are subject to the environmental and design conditions listed in Section 3.11.

7.7.1.11.3.2 GRS Local Instrument Panels

The local instrument panels are located in the operating area outside of the process stream's shield wall. The environmental conditions are the same as described above (Section 3.11).

7.7.1.11.3.3 GRS Special Considerations

The instrument sensing lines are rated for 2500 psig. This is sufficient to resist a hydrogen detonation in the process line, or in the tubing.

7.7.1.11.4 GRS Operational Considerations

7.7.1.11.4.1 GRS General Information

No operator action is required on the equipment described unless an alarmed condition occurs.

7.7.1.11.4.2 GRS Reactor Operator Information

Operator indicators and alarms are shown in drawing M-69.

7.7.1.11.5 GRS Setpoints

A hydrogen level of 2% alarms and annunciates in the control room .

7.7.1.12 Liquid Radwaste System - Instrumentation and Controls

7.7.1.12.1 LRS Identification

7.7.1.12.1.1 LRS Function

The objective of the LRS is to control the release of liquid and solid radioactive waste material to the environs.

7.7.1.12.1.2 LRS Classification

This system is required for power generation only and is classified as not related to safety.

7.7.1.12.1.3 LRS Reference Design

Table 7.1-2 lists reference design information.

7.7.1.12.2 LRS Power Sources

a. Normal: The 120 V ac instrument power is used for the liquid radwaste process control system.

b. Alternates: Because this is not an essential or safety system, no alternative power source is required.

7.7.1.12.3 LRS Equipment Design

The LRS is designed to process liquid waste water to remove particulates, impurities, and other materials and return the processed water for plant use.

Only those portions of the liquid radwaste system providing information that requires operator attention are described to show operator ability to take corrective action when needed.

7.7.1.12.3.1 LRS Equipment Operation

Waste water is collected in various sumps throughout the plant and is pumped into the radwaste collection tanks where it is processed. Excess processed liquids that are discharged from the plant are radiation-monitored, flow-controlled, and recorded.

The instrumentation and control system of the radwaste process is typical of a standard chemical and water treatment process. Tank levels are indicated and recorded in the radwaste control room and high tank levels are annunciated in the radwaste and main control room (drawings M-61, M-62, M-63 and M-64).

7.7.1.12.3.1.1 LRS Drywell Sumps Control

The drywell sumps discharge to the liquid radwaste system collection tanks (drawing M-61) by gravity. Flow integrators are provided in each sump discharge line to monitor flow out of the drywell sumps. The liquid discharge line from each drywell sump is provided with two drain valves for containment isolation and for sump level control during normal operation. When either isolation valve is closed, the liquid discharge from the drywell sump is stopped. Section 5.2.5.2.1.3.c gives a description of the operation of the sump discharge valves in conjunction with the drywell sump level monitoring system.

7.7.1.12.3.1.2 LRS Reactor and Turbine Enclosure Sumps

These sumps collect waste water from their respective areas and automatically pump out the sumps on level control. Alarm and annunciation in the radwaste and main control rooms occurs on a high-high and low sump level to allow the operator to take corrective action. Run-time meters with indicating lights are also provided to indicate the elapsed run-time of both sump pumps.

The discharge line from the floor drain sample tank to the cooling tower blowdown line isolates upon high radiation detection and alerts the operator. The discharge flow shutoff valves are operated by a key-lock switch that requires plant supervisory control of any releases.

7.7.1.12.3.1.3 LRS Tank Level and Process Control

All tanks containing waste liquids throughout the radwaste liquid processing system are provided with liquid level indicators, recorders, and alarm and annunciation in the radwaste and main control rooms to inform the operator that corrective action is to be taken for high or low liquid levels. The process is controlled by an operator from the radwaste control room panel. The control system is designed for manual startup and automatic stop when a process is completed (i.e., tank liquid contents have been emptied to the next process). Because this is a batch system, the operator has full control and responsibility for the system control process.

7.7.1.12.4 LRS Environmental Considerations

The radwaste control systems are not required for safety purposes or required to operate after the DBA. The radwaste control systems are required to operate in the normal plant environment for power generation purposes only. The environmental conditions are listed in Section 3.11.

7.7.1.12.5 LRS Operational Considerations

7.7.1.12.5.1 LRS General Information

The operator is in full control of the process system batches.

7.7.1.12.5.2 LRS Reactor Operator Information

Indicators and recorders are provided for all liquid tanks to inform the operator of the status of the system. Alarms and annunciation are provided to inform the operator that a tank must be emptied or processed, or that a particular piece of equipment malfunctioned, and corrective action must be taken.

7.7.1.12.5.3 LRS Setpoints

All tank levels are set to alarm and annunciate before reaching overflow level. This is sufficient time for the operator to take corrective action in the process control.

7.7.1.13 Solid Radwaste System - Instrumentation and Controls

7.7.1.13.1 SRS Identification

The SRS packages and solidifies radioactive wastes. The system contains the instruments and controls necessary to operate the principal process system. It is a power generation system and is classified as not related to safety. Table 7.1-2 lists reference design information.

7.7.1.13.2 SRS Power Sources

The power for the solids radwaste handling system is from an ac power source.

7.7.1.13.3 SRS Equipment Design

The process instrumentation and controls provided are as shown in drawings M-66 and M-67. The instrumentation and control equipment controls the operation of the system that is discussed in Section 11.4.

7.7.1.13.4 SRS Environmental Considerations

Controls and instrumentation for the solids radwaste handling system are designed to operate during those environmental conditions listed in Section 3.11.

7.7.1.13.5 SRS Operational Considerations

The SRS provides a means of monitoring parameters of the system and permits operator intervention if required.

7.7.1.14 Fuel Pool Cooling and Cleanup System – Instrumentation and Controls

7.7.1.14.1 FPCC Identification

7.7.1.14.1.1 FPCC General

The objective of the FPCC is to remove decay heat from the spent fuel storage pool water to ensure adequate cooling of irradiated stored assemblies. The fuel pool cooling system also purifies the spent fuel storage pool water. It maintains water clarity for fuel handling operations and fills and drains the fuel transfer canal. The process instrumentation and controls are shown in drawing M-53.

7.7.1.14.1.2 FPCC Classification

This system is required for power generation only and is classified as not related to safety.

7.7.1.14.1.3 FPCC Reference Design

Table 7.1-2 lists reference design information.

7.7.1.14.2 FPCC Power Sources

The 120 V ac instrument bus provides power for the FPCC system instrumentation.

7.7.1.14.3 FPCC Equipment Design

The following process instrumentation is provided:

a. Fuel pool water level alarms in the control room

b. Skimmer surge tank water level alarms in the main control room

c. Fuel pool cooling pump suction and discharge low pressure alarms in the main control room

d. Fuel pool cooling heat exchangers inlet temperature recorder and alarms in the main control room

e. Fuel pool cooling heat exchangers outlet temperature recorder and alarms

7.7.1.14.4 FPCC Environmental Considerations

Controls and instrumentation for the FPCC system are designed to operate during those environmental conditions listed in Section 3.11.

7.7.1.14.5 FPCC Operational Considerations

7.7.1.14.5.1 FPCC General Information

No operator action is required unless an alarm condition occurs.

7.7.1.14.5.2 Reactor Operator Information

See Section 7.7.1.14.3.

7.7.1.15 Refueling Interlocks - Instrumentation and Controls

7.7.1.15.1 RI Identification

The purpose of the RI is to restrict the movement of the control rods and the operation of refueling equipment to reinforce operational procedures that prevent the reactor from becoming critical during refueling operations.

This equipment is not required to operate during a seismic event. The operability of the equipment can be verified after a seismic event without jeopardizing safety.

7.7.1.15.2 RI Power Sources

There is only one source of power for both channels of the logic circuits. However, this power source supplies the CRD system as well. A failure of this power supply prevents any rod motion.

7.7.1.15.3 RI Equipment Design

7.7.1.15.3.1 RI Circuit Description

The refueling interlock circuitry senses the condition of the refueling equipment and the control rods. Depending on the sensed condition, interlocks are actuated to prevent the movement of the refueling equipment or withdrawal of control rods (rod block). Redundant circuitry is provided to sense the following conditions:

a. All rods inserted (Section 7.7.1.15.3.2)

b. Refueling platform positioned near or over the core

c. Refueling platform main hoist, fuel-loaded

d. Deleted

e. Reactor mode switch in REFUEL position

7.7.1.15.3.2 RI Logic and Sequencing

The indicated conditions are combined in logic circuits to satisfy all restrictions on refueling equipment operations and control rod movement (drawings C11-1030-F-008, C11-1030-F-009, C11-1030-F-010, C11-1030-F-011, C11-1030-F-012, C11-1030-F-013, and C11-1030-F-014). A two channel circuit indicates that all rods are in. The rod-in condition for each rod is established by the closure of a magnetically operated reed switch in the rod position indicator probe. The rod-in switch must be closed for each rod before the all-rods-in signal is generated. This is not the same switch that provides rod numerical position information to the plant monitoring system (PMS) and four rod position display. Both channels must register the all-rods-in signal before the refueling interlock circuitry can indicate the all-rods-in condition.

During refueling operations, no more than one control rod is permitted to be withdrawn from core cells loaded with any fuel assemblies. This is enforced by a redundant logic circuit that uses the all-rods-in signal and a rod selection signal to prevent the selection of a second rod for movement with any other rod not fully inserted. Control rod withdrawal is prevented by comparison checking between the A and B portions of the RMCS and subsequent message transmission to the affected control rod. The simultaneous selection of two control rods is prevented by the interconnection arrangement of the select push buttons. With the mode switch in the refuel position, the circuitry prevents the withdrawal of more than one control rod and the movement of the refueling platform with the main hoist fuel-loaded over the core with any control rod withdrawn from core cells with any fuel assemblies.

The operation of refueling equipment is prevented by interrupting the motion commands to the equipment. The refueling platform is provided with two mechanical switches attached to the platform, which are tripped open by a long, stationary ramp mounted adjacent to the platform rail. The switches open before the platform or any of its hoists are physically located over the reactor vessel to indicate that the platform is approaching its position over the core.

Load cell readout is provided for all hoists. Indicators display given hoist loads directly to the hoist operator. Load sensing is by electronic load cells. Associated interlock functions are performed by electronic switches that compare the setpoint values with the signal generated by the electronic load cells.

The main hoist on the refueling platform is provided with switches that open when the hoist is fuel-loaded. The switches open at a load weight that is lighter than that of a single fuel assembly. This indicates when fuel is loaded on any hoist.

7.7.1.15.3.3 RI Bypasses and Interlocks

The rod block interlocks and refueling platform travel interlocks provide two independent levels of interlock action. The interlocks that restrict operation of the platform hoist and grapple provide a

third level of interlock action because they would be required only after a failure of a rod block and refueling platform travel interlock. The strict procedural control exercised during refueling operations is a fourth level of backup, even though this is actually the primary means of control.

7.7.1.15.3.4 RI Redundancy and Diversity

Although the refueling interlocks are not designed or required to meet the IEEE 279 (1971) criteria for nuclear power plant protection systems, a single component failure does not cause an interlock failure. Refueling interlocks are provided for use during planned refueling operations. Criticality is prevented during fuel assembly insertion, provided that the control rod in the associated control cell is fully inserted. The interlock systems accomplish this by:

a. Preventing operation of fuel-loaded refueling equipment over the core whenever any control rod is withdrawn

b. Preventing control rod withdrawal whenever fuel-loaded refueling equipment is over the core

c. Preventing withdrawal of more than one control rod when the mode switch is in the REFUEL position

The refueling interlocks have been designed utilizing redundancy of sensors and circuitry to provide a high level of reliability and assurance that the design bases are met. Each of the individual refueling interlocks discussed above need not meet the single failure criteria because the four essentially independent levels (including procedural control) of protection ensure that the design basis is met. For any of the "situations" listed in Table 7.7-3, a single interlock failure does not cause an accident, result in potential physical damage to fuel, or result in abnormal radiation exposure to personnel during fuel handling operations.

7.7.1.15.3.5 RI Actuated Devices

The refueling interlocks from the RMCS to the refueling equipment trip logic in the refueling equipment controls that interrupts motion commands to the equipment. This prevents fuel-loaded hoist operation over the core.

The interlocks from the refueling equipment to the RMCS actuate circuitry that provides a control rod block. The rod block prevents the operator from withdrawing any control rods.

7.7.1.15.3.6 RI Separation

The refueling interlocks are not designed to, or required to meet, the IEEE 279 (1971) criteria for nuclear power plant protection systems. However, a single interlock failure does not cause an accident. The interlocks are used in conjunction with administrative controls during planned refueling operations. Criticality is prevented during fuel insertion, provided that the control rod in the associated control cell is fully inserted.

7.7.1.15.3.7 RI Testability

Complete functional testing of all refueling interlocks prior to use positively indicates that the interlocks operate in the situations for which they are designed. The interlocks can be subjected to valid operational tests by loading the hoist with a dummy fuel assembly, positioning the refueling

platform, and withdrawing the control rods. Where redundancy is provided in the logic circuitry, tests can be performed on a periodic basis to ensure that each redundant logic element can independently perform its function.

7.7.1.15.4 RI Environmental Considerations

Refueling equipment is subjected to the conditions listed in Section 3.11 during normal operation.

Refueling components are designed to withstand design basis events such as earthquakes, accidents, and anticipated operational occurrences without consequential damage, but they are not required to be functional during or after the event without repair.

7.7.1.15.5 RI Operational Considerations

7.7.1.15.5.1 RI General Information

The refueling interlocks are provided for use during planned refueling operations.

7.7.1.15.5.2 RI Reactor Operator Information

In the refueling mode, the control room operator has indication whenever all control rods are fully inserted. This indication is control rod position data from the computer as well as control rod in and out status on the full core status display. Furthermore, whenever a control rod withdrawal block situation occurs, the operator receives annunciation and computer logs of the rod block. He can compare these outputs with the status of the variable providing the rod block condition. Both channels of the control rod withdrawal interlocks must agree that permissive conditions exist in order to move control rods; otherwise, a control rod withdrawal block is placed into effect. Failure of one channel may initiate a rod withdrawal block and does not prevent application of a valid control rod withdrawal block from the remaining operable channel.

In terms of refueling platform interlocks, the platform operator has digital-type readout indicators for the platform main hoist X-Y position relative to the reactor core.

The position of the grapple is shown on a digital indicator. Digital load cell indications of hoist loads are given for each hoist by locally mounted indicators. Individual joysticks or pendants are provided for local control of the platform and its hoists. The platform operator can immediately determine whether the platform and hoists are responding to his local instructions and can, in conjunction with the control room operator, verify proper operation of each of the three categories of interlocks listed previously.

7.7.1.15.5.3 RI Setpoints

There are no safety setpoints associated with this system because this system does not perform a safety function.

7.7.1.16 Leak Detection System - Instrumentation and Controls

The nonsafety-related portion of the leak detection system consists of the following systems:

a. Recirculation pump seal leak detection

b. RHR system leak detection

c. Drywell leak detection

d. Safety/relief valve leak detection

e. Reactor pressure vessel head leak detection

f. Core spray system leak detection

7.7.1.16.1 LDS System Identification

This section describes the instrumentation and controls associated with the nonsafety-related portion of the leak detection system. Section 7.6 describes the instrumentation and controls in the safety-related portion. This system is discussed in Section 5.2.5.

The purpose of the leak detection system instrumentation and controls is to detect and annunciate before predetermined limits are exceeded.

7.7.1.16.2 LDS Power Sources

Power for the nonsafety-related portion of the leak detection system is supplied from a reliable 120 V ac instrument bus.

7.7.1.16.3 LDS Equipment Design

7.7.1.16.3.1 LDS General

The systems or parts of systems that contain water or steam coming from the reactor vessel or supply water to the reactor vessel and that are in direct communication with the reactor vessel are provided with leakage detection systems.

The systems within the primary containment share a common area. Therefore, a common leakage detection system is used. Each of the methods used for leakage detection inside the primary containment is designed with the capability to detect leakage at less than the established leakage rate limits.

Major components within the primary containment are, by nature of their design, sources of leakage (e.g., pump seals, valve stem packing, and equipment warming drains), but have their leakage contained and piped to an equipment drain sump and are thereby identified.

Steam or water leaks from other equipment are collected in the floor drain sumps.

Each of the sumps is protected against overflowing to prevent leaks of an identified source from masking those from unidentified sources.

7.7.1.16.4 Recirculation Pump Seal Leak Detection System

7.7.1.16.4.1 RPS-LDS Identification

There are two recirculation pump seal leak detection systems, one for each of the pumps in the recirculation loops. The recirculation pump leak detection system consists of two types of monitoring circuits (Figure 7.6-2). The first of these monitors the pressure levels within the seal cavities, presenting the plant operator with a visual display of the sensed pressure in each of the two cavities. The second type of monitoring circuit used by the leak detection system monitors the rate of liquid flow from the seal cavities.

7.7.1.16.4.2 RPS-LDS Pump Seal Cavity Pressure Monitoring

7.7.1.16.4.2.1 Circuit Description

The pressure levels within seal cavity number 1 and seal cavity number 2 are measured with identical instruments arranged similarly. The pressure within the seal cavities is measured using a pressure transmitter. The pressure transmitter produces an output signal whose magnitude is proportional to the sensed pressure within its dynamic range. This output signal is then transmitted to a pressure indicator for plant operator readout.

7.7.1.16.4.2.2 Logic and Sequencing

No automatic action is initiated by the pump seal cavity pressure monitoring circuit.

7.7.1.16.4.2.3 Bypasses and Interlocks

No bypasses and interlocks are provided.

7.7.1.16.4.2.4 Redundancy and Diversity

No redundancy is provided in this monitoring circuit. The pump seal cavity pressure monitoring is a diverse method of leak detection to the seal cavity flow rate monitoring.

7.7.1.16.4.3 RPS-LDS Liquid Flow Rate Monitoring

7.7.1.16.4.3.1 Circuit Description

All condensate flowing past the recirculation pump seal packings and into the seal cavities is collected and sent by one of two drain systems to the primary containment equipment sump for disposal. The first drain system drains the major portion of the condensate collected within the Number 2 seal cavity. The condensate flow rate through the drain system is monitored by a flow switch. The point at which the flow switch contacts close can be adjusted so that the switch is actuated only above or below certain flow rates. Excessively high or low flow rates through this drain system activate an annunciator in the control room.

The second drain system drains the cavity beyond the Number 2 seal cavity collecting the condensate that has seeped (or leaked) past the outer seal. Flow instrumentation monitors the condensate flow through this drain system. A high rate through this system activates an annunciator in the control room.

7.7.1.16.4.3.2 Logic and Sequencing

No automatic action is initiated by the seal cavity flow and the second drain system's monitoring circuit.

7.7.1.16.4.3.3 Bypasses and Interlocks

There are no bypasses or interlocks provided.

7.7.1.16.4.3.4 Redundancy and Diversity

Redundancy is not provided. Backup indication of seal leakage is provided, however, by monitoring both seal cavities to verify seal failure.

Seal cavity monitoring diversity is provided by monitoring seal cavity pressure.

7.7.1.16.5 Residual Heat Removal Leak Detection System

7.7.1.16.5.1 RHR-LDS Identification

The leak detection system constantly monitors the steam lines of the RHR system for leaks. Leaks are detected by steam flow rate monitoring in the common RHR/HPCI steam line. If the monitored parameter indicates that a leak exists, the RHR-LDS activates an annunciator in the control room and initiates an HPCI isolation signal.

The RHR-LDS consists of three types of monitoring circuits. The first of these monitors equipment area ambient and differential temperature, actuating an annunciator when the temperature rises above a present maximum. The second type of circuit monitors the flow rate (differential pressure) through the common RHR/HPCI steam line, actuating an annunciator when the differential pressure (flow) rises above a present maximum. The third type of circuit monitors the shutdown cooling water flow rate and is also annunciated.

Detection of leakage from the ECCS during the long-term post-LOCA cooldown recovery involves detecting leaks from the RHR system. RHR room ambient and differential temperatures can be monitored from the control room. RHR flow and reactor water level can be also monitored from the control room to detect a large leak in the RHR system. All of these instruments are Class 1E instruments.

7.7.1.16.5.2 RHR-LDS Area Temperature Monitoring Leak Detection

7.7.1.16.5.2.1 Circuit Description

The LDS constantly monitors the RHR compartment of the RHR system. Leaks are detected by equipment area ambient and differential temperature, which actuates an annunciator when the temperature rises above a preset limit.

7.7.1.16.5.2.2 Logic and Sequencing

The RHR and ambient and differential temperature monitoring circuit activates an annunciator when the observed temperature exceeds a preset limit.

7.7.1.16.5.2.3 Bypasses and Interlocks

No bypasses or interlocks are associated with this system.

7.7.1.16.5.2.4 Redundancy and Diversity

One channel for ambient and one channel for differential temperature monitoring detect leaks in each RHR system equipment area.

Diversity is satisfied by providing ambient temperature, differential temperature, and RHR/HPCI steam line flow monitoring.

7.7.1.16.5.3 RHR-LDS Flow Rate Monitoring

7.7.1.16.5.3.1 Circuit Description

Flow rate is monitored on the RHR shutdown cooling return line.

7.7.1.16.5.3.2 Logic and Sequencing

Minimum flow bypass actuation is the only action initiated by RHR flow monitoring.

7.7.1.16.5.3.3 Bypasses and Interlocks

No bypasses or interlocks are associated with the process line pressure monitoring instrumentation for the RHR/HPCI common steam flow line.

7.7.1.16.5.3.4 Redundancy and Diversity

Isolation of the RHR system on a low pressure condition occurs by signaling a closure of both the common RHR/HPCI inboard and outboard isolation valves. Two redundant pressure sensing switch contacts are used in two-out-of-two coincidence in each logic division (i.e., A and B) to provide pressure monitoring in the common steam line feeding the HPCI and RHR systems. Because the RHR system is isolated by independent actuation of either logic channel, a single failure of a system component in either channel does not prevent the required isolation function.

Diversity is accomplished through isolation by the following monitored variables: steam line high flow, steam line pressure, and ambient and differential temperature.

7.7.1.16.6 Drywell Leak Detection System

7.7.1.16.6.1 D-LDS Identification

Drywell leak detection is accomplished by detecting the level change in two sumps. The level is monitored to detect a rate change that could indicate an abnormality within the primary containment. This instrumentation detects a small leak and provides early warning to the control room operator, permitting corrective measures to be implemented before the abnormality becomes severe (drawings M-61).

7.7.1.16.6.2 D-LDS Circuit Description

Each sump is continuously monitored by a transmitter. The signal, which is proportional to level, is linearized for the cylindrical shape of the sump tank and is converted to a flow rate. The flow rate into each sump tank is indicated and alarmed. Flow from each sump tank to radwaste is recorded and alarmed. The alarms are described in sections 5.2.5.2.1.3 and 9.3.3.5.

7.7.1.16.6.3 D-LDS Logic and Sequencing

Annunciation actuation is the only action initiated by the drywell leak detection monitoring circuit.

7.7.1.16.6.4 D-LDS Bypasses and Interlocks

There are no bypasses or interlocks associated with this subsystem.

7.7.1.16.7 Safety/Relief Valve Leak Detection System

7.7.1.16.7.1 SRV-LDS Identification

Normally, the SRVs are in the shut-tight condition and are all at about the same temperature. Steam passage through a valve increases the monitored temperature at the exhaust, causing an abnormal temperature reading on the Data Acquisition System (DAS). Relay contacts on the DAS, configured to actuate at a predetermined setpoint, close to complete an annunciator circuit. Leakage from a valve is usually characterized by a temperature increase on a single relief valve exhaust line.

7.7.1.16.7.2 SRV-LDS Discharge Line Temperature Monitoring

7.7.1.16.7.2.1 Circuit Description

A temperature element is placed in the discharge pipe of each SRV for remote indication of leakage. The output of each temperature element is connected to the BOP-DAS.

7.7.1.16.7.2.2 Logic and Sequencing

Annunciator actuation is the only action initiated by the SRV temperature monitoring circuit.

7.7.1.16.7.2.3 Bypasses and Interlocks

There are no bypasses or interlocks associated with this system.

7.7.1.16.7.2.4 Redundancy and Diversity

No redundancy or diversity is required for this system.

7.7.1.16.8 Reactor Pressure Vessel Head Leak Detection System

7.7.1.16.8.1 RPVH-LDS Identification

Pressure between the inner and outer head seal-ring is sensed by a pressure switch. If the inner seal leaks, the pressure sensor senses the increased pressure and actuates an alarm. The plant continues to operate with the outer seal as a backup. If both the inner and outer head seals leak, the leak is detected by an increase in drywell temperature and pressure.

7.7.1.16.8.2 RPVH-LDS Head Seal Integrity Pressure Monitoring

7.7.1.16.8.2.1 RPVH-LDS Circuit Description

A pressure sensor monitors the pressure between the inner and outer head seals.

7.7.1.16.8.2.2 RPVH-LDS Logic and Sequencing

No action is initiated by the reactor vessel head pressure monitoring circuit.

7.7.1.16.8.2.3 RPVH-LDS Bypasses and Interlocks

There are no bypasses or interlocks associated with this system.

7.7.1.16.8.2.4 Redundancy and Diversity

Redundant pressure-sensing instrumentation for detecting inner seal failure is not provided and the outer seal assembly provides backup if an inner seal leak occurs.

7.7.1.16.9 Core Spray System Leak Detection System

7.7.1.16.9.1 CS-LDS Identification

CS-LDS is designed to provide core spray cooling to the reactor core. CS-LDS has a safety-related function and is required to be operable following a LOCA.

7.7.1.16.9.2 CS-LDS Circuit Description

CS-LDS leaks are detected by the pressure differential across the reactor nozzle and core shroud actuating an annunciator when the pressure differential rises above a preset limit (drawings M-52).

7.7.1.17 Emergency Response Facility Data System Instrumentation and Controls

7.7.1.17.1 ERFDS Identification

The ERFDS is a part of the Plant Monitoring System described in Section 7.7.1.22. ERFDS performs the software functions described in this section utilizing the PMS hardware platform described in Section 7.7.1.22.3.

The ERFDS performs two major functions. First, it is the system that conforms with regulatory requirements for a SPDS. The ERFDS can generate real-time and historical visual displays, print records and plots which can be used to provide plant information that aid plant personnel during abnormal and emergency conditions in determining and controlling the value and trend of the key reactor and primary containment control parameters. In addition to the parameters required by Regulatory Guide 1.97 (Rev 2), as discussed in Section 7.5, the ERFDS will monitor the following safety-related parameters:

a. APRM

b. Scram signals

c. HPCI, initiation, speed, discharge pressure, EGM output, ramp output, flow controller output, steam line ΔP

d. RCIC parameters same as HPCI

e. RHR heat exchanger level and pressure

f. RCIC suction pressure control output

The SPDS portion of the LGS ERFDS meet the requirements of NUREG-0737 Supplement 1 as discussed below.

The other function is TRA, which provides a real-time and historical perspective for the operation of the power plant. The TRA functions provide high resolution recording capabilities for various plant parameters and the means for event monitoring, data archival, plotting, trending and analyzing in order to support the determination and analysis of plant transients.

7.7.1.17.2 Safety Parameter Display System

7.7.1.17.2.1 SPDS Human Factors

The SPDS portion of the LGS ERFDS meets the NRC requirements for an SPDS, in that, it provides aid to the operator in determining the safety status of the plant during abnormal or emergency conditions. The graphic displays available to the control room operator are based on the current revision of the EPGs and are formatted to give maximum assistance in following the LGS EOPs.

Human factors engineering has also been taken into account during development of the LGS SPDS to maximize the operator's ability to readily determine plant status and to minimize errors by the operator during its use.

The SPDS portion of the LGS ERFDS displays is a subset of the generic GE Emergency Response Information System displays. As such, its displays use patterns and colors for conveying current parameter values, trends, limit indications, and validation status that are based upon those used in the generic GE Emergency Response Information System displays.

The human factors reviews of the generic GE Emergency Response Information System displays consisted of a static review by human factor engineering professionals and a dynamic review which emphasized operator integration under dynamic conditions. This dynamic review consisted of a human factor engineering check using a checklist approach, the administration of 12 unique simulated transients, operator/system performance evaluations during the transients using the Perry Nuclear Power Plant EOPs, and data collection for the measurement of the usefulness of the Emergency Response Information System SPDS-related displays.

In general, the Emergency Response Information System was perceived by the operators as a significant aid in plant control during emergencies and was judged as presenting an exceptional source of synthesized/centralized information with regard to plant performance.

The SPDS will be operational during all modes of reactor operation defined in table 1.2 of the LGS Technical Specifications. However, operability of the SPDS does not constitute a Limiting

Condition for Operation because hardwired Class 1E instrumentation is available in the control room for the operator if the SPDS should become inoperable.

7.7.1.17.2.2 SPDS Parameter Validation

A means is incorporated in the design to assure that the data displayed are valid. The validation method used in the LGS SPDS is identical to the method common to all GE SPDSs. The following is a summary of the generic design.

All SPDS-related control parameters of the LGS ERFDS are validated parameters. The validation process generates a weighted average of control parameter signals consisting of either an average of all consistent signals or an average of all in-range signals if there are less than two consistent signals. The validation process generates a validation status that defines whether the average is validated (signals are consistent), nonvalidated (signals are in-range but not consistent), or bad data (signals cannot be measured). If the average cannot be determined, the validation process parameter is assigned "bad data" and the parameter value is replaced with asterisks. The signal average calculated is used to represent the instrument readings of the process variable unless additional compensation is performed on the signal average (e.g., reactor power), in which case the compensated value is used to represent the adjusted instrument reading. For those parameters that are not directly measured (e.g., RPV temperature and other bulk temperatures), calculations are performed to derive these variables from measured parameters.

7.7.1.17.2.3 SPDS Display Description

The LGS SPDS control room displays present the fundamental information needed by nuclear power plant personnel to respond to an emergency. Using standard computer keyboard and mouse at the graphic HMI display console, the user can manually select displays for viewing on the monitor.

The displays available at each graphic display console consist of:

		No. of Displays
a.	RPV Control display	1
b.	Containment Control display	1
c.	Critical plant variables	1
d.	Two-dimensional plots	11
e.	Trend plots	12
f.	Validation status displays	8
g.	H2 / O2 Control	1
h.	Containment Isolation Status	10
i.	Remote Manual Isolation Valve Menu	5

j.	System Status	16
k.	Plant Parameter Status	1

These displays provide real-time data with emphasis on showing the current plant status and recent trend history. RPV Control and Containment Control displays are keyed to the appropriate LGS EOPs. The critical plant variables display shows the LGS EOP entry conditions for Reactor Pressure Vessel (RPV) Control and Primary Containment Control. Trend plot displays contain real-time digital information, but their overall emphasis is to show the most recent trends. Two-dimensional plots present the limits defined in the LGS EOPs which are curves showing the relationship between two or more parameters. Validation status displays supply an evaluation of plant control parameter signals.

7.7.1.17.2.3.1 RPV Control Display

This display provides control room operators with the primary plant information required to execute the LGS EOPs developed from the RPV Control Guideline. This display is not intended to provide information to unlicensed personnel or personnel whose emergency response functions are not defined by the EOPs (e.g., engineers, supervisor, or management), although these personnel may use this display for detailed plant status information.

7.7.1.17.2.3.1.1 Event Targets

There are four event targets on the RPV Control Display. They give the status of the following events.

a. Group Isolation - Has a demand for isolation occurred and has the required isolation been successfully completed?

b. Safety/Relief Valve - Is any SRV open?

c. Main Steam Isolation Valve - Is an MSIV closure signal present and are the MSIVs open or shut?

d. Scram - Has a scram been initiated and have all control rods been fully inserted?

The event labels and color coding for border and text indicate event status of INACTIVE, SAFE, CAUTION, and ALARM.

7.7.1.17.2.3.1.2 Control Parameter Trend Plots

Each control parameter, as defined by the EPG, is presented in a trend plot minidisplay consisting of a time history data plot, bar graph, and digital readout. Control parameters for the RPV Control display are RPV water level, pressure, reactor power, and RPV temperature.

The horizontal scale of the time history data plot for all control parameters is the most recent ten minutes.

The bar graph and digital readout are used to highlight and pinpoint the current value of the control parameter. The color of the bar graph and border around the digital readout reflects the control parameter validation status.

A trend line tracks the value of each control parameter, and its color coding is the same as that for the bar graph. Whenever the trend line goes off the vertical scale, it appears either at the top of the plot if above scale or at the bottom of the plot if below scale. The user can manually enter upper and lower values of the desired scale range to establish the vertical plot scales.

7.7.1.17.2.3.1.3 Limit Tags

A control parameter may have up to five limit tags associated with it, each corresponding to a process limit identified by the LGS EOPs. Table 7.7-8 lists the limit tags that are associated with each of the trend plots on the RPV control display. The process limits are of two types: dynamic limits and control parameters and, therefore, may change with time. Static limits are limits that remain constant with time. In addition, each of the two types of process limits fall into two categories: upper limits and lower limits. Upper limits are limits that alert the system user when the limit is approached or exceeded from below. Lower limits are limits that alert the system users when the limit is approached or exceeded from above. The process limits further belong to two classes: alarm limits and permissive limits. An alarm limit informs the operator that an operating limit has been exceeded, whereas a permissive limit lets the operator know when an action is capable of being performed (e.g., 100% bypass value).

The process limit status is indicated by the color of the limit tag border. For permissive limit tags, the border colors indicate INACTIVE, ACTIVE, or BAD DATA/DATA NOT MEASURED. Permissive limit tags are ACTIVE, when the control parameter equals or exceeds the process limit and INACTIVE otherwise. For alarm limit tags, the border colors reflect SAFE, CAUTION, ALARM, or BAD DATA/DATA NOT MEASURED. Alarm limit tags are in the "alarm" state when the control parameter equals or exceeds the process limit, the "caution" state when the control parameter approaches the process limit, and the "safe" state if not in the "alarm" or "caution" state.

Limit lines are presented with trend lines to track the value of dynamic limits associated with the control parameters. Whenever data for a limit line is bad or not measured, the limit line is not plotted.

7.7.1.17.2.3.2 Containment Control Display

This top level display provides control room operators with the primary plant information required to execute the LGS EOP developed from the Containment Control Guideline.

7.7.1.17.2.3.2.1 Event Targets

There are four event targets on the Containment Control display. They give the status of the following events:

a. Group isolation (Section 7.7.1.17.2.3.1.1)

b. Safety/Relief Valve (Section 7.7.1.17.2.3.1.1)

c. Scram (Section 7.7.1.17.2.3.1.1)

d. HPCI - Should HPCI flow be reduced or should HPCI be secured?

The event labels border and text are color coded to indicate event status of INACTIVE, SAFE, CAUTION, and ALARM.

7.7.1.17.2.3.2.2 Control Parameter Trend Plots

Control parameters plotted for the Containment Control display are containment level, drywell pressure, drywell temperatures, wetwell pressure, suppression pool temperature, and suppression pool water level. Except for the drywell temperatures, all containment control parameters are validated parameters. The trend plot description is the same as given in Section 7.7.1.17.2.3.1.2.

7.7.1.17.2.3.2.3 Limit Tags

As on the RPV Control display, limit tags are associated with each of the trend plots on the Containment Control display. In addition, limit tags for primary containment hydrogen and oxygen concentrations are provided. The limit tag description is the same as given in Section 7.7.1.17.2.3.1.3. Table 7.7-9 lists the limit tags that are associated with each of the trend plots on the Containment Control display.

7.7.1.17.2.3.3 Critical Plant Variables Display

This top level display provides the control room operators, shift supervisor, TSC supervisor, and emergency director with the status of the critical plant variables, which are the variables controlled by the LGS EOPs.

The Critical Plant Variables display is an image of the plant and presents two types of EOP information: control parameters and their limits, and event indications. For each control parameter, the current digital readout is shown with the upper limit above and/or lower limit below. The label and color coding for each digital readout, limit tag, and event indication are identical to the corresponding digital readout, limit tag, or event indication in the RPV or Containment Control displays.

7.7.1.17.2.3.4 Trend Plot Displays

Trend plot displays are available for all control parameters. Each trend plot consists of a time history data plot, a bar graph giving the current reading, and a digital readout. Limit tags and limit lines are also supplied. The bar graph, digital readout, limit tags, trend lines, and limit lines are as specified for the control parameter trend plots and limit tags in the RPV or Containment Control displays.

The horizontal plot scale for all inputs is the most recent 30 minutes, except for Drywell/Suppression Pool Hydrogen Concentration and Drywell/Suppression Pool Oxygen Concentration which are the most recent 60 minutes. The plot displays include:

a. RPV Water Level

b. Suppression Pool Level

c. RPV Pressure

d. Reactor Power

e. RPV Temperature

f. Containment Water Level

g. Drywell Pressure

h. Wetwell Pressure

i. Suppression Pool Temperature

j. Drywell Temperature

k. Drywell/Suppression Pool Hydrogen Concentration

l. Drywell/Suppression Pool Oxygen Concentration

7.7.1.17.2.3.5 Two-Dimensional Plot Displays

These lower level displays provide operators in the control room and plant engineers in the control room and TSC with plots of the two-dimensional limits defined in the EOPs. These limits are also presented as limit tags on the RPV and Containment Control displays.

There are dynamic and static two-dimensional plot displays. Each two-dimensional display consists of an x-y plot with a forbidden region and a historical track, and digital readings of the current values of the dependent and independent parameters. Color coding for digital readings of control parameters is as specified for the RPV and Containment Control displays. Each two-dimensional display will show the forbidden regions with cross hatch line or SAFE/UNSAFE designated areas, the forbidden region appears on each plot as cross hatch, and the historical track is the curve that continuously tracks the values of the two parameters. The cursor at one end of the historical track represents the current plant status and is color coded the same as the limit status. The two-dimensional displays include:

a. Safety Relief Valve Tail Pipe Level Limit (dynamic)

b. Heat Capacity Temperature Limit (dynamic)

c. Primary Containment Pressure Limit A (dynamic)

d. Primary Containment Pressure Limit B (dynamic)

e. Pressure-Suppression Pressure (dynamic)

f. Minimum Pre-Depressurization Reactor Water Level A (static)

g. Minimum Pre-Depressurization Reactor Water Level A (static)

h. Reference Leg Saturation Limit (dynamic)

i. Drywell Spray Initiation Pressure Limit (dynamic)

j. Reactor Pressure Vessel Pressurization Limit (dynamic)

k. Decay Heat Removal Injection Rate (static)

7.7.1.17.2.3.6 Validation Status Displays

These lower level displays provide operators in the control room and plant engineers in the control room and TSC with an evaluation of the signals for all the control parameters plus core flow. The displays list each instrument that supplies a control parameter signal; indicate if the instrument raw data value is within its calibrated range; compensate individual signals if appropriate; present the compensated value; indicate if these values are consistent with each other; and average these values for a final value, with weighting factors if appropriate.

The upper right field of the display presents the final averaged value, plus indication if that value is compensated and/or validated. The color coding of the readouts are consistent with the control parameter trend plots in Section 7.7.1.17.2.3.1.2. The validation displays include:

a. RPV Level

b. RPV Pressure

c. Reactor Power

d. RPV Temperature

e. Drywell Pressure

f. Drywell Temperature

g. Pool Level

h. Pool Temperature

i. Reactor Core Flow

j. Containment Level

k. Wetwell Pressure

7.7.1.17.2.4 SPDS Isolation Devices

Except for the inputs from PRNM, isolation for Class 1 E SPDS signals connected to the LGS ERFDS is provided by analog and digital isolation amplifiers, provided by Scientech I&C. The isolators have been tested generically for electrical isolation, environmental qualification, and seismic qualification.

The analog isolation amplifier isolates the input, safety related, circuitry from the output, non-safety related, circuitry with three components. An isolation amplifier chip transmits each analog signal across a capacitive barrier in a pulse width modulated format. The power and

common for the circuitry on the input side of the isolator is separated from the output by isolated DC-DC converters. The circuit board of the isolator module has an isolation gap between input and output circuits. The adequacy of these insulation barriers has been tested by the application of credible live fault voltages to the output circuitry in a fault isolation test.

The digital isolation amplifier isolates the input, safety related, circuitry from the output, non-safety related, circuitry with three components. Each digital signal is optically coupled across the isolation barrier by an IC chip. The power and common for the circuitry on the input side of the isolator is separated from the output by isolated DC-DC converters. The circuit board of the isolator module has an isolation gap between input and output circuits. The adequacy of these insulation barriers has been tested by the application of credible live fault voltages to the output circuitry in a fault isolation test.

7.7.1.17.2.5 Verification and Validation Program

Historical Information: GE V&V information is historical information pertaining to the original SPDS creation for Limerick.

The Verification and Validation Program used in the development of the original GE LGS SPDS was identical to the program generically used for all GE-supplied SPDSs.

The methods employed in the Verification and Validation procedures ensure that the LGS SPDS will have the functions and characteristics required and that the functions perform correctly. The review and testing processes are designed to identify problems or weaknesses in the design requirements, the design, and the implementation of the design, and to correct those problems and weaknesses.

The specific V&V plan identifies quality audit points along the LGS SPDS development path. These quality audit points range from performing specification reviews to code walk-throughs to several levels of software and system testing. Heavy emphasis is placed on achieving independent V&V; that is, employing reviewers and testers who have not been directly involved in the design.

Major V&V milestones consist basically of preparation and review of design specifications, coding and review of coding, development of test plans and procedures, conductance of tests and review of test results. The V&V procedure is not only sequential but also iterative. Results that identify areas requiring correction are used to modify the design or further define requirements in order to resolve concerns.

The review of specifications is accomplished by the reviewers documenting comments on a controlled issued document during the development of these specifications. Each comment must be resolved by the responsible engineer to the satisfaction of the reviewers prior to the issue of any document. The testing phases produce test reports which show any discrepancies between expected and actual test results, these discrepancies must be resolved by the responsible engineer of the design group and the test repeated.

By performing the V&V procedures, a systematic and structured method is implemented to ensure that the correct functions are provided and that the functions provided are correct.

The RTime SPDS mirrors the original SPDS. RTime SPDS was verified using the SPDS Software Requirements Specifications and Software Design Documentation. RTime SPDS was validated during Factory Acceptance Testing, Site Acceptance Testing, and Modification Acceptance Testing.

7.7.1.17.3 Transient Recording and Analysis

The TRA function is used to record, monitor and display plant parameters during the startup testing and at rated power but does not provide control interaction. The system provides transient recordings of the parameters during startup and monitors them at full power.

7.7.1.18 Containment Instrument Gas System - Instrumentation and Controls

7.7.1.18.1 CIGS Identification

This system is designed to provide instrument gas to the pneumatic devices located inside the drywell and suppression chamber. The CIGS has no safety-related function and is not required to be operable following a LOCA. Two parts of this system are safety-related. One is the isolation valves provided on all instrument gas lines that penetrate the containment. These valves are part of the primary containment and reactor vessel isolation control system that is described in Section 7.3.1.1.2. The other part provides nitrogen gas to the ADS valves. This portion is described in Section 7.6.

7.7.1.18.2 CIGS Power Sources

The instrument panel power supply is provided by a 120 V ac Class 1E source to 120 V ac / 24 V dc power supply. The power to the instrument panel is shed after receiving a LOCA signal. The power may be manually reapplied as loading on the Class 1E buses permits.

7.7.1.18.3 CIGS Equipment Design

Equipment design is described in Section 9.3.1.

7.7.1.18.3.1 CIGS Initiating Circuits

A signal from a pressure switch located on the instrument gas receiver automatically starts and stops the instrument gas compressor.

7.7.1.18.3.1.1 CIGS Logic and Sequencing

Sequencing is not applicable for this system.

During normal unit operation, one of the two instrument gas compressors is selected as the lead compressor and is automatically started or stopped in response to the instrument gas system demand. The other instrument gas compressor serves as a standby. The standby compressor starts automatically if the lead compressor fails or if the lead compressor's continuous operation cannot meet the instrument gas system demand. The two trains are cross-connected by a common header. A backup to the PCIG system is provided by an intertie to the instrument air system.

7.7.1.18.3.1.2 CIGS Bypasses and Interlocks

This switch must be in the closed position for the bypass permissive to be satisfied. A separate switch is provided for the valves in each division. Placing the bypass switch in the bypass position initiates an alarm in the control room.

7.7.1.18.3.1.3 CIGS Redundancy and Diversity

Instrumentation and controls are provided on a one-to-one basis with the mechanical equipment.

7.7.1.18.3.2 CIGS Actuated Devices

The instrument gas compressors are actuated by hand switches in the instrument gas compressor control panel and by pressure switches located in the instrument gas receiver.

7.7.1.18.3.3 CIGS Separation

The outboard isolation valves, except for the valve in the A line header, are treated as Division II isolation valves. The inboard isolation valve and A line header outboard isolation valve 1 are treated as Division I isolation valves. This arrangement ensures that both instrument gas supply lines are not isolated on the trip of only one isolation logic. The power to the instrument panels is separated in accordance with their respective header isolation valves.

7.7.1.18.3.4 CIGS Testability

The isolation valves can be tested as described in Section 7.3.1. However, operation of the instrument gas system is disrupted during the test.

7.7.1.18.4 CIGS Environmental Considerations

The controls for this system are located in the reactor enclosure and the control room. For environmental considerations, see Section 3.11.

7.7.1.18.5 CIGS Operational Considerations

See Section 9.3.1.

7.7.1.19 Fire Protection and Suppression System - Instrumentation and Controls

7.7.1.19.1 FPSS Identification

7.7.1.19.1.1 FPSS General

The FPSS as related to the PGCC is described below. A detailed description and analysis of the PGCC can be found in GE topical report NEDO-10466-A, "Power Generation Control Complex."

The defense in depth concept of fire protection and suppression is implemented in the PGCC by operator use of hand-held fire extinguishers as a backup during fires involving the PGCC.

The total plant FPSS description is found in Section 9.5.1.

7.7.1.19.1.2 FPSS Classification

The PGCC fire protection and suppression system is classified as not related to safety.

7.7.1.19.1.3 FPSS Reference Design

The total plant fire protection design is discussed in Section 9.5.1.

7.7.1.19.2 FPSS Power Sources

The fire detection and alarm systems are provided with a 120 VAC emergency diesel/generator backed power supply, a 125 VDC BOP battery supply, and a 24 VDC battery backed power supply. Some heat detectors are powered by the 125 VDC BOP batteries. The other heat detectors are powered by 24 VDC from BOP converters, backed by 24 VDC batteries. The smoke detectors are powered by the 120 VAC emergency diesel/generator backed supply. The power source used for the automatic heat detection also provides power to the electrically operated valves of the automatic suppression system.

7.7.1.19.3 FPSS Equipment Design

7.7.1.19.3.1 FPSS General

The PGCC FPSS consists of products of combustion and rate-compensated/temperature detectors with a Halon 1301 fire suppressant system. In-plant fire water service and distribution systems are described in Section 9.5.1.

7.7.1.19.3.2 FPSS Equipment Arrangement

PGCC design provides a defense-in-depth approach to fire protection. Each floor section contains four smoke detectors and eight thermal detectors. Fire-stops of refractory material covered by silicone rubber are installed in the cable ducts. A Halon 1301 extinguishing agent is introduced into the floor section cable ducts via a header manifold and nozzle distribution system. This provides at least a 6% concentration of Halon within 10 seconds of activation, and with additional discharge to reach a 20% concentration within 45-55 seconds, there is sufficient Halon to maintain a 20% concentration for at least 20 minutes. In addition, the floor plate design allows for quick removal so that the control room operators may use hand-held fire extinguishers when required.

There are four smoke detectors in each termination cabinet. The various detectors are wired to contact points in the termination cabinets.

The gas bottles, gas control, suppression initiation and alarm annunciation equipment as well as the total plant alarm system are covered in Section 9.5.1.

7.7.1.19.3.3 FPSS Testability

Each hazard area was tested with Halon 1211 or carbon dioxide to check the pneumatic remote control, the tightness of the system and also verified that all pressure-operated controls functioned as specified and that all discharge nozzles were not obstructed.

A discharge concentration test of the Halon suppression system was performed and determined that the design concentration of Halon was obtained within the design discharge time in accordance with previously approved calculations. Each system is provided with a thermal detector for test purposes.

7.7.1.19.4 FPSS Environmental Considerations

The PGCC fire protection system will operate satisfactorily through a temperature range from -65°F to 104°F and through a humidity range from 50% to 100% relative humidity.

7.7.1.19.5 FPSS Operational Considerations

7.7.1.19.5.1 FPSS General

The PGCC detectors provide annunciation at the trouble panel located near the control room entrance. The trouble panel provides an alarm in the control room, and indicates a trouble condition in the PGCC area.

Activation of the Halon suppression system is automatic or manual by the panel operator. Shift supervision has key-lock access to the Halon Release Control Panel to deactivate the Halon suppression system during repair work. Safe operation procedures for use and testing of the total plant fire protection system are covered in Section 9.5.1.

7.7.1.19.5.2 FPSS Reactor Operator Information

Operator indications and alarms are shown in drawings M-22.

7.7.1.20 Nonsafety-Related Equipment Area Cooling Ventilation Systems - Instrumentation and Controls

7.7.1.20.1 Reactor Enclosure Ventilation System

See Section 9.4.2 for a description of this system.

7.7.1.20.2 Turbine Enclosure Ventilation System

See Section 9.4.4 for a description of this system.

7.7.1.20.3 Radwaste Enclosure and Chem. Lab. Expansion Ventilation System

See Section 9.4.3 for a description of this system.

7.7.1.20.4 Hot Maintenance Shop Ventilation System

See Section 9.4.8 for a description of this system.

7.7.1.20.5 Miscellaneous Enclosures Ventilation Systems

See Section 9.4.9 for descriptions of these systems.

7.7.1.21 Rod Worth Minimizer - Instrumentation and Controls

7.7.1.21.1 RWM Identification

7.7.1.21.1.1 RWM General

The NUMAC RWM is a dedicated microprocessor-based system with an RWM operator display, and a continuous operating self-test feature. It monitors and enforces adherence to established low power level rod insert and withdraw sequences. This function prevents the operator from establishing control rod patterns that are not consistent with the prescribed sequence by initiating appropriate rod insert block, rod withdraw block, and RWM inoperable. The RWM enforces control rod sequences designed to limit (and thereby minimize) individual control rod worths to acceptable levels as determined by the rod-drop accident design basis. The RWM function does not interfere with normal reactor operation and, in the event of failure, does not itself cause rod patterns to be established which would violate the rod-drop accident design basis. The RWM can operate independently of the PMS computer.

The RSCS has been deleted from the LGS plant. It's function is performed by the RWM system. The RWM acts to prevent withdrawal of an out-of-sequence control rod, to prevent continuous control rod withdrawal errors during reactor startup, and to minimize the core reactivity transient during a rod-drop accident. The consequences of a rod withdrawal error in the startup range are analyzed in Appendix 15B, demonstrating that the licensing basis criterion for fuel failure is still satisfied even when the RWM fails to block rod withdrawal. Thus, the RWM is not safety-related. The safety action required for the continuous control rod-drop incident (a reactor scram) is provided by the safety-related IRM system of the NMS. If the core flux scram trip setpoint is reached during a flux transient, the IRM will both block further rod withdrawal and initiate a scram. Furthermore, a second safety-related NMS scram trip, supplied the APRM, can terminate the core power transient. The RWM does not interface with safety-related systems. Refueling interlocks are not considered safety-related.

7.7.1.21.1.2 RWM Classification

The RWM is a power generation system and is classified as a system not related to safety.

7.7.1.21.1.3 RWM Reference Design

This system is an operational system and has no safety function. Table 7.1-2 lists the reference design information. There are no safety design differences between this system and the reference design since neither system performs a safety function. This system is functionally identical to the referenced system.

7.7.1.21.2 RWM Power Sources

The power for the RWM is supplied by a reliable source.

7.7.1.21.3 RWM Equipment Design

7.7.1.21.3.1 RWM Circuit Description

The RWM has the following system characteristics:

a. Capacity for four selectable operating sequences

b. Selection of operate/bypass/test inop modes

c. Substitute rod position entry capability from the RWM operator's display under key-lock (procedural) control

d. Capability to remove/restore rod from/to group, under key-lock (procedural) control

e. Rod coordinate indication of insert and withdraw error

f. Status indication of insert and withdraw blocks

g. Annunciation of RWM failure to RPIS

h. Identity and position of rods with an insert or withdraw error

i. Single group identification with subgroup capability

j. Text error messages at the RWM operator's display and RWM chassis

k. Rod by rod and group by group sequence control

l. Rapid power reduction

7.7.1.21.3.2 RWM Testability

The RWM processor design includes a self-test capability that identifies a failure to a functional module, annunciates the failure, and provides testing capability for verification of repair. The primary function of the self-test feature is to maximize instrument channel availability.

7.7.1.21.4 RWM Environmental Considerations

The instrument is designed for normal operation in the range of 5°C to 50°C and 10% to 90% relative humidity (noncondensing). It meets EMI requirements for the control room environment.

7.7.1.21.5 RWM Operational Considerations

7.7.1.21.5.1 RWM Operator Information

Display information includes multiple displays for different modes of operation and level of detail. Alternate displays are selected from the display panel through the use of SOFT SWITCHES whose functions are clearly marked on the panel. The use of alternate displays provides additional detail or an alternate set of displays for different modes of operation.

7.7.1.21.5.2 RWM System Interface

The RWM is designed to interface with other plant systems as follows:

a. RWM interfaces RPIS and RMCS data to the PMS via a fiber-optic multiplexed data link.

b. Rod identity and position data, and the identification of the selected rod, are obtained from the RPIS.

c. Interface to the RWM, for downloading, uploading, and printing sequences and for obtaining certain RWM status messages is accomplished via PMS terminal and printer.

d. Connections for ROD SELECTED AND DRIVING, RPIS INOP, LOW POWER SETPOINT, and LOW POWER ALARM POINT are input to the RWM. The RWM transmits these points to the PMS computer.

e. Required output from the RWM include INSERT PERMISSIVE, WITHDRAW PERMISSIVE, RWM OPERABLE, and RWM INOPERABLE signals. These signals interface to Channel 2 of the rod drive control system. The RWM is a dedicated processor with a continuously operating self-test feature. In the event of failure of the RWM, rod blocks and RWM INOP are applied. When the reactor power level is above the LOW POWER SETPOINT, the RWM rod blocks are automatically inhibited by the RWM.

f. Required inputs from the feedwater system are LOW POWER SETPOINT and LOW POWER ALARM POINT.

7.7.1.21.5.3 RWM Function

The RWM acts to prevent withdrawal of an out-of-sequence control rod, to prevent continuous control rod withdrawal errors during reactor startup, and to minimize the core reactivity transient during a rod-drop accident. The consequences of a rod withdrawal error in the startup range are analyzed in Appendix 15B, demonstrating that the licensing basis criterion for fuel failure is still satisfied even when the RWM fails to block rod withdrawal. Thus, the RWM is not safety-related. The safety action required for the continuous control rod-drop incident (a reactor scram) is provided by the safety-related IRM system of the NMS. If the core flux scram trip setpoint is reached during a flux transient, the IRM will both block further rod withdrawal and initiate a scram. Furthermore, a second safety-related NMS scram trip, supplied by the APRM, can terminate the core power transient. The RWM does not interface with safety-related systems. Refueling interlocks are not considered safety-related.

7.7.1.22 Plant Monitoring System - Instrumentation and Controls

7.7.1.22.1 PMS Identification

7.7.1.22.1.1 PMS General

The PMS performs six major functions. First, it performs the ERFDS functions as described in section 7.7.1.17. The ERFDS is the system that conforms with regulatory requirements for a SPDS. The PMS can generate real-time and historical visual displays, print records and plots which can be used to provide plant information that aid plant personnel during abnormal and emergency conditions in determining and controlling the value and trend of the key reactor and primary containment control parameters. The second function that the PMS performs is the necessary evaluation of the NSSS portion of nuclear power plant operation. The PMS gathers data, processes data, and provides current outputs for analysis and evaluation purposes. The NSSS programs perform the calculations and data logging required to provide current reactor core

performance information. Evaluations can be performed, including thermal power distribution, power ratios, energy summaries, enthalpies, data summaries, and calibration and diagnostics for the analysis of the nuclear steam supply. The third function performs BOP performance calculations such as turbine cycle, condenser, electrical, and heat exchanger performance. The fourth function is point log and alarm, which provides alarm display and logging, group point display, log generation and reporting, log and display editor, point data display/change, summary processing and reporting, trend pen recorder, and alarm sequence of events functions. The fifth function is transient recording and analysis, which provides a real-time and historical perspective for the operation of the power plant. The TRA functions provide high resolution recording capabilities for various plant parameters and the means for event monitoring, data archival, plotting, trending, analyzing, and automatic and on-demand logging in order to support the determination and analysis of plant transients. The sixth function is to collect and display meteorological data from the meteorological instrumentation described in Section 2.3 and transmit this meteorological data to the EPDS computer.

7.7.1.22.1.2 PMS Classification

The PMS is classified as a power generation system and is not required to perform any safety-related functions.

7.7.1.22.1.3 PMS Reference Design

The PMS is an operational system and has no safety function. Table 7.1-2 lists the reference design information. There are no safety design differences between this system and the reference design since neither system performs a safety function. This system is functionally identical to the referenced system.

7.7.1.22.2 PMS Power Sources

The power for the computer system is supplied by a reliable source. The DAS is supplied with divisional power as required.

7.7.1.22.3 PMS Equipment Design

7.7.1.22.3.1 PMS Circuit Description

The PMS hardware consists of three major elements:

a. The DAS, which consists of Chassis, I/O cards, node processor, and the chassis processor

b. Central processor units and their peripherals

c. Human Machine Interface (HMI) and peripheral devices

7.7.1.22.3.1.1 Data Acquisition System

The DAS used for PMS samples signals at high rates to allow high resolution of sequence of events or to perform transient analysis. The deletion of a point from processing shall not remove it from its normal scheduled scan by the I/O equipment and the scanned value shall be available for system maintenance and troubleshooting functions. This value shall be available as adjusted counts, raw signal and EU value when displayed.

Features of the DAS include the following:

a. RTP 3000 Series Chassis and I/O cards.

b. Processor cards send plant signals to the PMS (non-Class 1 E) through copper and fiber optic cables. For Class 1 E Panels, an isolation device has been installed between the field signals and the RTP chassis so as to meet the divisional separation and isolation.

7.7.1.22.3.1.2 Central Processing Unit

The CPU 64 bit, high speed and high throughput virtual memory computer. The processor's instruction set includes integral floating point, packed decimal arithmetic, and character string instructions. The virtual memory operating system provides for a multiuser, multi-language programming environment. There are two CPUs which are configured in a primary/backup arrangement. This allows CPU failover to be executed in the event of a CPU failure.

7.7.1.22.3.1.3 Human Machine Interface (HMI) and Peripheral Devices

In the man/machine interface, a color graphic display system is used. Internal memory capacity of this display system is capable of storing over 200 displays. The color graphics display terminals, along with smaller display terminals, allow access to the PMS functions. The system also includes other peripheral devices such as printer, display, hard copy devices, and high speed line printers.

7.7.1.22.3.2 PMS Testability

The PMS has certain self-checking provisions. It performs diagnostic checks to determine the operability of certain portions of the system hardware and performs internal programming checks to verify that input signals and selected program computations are either within specific limits or within reasonable bounds.

7.7.1.22.4 PMS Environmental Considerations

All the computer equipment, except for peripherals, is designed for continuous-duty up to 24°C and 60.0% relative humidity. The peripherals are designed to operate at up to 30°C and 90% (noncondensing) relative humidity.

7.7.1.22.5 PMS Operational Considerations

7.7.1.22.5.1 PMS NSSS Performance Calculation Programs

The NSSS subsystem is designed to enable plant operating personnel to calculate core performance data rapidly to allow the nuclear steam supply to be operated as close to its limits as

possible, to aid in safe operation of the plant, and to monitor fuel for uniform exposure and reloading purposes.

The functions of the nuclear steam supply performance evaluation subsystem include:

a. Periodic programs for logging a range of reactor performance data.

b. On-demand programs for reactor performance analysis.

c. Programs for a variety of other functions.

7.7.1.22.5.2 PMS Reactor Operators Information (Monitor, Alarm, and Logging Program)

a. Alarms

The PMS includes the capability to provide alarm notification and handle their acknowledgement by the user. Alarms are initiated automatically in response to a variable that has reached a specified condition. These alarms are provided for information, user acknowledgment, and historical perspective. The following features are included:

1. Choice of views; i.e., total plant or selected category

2. Use of color for conveying status

3. Alarm prioritization

4. Alarm chronology

5. Ability to segregate acknowledged and unacknowledged alarms

b. Logs

The logging function provides the capability to print out or display various logs on demand or control the automatic initiation of the logs which are either printed on a periodic basis or triggered by various plant conditions. The logging functions include special logs, periodic logs, post-trip/scram logs, turbine/generator logs, and SOE logs.

The system has been designed to avoid the loss of data if a log printer fails.

c. Sequence of Events

The SOE log is used as follows:

1. To aid in establishing the cause of a reactor scram and determine whether the reactor can be returned to normal operation

2. To provide records of RPS sensor trips

3. To verify proper operation of the ECCS

All SOE point changes will automatically be logged when a change of state occurs for any SOE input. The SOE function is capable of monitoring 500 digital points, and order of occurrences can be resolved to 100 ms.

7.7.1.22.5.3 PMS BOP Performance Calculation Programs

These programs perform calculations and log plant performance data not directly related to the nuclear system. The data stored by the BOP program can be printed out on logs. The BOP Periodic Log gives hourly and daily values for temperatures, power outputs, and flows associated with the main generator and turbines, and with the feedwater, recirculation, and RWCU systems. The BOP Monthly Log contains monthly averages and accumulations for plant gross and net power outputs, load distributions, turbine heat rates, and fuel burnup. Standard BOP performance calculations include the flow calculations, electrical calculations, turbine cycle performance calculations, condenser calculations, feedwater heater and moisture separator performance calculations, and unit performance calculations.

7.7.1.22.5.4 Collection and Display of Meteorological Data

The PMS automatically collects current meteorological data from the meteorological instrumentation described in Section 2.3 through a dedicated data link. Data collection and storage is per the requirements of Regulatory Guide 1.23, rev. 1. This data is available for display during normal operating conditions through PMS displays. These displays may also be available under post accident conditions.

The collected meteorological data is transmitted to the EPDS computer for display and use by the dose assessment model to calculate atmospheric dispersion values and dose from an accidental release of gaseous effluent.

The collected meteorological data is transmitted to the meteorological consultant for performance of activities described in Section 2.3.

7.7.2 ANALYSIS

The purpose of this subsection is to:

a. Demonstrate by direct or referenced analysis that the systems described are not required for any plant safety function

b. Demonstrate by direct or referenced analysis that the safety-related systems described elsewhere are capable of coping with all failure modes of the subject control systems

In response to Item (a), after considering and evaluating the design basis (Section 7.1.1), descriptions, and evaluations presented herein relative to the system, it can be concluded that these systems do not perform any safety function.

For consideration of Item (b), it is necessary to refer to the safety evaluations in Chapter 15. These sections demonstrate that the subject systems do not provide any design basis safety function and that any required safety functions are provided by other qualified systems.

7.7.2.1 Reactor Vessel Instrumentation

7.7.2.1.1 RVI General Functional Requirements Conformance

The RPV instrumentation is designed to provide redundant or augmented information from the safety-related systems. The operator uses this information to start up, operate at power, shut down, and service the reactor system in an efficient manner. None of this instrumentation is required to initiate or control any safety-related system.

7.7.2.1.2 RVI Specific Regulatory Requirements Conformance

Following are the specific regulatory requirements as well as those in 10CFR50, Appendix A, General Design Criteria requirements imposed on this sector vessel instrumentation.

7.7.2.1.2.1 RVI Conformance to Regulatory Guides

7.7.2.1.2.1.1 RVI - Regulatory Guide 1.11 (1971) - Instrument Lines Penetrating Primary Reactor Containment (Safety Guide 11)

Conformance to Regulatory Guide 1.11 is addressed in Section 6.2.4.

7.7.2.1.2.1.2 RVI - Regulatory Guide 1.75 (1978) - Physical Independence of Electric Systems

Conformance to Regulatory Guide 1.75 is discussed in Section 7.1.2.5.19.

7.7.2.1.2.2 Conformance to 10CFR50, Appendix A, General Design Criteria

7.7.2.1.2.2.1 RVI - GDC 13 - Instrumentation and Controls

The RPV information provides the operator with information on the reactor vessel operating variables during normal plant operation and anticipated operational occurrences so that the need to use the safety systems, although ready and able to respond, is minimized. Portions of this instrumentation are used in the feedwater system to maintain the reactor vessel operating variables within prescribed operating ranges.

7.7.2.1.2.2.2 RVI - GDC 24 - Separation of Protection and Control Systems

This instrumentation is not part of, or related to, any safety system. The circuitry of the safety systems is completely independent of this instrumentation so that failures of this instrumentation do not prevent the safety systems from initiating any action when required.

7.7.2.1.2.3 RVI Conformance to Industry Codes and Standards

7.7.2.1.2.3.1 RVI - IEEE 279 (1971), Paragraph 4.7 - Control and Protection System Interaction

This instrumentation is separate from and independent of the safety systems circuitry. There is no direct circuit-to-circuit or functional interactions between this instrumentation and the safety systems. No failures in this instrumentation can prevent the safety systems from meeting their minimum performance requirements.

7.7.2.2 Reactor Manual Control System - Instrumentation and Controls

7.7.2.2.1 RMCS General Functional Requirements Conformance

The circuitry described for the RMCS is completely independent of the circuitry controlling the scram valves. This separation of the scram and normal rod control functions prevents failures in the reactor manual control circuitry from affecting the scram circuitry. The scram circuitry is discussed in Section 7.2. Because each control rod is controlled as an individual unit, a failure that energizes any of the insert or withdraw solenoid valves affects only one control rod. The effectiveness of a reactor scram is not impaired if any one control rod malfunctions. It can be concluded that no single failure in the RMCS can prevent a reactor scram, and that repair, adjustment, or maintenance of RMCS components does not affect the scram circuitry.

Chapter 15 examines the various failure mode considerations for this system. The expected and abnormal transients and accident events analyzed envelop the NSOA associated with this system's components. These include the following:

a. Control rod withdrawal errors

b. Control rod-drop accident

The following are cited:

a. The RMCS is not required for plant safety functions. This system has no function associated with any DBA.

b. This system is not used for plant shutdown resulting from an accident or nonstandard operational conditions.

c. The function of the RMCS is to control core reactivity and thus power level. Interlocks from many different sources are incorporated to prevent the spurious operation of control rod drives or undesirable rod patterns throughout all ranges of operation.

d. This system contains no components, circuits, or instruments required for reactor trip. There are no operator manual controls that can prevent scram.

e. The requirements for the portions of the RMCS that interface with any safety system function include tolerance to single failures and component quality.

f. The rod withdrawal block trip function prevents an operator from carrying out actions that, if unchecked, could result in a RPS action (scram). A fixed margin separates the rod withdrawal block setpoints and the scram setpoints in IRM and APRM. There are no safety considerations.

g. No specific regulatory requirements apply to the rod block trip function. The circuits are designed to be normally energized (trip on loss of power) and are single active component failure tolerant. The equipment is designed to prevent the rod block trip circuitry from affecting the RPS trips in the IRM and APRM channels through the use of separate trip circuits and relays. IEEE standards do not apply because rod block trips are not required for any postulated design basis accident or for safe shutdown.

7.7.2.2.2 RMCS Specific Regulatory Requirements Conformance

The following statements represent the RMCS level of compliance with these applicable requirements.

7.7.2.2.2.1 RMCS Conformance to 10CFR50, Appendix A, General Design Criteria

7.7.2.2.2.1.1 RMCS - GDC 24 - Separation of Protection and Control Systems

No part of the RMCS is required for scram. The rod block functions provided by the NMS are the only instances where the RMCS uses any instruments or devices related to RPS functions. The rod block signals received from the NMS prevent improper rod motion before limits causing reactor scram are reached. Common APRM and IRM, detectors are used, but the signal is electrically isolated before its use in the RMCS (See Sections 7.6.1.4 and 7.6.2.4 for a description of this interface). This isolation is achieved through two separate relay trip units that prevent any feedback from the RMCS to the RPS. Single failure of a control component therefore does not degrade the RPS.

7.7.2.2.2.1.2 RMCS - GDC 26 - Reactivity Control System Redundancy and Capability

The RMCS is one of the two independent reactivity control systems as required by this GDC.

7.7.2.2.3 RMCS Power Generation Design Basis

The RMCS conforms to the provisions of the power generation design basis as discussed in the following.

a. The RMCS design limits the potential for inadvertent rod withdrawal, which could lead to RPS protective action by requiring deliberate operator action to effect rod withdrawal. The control buttons for rod withdrawal are spring-returned to the off position; two buttons must be held depressed for continuous rod withdrawal. Rod selection circuitry design prevents the withdrawal of more than one rod at a time.

b. Rod block interlocks in the RMCS design inhibit erroneous control rod motion to prevent circumstances that require an RPS protective action. Pertinent interlocks include the SDV high water level trip, APRM Simulated Thermal Power upscale trip, and IRM upscale trip (Section 7.7.1.2.3.2.3).

c. Rod block interlocks in the RMCS design inhibit erroneous control rod motion that could result in local fuel damage or undesirable core reactivity conditions. Pertinent interlocks include mode switch in SHUTDOWN, the RWM function, RBM (NMS) upscale and APRM recirculation flow upscale (Section 7.7.1.2.3.2.3).

d. Rod block interlocks inhibit rod movement whenever instrumentation is incapable of monitoring the core response or when protective system operating bypasses are in effect. Pertinent interlocks include APRM and RBM downscale or inoperative; APRM less than minimum number of LPRMs; IRM and SRM not fully inserted, downscale, or inoperative; rod position indicator malfunction; and SDV high level scram bypassed.

e. The RMCS design provides the operator with the information necessary to achieve prescribed control rod patterns and to provide information pertinent to the position and motion of the control rods. Each rod is instrumented to show its position if fully inserted or if fully withdrawn. The rod pattern controller provides information to the operator concerning rod inhibits, modes, and position.

7.7.2.3 Recirculation Flow Control System - Instrumentation and Controls

7.7.2.3.1 RFCS General Functional Requirements Conformance

The ASD has no mechanical inertia and will not supply any coast-down power to the pump motor after loss of ac power to the ASD or any other condition which trips the ASD. However, upon loss of the speed demand signal, the ASD will enforce a speed hold and continue to supply power to the pump motor to maintain the speed prior to the loss of control signal.

The analyses in Chapter 15 examine various failure modes and show that no malfunction in the RFCS can cause enough of a transient to damage the fuel barrier or exceed the nuclear system pressure limits as required by the safety design basis. Therefore, the system is classified as not required for safety.

7.7.2.3.2 RFCS Specific Regulatory Requirements Conformance

The RFCS is designed in compliance with the following GDC of Appendix A to 10CFR50; IEEE 279, Paragraph 4.7; and regulatory guides.

7.7.2.3.2.1 RFCS Conformance to 10CFR50, Appendix A, General Design Criteria

7.7.2.3.2.1.1 RFCS - GDC 12 - Suppression of Reactor Power Oscillations

See Section 7.1.2.6.7 for compliance discussion.

7.7.2.3.2.1.2 RFCS - GDC 13 - Instrumentation and Control

The RFCS is capable of monitoring and controlling its variables over their anticipated range for normal operation and for anticipated operational occurrences.

7.7.2.3.3 RFCS Power Generation Design Basis

The reactor RFCS conforms to the power generation design basis as follows:

The RFCS is designed to control the reactor power level, over a limited range, by controlling the flow rate of the reactor recirculating water. The control involves varying the speed of the recirculation pumps by supplying a demand signal to the ASD controller..

7.7.2.4 Feedwater Control System - Instrumentation and Controls

7.7.2.4.1 FCS General Functional Requirements Conformance

The FCS is a power generation system designed to maintain proper vessel water level. Interlocks are provided to lock the flow changing capabilities in the as-is condition if there is a control signal failure. If the vessel level rises too high, the feedwater pumps and plant main turbine are tripped. This is an equipment protective action that results in reactor shutdown by the RPS system as outlined in Section 7.2. Lowering the vessel level also causes the RPS to shut down the reactor.

The analyses in Chapter 15 examine the various failure mode considerations for this system relative to plant safety and operational effects. The analyses show that malfunctions of the FCS cannot cause enough of a transient to damage the fuel barrier or exceed the nuclear system pressure limits as required by the safety design basis. Therefore, the system is classified as not required for safety.

7.7.2.4.2 FCS Specific Regulatory Requirements Conformance

The FCS is not a safety-related system and is not required for safe shutdown of the plant, nor is it required during or after accident conditions.

No specific regulatory requirements are imposed on the system; however, the following general considerations are offered.

See Section 7.7.1.4 for a discussion of compliance details to the General Design Criteria.

7.7.2.4.3 FCS Power Generation Design Basis

The FCS, along with portions of RVI, regulates the feedwater flow over the entire power range of the reactor to maintain adequate water level in the reactor vessel, such that unnecessary initiation of safety-related systems because of low water level are prevented. The FCS instrumentation therefore augments safety-related information so that the operator can startup, operate, and shut down the reactor in an efficient manner.

7.7.2.5 Pressure Regulator and Turbine-Generator System - Instrumentation and Controls

7.7.2.5.1 PRTGS General Functional Requirements Conformance

Turbine speed and acceleration are controlled by a pressure regulator that controls steam throttle valve position to maintain constant reactor pressure. The turbine speed governor overrides the pressure regulator during an increase of system frequency or loss of generator load. Excess steam is automatically bypassed directly to the main condenser by the pressure-controlled bypass valves.

The analyses described in Chapter 15 examine the various failure mode considerations for this system relative to plant safety and operational effects. The analysis shows that malfunctions of the

PRTGS cannot cause enough of a transient to damage the fuel barrier or exceed the nuclear system pressure limits as required by the safety design basis. Therefore the system is classified as not required for safety.

7.7.2.5.2 PRTGS Specific Regulatory Requirements Conformance

No specific regulatory requirements are imposed on the PRTGS. However, the following general considerations should be noted.

See Section 7.7.1.5 for a discussion of compliance details to the General Design Criteria.

7.7.2.5.3 PRTGS General

The turbine-generator control system is not a safety-related system. The equipment protection systems provided as an integral part of the turbine-generator equipment override the turbine-generator control system. If there is a turbine-generator trip due to an equipment protection action, the control valve fast closure and the stop valve closure inputs to the RPS initiate reactor scram (Sections 7.2.1.1.4.2.d and 7.2.1.1.4.2.e).

Pressure regulator malfunctions that lead to low turbine inlet pressure are detected by pressure sensors provided in the PCRVICS which in turn initiate closure of the main steam line isolation valves (Section 7.3.1.1.2.4.5). Similarly, high turbine inlet pressure causes the RPS to detect high reactor pressure, which initiates reactor scram (Section 7.2.1.1.4.2.b).

Control malfunction (e.g., pressure regulation malfunction - upscale) that results in high flow through the turbine control valves and the bypass valves is detected by main steam flow sensors provided in the PCRVICS, which then initiate closure of the main steam line isolation valves (Section 7.3.1.1.2.4.5) and a subsequent reactor scram (Section 7.2.1.1.4.f).

Interfaces between the subject nonsafety-related system and safety-related systems (RPS and PCRVICS) are designed so that failure of the nonsafety-related components does not negate the necessary safety system functions.

7.7.2.5.4 PRTGS Power Generation Design Basis

See Section 7.1.2.1.10.3.

7.7.2.6 Neutron Monitoring System - Instrumentation and Controls

7.7.2.6.1 Source Range Monitor System

7.7.2.6.1.1 SRM General Functional Requirements Conformance

The arrangement of the neutron sources and startup chambers in the reactor is shown in Figure 7.6-1. This arrangement produces at least 3 counts/second in the SRM using the sensitivity noted in Section 7.7.1.6.1 and the design source strength at initial reactor startup. With the discriminator setting adjusted to produce the specified sensitivity, the signal-to-noise count ratio is above the 2:1 design basis for cold startup.

If the multiplication of one section of the core increases to put that section of the reactor on a 20 second period, the nearest SRM chamber shows an increase in count rate. In general, at least one detector indicates the change in multiplication.

Normal startup procedures ensure that withdrawal of control rods is distributed about the core to prevent excessive multiplication in any one section of the core.

Hence, each SRM chamber can respond in some degree during the initial rod withdrawal. During startup withdrawal, one of the four control rods adjacent to each SRM chamber and one control rod adjacent to each neutron source is withdrawn before the reactor is critical. This procedure reduces source and detector shadowing by the control blade and ensures increases in the detector signals as the core average neutron multiplication increases. Detector shadowing caused by the control blade reduces the SRM's ability to detect neutrons.

Examination of the sensitivity of the SRM detectors and their operating ranges of 10^6 counts/second indicates that the IRM is on scale before the SRM reaches full-scale (Figure 7.6-8).

7.7.2.6.1.2 SRM Specific Regulatory Requirements Conformance

There are no specific regulatory or IEEE requirements for the SRM system.

7.7.2.6.1.3 SRM Power Generation Design Basis

The SRM design conforms to the provisions of the power generation design basis as follows:

a. The SRM is designed so that over the operating range the ratio of signal-to-noise does not fall below a factor of two. Before initial power operation and with the control rods fully inserted, a count rate of at least 3 counts/ second will be detected from the installed source.

b. Under the worst possible startup rod withdrawal conditions, the SRM is capable of indicating a measurable increase in output signal from at least one detecting channel before the reactor period is less than 20 seconds.

c. During normal reactor startup the SRM is capable of indicating a substantial increase in output signals with the maximum permissible number of SRM channels out-of-service.

d. The indication on the upper scale of the SRM overlaps the indication on the lower scale of the IRM during reactor startup. The upper limit of the SRM range is $1x10^9$ nv nominal, and the lower limit of the IRM range is $1x10^8$ nv.

e. The SRM signal conditioning equipment processes the input to provide an output corresponding to the reactor period. This output is displayed in the control room and is also provided to remote recorders.

f. The SRM system has trips for SRM upscale, downscale, and instrument inoperable. With the reactor mode switch in STARTUP or REFUEL, any of these trips will initiate a rod block.

g. The SRM is designed to function in the maximum environmental conditions specified in Section 3.11.

h. Loss of single power bus will de-energize only half of the SRM channels and will not disable the monitoring and alarm functions of the remaining channels.

7.7.2.6.2 Rod Block Monitor System

7.7.2.6.2.1 RBM General Functional Requirements Conformance

Motion of a control rod causes the LPRMs adjacent to the control rod to respond strongly to the change in power in the region of the rod in motion. Figures 7.7-15 and 7.7-16 illustrate the calculated response of the two RBMs to the full withdrawal of a selected control rod from a region in which the design limits on power and flow exist. Curves are shown for the response when all LPRMs are operable and for cases when certain LPRMs are inoperable.

Because MCPR cannot reach 1.0 until the control rod is withdrawn through greater than half its stroke, the highest rod block setpoint halts rod motion well before local fuel damage can occur. This is true even with the adjacent and nearest LPRM detector assemblies failed.

7.7.2.6.2.2 RBM Specific Regulatory Requirements Conformance

IEEE standards and regulatory guides do not apply to the RBM system because it is not a protection system.

7.7.2.6.2.2.1 RBM Conformance to 10CFR50, Appendix A, General Design Criteria

7.7.2.6.2.2.1.1 RBM - GDC 24 - Separation of Protection and Control Systems

The RBM provides an interlocking function in the control rod withdrawal portion of the CRD RMCS. This design is separated from the protective functions in the plant to ensure their independence.

The RBM is designed to prevent inadvertent control rod withdrawal given an imposed single failure within the RBM. One of the two RBM channels is sufficient to provide an appropriate control rod withdrawal block.

7.7.2.6.2.3 RBM Power Generation Design Basis

The RBM design conforms to the provisions of the power generation design basis as follows:

a. The RBM inhibits erroneous control rod motion that could result in local fuel damage. An RBM upscale trip initiates the rod block. A rod block is also initiated by an RBM inoperative trip for any position of the reactor mode switch or RBM downscale with the mode switch in RUN, unless the RBM is correctly bypassed. One of the two RBM channels can be bypassed without loss of subsystem function because a trip signal from either RBM channel initiates a rod block.

b. RBM signal level is displayed to the operator and indicates the change in relative local power level.

7.7.2.6.3 Traversing Incore Probe System

7.7.2.6.3.1 TIP General Functional Requirements Conformance

An adequate number of TIP machines is supplied to ensure that each LPRM assembly can be probed by a TIP and that one LPRM (the central one) can be probed by every TIP to allow intercalibration. Typical TIPs are tested to prove linearity. The system has been field tested in an operating reactor to ensure reproducibility for repetitive measurements. The mechanical equipment has undergone life testing under simulated operating conditions to ensure that all specifications can be met. The system design allows semiautomatic operation for LPRM calibration and Plant Monitoring System use. The TIP machines can be operated manually for pointwise flux mapping.

7.7.2.6.3.2 TIP Specific Regulatory Requirements Conformance

There are no specific regulatory requirements for the TIP system.

7.7.2.7 Deleted

7.7.2.8 Reactor Water Cleanup System - Instrumentation and Controls

7.7.2.8.1 RWCU General Functional Requirements Conformance

The RWCU system is designed and supplied for plant equipment protection and operator information only. None of this instrumentation and control is required to initiate or control any safety-related system.

A high differential pressure across the filter/demineralizer or its discharge strainer automatically closes the unit's outlet valve after sounding an alarm. The holding pump starts whenever there is low flow through a filter/demineralizer. The precoat pump will not start or stop when the level in the precoat tank is low.

7.7.2.8.2 RWCU Specific Regulatory Requirements Conformance

7.7.2.8.2.1 RWCU Conformance to Regulatory Guides

7.7.2.8.2.1.1 RWCU - Regulatory Guide 1.56 (1978) - Maintenance of Water Purity in Boiling Water Reactors

The RWCU system provides the recorded conductivity measurements and alarms of influents and effluents of the demineralizers and records of the flow rate through each demineralizer as recommended in Regulatory Guide 1.56.

7.7.2.8.2.2 RWCU Conformance to 10CFR50, Appendix A, General Design Criteria

7.7.2.8.2.2.1 RWCU - GDC 63 - Monitoring Fuel and Waste Storage

To meet the requirements of GDC 63, monitors are placed in fuel and waste storage areas to give a continuous display of gamma levels and to alarm if a level exceeds the preselected level.

7.7.2.8.3 RWCU Power Generation Design Basis

The RWCU system design conforms to the power generation design basis as discussed in the following:

a. The RWCU system continuously processes reactor water to maintain water purity within specified limits. The system can be operated during normal plant operation, or during startup, shutdown, and refueling. The installed filter/demineralizer removes fission products, corrosion products, and other soluble and insoluble impurities.

b. Excess water can be removed from the reactor via the RWCU system to the main condenser, to the condensate storage tank, or to the equipment drain collection tank.

7.7.2.9 Process Radiation Monitoring Systems – Instrumentation and Controls

7.7.2.9.1 South Stack Effluent Radiation Monitoring System

7.7.2.9.1.1 SSE-RMS General Functional Requirements Conformance

The SSE-RMS is designed to draw two representative, isokinetic samples from each of the two unitized ducts in the south stack and to monitor these samples for radioactive particulates, iodines, and noble gases. These ducts provide exhaust venting for the reactor enclosure ventilation system. The monitoring systems are completely redundant and independent to ensure that monitoring capability is continuous during periods of maintenance. However, the system is not qualified for seismic Category I or IEEE Class 1E. If there is an accident, the south stack is isolated, and the SSE-RMS is not functional.

7.7.2.9.1.2 SSE-RMS Specific Regulatory Requirements Conformance

7.7.2.9.1.2.1 SSE-RMS Conformance to Regulatory Guides

7.7.2.9.1.2.1.1 SSE-RMS - Regulatory Guide 1.21 (1974) - Measuring, Evaluating, and Reporting Radioactivity in Solid Wastes and Releases of Radioactive Materials in Liquid and Gaseous Effluents from Light-Water-Cooled Nuclear Power Plants

The SSE-RMS is designed to comply with Regulatory Guide 1.21. Data generated by this instrument is transmitted to the RMMS (Section 11.5.6) to be incorporated into periodic Regulatory Guide 1.21 reports. Alarms are annunciated in the control room if radioactive concentrations exceed preset limits, but no control action is provided.

7.7.2.9.1.2.2 SSE-RMS Conformance to 10CFR50, Appendix A, General Design Criteria

7.7.2.9.1.2.2.1 SSE-RMS - GDC 13 - Instrumentation and Control

Instrumentation is provided to monitor radioactive effluents over their anticipated ranges for normal operation as well as anticipated operational occurrences.

7.7.2.9.1.2.2.2 SSE-RMS - GDC 64 - Monitoring Radioactivity Releases

Means are provided for monitoring effluent discharge paths for radioactivity that may be released from normal operations and anticipated operational occurrences.

7.7.2.9.1.2.3 SSE-RMS Conformance to 10CFR50, Appendix I

The SSE-RMS affords instrumentation with state-of-the-art sensitivity and quick response times to provide the operator with information that will ensure that radioactive effluents are as low as is reasonably practicable. In-place detectors for particulates, iodines, and noble gases provide real-time outputs in the control room to alert personnel to the escape of radioactive material in its early stages.

7.7.2.9.2 Radwaste Equipment Rooms Ventilation Exhaust Radiation Monitoring System - Instrumentation and Controls

7.7.2.9.2.1 RERV-RMS Power Generation Design Basis

This system is designed to provide a display and alarm capability in the control room for concentrations of radioactive material in the ventilation exhaust from the charcoal offgas treatment compartments. This monitoring system indicates leakage of radioactive material from the charcoal beds into the surrounding air.

7.7.2.9.2.2 RERV-RMS General Functional Requirements Conformance

This is an off-line process radiation monitoring system that measures the intensity of gamma radioactivity using a detector in a sampling chamber. High/downscale trip alarms are transmitted to annunciators in the control room.

7.7.2.9.2.3 RERV-RMS Specific Regulatory Requirements Conformance

Because the only purpose of this system is leak detection, it serves no safety-related function. The system is not required to meet any specific IEEE standards or regulatory guides. This system is used to detect a malfunction of the charcoal offgas treatment system, complying with GDC 60, because the charcoal treatment system controls releases of radioactive materials to the environment.

7.7.2.9.3 Charcoal Treatment System Process Exhaust Radiation Monitoring System - Instrumentation and Controls

7.7.2.9.3.1 CTSP-RMS Power Generation Design Basis

This system is designed to provide a display and alarm capability in the control room for concentrations of radioactive material in the effluents from the charcoal offgas treatment system. This monitoring system provides an indication of the effectiveness of the offgas treatment system in arresting radioactive discharges to the north stack.

7.7.2.9.3.2 CTSP-RMS General Functional Requirements Conformance

This is an off-line process radiation monitoring system that measures the intensity of gamma radioactivity by means of a detector in a sampling chamber. High/downscale trip alarms are transmitted to annunciators in the control room.

7.7.2.9.3.3 CTSP-RMS Specific Regulatory Requirements Conformance

There are no specific IEEE standards or regulatory guides that this system is required to meet. The system conforms to GDC 60, providing the operator with information on the effectiveness of the charcoal effluent treatment system in controlling releases of radioactive materials to the environment.

7.7.2.9.4 Recombiner Rooms and Hydrogen Analyzer Compartments Exhaust Radiation Monitoring System – Instrumentation and Controls

7.7.2.9.4.1 RRHAC-RMS - Power Generation Design Basis

This system is designed to provide a display and alarm capability in the control room if radioactive gaseous effluents leak from the recombiners, hydrogen analyzers, or equipment drain sumps. It can also localize the source of such leakage.

7.7.2.9.4.2 RRHAC-RMS General Functional Requirements Conformance

This is an off-line process radiation monitoring system that measures concentrations of radioactive gaseous effluents in the ventilation ducting from the recombiner compartments, hydrogen analyzer compartments, and equipment drain sump. High/downscale trip alarms are transmitted to an annunciator in the control room. A hand selector switch actuating a set of solenoid valves is provided for determining the source of the high radiation indication.

7.7.2.9.4.3 RRHAC-RMS Specific Regulatory Requirements Conformance

There are no specific IEEE standards or regulatory guides that this system is required to meet.

7.7.2.9.5 Steam Exhauster Discharge and Vacuum Pump Exhaust Radiation Monitoring System - Instrumentation and Controls

7.7.2.9.5.1 SEDVP-RMS Power Generation Design Basis

This monitoring system is designed to detect the presence of short half-life radioactive isotopes leaking from the steam seals of the turbines or excessive radioactivity in the mechanical vacuum pump exhaust.

7.7.2.9.5.2 SEDVP-RMS General Functional Requirements Conformance

This is an off-line process radiation monitoring system that measures the intensity of gamma radioactivity by a detector in a sampling chamber.

7.7.2.9.5.3 SEDVP-RMS Specific Regulatory Requirements Conformance

There are no specific IEEE standards or regulatory guides that this system is required to meet. It is a power generation system and serves no safety-related function.

7.7.2.9.6 Radwaste Enclosure Ventilation Radiation Monitoring System - Instrumentation and Controls

7.7.2.9.6.1 REV-RMS Power Generation Design Basis

This system is designed to provide a display and alarm capability in the control room if unacceptable radioactive concentrations leak into the radwaste enclosure ventilation exhaust.

7.7.2.9.6.2 REV-RMS General Functional Requirements Conformance

This is an off-line process radiation monitoring system that measures the concentration of gamma radioactivity in the ventilation exhaust from the radwaste enclosure by means of a detector in a shielded sampling chamber. Evidence of leakage in this system is to be used for diagnostic purposes.

7.7.2.9.6.3 REV-RMS Specific Regulatory Requirements Conformance

This is a power generation system and serves no safety-related function. There are no specific IEEE standards or regulatory guides that this system is required to meet.

7.7.2.9.7 Air Ejector Offgas Effluent Radiation Monitoring System - Instrumentation and Controls

7.7.2.9.7.1 AEO-RMS General Functional Requirements Conformance

The AEO-RMS monitors the offgas effluents downstream of the recombiner and provides indication and alarm under appropriate OUT OF ACCEPTABLE RANGE radiation levels.

The AEO-RMS monitors have characteristics sufficient to provide accurate indication of radioactivity in the air ejector offgas. Sufficient redundancy is provided to allow maintenance on one channel without losing the system indications.

7.7.2.9.7.2 AEO-RMS Specific Regulatory Requirements Conformance

No specific regulatory guides or IEEE standards apply to this system.

7.7.2.9.7.2.1 AEO-RMS Conformance to 10CFR50, Appendix A, General Design Criteria

7.7.2.9.7.2.1.1 AEO-RMS - GDC 13 - Instrumentation and Control

The system conforms to GDC 13 in that the instruments used cover the anticipated range of radiation under normal operating conditions with enough margin to include postulated accident conditions.

7.7.2.9.7.2.1.2 AEO-RMS - GDC 64 - Monitoring Radioactivity Releases

The system conforms to GDC 64 in that it monitors radioactive releases resulting from normal operations including anticipated operational occurrences.

7.7.2.9.8 Primary Containment Leak Detection Radiation Monitoring System - Instrumentation and Controls

7.7.2.9.8.1 PCLD-RMS General Functional Requirements Conformance

The PCLD-RMS supplements the leak detection instrumentation for the primary containment. This monitoring system continually samples the containment (drywell) atmosphere for radioactive noble gases. It is designed to respond to increases in the concentration of radioactivity in the containment atmosphere.

This system is not intended for use during or after a LOCA. In this eventuality, the PCLD-RMS will be automatically isolated from the containment. The PCLD-RMS is a power generation system, and is not safety-related.

7.7.2.9.8.2 PCLD-RMS Specific Regulatory Requirements Conformance

7.7.2.9.8.2.1 PCLD-RMS Conformance to Regulatory Guides

7.7.2.9.8.2.1.1 PCLD-RMS - Regulatory Guide 1.45 (1973) - Reactor Coolant Pressure Boundary Leakage Detection Systems

The PCLD-RMS is designed to provide one of the three independent means of detecting RCPB leakage. The systems provided meet the intent of Regulatory Guide 1.45 and meet or exceed the recommendations of ANSI/ISA S67.03.

7.7.2.9.8.2.2 PCLD-RMS 10CFR50, Appendix A, General Design Criteria

7.7.2.9.8.2.2.1 PCLD-RMS - GDC 2 - Design Bases for Protection Against Natural Phenomena

The PCLD-RMS is not designed to continue its leak detection capability after a SSE. The other RCPB leak detection systems are designed to withstand an SSE (sump level) or an OBE (drywell chiller drains).

7.7.2.9.8.2.2.2 PCLD-RMS - GDC 13 - Instrumentation and Control

The PCLD-RMS is designed to monitor for containment internal leakage over normal operation and anticipated occurrences, but not for accidents that result in containment isolation.

7.7.2.9.8.2.2.3 PCLD-RMS - GDC 64 - Monitoring Radioactivity Releases

The PCLD-RMS provides a means of monitoring the containment atmosphere for radioactivity released from the RCPB during normal operations and anticipated operational occurrences.

7.7.2.9.9 Hot Maintenance Shop Ventilation Exhaust Radiation Monitoring System - Instrumentation and Controls

7.7.2.9.9.1 HMS-RMS General Functional Requirements Conformance

The HMS-RMS monitors the effluents from the hot maintenance shop exhaust filters in the ventilation duct. All instrumentation is local. This system provides to the RMMS an ongoing record of the number of concentration of particulates and iodines discharged from the hot maintenance shop to the environment. Under normal operating conditions, this radioactive effluent is insignificant. If there is an anomalous occurrence, an alarm annunciator alerts hot maintenance personnel of a malfunction.

7.7.2.9.9.2 HMS-RMS Specific Regulatory Requirements Conformance

7.7.2.9.9.2.1 HMS-RMS Conformance to Regulatory Guides

7.7.2.9.9.2.1.1 HMS-RMS - Regulatory Guide 1.21 (1974) - Measuring, Evaluating, and Reporting Radioactivity in Solid Wastes and Releases of Radioactive Materials in Liquid and Gaseous Effluents from Light-Water-Cooled Nuclear Power Plants

The HMS-RMS is designed to comply with Regulatory Guide 1.21. Data generated by this instrument are transmitted to the RMMS (Section 11.5.6) to be incorporated into periodic Regulatory Guide 1.21 reports.

7.7.2.9.9.2.2 HMS-RMS Conformance to 10CFR50, Appendix A, General Design Criteria

7.7.2.9.9.2.2.1 HMS-RMS - GDC 13 - Instrumentation and Control

Instrumentation is provided to monitor radioactive effluents over their anticipated ranges for normal operation as well as for anticipated operational occurrences.

7.7.2.9.9.2.2.2 HMS-RMS - GDC 64 - Monitoring Radioactivity Releases

Means are provided for monitoring an effluent discharge path for radioactivity that may be released from normal operations and anticipated operational occurrences.

7.7.2.9.10 Liquid Radwaste Discharge Radiation Monitoring System - Instrumentation and Controls

7.7.2.9.10.1 LRD-RMS Power Generation Design Basis

This system is designed to trip the valves in the liquid radwaste discharge line when the concentration of radioactive effluents in the liquid radwaste discharge is unacceptable. The monitoring system also provides ongoing records of radioactive releases, together with displays in the radwaste control room and alarm annunciation in the main control room.

7.7.2.9.10.2 LRD-RMS General Functional Requirements Conformance

This is an off-line process radiation monitoring system that measures the gross concentration of radioactive isotopes in the liquid radwaste discharge. Combined with flow rate data, the radiation data are used to keep an inventory of the total liquid radioactive discharge from the plant. When concentrations of the discharges exceed permissible limits, these discharges are automatically stopped.

7.7.2.9.10.3 LRD-RMS Specific Regulatory Requirements Conformance

No specific IEEE standards apply to this system.

7.7.2.9.10.3.1 LRD-RMS Conformance to Regulatory Guides

7.7.2.9.10.3.1.1 LRD-RMS - Regulatory Guide 1.21 (1974) - Measuring, Evaluating, and Reporting Radioactivity in Solid Wastes and Releases of Radioactive Materials in Liquid and Gaseous Effluents from Light-Water-Cooled Nuclear Power Plants

The system conforms to Regulatory Guide 1.21 in maintaining records of discharges of radioactive effluents from the plant and in holding the discharges within permissible limits.

7.7.2.9.10.3.2 LRD-RMS Conformance to 10CFR50, Appendix A, General Design Criteria

7.7.2.9.10.3.2.1 LRD-RMS - GDC 60 - Control of Releases of Radioactive Materials to the Environment

The system controls releases of radioactive materials to the environment.

7.7.2.9.10.3.2.2 LRD-RMS - GDC 64 - Monitoring Radioactive Releases

The system provides a means of monitoring an effluent discharge path for radioactivity that may be released from normal operations and anticipated operational occurrences.

7.7.2.9.11 Service Water Radiation Monitoring System - Instrumentation and Controls

7.7.2.9.11.1 SW-RMS Power Generation Design Basis

This system is designed to provide a display and alarm capability in the control room if there is leakage of radioactive material into the plant service water. Concentrations of radioactive materials in the service water are detected in the discharge to the cooling tower. A display, an ongoing record, and an alarm annunciation capability are provided in the control room.

7.7.2.9.11.2 SW-RMS General Functional Requirements Conformance

This is an off-line process radiation monitoring system that measures the concentration of radioactive materials in the service water discharges. High/downscale trip alarms are transmitted to an annunciator in the control room. This information is used for diagnostic purposes.

7.7.2.9.11.3 SW-RMS Specific Regulatory Requirements Conformance

There are no specific IEEE standards or regulatory guides that this system is required to meet. It partially satisfies GDC 64, in that it monitors radioactive releases to the cooling tower resulting from normal operations and anticipated malfunctions.

7.7.2.9.12 Reactor Enclosure Cooling Water Radiation Monitoring System - Instrumentation and Controls

7.7.2.9.12.1 RECW-RMS Power Generation Design Basis

This system is designed to provide a display and alarm capability in the control room if there is leakage of radioactive material into the RECW. Such a condition could occur only if a leak occurs in the interface between the reactor enclosure cooling water system and the service water system, and if radioactive contamination is already present in the plant service water system. Consequently, the probability of a high radiation alarm is remote.

7.7.2.9.12.2 RECW-RMS General Functional Requirements Conformance

This is an off-line process radiation monitoring system that measures the concentration of radioactive materials in the cooling water. High/downscale alarm trips are transmitted to an annunciator in the control room. This information is used for diagnostic purposes.

7.7.2.9.12.3 RECW-RMS Specific Regulatory Requirements Conformance

There are no specific IEEE standards or regulatory guides that this system is required to meet.

7.7.2.10 Area Radiation Monitoring System - Instrumentation and Controls

7.7.2.10.1 ARMS General Functional Requirements Conformance

a. Sensor/converters monitor the gamma radiation levels at the selected locations and send a dc signal, proportional to the gamma level, to the control room where indicator/trip units display the signal.

b. Wherever it is necessary to have the local indication and alarm, an auxiliary unit and a horn are installed at the desired location. The auxiliary unit receives the signal from the indicator/trip unit both for display and alarm. The local alarm consists of an indicator and a red light. The light and horn are energized if the alarm level is exceeded.

7.7.2.10.2 ARMS Specific Regulatory Requirements Conformance

7.7.2.10.2.1 ARMS Conformance to Regulatory Guides

7.7.2.10.2.1.1 ARMS - Regulatory Guide 1.97 (1980) - Instrumentation for Light-Water-Cooled Nuclear Power Plants to Assess Plant and Environs Conditions During and Following an Accident

Section 7.5.2.5.1.1.2 contains a discussion of the degree of conformance.

7.7.2.10.2.2 ARMS Conformance to 10CFR50, Appendix A, General Design Criteria

7.7.2.10.2.2.1 ARMS - GDC 63 - Monitoring Fuel and Waste Storage

To meet the requirements of GDC 63, monitors are placed in fuel and waste storage areas to give a continuous display of gamma levels and to alarm if the levels exceed preselected heights.

7.7.2.11 Gaseous Radwaste System - Instrumentation and Controls

7.7.2.11.1 GRS General Functional Requirements Conformance

This is not a safety-related system.

The offgas flow recorder is provided to keep a record of all discharge volumes.

All instrumentation with connections to the offgas process lines is purchased and installed not to exceed a maximum leak rate of $1x10^{-6}$ atm-cc/sec to limit release of radioactive gases other than through the controlled process system release point after treatment.

Chapter 15 examines the various failure mode considerations for this system. These include:

a. Failure of the charcoal bed

b. Failure of the delay piping

7.7.2.11.2 GRS Specific Regulatory Requirements Conformance

7.7.2.11.2.1 GRS Conformance to Regulatory Guides

7.7.2.11.2.1.1 GRS - Regulatory Guide 1.21 (1974) - Measuring, Evaluating, and Reporting Radioactivity in Solid Wastes and Releases of Radioactive Materials in Liquid and Gaseous Effluents from Light-Water- Cooled Nuclear Power Plants

The stack measurements (which include the offgas system effluents) provide the methods of measuring the effluents that are required to be reported.

7.7.2.12 Liquid Radwaste System - Instrumentation and Controls

7.7.2.12.1 LRS General Functional Requirements Conformance

The liquid radwaste flow for discharge to the blowdown line is flow controlled and monitored for activity level. The discharge flow shutoff valves are operated by key-lock switches that require plant supervisory control of any releases. The flow is recorded in the radwaste control room.

The packaged wastes are stored in a plant storage area set aside for this purpose. The radioactivity and quantity is the responsibility of plant supervisory personnel.

7.7.2.12.2 LRS Specific Regulatory Requirements Conformance

7.7.2.12.2.1 LRS Conformance to Regulatory Guides

7.7.2.12.2.1.1 LRS - Regulatory Guide 1.21 (1974) - Measuring, Evaluating, and Reporting Radioactivity in Solid Wastes and Releases of Radioactive Materials in Liquid and Gaseous Effluents from Light-Water- Cooled Nuclear Power Plants

The radwaste flow measurements provide the method of measuring effluents that are required to be reported.

7.7.2.13 Solid Radwaste System - Instrumentation and Controls

7.7.2.13.1 SRS General Functional Requirements Conformance

The solid radwaste handling system is not a safety-related system. Therefore, the instrumentation supplied is for system equipment protection and for operator information only.

7.7.2.13.2 SRS Specific Regulatory Requirements Conformance

No specific regulatory requirements are imposed on the subject system instrumentation and controls.

7.7.2.14 Fuel Pool Cooling and Cleanup System – Instrumentation and Controls

7.7.2.14.1 FPCC General Functional Requirements Conformance

The FPCC system is not a safety-related system. Indicators and alarms are not needed to prevent an accident and are only used as an operator aid for plant equipment protection and for operator information.

The primary function of the FPCC system is to remove decay heat from the spent fuel storage pool water to ensure adequate cooling of irradiated stored assemblies. The FPCC system also purifies the spent fuel storage pool water. It maintains water clarity for fuel handling operations and fills and drains the fuel transfer canal.

The pool water temperature is controlled manually; automatic temperature control is not required. Once the desired cooler duty has been established, the cooling load changes gradually with time; only when spent fuel is added to or taken from the pool does the cooling load change rapidly. The two fuel pool cooling system pumps are controlled from the control room. All other functions of the FPCC system are accomplished by local manipulation of valves and control of the equipment.

The instrumentation in the FPCC system provides measurements that are used to indicate and alarm as indicated in Section 7.7.1.14.

The FPCC system is monitored for conductivity, temperature, pool level, flow rate, and leakage.

The conductivity measurement provides the operator with the information required to ensure that impurities in the water are maintained at acceptable levels.

Low flow (pump discharge pressure) and temperature monitoring provide the operator with the information required to ensure that the desired temperature is not exceeded and that filtering is maintained. Pool level and leakage monitoring provide the operator with information ensuring the maintenance of adequate shielding and cooling.

The FPCC system is an independent system during normal operation. Evaporative losses in the system can be replaced from the Demin Water System or by the condensate storage system. If the heat load becomes excessive, the shutdown cooling portion of the RHR system can be operated in parallel with the FPCC system to remove the excess heat, when in the shutdown mode.

7.7.2.14.2 FPCC Specific Regulatory Requirements Conformance

7.7.2.14.2.1 FPCC Conformance to 10CFR50, Appendix A, General Design Criteria

7.7.2.14.2.1.1 FPCC - GDC 61 - Fuel Storage and Handling and Radioactivity Control

The fuel pool cooling and cleanup system filters and cools the spent fuel pool water to remove residual heat and maintain pool water clarity for refueling operations. The controls and instrumentation designed for this system provide monitoring to ensure proper operation of the fuel pool cooling and cleanup system so that conductivity, temperature, levels, flow, and leakage are maintained at normal levels.

7.7.2.15 Refueling Interlocks - Instrumentation and Controls

7.7.2.15.1 RI General Functional Requirements Conformance

The refueling interlocks, in combination with core nuclear design and refueling procedures, limit the probability of an inadvertent criticality. The nuclear characteristics of the core ensure that the reactor is subcritical even when the highest worth control rod is fully withdrawn. Refueling procedures are written to avoid situations in which inadvertent criticality is possible. The combination of refueling interlocks for control rods and refueling platform interlocks provides redundant methods of preventing inadvertent criticality even after procedural violations. The interlocks on hoists provide yet another method of avoiding inadvertent criticality.

Table 7.7-3 illustrates the effectiveness of the refueling interlocks. This table considers various operational situations involving rod movement, hoist load conditions, refueling platform movement and position, and mode switch manipulation. The initial conditions in situations 4 and 5 appear to contradict the action of refueling interlocks, because the initial conditions indicate that more than one control rod is withdrawn, yet the mode switch is in REFUEL. Such initial conditions are possible if the rods are withdrawn when the mode switch is in STARTUP, and then the mode switch is turned to REFUEL. In all cases, correct operation of the refueling interlock prevents either the operation of loaded refueling equipment over the core when any control rod is withdrawn, or the withdrawal of any control rod when fuel-loaded refueling equipment is operating over the core. In addition, when the mode switch is in REFUEL, only one rod can be withdrawn; selection of a second rod initiates a rod block.

7.7.2.15.2 RI Specific Regulatory Requirements Conformance

No specific regulatory requirements apply to refueling interlocks. The refueling interlocks are designed to be normally energized (fail-safe) and single failure tolerant of equipment failures.

IEEE standards do not apply because the refueling interlocks are not required for any postulated DBA or for safe shutdown. The interlocks are required only for the refueling mode of plant operation. The requirements of 10CFR50, Appendix B, are met in the manner set forth in Chapter 17.

No specific GDC requirements apply to this system.

7.7.2.16 Leak Detection System - Instrumentation and Controls

7.7.2.16.1 LDS General Functional Requirements Conformance

Following are the analyses to demonstrate how various general function requirements listed under the leak detection system (Section 7.7.1.16) are satisfied.

7.7.2.16.2 LDS Specific Regulatory Requirements Conformance

7.7.2.16.2.1 LDS Conformance to Regulatory Guides

7.7.2.16.2.1.1 LDS - Regulatory Guide 1.45 (1973) - Reactor Coolant Pressure Boundary Leakage Detection Systems

Leakage into the primary reactor containment from identified sources such as valve stem packing, recirculation pump seal, head seal, etc., is separated so that flow rates are monitored separately from unidentified leakages and total flow rates can be established and monitored as described in Section 5.2.5.2.1.3.

Similarly, the flow rate for unidentified leakage is monitored to detect a pipe break in the primary containment.

Condensation from the drywell air coolers is monitored to provide a diverse means of detecting RCPB leakage. This monitoring provision is described in Section 5.2.5.2.1.4.

Noble gas radioactivity monitoring is also provided to supplement the flow measurement methods of RCPB leak detection, as described in Section 5.2.5.2.1.5.

The RCPB leak detection systems and equipment provided at LGS meet the intent of Regulatory Guide 1.45 and meet or exceed the recommendations of ANSI/ISA S67.03.

7.7.2.16.2.2 LDS Conformance to 10CFR50, Appendix A, General Design Criteria

7.7.2.16.2.2.1 LDS - GDC 13 - Instrumentation and Control

The leak detection sensors and associated electronics are designed to monitor reactor coolant leakage over all expected ranges required for the safety of the plant.

7.7.2.16.2.2.2 LDS - GDC 19 - Control Room

Controls and instrumentation are provided in the control room.

7.7.2.16.2.2.3 LDS - GDC 30 - Quality of Reactor Coolant Pressure Boundary

The system provides the means for detecting and locating the source of the reactor coolant leakage. This also applies to the sump drywell, recirculating pump, and SRV leak detection equipment.

7.7.2.16.2.2.4 LDS - GDC 34 - Residual Heat Removal

Leak detection is provided for the RHR shutdown cooling lines penetrating the drywell.

7.7.2.16.2.2.5 LDS - GDC 54 - Piping Systems Penetrating Containment

Leak detection is provided for the RHR shutdown cooling lines penetrating the containment. Sump fill rate monitoring provides leak detection for other pipes penetrating the containment and reactor enclosures.

7.7.2.16.2.3 LDS Conformance to Industry Codes and Standards

7.7.2.16.2.3.1 LDS - IEEE 344 (1971) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations

The RHR and the drywell leak detection systems comply with this standard. See Section 3.10.

7.7.2.16.2.3.2 LDS - ANSI/ISA S67.03

The RCPB leak detection systems and equipment provided at LGS meet or exceed the recommendations of this standard.

7.7.2.17 Emergency Response Facilities Data System - Instrumentation and Controls

7.7.2.17.1 ERFDS General Functional Requirements Conformance

The ERFDS is designed to provide the operator with certain categories of information. The system augments information from other systems so that the operator can startup, operate at power, and shutdown in an efficient manner. This system is not required to initiate or control any safety-related system.

7.7.2.17.2 ERFDS Specific Regulatory Requirements Conformance

The ERFDS is not classified as a safety system and does not initiate any safety-related functions.

The ERFDS has provisions for appropriate isolation from interfacing equipment classified as Class 1E, and the maintenance of the ERFDS is possible without affecting the function of the interfacing Class 1E systems.

The following summarizes the requirements given in section 4.1 of NUREG-0737, Supplement 1 and generic design implementation characteristics which are fully applicable to LGS:

a. "Displays shall be available..."

Reliability has been designed into the ERFDS by providing

1. redundant and validated signals
2. on-line failure diagnostics
3. processor backup
4. use of quality components

"Provide concise displays of critical plant variables..."

This requirement is met by all top level displays discussed in Section 7.7.1.17.

b. "Continuous display of SPDS parameters shall be located conveniently to the control room operator..."

The installed ERFDS configuration ensures that this requirement will be met.

Graphic display consoles are located in the LGS control room. These consoles provide continuous display of SPDS parameters.

c. "The SPDS shall be suitably isolated from...safety systems."

This concern is addressed in Section 7.7.1.17 2.4.

d. "Prompt implementation of SPDS...information."

The schedule for implementation of the LGS SPDS is provided in Section 1.13, Item I.D.1. The selection of parameters included in the ERFDS was based on the guidance provided in NUREG-0696.

e. "The SPDS shall be designed to incorporate accepted human factors principles..."

This concern is addressed in Section 7.7.1.17.2 1.

f. "The minimum information to be provided shall be sufficient to provide information to plant operators about:"

"(i) Reactivity Control"

Reactor power is one of the EPG control parameters. Its control is addressed by the RPV Control display which includes the reactor power trend plot and the SCRAM event target. Expanded trend information is also given by the full page reactor power trend plot.

"(ii) Reactor core cooling and heat removal from the primary system"

Core cooling and heat removal are evidence by EPG control parameters of RPV water level and pressure. The RPV Control Display provides trend and value information for these parameters as well as for RPV temperature when the reactor is shutdown. It also provides event targets (e.g., SRV, MSIV). Expanded trend information is also given by the full page trend plot displays.

"(iii) Reactor coolant system integrity"

A breach of the reactor coolant boundary would be evident by the reactor and containment response (the latter for breaches in the primary containment). The initial alert would be evident on the Critical Plant Variables Display and/or the RPV Control and Containment Control Displays. Sufficient information to mitigate the consequences of a RCS breach in accordance with the LGS EOPs is given on the RPV Control and Containment Control Displays through indication of RPV water level, RPV pressure, SRV positions, drywell temperature, and drywell pressure.

"(iv) Radioactivity Control"

The LGS ERFDS monitors selected process and area radiation monitors in the plant. However, the computer-based system with primary responsibility for providing the process, area, and stack effluent radiation data required for radioactivity control is the RMMS. An RMMS color graphic CRT with keyboard is located in close proximity (within approximately 6 feet) of the ERFDS CRT in the control room. This provides control room personnel with concise displays of radioactivity control data in close proximity to the SPDS displays provided by the ERFDS. A description of the RMMS is given in Section 11.5.6.

"(v) Containment conditions"

Trends and values of containment control parameters and event indications that affect containment conditions (e.g., SRV OPEN, ISOLATION VALVE CLOSURE), are given on the Containment Control Display. Key top level information is given on the Critical Variables Display and expanded trend information on the full page trend plot displays.

7.7.2.18 Containment Instrument Gas System - Instrumentation and Controls

7.7.2.18.1 CIGS General Functional Requirements Conformance

Following are analyses that demonstrate how the CIGS satisfies applicable plant design requirements.

7.7.2.18.2 CIGS Specific Regulatory Requirements Conformance

7.7.2.18.2.1 CIGS Conformance to Regulatory Guides

7.7.2.18.2.1.1 CIGS - Regulatory Guide 1.30 (1972) - Quality Assurance Requirements for the Installation, Inspection, and Testing of Instrumentation and Electric Equipment (Safety Guide 30)

See Section 8.1.6.1.

7.7.2.18.2.2 CIGS Conformance to 10CFR50, Appendix A, General Design Criteria

7.7.2.18.2.2.1 CIGS - GDC 13 - Instrumentation and Control

Instrumentation is provided to monitor the operation of the CIGS over its anticipated range of operating conditions. Manual operation of the system is possible from the local control panels.

7.7.2.18.2.2.2 CIGS - GDC 56 - Primary Containment Isolation

The suction line has two automatic isolation valves: one inside and one outside containment. The CIGS supply lines have an automatic isolation valve outside containment and a check valve inside containment.

7.7.2.18.2.3 CIGS Conformance to Industry Codes and Standards

7.7.2.18.2.3.1 CIGS - IEEE 336 (1971) - Installation, Inspection, and Testing Requirements for Instrumentation and Electric Equipment During the Construction of Nuclear Power Generating Stations

See Section 8.1.6.1.

7.7.2.18.2.3.1.2 CIGS - IEEE 384 (1974) - Criteria for Separation of Class 1E Equipment and Circuits

See Section 7.1.2.7.9.

7.7.2.19 Fire Protection and Suppression System - Instrumentation and Controls

7.7.2.19.1 FPSS General Functional Requirements Conformance

A local annunciator panel located in the auxiliary equipment room will receive a signal from the smoke detectors located in the raised floor. This panel will indicate which PGCC floor section has alarmed. The plant operator will decide, in case of fire, either to use a portable fire extinguisher through removable floor plates or to manually initiate the Halon system from a remote station. Automatic actuation is initiated by thermal detection.

7.7.2.19.2 FPSS Specific Regulatory Requirements Conformance

The PGCC design complies with the applicable requirements of the standards described in the GE topical report NEDO-10466-A, "Power Generation Control Complex."

7.7.2.20 Nonsafety-Related Equipment Area Cooling Ventilation Systems - Instrumentation and Controls

7.7.2.20.1 Power Generation Design Basis

Instruments and controls are provided to ensure adequate ventilation for equipment and personnel located in the areas serviced by the nonsafety-related equipment area cooling ventilation systems during normal plant operation.

7.7.2.20.2 General Functional Requirements Conformance

7.7.2.20.2.1 Reactor Enclosure Ventilation System

Instrumentation and controls are designed to provide the operator with information necessary to operate the reactor enclosure ventilation system in an efficient manner during normal plant operation. None of this instrumentation is required to initiate or control any safety-related systems because, after a DBA, operation is terminated upon initiation of the REIS.

7.7.2.20.2.2 Turbine Enclosure Ventilation System

Instrumentation and controls are designed to provide the operator with the information necessary to operate the turbine enclosure ventilation system efficiently during normal plant operation. The

turbine enclosure ventilation system is not safety-related and does not operate after a DBA. See Section 9.4.4.5 for instrumentation requirements.

7.7.2.20.2.3 Radwaste Enclosure and Chem. Lab. Expansion Ventilation System

Instrumentation and controls are designed to provide the operator with the information necessary to operate the radwaste enclosure and chem. lab. expansion ventilation system efficiently during normal plant operation. The radwaste enclosure ventilation system is not safety-related and does not operate after a DBA. See Section 9.4.3.5 for instrumentation requirements.

7.7.2.20.2.4 Hot Maintenance Shop Ventilation System

Instrumentation and controls are designed to provide the operator with the information necessary to operate the hot maintenance shop ventilation system efficiently during normal plant operation. The hot maintenance shop ventilation system is not safety-related and does not operate after a DBA. See Section 9.4.8.5 for instrumentation requirements.

7.7.2.20.2.5 Miscellaneous Enclosure Ventilation System

Instrumentation and controls are designed to provide the operator with the information necessary to operate the miscellaneous enclosure ventilation systems efficiently during normal plant operation. The miscellaneous enclosure ventilation systems are not safety-related and do not operate after a DBA. See Section 9.4.9.5 for instrumentation requirements.

7.7.2.20.3 Specific Regulatory Requirements Conformance

There are no specific IEEE standards or regulatory guides with which these systems must comply.

7.7.2.21 Rod Worth Minimizer - Instrumentation and Controls

7.7.2.21.1 RWM General Functional Requirements Conformance

7.7.2.21.1.1 RWM Power Generation Design Basis

The RWM monitors and enforces operator adherence to established startup, shutdown, and low power level control rod sequences. The startup or shutdown of the reactor can continue without the RWM when a second licensed operator or a technically qualified member of the unit technical staff is present to check rod movements.

7.7.2.21.2 RWM Specific Regulatory Requirements Conformance

The RWM is not classified as a safety-related system and is not required to initiate any safety-related functions.

7.7.2.21.2.1 RWM Conformance to Regulatory Guides

7.7.2.21.2.1.1 RWM - Regulatory Guide 1.29 (1978) - Seismic Design Classification

The RWM operator display panel meets the applicable portions of the regulatory guide.

7.7.2.21.2.2 RWM Conformance to Industry Codes and Standards

7.7.2.21.2.2.1 RWM - IEEE 388 (1974) - Standard for Type Test of Class 1E Electric Cables, Field Splices, and Connections for Nuclear Power Generating Stations

The RWM operator display panel and interconnecting cable meet the applicable portions of the regulatory guide.

7.7.2.22 Plant Monitoring System - Instrumentation and Controls

7.7.2.22.1 PMS General Functional Requirements Conformance

The plant monitoring system is designed to provide the operator with certain categories of information. The system augments information from other systems so that the operator can start up, operate at power, and shut down in an efficient manner. This system is not required to initiate or control any safety-related system. The analyses for the RWM function are contained in Section 7.7.1.21.

7.7.2.22.2 PMS Specific Regulatory Requirements Conformance

The PMS is not classified as a safety system and does not initiate any safety-related functions.

The PMS has provisions for appropriate isolation from interfacing equipment classified as Class 1E, and the maintenance of the PMS is possible without affecting the function of the interfacing 1E systems.

The PMS data acquisition system employs signal isolation and fiber optics cables designed to prevent electrical interference between the PMS and Class 1E safety systems. Thus the PMS conforms with all electrical isolation requirements.

7.7.2.22.2.1 PMS Conformance to Industry Codes and Standards

7.7.2.22.2.1.1 PMS - IEEE 323 (1974) - IEEE Trial Use Standard: General Guide for Qualifying Class 1 Electric Equipment for Nuclear Power Generating Stations

These DAS I/O modules are not Class 1E qualified but the Scientech I/C Isolators conform to this standard. Class 1E qualifications and conformance to the IEEE Standards applies only to those modules that provide isolation between Class 1E and Non-Class 1E circuits. (NUREG-0588 Category I)

7.7.2.22.2.1.2 PMS - IEEE 344 (1975) - Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations

These DAS I/O modules are not Class 1E but the Scientech I/C Isolators conform to this standard. Class 1E qualifications and conformance to the IEEE Standards applies only to those modules that provide isolation between Class 1E and Non-Class 1E circuits. See Section 3.10.

7.7.2.22.2.1.3 PMS - IEEE 383 (1974) - Guide for Type Test of Class 1 Electric Cables, Field Splices, and Connections for Nuclear Power Generating Stations

These DAS I/O modules are not Class 1E qualified but the Scientech l/C Isolators conform to this standard. Class 1E qualifications and conformance to the IEEE Standards applies only to those modules that provide isolation between Class 1E and Non-Class 1E circuits.

7.7.2.22.2.1.4 PMS - IEEE 384 (1981) - Criteria for Independence of Class 1E Equipment and Circuits

These DAS I/O modules are not Class 1E qualified but the Scientech l/C Isolators conform to this standard. No fault on the isolator output wiring can affect any isolator input signal. Class 1E qualifications and conformance to the IEEE Standards applies only to those modules that provide isolation between Class 1E and Non-Class 1E circuits.

REFUELING INTERLOCK EFFECTIVENESS

SITUATION	REFUELING PLATFORM POSITION	HOISTS FG	CONTROL RODS	MODE SWITCH	ATTEMPT	RESULT
1	Not near core	UL	All rods in	Refuel	Move refueling platform over core	No restrictions
2	Not near core	UL	All rods in	Refuel	Withdraw rods	Cannot withdraw more than one rod
3	Not near core	UL	One rod withdrawn	Refuel	Move refueling platform over core	No restrictions
4	Not near core	L	One or more rods withdrawn	Refuel	Move refueling platform over core	Platform stopped before over core
5	Not near core	UL	More than one rod withdrawn	Startup	Move refueling platform over core	Platform stopped before over core
6	Over core	UL	All rods in	Refuel	Withdraw rods	Cannot withdraw more than one rod
7	Over core	Either Hoist L	All rods in	Refuel	Withdraw rods	Rod block
8	Not near core	UL	All rods in	Refuel	Withdraw rods	Rod block
9	Not near core	UL	All rods in	Refuel	Operate service platform hoist	No restrictions
10	Not near core	UL	One rod withdrawn	Refuel	Operate service platform hoist	Hoist operation Prevented
11	Not near core	UL	All rods in	Startup	Move refueling platform over core	Platform stopped before over core
12	Not near core	UL	All rods in	Startup	Operate service platform hoist	No restrictions
13	Not near core	UL	One rod withdrawn	Startup	Operate service platform hoist	Hoist operation prevented
14	Not near core	UL	All rods in	Startup	Withdraw rods	Rod block
15	Not near core	UL	All rods in	Startup	Withdraw rods	No restrictions
16	Over core	UL	All rods in	Startup	Withdraw rods	Rod block
17	Over core	UL	One or more rods withdrawn	Refuel	Lift a fuel assembly with FG	(Main) Hoist Operation prevented

FG - Fuel Grapple UL - Unloaded L - Fuel Loaded

Table 7.7-4

SRM SYSTEM TRIPS

TRIP FUNCTION	NORMAL SETPOINT	TRIP ACTION
SRM upscale	10^5 counts/second	Rod block, amber light display annunciator
SRM instrument inoperative	(1)	Rod block, amber light display annunciator
Detector retraction permissive (SRM downscale)	100 counts/second	Bypass detector full-in limit switch when above preset limit, annunciator, green light display, rod block when below preset limit with IRM range switches on first two ranges.
SRM period	50 sec	Annunciator, amber light display
SRM downscale	3 counts/second	Rod block, annunciator, white light display
SRM bypassed		White light display

(1) SRM is inoperative if module interlock chain is broken, OPERATE-CALIBRATE switch is not in operate position or detector polarizing voltage is below 90% of normal operating voltage (operationally determined).

Table 7.7-5

RBM SYSTEM TRIPS

TRIP FUNCTION	NOMINAL SETPOINT	TRIP ACTION
RBM upscale	To be provided in Technical Specifications	Rod block, annunciator, amber light display, RBM ODA
RBM inoperative	(1)	Rod block, annunciator, amber light display, RBM ODA
RBM downscale	To be provided in Technical Specifications	Rod block, annunciator, white light display, RBM ODA
RBM bypassed	Manual switch or peripheral rod selected or APRM reference below 30%	White light display, RBM ODA

(1) RBM is inoperative if module interlock chain is broken, chassis mode switch is not in the OPERATE position, less than 50% of available LPRM signals are above 3% threshold, or internal self-test logic indicates trouble.

NOTE: These values are for unit cycle 6 only. The Core Operating Limit Report specifies these values for each cycle.

Table 7.7-6

ANALYSIS METHODOLOGY

A. Michelson Concern (Reference line failure + single additional failure in a protective channel not dependent on the failed sensing line).

1. Determine the logic for combining channel trips to achieve protective actions.

2. Identify each case where a reactor vessel water level tap or sensing line failure concurrent with an additional random signal electrical failure induces a transient and precludes the automatic operation of a RPS and/or ESF system.

3. For each case identified, demonstrate how the redundancy or diversity of the plant design provides the reactor protection or safety system operation within acceptable limits. Typically, at this point all but one or two cases identified in Step 2 can be eliminated as concerns due to the redundancy of protection and/or ESF systems. For the one or two remaining cases (worst failure combination scenarios), transient analyses are performed to demonstrate that plant safety is not compromised.

4. Where manual action is required by the operators, identify the instrumentation and time available for the operator to take corrective action.

Note: For LGS, which has 4 instrumentation divisions, automatic protection is available under all scenarios so Step 4 is not required.

Table 7.7-7

CHAPTER 8 - ELECTRIC POWER

8.1 INTRODUCTION

8.1.1 GENERAL

The electric power systems of the LGS Units 1 and 2 are designed to generate and transmit electric power into the PJM power network.

The two independent offsite electric power source connections to LGS are designed to provide reliable power sources for plant auxiliary loads and the engineered safeguard loads of both units. An alternate independent, but currently not connected, 13 kV offsite source, available as a potential source, can be connected to supply the engineered safeguard loads of both units in the event of the loss of one of the connected offsite power sources.

The onsite ac electric power system consists of Class 1E and non-Class 1E power systems. The two offsite power systems provide the preferred ac electric power to all Class 1E loads. One source is the 220-13 kV startup transformer in the 220 kV substation. The second source is from a 13 kV tertiary winding of the 220-500 kV bus tie autotransformer in the 500 kV substation. In the event of total LOOP sources, eight onsite independent diesel generators (four diesel generators per unit) provide the standby power for all engineered safeguard loads.

The non-Class 1E ac loads are normally supplied through the unit auxiliary transformer from the main generator. However, during plant startup, shutdown, and postshutdown, power is supplied from the offsite power sources through the 220-13 kV startup transformer and the 220-500 kV bus tie autotransformer.

Onsite Class 1E and non-Class 1E dc systems supply all dc power requirements of the plant.

8.1.2 UTILITY POWER GRID AND OFFSITE POWER SYSTEMS

The Unit 1 and 2 generators are connected by a separate isophase bus to their respective main step-up transformer banks as shown in Drawing E-1. The Unit 1 main step-up transformer bank, with three single-phase power transformers, steps up the 22 kV generator voltage to 242 kV; the Unit 2 bank, with three single-phase power transformers, steps up the 22 kV generator voltage to 500 kV. The 220 kV and 500 kV substations each use a breaker and one-half scheme arranged in an interior main bus hop-over design. Each substation has three elements initially and is arranged for future expansion to four or more elements. Element refers to each bus-to-bus connection and includes the associated disconnect switches, potential transformers, protective relaying, and control systems. The substations are approximately 2150 feet apart and are interconnected by a 500-220 kV bus tie transformer and transmission line. The 500 kV substation feeds two substations on the PECO Energy system, Whitpain and PBAPS North, which are part of the Keystone 500 kV grid. Both the 500 kV and 220 kV substations and the associated transmissions are tied into the PJM Interconnection.

The 13 kV alternate offsite source to LGS is made available from the Limerick 66-13 kV substation. The substation receives bulk power from the Moser and Cromby Stations.

Plant startup power, which is the preferred power for the engineered safeguard systems, is provided from two independent offsite power sources. The power for the engineered safeguard systems can also be provided from the alternate offsite source. The three sources are as follows:

a. 220-13 kV transformer connected to the 220 kV substation

b. A 13 kV tertiary winding on the 500-220 kV bus tie autotransformer

c. 66-13 kV transformer connected to the 66 kV Cromby-Moser tie line

The Perkiomen pumping station receives power from two 33 kV transmission circuits to supply power to the makeup water pumps and their auxiliaries.

The offsite power systems and their interconnections are described in detail in Section 8.2.

8.1.3 ONSITE POWER SYSTEMS

The onsite power system for each unit is divided into two major categories:

a. Class 1E Power System

The Class 1E power system supplies all Class 1E loads and other loads that are needed for safe and orderly shutdown and maintaining the plant in a safe shutdown condition.

The Class 1E power system for each unit consists of four independent channels, A, B, C, and D, which provide power to four divisions of Class 1E loads. With the exception of the ESW system, the RHRSW system, the SGTS, CSCWS and the control room and control structure ventilation systems, which are common systems, any combination of three-out-of-four divisions of Class 1E loads in each unit meets the design basis requirements. Common loads for the ESW and the RHRSW systems are split between the Unit 1 and Unit 2 Class 1E power supplies. Common redundant loads for the SGTS, CSCWS and the control room and control structure ventilation systems are fed from Unit 1 Class 1E power supplies.

Any combination of three-out-of-four divisions (EDGs) is acceptable for a single failure. However, for ECCS requirements (as stated in paragraph 6.3.1.1.2), an EDG operable configuration of 2 out of 4 is also acceptable.

Load division separation is shown in Tables 7.1-4, 7.1-5 and 7.1-6. Electrical channel separation is shown in Table 8.1-1. Physical separation is discussed in Section 8.1.6.1.14.

The Class 1E power system is shown on drawings E-15, E-16, E-28, E-29, E-33, and E-34.

A detailed description of the onsite ac and dc power systems is found in Sections 8.3.1 and 8.3.2, respectively.

b. Non-Class 1E Power System

The non-Class 1E onsite power system supplies electric power to nonsafety-related plant auxiliary loads. The non-Class 1E auxiliary system distributes power at 13.2 kV, 2.3 kV, 440 V, and 208/120 V voltage levels. These distribution levels are grouped into two symmetrical bus systems emanating from the 13.2 kV level as shown in drawing E-1.

Power transmitted to the utility grid is discussed in Section 8.2.

A detailed description of the onsite ac and dc power systems is found in Sections 8.3.1 and 8.3.2, respectively.

8.1.4 SAFETY-RELATED LOADS

The Class 1E loads supplied by the standby ac power system are listed in Table 8.3-3. Class 1E loads supplied by the Class 1E dc system are listed in Tables 8.3-19 through 8.3-26.

8.1.5 DESIGN BASES

The following design bases are applied to the design of the onsite and offsite power systems:

8.1.5.1 Offsite Power System

a. Electric power from the offsite power sources to the onsite distribution system is provided by two physically separated transmission lines designed and located to minimize the likelihood of simultaneous failure.

b. The loss of a generating unit, or the loss of the most critical unit on the power grid, does not result in total LOOP.

c. If there is the loss of one of the offsite power sources, a third separate power source can be connected within a 72 hour period to meet Regulatory Guide 1.93. This source has more than adequate capacity to provide power to the safeguard loads of both units.

8.1.5.2 Onsite Power System

a. One unit auxiliary transformer per generating unit is provided to supply power to the plant electrical auxiliary distribution system.

b. The two offsite sources common to both units are provided to supply offsite power to the safeguard power system. The offsite sources also supply power to their respective plant auxiliary ac loads during plant startup, shutdown, and postshutdown.

c. An alternate offsite power source is provided that can be connected if there is a loss of one of the offsite sources. This alternate offsite source can be connected within 72 hours.

d. A spare safeguard transformer is provided that can be connected if there is a failure of either safeguard transformer.

e. The onsite Class 1E electric power system is divided into four independent divisions per unit. With the exception of the power supply requirements for the ESW system, the RHRSW system, the SGTS, CSCWS and the control room and control structure ventilation systems, which are common systems, any combination of three-out-of-four divisions of Class 1E power in each unit can shut down the unit safely and maintain it in a safe shutdown condition. Common loads for the ESW and RHRSW systems are split between the Unit 1 and Unit 2 Class 1E power systems. Common redundant loads for the SGTS, CSCWS and the control room and control structure ventilation systems are fed from Unit 1 Class 1E power supplies.

   Any combination of three-out-of-four divisions (EDGs) is acceptable for a single failure. However, for ECCS requirements (as stated in paragraph 6.3.1.1.2), an EDG operable configuration of 2 out of 4 is also acceptable.

f. Each unit has four independent dc Class 1E power systems corresponding to the four standby ac power system divisions and one independent dc non-Class 1E power system for the non-Class 1E dc loads.

g. Raceways are not shared by Class 1E and non-Class 1E cables, except where cables feed nonsafeguard equipment from Class 1E buses. Under these conditions, the non-Class 1E cables that are treated and identified as Class 1E are routed through one division of Class 1E raceways exclusively. Sharing of raceways in such cases is not considered to jeopardize the raceway separation, because the cables in such cases are isolated from the buses, by Class 1E isolation devices.

h. Special identification criteria as discussed in Section 8.1.6.1.14 are applied for Class 1E equipment, cabling, and raceways.

i. Separation criteria are established for preserving the independence of redundant Class 1E systems and providing isolation between Class 1E and non-Class 1E equipment.

j. The Class 1E electric systems are designed to satisfy the single failure criterion in accordance with IEEE 379.

k. Class 1E equipment and systems have been designed with the capability for periodic testing.

8.1.6 REGULATORY GUIDES AND IEEE STANDARDS

The design of the offsite power system complies with the requirements of GDC 5, GDC 17, and GDC 18 as discussed in Section 8.2.

Codes and standards applicable to the onsite power system are listed in Table 3.2-1. The design of the onsite power system complies with the requirements of GDC 2, GDC 4, GDC 5, GDC 17, GDC 18, and GDC 50 as discussed in Sections 8.3.1.2.1 and 8.3.2.2.1.

8.1.6.1 Conformance with Regulatory Guides

Conformance with applicable Regulatory Guides 1.6, 1.9, 1.22, 1.29, 1.30, 1.32, 1.40, 1.41, 1.47, 1.53, 1.62, 1.63, 1.73, 1.75, 1.81, 1.89, 1.93, 1.100, 1.106, 1.108, 1.118, 1.128, 1.129, and 1.131 is discussed below.

8.1.6.1.1 Regulatory Guide 1.6 (March 1971) - Independence Between Redundant Standby (Onsite) Power Sources and Between Their Distribution Systems (Safety Guide 6)

The design of the standby power system is in conformance with Regulatory Guide 1.6.

The standby power system consists of four independent divisions per unit. All safety-related loads are divided among the divisions so that loss of any one division does not prevent the minimum safety functions from being performed. Each division consists of both standby ac and dc power systems.

The ac loads of each division have connections to two independent offsite power supplies and to a single onsite diesel generator. The power feeder breakers to each division are interlocked so that only one of the power supplies can be connected at any one time, except during the diesel generator load test where the diesel generator is synchronized to one of the preferred offsite power sources. Only one diesel generator is tested at a time.

Each diesel generator is exclusively connected to the corresponding division. When operating from the standby sources, the diesel generator of one division cannot be paralleled, either manually or automatically, with the diesel generator of another division.

The dc power system of each unit consists of four division dc systems; two 125/250 V, 3-wire systems; and two 125 V, 2-wire systems. Each division is energized by its own batteries and chargers. The battery charger is supplied by its corresponding Class 1E ac power system. The dc power system of any one division is independent of any other dc power system.

8.1.6.1.2 Regulatory Guide 1.9 (March 1971) - Selection of Diesel Generator Set Capacity for Standby Power Supplies (Safety Guide 9)

The standby diesel generator capacities are in compliance with this edition of Regulatory Guide 1.9. Revisions 1 and 2 of the guide are not applicable to LGS as discussed in Section 1.8.

The continuous or the 2000 hour rating of the standby diesel generators is greater than the sum of conservatively estimated loads needed to be supplied following any design basis event. Load requirements are listed in Table 8.3-2.

The standby diesel generators are capable of starting and accelerating all engineered safeguard loads to the rated speed within the time and in the sequence shown in Table 8.3-1. They are capable of maintaining, during the steady-state and loading sequence, the frequency and voltage above a level that may degrade the performance of any of the loads below their minimum requirements. The standby diesel generators are capable of recovering from transients caused by step load increases or resulting from the disconnection of a partial or full load. Specifically, the standby diesel generators are designed to maintain frequency and voltage to not less than 95% and 75% of nominal, respectively, following a step load change. The frequency and voltage are restored to within 2% and 10% of nominal, respectively, within 60% of each load sequence time interval except for the time interval (3 seconds) between the RHR pump motor start and the load center breaker closure. However, during the preoperational tests, these loads started, accelerated, and operated successfully. In addition, during the recovery from transients caused by step load increases or

resulting from the disconnection of the largest single load, the speed of the diesel generator will not exceed 75% of the difference between the nominal speed and the overspeed trip setpoint or 115% of nominal, whichever is lower.

8.1.6.1.3 Regulatory Guide 1.22 (February 1972) - Periodic Testing of Protection System Actuation Functions (Safety Guide 22)

Refer to Section 7.1.2.5 for discussion of this guide.

8.1.6.1.4 Regulatory Guide 1.29 (February 1978) - Seismic Design Classification

The electrically related structures, systems, and components of this plant are in compliance with Regulatory Guide 1.29, except for paragraph C.1.m concerning the CRD manual control. Seismic design classification is discussed in Section 3.2.1.

8.1.6.1.5 Regulatory Guide 1.30 (August 1972) - Quality Assurance Requirements for the Installation, Inspection, and Testing of Instrumentation and Electric Equipment (Safety Guide 30)

The guidelines of ANSI N45.2.4 (1972) [IEEE 336 (1971)], as endorsed by this regulatory guide, have been met by the quality assurance program for the installation of safety-related items, although the standard is not specifically referenced in the constructor's quality assurance procedures. For QA during construction see the document "Limerick Generating Station Units 1 and 2; Summary Description of the Quality Assurance Program for Design and Construction," referenced in FSAR Section 17.1.

Conformance to the guide during plant operation is discussed in Section 17.2.

8.1.6.1.6 Regulatory Guide 1.32 (February 1977) - Criteria for Safety-Related Electric Power Systems for Nuclear Power Plants

All safety-related electric systems are in compliance with Regulatory Guide 1.32, except as it refers to Regulatory Guide 1.75, which is discussed in Section 8.1.6.1.14. The portions of Regulatory Guide 1.32 applying to offsite power and dc power are discussed in Sections 8.2 and 8.3.2, respectively.

IEEE 308 (1974), "IEEE Standard Criteria for Class 1E Power Systems for Nuclear Power Generating Stations" is generally accepted by Regulatory Guide 1.32.

Class 1E ac power systems are designed to ensure that any design basis event, as listed in table 1 of IEEE 308, does not cause either loss of electric power to more than one division, surveillance device, or protection system that could jeopardize the safety of the reactor unit; or transients in the power supplies, which could degrade the performance of any system.
Controls and indicators for the Class 1E 4 kV bus supply breakers are provided in the control room and on the switchgear. Controls and indicators for the standby ac power supplies are also provided in the control room and on the local diesel generator control panels. Control and indication for the standby power system is described in Section 8.3.1.

Class 1E equipment is distinctly identified in the field and in associated design, operating, and maintenance documents. Physical identification is described in Section 8.3.1.3.

Class 1E equipment is qualified by analysis, by successful use under required conditions, or by actual testing to demonstrate its ability to perform its function under any applicable design basis events.

The surveillance requirements of IEEE 308 are followed in design, installation, and operation of Class 1E equipment and consist of:

a. Preoperational equipment tests and inspections are performed in accordance with the requirements described in Chapter 14, with all components installed. These tests and inspections demonstrate:

   1. All components are correct and are properly mounted.

   2. All connections are correct, and circuits are continuous.

   3. All components are operational.

   4. All metering and protective devices are properly calibrated and adjusted.

b. Preoperational system tests are performed in accordance with the requirements described in Chapter 14, with all components installed. These tests demonstrate that the equipment operates within design limits and that the system is operational and meets its performance specifications. These tests also demonstrate:

   1. The Class 1E loads can operate on the preferred power supply.

   2. The loss of the preferred power supply is detected.

   3. The standby power supply is started and accepts design load in the sequence and time duration shown in Table 8.3-1.

   4. The standby power supply is independent of the preferred power supply.

c. Periodic equipment tests are performed at scheduled intervals in accordance with the requirements of Chapter 16 to detect the deterioration of the equipment toward an unacceptable condition, to demonstrate that standby power equipment and other components that are not running during normal operation of the station are operable, and to demonstrate the operational readiness of the system.

The standby ac power supplies are not shared by the two units. The standby capacity of each unit is sufficient to operate the engineered safeguard loads following a DBA on that unit.

The two preferred offsite power supplies are shared by both units. The capacity of each offsite power supply is sufficient to operate the loads required for safe shutdown of both units with a LOCA in one unit and a simultaneous safe shutdown of the other unit.

Battery testing is described in Technical Specifications.

8.1.6.1.7 Regulatory Guide 1.40 (March 1973) - Qualification Tests of Continuous-Duty Motors Installed Inside the Containment of Water-Cooled Nuclear Power Plants

Limerick complies with the intent of Regulatory Guide 1.40. Refer to Section 3.11.4 for a discussion of qualification testing.

8.1.6.1.8 Regulatory Guide 1.41 (March 1973) - Preoperational Testing of Redundant Onsite Electric Power Systems to Verify Proper Load Group Assignments

The preoperational testing program is described in Chapter 14, and is in conformance with Regulatory Guide 1.41 except as may be modified by the general statement on regulatory guides in Section 14.2.

The onsite Class 1E electric power system, designed in accordance with Regulatory Guide 1.6 and Regulatory Guide 1.32, is tested as part of the preoperational testing program and also after major modifications. The tests are performed in accordance with the requirements outlined in Chapter 14. These tests verify the independence between the redundant onsite power sources and their loads.

The onsite Class 1E electric power system is tested functionally, one division at a time, by allowing one division to be powered only by its associated diesel generator while the bus is isolated from the preferred offsite power source. The offsite power source is isolated by direct actuation of undervoltage relays monitoring the safeguard system.

A safety injection signal is simulated to start the diesel generators and initiate automatic sequencing. Functional performance of the loads is checked. Each test is of sufficient duration to achieve stable operating conditions, thus permitting the onset and detection of adverse conditions that could result from improper assignment of loads.

Testing of each division is performed to indicate that no interconnection of the divisions exists. The buses and loads of the division under test are monitored to verify absence of voltage on these buses and loads while the remaining redundant divisions are energized.

8.1.6.1.9 Regulatory Guide 1.47 (May 1973) - Bypassed and Inoperable Status Indication for Nuclear Power Plant Safety Systems

The design of this plant is in compliance with Regulatory Guide 1.47, as follows:

a. An annunciator system is provided in the control room to automatically indicate, at the system level, the bypass or deliberately induced inoperability of the protection system, its auxiliary or supporting systems, and the systems actuated or controlled by the protection system.

b. Indication lights are used to indicate any bypass or inoperability status of components in the systems described in Item (a) above.

c. Manual capability to activate each system level annunciator is provided in the control room. Additional discussion is provided in Section 7.1.2.5.

8.1.6.1.10 Regulatory Guide 1.53 (June 1973) - Application of the Single Failure Criterion to Nuclear Power Plant Protection Systems

The design of the electric power systems complies with the position statements of this regulatory guide.

Consistent with the single failure criterion, only one failure is assumed to occur in the system following a design basis event. No single component failure results in the simultaneous loss of ac power to the four divisions. A single failure cannot propagate to another load division.

Cables and raceways of different channels are physically separated in accordance with the provisions of Regulatory Guide 1.75, as discussed in Section 8.1.6.1.14.

8.1.6.1.11 Regulatory Guide 1.62 (October 1973) - Manual Initiation of Protective Actions

The LGS design is in conformance with Regulatory Guide 1.62, as follows:

a. Manual initiation of each protective action is provided at the system level.

b. Manual initiation of a protective action at the system level performs all actions performed by automatic initiation.

c. The switches for manual initiation of protective actions at the system level are located in the control room.

Further details for controls and instrumentation are provided in Section 7.1.2.6.

8.1.6.1.12 Regulatory Guide 1.63 (October 1973 and July 1978) - Electric Penetration Assemblies in Containment Structures for Water-Cooled Nuclear Power Plants

The design of electric penetration assemblies is in compliance with Revision 0 (10/73) of Regulatory Guide 1.63, which endorses and amends IEEE 317 (1972), "IEEE Standard for Electric Penetration Assemblies in Containment Structures for Nuclear Power Generating Stations." Compliance with Revision 2 (7/78) of Regulatory Guide 1.63, which endorses IEEE 317 (1976), is also discussed in this section.

In accordance with Regulatory Guide 1.63, the electrical penetration assemblies are designed to withstand, without loss of mechanical integrity, the maximum fault condition versus time conditions that could occur as a result of a single random failure of circuit overload devices. The circuit breakers used for primary and backup protection are checked preoperationally and calibrated for time-overcurrent and instantaneous performance. These breakers, both Class 1E and non-Class 1E, will be checked periodically to ensure that their tripping characteristics have not changed. The fuses used for primary and backup protection are checked preoperationally for continuity and for proper model and size. The following system features are provided to ensure compliance with the regulatory guide:

a. Medium Voltage System

The only medium voltage loads in the primary containment are two variable-frequency reactor recirculating pump motors. Each recirculation pump motor is fed by an ASD which is capable of providing up to 4 kV. The ASDs are located in the turbine enclosure.

To protect the penetration assemblies, two redundant Class 1E circuit breakers are used in series to provide the required primary and backup protection. Separate divisions of 125 V dc control power are used for the operation of these breakers. Tripping signals for these primary and backup breakers are independent, physically separated, and powered from separate sources.

The mechanical integrity of the penetration assemblies is maintained under the most severe fault condition, including the most severe fault condition.

b. 440 V System

In addition to the primary circuit breaker or primary circuit breaker with thermal overload relay, a backup breaker located in the same MCC cubicle is connected in each circuit to provide backup protection of the penetration assemblies. For all such Class 1E circuits, the primary and backup breaker overload and short-circuit protection systems are qualified for the environmental conditions. For all non-Class 1E circuits that penetrate into the containment, two breakers are connected in series to provide primary and backup protection. These non-Class 1E breakers are identical in design and construction to that of Class 1E breakers, thereby assuring high reliability.

Typical time-current characteristics of these protective devices indicate that the penetration assemblies can withstand the available fault current for the time duration required to trip either or both the primary and backup circuit breakers.

c. 208 V and Lower Voltage Systems

The low voltage control circuits powered from control power transformers are self-limiting in that the circuit resistance and/or short-circuit capability limits the fault current to a level that does not damage the penetration assemblies. The maximum initial fault current available from the control circuit transformers at the penetration assembly is as follows:

Transformer Size	Maximum Initial Fault Current
120 VA	15.1 A
200 VA	40.6 A

The minimum conductor size for control circuits powered from control power transformers through the electrical penetrations is #12 AWG. The maximum fault current values indicated above are initial fault current values. The final short circuit values are less than these values due to increased resistance of conductor and control power transformer at elevated temperature caused by the short circuit. A #12 AWG conductor can withstand 41A for a duration of 1000 hours. The final value of the short circuit current after taking increased resistance of cable and transformer is 35A. The smallest wire size used in control circuits is #14 AWG. PECo Test Report 48503 shows that a #14 AWG wire can carry 75 A continuously without insulation breakdown. Based on the above, it is concluded that both the conductor through the penetration and the remainder of the control circuit can carry the maximum fault current developed by the control circuit transformers.

The remaining control and power circuits have a primary and backup fuse or breaker to ensure fault isolation. Typical time-current characteristics of these protective devices substantiate that the penetration assemblies can withstand the available fault current for the time duration required to trip either or both the primary and backup circuit breakers/fuses.

Field cables inside containment are connected to the containment penetration conductors in terminal boxes located next to the penetration. The method for connecting field cables to the penetration conductors is as follows:

1. Medium Voltage Power Penetration

   The terminal lug on the field cable is bolted to the penetration connector assembly. The terminal lug and the connector assembly are then covered by heat shrink tubing. These are non-Class 1E terminations.

2. Low Voltage Power, Control and Instrumentation, Thermocouple and Low Level Signal

   i. For penetration conductors that are 250 MCM, the terminal lugs on the penetration conductors and field cables are bolted and then covered by heat shrink tubing.

   ii. For all other cases, the penetration conductors and field cable are spliced by in-line barrel splice connectors covered by heat shrink tubing.

3. Control Rod Drive Penetration

   Field cables and penetration conductors are terminated by circular pin connectors. These are non-Class 1E terminations. The failure of the circular pin connectors will not degrade the containment pressure boundary integrity because the circular pin connectors do not form part of the pressure boundary.

4. Neutron Monitoring Penetration

   i. Field coaxial cables to penetration coaxial conductors are connected by coaxial connectors covered by heat shrink tubing.

   ii. Field coaxial cables to penetration #16 AWG conductors are spliced by in-line barrel splice connectors covered by heat shrink tubing.

All splices discussed in (2) and (4) are qualified to withstand a LOCA or steam line break accident. Supportive documentation that confirms the qualification of the splices is included in the LGS EQR.

d. Instrument Systems

The overload and short-circuit capability in the instrument systems are sufficiently low so that no damage can occur to the penetration assemblies.

Figures 8.1-2 through 8.1-5 provide time-current curves for penetrations in use at LGS. These curves include I^2t penetration and cable rating curves for instantaneous, long and short time overcurrent trips provided by primary and backup protective devices. In addition these curves include circuit configuration.

The LGS purchase order for electrical penetrations was issued on January 15, 1974, which precedes the issuance of Revisions 1 (5/77) and 2 (7/78) of the guide and the issuance of IEEE 317 (1976) as endorsed by these revisions of the guide. Therefore, LGS did not use the latest revisions of the guide.

However, the LGS electrical penetrations are in conformance with Regulatory Guide 1.63 (Rev 2 - 7/78), except as discussed and clarified by the following:

a. Rated Short-Circuit Current and Duration

The rated short-circuit current and duration for the electrical penetrations are based on maximum available fault currents, which were calculated using methods accepted by the industry, and on required breaker clearing time. The penetration manufacturer performed tests that were more severe than LGS service requirements. However, the latest revision of the guide requires that the short-circuit current must be based on the symmetrical current being initially fully offset by a dc component having a decrement based on specified x/r ratios. This was not specified for the LGS electrical penetrations and therefore not verified by the manufacturer.

b. Test Margins

The test parameters that were specified for qualification testing were conservative as compared to the maximum possible service conditions. In addition, the manufacturer exceeded these parameters in the conservative direction during qualification testing. Test margins according to IEEE 317 (1976) were not specified for the LGS penetrations.

c. Materials Flammability

All nonmetallic materials are required to be classified by testing as "nonburning" or "self-extinguishing" as defined by IEEE 317. An adhesive used on the interior of some types of shrink tubing used in the penetrations is flammable. It is noted that the use of this adhesive in a splice as used by Conax has been qualified by test to the flame test requirements of IEEE 383 (1974). The adhesive used in a splice is protected by the shrink tubing and, except for a small portion that oozes from the ends of the splice, is not exposed to air or open flames. The latent heat content of the exposed adhesive is much less than in an ordinary wooden match. The small amount that is present and its slow-burning characteristic mean that it could not be a significant source of flame or fire damage. This adhesive is a small amount of combustible material surrounded by a relatively large amount of noncombustible and self-extinguishing material. Therefore, it does not constitute a hazard.

d. Thermal Aging

To demonstrate that the assembly will survive an accident condition the prototype assembly was qualified by accelerated thermal aging equivalent to a 40 year plant life in the normal service environment, in accordance with IEEE 317 (1972). IEEE 317 (1976) and Regulatory Guide 1.63 require accelerated thermal aging tests in accordance with IEEE 98 and IEEE 101, at a minimum aging time of 5000 hours.

e. Type Tests

LGS penetration assembly prototype tests conform to IEEE 317 (1972). IEEE 317 (1976) as amended by the guide contains the following requirements, which were not considered for LGS penetration assembly prototype tests:

1. Specified sequence of required tests

2. Impulse withstand test on medium voltage power conductors

3. Partial discharge (corona) test

4. Cycling and aging test as related to shipping, storage, welding, and thermal cycling

5. Seismic tests in accordance with IEEE 344 (1975)

8.1.6.1.13 Regulatory Guide 1.73 (January 1974) - Qualification Tests of Electric Valve Operators Installed Inside the Containment of Nuclear Power Plants

Selection of electric valve operators for use inside the containment is in compliance with Regulatory Guide 1.73.

The electric valve operators for service inside the containment are tested in accordance with IEEE 382 (1972), as modified by Regulatory Guide 1.73. The tests consist of aging, seismic, and accident or other special environmental requirements. Test parameters are discussed in Section 3.11.2.

8.1.6.1.14 Regulatory Guide 1.75 (September 1978) - Physical Independence of Electric Systems

The requirements of Regulatory Guide 1.75 are met, except as discussed and clarified below. The regulatory guide endorses the IEEE 384 (1974), "IEEE Trial Use Standard Criteria for Separation of Class 1E Equipment and Circuits," subject to the additions and clarifications delineated in section C of the guide.

a. General Separation Criteria

1. Required Separation

Electrical equipment and wiring for the engineered safeguard system and the RPS are segregated into separated channels/divisions as shown in Tables 7.1-4, 7.1-5, 7.1-6 and 8.1-1, so that no single credible event is capable of disabling sufficient equipment to prevent reactor shutdown, removal of decay heat from the core, or isolation of the primary containment if there is an accident. The engineered safeguard system and RPS are separated from

each other, and each is further separated into four channels/divisions. Separation requirements apply to control and instrument power and motive power for all systems concerned. The degree of separation required varies with the potential hazards in a particular area.

Arrangement and/or protective barriers ensure that no locally generated force or missile can destroy redundant portions of the engineered safeguard system and/or RPS.

The arrangement of wiring is designed to eliminate, insofar as is practicable, all potential for fire damage to cables and to separate the engineered safeguard or RPS channels/divisions so that fire in one division does not propagate to another division.

Equipment and circuits requiring separation are identified on documents and drawings in a distinctive manner.

2. Methods of Separation

The separation of circuits and equipment is achieved by separate safety class structures, distance, or barriers, or combination thereof.

The following isolation devices are used at LGS to provide isolation between Class 1E and non-Class 1E circuits:

(a) 4 kV circuit breakers

(b) 480 V circuit breakers

(c) 480 V motor starters

(d) Auxiliary relays

(e) Optic isolators

(f) Control switches

(g) Voltage transducers

(h) Electronic isolation amplifiers

(i) Electronic, magnetically coupled signal isolators

(j) Electronic, magnetically coupled signal converters

The circuit breakers and motor starters are qualified to perform an isolation function through prototype tests performed to NEMA and ANSI standards. In addition, the devices are qualified for seismic and environmental conditions in accordance with NUREG-0588 as discussed in Sections 3.10 and 3.11.

The auxiliary relays used as isolation devices are listed in section I.C. of Reference 8.1-1. The devices were tested for both overvoltage and overcurrent isolation. The test results are given in section 5.4 of the test report.

Optic isolators are seismically and environmentally qualified. The fiber optic cable inherently isolates the Class 1E input from the non-Class 1E system at the receiving end of the cable.

Isolation via qualified electronic magnetically coupled signal isolators and converters is achieved in various system applications such as RCIC. The magnetic coupling of component's input and output signals provides a high degree of passive isolation of damaging fault conditions.

Control switches are seismically qualified and located in a mild environment. The manufacturer's test data on breakdown voltages and current interrupting capacity of the contacts are used to determine the adequacy of the device for isolation purposes.

The voltage transducers are seismically qualified and located in a mild environment. They have been tested and accepted as isolation devices.

3. Compatibility with Mechanical Systems

The separation of Class 1E circuits and equipment ensures that the required independence is not compromised by the failure of mechanical systems served by the Class 1E systems. For example, Class 1E circuits are routed and/or protected so that the failure of related mechanical equipment of one redundant system cannot disable Class 1E circuits or equipment essential to the operation of the other redundant system(s).

4. Associated Circuits

Associated circuits are not uniquely identified as such. These circuits are treated and identified as Class 1E up to an isolation device and are isolated on a LOCA signal, with the following clarifications and exceptions:

(a) When relays and other devices are used as isolation devices between Class 1E and non- Class 1E circuits, the 6 inch separation

requirement at the device terminals is not maintained in accordance with IEEE 384 (1974), section 4.6.1. The basis for not providing 6 inches of separation at the device terminals is based on test results given in section 5.4 of the above mentioned test report, which shows that no separation is required between wires terminating on isolation relays.

(b) All feeders to non-Class 1E 4 kV motor loads and to all non-Class 1E 440 V MCCs that are fed from Class 1E buses are treated and identified as Class 1E even beyond the isolation device. However,

these loads are tripped in the event of a LOCA in the unit they are associated with and are routed in dedicated Class 1E raceways. They do not become associated with any other Class 1E division. The non-Class 1E motor loads that are fed from the Class 1E buses are in full compliance with IEEE 384 (1974), section 4.5.(2). The isolation device is the Class 1E 4 kV circuit breaker. The cable schemes associated with these breakers are Class 1E and are routed as such. Where these cables enter equipment, they are treated as non-Class 1E for separation purposes. These cables are isolated on an accident signal; therefore, they may be treated as non-Class 1E in accordance with IEEE 384 (1981).

(c) The public address and fire alarm panel that feeds non-Class 1E loads is fed from a Class 1E bus. This panel is not tripped on LOCA, because intentional disconnection of the fire alarm system is a violation of the National Fire Code and is considered unacceptable for plant safety. The distribution transformer and panel are qualified and seismically supported to Class 1E criteria. All circuits originating from this panel are run in conduits that contain only PA or fire alarm system wiring. All circuits originating from this panel are protected by thermal magnetic circuit breakers in the panel. In addition, the 440 V feed to the transformer is protected by a molded-case circuit breaker in the motor control center. Each of these circuit breakers is qualified and purchased as Class 1E; therefore, two Class 1E isolation devices exist between the non-Class 1E public address and fire alarm circuits and the Class 1E 440 V bus.

(d) Several non-Class 1E drywell cooler fan motors located inside the drywell are fed from a Class 1E bus, and the cabling is routed as Class 1E. The non-Class 1E RPS/UPS inverters are fed from a Class 1E dc bus, and the cabling is routed non-Class 1E. Two Class 1E circuit breakers are provided for redundant overcurrent protection on each of these circuits. These breakers provide isolation between the non-Class 1E load and the Class 1E bus and will be periodically tested. The non-Class 1E RCIC barometric condenser vacuum pump, RCIC vacuum tank condensate pump, HPCI vacuum tank condensate pump, and HPCI gland seal condenser vacuum are fed from a Class 1E bus, and the cabling is routed as Class 1E. Two class 1E fuses are provided on both the positive and negative feeds for redundant overcurrent protection. The non-Class 1E H2-O2 analyzers are fed from a Class 1E AC bus. Two Class 1E fuses are provided on each phase of the circuit for redundant overcurrent protection. The H2-O2 analyzers' cabling is routed as Class 1E up to the fuses, which are installed locally near the analyzers. The cabling downstream of the fuses is non-Class 1E. These loads are not automatically isolated on a LOCA signal.

(e) In several cases, redundant Class 1E overcurrent devices (e.g., fuses or breakers) are provided in series for isolation between Class 1E power sources and non-Class 1E instrumentation and controls.

5. Non-Class 1E Circuits

Non-Class 1E circuits are separated from Class 1E circuits by the separation requirements specified in Section 8.1.6.1.14.b. Non-Class 1E 440 V loads that are fed from Class 1E MCCs use a shunt trip device on the MCC breaker or a trip logic in the combination starter controls to isolate the circuit on a LOCA signal from the unit from which they are powered. These circuits are treated as non-Class 1E from the MCC to the load and control devices or they are routed as Class 1E only in the division with which they are associated.

6. Class 1E Circuits

Class 1E circuits are separated from Class 1E circuits of a different channel/division as described in items a.1, a.2, and a.3 above, except as discussed and clarified below.

The RCIC steam supply line inboard containment isolation valve is provided with a manually actuated power transfer switch which allows manual transfer from the valve's normal Division 3 source to an emergency Division 1 source. Physical independence is not maintained when the manual transfer switch is actuated to the emergency position because the valve's power and control cables, which are identified and routed as Division 3, are powered from Division 1 in this situation. The manual transfer switch enables this valve to be powered and controlled from a Division 1 emergency source in order to permit the valve to be opened in the event of a fire that requires the RCIC system for safe shutdown but which has caused the valve to spuriously close with subsequent loss of Division 3 ac power.

The manual transfer switch consists primarily of two molded-case circuit breakers with an interconnecting mechanical linkage that allows closure of only one breaker at a time. Qualification of the manual transfer switch ensures that the switch is capable of performing its safety function and/or remaining in a safe mode under all conditions postulated to occur during its installed life. Locking closed the door of the terminal box in which the manual transfer switch is located, locking open the Division 1 feeder breaker, and maintaining the keys to these locks under administrative control assures that control of the manual transfer switch and the Division 1 feeder breaker is limited to, aside from testing, operator discretion only in the event of a fire with concurrent loss of Division 3 ac power.

In addition, plant procedures require that:

(a) The valve be controlled from the remote shutdown panel with the remote shutdown panel transfer switch in the emergency position when using Division 1 power. This limits the interconnection of Division 3 circuits with Division 1 power to the MCC, the remote

shutdown panel and interconnecting wiring. Control complex wiring and circuits will not be involved.

(b) Division 3 power shall always be removed from the manual transfer switch (by opening one of the two circuit breakers in Division 3) before Division 1 power is connected and Division 1 power shall always be removed from the manual transfer switch (by opening one of the two circuit breakers in Division 1) before Division 3 is reconnected. This limits the number of power divisions connected to the manual transfer switch at any time to one.

Annunciation and indication of the manual transfer switch in the emergency position meets the requirements of Regulatory Guide 1.47. Testing of the manual transfer switch is limited to operating conditions 4 and 5 as defined by the Technical Specifications. Limiting the testing of the manual transfer switch to those operating conditions when the reactor is at low pressure provides adequate assurance that any potential consequence which might arise due to these Division 3 power and control cables becoming energized from a Division 1 source could not affect the operability of the minimum number of operable ac power sources specified by the Technical Specifications for these operating conditions.

b. Specific Separation Criteria

1. Cables and Raceways

The minimum separation distances for raceways are given in paragraphs 4 and 5 below. The following general criteria apply to all cable installations:

(a) Cable splices in raceways are prohibited. Cable splices are only made in manholes, boxes or suitable fittings. Splices in cables passing through the containment penetration assemblies are made in terminal boxes located next to the assemblies.

(b) Cables and raceways are flame retardant.

(c) The design basis is that the cable trays are not filled above the side rails. Tray fill for control cable trays and instrumentation cable trays is 50% maximum, i.e., the cross-sectional area of the cable in the tray will not exceed 50% of the available cross-sectional area of the tray, and 40% maximum for cable trays containing power cables. If tray fill exceeds the above stated maximum fill, tray fill is justified and documented.

(d) Some RPS cables are routed in ESF raceway. These cables are identified as RPS and routed in steel flexible conduit in accordance with GE design requirements. This installation is acceptable because flexible conduit provides the required system fail-safe protection and because none of the RPS cables are redundant to the ESF cables located in the same raceway.

2. Identification of Non-PGCC Cables and Raceways

Exposed Class 1E raceways are identified in a distinct and permanent manner at intervals not to exceed 15 feet. In addition, these raceways are also identified where they pass through walls and/or floors. Class 1E raceways are identified before the installation of their cables.

Cables installed in cable trays are identified at intervals not exceeding 5 feet, to facilitate initial verification that the installation conforms to the separation criteria. These cable identifications are applied before or during their installation.

Class 1E cables are identified by a permanent marker at each end in accordance with the design drawings or cable schedule.

Color coding is used to meet the above requirements and to distinguish between Class 1E systems and between Class 1E and non-Class 1E systems. The coding precludes the need to consult any reference material to distinguish between redundant Class 1E and between Class 1E and non-Class 1E systems.

Panel internal wiring is marked with its connection diagram identity at each point of termination.

3. Identification of PGCC Cables and Raceways

Cables run in the floor sections are color banded every ten feet. The longitudinal floor ducts of the power generation control complex are marked with color coded raceway markers on the top of the steel side beam. The cables contained in each duct are generally of one division only. A cable of one division may be run in the duct of another division only if it is run in flexible steel conduit. Because of the congestion of these ducts, only the top several cables are visible when the floor cover is removed.

The purpose of the requirement of IEEE 384 to color code cables every five feet is to aid in the installation of these cables to ensure that they are pulled into the correct raceway. Cable installation has been performed to approved quality control procedures and in accordance with the system cable routing document provided by GE.

Based on the above, we believe that no increase in plant safety would be achieved by marking the cables in the power generation control complex floor every five feet and that the present ten foot interval meets the intent of IEEE 384.

4. Cable Spreading Room/Control Complex

The control complex consists of control room, cable spreading room, and auxiliary equipment room. The auxiliary equipment room mainly consists of relay panels and terminal cabinets integrated with module-type floor sections, with lateral and longitudinal ducts that are used as raceways and barriers.

This module-type assembly, which is the PGCC, is covered separately in paragraph 6.

The control complex does not contain high energy equipment (such as switchgear and transformers) or potential sources of missiles or pipe whip and is not used for storing flammable materials.

Circuits in the cable spreading room and control room are limited to control functions, instrument functions, and those power supply circuits and facilities serving the control room. Power supply feeders to distribution panels are installed in enclosed raceways that qualify as barriers. The circuits passing through the cable spreading room are limited to 120/208 V ac and 250 V dc, except for lighting feeder circuits in the cable spreading area. The lighting feeder circuits are 277 V ac, but are routed in conduits used explicitly for lighting.

The minimum separation distance between the redundant Class 1E cable trays is 1 foot horizontally and 3 feet vertically. Where a 1 foot horizontal separation is not possible, lesser separation is justified by test and analysis or one of the following barrier arrangements is used: a flame retardant barrier is placed between the redundant cable trays and extends 1 foot above the trays or to the ceiling; or cables are installed in totally enclosed raceways up to a point where the minimum horizontal separation justified by test and analysis is met. Where cable trays of redundant channel/divisions must be stacked one above the other with less than 3 feet vertical spacing, lesser separation is justified by test and analysis or one of the following barrier arrangements is used: a flame retardant barrier is placed between the trays and extended to 6 inches beyond each side of the tray system or to the wall; or the cables are installed in totally enclosed raceways to a point where the minimum vertical separation justified by test and analysis is met. Where a crossover of one tray over another carrying a redundant channel/division is made, and minimum vertical separation distance (as determined by test and analysis) cannot be maintained, either fire barriers are installed between the trays extending a minimum of 1 foot beyond the crossing tray or cables are installed in enclosed raceway extending a minimum of one foot beyond the intersection. Separation requirements between Class 1E and non-Class 1E circuits are the same as for separation of redundant channel/divisions except where justified by test and analysis.

In general, a minimum separation of 1 inch is maintained between redundant enclosed raceways and between Class 1E and non-Class 1E enclosed raceways except in those cases where lesser separation is justified by test and analysis.

The separation provided between a totally enclosed raceway and a cable tray is the same as that provided between redundant cable trays except where lesser separation is justified by test and analysis.

The minimum separation required between redundant Class 1E dropout cables or between Class 1E and non-Class 1E dropout cables is one foot

horizontal and 3 feet vertical except in those cases where lesser separation has been justified by test and analysis. Dropout cables are defined as any cable length not routed within a raceway. In cases where the minimum separation criteria justified by test and analysis cannot be met, dropout cables are wrapped with a fiberglass sleeving to the point where the minimum separation criteria is achieved.

The test results and analysis contained in Wyle Laboratories Test Report 46960-3 are the basis for the lesser raceway and dropout cable separation referenced in paragraphs 4 and 5. The separation criteria derived from this analysis are contained in LGS drawing 8031-E-1406, section 2.0.

5. General Plant Areas

In plant areas where potential hazards such as missiles and pipe whip are excluded, the separation distance between redundant Class 1E cable trays is 3 feet between trays separated horizontally, if no physical barrier exists between trays. If a horizontal separation of less than 3 feet exists, alternate methods as stated in paragraph 4 above are required. Vertical stacking of trays is avoided wherever possible; however, where cable trays of redundant channel/divisions are stacked, a vertical separation distance of 5 feet is required, or alternate methods as stated in paragraph 4 above are required. Where a crossover of one tray over another carrying a redundant channel/division is made, and the minimum vertical separation distance as determined by test and analysis cannot be maintained, either fire barriers are installed between the trays extending a minimum of 3 feet beyond the crossing tray or cables are installed in enclosed raceway extending a minimum of 3 feet beyond the intersection.

Separation requirements between Class 1E and non-Class 1E circuits are the same as for separation of redundant channel/divisions except where justified by test and analysis.

The separation requirements between totally enclosed raceways and between a totally enclosed raceway and a cable tray are the same as stated in paragraph 4 above.

The minimum separation required between redundant Class 1E dropout cables or between Class 1E and non-Class 1E dropout cables is 3 feet horizontal and 5 feet vertical except in those cases where lesser separation has been justified by test and analysis. In cases where the minimum separation criteria justified by test and analysis cannot be met, dropout cables are wrapped with a fiberglass sleeving to the point where the minimum separation criteria are achieved.

NMS cables located in the subpile room under the RPV are exceptions to these separation criteria. These cables are separated and routed in flexible conduit in this room wherever possible, but they may touch wherever necessary due to spatial limitation. Cables of different NMS divisions in this

room are not bundled together where they are not in flexible conduit. Bundling of stainless steel jacketed LPRM cables is permitted.

6. Power Generation Control Complex

Detailed design basis, description, and safety evaluation aspects for the PGCC system are documented and presented in Reference 8.1-2. The separation criteria used for the internal panel wiring of the PGCC are given in Section 8.1.6.1.14.b.9.

Series-connected redundant protective devices are not required to clear faults internal to flexible conduit or to prevent overheating of adjacent cables. All flexible conduits in the power generation control complex are positively grounded to panel steel and were checked to ensure that the resistance to ground on the conduit is less than 4 ohms at all points. The probability of the failure of a single fuse to clear a fault was given in WASH-1400, appendix III, table III.2-1, as $3x10^{-5}$ to $3x10^{-6}$, which shows that this scenario is an extremely low probability event. In addition, the test results presented in section 5.3.2 of the above mentioned test report show that the damage of adjacent essential cables due to an uncleared internal conduit fault is not a credible event. For this reason, it is not necessary to install redundant overcurrent devices in circuits that run in flexible conduit.

7. Power Supply

(a) Standby Diesel Generators

Standby diesel generators are housed in separate compartments within a seismic Category I structure. The auxiliaries and local controls of each unit are housed in the same compartment as the unit they serve.

(b) DC System

Redundant Class 1E batteries and their associated chargers are located in separate compartments within a seismic Category I structure. Each battery room is exhausted by an individual ventilation duct to a common exhaust plenum. Two redundant Class 1E axial flow exhaust fans service the common exhaust duct-work.

Also, the battery chargers of redundant load groups are physically separated in accordance with the requirements of Regulatory Guide 1.75.

(c) AC Distribution System

All redundant Class 1E switchgear, MCCs, and distribution panels are physically separated in accordance with Regulatory Guide 1.75.

8. Penetrations

Redundant Class 1E containment electrical penetrations are dispersed around the circumference of the containment and are physically separated in accordance with the requirements of section 5.5 of IEEE 384 (1974). In general, non-Class 1E and RPS circuits are not routed in penetrations containing Class 1E circuits. Where Class 1E, RPS and non-Class 1E circuits are routed in the same penetration, separation is maintained by routing the cables in flex conduit or fiberglass sleeving up to the penetration feedthrough. Class 1E, RPS and non-Class 1E wiring are not routed through common feedthroughs. The feedthrough steel casing forms the separation barrier between Class 1E feedthrough of different divisions and between Class 1E and non-Class 1E feedthroughs and between ESF and RPS feedthroughs. Two divisions of Class 1E RTD wiring are also routed through the suppression pool penetration in this manner to maintain separation.

9. Control Room and Auxiliary Equipment Room Panels

The main control panels are located in a control room within a seismic Category I structure. The control room is protected from, and does not contain, high energy equipment such as switchgear, transformers, rotating equipment, or potential sources of missiles or pipe whip.

No single control panel includes wiring essential to the protective function of two systems that are redundant to each other, except as allowed by the following:

(a) Floor-to-panel fireproof barriers are provided between adjacent panels of different channels/ divisions.

(b) Penetration of separation barriers within a subdivided panel is permitted, provided that such penetrations are sealed or otherwise treated so that an electrical fire could not reasonably be expected to propagate from one section to the other and destroy the protective function.

(c) When locating manual control switches of redundant divisions on separate panels is considered prohibitively (or unduly) restrictive to manual operation of equipment, the switches are located on the same panel, provided that no credible single event in the panel can disable both sets of redundant manual or automatic controls.

The design basis for the internal panel separation criteria is presented in section 2.1 of the WASH-1400 test report. The basis of that test report is reflected in the description of the separation requirements for Class 1E components mounted in control panels (Item (5) below). The test program showed that the revised separation criteria are adequate for protection against the consequences of a sustained overcurrent condition on one of the circuits in the panel. The criteria are not designed to protect against an exposure fire in the panel because alternate safe shutdown methods are provided in

accordance with 10CFR50, Appendix R, in the event of a fire in the control room.

Wherever wiring of two divisions exists in a single panel section, separation is maintained as follows:

(1) A minimum of 6 inches spatial separation is maintained between Class 1E wiring of different divisions. IEEE 384 (1981), section 6.6.2, states that Class 1E cables and wires internal to control panels are to be separated by 6 inches, or a barrier shall be installed between redundant Class 1E wiring. The same separation is maintained between Class 1E and non-Class 1E wiring. Redundant Class 1E cables entering the control panel enclosure also meet these requirements.

External to the panel, the raceways meet the separation requirements of IEEE 384 for nonhazard areas. Where the cables pass through blockouts into the panels, they are separated by fire barriers.

(2) A minimum of 6 inches spatial separation is maintained between Class 1E and non-Class 1E wiring.

(3) Where the above spatial separation cannot be maintained, one or a combination of the following shall be provided:

- One of the divisions of wiring is enclosed in flexible steel conduit to the point where the above separation is achieved.

- Hygrade Thermoflex 1200 fiberglass sleeving is installed on control and instrumentation wiring to the point where the above separation is achieved.

- One inch spatial separation is maintained between Class 1E and non-Class 1E wiring where the non-Class 1E wiring is secured with stainless steel cable ties, and between redundant Class 1E wiring where both the divisions of wiring are secured with stainless steel cable ties.

(4) The following exceptions to the above separation criteria are allowed:

- Relays Used as Isolation Devices:

  Non-Class 1E wires terminating on contacts of isolation relays are not separated from other wires in

the same panel, regardless of safety status or division. They are not bundled with Class 1E wires.

Redundant Class 1E wires terminating on a common isolation relay are not separated from each other at the relay terminals. They are routed away from the relay to achieve the required separation within a minimum distance.

- Where Class 1E wiring is located above #10 AWG or smaller non-Class 1E wiring, one inch separation will be provided.

- Thermocouple wires of different divisions of the steam leak detection system do not require separation from any other thermocouple wires in panels C609, C611, C620, and C640. These thermocouple wires are separated from power and control cables using the separation criteria above. Bases for this exception are as follows:

  i) All thermocouple wires are #16 AWG, which will not ignite due to overcurrent.

  ii) All thermocouple cables for this system are routed in instrumentation trays that do not contain power or control cables; therefore, no potential overcurrent source exists for these wires.

- In certain cases, less than one inch separation is allowed between redundant enclosed raceways. The rationale for this exception is discussed in section 5.3.2 of Reference 8.1-1.

(5) Class 1E components of different divisions, but which are not redundant, installed on a common panel are separated by one inch or a flame retardant barrier. Non-Class 1E components are separated by one inch or a flame retardant barrier from Class 1E components. Class 1E components that serve redundant systems are separated by 6 inches or a flame retardant barrier, e.g., core spray A from core spray B. The fire-resistant materials that are used as barriers for internal panel separation are panel steel, solid or flexible steel conduit and fiberglass sleeving. Where a barrier is required between devices in a common panel, the metal casing of the device is considered to be an adequate barrier for containing internal device failures. The analyses that shows that a failure of one circuit will not affect an adjacent circuit are provided in Reference 8.1-1.

Exceptions to these component separation criteria are allowed in cases where it has been shown that a sustained overcurrent through the device will not cause the ignition of that device. Indicating lamps, isolation relays, panel meters, and terminal blocks are specific examples of this exception.

(d) Panel internal Class 1E wiring is not color coded. Wires are marked with their respective connection diagram identity at each point of termination. The connection diagram denotes the separation division for each cable.

10. Instrument Racks and Panels:

Redundant Class 1E instruments and instrument racks are separated so that any design basis event will not cause the failure of more than one division of instrumentation needed to mitigate the effects of that event.

Physical separation of redundant circuits and devices is provided within each instrument panel as discussed in paragraph 9 above.

11. Sensors and sensor-to-process connections:

Redundant Class 1E sensors and their connections to the process system have been sufficiently separated so that the functional capability of the protection system is maintained despite any single design basis event or result therefrom, including the secondary effects of design basis events, such as pipe whip, steam release, radiation, missiles, or flooding.

Where practicable, redundant Class 1E sensors and process connecting lines are brought out at widely divergent points, using large components, such as pressure vessels or pipes, as protective barriers. Where necessary, additional barriers are provided to protect against damage from a credible common cause.

12. MSIV and Turbine Stop Valve Terminal Boxes

In the MSIV and turbine stop valve terminal boxes, separation is not maintained within these boxes as any postulated failure in the box will not prevent the RPS from performing its intended safety function. Bases for this exception are provided below.

In each MSIV terminal box, two divisions of wiring are present, i.e., RPS ac (nonsafety-related) and one Class 1E dc division. Given a failure in the terminal box, three types of failures can be assumed:

i) Open circuit

ii) Hot short

iii) Short to ground

For the first scenario, the MSIVs would fail closed because the pilot solenoids would be de-energized. For the second scenario, while it could be postulated that the pilot solenoids would stay energized, the redundant MSIVs would not be affected because the outboard MSIV pilot solenoids are fed from different ac and dc buses than are the inboard MSIVs. For the third scenario, refer to item iii) below.

Any failure within these terminal boxes would not degrade the safety-related dc system because:

i) Given any failure, only one division of the four safety-related dc divisions would be involved.

ii) There is a 5 A fuse in both dc feed legs in the logic panel feeding the dc solenoids. There is also a 30 A fuse in each leg at the dc distribution panel. Because these two fuses are in series between the terminal box and the dc distribution bus, the probability of both fuses failing to clear a hot short is conservatively estimated to be $9x10^{-10}$ based on failure information given in WASH-1400, appendix III, table III.2-1. This is considered to be acceptable.

iii) A short of the dc feed to ground would not unacceptably degrade the dc system because each dc system is ungrounded. The ground would be detected by a Class 1E ground detector and the dc system would continue to operated as designed.

Other exceptions to the above criteria may be allowed. These exceptions will be analyzed to consider the magnitude and duration of a credible high impedance faulted condition and will be documented.

13. CAC Inboard Nitrogen Purge Isolation Valves

The control circuits for the two primary containment nitrogen purge inboard PCIVs, one valve for the drywell (HV-057-*21) and the other for the suppression chamber air space (HV-057-*31), are supplied from the same electrical division. A single failure is prevented by electrical interlocks between the valves, which utilize contacts in the position switches on the two valves. A normally open contact in the position switch of both valves is wired in series with the other valve control circuit. This arrangement prevents both valves from being open at the same time. The cables between the interlocks and the valves are run in separate conduits.

If one of the position switch contacts failed open, the interlocked valve would be prevented from being opened. If one of the contacts failed closed, the interlocked valve could be opened, however, the first valve would then go closed due to the interlock. Hot shorts between contacts on the position switches are not considered, since contacts on a switch have been evaluated to provide acceptable divisional separation. Shorts between cables are not credible since they are routed in separate conduits.

With the interlocks in place, electrical systems separation criteria (ref. UFSAR Section 7.1.2.2.3.2.2) and the single-failure criterion (IEEE 379, 1972 or 1979) are met.

8.1.6.1.15 Regulatory Guide 1.81 (January 1975) - Shared Emergency and Shutdown Electric System for Multi-Unit Nuclear Power Plants

The design of the standby electric power systems is in conformance with Regulatory Guide 1.81.

The dc power systems are not shared between the units.

Each unit is provided with separate and independent onsite ac and dc electric systems.

8.1.6.1.16 Regulatory Guide 1.89 (November 1974) - Qualification of Class 1E Equipment for Nuclear Power Plants

Regulatory Guide 1.89, Revision 0, does not apply to LGS. LGS electrical equipment requiring qualification was qualified in accordance with NUREG-0588, Category II as described in Sections 3.11 and the LGS EQR. Replacement components for electrical equipment requiring qualification that were installed after February 1985 are qualified to the requirements of 10CFR50.49 unless there are sound reasons to the contrary, as defined in Regulatory Guide 1.89 Rev. 1.

8.1.6.1.17 Regulatory Guide 1.93 (December 1974) - Availability of Electric Power Sources

LGS complies with this regulatory guide as discussed in the Technical Specifications.

8.1.6.1.18 Regulatory Guide 1.100 (August 1977) - Seismic Qualification of Electric Equipment for Nuclear Power Plants

This guide is not applicable to LGS per its implementation section.

Regulatory Guide 1.100 endorses and modifies IEEE 344 (1975), "Seismic Qualification of Class 1E Power and Protection Systems." LGS Class 1E equipment is in full compliance with IEEE 344 (1971) for components purchased before issuance of IEEE 344 (1975). All electrical equipment purchased later is qualified to IEEE 344 (1975). Seismic qualification of electrical equipment is discussed in Section 3.10.

8.1.6.1.19 Regulatory Guide 1.106 (March 1977) - Thermal Overload Protection for Electric Motors on Motor- Operated Valves

This guide is not applicable to LGS per its implementation section, nevertheless, the thermal overload design for motors on MOVs is in conformance with Regulatory Guide 1.106, except for Item b below.

Either thermal overload protection devices are not used, have permanent electrical jumpers installed, or are bypassed during an accident condition. The overload bypass philosophy on MOVs with overloads that do not have permanent jumpers is incorporated as follows:

a. MOVs with spring return-to-center control switches.

These MOVs can be initiated manually or automatically.

1. Manual initiation

During manual operation, the thermal overload is normally in the trip circuit; however, the thermal overload can be bypassed by holding the control switch

in the appropriate OPEN or CLOSE position. The associated OUT OF SERVICE annunciator will alarm, along with a white indicating light on the system's vertical board indicating a valve motor overload or loss of power condition. By checking the valve indicating lights, the operator can determine whether the alarm is due to loss of voltage or motor overload.

2. Automatic initiation

The thermal overload is bypassed in automatic operation of the Class 1E MOVs in which the same annunciation sequence occurs as described in Item 1 above.

b. MOVs with maintained contact control switches:

1. Valves not required to operate automatically during an accident.

The thermal overloads do not interrupt the MOV power circuit, but they alarm on an overload condition in the control room. The operator has the option to allow the valve to continue to operate or to interrupt power to the MOV by placing the control switch in the STOP position.

2. Valves required to operate automatically during an accident.

(a) Whenever the MOV operates, the thermal overloads do not interrupt the MOV power circuit, but they alarm on an overload condition in the control room.

8.1.6.1.20 Regulatory Guide 1.108 (August 1977) - Periodic Testing of Diesel Generator Units Used as Onsite Electric Power Systems at Nuclear Power Plants

The periodic testing of the diesel generator units will be in conformance with the requirements of Regulatory Guide 1.108 and IEEE 387 (1977) as follows:

a. The preoperational testing will be performed in accordance with the site test outlined in section 6.4 of IEEE 387 (1977).

b. A starting test as described in section 6.6.1 of IEEE 387 (1977) will be performed on each diesel generator as determined by Technical Specifications.

c. Periodic testing in accordance with section 6.6.2 of IEEE 387 (1977). Test frequency is determined by Technical Specifications.

In accordance with Station Blackout requirements, an emergency diesel generator reliability program which meets the requirements of USNRC Regulatory Guide 1.155 “Station Blackout” is in place.

8.1.6.1.21 Regulatory Guide 1.118 (June 1978) - Periodic Testing of Electric Power and Protection Systems

The LGS design provides the necessary capability for periodic testing of electric power systems in conformance with Section 5 of IEEE 338 (1977) as endorsed and amended by the guide.

Periodic testing capability of instrumentation and controls systems is discussed in Section 7.1.2.5.

Periodic testing of the Class 1E systems will be in accordance with Regulatory Guide 1.118 and IEEE 338 (1977).

8.1.6.1.22 Regulatory Guide 1.128 (October 1978) - Installation Design and Installation of Large Lead Storage Batteries for Nuclear Power Plants

This guide does not apply to LGS per its implementation section. Regulatory Guide 1.128 endorses and amends IEEE 484 (1975), "IEEE Recommended Practice for Installation Design and Installation of Large Lead Storage Batteries for Generating Stations and Substations." The installation design and installation of the Class 1E batteries for LGS are in conformance with IEEE 484 (1975).

8.1.6.1.23 Regulatory Guide 1.129 (February 1978) - Maintenance, Testing, and Replacement of Large Lead Storage Batteries for Nuclear Power Plants

The maintenance and testing of the LGS batteries will be performed in accordance with IEEE 450 (1995).

An acceptance test of the battery capacity was performed at the factory prior to initial shipment. A service test, as described in IEEE 450-1980, Section 5.3, was performed on the Class 1E batteries on completion of the initial installation. Replacement batteries will receive an equivalent level of testing that envelopes both the acceptance and service tests. Thereafter, a service test, as described in IEEE 450 (1995), will be performed periodically in accordance with the Surveillance Frequency Control Program. Also, to determine the service life remaining in the battery, a performance test will be conducted at least once per 60 months. A modified performance test may be performed in lieu of the service test as described in IEEE 450 (1995).

IEEE 450-1995 is used for its recommendations regarding battery connection resistance as indicated in Annex D, Section D.2 of the standard, for specific gravity correction per Section 3.3.1.6 and 3.4.2 of the standard and for providing an alternative method to determine the state of charge of the battery per Section 4.5 of the standard.

8.1.6.1.24 Regulatory Guide 1.131 (August 1977) - Qualification Tests of Electric Cables, Field Splices, and Connections for Light-Water-Cooled Nuclear Power Plants

Regulatory Guide 1.131 endorses and modifies IEEE 383 (1974), "Type Test for Class 1E Electric Cables, Field Splices, and Connections for Nuclear Power Generating Stations." LGS Class 1E cables, splices, and connections except for the battery cart intercell/intercart jumpers and cart to battery jumpers are in full compliance with IEEE 383 (1974). Compensatory measures are taken to mitigate the consequences of cable ignition in the area(s) in which the Non-IEEE 383 battery cart intercell/intercart cables and cart to battery cables are used. For further information on qualification testing refer to Section 3.11.

8.1.6.1.25 Regulatory Guide 1.155 (June 1988) - Station Blackout

LGS complies with Regulatory Guide 1.155 and was evaluated in accordance with the requirements using guidance from NUMARC 87-00, except where RG 1.155 takes precedence.

For LGS Units 1 and 2, the minimum required Station Blackout coping duration shall be four hours as determined by NUMARC 87-00 guidelines.

LGS has opted to use an alternate ac power (AAC) approach (excess diesel generator capacity) to cope with and recover from a station blackout. AAC power is available within one hour of the station blackout. For LGS Units 1 and 2, the AAC power source satisfies the requirements for station blackout.

For LGS Units 1 and 2, Emergency Diesel Generator target reliability levels are maintained at or above 0.95 per demand. An Emergency Diesel Generator reliability program is established to ensure that target reliability program is established to ensure that target levels are maintained.

Station Blackout is further described in Section 15.12.

8.1.6.2 Conformance with IEEE Standards

8.1.6.2.1 IEEE 387 (1972) - Criteria for Diesel Generator Units Applied as Standby Power Supplies for Nuclear Power Generating Stations

The design of the standby power supplies is in compliance with IEEE 387 (1972). The following paragraphs analyze compliance.

a. Adequate cooling and ventilation equipment is provided to maintain an acceptable service environment within the diesel generator compartments during and after any design basis event, even without support from the preferred power supply.

b. Each diesel generator is capable of starting, accelerating, and accepting load as described in Section 8.3.1. The diesel generator automatically initiates its cooling equipment within an acceptable time after starting.

c. Frequency and voltage limits and the basis of the continuous rating of the diesel generator are discussed in the compliance statement to Regulatory Guide 1.9 in Section 8.1.6.1.2.

d. Mechanical and electrical systems are designed so that a single failure affects the operation of only a single diesel generator.

e. Design conditions such as vibration, torsional vibration, and overspeed are considered in accordance with the requirements of IEEE 387 (1972).

f. Each diesel governor can operate in either the isochronous or droop mode and the voltage regulator can operate in either the parallel or nonparallel mode. During testing, the diesel generator is connected to and operated in parallel with the offsite power source. The electric governor is set in the droop mode whenever connected in parallel with a system in which another prime mover is controlling the frequency. Under automatic or emergency start conditions, the electric governing system and the voltage regulator are set automatically for isochronous and nonparallel mode, respectively.

g. Each diesel generator is provided with control systems permitting automatic and manual control. The automatic start signal is functional except when the diesel generator is in the maintenance mode. Provision is made for controlling the diesel

generator from the control room and from the diesel generator room. Section 8.3.1 provides further description of the control systems.

h. Voltage, current, frequency, and output power metering is provided in the control room to permit assessment of the operating condition of each diesel generator.

i. Surveillance instrumentation is provided in accordance with IEEE 387 as follows:

1. Starting system - starting air pressure low alarm

2. Lubrication system - lube oil pressure low, lube oil temperature high, lube oil level low, and lube oil keep-warm failure alarms

3. Fuel system - fuel oil level in day tank high and low, fuel oil pressure low, fuel oil strainer differential pressure high, fuel oil filter differential pressure high, fuel oil level in storage tank high, and low alarm

4. Primary cooling system - ESW low pressure

5. Secondary cooling system - jacket water temperature high, jacket water keep-warm failure, jacket water pressure low, and jacket water expansion tank level low alarms

6. Combustion air systems - no alarm is provided, because the diesel generator duct-work does not contain any automatic dampers or features to cause failure in the combustion air supply

7. Exhaust system - pyrometers located at local gauge panel

8. Generator - generator differential overcurrent, ground neutral overcurrent, generator phase overcurrent, and antimotoring trip and alarm

9. Excitation system - generator loss of excitation and overexcitation alarm and field ground alarm

10. Voltage regulation system - generator overvoltage alarm

11. Governor system - engine overspeed trip

12. Auxiliary electric system - 480 V ac auxiliary power off, 125 V dc control power off, dc fuel pump power off alarms

A detailed list of trip and alarm functions and testing of the diesel generator is discussed in Section 8.3.1.1.3.

8.1.6.3 Conformance with Branch Technical Positions

Conformance with applicable BTPs ICSB 4, ICSB 8, ICSB 11, ICSB 18, ICSB 21, PSB 1 and PSB 2 is discussed below.

8.1.6.3.1 BTP - ICSB 4 (November 1975) - Requirements on Motor- Operated Valves In The ECCS Accumulator Lines

This BTP is not applicable to LGS because LGS is a BWR and therefore does not have safety injection tanks in the ECCS.

8.1.6.3.2 BTP - ICSB 8 - Use of Diesel Generator Sets for Peaking

LGS is in compliance with BTP ICSB 8. The diesel generator sets will not be used for peaking service. To preclude a potential for common failure modes, onsite and offsite sources are not interconnected except for short periods during testing when only one diesel at a time is tested.

8.1.6.3.3 BTP - ICSB 11 - Stability of Offsite Power Systems

A discussion of the grid stability analysis is given in Section 8.2.2.

8.1.6.3.4 BTP - ICSB 18 - Application of the Single Failure Criterion to Manually Controlled Electrically Operated Valves

LGS is in compliance with ICSB 18, except for the requirement for redundant position indication in the main control room.

Valves HV-13-109 and HV-13-110 (ESW supply and return to reactor recirculation pump seal and motor oil cooler valves) have been locked in the closed position. The power feeds to the motor operators have been disconnected at the operator terminals and at the 480 V ac MCC compartments.

Remote position indication of these valves is not provided in the control room. Valve position is administratively controlled; the valves are locked in the required position and access to the keys is administratively controlled.

The position of these valves will be identified in a valve checkoff list. When verification of system operability is required, performance of the valve checkoff list in conjunction with the applicable lineup procedure is one method which may be used. When operability is verified in this manner, an independent verification of valve lineup will be accomplished by redundant performance of each valve checkoff list used. Use of a lineup procedure with its associated valve checkoff lists will not be the exclusive method available for verification of operability, but can be used in any circumstance. If valve positions are to be changed for surveillance or maintenance purposes, the procedure or other administrative control will have steps requiring return-to-normal valve lineup prior to completion. The shift supervisor will not consider the system operable until all valves identified within the boundaries of the surveillance/maintenance activities have been returned to the position specified in the valve checkoff list. If valve positions are changed for operational purposes, these changes will be made in accordance with procedures having similar administrative controls.

8.1.6.3.5 BTP - ICSB 21 - Guidance for Application of Regulatory Guide 1.47

LGS is in compliance with BTP ICSB 21. Compliance with this position is discussed in Sections 8.1.6.1.9 and 7.1.2.5.11.

8.1.6.3.6 BTP - PSB 1 - Adequacy of Station Electric Distribution System Voltages

LGS is in compliance with BTP PSB 1.

BTP PSB 1 is met at LGS using the same degraded grid voltage monitoring system that was accepted by the NRC for PBAPS Units 2 and 3 (Reference 8.1-3). The following discussion responds to the numbered positions of BTP PSB 1.

a. On both offsite sources to each Class 1E bus, an ITE-27N definite time-delay relay with a 60 second timer monitors the offsite source voltage. This relay is set to drop out at 0.94 per unit voltage. Actuation of this relay after a 60 second time-delay will trip the associated 4 kV bus feeder breaker. Loss of voltage on the 4 kV bus actuates a GPI relay which initiates a diesel generator start and a transfer to the alternate source respectively. The purpose of the 60 second time-delay is to allow sufficient time for the automatic load tap changers on the 101 and 201 safeguard transformers to adjust and counter the degraded voltage condition.

   An ITE-27 inverse-time relay with a timer is also installed on the source side of each offsite source to each Class 1E bus. This relay will be set at 0.875 per unit voltage with a total time-delay of 60 seconds or less. It performs the same function as the ITE-27N and provides inverse time-delay with degrading voltage for protection of Class 1E equipment between 0.875 and 0.70 per unit voltage.

   The time-delays associated with the ITE-27N and ITE-27 relays are automatically bypassed 9 seconds after the ITE-27N relay initiates when a LOCA signal is present. This limits the exposure of Class 1E equipment to degraded voltage condition to 9 seconds after the undervoltage relay operates while preventing spurious trips of the offsite source breaker during voltage transients caused by motor starts.

   An NGV relay with a 0.9 second timer is also installed on the source side of each offsite source to each Class 1E bus. The relay is set at 0.70 per unit voltage and will perform the same function as the above relays. This relay provides for the start of the diesel generator and the transfer of the bus on the total loss of the associated offsite source.

   A GPI relay monitors the voltage on each Class 1E 4 kV bus. The relay functions with no appreciable time-delay when the voltage on the bus falls below 0.40 per unit. Actuation of this relay initiates load shedding and after a time-delay provides a permissive signal to start the diesel generator and allow the affected bus to transfer to the alternate source. This relay also provides an automatic closure signal to the diesel generator breaker after further time-delay if the automatic transfer fails.

   An NGV relay for Unit 1 and an ITE-59D relay for Unit 2 with a setpoint of approximately 0.95 per unit also monitor the bus voltage on the 4 kV Class 1E buses. Actuation of either one of these relays initiates load sequencing after the voltage is restored to the bus. It is sealed in by the GPI relay to allow the load sequencing to continue during motor starting transients.

   The above voltage monitoring scheme does not provide coincident logic to preclude spurious trips to conform to BTP PSB 1. However, spurious action of one undervoltage relay will only start one diesel generator and then transfer the affected

bus to the alternate power source. The actuation of a second undervoltage relay is necessary to transfer the bus to the diesel generator. If the ITE-27N should fail to operate, it is backed up by the ITE-27. Therefore, this scheme conforms to the intent of the requirements of BTP PSB 1.

For periodic testing of this scheme, the individual relays can be bypassed with a permanently installed test block. When the test block bypass is in effect, the condition is annunciated in the control room, thereby meeting the requirements of the BTP and Regulatory Guide 1.47.

b. The GPI relay discussed above provides the load shedding on the Class 1E 4 kV buses. It is not bypassed during load sequencing because its setpoint for dropout is low enough to preclude spurious tripping under all load sequences.

c. The analyses required by this section of BTP PSB 1 were performed and were used in selecting the settings of the relays discussed above.

d. The tests required by this section of BTP PSB 1 will be performed during the startup test program.

Preoperational Test P-100.1 and the Voltage Regulation Verification Test, which is required by BTP-PSB-1 measure various bus voltages as loads are applied. These tests verify that proper voltage regulation on the 13.2 kV and 4 kV buses is maintained.

8.1.6.3.7 BTP - PSB 2 - Criteria For Alarms and Indications Associated With Diesel Generator Unit Bypassed And Inoperable Status

LGS is in compliance with BTP PSB 2. Compliance with this position is discussed in Sections 8.1.6.1.19 and 7.1.2.5.11.

8.2 OFFSITE POWER SYSTEM

8.2.1 DESCRIPTION

8.2.1.1 Offsite Power Sources

Offsite power is supplied from two independent, physically separated sources:

a. A 220-13 kV transformer No. 10 located at the LGS 220 kV substation

b. A 13 kV tertiary winding on the No. 4A and 4B 500-220 kV bus tie autotransformers through the No. 20 13-13 kV regulating transformer located in the LGS 500 kV substation

Physical and schematic representations of offsite and onsite transmission systems are shown in Figures 8.2-1, 8.2-2, and 8.2-6.

The LGS 220 kV substation supplies offsite power at 13.2 kV via the No. 10 220-13 kV transformer which has a nominal capacity of 61.6 MVA at 65°C and a 15 kV underground cable run of 1000 feet outside the station. A transition to cable bus is made inside the turbine enclosure, where the cable bus continues for 330 feet to the station auxiliary bus 10A103. The underground installation protects the power supply from variable weather conditions such as high velocity winds, icing, and lightning.

The line primary protective relaying consists of three differential relays, which under fault conditions trip and lock out station auxiliary bus 10A103 breakers and breaker 105 in the 220 kV substation. Phase overcurrent and ground overcurrent relays provide backup relay protection. Breaker 105 is also tripped by No. 10 transformer protective relays and 220 kV bus No. 7 protective relays.

In addition, both the No. 10 Station Auxiliary transformer and the 101 Safeguard transformer have Open Phase Detection (OPD) protective relaying. During an Open Phase Condition (OPC) event on the 10 Station Auxiliary transformer, the SEL relay monitoring this transformer will annunciate in the Control Room. After investigation and validation of the OPC, the 105 Substation Breaker (105 BRKR), the 25 Substation Breaker (25 BRKR), the 715 Substation Breaker (715 BRKR), the 725 Substation Breaker (725 BRKR), the 735 Substation Breaker (735 BRKR) and opens the No. 10 Circuit Switcher will be manually opened to isolate the 10 Station Auxiliary transformer.

During an OPC event on the 101 Safeguard transformer, the SEL relay monitoring this transformer will annunciate in the Control Room. After investigation and validation of the OPC, breakers 252-10301 and 252-10302 will be manually opened to isolate the 101 Safeguard transformer.

The 220 kV substation is supplied from three transmission sources:

a. 220-60 line which has a capacity[(1)] of 1200 MVA is routed on the east side of the Schuylkill River from the LGS 220 kV substation to a point opposite Cromby Station. From that point, the line leaves a railroad right-of-way, joins an existing PECO Energy right-of-way, and crosses the Schuylkill River to enter Cromby Station.

b. 220-61 line which has a capacity[1] of 1200 MVA is routed from the LGS 220 kV substation along the west side of the Schuylkill River on a railroad right-of-way to Lock Substation. The two 230 kV lines do not cross each other at any point.

c. The No. 4A and 4B bus tie autotransformers which interconnect the 220 kV and 500 kV substations and have a nominal capacity of 420 MVA each.

---

[1] Capacity values provided are nominal; utilized values are higher.

The LGS 500 kV substation supplies offsite power at 13.2 kV to station auxiliary bus 20A103 from the tertiary winding of one of the No. 4A or 4B bus tie autotransformers through the No. 20 13-13 kV regulating transformer. The tertiary winding has a nominal capacity of 95.7 MVA and the No. 20 transformer has a nominal capacity of 58 MVA. This substation is physically located 2150 feet from the LGS 220 kV substation, effectively minimizing the likelihood of their simultaneous failure under operating conditions, postulated accidents, and natural disasters. The 13.2 kV power is transmitted 2100 feet to the station via an underground cable run and 400 feet of cable installed in a tray beneath the site access railroad bridge that spans Possum Hollow Run ravine. A transition to cable bus is made inside the turbine enclosure, where the cable bus continues for a distance of 330 feet to station auxiliary bus 20A103. The underground installation avoids exposure to adverse weather conditions.

As shown in Figures 8.2-1 and 8.2-2, the two offsite power sources do not share any common structures, systems, or components external to the generating station. Internal to the generating station, the offsite sources terminate in a common room on separate and independent buses that are approximately 90 feet apart. The No. 4 bus tie autotransformer that provides load flow stability between the 220 kV and 500 kV substations represents a common link between the two offsite sources; however, at least one 13 kV and two 220 kV circuit breakers provide isolation between the two startup feeds as shown in Figure 8.2-2.

Pilot wire relaying is used for line primary protection that, under fault conditions, trips and locks out station auxiliary bus 20A103 breakers and breaker 205 in the 500 kV substation. Backup relay protection is provided by phase overcurrent and ground overcurrent relays. Breaker 205 is also tripped by No. 4 transformer protective relays, 500-220 kV bus tie protective relays, and No. 20 regulating transformer protective relays.

In addition, both the No. 20 Regulating transformer and the 201 Safeguard transformer have OPD protective relaying. During an OPC event on the 20 Regulating transformer, the SEL relay monitoring this transformer will annunciate in the Control Room. After investigation and validation of the OPC, breaker 205 will be manually opened to isolate the 20 Regulating transformer. During an OPC event on the 201 Safeguard transformer, the SEL relay monitoring this transformer will annunciate in the Control Room. After investigation and validation of the OPC, breakers 252-10303 and 252-10304 will be manually opened to isolate the 201 Safeguard transformer.

The 500 kV substation is supplied from four transmission sources:

a. 5010 line which has a capacity[2] of 2780 MVA crosses the Schuylkill River from the west and runs above both of the 230 kV transmission lines. It is terminated in the LGS 500 kV substation. Where the existing 5010 line leaves the 500 kV substation towards the east, it becomes the 5030 line.

b. 5030 line which has a capacity(2) of 2780 MVA.

c. 5031 line which has a capacity(2) of 2780 MVA parallels the 5030 line from the 500 kV substation to Whitpain for the operation of LGS Unit 2.

d. The No. 4A and 4B bus tie autotransformers.

---

(2) Capacity values provided are nominal; utilized values are within 2% of nominal.

From Figure 8.2-6, it can be seen that the requirements of GDC 17 are met in that in the unlikely event of the 5010 line falling and causing the failure of both 230 kV transmission lines, the 5030 line would still be available to provide an offsite source of power for the safe shutdown of the plant.

During unit operation, normal auxiliary power for the station is supplied from two 47 MVA unit auxiliary power transformers (one per unit) connected to the generator leads. Startup and Class 1E bus power is provided from the two independent offsite sources. Either offsite source can supply the 13.2 kV unit auxiliary buses and the 4 kV Class 1E buses for normal plant startup and shutdown and supply all normally connected loads including loads that may be automatically transferred to them when a LOCA in one unit coincides with a safe shutdown in the remaining unit. Each offsite source supplies an emergency auxiliary (safeguard) transformer with a nominal capacity of 14 MVA that steps down the 13.2 kV to 4.16 kV and connects through interlocked circuit breakers to every 4 kV Class 1E bus. Both offsite sources are available continuously to the Class 1E buses.

A spare 14 MVA 13.2/33-4.16 kV transformer is located onsite solely as a replacement for either the Unit 1 or Unit 2 13.2-4.16 kV safeguard transformer. The spare transformer has the same capacity as the safeguard transformers, which is more than adequate for safe shutdown of the plant. In the event of failure of either the Unit 1 or Unit 2 safeguard transformer, the faulty safeguard transformer will be removed and physically replaced by the spare.

The 6680, 66 kV transmission line serves as a potential, but currently not-connected alternate offsite source for use in the event of loss of one of the normal offsite sources. Line 6680 is tapped and provides power to the Limerick 66-13 kV substation. Aerial cable is installed between the 66-13 kV substation to a terminal pole located outside of the 220 kV substation where it converts to underground cable and is routed to the alternate offsite source breaker (No. 252-55401) installed north of the Unit 1 turbine building. In the event of loss of one of the normal offsite sources resulting in an outage time in excess of 72 hours, cables will be connected between breaker 252-55401 and the affected safeguard transformer. All work necessary to implement this alternate offsite source is expected to be accomplished within a 72 hour period to avoid a limiting condition of operation.

The capability to test the transfer of power from one offsite source to the other circuit can be accomplished from the control room (Drawing E-1). By tripping either the 101 or 201 transformer breaker, the loss of one offsite source will be simulated and the automatic transfer to the other offsite source will be initiated on the four Class 1E buses that are normally fed from that source. These buses can then be manually transferred back to their preferred source after the transformer breaker is closed.

The 66-13 kV substation has a capacity rating of 24 MVA which is sufficient to supply all connected and automatically transferred loads when a LOCA in one unit coincides with a safe shutdown in the

remaining unit. The 6680 line terminates at Cromby Station and Moser Substation. Moser substation receives bulk power from the Cromby Station via two 66 kV transmission lines, is solidly tied into the 33 kV distribution system and has three combustion turbine generators.

8.2.1.2 Switchyards

Both the 220 kV and 500 kV substations use a breaker and one-half scheme. This arrangement is shown in Figures 8.2-1 and 8.2-2. Both substations have three bus elements initially, with provisions for future expansion to four bus elements. Element refers to each bus-to-bus connection. The 500 kV substation contains a manually or automatically switched 200 Mvar shunt capacitor bank which is part of the PJM system of 500 kV capacitors. Both substations employ primary and backup relay protection plus breaker failure protection schemes. The substations are interconnected by a 500-220 kV bus tie transformer and a 220 kV transmission line. The tie line is approximately 100 feet from the Unit 1 generator line at the 220 kV substation and is approximately 200 feet from the Unit 2 generator line at the 500 kV substation. Both LGS substations ultimately interconnect with the PJM Interconnection through their respective transmission lines.

Each main generator is connected by an isolated phase bus to its respective step-up transformer bank. The Unit 1 maximum gross generator output of approximately 1240 MWe is fed to the 220 kV substation via three 22-242 kV, 525 MVA Unit 1 main transformers. The Unit 2 maximum gross generator output of approximately 1240 MWe feeds into the 500 kV substation via three 22-500 kV, 525 MVA Unit 2 main transformers. A system spare 22-220 kV 422 MVA transformer is installed next to the C phase Unit 1 transformer for immediate use should a fault occur on one of the three operating transformers. A system spare for the Unit 2 22-500 kV transformers is stored next to the Water Treatment Plant.

The relaying associated with the 220 kV and 500 kV substations and transmission lines is shown in Figure 8.2-4. Three separate protective relaying schemes are used on the 500 kV and 220 kV transmission lines. The first two schemes use primary and backup high speed relays with a power line carrier for directional comparison relaying logic. In the 500 kV substation, carrier relaying is on A phase and B phase of the transmission lines except for line 5031 which uses Fiber Synchronous Optical Network (SONET) for both primary and backup relaying. The 220 kV substation transmission line carrier relay protection is on A phase and C phase, except for line 220-61 which uses SONET for both primary and backup relaying. The redundant relays operate from separate current transformers and separate secondary windings of the same potential device. Each substation has its own dc battery and battery charger. The charger is fed from an essential ac bus which has two alternate feeds with an automatic throw-over. Low dc voltage is alarmed in the substation control house and the LGS control room. Because this dc system and the substation protective relays are non-Class 1E, redundancy is not required. Direct current control circuits are fused separately for the redundant relay protection channels. Each line relaying initiates operation of separate redundant trip coils at the 500 kV circuit breakers and one trip coil at the 220 kV circuit breakers. The third scheme is breaker failure protection for a stuck breaker. This is provided by tripping adjacent breakers and transmitting signals to trip the circuit breaker at the remote line terminal. Separate carrier paths or channels are provided for each line relaying scheme.

The use of three relaying schemes with independently fused direct current feeds and independent 500 kV circuit breaker trip coils, along with current shorting switches and potential switches, permits inservice shutdown and test of any one relay and control scheme while maintaining two protective relaying schemes in service. The use of the breaker and one-half arrangement allows for the outage of one breaker without taking a line, transformer, or generator out-of-service. Testing equipment is

installed for carrier line relaying to allow inservice functional testing of the directional comparison relaying logic. After initial calibration, the equipment is periodically inspected, and readings are recorded.

OPD protective relaying is installed on both the No. 10 Station Auxiliary transformer and 20 Regulating transformer in the Substations. These are independent schemes on the 500 kV and 220 kV sources which communicate with relays inside the station to protect the 10 and 20 Buses and their associated transformers.

Each 500 kV and 220 kV bus element has two protective bus differential relaying schemes, either of which may be shut down for testing while maintaining the other in service for bus protection. All control operations, except actual tripping of the breakers, can be done while maintaining the bus in service.

The 220 kV and 500 kV breakers in both the substations are controlled from the substation control houses. These breakers are also controlled via a SCADA system from the SAMAC Control Center with the following exceptions: Unit 1 breakers 535 and 635, Unit 2 breakers 235 and 335 and breakers 105 and 205. The above mentioned exceptions are controlled via independent hard-wired circuits from the LGS control room.

All circuit breakers have sufficient stored energy for at least one open-close-open operation after loss of power.

Figure 8.2-5 shows the cable trench arrangements in the 220 kV and 500 kV switchyards. All control power circuits to the switchyard equipment are routed in these trenches. Control circuits for the various pieces of equipment are separated into individual cables. Primary and backup relay and control circuits are separately fused and are separated into individual cables. All cables are direct-buried in the trenches.

Relay and circuit breaker functional trip tests on all of the offsite power sources are made periodically.

The substation control batteries are tested periodically as follows:

a. Weekly - Voltage and specific gravity of the pilot cell are recorded. Overall voltage of the battery is recorded.

b. Quarterly - Voltage is recorded for each cell, and specific gravity is recorded for at least 10% of cells. Overall battery voltage is recorded.

c. Yearly - Annual battery inspection in addition to the quarterly tests.

8.2.1.3 Control Room Monitoring of Offsite Power Systems

The status of the offsite power system is monitored in the control room. A dedicated supervisory system provides the following status indications along with other pertinent information:

a.[3] Transmission Line Current for:

220-60 Line	5030 Line
220-61 Line	5031 Line
5010 Line

g.[3] #4 Tie Transformer current

h.[3] #105 Startup Breaker Position

i.[3] #205 Startup Breaker Position

j. Miscellaneous 220 kV and 500 kV Substation Alarms

8.2.1.4 Conclusion

The offsite power system has been designed for maximum reliability. All three sources of offsite power, including transmission lines and transformers, have sufficient capacity to supply all connected loads including loads that may be automatically transferred to them when a LOCA in one unit coincides with a safe shutdown in the remaining unit. The design and configuration of the offsite power system with provisions for periodic testing are in full conformance with GDC 5, GDC 17 and GDC 18, and Regulatory Guide 1.32 (1977) and Regulatory Guide 1.93 (1974).

8.2.2 ANALYSIS

8.2.2.1 Transient Stability

Detailed transient stability studies were made for both LGS units using load flow (POWERFLO) and transient stability (TRANSTAB) computer simulation programs. These computer programs are widely recognized in the electric utility industry and are being used by over 140 domestic and foreign utilities, government agencies, and universities.

---

[3] Upon loss of the Unit 1 Plant Monitoring System, these items are available from the PECO Energy load dispatcher via dedicated phone line.

The stability evaluation consisted of analysis of prefault and postfault load flow simulations and of transient stability digital computer calculations. Examination of the 1985 peak and light load levels showed the light load level to be most critical for stability because of the higher impedance and lower system inertia seen by the LGS units. Thus, all results are based on 1985 light load conditions. For all load flow simulations and associated stability calculations, a detailed representation of the PECO Energy system and the other PJM Interconnection systems was modeled including a significant representation of the systems in the surrounding Interconnected Power Pools. Altogether 1208 buses, 2158 lines, and 180 individual generators were represented in the model. The LGS units and other PJM Interconnection generators were represented in the transient stability calculations by appropriate inertias and machine reactances, with generator excitation systems and turbine governors being modeled in great detail to accurately simulate generator transient performance. The generating units of companies outside the PJM Interconnection were represented by their transient reactances and inertias.

The results of the studies show that both LGS units are stable for the most severe type of fault (three-phase) at the most critical locations on the electric network system. Specifically, the LGS generating units are stable for the following conditions:

a. A three-phase fault on any single 500 kV or 230 kV LGS circuit that is cleared by primary protective equipment.

b. A three-phase fault on any single 500 kV or 230 kV LGS circuit, where the most critical LGS circuit breaker fails to open and the fault is cleared at LGS by backup protective equipment.

c. A three-phase fault on the transformer connecting the LGS 500 kV and 230 kV buses that is cleared by primary protective equipment.

d. A three-phase fault on the transformer connecting the LGS 500 kV and 230 kV buses, where the most critical circuit breaker fails to open and the fault is cleared at LGS by backup protective equipment.

e. Simultaneous three-phase faults on both LGS to Whitpain 500 kV circuits that are cleared by primary protective equipment.

Load flow simulations and stability calculations were examined to evaluate the transient and post-transient system conditions after the most serious network faults and after the sudden tripping of either LGS unit. The analysis of circuit loadings and bus voltages showed no adverse system conditions either during periods of steady-state operation or during system oscillations caused by a fault and its subsequent clearing.

Additional transient stability analyses were also completed to address the following three events:

a. Loss of the largest generating station, i.e., loss of PBAPS Units 2 & 3

b. Loss of the largest load

c. Loss of the most critical right-of-way, i.e., a three-phase fault on the four transmission lines on the 130-30 right-of-way:

1. 130-30 line, 138 kV
2. 220-62 line, 230 kV
3. 5030 line, 500 kV
4. 5031 line, 500 kV

The transmission system remained stable for all three cases with either one or both LGS units in service. The loss of both PBAPS units was the worst case affecting system frequency. A minimum system frequency of 59.95 Hz occurred 0.35 seconds after the trips, and it ran out to 0.48 seconds. During this transient, the LGS units will experience a minimum frequency 59.89 Hz. This is well within the design capabilities of all LGS electrical equipment.

The effect of the 200 Mvar manually or automatically switched shunt capacitor on the 500 kV substation bus and on Limerick generator stability was analyzed. The analysis showed no detrimental affect on the generator's stability even with the voltage regulators out of service. The study indicated voltage is slightly improved with the capacitor in service.

Additional transient stability studies are performed as major system changes occur. Recent examples include, Power Rerate Projects, Turbine Retrofit Projects, 500 kV capacitor additions, etc. The transmission system is tested against the MAAC Reliability Principles and Standards: Transmission Requirements. All single, double, double circuit/stuck breaker contingencies are run as part of these additional studies. These contingencies are tested at the peak, intermediate and light load levels, with and without the increase of Limerick 1 & 2 Unit outputs. All MAAC transmission lines, 230 kV and above are monitored for any voltage and thermal limit violations. Faults are initiated at the 500 kV and 230 kV buses in the Limerick area. The MAAC system was found to remain stable for all tested faults which are cleared by either the primary and/or backup protective equipment.

> Note: The information presented above regarding the Transient Stability is historical and is based on the original design basis conditions and does not represent current methodology required for licensing basis. The above transient stability studies were preformed in compliance with Mid-Atlantic Area Council (MAAC) standards. MAAC was replaced with Reliability First Corporation (RFC) as the regional reliability organization to monitor and enforce compliance with North American Electric Reliability Council (NERC) standards.

The Transient Stability study is performed by the Transient Planning Entity (PJM) periodically and per request basis for major system modifications. The Transmission Planning Entity normal stability testing enforces the NERC criteria including contingencies under NER standards:

- TPL-001 – Category A (Transmission Planning Standard for System Performance Under Normal Conditions),
- TPL-002 – Category B (Transmission Planning Standard for System Performance Following Loss of a Single Bulk Electric System Element), and
- TPL-003 – Category C (Transmission Planning Standard for System Performance Following Loss of Two or More Bulk Electric System Elements).

In addition to the NERC standard criteria, the Transmission Planning Entity reviews and enforces additional criteria testing as required by Nuclear Plant Interface Requirement (NPIR) for planning analyses of the electric system.

To satisfy the requirements of 10 CFR 50 Appendix A General Design Criterion – Electrical power systems (GDC 17), the results of the grid stability study must show that loss of the largest single supply to the grid does not result in the complete loss of preferred power. The analysis should consider the loss, through a single event, of the largest capacity being supplied to the grid, removal of the largest load from the grid, or loss of the most critical transmission line. This could be the total output of the station, the largest station on the grid, or possibly several large stations if these use common transmission tower, transformer, or a breaker in a remote switchyard or substation.

The above licensing basis requirements are considered Category B contingencies for which the Transmission Planning Entity ensures that they will not cause grid instability.

8.2.2.2 Outages of Transmission Lines in the Vicinity of LGS

To demonstrate the reliability of the transmission lines associated with LGS unscheduled outages of existing transmission lines in the area were investigated. The lines included in the study are the PBAPS to Whitpain 500 kV line, the three Whitpain to Plymouth Meeting 230 kV lines, and the Whitpain to North Wales 230 kV line. These lines were chosen because they presently link the substations associated with the LGS project.

8.2.2.3 Unscheduled Outages

Historically, outages in this area have been caused by lightning strikes, flashovers, galloping conductors, airplanes, and equipment failures.

Of the 14 outages listed in Table 8.2-1, 9 lasted less than one hour, 4 lasted less than one day, and one lasted 5 days.

Table 8.2-1

UNSCHEDULED OUTAGES

Lines	Length (mi)	1971	1972	1973	1974	1975	1976
PBAPS - Whitpain	72.4	0	0	1	0	1	5[1]
Plymouth Meeting - Whitpain	5.1	0	0	0	0	1	1
Plymouth Meeting - Whitpain	5.1	0	0	0	0	1	0
Plymouth Meeting - Whitpain	5.1	0	0	0	0	1	0
North Wales - Whitpain	3.5	0	0	1	0	0	2

(1) The PBAPS - Whitpain 500 kV line was interrupted four times on the same day in 1976 because of galloping conductors. Equipment has since been installed to prevent recurrence of the galloping conductors.

8.3 ONSITE POWER SYSTEMS

8.3.1 AC POWER SYSTEMS

8.3.1.1 Description

The onsite ac power systems are divided into Class 1E and non-Class 1E systems. Drawing E-1 shows a single-line diagram of both systems.

The onsite ac power systems consist of main generators, main step-up transformers, unit auxiliary transformers, safeguard transformers, and diesel generators, among other distribution system equipment. The onsite ac power distribution system has nominal bus voltage ratings of 13.8 kV, 4.16 kV, 2.4 kV, 480 V, and 208/120 V. Throughout this discussion and on all design drawings, the equipment utilization voltages are designated as 13.2 kV, 4 kV, 2.3 kV, 440 V, and 208/120 V.

8.3.1.1.1 Non-Class 1E Ac System

The non-Class 1E portion of the onsite power systems provides ac power for non-Class 1E loads. A limited number of non-Class 1E loads are important to the power generating equipment integrity and are fed from the Class 1E distribution system through the isolation devices.

The unit auxiliary transformer supplies all the non-Class 1E unit auxiliary loads. The unit auxiliary transformer primary is connected to the main generator isolated phase bus duct tap, while the secondary of the transformer is connected to the two 13.2 kV unit auxiliary buses through a nonsegregated phase bus.

During plant startup, shutdown, and postshutdown, power to the 13.2 kV buses is supplied from the offsite power sources, with one bus from each unit normally supplied through the 220-13kV startup transformer and one bus from each unit normally supplied through the 13 kV tertiary winding of either the No. 4A or 4B 500-220 kV bus tie autotransformer; the tertiary of the other autotransformer is available as a back-up source. In addition, during these conditions, manual or automatic fast transfer is provided to transfer the unit auxiliary buses to the startup power source to maintain continuity of power at the unit auxiliary distribution system. The interconnecting breakers are interlocked to prevent the connection of the startup power source and the unit auxiliary power source to the unit auxiliary buses at the same time.

In addition to the loading conditions mentioned in the above paragraph, the 13.2 kV startup buses also supply the power to the Class 1E loads through their respective 13.2 - 4.16 kV safeguard transformers, as discussed in Section 8.3.1.1.2.

The 13.2 kV unit auxiliary switchgear provides power to large auxiliary loads, 2.3 kV switchgears, and 440 V load centers. The 13.2 kV switchgear feeds double-ended 440 V load centers. A manual tie breaker is provided for each set of load centers to intertie the two load centers if there is a failure of one load center transformer. To prevent paralleling of the two power supplies to each set of load centers, bus tie breakers are electrically interlocked with corresponding bus breakers such that one bus breaker must be open before the tie breaker may be closed. If the tie breaker is closed, closing of both bus breakers will automatically open the tie breaker. Load centers generally supply power to 440 V loads larger than 100 hp and power for their respective motor control centers. The motor control centers supply 440 V loads smaller than 100 hp, while 440 V, 480/277 V, and 208/120 V panels provide miscellaneous loads such as unit heaters, space heaters, lighting systems, etc. The

13.2 kV switchgear also feeds a 2.3 kV switchgear which supplies power to general plant services loads.

Two uninterruptible 120 V ac distribution panels for the RPS and UPS are provided for each unit. Each 120 V UPS ac power system is fed from two sources through a static transfer switch. The preferred source is the 250 V dc MCC via an inverter. The 250 V dc MCC is normally fed from battery chargers/rectifiers which are backed up by class 1E batteries. The alternate source is a 480/120 V transformer, which is supplied through a transfer switch either from a non-Class 1E 440 V MCC or from a non-Class 1E 440 V MCC energized by a non-Class 1E UPS. Between the static transfer switch and the distribution panel, two circuit breakers in series are provided with redundant trip circuits that trip the breakers on overvoltage, undervoltage, and underfrequency conditions to provide protection of the RPS during any failure of the non-Class 1E power supply.

Two uninterruptible 120 V ac distribution panels for the APRM and RBM electronics, the SRVPI system, and the RPIS are provided for each unit. Each panel is fed from two sources through a static transfer switch. The preferred source is the non-Class 1E 125 V dc batteries through a static inverter. The alternate source is the 120 V ac RPS uninterruptible power supply.

480 V ac UPS power supply feeds (144D-C-F) are provided for the Unit 1 and 2 Plant Monitoring Systems (PMS).

For the Unit 1 PMS, one supply breaker feeds two computer power centers (10Y506 and 10Y507), located in the Technical Support Center and a 120V ac distribution panel (10Y161), located in the Auxiliary Equipment Room. The computer power centers contain a main breaker, transformer, and 120/208 V ac distribution panel which in turn feed the various computer hardware. Distribution Panel 10Y161 supplies the Data Acquisition System equipment that multiplexes Unit 1 plant signals to the PMS.

For the Unit 2 PMS, four supply breakers feed four computer power centers (00Y591, 00Y592, 00Y593, and 00Y594), located in the Technical Support Center. The computer power centers are designed as described above and feed the various computer hardware.

One additional supply breaker feeds computer power center 00Y595, located in the Unit 1 Inverter Room. The Unit 1 and 2 control room PMS console displays are fed from this panel.

The non-Class 1E ac equipment capacities are listed below:

a. Transformers

Main transformer (Unit 1)	3-1ϕ, 525 MVA, ODAF, 65°C 22-242 GRD Y/139.78 kV
Main transformer (Unit 2)	3-1ϕ, 525 MVA, ODAF 65°C 22-531 GRD Y/306 kV
Unit auxiliary transformers (both units)	1-3ϕ 31.47/41.95/52.45 MVA, OA/FA/FOA, 65°C 22-13.8 GND Y/7.96 kV 22Y-13.8 GRD Y/7.96-7.2 kV

Station auxiliary (startup) transformer (Unit 1)	1-3ϕ 36.96/49.28/61.6 MVA, OA/FOA/FOA, 65°C 230-14.18 Y/8.187 kV, LTC ±10% of 14.18 kV, automatic, on-line
Autotransformers, tertiary winding (startup) (Unit 2)	2-3ϕ OA/FOA/FOA H 252/336/420 MVA, 65°C X 252/336/420 MVA, 65°C Y 57.4/76.5/95.7 MVA, 65°C 515 GRD Y/297.3 -230 GRD Y/132.8-13.8 kV, LTC ±10% of 515 kV automatic, on-line
Safeguard transformers (both units)	1-3ϕ 11.2/14.0 MVA, OA/FA, 65°C 13.2-4.16 Y/2.4 kV, LTC ±10% of 4.16 kV, automatic, on-line
Transformers (Perkiomen Pumping Station) (Common to Units 1 and 2)	2-3ϕ 5.6/7.0 MVA, OA/FA, 65°C 34.4-4.16 Y/2.4 kV
Plant services transformers (both units)	1-3ϕ 5600/7000 kVA, OA/FA, 65°C, 13.2-2.4 Y/1.386 kV
Regulating Transformer (startup) (Unit 2)	1-3ϕ 35/46.667/58.333 MVA OA/FA/FA, 65°C 13.8 Y/7.97 - 13.8 Y/7.97-4.815 kV LTC -10.3 to +19.7% of 13.8 kV, automatic, on-line

b. Switchgear

13.2 kV Switchgear	1200/2500 A continuous rating, 750 MVA, 3ϕ 37,500 A rms symmetrical interrupting rating
2.3 kV Switchgear	1200/2000 A continuous rating 250 MVA 3ϕ class 37,500 A rms symmetrical interrupting rating

c.	440 V Unit load centers	
	Transformers	1000 kVA AA and 1000/1333 kVA AA/FA, 3ϕ, 60 Hz, 13200-480 GRD Y/277 V
	Horizontal Bus	1600 A continuous rating
	Vertical Bus	600 A continuous rating
	Breakers (metal clad)	22,000 A rms symmetrical, minimum interrupting rating
d.	440 V Unit load centers (Perkiomen Creek - common to Units 1 and 2)	
	Transformers	300 kVA AA, 3ϕ, 60 Hz, 4160-480 GRD Y/277 V
	Horizontal Bus	600 A continuous rating
	Vertical Bus	600 A continuous rating
	Breakers (metal clad)	22,000 A rms symmetrical minimum interrupting rating
e.	440 V MCCs	
	Horizontal bus	600 A continuous rating, 42,000 A rms symmetrical bracing
	Vertical bus	300 A minimum continuous rating, 42,000 A rms symmetrical bracing
	Breakers (molded-case)	22,000 A rms symmetrical, minimum interrupting rating
f.	120 V Instrument ac distribution panels	
	Buses	100/225A continuous rating 10,000 A rms symmetrical bracing
	Breakers (molded-case)	100 A frame size 5,000 A rms symmetrical interrupting rating

g.	120 V ac UPS and computer distribution panels	
	Buses	400 A continuous rating 5,000 A rms symmetrical bracing
	Fuses	200,000 A rms symmetrical interrupting rating

8.3.1.1.2 Class 1E Ac Power System

The Class 1E ac power system is the portion of the onsite power system that is shown after the 4 kV nonsegregated bus in Drawings E-15 and E-16 at the incoming 4 kV breaker.

The Class 1E ac system distributes power at 4 kV, 440 V, and 208/120 V. The loads that are fed by this Class 1E ac system are divided into four divisions in each unit and are shown in Drawings E-15 and E-16. Each load division has its own distribution system and power supplies.

The 4 kV bus of each Class 1E load division is provided with connections to two offsite power sources, designated as preferred and alternate power supplies. In addition, provisions exist for connection to a third offsite power source through a spare transformer if there is a failure of one of the two offsite sources or either of the safeguard transformers. Diesel generators are provided as a standby power supply if there is a total loss of the preferred and alternate power supplies. Standby power supply is discussed in Section 8.3.1.1.3.

The Class 1E ac power system and its components, and the diesels and their auxiliaries, are located in seismic Category I structures that provide protection from the effects of tornadoes, tornado missiles, turbine missiles, and external floods. The Class 1E AC Power System and its components are designated Class 1E safety related, and the diesels and their required auxiliaries are designated safety related for procurement and quality assurance purposes and have been qualified for seismic and hydrodynamic loads as well as environmental conditions that they may experience during normal operation and postulated accidents.

None of the electrical equipment that is required to mitigate the effects of a design basis event will become submerged as a result of a LOCA. The only electrical equipment that may experience temporary submergence is penetration assembly JX230A, which becomes submerged during the pool-swell experienced during an SRV discharge. To ensure that suppression pool temperature indication which is monitored by this penetration is maintained during the pool-swell, the entire penetration is encased by an enclosure to a point above the maximum pool level, thereby assuring that the electrical portion of the penetration will not be affected by the pool-swell.

The following material describes the various features of the Class 1E ac power system.

8.3.1.1.2.1 Power Supply Feeder

Each Class 1E 4 kV switchgear is provided with a preferred and an alternate offsite power supply feeder and one standby diesel generator feeder. Each bus is normally energized by the preferred power supply. If the preferred power source is not available at the 4 kV bus, automatic transfer is

made to the alternate power source, as described in Section 8.3.1.1.2.4. If both the preferred and the alternate power sources become unavailable, the loads on each bus are picked up automatically by the standby diesel generator assigned to that bus, as described in Section 8.3.1.1.3.

8.3.1.1.2.2 Bus Arrangement

The Class 1E ac power system for each unit is divided into divisions A, B, C, and D. Power supplies for each load division are discussed in Section 8.3.1.1.2.1. With the exception of the ESW system, the RHRSW system, the SGTS, CSCWS and the control room and control structure ventilation systems, which are common systems, all other Class 1E ac loads in each unit are divided among the four divisions so that any combination of three out of four divisions has the capability to supply the minimum required safety loads to safely shut down the unit. Common loads for the ESW and the RHRSW systems are split between the Unit 1 and Unit 2 Class 1E power supplies. Common redundant loads for the SGTS, CSCWS and the control room and control structure ventilation systems are fed from Unit 1 Class 1E power supplies.

Any combination of three-out-of-four divisions (EDGs) is acceptable for a single failure as shown on Table 8.3-2. However, for ECCS requirements (as stated in paragraph 6.3.1.1.2), an EDG operable configuration of 2 out of 4 is also acceptable.

The distribution system of each division consists of a 4 kV bus, a 440 V load center, several motor control centers, and several low voltage distribution panels. The 4 kV, load center, and motor control center bus arrangements are shown in Drawings E-15, E-16, E-18, and E-29.

8.3.1.1.2.3 Loads Supplied from Each Bus

Table 8.3-3 lists all the loads supplied from each Class 1E bus.

8.3.1.1.2.4 Manual and Automatic Interconnections Between Buses, Buses and Loads, and Buses and Supplies

No provisions exist for automatically connecting one Class 1E load division to another redundant Class 1E load division or for automatically transferring loads between load divisions. The incoming preferred power supply associated with a load division can supply the 4 kV Class 1E bus of the other load division by manual operation of the requisite 4 kV circuit breakers, when required.

For each load division, one 4 kV feeder circuit breaker is provided for the normal incoming preferred power source, and another 4 kV feeder circuit breaker is provided for the alternate power source. Safeguard bus 101 is the preferred power source for channels A and C for Unit 1 and channels B and D for Unit 2. Safeguard bus 201 is the preferred power source for channels B and D for Unit 1 and channels A and C for Unit 2. The normal preferred power source to each bus is electrically interlocked with the alternate power source such that the bus can be connected to only a single power source at any one time. In the event of loss of preferred power to the load division, the undervoltage relay on the bus initiates after a time-delay an emergency diesel generator start and after a further time delay an automatic transfer to the alternate power source. The time needed to complete this transfer varies depending on the magnitude of back electromagnetic force generated on the bus by large motor loads and by the voltage level of the degraded offsite source. In all cases, the transfer is complete in less than the 13 seconds it would take to re-energize the bus from the diesel generator on the loss of all offsite power. If automatic transfer fails, the undervoltage relay after a further time-delay enables a transfer of the bus to the diesel generator. In the event of losing both preferred and alternate power supplies, the diesel breaker closes when the generator reaches 95% of rated voltage and frequency at which time the division becomes powered from the diesel generator.

When the power system is operating from the diesel generator supply (LOOP), redundant load divisions cannot be manually connected together because the 4 kV circuit breakers controlling the incoming preferred and alternate power supplies to the Class 1E buses are interlocked to prevent the paralleling of the diesel generators.

During manually initiated bus transfers or testing, one diesel generator may be paralleled with the preferred or alternate source.

8.3.1.1.2.5 Interconnections Between Class 1E and Non-Class 1E Buses, Non-Class 1E Loads, and Class 1E Buses

The offsite power supply feeders through the startup buses, which supply power to both the Class 1E and non-Class 1E buses, are exempt from the associated circuit requirements in IEEE 384 (1974), section 4.5. There are no other bus ties between the Class 1E and non-Class 1E buses.

A further discussion of interconnections between Class 1E and non-Class 1E buses, non-Class 1E loads, and Class 1E buses is presented in Section 8.1.6.

8.3.1.1.2.6 Redundant Bus Separation

The Class 1E switchgear for the redundant Class 1E load divisions is located in separate seismic Category I rooms in the control and reactor enclosures to ensure electrical and physical separation. Electrical equipment separation is further discussed in Section 8.1.6.

8.3.1.1.2.7 Distribution Equipment Capacities

a.	4 kV Switchgear	1200 A continuous rating, 350 MVA, 3ϕ, 50,000 A rms symmetrical interrupting rating
b.	4 kV Switchgear (ATWS)	1200 A continuous rating, 250 MVA, 3ϕ, 37,500 A rms symmetrical interrupting rating
c.	440 V Unit load centers	
	Transformers	1000 kVA, AA, 3 phase, 60 Hz, 4160-480 GRD Y/277 V
	Horizontal Bus	1600 A continuous rating
	Vertical Bus	600 A continuous rating
	Breakers (metal clad)	22,000 A rms symmetrical, minimum interrupting rating

d.	440 V MCCs	
	Horizontal bus	600 A continuous rating 42,000 A rms symmetrical bracing
	Vertical bus	600 A continuous rating 42,000 A rms symmetrical bracing
	Breakers (molded-case)	22,000 A rms symmetrical, minimum interrupting rating and 14,000 A rms symmetrical with integral current limiter
e.	120 V Instrument ac distribution panels	
	Buses	225 A continuous rating 10,000 A rms symmetrical bracing
	Breakers (molded-case)	100 A frame size 5,000 A rms symmetrical interrupting rating

8.3.1.1.2.8 Automatic Load Shedding and Sequential Loading

Shedding of the loads off the Class 1E buses is achieved by using undervoltage relays that automatically trip the breakers on bus undervoltage or a LOCA signal in the unit with which the loads are associated. Load sequencing is accomplished by using time-delay relays on individual breaker control circuits.

The following describes load shedding and sequential loading after a LOCA:

a. With offsite power available, all Class 1E 4 kV breakers on the unit with the LOCA, except for the RHR pump motor feeder breakers and incoming source breakers, are tripped. The required Class 1E loads are then started in a preset time sequence as shown on Table 8.3-1(b). Common loads supplied from the unit without the LOCA, which are required to support the unit with the LOCA, are also started.

b. For a total LOOP, all Class 1E 4 kV breakers on the unit with the LOCA are tripped and the required Class 1E loads are then started in a preset time sequence as shown on Table 8.3-1(a). All Class 1E 4 kV breakers on the non-LOCA unit are also tripped with the exception of the load center feeder breakers. Common loads supplied by the non-LOCA unit, which are necessary to support the LOCA unit, are started automatically. All other 4 kV loads in the non-LOCA unit are started manually as required for emergency shutdown.

For further information, see Section 8.3.1.1.3.6.

8.3.1.1.2.9 Class 1E Equipment Identification

A clear identification is provided to distinguish between Class 1E and non-Class 1E equipment. Each division of the Class 1E cable and raceway is identified by a unique color and a numbering system. Section 8.3.1.3 discusses Class 1E and non-Class 1E equipment identification in detail.

8.3.1.1.2.10 Instrumentation and Control Systems for the Applicable Power Supply Identified

Power for the four divisions of Class 1E instrumentation and control circuits is supplied by the respective division of the Class 1E instrumentation and control distribution equipment. The power supplies for instrumentation and control circuits are described below.

a. Instrumentation - The instrumentation ac system supplies power for the Class 1E instruments.

   Four independent Class 1E 208/120 V ac power supplies are provided to supply the associated four channels of the instruments. The four bus arrangement provides a separate electric power supply to each of the four channels that are electrically and physically isolated from the other channels. Each power supply consists of a 480-208Y/120 V transformer and one or more distribution panels. The 440 V power supply is provided by the corresponding 440 V Class 1E MCC.

b. Control Circuits - Control power for the 4 kV Class 1E switchgear is supplied by the Class 1E 125 V dc system, while load centers and MCCs use 120 V ac for control power.

   Dc control power for the Class 1E switchgear is provided from Class 1E batteries of the same division. Four divisions of Class 1E batteries supply control power to the associated four divisions of the Class 1E switchgear. For a further description of the dc system, see Section 8.3.2.

   For each Class 1E load center, control power is supplied from a control bus connected to the load center power bus through a control transformer.

   MCC control power is supplied by individual control transformers connected to those breakers requiring control power. For selected control circuits, Class 1E 125 V dc control power is used to supplement the Class 1E 120 V ac supplied by individual control transformers.

8.3.1.1.2.11 Electric Circuit Protection Systems

Protective relay schemes and direct-acting trip devices on primary and backup circuit breakers are provided throughout the onsite power system to:

a. Isolate faulted equipment and/or circuits from unfaulted equipment and/or circuits

b. Prevent damage to equipment

c. Protect personnel

d. Minimize system disturbances

e. Maintain continuity of the power supply

The short-circuit protective system is analyzed to ensure that the various adjustable devices are applied within their ratings and set to be coordinated with each other to attain selectivity in their operation. The combination of devices and settings applied affords the selectivity necessary to isolate a faulted area quickly, with minimum disturbance to the rest of the system.

Each circuit breaker and protective relay is equipped with a visual indicator to identify its actuation.

To avoid spurious trips and to ensure correct selective operation of the protective devices and their associated breakers, minimum time intervals are maintained between the characteristic tripping curves of the various protective devices to account for pickup tolerances.

When coordinating inverse-time overcurrent relays, the time interval between relay characteristics is a minimum of 0.3-0.4 seconds. The interval consists of 0.08 seconds for circuit breaker operating time, 5 cycles, 0.10 seconds for relay overtravel, and 0.12-0.22 seconds for safety factor. The minimum time interval between relay characteristics and fuse characteristic curves is 0.2 seconds. The current pickup intervals between relay characteristics are selected to maintain tripping selectivity, which includes the separation margins required by relay pickup tolerances.

When coordinating low voltage power circuit breakers, molded-case circuit breakers and fuses, the characteristic curves generally do not overlap. In general, only a slight separation is made between the different characteristic curves because the curves represent minimum and maximum clearing times and include the tolerances of the protective device.

Per the LGS Fire Protection Plan, presented in Appendix 9A, Section 9A.6.1.1, all systems and components that are relied on for achieving safe shutdown receive power from the Class 1E ac distribution system or Class 1E dc power system. Offsite power may be credited as the source for the Class 1E ac distribution system for fire areas which do not require Alternative Shutdown and for which the offsite source(s) to the 4kV switchgear is not affected by fire damage. All circuits, both Class 1E and non-Class 1E, are individually protected by coordinated fault actuated protective devices. Proper coordination among these protection devices is discussed in Section 9A.6.1.1, and demonstrated by time-current coordination curves shown in Figures 9A-13 through 9A-20.

Time-current coordination curves for drywell penetrations are shown in UFSAR Figures 8.1-2 through 8.1-5.

Major types of protection measures employed include the following:

a. Bus differential relaying

   A bus differential relay scheme is provided for each Class 1E 4 kV bus. These relays provide high speed clearing of internal bus faults by tripping all circuit breakers connected to the faulted bus.

b. Overcurrent relaying

Each Class 1E 4 kV bus feeder circuit breaker is equipped with three very inverse-time overcurrent relays and one inverse-time ground fault relay to sense, and protect the bus from, overcurrent condition and to provide backup for feeder circuit protective relays.

Each 4 kV motor feeder circuit breaker has three overcurrent relays, each with one long-time, one high dropout instantaneous, and one standard instantaneous element for overload, locked rotor, and short-circuit protection. Each breaker is also equipped with an instantaneous ground sensor relay. Each 4 kV Class 1E motor is also provided with an overload alarm.

For 4 kV Class 1E motors, the circuit inverse-time protection is set for overload alarm at approximately 115% of motor full load current for motors with service factor (SF) = 1.0 and at approximately 130% full load current for SF = 1.15. The high dropout instantaneous element is set at 175% full load current and will trip for locked rotor and short-circuit currents, provided the inverse-time element has operated. The standard instantaneous element is set at greater than or equal to 160% of motor locked rotor current for short-circuit trip.

Each Class 1E 4 kV supply circuit breaker to a 480 V load center transformer is protected by three extremely inverse-time overcurrent relays with long-time and instantaneous elements. An instantaneous overcurrent ground sensor relay provides sensitive ground fault protection.

For Class 1E 480 V load center transformers, the transformer primary inverse-time protection is set between 200% to 300% of the transformer AA rating.

c. Undervoltage relaying

Each 4 kV Class 1E bus is equipped with undervoltage relays for initiating a diesel generator start, an automatic transfer from the preferred to the alternate offsite power source, shedding the loads off the 4 kV Class 1E buses as described in Section 8.3.1.1.2.8, and loading the diesel generator when both the preferred and alternate offsite power sources are not available.

Each Class 1E 4 kV bus feeder is equipped with three undervoltage relays for starting the diesel generator and automatic transfer to an alternate source upon sensing degraded grid voltage. Section 8.1.6.3.6 gives a description of the degraded grid voltage monitoring system. This design is in compliance with the intent of BTP PSB1.

d. Diesel generator differential relaying

Each diesel generator is equipped with differential relaying protection. This circuitry provides high speed disconnection to prevent severe damage in case of diesel generator internal faults.

e. 440 V Load center protection

Each load center circuit breaker is equipped with integral, solid-state, adjustable, direct-action trip devices providing instantaneous and/or inverse-time overcurrent

protection. Motor feeders are equipped with solid-state adjustable instantaneous and long-time overcurrent trip devices.

The overcurrent devices for breakers supplying 440 V MCCs are set to protect the feeder cables from short-circuit and thermal damage and to be selective with downstream protective devices.

Motor feeder long-time overcurrent devices are set at 145% to 150% motor full load current for motors with service factor (SF) = 1.15, and 130% to 135% full load current for motors with SF = 1.0. The instantaneous trip is set greater than or equal to 160% motor locked rotor current. The time-delay setting is adjusted for the motor characteristics such that acceleration is permitted, while protecting the motor for a locked rotor condition and thermal overload.

Each Class 1E load center feeder circuit breaker supplying non-Class 1E MCCs is equipped with an instantaneous undervoltage relay, which is set for pickup at 80% and dropout adjustable between 30% and 60% of nominal voltage.

f. 440 V MCC protection

Molded-case circuit breakers provide inverse-time overcurrent and/or instantaneous short-circuit protection for all connected loads. For motor circuits, the molded-case circuit breakers are equipped with an adjustable instantaneous magnetic trip function only. Motor thermal overload protection is provided by the heater element trip unit in each phase of the motor feeder circuit. The molded-case breakers for nonmotor feeder circuits provide thermal inverse-time overcurrent protection and instantaneous short-circuit protection. The thermal overload trip units for safety-related MOVs are bypassed in accordance with Section 8.1.6.1.19.

Thermal overload heater elements for Class 1E 460 V continuous-duty motors are selected taking into account the applicable ambient temperature compensation factor, voltage considerations and -10% manufacturing tolerance. The magnetic instantaneous trip on the molded-case breaker is set at approximately 200% locked rotor current to override the motor locked rotor current and to provide short-circuit protection. However, the final instantaneous trip setting may deviate from these guidelines based on test data obtained by field personnel.

The thermal magnetic breakers for nonmotor feeder circuits are set to have a thermal pickup at approximately 125% full load current and a magnetic instantaneous trip setting in excess of the load inrush current.

8.3.1.1.2.11.1 The information from this section has been relocated to the TRM.

8.3.1.1.2.12 Testing of the Ac System During Power Operation

All Class 1E power system equipment for which the Technical Specifications require periodic testing more frequently than every 24 months is provided with means to perform the required testing during power operation.

8.3.1.1.2.13 Power Systems and Equipment Shared Between Units

Each unit is provided with separate and independent onsite Class 1E ac power systems. The Class 1E power system for each unit consists of four independent Class 1E buses, powered by four independent diesel generators, which provide power to four divisions of Class 1E loads. The RHRSW and the ESW systems are considered common systems because each system supplies two independent cooling water loops which are common to both units. However, even though they are considered common systems, there is redundant equipment for these systems in each unit. The redundant equipment in each unit is powered by independent diesel generators in each unit and has the capacity to supply 100% of the required cooling water per unit. The SGTS, CSCWS and the control room and control structure ventilation systems are common systems, each with two 100% capacity redundant trains with common redundant components in each train powered from an independent diesel generator in Unit 1.

8.3.1.1.3 Standby Power Supply

The standby power supply for each division consists of one diesel generator set complete with accessories and fuel storage and transfer systems. Each diesel generator is connected to only one 4 kV Class 1E bus and is interlocked to prevent parallel operation during LOOP. The four Class 1E buses for each reactor unit are operated as separate buses (split bus system) and are not synchronized. Each diesel generator set is operated independently (from the other sets) and is disconnected from the utility power system, except during tests.

Each unit has four channels of standby power supply and four load divisions. With the exception of the standby power supply requirements for the ESW system, the RHRSW system, the SGTS, the CSCWS and the control room and control structure ventilation systems, which are common systems, the operation of three out of four channels of the standby power supply in each unit is adequate to satisfy minimum Class 1E load demand caused by a LOCA or LOOP sources. Common loads for the ESW and the RHRSW systems are split between Unit 1 and Unit 2 standby power supplies. Common redundant loads for the SGTS, the CSCWS and the control room and control structure ventilation systems are fed from Unit 1 standby power supplies. A detailed discussion of the load demand on each diesel, which includes load characteristics, load sequencing, bus assignments, etc., is covered in Section 8.3.1.1.3.6.

Any combination of three-out-of-four divisions (EDGs) is acceptable for a single failure. However, for ECCS requirements (as stated in paragraph 6.3.1.1.2), an EDG operable configuration of 2 out of 4 is also acceptable.

The diesel generators are capable of supplying power to the loads necessary to shut down and cool down the associated unit safely. The diesel engine is a 12-cylinder, model 38-TD8-1/8 colt. The generator is a single bearing bracket, model TGZDJ Beloit Power Systems/Fairbanks Morse. Each diesel generator is rated at 2850 kW for continuous operation and at 3135 kW for two hours of short-time operation in any 24 hour period and is qualified to a 100 start test. The diesel generators are selected so that their ratings satisfy the requirements of Regulatory Guide 1.9, as discussed in Section 8.1.6.1.2. In addition, the diesel generators are capable of operating for extended periods of time at either low load or unloaded in the case of a LOCA occurring with the availability of offsite power. For extended periods of low load operation (up to 30% load), the diesel generators are operated at 50% load or greater for at least one hour in every 12 hour period. The manufacturer's recommendations will be followed for loading up to 50% load. This prevents possible accumulation of combustion and lube oil products in the exhaust system. If a LOCA should occur and offsite power is available, the diesel generators in the unit experiencing

the LOCA would start automatically and run unloaded. After the offsite power grid, reactor parameters, and support systems have been stabilized and the LOCA signal reset, the unloaded diesel generators would be manually stopped and returned to standby. Even though the diesel generators would not be expected to run in this condition for an extended period of time, the capability to manually load the diesel generators to remove possible combustion and lube oil products from the exhaust system is provided.

The following sections discuss the functional aspects of the diesel generator.

8.3.1.1.3.1 Starting Initiating Circuits

The diesel generators are started by any of the following conditions:

a. LOOP at the 4 kV Class 1E buses

b. Low reactor water level (associated unit only)

c. High drywell pressure coincident with low reactor pressure (associated unit only)

d. Manual actuation of the start/automatic/stop control switch in the control room when the remote/local selector switch is in the REMOTE position

e. Manual actuation of the start/stop control switch on a local control station when the remote/local selector switch is in the LOCAL position

Two redundant control/starting circuits are provided for each diesel generator. The failure of one circuit does not prevent the respective diesel generator from starting or from operating continuously.

Although started automatically, the diesel generators are not automatically connected to their associated 4 kV Class 1E buses until the generator voltage and frequency are established, the breakers connecting the emergency buses to the offsite sources are tripped, and the bus voltage is zero. The diesel generator is stopped by the operator after he/she determines that continued operation of the diesel is not required. Diesel generator steady state operating frequency is maintained within a band as determined by the Technical Specifications.

8.3.1.1.3.2 Diesel Starting Mechanism and System

The diesel generator start system is described in Section 9.5.6. Each diesel engine is provided with immersion heaters in the engine jacket water and the lube oil system to maintain the engine coolant and lube oil temperature at an operable level for fast and reliable starting of the diesel engines. The standby jacket coolant heater and the standby jacket coolant circulating pump are interlocked for simultaneous operation when the jacket water temperature drops below the preset temperature and the engine is below the preset speed. The standby lube oil heater and the standby lube oil circulating pump are interlocked for simultaneous operation when the oil is below a preset temperature and the engine is below a preset speed. See Sections 9.5.5 and 9.5.7 for further description.

8.3.1.1.3.3 Tripping Devices

Each diesel and/or related generator circuit breaker, while supplying loads during a LOCA, are tripped only for the following conditions:

a. Engine overspeed

b. Diesel generator differential overcurrent

c. 4 kV bus differential overcurrent

When the diesel generator receives an emergency (LOCA) start signal, the LOCA relay is energized and the following trips are bypassed; specifically, the generator circuit breaker trip and/or engine shutdown functions for the following abnormal conditions will be overridden:

a. Generator phase overcurrent

b. Generator ground neutral overcurrent

c. Antimotoring

d. Jacket coolant high temperature

e. Jacket coolant low pressure

f. Lube oil high temperature

g. Lube oil low pressure

h. Deleted

i. 4 kV bus phase overcurrent

j. 4 kV bus ground overcurrent

The bypass circuitry contains the following:

a. A NORMAL/TEST switch is provided at the generator control panel to arm the bypassed engine shutdown functions during simulated LOCA testing.

b. The following abnormal conditions of the bypassed parameters are annunciated in the main control room:

    1. Generator phase overcurrent

    2. Generator ground neutral overcurrent

    3. Diesel generator protective trips not bypassed for LOCA test.

The following abnormal conditions of the bypassed parameters are annunciated at the local control panel and at a common DIESEL GENERATOR TROUBLE alarm in the main control room.

1. Jacket coolant temperature high

2. Jacket coolant pressure low

3. Lube oil temperature high

4. Lube oil pressure low

5. Diesel generator protective trip not bypassed for LOCA test.

c. Following a simulated LOCA test (after the LOCA signal is reset and the engine is stopped), the bypass trip circuit is manually reset by returning to NORMAL at the local panel. This rearms the trips for routine testing and permits them to be bypassed by an actual LOCA start signal.

The annunciator system for these trips provides indication of first out alarm. For example, when one or more abnormal conditions are annunciated at the local control panel, the DIESEL GENERATOR TROUBLE alarm in the main control room notifies the operator of a problem. The local control panel gives indication of which abnormal condition occurred first.

Directional overcurrent (reverse power) protection is provided but is permitted to trip the 4 kV bus breakers only during operation of the diesel generator in parallel with the preferred power supply during manually initiated testing.

To prevent spurious tripping of the engine due to malfunction of an engine protective device, three independent sensors are provided and connected in a two-out-of-three tripping logic for all trip conditions except engine overspeed and protective relays. The overspeed trip device is a simple, highly reliable mechanical device for which two-out-of-three tripping logic is unnecessary.

The starting circuit is equipped with a "fail to start" relay that interrupts the starting of the diesel generator if the diesel generator does not reach 200 rpm within a preset time following a start initiation. The "fail to start" relay causes the "start relay" and the "ready for auto start" relay to become deenergized, and provides a failure to start alarm both locally and in the main control room. Energizing the "fail to start" relay will prevent a subsequent auto or manual start. After correcting the trouble, the "fail to start" relay must be reset at the diesel generator by manually operating the engine shutdown reset located at the diesel generator local control panel.

8.3.1.1.3.4 Breaker Interlocks

Interlocks are provided in the closing and tripping of the 4 kV Class 1E circuit breakers to protect personnel and equipment from the following conditions:

a. Automatic energizing of electric devices or loads during maintenance

b. Automatic closing of the diesel generator breaker to any energized or faulted bus

c. Connecting two sources out of synchronism

8.3.1.1.3.5 Control Permissive

A single key-operated local/remote selector switch at the local control panel is provided for each diesel generator to block automatic start signals when the diesel is out-of-service for maintenance. An annunciator alarm in the control room indicates DIESEL NOT IN AUTO when the switch is not in the REMOTE position.

A control switch in the control room and a local control switch on the local control panel in the diesel generator room are provided to allow manual starting of the diesel when all protective systems are permissive. During periodic diesel generator tests, permissives and interlocks are designed to permit manual synchronizing and loading of the diesel generator with either offsite power source.

8.3.1.1.3.6 Loading of Diesel Generators

The diesel generators are designed to start and attain the required voltage and frequency within 10 seconds. The generator, static exciter, and voltage regulator are designed to permit the unit to accept the load and to accelerate the motors in the sequence and time requirements shown in Table 8.3-1(a). LGS does not use an emergency load sequencer associated with the offsite and onsite power sources. Sequencing of loads on the Class 1E buses is achieved by individual time-delay relays for each load. There are no short-circuits that could render both the onsite and offsite power sources unavailable.

Voltage drop calculations on starting large motors have been made to ensure proper acceleration of the pumps under the required conditions for core cooling after a DBA. Proper control and timing relays are provided so that each load is applied automatically at the proper time and in the starting sequence indicated in Table 8.3-1(a). When the automatic loading sequence of the Class 1E loads is completed, the operator may manually add additional loads as assigned in Table 8.3-3 but these loads should not exceed the available capacity of the diesel generator as limited by fuel consumption. The operator may also trip Class 1E loads if their continued operation is not necessary. Load shedding before diesel generator operation is discussed in Section 8.3.1.1.2.8.

Table 8.3-2 summarizes the maximum loading conditions of any one diesel generator for the situation in which all four diesel generators in each unit are in service and also for the situation in which any one of the eight diesel generators is out-of-service. Tables 8.3-3, 8.3-9 through 8.3-17 provide detailed backup data for the summary of Table 8.3-2. The Table 8.3-2 summary also incorporates both load center transformer losses and a load factor for frequency/voltage uncertainties. Table 8.3-3 shows the assignment of individual loads to the eight emergency buses and the eight diesel generators. Tables 8.3-9 through 8.3-17 indicate how heavily a diesel generator may be loaded during a Unit 1 DBA and a spurious LOCA in Unit 2 followed by an emergency shutdown of Unit 2 for time intervals of 0-10 minutes, 10-60 minutes, and beyond 60 minutes. These tables show that the calculated maximum loading of any one diesel generator for all time periods following a DBA is within the DEMA continuous rating of typical diesel generators that have been qualified and furnished for nuclear standby service. These tables also show that the loading is within the rating of each diesel generator as limited by fuel consumption.

8.3.1.1.3.7 Testing

Diesel generator testing consists of the following:

a. Preoperational test - Each diesel generator is tested at the site before reactor fuel loading, in accordance with the requirements of Chapter 14.

b. Periodic test - The diesel generator surveillance test program will provide for a minimum loading of 25% of rated load.

Equipment will undergo periodic surveillance testing in accordance with LGS Technical Specifications. This testing is implemented as part of the surveillance test program.

The manufacturer technical manuals and preventive maintenance recommendations will be reviewed and appropriate preventive maintenance actions will be incorporated into the preventive maintenance program. Equipment maintenance histories will be kept for the diesel generators, and completed preventive maintenance will be documented in the history. This will aid in the detection of repetitive failures that may be analyzed for corrective action directed at the cause of failure. The preventive maintenance program will be enforced and controlled as delineated in the administrative procedure for this program.

Within the maintenance program procedures, a "Return-to-Normal" section will be included to specify steps necessary to return the diesel generator system to operational status. After completion of "Return-to- Normal" section and required surveillance testing, the unit can be returned to the control room operator in automatic standby mode.

If the diesel generator is running in the test mode and an emergency demand start diesel signal is received, the diesel generator controls will automatically convert the governor from the droop to the isochronous mode and the automatic voltage regulator to the isolated mode. The generator breaker will also be automatically tripped if offsite power is available. Thus, the control of the diesel generator is returned to the automatic control system and loading may proceed as discussed in Sections 8.3.1.1.2.8 and 8.3.1.1.3.6.

Compliance with Regulatory Guide 1.108, "Periodic Testing of Diesel Generator Units Used as Onsite Electric Power Systems at Nuclear Power Plants," is discussed in Section 8.1.6.1.20.

8.3.1.1.3.8 Fuel Oil Storage and Transfer System

The diesel generator fuel oil system is described in Section 9.5.4.

8.3.1.1.3.9 Diesel Generator Cooling and Heating Systems

The diesel generator cooling and heating systems are discussed in Section 9.5.5.

8.3.1.1.3.10 Instrumentation and Control Systems for Standby Power Supply

Control hardware is provided in the control room for each diesel generator for the following operations:

a. Starting and stopping

b. Manual synchronization

c. Frequency and voltage adjustment

Control hardware is provided at each of the local control panels for the following operations:

a. Starting and stopping

b. Frequency and voltage adjustment

c. Automatic or manual voltage regulator selection

d. Local or remote control selection (key-operated switch)

Electric metering instruments are provided in the control room for surveillance of the following diesel generator parameters:

a. Voltage

b. Current

c. Frequency

d. Power output (watts)

e. Reactive power output (var)

f. Field voltage

g. Field current

Electrical metering instruments are provided at the local control panel for surveillance of the following diesel generator parameters:

a. Voltage

b. Current

c. Frequency

d. Power output (watt)

e. Reactive power output (var)

f. Energy output (watt-hour)

g. Field voltage

h. Field current

The following abnormal diesel engine and generator conditions are annunciated at the local control panel:

a. Lube oil pressure low

b. Lube oil keep-warm failure

c. Lube oil temperature high

d. Lube oil filter differential pressure high

e. Lube oil strainer differential pressure high

f. Lube oil level low

g. Lube oil or jacket water circulating pump failure

h. Jacket water keep-warm failure

i. Jacket water temperature high

j. Jacket water expansion tank level low

k. Jacket water pressure low

l. Starting air pressure low

m. Fuel oil pressure low

n. Fuel oil strainer differential pressure high

o. Fuel oil filter differential pressure high

p. Fuel oil day tank level low

q. Fuel oil day tank level high

r. Overspeed trip

s. Crankcase pressure high

t. Drip pan/dirty fuel oil tank level high

u. Start failure

v. Not ready for autostart

w. Generator stator temperature high

x. Generator bearing temperature high

y. Generator field ground

z. Generator loss of excitation

aa. Generator overexcitation

bb. Field flash voltage loss

cc. Emergency stop

dd. Dc fuel pump running

ee. Fuel oil transfer strainer differential pressure high

ff. 480 V ac auxiliary power off

gg. 125 V dc control power off

hh. Dc fuel pump power off

ii. Generator overvoltage

jj. Switch not in auto

kk. Fuel oil day tank temperature high

ll. Diesel generator protective trips not bypassed for LOCA test

mm. Intercooler coolant pressure low

nn. Fire/local control diff/ground trip bypass for 1AG501 only
Fire/local control for 2AG501 only

oo. Diesel generator exhaust heat tracing trouble

The following abnormal diesel engine and generator conditions are annunciated at the main control panels:

a. Diesel generator trouble (for alarms (a) through (oo), above)

b. Diesel generator differential/ground lockout

c. Generator overcurrent

d. Generator neutral overcurrent

e. Diesel generator not in auto

f. Diesel generator failed to start

g. Diesel generator fuel oil storage tank high or low

h. Diesel generator not reset

i. Diesel generator protective trip not bypassed for LOCA test

8.3.1.1.3.11 Prototype Qualification Testing

To confirm the ability of the diesel generator to perform as required, in September 1968 the diesel generator manufacturer conducted a series of tests designed to:

a. Simulate the conditions experienced during nuclear plant protection service

b. Record performance under such simulated conditions

c. Allow the use of recorded performance data to design optimized generator and excitation system

d. Demonstrate starting and load acceptance reliability

The details of the motor starting test program are covered in Reference 8.3-1.

The diesel generator manufacturer has extensive operational experience with skidded control systems, including the many nuclear protection units already tested and delivered.

As discussed in Sections 1.8 and 8.1.6.2, LGS is committed to Regulatory Guide 1.9 (Rev. 0) and IEEE 387 (1972). The diesel generators, therefore, are not required to pass a 300 consecutive start qualification test. However, the 12-cylinder model 38-TD8-1/8 Colt diesel engine used at LGS was qualified to a 100 start test conducted in 1968. This model engine has been used in the following plants that have received Operating Licenses:

Robinson 2	Duane Arnold
Prairie Island 1 & 2	North Anna 1 & 2
Vermont Yankee	Millstone 1 & 2
Three Mile Island 1 & 2	Farley 1 & 2
Calvert Cliffs 1 & 2	Arkansas Nuclear One, 2
Crystal River 3	PBAPS 2 & 3
E.I. Hatch 1 & 2	Fermi 2

The LGS diesel generators are nearly identical to the diesel generators used to demonstrate start and load acceptance reliability tests. The differences are that LGS diesel generator units have tubular heat exchangers while the test unit was radiator-cooled, and the LGS units have combustion air that passes from the turbocharger to the blower while the order is reversed for the test unit. These differences are judged to be an improvement of reliability and load acceptance capability. Therefore, the tests are applicable to the LGS diesel generator units.

8.3.1.1.3.12 Conditions Prohibiting Diesel Generator Automatic Emergency Start and Associated Main Control Room Annunciators

Two groups of conditions render the diesel generator incapable of responding to an automatic start signal:

a. Abnormal conditions that may prevent start or cause trip or impede sustained operation

b. Control switch(es) in incorrect positions

The following is a tabulation of such conditions for both of these groups:

a. Abnormal Conditions

1. Engine overspeed
2. Generator differential overcurrent
3. 4 kV bus differential overcurrent
4. Generator antimotoring relay operation
5. Generator phase overcurrent
6. Generator neutral overcurrent
7. Lube oil low pressure
8. Lube oil high temperature
9. Jacket coolant low pressure
10. Jacket coolant high temperature
11. Failure to start relay operation
12. Crankcase high pressure
13. Diesel cell fire protection system activated(1)
14. Loss of 125 V dc control voltage to diesel control panel
15. Loss of 125 V dc to field flashing contacts
16. Loss of 125 V dc control voltage to 4 kV bus breakers and/or diesel generator breaker

---

(1) Fire protection system actuation will not prevent an automatic start of the diesel generator, but sustained operation cannot be guaranteed.

17. 4 kV bus breakers and/or diesel generator breaker racked out
18. ESW valves closed

19. Starting air pressure low

20. Nonsafeguard 4 kV loads on 4 kV bus with loss of breaker trip voltage

b. Control Switch Incorrect Positions

21. Remote/local selector switch in LOCAL

22. Exciter shutdown reset switch in SHUTDOWN

23. Engine shutdown reset switch not RESET

24. Emergency stop switch in STOP

25. Generator 4 kV breaker control switch in PULL-TO-LOCK

26. Diesel control switch in PULL-TO-LOCK

27. Diesel start logic bypass switches (two of two per diesel) in BYPASS

The following annunciator legends are provided in the control room for diesel generator alarms for each diesel generator:

1. DG breaker trip

2. DG differential/ground lockout

3. Diesel failed to start

4. Diesel not in AUTO

5. Diesel running

6. DG breaker autoclose

7. DG not RESET

8. DG trouble

9. Standby ac power system out-of-service

10. Generator neutral overcurrent

11. DG protection trip not bypass for LOCA test

12. Generator overcurrent

13. Fire protection alarm panel 00C926 Trouble
(common for all diesel generators)

For each of the conditions listed above (conditions 1-26), the following annunciators are received in the control room:

Condition	Alarms
1	1, 8
2	1, 2
3	Bus Diff/Overcurrent Lockout
4	1
5	1, 12
6	1, 10
7	1, 8
8	1, 8
9	1, 8
10	1, 8
11	3, 8
12	8
13	13
14	8
15	8
16	9
17	9
18	9
19	8
20	9
21	4, 7, 8, 9
22	4, 7, 8, 9
23	7, 9
24	7, 8, 9
25	9
26	4
27	8

Each condition that brings up the system out-of-service alarm (#9) lights an indicating light on the system vertical board in the control room to allow the operator to distinguish what condition has caused the alarm.

The following control room annunciators that were listed above are also triggered by the indicated conditions that were not listed above:

Annunciator	Conditions
DG Trouble	• All conditions that alarm at the local diesel annunciator panel. These conditions are listed in Section 8.3.1.1.3.10.
Standby AC Power System Out-of-Service	• Bus undervoltage relays in test/loss of voltage

	• Safeguard load center breaker not connected/loss of control voltage • Out-of-service alarm manually initiated
Diesel Not In Auto	• Any of the following control switches are not in AUTO: - Jacket coolant heater - Coolant circulating pump - Lube oil heater - Lube oil circulating pump - Generator space heater - Dc auxiliary fuel oil pump

There are no conditions that render the diesel generator incapable of starting that are not alarmed in the control room.

8.3.1.1.3.13 The material in this Section has been rewritten and relocated to Section 13.2.1.7.

8.3.1.1.4 Electrical Equipment Layout

Class 1E switchgear, load centers, MCCs, and distribution panels of redundant channels are in separate rooms or are spatially separated by a predetermined safety distance or barrier. They are located in the reactor enclosure, the control enclosure, or the spray pond pumphouse.

Standby diesel generators, related Class 1E MCC's, and associated equipment are in separate rooms of the seismic Category I diesel generator enclosure. Each room is provided with a separate ventilation system.

The diesel generators do not generate harmful torsional vibrations when operating at any speed from 0% to 115% of rated speed. The engine gauge panel is located on the engine generator skid; however, it is mounted in a cradle on isolation springs. Colt (the manufacturer) has successfully used this method of mounting engine gauge boards for several years. Further, items critical to the continued operation of the unit are not mounted in the gauge panel. The annunciator and other sensitive items are located in freestanding electrical control panels. The control panel is physically separated from the diesel generator.

The following electrical equipment however, is located on the diesel generator skid:

a. Generator terminal box containing connections from the diesel generator to the local control panel.

b. Generator neutral box containing the connectors from the generator neutral grounding resistor.

c. Motor starter and heater control panel - All pump motors have automatically controlled magnetic starters, and the keep-warm heaters have automatically controlled contactors. The starter and contactors for the following motors and heaters are located in the starter panel at the generator end of the skid:

1. Jacket coolant heater

2. Jacket coolant circulating pump

3. Lube oil heater

4. Lube oil circulating pump

5. Generator space heater

6. Dc auxiliary fuel oil pump

d. Circuit breaker panel board - The following ac equipment on the skid is protected by circuit breakers that are located in the circuit breaker panel at the generator end of the skid:

1. Jacket coolant heater

2. Jacket coolant circulating pump

3. Lube oil heater

4. Lube oil circulating pump

5. Prelube pump

6. Generator space heater

e. Engine gauge panel - The following instruments are mounted in the engine gauge panel at the turbocharger end of the skid:

Instrument	Monitoring Function
6 Duplex Pressure Gauges	• Jacket water pump discharge pressure duplexed with air cooler coolant heat exchanger outlet pressure. • Fuel oil pressure upstream and downstream of the line filter in the discharge piping of the engine-driven fuel oil pump. • Fuel oil pressure upstream and downstream of the line filter in the discharge piping of the motor-driven fuel oil pump. • Engine inlet lube oil pressure duplexed with engine-driven oil pump discharge pressure.

	• Upper engine header pressure duplexed with the turbo-charger oil pressure. • Starting air pressure upstream of both air start valves.
2 Differential Pressure Indicators (mounted on separate adjacent gauge panel)	• Basket strainer differential pressure on the engine-drive fuel oil pump. • Basket strainer differential pressure on the motor-driven fuel oil pump.
1 Simple Pressure Gauge	• Scavenging air blower discharge pressure.
2 U-tube manometers	• Crankcase pressure. • Turbocharger inlet pressure.
3 Duplex temperature gauges	• Engine suction lube oil temperature duplexed with the engine-driven pump discharge lube oil temperature. • Jacket water temperature on both the engine-driven pump suction and the header discharge. • Scavenging air blower discharge temperature duplexed with the air cooler coolant inlet temperature.
1 15-point pyrometer	• Points 1 to 12 measure the individual cylinder exhaust temperatures, points 13 and 14 measure the turbocharger inlet temperatures, and Point 15 measures the combined exhaust temperature.
1 Tachometer	• Provides local indication of engine rpm.
1 Indicating Light	• Verifies that the local alarm circuits are armed.

Equipment associated with these instruments is housed within the engine gauge panel enclosure and is accessed through a fully gasketed dust-tight door.

The entire panel assembly is mounted in a cradle on isolation springs such that vibration-induced loads will not affect the performance of the instrumentation. Also, no items that are critical to the operation of the diesel under emergency conditions are housed within this enclosure.

f. Dc control relay and terminal box - The following relays are found in the relay and terminal box located at the generator end of the skid:

1. Emergency start relays

2. Normal start relays

3. Other control relays

4. Coolant temperature high switch

5. Coolant pressure low switch

6. Lube oil temperature high switch

7. Lube oil pressure low switch

8. Alarm relays

The relay and terminal box is mounted at the generator end of the skid. The box is not mounted on an isolation spring; however, the box is anchored to the skid at its base and supported at the top by two lengths of angle iron.

This is the manufacturer's standard design for mounting this box on the diesel generator skid. This box is supported and mounted to prevent any vibration-induced damage of the relays. The manufacturer has shown by over 20 years of use that this support design adequately protects the internal components in the relay and terminal box from harmful vibration levels.

The seismic qualification of the relays in the relay and terminal box has been addressed in the equipment qualification program, and the information is contained in the dynamic qualification package for the diesel generators. Vibrational aging was not performed on these relays as there is no valid method of performing accelerated aging for vibrational effects and because the vibrational levels which these relays may see have been shown through operating experience as not having any detrimental effects on the operation of these relays.

The licensee contacted several other nuclear stations which employ the same mounting design of the relay and terminal box as LGS. The stations contacted reported that there have been no vibration induced failures of the relays in question. In addition, the failure record at the stations contacted indicates that there have been no problems with the relays installed in the relay and terminal box.

The manufacturer, who is notified if there are any problems with the diesel generator equipment, stated that no vibration induced failures have been reported by any station.

For the reasons listed above, we believe that the relay and terminal box is adequately supported and that the components in this box are proven by experience to be protected against harmful vibration levels.

The above described methods of mounting have been the manufacturer's standard design for over 20 years. Neither the manufacturer nor the applicant, whose PBAPS units have been in service for about 10 years, have reported any vibration-induced failures in any of the components mounted on the diesel generator skid.

8.3.1.1.5 Design Criteria for Class 1E Equipment

The following design criteria are applied to the Class 1E equipment supplied from the onsite ac power system:

a. Motor size - Motor size (horsepower capability) is equal to or greater than the maximum horsepower required by the driven load under normal running, run-out, or discharge valve (or damper) closed condition.

b. Minimum motor accelerating voltage - The electrical system is designed so that the total voltage drop during the start of the last largest motor on the system is less than 25% and 20% of the nominal bus voltage at the 4 kV and 440 V buses, respectively. The Class 1E motors are specified with accelerating capability at 80% nominal voltage at their terminals for 460 V motors and 75% for 4 kV motors.

c. Motor starting torque - The motor starting torque is capable of starting and accelerating the connected load to normal speed within sufficient time to perform its safety function for all expected operating conditions, including the design minimum terminal voltage.

d. Minimum motor torque margin over pump torque through accelerating period - The minimum motor torque margin over pump torque through the accelerating period is determined by using actual pump torque curves and calculated motor torque curves at 75% or 80% terminal voltage. The minimum torque margin (accelerating torque) is such that the pump motor assembly reaches nominal speed in less than 5 seconds. This margin is usually not less than 10% of the pump torque.

e. Motor insulation - Insulation systems are selected on the basis of the ambient conditions to which the insulation is exposed. For Class 1E motors located within the containment, the insulation system is selected to withstand the postulated accident environment.

f. Temperature monitoring devices provided in large horsepower motors - Six RTDs or TCs, two per phase, are provided in the motor stator slots for Class 1E motors, as shown in Drawings E-15 and E-16. In normal operation, the RTDs or TCs at the hottest location (selected by test) monitors the motor temperature and provides an alarm on high temperature. Each bearing has a Type T copper-constant thermocouple bearing temperature device to alarm on high temperature.

g. Interrupting capabilities - The interrupting capabilities of the protective equipment are determined as follows:

    1. Switchgear

Switchgear interrupting capabilities are greater than the maximum short-circuit current available at the point of application. The magnitude of short-circuit currents in medium voltage systems is determined in accordance with ANSI C37.010 (1972). The offsite power system, a single operating diesel generator, and running motor contributions are considered in determining the fault level. Medium voltage power circuit breaker interrupting capability ratings are selected in accordance with ANSI C37.06 (1971).

2. Load centers, MCCs, and distribution panels

Load center, MCC, and distribution panel interrupting capabilities are greater than the maximum short-circuit current available at the point of application. The magnitude of short-circuit currents in low voltage systems is determined in accordance with ANSI C37.13 (1973) and NEMA AB1. Low voltage power circuit breaker interrupting capability ratings are selected in accordance with ANSI C37.16 (1973). Molded-case circuit breaker interrupting capabilities are determined in accordance with NEMA AB1.

h. Electric circuit protection - Electric circuit protection criteria are discussed in Section 8.3.1.1.2.11.

i. Grounding requirements - Equipment and system grounding are designed in accordance with the applicable industry codes and standards.

8.3.1.1.6 Logic and Schematic Diagrams

Sufficient logic and schematic diagrams are provided herein to permit an independent evaluation of compliance with safety criteria (Section 1.7).

8.3.1.1.7 Cable Derating and Cable Tray Fill

Cables are sized and cable trays are filled in accordance with the applicable codes and standards. The cables are properly derated for specific application in the location where they are installed.

a. Cable derating

The power and control cable insulation is designed for a conductor temperature of 90°C. The allowable current carrying capacity of the cable is based on not exceeding the insulation design temperature while the surrounding air is at an ambient temperature of 65°C for the primary containment and 40°C to 49°C for all other areas. The design operating conditions of all Class 1E cables are discussed in Section 3.11.

The power cable ampacities are established in accordance with ICEA (also known as IPCEA) publications P-53-426, P-54-440, and P-46-426. They are derated based on the type of installation, the conductor and ambient temperatures, the number of cables in a raceway, and the grouping of the raceways. The method of calculating these derating factors is determined from the ICEA publications and other applicable standards. For unique raceway configurations where the use of the applicable standard results in very conservative ampacity values, cables may be derated using

a heat transfer model which considers load diversity among the cables installed in the raceway.

For control circuits, which usually carry currents of less than 10 amperes, minimum #14 AWG conductors are generally used.

Instrumentation cable insulation is also designed for a conductor temperature of 90°C. The operating currents of these cables are low (usually mA or mV) and do not cause the design temperature to be exceeded at maximum design ambient temperature.

b. Cable tray fill

Section 8.1.6.1.14.b.1(c) gives cable tray fill criteria. The total weight of tray and cable does not exceed 36 pounds per linear foot for Unit 1 and does not exceed 45 pounds per linear foot for Unit 2.

Conduit fill is in compliance with tables I and II, chapter 9, National Electrical Code (1975).

c. Cable description

Power cables, control cables, and instrumentation cables are defined as follows:

1. Power cables

Power cables are those cables that provide electrical energy for motive power or heating to 13.2 kV ac, 4 kV ac, 2.3 kV ac, 440 V ac, 115 V ac, 240 V dc, and 120 V dc loads. For loads with voltage levels higher than 440 V ac, cables with 15 kV insulation are used. For loads with voltage levels at 440 V ac or lower, including dc loads, cables with 600 V insulation are used.

2. Control cables

Control cables are generally the cables for 120 V ac, 250 V dc, and 125 V dc, circuits between components responsible for the automatic or manual initiation of auxiliary electrical functions and the electrical indication of the state of auxiliary components. Control cables are rated 600 V insulation class.

3. Instrumentation cables

Instrumentation cables are those cables conducting low level instrumentation and control signals. These signals can be analog or digital. Typically, these cables carry signals from thermocouples, resistance temperature detectors, transducers, neutron monitors, etc.

8.3.1.1.8 Fire Barriers and Separation Between Redundant Trays

Electrical equipment and cabling is arranged to eliminate the propagation of an electrical fault from one separation group to another and to prevent the propagation of an exposure fire from affecting at least one safe shutdown group. Physical separation of cabling systems for compliance with Regulatory Guide 1.75 is discussed in Section 8.1.6.1.14.

Physical separation of cabling systems for compliance with 10CFR50, Appendix R, is discussed in Appendix 9A.

8.3.1.2 Analysis

8.3.1.2.1 General Design Criteria and Regulatory Guide Compliance

The following paragraphs analyze compliance with GDC 2, GDC 4, GDC 5, GDC 17, GDC 18, and GDC 50. All regulatory guides are discussed in Section 8.1.6.

8.3.1.2.1.1 GDC 2 - Design Bases for Protection Against Natural Phenomena

The requirements of the criteria are met, in that all components of the Class 1E onsite ac power system are housed in seismic Category I structures designed to protect them from natural phenomena. These components have been qualified to the appropriate seismic, hydrodynamic, and environmental conditions as described in Chapter 3.

8.3.1.2.1.2 GDC 4 - Environmental and Dynamic Effects Design Bases

The requirements of the criteria are met, in that all components of the Class 1E onsite ac power system are housed in seismic Category I structures designed to protect them from natural phenomena. These components have been qualified to the appropriate seismic, hydrodynamic, and environmental conditions as described in Chapter 3.

8.3.1.2.1.3 GDC 5 - Sharing of Structures, Systems, and Components

This criterion is met, in that there are no Class 1E components of the onsite ac power system that are shared between Units 1 and 2. There are common Class 1E loads that are shared by Unit 1 and Unit 2. These common loads are the RHRSW and ESW systems, for which the onsite ac power system from each unit supplies approximately half of the common equipment in each system; and common components of the SGTS, the CSCWS and the control room and control structure ventilation systems, which are supplied from the Unit 1 onsite ac power system.

8.3.1.2.1.4 GDC 17 - Electric Power Systems

An onsite electric power system is provided to permit the functioning of structures, systems, and components important to safety. With total loss of offsite power, the onsite power system provides sufficient capacity and capability to ensure that:

a. Specified acceptable fuel design limits and design conditions of the RCPB are not exceeded as a result of anticipated operational occurrences.

b. The core is cooled and containment integrity and other vital functions are maintained if there are postulated accidents.

Section 3.2 contains a list of structures, systems, and components important to safety. Tables 8.3-3 and 8.3-19 through 8.3-26 show that each of these loads important to safety is supplied from the onsite electric power supplies.

The onsite electric power system includes four load divisions per unit. With the exception of the ESW system, the RHRSW system, the SGTS, the CSCWS and the control room and control structure ventilation systems, which are common systems, the load divisions on each unit are redundant in that three load divisions are capable of ensuring (a) and (b) above. Common loads for the ESW and the RHRSW systems are split between the Unit 1 and Unit 2 onsite electric power systems. Common redundant loads for the SGTS, the CSCWS and the control room and control structure ventilation systems are included in the Unit 1 onsite electric power system. Sufficient independence is provided between redundant load divisions to ensure that postulated single failures affect only a single load division and are limited to the extent of total loss of that load division. The redundant load divisions remain intact to provide for the measures specified in (a) and (b) above.

During total LOOP, the Class 1E system is automatically isolated from the offsite power system and non-Class 1E onsite ac system.

In addition, each load division of the Class 1E power system is automatically isolated from the redundant load divisions. The combination of these factors in the design minimizes the probability of losing electric power from the onsite power supplies as a result of the loss of power from the transmission system or any disturbances of the non-Class 1E ac system.

The turbine-generator is automatically isolated from the switchyard following a turbine or reactor trip. Therefore, its loss does not affect the ability of either the transmission network or the onsite power supplies to provide power to the Class 1E system. Transmission system stability studies indicate that the trip of the most critical fully loaded generating unit does not impair the ability of the system to supply plant station service. Further discussion is provided in Section 8.2.2.

8.3.1.2.1.5 GDC 18 - Inspection and Testing of Electric Power Systems

The Class 1E system is designed to permit:

a. During equipment shutdown, periodic inspection and testing of wiring, insulation, connections, and relays to assess the continuity of the systems and the condition of components.

b. During normal plant operation, periodic testing of the operability and functional performance of onsite power supplies, circuit breakers, and associated control circuits, relays, and buses.

c. During plant shutdown, testing of the operability of the Class 1E system as a whole. Under conditions as close to design as practicable, the full operational sequence that brings the system into operation, including operation of signals of the ESF actuation system and the transfer of power between the offsite and the onsite power system, is tested.

A review of the electrical control circuitry associated with the safety systems reveals that an accident signal will override a test mode condition with the exception of the following:

a. Parts of the system that are bypassed or deliberately rendered inoperable to perform corrective maintenance or testing. For this case, only one redundant channel is bypassed at a time, and the system BYPASS/INOPERABLE status is alarmed in the control room. The redundant channels that remain in service are sufficient to ensure the initiation and completion of the required safety function.

b. The control system design of the HPCI and RCIC systems provides automatic alignment from test to operating mode if system operation is required except for the following:

1. The AUTO/MANUAL station is in manual on the flow controller. This feature is required for operator flexibility during system operation.

2. Steam inboard/outboard isolation valves; closure of either or both of these valves requires operator action to properly sequence their opening. An alarm sounds when either of these valves leaves the fully open position.

8.3.1.2.1.6 GDC 50 - Containment Design Basis

This criterion, as it relates to the design of circuits using containment electrical penetration assemblies, is met as discussed in Section 8.1.6.1.12.

8.3.1.2.2 Class 1E Equipment Exposed to Hostile Environment

The detailed information on all Class 1E equipment that must operate in a hostile environment during and/or subsequent to an accident is furnished in Section 3.11.

8.3.1.2.3 Loss of Instrumentation and Control Power System Bus

The Class 1E and non-Class 1E distribution panels which supply power to safety and non-safety related control systems and instrumentation which can be used to achieve cold shutdown have been reviewed. The identification of these systems and instruments was performed using the EOPs. The panels which supply the instruments and control systems identified are listed in Table 8.3-27.

There are ten Class 1E instrument ac panels per unit, two for each of the four Class 1E divisions plus two panels per unit for spray pond controls. These panels are fed ultimately from the safeguard 4 kV buses which also feed the 4 kV and 480 V loads associated with each Class 1E division of equipment. Because LGS is designed to be in compliance with the intent of Regulatory Guide 1.47, the loss of voltage to a 4 KV bus, 480 V safeguard load center and/or a safeguard 480 V MCC would result in several system level annunciator alarms being received in the control room. Undervoltage relays monitor control voltage availability to all Class 1E loads including pumps, fans and valves.

Upon sensing a loss of voltage to these components, an annunciator will indicate that the corresponding division of the appropriate safety system(s) is out of service. The following systems have OUT-OF-SERVICE (or TROUBLE) annunciators in the control room on loss of power:

RHR	Standby ac Power	Control Enclosure HVAC
Core Spray	PCRVICS	Reactor Enclosure
RCIC	ADS	Recirculation HVAC
HPCI	RPS	

ESW	REIS
	SGTS

When a system OUT OF SERVICE annunciator is initiated, a yellow status indicating light on the corresponding system vertical board will light to identify the cause of the out-of-service condition. Table 8.3-28 lists the status lights which alarm upon an undervoltage condition.

For the major power distribution buses, the alarms listed in Table 8.3-28, section II, annunciate in the control room to indicate an undervoltage condition.

In addition to the system level OUT-OF-SERVICE annunciators, the annunciators in section III of Table 8.3-28 alarm on loss of voltage to specific control and instrument loops that can be used in safe shutdown on the unit.

As shown in Table 8.3-29, at least one alarm is received in the control room when power is lost to the panels listed in Table 8.3-27. Not all of the alarms received for an undervoltage on these panels are shown. Additional secondary alarms may be received.

For those panels which are listed as having direct indication of loss of power, an undervoltage relay at the panel brings up an annunciator which specifically states that an undervoltage condition exists on the panel. For those panels which are shown as having indirect indications, the operator will be able to recognize that a particular panel has lost power from the description on his alarm response cards which list the possible causes of the alarm. Alarm response cards for the alarms listed in Table 8.3-29 for the panels shown as having indirect indication will note that panel loss of power is a possible cause of the alarm.

The control systems used to achieve a hot shutdown are designed to perform their intended function with a single active failure. As a result, the plant can be placed in a hot shutdown condition with the loss of any single power source. The plant can also be placed in a cold shutdown condition with any single power failure because two independent flow paths can be used. One utilizes the shutdown cooling mode of the RHR system. An alternate method of achieving a cold shutdown has been devised using the ADS valves, and the RHR system aligned with suction from the suppression pool and pump discharge through a RHR heat exchanger to the reactor via an LPCI line.

The instruments which provide information to the operator to help achieve a cold shutdown have been identified through a review of the EOPs, and are listed in Table 8.3-30. An analysis has been completed to determine if, for loss of power to the instrument, there is another instrument available that is fed from an independent bus which monitors the same parameter, or if an alternate method is available for determining the needed parameter. Along with the desired instruments, Table 8.3-30 lists the bus from which they are fed as well as the results of the loss of power evaluation.

8.3.1.3 Physical Identification of Safety-Related Equipment

Each circuit and raceway is given a unique alphanumeric identification, which distinguishes a circuit or raceway related to a particular voltage, function, or channel. In addition, channel identification for Class 1E cables and raceways is designated by a color scheme. One alpha character and the related color code are assigned to a load division on the basis of the following criteria:

a. Engineered safeguard channel A (blue) - Class 1E instrumentation, controls, and power cables, raceways, and equipment related to Division I loads

b. Engineered safeguard channel B (green) - Class 1E instrumentation, controls, and power cables, raceways, and equipment related to Division II loads

c. Engineered safeguard channel C (red) - Class 1E instrumentation, controls, and power cables, raceways, and equipment related to Division III loads

d. Engineered safeguard channel D (light brown) - Class 1E instrumentation, controls, and power cables, raceways, and equipment related to Division IV loads

e. Non-Class 1E - Non-Class 1E instrumentation, controls, and power cables, raceways, and related equipment

f. Separation group W - (blue/yellow) - RPS and NSSS instrumentation, control, and power cables, raceways, and equipment associated with Division A1 loads

g. Separation group X - (green/yellow) - RPS and NSSS instrumentation, control, and power cables, raceways, and equipment associated with Division B1 loads

h. Separation group Y - (red/yellow) - RPS and NSSS instrumentation, control, and power cables, raceways, and equipment associated with Division A2 loads

i. Separation group Z - (light brown/yellow) - RPS and NSSS instrumentation, control, and power cables, raceways, and equipment associated with Division B2 loads

The raceways are marked in a distinct, permanent manner at intervals that do not exceed 15 feet. The cables in these raceways are marked in a sufficiently durable manner and at intervals that do not exceed 5 feet throughout the entire cable length, except for portions of cable enclosed in conduit.

All Class 1E equipment will be labeled in a manner which identifies the equipment as class 1E, and distinguishes Unit 1 Class 1E equipment from Unit 2 class 1E equipment.

Design drawings provide identification of Class 1E equipment by showing the scheme or equipment number that contains the division identifier.

8.3.1.4 Independence of Redundant Systems

Section 8.1.6.1.14 contains the description of the criteria and their bases that establish the minimum requirements for the independence of redundant Class 1E electrical systems through physical arrangement and separation.

This section discusses the criteria and bases for the raceway and cable routing systems for preserving the independence of the redundant Class 1E power systems.

8.3.1.4.1 Raceway and Cable Routing

Cable trays and gutters are designated to route the following types of cable functions:

a. Both ac and dc power and control circuits below 600 V, including current and potential circuits for metering and relaying

b. Low level signal and instrumentation circuits

A raceway designated for one type of cable function contains cables of that function only. Wherever possible, trays are arranged so that power and control trays are at the top and instrumentation and low level signal trays on the bottom.

Exceptions to this separation requirement may be made in accordance with Specification E-1412.

4 kV Class 1E safety-related cables are routed in conduit only, as are all non-Class 1E cables above 600 V.

Cables corresponding to each channel separation group, as defined in Section 8.3.1.3, are run in separate conduits, cable trays, ducts, and penetrations.

8.3.1.4.2 Administrative Responsibilities and Controls for Ensuring Separation Criteria

The separation group identification described in Section 8.3.1.3 facilitates and ensures the maintenance of separation in the routing of cables and the connection of control boards and panels. At the time of the cable routing assignment, during design, the persons responsible for cable and raceway scheduling ensure that the separation group designation on the cable or raceway to be routed is compatible with a single-line diagram channel designation and other cables or raceways previously routed. Extensive use of computer facilities assists in ensuring separation correctness. Each cable and raceway is identified in the computer program, and the identification includes the applicable separation group designation. Auxiliary programs are made available specifically to ensure that cables of a particular separation group are routed through the appropriate raceways. The routing is also confirmed by quality control personnel during installation, to be consistent with the design document. Color identification of equipment and cabling (Section 8.3.1.3) assists field personnel in this effort.

8.3.2 DC POWER SYSTEMS

8.3.2.1 Description

Completely independent Class 1E and non-Class 1E dc power systems are provided for each unit. Except for the common systems described below, there are no common or shared dc power systems. The DC system for Unit 1 is shown in drawing E-33. The DC system for Unit 2 is shown in drawing E-34.

The RHRSW and the ESW system are considered common systems because each system supplies two independent cooling water loops which are common to both units. However, even though they are considered common systems, there is redundant equipment in each unit. For the redundant equipment in each unit, which has the capacity to supply 100% of the required cooling water per unit, the dc power is supplied by the Class 1E dc power systems in each unit. For the SGTS, CSCWS and the control room and control structure ventilation systems, which are common systems, each with two 100% redundant trains, the dc control systems, where applicable, and the isolation logic for the common redundant components in each train are supplied by the Class 1E dc power system in Unit 1.

There are four independent, four division Class 1E dc systems for each unit; two 125/250 V three-wire systems for Division I and II and two 125 V two-wire systems for Divisions III and IV. In

addition, each unit has a 250 V non-Class 1E dc system, and a 125/250 V non-Class 1E dc system, which are separate and independent from the Class 1E dc systems.

8.3.2.1.1 Class 1E Dc Power System

Each 125/250 V system is comprised of two 125 V batteries, each with its own charger, a fuse box for protection of each of the several 125 V power distribution circuits supplying 125/250 V MCCs (one for Division I and two for Division II), and three 125 V power distribution panels. There is a group of battery carts which can be connected to bypass defective battery cells in any one of the 125/250 V systems.

Each 125 V system is comprised of one 125 V battery with its own charger and a fuse box for protection of each of the several 125 V power distribution circuits supplying three 125 V power distribution panels. There is one battery cart which can be connected to bypass defective battery cells in any one of the 125 V systems.

The Class 1E dc power system and its components are located in seismic Category I structures that provide protection from the effects of tornadoes, tornado missiles, turbine missiles, and external floods. This system and its components are designated Class 1E for procurement and quality assurance purposes and have been qualified for seismic and hydrodynamic loads as well as environmental conditions that they may experience during normal operation and postulated accidents.

8.3.2.1.1.1 Class 1E Dc System Equipment Rating

a. 125 V dc Systems

Battery	60 lead-calcium cells, 250 amp-hr
Battery Cart	lead-calcium cells, 250 amp-hr
Charger	ac input - 480 V, 3ϕ, 60 Hz; dc output - 75 A continuous rating
Fuse box	
Bus	600 A continuous rating, 40,000 A short-circuit bracing
Fuse	10,000 A interrupting rating
Distribution panels	
Panel 1	
Main bus	200 A continuous rating, 40,000 A short-circuit bracing
Fuses	13,000 A interrupting rating
Panels 2 and 3	
Main bus	100 A continuous rating, 40,000 A short-circuit bracing

	Fuses	13,000 A interrupting capability
b.	125/250 V dc System	
	Battery	120 lead - calcium cells, 1500 amp-hr
	Battery Cart	lead - calcium cells, 1500 amp-hr
	Chargers	ac input - 480 V, 3ϕ, 60 Hz dc output - 300 A continuous
	Fuse box	
	Bus	2000 A continuous rating, 40,000 A short-circuit bracing
	Fuse	20,000 A interrupting rating
	Motor control centers	
	Main bus (horizontal)	600 A continuous rating 22,000 A short-circuit bracing
	Vertical bus	300 A continuous rating, 22,000 A short-circuit bracing
	Fuses	20,000 A minimum interrupting
	Distribution panels	
	Panel 1	
	Main bus	200 A continuous rating, 40,000 A short-circuit bracing
	Fuse	13,000 A interrupting rating
	Panels 2 and 3	
	Main bus	100 A continuous rating, 40,000 A short-circuit bracing
	Fuse	13,000 A interrupting capability

8.3.2.1.1.2 Class 1E Batteries

The 125/250 V battery consists of two sets of 60 shock-absorbent, clear plastic cells of the lead-calcium type. The 125/250 V battery is rated 1500 ampere-hours.

The 125/250 V battery carts consist of a set of shock absorbent, clear plastic cells of the lead-calcium type. The cells on the 125/250 V battery carts are rated 1500 ampere-hours.

The 125 V battery consists of a set of 60 shock-absorbent, clear plastic cells of the lead-calcium type. The 125 V battery is rated 250 ampere-hours.

The 125 V battery cart consist of a set of shock absorbent, clear plastic cells of the lead-calcium type. The cells on the 125 V battery cart is rated 250 ampere-hours.

Each Class 1E battery bank is sized to have sufficient capacity without its charger to independently supply the large break LOOP/LOCA load profile for 4 hours. During small break LOOP/LOCA and transients, the battery is designed to supplement the charger when ac is not available or when loads exceed the chargers capability. The capability of the dc and ac power systems to provide sufficient capacity to manage these events, which have undefined loading profiles, is bound by the large break LOOP/LOCA load profile tables and the capability of the battery chargers. Other design basis events (Fire - Safe Shutdown and SBO) require a battery to support specific ECCS equipment without the charger (e.g. for SBO, the analyses assume battery chargers are available one hour into the event). The various batteries are shown to be acceptable by analysis for the duration required by the event.

The battery chargers provide an equalizing voltage that is adjustable between 130 V dc and 145 V dc. The battery manufacturer recommended an equalizing voltage for the batteries between 139.8 V and 142.8 V for the 125 V dc system and between 279.6 V and 285.6 V for the 250 V dc system. The lead calcium batteries used at LGS are anticipated to require equalization on average only 15 days (4%) per year, during their operating life. Analysis has shown that the impact on connected components is an aging issue and that the change in expected life of these components due to battery equalization is considered negligible.

The rated (manufacturer's) battery capacity is 25% greater than required. In accordance with IEEE 450 (1995), "Battery Replacement Criteria," this margin allows replacement of the battery to be made when its capacity has decreased to 80% of its rated capacity (100% of design load).

All Class 1E 125V dc equipment which is required to operate under the design basis conditions is rated and qualified to operate at the voltage it will see during the battery duty cycle with the battery at the end of its life. The "end of its life" is defined as the battery capacity equal to 80% of its rated capacity. A system voltage analysis performed for circuits powered by Class 1E 125V dc distribution panels shows that the required Class 1E 125V dc components will have adequate voltage to operate under LOCA/LOOP, Station Blackout and fire safe shutdown conditions when the battery is required to supply the load. This analysis used an analytical voltage at the distribution panels derived from worst case conditions which was lower than that predicted by the Class 1E battery calculation.

Another Calculation for Class 1E 250V dc MCC's and associated circuits provided the maximum control and power cable lengths. This calculation used an analytical voltage level which is lower than that predicted by the Class 1E battery sizing calculation.

8.3.2.1.1.3 Class 1E Battery Chargers

The chargers are full wave, silicon-controlled rectifiers. The housings are free standing, NEMA Type I, and are ventilated. The chargers are suitable for float charging a lead-calcium battery. The chargers operate from a 440 V, 3-phase, 60 Hz supply. The chargers are supplied from separate 440 V MCCs. Each of these motor control centers is connected to an independent Class 1E ac bus. The chargers are in compliance with all applicable NEMA and ANSI standards.

The battery chargers are sized using the formula (1) in IEEE 946-1992 Section 6.2. The terms in this equation are as follows:

1) The continuous dc load is the expected load on the DC system at the end of the DBA duty cycle. Operator actions to manage the DC system load are acceptable. The loads in the DBA duty cycle are larger than the normal operating loads.

2) Ampere Hours (AH) is computed as the Ampere Hours removed by the DBA duty cycle. The design minimum charge state is the remaining battery charge after the DBA duty cycle. The Fully Charged state is approximately 98% charged, the state at which the charging current stabilizes.

The formula provides an estimate of recharge time. Two variables are not accounted for in the formula, electrolyte temperature and the recharge voltage. The cell voltage in the equalize range (>2.30 Vpc) provides assurance that the battery will charge correctly. Operator action is required to establish and to equalize voltage after a DBA duty cycle discharge. The temperature of the room will be maintained above the design minimum temperature during the charging process. The battery is estimated to be 98% charged when three consecutive battery charging current measurements are less than 2 amps for the LCR-21 and 1 amp for the KCR-7 batteries. The battery is sized to perform it's duty cycle at the 98% charged level. On float charge, battery cells will receive adequate current to optimally charge the battery. The voltage requirements are based on the minimum float voltage established by the battery manufacturer (2.20 Vpc, average, or 132 V at the battery terminals). Cell voltage is not an accurate measure of charge since it is logarithmic to the charging current and plate polarization voltage varies with age. The negative plate polarization voltage increases in aged batteries, decreasing the available polarization voltage on the positive plate. Electrolyte specific gravity does not return to the "full charge" value for several weeks.

3) The approximate recharge time is 16 hours.

The battery chargers are the constant voltage-type, adjustable between 120 V and 145 V, with capability of operating as battery eliminators. The battery eliminator feature is incorporated as a precautionary measure to protect against the effects of inadvertent disconnection of the battery. The battery chargers are designed to function properly and remain stable on the disconnection of the battery. Variation of the charger output voltage has been determined by testing to be less than ±1% with or without the battery connected. The charger will maintain the dc output voltage within ±1%, with a maximum ripple of 2%, for any load from 0% to 100%. There are no planned modes of operation that would require battery disconnection except for periodic battery discharge tests which are performed only during plant shutdown.

Each battery charger output voltage is protected against overvoltage by a high voltage shutdown circuit. The overvoltage protection feature is incorporated to protect equipment from damage due to high voltage. When high voltage occurs, the unit disconnects the auxiliary voltage transformer, which results in charger shutdown. Before the unit is reactivated, it must be reset manually.

The following provisions have been made for the dc system for compliance with Regulatory Guide 1.47:

a. Loss of ac power to the battery charger is annunciated in the control room by the battery charger trouble annunciator.

b. Tripping of the charger dc output breaker is also annunciated as indicated above.

c. Battery voltage and current are monitored by voltmeters and ammeters located in the control room.

d. The voltage level at each dc bus is monitored by an undervoltage relay. Upon loss of dc voltage to the bus, the condition is annunciated in the control room.

The dc power system includes the following monitors and alarms:

a. Battery charger output current is indicated on an ammeter provided on the charger.

b. Battery current is indicated on dual range ammeters provided in the control room.

c. Battery voltage is indicated on voltmeters provided in the control room.

d. Battery charger output voltage is indicated on a voltmeter provided on the charger.

e. A battery high discharge rate will result in an undervoltage on the dc bus which may be caused by a ground fault between the bus and the battery. Both of these conditions are alarmed in the control room; therefore, the addition of the high discharge rate alarm is not required.

f. Dc bus undervoltage is alarmed in the control room by voltage monitoring relays located at each dc distribution bus. Dc bus overvoltage can only result from a failed battery charger. The battery charger trouble annunciator will alarm in the control room on charger low or high dc voltage.

g. A ground on each dc system is annunciated in the control room by a Class 1E ground detector dedicated to that division.

h. The battery fuse integrity is continuously monitored in the control room by ERFDS as the voltage from the battery terminals is input to this computer system and updated at least every 30 seconds. When battery voltage reaches 125 V dc, the power systems status light changes colors on the ERFDS display to direct the operator to the power system subdisplay where the battery voltage value is displayed. Battery voltage will decay to 125 V dc within approximately 8 minutes of loss of the battery charger or removal of the main battery fuses.

i. The tripping of the battery charger output breaker is alarmed in the control room by the battery charger trouble annunciator. Low dc output current initiates this alarm.

j. A battery charger trouble alarm is provided in the control room for each battery charger. This alarm is initiated for the following conditions:

High/low dc voltage

Low dc current

Low ac voltage

A calculation which tabulated the dc system loads based on the design and the load information was prepared and the resulting voltage profiles were determined. The results verified that the dc

distribution bus voltages will remain above the design minimum voltages during the postulated accident or post accident mode of operation.

The stability of the battery charger is not load dependent. The charger will maintain the dc output voltage within ±1%, with a maximum ripple of 2%, for any load from 0% to 100%.

8.3.2.1.1.4 Class 1E Battery Loads

Loads are diversified among different battery systems so that each system serves loads that are identical and redundant, or are different but redundant to plant safety, or are backup equipment to the ac driven equipment.

Where two-channel or four-channel redundancy and separation are required, such as control power for the four diesel generators and the four emergency switchgear assemblies, the loads are divided among the four divisions.

Power required for the larger loads, such as dc motor-driven pumps and valves, is supplied at 250 V from the two 125 V sources of each system, connected in series and distributed through 250 V dc motor control centers.

Power required for most dc control functions, such as that required for the control of the 4 kV circuit breakers and control relays, is supplied at 125 V from the several 125 V sources and distributed through 125 V dc power distribution panels.

The loading and testing of the Class 1E DC system calculations are performed which demonstrate the battery has sufficient capacity, and is tested in accordance with procedures described in IEEE 450 (1975).

8.3.2.1.1.5 Separation and Ventilation

Each Class 1E dc system (battery bank, charger and switchgear) is located in a compartment separate from the other Class 1E dc systems. The battery compartments are ventilated by a system that is designed to preclude the possibility of hydrogen accumulation. Section 9.4 contains a description of the battery compartment ventilation system.

The batteries are separated so that no single hazard could cause the loss of more than one division.

8.3.2.1.1.6 Inspection, Maintenance, and Testing

Testing of the dc power systems is performed before plant operation in accordance with the procedures described in IEEE 450 (1975). A dc voltage verification test is performed and completed during the startup test program prior to exceeding 5% power to verify that individual cell limits are not exceeded during the design discharge test, to demonstrate that the dc loads will function as necessary to assure plant safety at a battery terminal voltage equal to the acceptance criterion that has been established for minimum battery terminal voltage for the discharge load test, and to assure that each battery charger is capable of floating the battery on the bus or recharging the completely discharged battery within 8 hours while supplying the largest combined demands of the various steady-state loads under all plant operating conditions.

The voltage verification test will measure voltage at all Class 1E dc distribution buses and at the Class 1E dc equipment that must be operational when the battery is at minimum terminal voltage.

A confirmatory analysis comparing the test results to calculated dc voltage drop values will also be completed prior to exceeding 5% power.

[NOTE: The above information is for historical purposes only.]

The periodic testing of the battery chargers will verify their current-limiting characteristics.

Service and performance testing as defined in IEEE 450 (1995), Section 6.6, will be performed during refueling outages at intervals controlled by the Surveillance Frequency Control Program. As recommended by IEEE 450, the individual cell voltage readings will be taken between respective posts of like polarity of adjacent cells so that the voltage drop of the intercell connectors is measured. With this method, specific resistance measurements are not required because the resistance is measured by the voltage drop across the cell and connector.

Inservice tests, inspections, and resulting maintenance of the dc power systems, including batteries, chargers, and auxiliary, are specified in Chapter 16.

8.3.2.1.2 Non-Class 1E Dc System

The non-Class 1E dc systems, which are comprised of a 250 V and a 125/250 V dc system, are separate and independent from the Class 1E dc systems. The non-Class 1E and Class 1E dc systems do not share any loads.

8.3.2.1.3 Cable Derating and Cable Tray Fill

A discussion of cable derating and cable tray fill is included in Section 8.3.1.1.7.

8.3.2.1.4 Fire Barriers and Separation Between Redundant Trays

A discussion of fire barriers and separation between redundant trays is included in Section 8.3.1.1.8.

8.3.2.2 Analysis

8.3.2.2.1 Compliance with General Design Criteria, Regulatory Guides, and IEEE Standards

The following paragraphs analyze compliance of the Class 1E dc power systems with GDC 2, GDC 4, GDC 5, GDC 17, GDC 18, and GDC 50; Regulatory Guide 1.6, Regulatory Guide 1.32, Regulatory Guide 1.41, Regulatory Guide 1.81, and Regulatory Guide 1.93; and IEEE 308 and IEEE 450.

8.3.2.2.1.1 GDC 2 - Design Bases for Protection Against Natural Phenomena

The requirements of these criteria are met, in that all components of the Class 1E dc system are housed in seismic Category I structures designed to protect them from natural phenomena. These components have been qualified to the appropriate seismic, hydrodynamic, and environmental conditions as described in Chapter 3.

8.3.2.2.1.2 GDC 4 - Environmental and Dynamic Effects Design Bases

The requirements of these criteria are met, in that all components of the Class 1E dc system are housed in seismic Category I structures designed to protect them from natural phenomena. These components have been qualified to the appropriate seismic, hydrodynamic, and environmental conditions as described in Chapter 3.

8.3.2.2.1.3 GDC 5 - Sharing of Structures, Systems, and Components

With the exception of the common systems described below, this criterion is met for a two plant operation, in that there are no Class 1E components of the dc system that are shared between Units 1 and 2. The RHRSW and the ESW systems are considered common systems because each system supplies two independent cooling water loops which are common to both units. However, even though they are considered common systems, there is redundant equipment for these systems in each unit. For the redundant equipment in each unit, which has the capacity to supply 100% of the required cooling water per unit, the dc control power is supplied by the Class 1E dc systems in each unit. For the SGTS, the CSCWS and the control room and control structure ventilation systems, which are common systems, each with two 100% redundant trains, the dc control systems, where applicable, and the isolation logic for the common redundant components in each train are supplied from the Class 1E dc system in Unit 1.

8.3.2.2.1.4 GDC 17 - Electric Power Systems

Consideration of GDC 17 leads to the inclusion of the following factors in the design of the dc power systems:

a. Separate and independent 125 V and 125/250 V dc systems supply control power for each of the Class 1E ac load divisions.

b. The ac power for the battery chargers in each of these dc systems is supplied from the same ac load division for which the dc system supplies the control power.

c. Four independent Class 1E dc systems are provided to ensure the availability of the dc power system for maintaining the reactor integrity during postulated accidents.

d. Each of the four independent Class 1E dc systems, including batteries, chargers, dc switchgear and distribution equipment, are physically separate and independent.

e. Sufficient capacity, capability, independence, redundancy, and testability are provided in the Class 1E dc systems to ensure the performance of safety functions, assuming that there is a single failure.

8.3.2.2.1.5 GDC 18 - Inspection and Testing of Electric Power Systems

Each of the Class 1E dc systems is designed to permit:

a. Inspection and testing of wiring, insulation, and connections during equipment shutdown to assess the continuity of the system and the condition of its components.

b. Periodic testing of the operability and functional performance of the components of the systems during normal plant operation.

The Class 1E dc systems are periodically inspected and tested to assess the condition of the battery cells, charger, and other components in accordance with Chapter 16. Preoperational testing is discussed in Section 8.3.2.2.1.9 below for assessing compliance with Regulatory Guide 1.41.

8.3.2.2.1.6 GDC 50 - Containment Design Basis

This criterion, as it relates to the design of dc circuits using containment electrical penetration assemblies, is met as discussed in Section 8.1.6.1.12.

8.3.2.2.1.7 Regulatory Guide 1.6 (1971) - Independence Between Redundant Standby (Onsite) Power Sources and Between Their Distribution Systems (Safety Guide 6)

Separate Class 1E dc systems supply power for each of the four Class 1E load divisions. Loss of any one of the Class 1E dc systems does not prevent the minimum safety function from being performed. The Class 1E chargers are supplied from the same ac load division for which the dc system supplies the control power. Each of the four dc systems, including the battery bank, charger, and distribution system, is independent of each other system and of each non-Class 1E dc system. No provision exists for transferring loads between redundant dc systems. Thus, sufficient independence and redundancy exist to ensure performance of minimum safety functions, assuming that there is a single failure.

8.3.2.2.1.8 Regulatory Guide 1.32 (1977) - Criteria for Safety- Related Electric Power Systems for Nuclear Power Plants

The battery charger capacity for each of the Class 1E dc systems complies with this regulatory guide.

Each Class 1E battery charger has sufficient capacity to supply the largest combined demand of the various steady-state loads and the charging current required to restore the battery from the 1`design minimum charge state to the fully charged state, regardless of the plant status during the time in which these demands occur.

8.3.2.2.1.9 Regulatory Guide 1.41 (1973) - Preoperational Testing of Redundant Onsite Electric Power Systems to Verify Proper Load Group Assignments

To comply with this Regulatory Guide, the Class 1E dc systems are designed in accordance with Regulatory Guide 1.6 and Regulatory Guide 1.32 and are tested as follows:

a. Testing of the dc power system, including an acceptance test of battery capacity, is performed after installation and periodically during unit operation in accordance with the requirements described in Chapters 14 and 16.

b. The charger, battery connections, and charger supply are verified for proper assignment of ac load division.

c. Class 1E dc systems are functionally tested along with the associated ac load division by disconnecting and isolating the other ac load division, its ac power sources, and the associated dc system. Each test includes simulation of an ESF actuation signal, startup of the standby diesel generator and the load division under test, sequencing of loads, and the functional performance of the loads. During these tests, the ability of the dc

system to perform its intended functions, e.g., control of diesel generators and Class 1E ac switchgear, is verified.

d. Testing of each division of the Class 1E dc system is performed to ensure that no interconnections exist with redundant dc divisions. The buses and loads of the dc system under test are monitored to verify the absence of voltage while the remaining redundant divisions remain energized.

8.3.2.2.1.10 Regulatory Guide 1.81 (1975) - Shared Emergency and Shutdown Electric Systems for Multi-Unit Nuclear Power Plants

The requirements of the regulatory guide are met. Each generating unit is provided with separate and independent onsite dc electric power systems capable of supplying power to the control systems of the Class 1E loads and loads such as valves and actuators required for attaining a safe and orderly cold shutdown of the unit, assuming that there is a single failure. The RHRSW and the ESW systems are considered common systems because each system supplies two independent cooling water loops which are common to both units. However, even though they are considered common systems there is redundant equipment for these systems in each unit. For the redundant equipment in each unit, which has the capacity to supply 100% of the required cooling water per unit, the control systems are supplied by the onsite dc electric power systems in each unit. For the SGTS, the CSCWS and the control room and control structure ventilation systems, which are common systems, each with two 100% redundant trains, the dc control systems, where applicable, and the isolation logic for the common redundant components in each train are supplied from the onsite dc electric power system in Unit 1.

8.3.2.2.1.11 Regulatory Guide 1.93 (1974) - Availability of Electric Power Sources

Compliance is discussed in Section 8.1.6.

8.3.2.2.1.12 IEEE 308 (1974) - Criteria for Class 1E Electrical Systems for Nuclear Power Generating Stations

The Class 1E dc systems provide power to Class 1E loads and for control and switching of Class 1E systems. Physical separation and electrical isolation are provided to prevent the occurrence of common mode failures. The design of the Class 1E dc systems includes the following:

a. The Class 1E dc systems are separated into four channels to provide power to the four redundant load divisions.

b. The safety action by each division of loads is independent of the safety actions provided by their redundant counterparts.

c. Each Class 1E dc system includes power supplies that consist of one battery bank and one or two chargers as required.

d. Each Class 1E distribution circuit is capable of transmitting sufficient energy to start and operate all required loads in that circuit. Distribution circuits to redundant equipment are independent of each other. The distribution system is monitored to the extent that it is shown to be ready to perform its intended function. The dc auxiliary

devices required to operate equipment of a specific ac load division are supplied from the same load division.

e. The status of each protective dc fuse is monitored by an undervoltage relay which provides a system out-of-service alarm in the control room when dc control power is lost to a safety system or any of its components.

Each battery supply is continuously available during normal operations and following the loss of power from the ac system to start and operate all the required loads.

The dc systems are ungrounded; thus, a single ground fault does not cause immediate loss of the faulted system. Ground detection and alarm is provided for each dc system so that ground faults can be readily located and removed.

The Class 1E dc system equipment is protected and isolated by fuses for short circuits. The status of each dc system is monitored by checking for system undervoltage, system grounding, and battery charger trouble (ac power failure, charger failure, or charger output breaker trip).

The batteries are maintained in a fully charged condition and have sufficient stored energy to operate all necessary circuit breakers and provide an adequate amount of energy for all required Class 1E loads for 4 hours after loss of ac power.

Each battery charger has an input ac and output dc circuit breaker for isolation of the charger. Each battery charger is designed to prevent the ac supply from becoming a load on the battery due to a power feedback as the result of the loss of ac power to the chargers.

The battery charger ac supply breaker is periodically opened to verify the load-carrying ability of the battery.

Each Class 1E dc system is designed to meet seismic Category I requirements, as stated in Section 3.10. The batteries, battery chargers, and other components of the dc system are housed in the control enclosure, which is a seismic Category I structure.

Cracking of the Class 1E battery cases due to the battery stress points and their relationship with the battery rack support has been evaluated and will not occur to the LGS batteries based on test data. Cracking of the battery cases did not occur during qualification testing, which included seismic testing of an aged battery mounted in a battery rack. The arrangement used during qualification testing simulated the LGS battery/battery rack installation.

The battery carts are designed to support cells and confine their motion in the same manner as the battery racks. The carts amplify seismic floor motions to a lesser degree than the racks since they are only one battery tier high. Thus, when operating with cart mounted batteries, the same assurance against battery case cracking is provided as with the rack mounted batteries.

The connections between the cart mounted batteries and the rack mounted batteries are by means of flexible jumper cables fitted with clamps which are tightened onto the terminals. This arrangement assures that the connections between the cart mounted batteries and the rack mounted batteries remain intact during postulated dynamic events.

The periodic testing and surveillance requirements for the Class 1E batteries are detailed in Technical Specifications.

8.3.2.2.1.13 IEEE 450 (1995)-IEEE Recommended Practice for Maintenance, Testing, and Replacement of Large Lead Storage Batteries for Generating Stations and Substations

As discussed in Technical Specifications, the recommended practices of IEEE 450 (1995) for maintenance, testing, and replacement batteries are followed for the class 1E batteries with the exception of specific gravity monitoring frequency.

8.3.2.2.2 Physical Identification of Safety-Related Equipment

Physical identification of Class 1E equipment is discussed in Section 8.3.1.3.

8.3.2.2.3 Independence of Redundant Systems

The general considerations for the independence of Class 1E dc power systems are described in Section 8.3.1.4. The physical separation criterion is discussed in Section 8.1.6.1.14.

8.3.3 FIRE PROTECTION FOR CABLE SYSTEMS

The measures employed for the prevention of and protection against fires in electrical cable systems are covered in Sections 9.5.1, 8.3.1.1.7, and 8.3.1.1.8.

TABLE 8.3-2 (Page 1 of 2)
SUMMARY OF LOADING
DIESEL GENERATOR AND EMERGENCY BUSES
SAFEGUARD AND SELECTED NON-SAFEGUARD LOADS

TABLE NO.	DESCRIPTION	MAXIMUM LOADING OF ANY ONE DIESEL GENERATOR (kW) 0 - 10 MIN	10 MIN - 1 HOUR	1 HOUR and LONGER
8.3 - 3	Assignment of safeguard and selected non-safeguard loads to diesel generators and emergency buses Both units in operation Unit 1 DBA; Unit 2 spurious LOCA	--	--	--
8.3 - 9	All D/G in service	2482	1999	1999
8.3 - 10	D11 D/G out-of -service	2487	2266	2266
8.3 - 11	D12 D/G out-of-service	2482	2341	2341
8.3 - 12	D13 D/G out-of-service	2482	1999	1999
8.3 - 13	D14 D/G out-of-service	2482	2307	2307
8.3 - 14	D21 D/G out-of-service	2482	2158	2158
8.3 - 15	D22 D/G out-of-service	2482	1982	1932
8.3 - 16	D23 D/G out-of-service	2482	2151	2151
8.3 - 17	D24 D/G out-of-service	2482	1925	1925

The above loadings are based on the minimum required engineered safeguard and selected non-safeguard loads for the following situation:

* Unit 1 DBA with a spurious LOCA in Unit 2 for the 0 -10 minute period following by an emergency shutdown of Unit 2.

TABLE 8.3-2 (Cont'd)

The case for a Unit 2 DBA is not tabulated. Due to the similarity in loading between Unit 1 and Unit 2, it has been determined that, for a Unit 2 DBA with a spurious LOCA and ESD in Unit 1, Unit 2 data on the following tables are conservative for Unit 1 and Unit 1 data are conservative for Unit 2.

All loads in the 0-10 minute period are automatically applied. Beyond 10 minutes, the major loads are manually connected or disconnected.

Nonsafeguard loads are tripped by the LOCA signal and may be manually added after the 0-10 minute period as permitted by the available capacity of the diesel generators (limited by fuel consumption) and as indicated in the table below.

The required minimum operation of ECCS pumps indicated is shown below:

	DESIGN BASIS ACCIDENT			EMERGENCY SHUTDOWN		
	0-10 min	10 min - 1 hr	Beyond 1 hr	0-10 min	10 min - 1 hr	Beyond 1 hr
RHR pumps	3	1	1	0	1	1
CS pumps	2	2	2	0	0	0
RHRSW pumps	0	1	1	0	1	1

Any combination of three-out-of-four divisions (EDGs) is acceptable for a single failure. However, the ECCS requirements (as stated in paragraph 6.3.1.1.2), an EDG operable configuration of two-out-of-four is also acceptable.

LEGEND

(6) THE SPRAY POND PUMP STATION HEATING COILS ARE TRIPPED BY A LOCA SIGNAL.

(7) ASSIGNMENT OF THE LOADING ON THE DIESEL GENERATORS IS SUCH THAT THE SITUATION OF A DBA ON ONE UNIT AND SPURIOUS LOCA ON THE OTHER UNIT DOES NOT PRECLUDE SAFE SHUTDOWN OF THE UNITS. A SPURIOUS LOCA IS DEFINED AS A LOCA FOR 0-10 MINUTES AND EMERGENCY SHUTDOWN FOR BEYOND 10 MINUTES.

(11) HEATING LOADS AND COOLING LOADS ARE NOT COINCIDENT. THE COINCIDENT COOLING LOAD IS LARGER THAN THE COINCIDENT HEATING LOAD, THEREFORE, THE COOLING LOADS ARE SHOWN ENERGIZED.

LEGEND

(6) THE SPRAY POND PUMP STATION HEATING COILS ARE TRIPPED BY A LOCA SIGNAL.

(7) ASSIGNMENT OF THE LOADING ON THE DIESEL GENERATORS IS SUCH THAT THE SITUATION OF A DBA ON ONE UNIT AND SPURIOUS LOCA ON THE OTHER UNIT DOES NOT PRECLUDE SAFE SHUTDOWN OF THE UNITS. A SPURIOUS LOCA IS DEFINED AS A LOCA FOR 0-10 MINUTES AND EMERGENCY SHUTDOWN FOR BEYOND 10 MINUTES.

(11) HEATING LOADS AND COOLING LOADS ARE NOT COINCIDENT. THE COINCIDENT COOLING LOAD IS LARGER THAN THE COINCIDENT HEATING LOAD, THEREFORE, THE COOLING LOADS ARE SHOWN ENERGIZED.

LEGEND

(6) THE SPRAY POND PUMP STATION HEATING COILS ARE TRIPPED BY A LOCA SIGNAL.

(7) ASSIGNMENT OF THE LOADING ON THE DIESEL GENERATORS IS SUCH THAT THE SITUATION OF A DBA ON ONE UNIT AND SPURIOUS LOCA ON THE OTHER UNIT DOES NOT PRECLUDE SAFE SHUTDOWN OF THE UNITS. A SPURIOUS LOCA IS DEFINED AS A LOCA FOR 0-10 MINUTES AND EMERGENCY SHUTDOWN FOR BEYOND 10 MINUTES.

(11) HEATING LOADS AND COOLING LOADS ARE NOT COINCIDENT. THE COINCIDENT COOLING LOAD IS LARGER THAN THE COINCIDENT HEATING LOAD, THEREFORE, THE COOLING LOADS ARE SHOWN ENERGIZED.

LEGEND

(6) THE SPRAY POND PUMP STATION HEATING COILS ARE TRIPPED BY A LOCA SIGNAL.

(7) ASSIGNMENT OF THE LOADING ON THE DIESEL GENERATORS IS SUCH THAT THE SITUATION OF A DBA ON ONE UNIT AND SPURIOUS LOCA ON THE OTHER UNIT DOES NOT PRECLUDE SAFE SHUTDOWN OF THE UNITS. A SPURIOUS LOCA IS DEFINED AS A LOCA FOR 0-10 MINUTES AND EMERGENCY SHUTDOWN FOR BEYOND 10 MINUTES.

(11) HEATING LOADS AND COOLING LOADS ARE NOT COINCIDENT. THE COINCIDENT COOLING LOAD IS LARGER THAN THE COINCIDENT HEATING LOAD, THEREFORE, THE COOLING LOADS ARE SHOWN ENERGIZED.

LEGEND

(6) THE SPRAY POND PUMP STATION HEATING COILS ARE TRIPPED BY A LOCA SIGNAL.

(7) ASSIGNMENT OF THE LOADING ON THE DIESEL GENERATORS IS SUCH THAT THE SITUATION OF A DBA ON ONE UNIT AND SPURIOUS LOCA ON THE OTHER UNIT DOES NOT PRECLUDE SAFE SHUTDOWN OF THE UNITS. A SPURIOUS LOCA IS DEFINED AS A LOCA FOR 0-10 MINUTES AND EMERGENCY SHUTDOWN FOR BEYOND 10 MINUTES.

(11) HEATING LOADS AND COOLING LOADS ARE NOT COINCIDENT. THE COINCIDENT COOLING LOAD IS LARGER THAN THE COINCIDENT HEATING LOAD, THEREFORE, THE COOLING LOADS ARE SHOWN ENERGIZED.

LEGEND

(6) THE SPRAY POND PUMP STATION HEATING COILS ARE TRIPPED BY A LOCA SIGNAL.

(7) ASSIGNMENT OF THE LOADING ON THE DIESEL GENERATORS IS SUCH THAT THE SITUATION OF A DBA ON ONE UNIT AND SPURIOUS LOCA ON THE OTHER UNIT DOES NOT PRECLUDE SAFE SHUTDOWN OF THE UNITS. A SPURIOUS LOCA IS DEFINED AS A LOCA FOR 0-10 MINUTES AND EMERGENCY SHUTDOWN FOR BEYOND 10 MINUTES.

(11) HEATING LOADS AND COOLING LOADS ARE NOT COINCIDENT. THE COINCIDENT COOLING LOAD IS LARGER THAN THE COINCIDENT HEATING LOAD, THEREFORE, THE COOLING LOADS ARE SHOWN ENERGIZED.

LEGEND

(6) THE SPRAY POND PUMP STATION HEATING COILS ARE TRIPPED BY A LOCA SIGNAL.

(7) ASSIGNMENT OF THE LOADING ON THE DIESEL GENERATORS IS SUCH THAT THE SITUATION OF A DBA ON ONE UNIT AND SPURIOUS LOCA ON THE OTHER UNIT DOES NOT PRECLUDE SAFE SHUTDOWN OF THE UNITS. A SPURIOUS LOCA IS DEFINED AS A LOCA FOR 0-10 MINUTES AND EMERGENCY SHUTDOWN FOR BEYOND 10 MINUTES.

(11) HEATING LOADS AND COOLING LOADS ARE NOT COINCIDENT. THE COINCIDENT COOLING LOAD IS LARGER THAN THE COINCIDENT HEATING LOAD, THEREFORE, THE COOLING LOADS ARE SHOWN ENERGIZED.

LEGEND

(6) THE SPRAY POND PUMP STATION HEATING COILS ARE TRIPPED BY A LOCA SIGNAL.

(7) ASSIGNMENT OF THE LOADING ON THE DIESEL GENERATORS IS SUCH THAT THE SITUATION OF A DBA ON ONE UNIT AND SPURIOUS LOCA ON THE OTHER UNIT DOES NOT PRECLUDE SAFE SHUTDOWN OF THE UNITS. A SPURIOUS LOCA IS DEFINED AS A LOCA FOR 0-10 MINUTES AND EMERGENCY SHUTDOWN FOR BEYOND 10 MINUTES.

(11) HEATING LOADS AND COOLING LOADS ARE NOT COINCIDENT. THE COINCIDENT COOLING LOAD IS LARGER THAN THE COINCIDENT HEATING LOAD, THEREFORE, THE COOLING LOADS ARE SHOWN ENERGIZED.

LEGEND

(6) THE SPRAY POND PUMP STATION HEATING COILS ARE TRIPPED BY A LOCA SIGNAL.

(7) ASSIGNMENT OF THE LOADING ON THE DIESEL GENERATORS IS SUCH THAT THE SITUATION OF A DBA ON ONE UNIT AND SPURIOUS LOCA ON THE OTHER UNIT DOES NOT PRECLUDE SAFE SHUTDOWN OF THE UNITS. A SPURIOUS LOCA IS DEFINED AS A LOCA FOR 0-10 MINUTES AND EMERGENCY SHUTDOWN FOR BEYOND 10 MINUTES.

(11) HEATING LOADS AND COOLING LOADS ARE NOT COINCIDENT. THE COINCIDENT COOLING LOAD IS LARGER THAN THE COINCIDENT HEATING LOAD, THEREFORE, THE COOLING LOADS ARE SHOWN ENERGIZED.

EVALUATIONS

A. There is more than one instrument in the control room to monitor this parameter and these instruments are not fed from the same bus; therefore, the loss of one bus will not affect the operator's ability to determine the value of this parameter.

B. This parameter can be determined from other parameters or local instruments if needed. Loss of this parameter would not affect the capability of achieving a cold shutdown condition.

C. The RPIS receives data from the RMCS and is fed from non-Class 1E instrument buses. If power to these buses is lost, rod position indication will be lost in the control room. Loss of rod position indication does not prohibit a manual or automatic SCRAM; therefore, the capability to achieve a cold shutdown condition is not affected by loss of power to the RMCS or the RPIS.

D. Loss of this parameter does not affect the ability to achieve a cold shutdown condition.

E. The SLCS has been redesigned per ATWS requirements. The controls and instrumentation of this system have been designed to perform their function with a single failure; therefore, loss of power to a single division will not prevent the achievement of a cold shutdown condition.

Table 8.3-30 (Cont'd)

F. CST level indication will be lost when Y106 is lost; however, the tank HI/LOW level alarm will still be operable.

G. If power from panel BD102 is lost, the HPCI becomes inoperative. If this occurs, the ADS will be used to depressurize the reactor vessel so that the RCIC and RHR and core spray systems can be used to achieve a cold shutdown condition. Loss of HPCI due to loss of panel BD102 will not affect the ability to achieve a cold shutdown condition.

H. If power from panel AD102 is lost, the RCIC system becomes inoperative. If this occurs, the HPCI system can be used in its place; therefore, the loss of the RCIC system due to the loss of power from panel AD102 will not affect the ability to achieve a cold shutdown condition.

K. Core spray system instrumentation for Loop A is fed from Division 1 Class 1E power. Loop B instrumentation is fed from Division II. Loss of panel Y101 will cause loss of Loop A flow indication in the control room. Loss of Y102 will cause loss of Loop B flow indication. Loss of either of these panels does not affect the operability of the core spray system; therefore, the ability to achieve a cold shutdown condition is not affected.

L. Both of the supply panels must be lost in order to lose indication of this parameter.

M. The RHR system is composed of two redundant loops, each consisting of two pumps and one RHR heat exchanger. The pressure controllers, flow indicators, and pressure indicators for the A loop are fed from separate power panels than those for the B loop. The loss of one bus feeding RHR instrumentation would not affect the operating capability of the RHR system and therefore, would not affect the ability to achieve a cold shutdown.

N. This system has redundant loops. The instrumentation on each loop is fed from separate buses; therefore, the loss of one loop or panel will not affect the ability to achieve a cold shutdown condition with the remaining loop.

O. There is more than one instrument in the control room to monitor this parameter and these instruments are fed by two buses (redundant power); Therefore, the loss of one bus will not affect the operator’s ability to determine the value of this parameter.

CHAPTER 9 - AUXILIARY SYSTEMS

9.1 FUEL STORAGE AND HANDLING

The fuel storage and handling facilities provide safe and effective means of storage, cooling, transportation, and handling of nuclear fuel from the time it reaches the plant in a non-irradiated condition until it leaves the plant after post-irradiation cooling. These systems have no function related to the safe shutdown of the plant.

Additional spent fuel storage is provided on site and within the plant protected area boundary by an Independent Spent Fuel Storage Installation (ISFSI) meeting the requirements of 10CFR72. Safety evaluations for the ISFSI are covered in separate "10CFR72.212" documents, and are therefore not detailed here. It is noted that existing UFSAR Section 9.1.4 and 9.1.5 references to a "cask" are actually referring to the shipping cask referred to above for the function to "leaves the plant after post-irradiation cooling." Minor differences for the ISFSI "transfer cask" (TC) and HI-TRAC VW cask handling, such as cask positioning for preparations for loading and post-loading decontamination, lids placement and sealing, are not covered herein.

9.1.1 NEW FUEL STORAGE

The new fuel is brought onsite prior to a scheduled refueling and is inspected and then stored in the spent fuel racks, which are located in the refueling area in the spent fuel pool (drawings M-122 and M-137).

9.1.1.1 Design Bases

New fuel is stored in the spent fuel pool. The design bases are discussed in Section 9.1.2.1.

9.1.1.2 Facility Description

The new fuel is stored in the spent fuel storage racks. The facility description is discussed in Section 9.1.2.2. Section 9.1.4 describes receipt inspection and handling of new fuel within the reactor enclosure.

9.1.1.3 Safety Evaluation

New fuel is stored in the spent fuel pool. Storage of new fuel bundles in the storage vault is prohibited by existing fuel handling procedures that require new fuel to be stored in the spent fuel pool. The safety evaluation is discussed in Section 9.1.2.3.

9.1.2 SPENT FUEL STORAGE

The spent fuel storage facility provides specially designed underwater storage space for the new and spent fuel assemblies. The facility is located in the refueling area and is shown in drawings M-122 and M-137. Prior to each refueling, new fuel is brought onsite, inspected, and stored in the spent fuel storage racks.

9.1.2.1 Design Bases

The following design bases for the spent fuel storage facilities are discussed in the indicated sections:

a.	Seismic and quality group classification	Section 3.2
b.	Protection from wind and tornado effects	Section 3.3
c.	Flood design	Section 3.4
d.	Missile protection	Section 3.5
e.	Protection against dynamic effects associated with postulated rupture of piping	Section 3.6
f.	Seismic design	Section 3.7
g.	Environmental design	Section 3.11
h.	Fire protection	Section 9.5.1

In addition to the design bases listed above, the following design bases and codes and standards are applicable to the spent fuel storage facilities:

a. The spent and new fuel storage facility is designed to store fuel assemblies so that a k_{eff} less than or equal to 0.95 is maintained, assuming that the fuel storage racks are fully loaded with fuel of the highest anticipated enrichment and flooded with nonborated water, in compliance with GDC 62. This is achieved through use of a neutron poisoning material (Boral) sandwiched in the racks between adjoining fuel assemblies to ensure subcriticality by at least 5% Δk under all conditions. The presence of Boral is verified by receipt and inservice testing.

b. The spent fuel storage facility and all piping connections are designed to prevent a loss of cooling water from the spent fuel pool that could uncover stored fuel.

c. The spent fuel storage facility is designed to remain functional following an SSE.

d. Failures of systems or structures not designed to seismic Category I standards and located in the vicinity of the spent fuel storage facility do not cause a decrease in the subcriticality provided.

e. The design of the spent fuel storage racks is such that a fuel assembly can be inserted into any designated rack storage location.

f. The spent fuel storage facility is designed to prevent accidental criticality of stored fuel under adverse environmental and postulated fuel handling accident conditions.

g. The spent fuel pool is designed to withstand thermal- stresses resulting from the pool water boiling.

h. The spent fuel pool is designed to accommodate the storage of approximately 539% of the total number of fuel assemblies in the reactor core. (Placement of the storage racks which contain control rod blades and/or defective fuel assemblies in the fuel pool could limit fuel storage capability to approximately 513%.) Storage capacity is dependent on rack installation.

i. Shielding for the stored spent fuel assemblies is designed to protect plant personnel from exposure to direct radiation greater than that permitted for continuous occupational exposure during normal operations.

j. Applicable codes and standards are provided in Table 9.1-21.

9.1.2.2 Facility Description

9.1.2.2.1 General Description

The spent fuel storage facility consists of the spent fuel pool, containing spent fuel storage racks, and serves as the storage area for irradiated fuel assemblies. The spent fuel pool and the adjacent reactor well, dryer/separator pool, and cask loading pit are located in the refueling area as shown in drawings M-122 and M-137. Figure 9.1-34 shows the initial layout of the Unit 1 fuel storage pool with a storage capacity of 3665 fuel assemblies (3714 fuel assemblies including the control rod blade/defective fuel storage rack). Figure 9.1-36 shows the initial layout of the Unit 2 fuel storage pool with a storage capacity of 3921 fuel assemblies (3970 fuel assemblies including the control rod blade/defective fuel storage rack). Figures 9.1-35 and 9.1-37 depict the potential maximum capacity layout for Unit 1 and Unit 2 (respectively) with a fuel storage capacity equal to the maximum licensed capacity of 4117 fuel assemblies. Cooling and cleanup of the spent fuel pool water is discussed in Section 9.1.3. Fuel handling systems are discussed in Section 9.1.4. The reactor enclosure crane is discussed in Section 9.1.5.

9.1.2.2.2 Component Description

9.1.2.2.2.1 Spent Fuel Pool

The spent fuel pool is a post-tensioned, reinforced concrete structure that forms an integral part of the reactor enclosure. The pool has a volume of approximately 46,000 ft^3 and is filled with demineralized water to a normal depth of 38'-3". This provides about 23 feet of water above the tops of the stored fuel assemblies.

The spent fuel pool is lined with stainless steel plate (Table 9.1-14) to minimize leakage and reduce corrosion product formation. A leakage collection system is provided to permit expedient detection of leaks through the stainless steel liner plate and to prevent the uncontrolled loss of pool water to areas below the pool. Drainage paths, designed to permit free gravity flow, are formed by welding channels behind the pool wall liner welded joints and by two trench monitoring systems embedded in the floor slab below the floor liner. The design of a typical drainage system is shown in Figure 9.1-40. Pool leakage is routed through a piping system, provided at the base of the pool wall, one of three dirty radwaste funnels as shown in drawing M-53. Leakage from each of seven segments of the leak collection system is routed through separate piping to enable identification of the area of the liner that is leaking.

Leakage is detected by observation of water flowing out of the piping into the dirty radwaste funnel (drawing M-53) or by low level indication in the skimmer surge tank or the spent fuel pool (drawing

M-53). Flow into the funnels is observed during periodic operator inspections. Skimmer surge tank low level alarms and trips are described in Section 9.1.3.5.

9.1.2.2.2.2 Spent Fuel Storage Racks

The Unit 1 and Unit 2 spent fuel pools are licensed for a maximum fuel storage capacity of 4117 fuel assemblies each. Analyses were performed prior to the installation of maximum density fuel storage racks for the Unit 2 spent fuel pool. All analyses performed for the Unit 2 spent fuel pool are bounding for the Unit 1 spent fuel pool design and installation.

The high density fuel storage racks are installed in the Unit 1 spent fuel storage pool in such a manner as to ensure that there is a Boral plate between each adjoining fuel storage position. Each storage module is level with each other module at the top. There are 7.25 inches of clearance from the bottom of the module to the pool floor. This ensures adequate clearance for cooling water to enter each fuel cell and, through natural convection, keep each fuel assembly adequately cooled.

The maximum density spent fuel storage racks are modular, freestanding, top entry racks designed to maintain the spent (and new) fuel in a space geometry whereby each fuel assembly has a neutron poisoning material between it and any adjoining fuel assemblies. This precludes the possibility of criticality under normal and abnormal conditions. The only point of contact of the maximum density spent fuel storage rack is with the bottom liner plate.

The maximum density spent fuel storage racks (Figure 9.1-41) consists of five basic structural components: the storage box subassembly, the baseplate, the neutron poison material, the picture frame sheathing, and the support legs. The storage box subassemblies (Figure 9.1-41) are fabricated from two precision formed stainless steel channels by seam welding. Each storage box subassembly has two lateral holes punched near the bottom edge to provide an auxiliary flow path. The stainless steel picture frame sheathing is attached to each side of a storage box subassembly by welds. The picture frame sheathing serves as the locator and retainer of the neutron poison material. A storage cell box subassembly, with picture frame sheathing and neutron poison material on all four sides is referred to as a composite box. The composite boxes are arranged in a checkerboard array and welded corner to corner to form an assemblage of storage cell locations (Figure 9.1-41). This assemblage is welded to the baseplate. The baseplate is 3/4 inches thick and provides a continuous horizontal surface for supporting the fuel assemblies. The baseplate has a concentric hole with a 45° taper in each storage cell location to provide a seating surface conforming to the fuel assembly. Adjustable support legs are welded to each corner of the baseplate. Each adjustment support leg is provided with a socket to enable remote leveling of the maximum density spent fuel storage rack after its placement in the fuel pool.

There are various sizes of maximum density spent fuel storage racks (Figures 9.1-35 through 9.1-37 and Table 9.1-23). The nominal center-to-center spacing between fuel assemblies in a maximum density spent fuel storage rack is 6.244 inches.

The neutron poison material used in the maximum density spent fuel storage racks is Boral. Boral is a thermal neutron poison material composed of boron carbide and 1100 alloy aluminum. The Boral is in plate form and is located and retained by the picture frame sheathing (Figure 9.1-41). The sheathed volumes which contain the Boral plates are vented.

The maximum density fuel storage racks are installed in the spent fuel storage pool in such a manner as to ensure that there is a Boral plate between each adjoining fuel storage position. Each maximum density spent fuel storage rack is level with each other rack at the top. There is a clearance of

approximately 7.00 inches between the bottom of the rack and the fuel pool floor liner. This ensures adequate clearance for cooling water to enter each fuel storage cell.

All materials used for construction are specified in accordance with the issue of the ASTM specifications. Traceability of major rack components to a heat lot are maintained. In addition, the suppliers' quality assurance/ quality control program was audited by the manufacturer and user to ensure that the Boral has the required minimum B_4C density and uniform B_4C distribution in each sheet. Boral traceability is maintained.

A dimensional, visual, and functional (including testing with a dummy fuel assembly) inspection of the racks is performed prior to shipment by the rack manufacturer.

The rack materials will have no significant degradation due to the total radiation doses expected in the spent fuel pool over the design life.

The racks are designed to withstand the loading under the following loading conditions: dead, live, jammed fuel assembly, dropped fuel assembly, thermal, OBE and design basis event seismic, SRV, and LOCA or chugging.

An ISI program will be in effect throughout the period in which spent fuel is stored in the spent fuel pool to ensure that the quality of the poisoned racks is maintained (Section 9.1.2.4).

9.1.2.2.2.3 Refueling Area Cavities

As shown in drawing M-122 and M-137, adjacent to the spent fuel pool, but on opposite sides of it, are the cask loading pit and the reactor well. Adjacent to the reactor well is the dryer/separator pool. The cask loading pit is common to the two reactor units. Like the spent fuel pool, these cavities are lined with stainless steel plate and are provided with liner leakage collection systems. The reactor well and the cask loading pit are connected to the spent fuel pool by fuel transfer canals approximately 4 feet wide. Each canal is provided with two gates to prevent loss of water from the spent fuel pool during periods when the adjacent cavity is not filled with water.

The cask loading pit is used for Low Level Radwaste (LLW) storage. In the cask loading pit free standing storage racks containing Storage Containers (SCs). The rack compartments hold LLW including control rod blades (CABs), fuel channels in sheaths, LPRM strings, velocity limiters, filters, stellite ball bearing and other small components. During LLW processing, processing equipment will be placed in the cask loading pit or on the Refuel Floor. The equipment can be removed when not in use. Equipment includes Activated Services Compactor (ASC) and Control Rod Blade Compactor (CABC), grapple, shear and punching tools, and supporting equipment. All LLW components are classified as non-safety related and Seismic II/I components. Because of the LLW stored in the cask loading pit, it must remain full at all times.

The cask loading pit is designed to permit the underwater loading of spent fuel assemblies into ISFSI transfer cask, HI-TRAC VW cask, and/or spent fuel shipping casks. Decontamination of the spent fuel shipping, HI-TRAC VW cask, and/or ISFSI transfer cask can be performed on the refueling floor adjacent to the cask loading pit. Cross connecting the Unit 1 and 2 spent fuel pools (SFPs) through the cask loading pit allows the transfer of spent fuel and equipment from one Unit's Spent Fuel Pit to the other unit's SFP. Prior to transferring fuel or equipment, adequate spent fuel pool cooling capacity must be verified.

The reactor well is a basically circular cavity located directly above the primary containment. Removal of the drywell head and reactor vessel head provides direct access from the reactor well to the inside of the reactor vessel. The reactor well is filled with water during transfer of fuel assemblies between the well and the spent fuel pool. Seals are provided at the bottom of the reactor well between the drywell and reactor well wall and a refueling bellows is provided between the reactor vessel and containment seal plate to prevent leakage of water out of the well.

The dryer/separator pool provides a place for storage of the steam dryer and steam separator when these two reactor components are removed from the reactor vessel. The dryer/separator pool is connected to the reactor well to permit underwater transfer of components between the two cavities. Seal plugs are provided to prevent loss of water during periods when the adjacent cavity is not filled with water.

9.1.2.2.2.4 Other Features

The ventilation system for the refueling floor area is designed to minimize potential offsite exposures if there is a significant release of radioactivity from the spent fuel storage facility. The ventilation system for the refueling floor area is discussed in Section 9.4.2.

The area radiation monitoring equipment for the spent fuel storage facility is described in Section 12.3.4.

9.1.2.3 Safety Evaluation

The subcriticality of the fuel assemblies stored in the spent fuel storage racks is the result of the geometrical arrangement of the fuel array and the presence of neutron-absorbing materials. The arrangement of the fuel assemblies in the spent fuel storage racks results in k_{eff} less than or equal to 0.95, assuming that the spent fuel storage racks are fully loaded with fuel of the highest anticipated enrichment. This is discussed in Section 9.1.2.3.1.

The design is in conformance with Regulatory Guide 1.13.

The bottoms of the fuel transfer canals between the spent fuel pool and the reactor well and between the spent fuel pool and cask loading pit are above the top of the stored spent fuel, thus ensuring that failure of the gates in these canals cannot result in the uncovering of the fuel.

To ensure that the spent fuel pool water level is not lowered by a malfunction of the fuel pool cooling and cleanup system, the system takes suction from the pool near the normal water level via the skimmer surge tanks. The system return lines enter the spent fuel pool from above the normal water level and are provided with siphon breaker holes near the normal water level to preclude the possibility of siphoning the pool.

The spent fuel storage facility is designed in accordance with seismic Category I requirements as specified in Section 3.2. The components (and supporting structures) of any system, equipment, or structure that is not seismic Category I and whose collapse could result in loss of a required function of the spent fuel storage facility are analytically checked to determine that they will not collapse when subjected to seismic loading resulting from the SSE.

All spent fuel pool gates and liners are seismic Category I.

Liner leakage detection system piping, the fuel pool cooling and cleanup system piping, and the wave suppression scupper piping are all seismic Category IIA. The only other piping attached to or in the spent fuel pool is from the RHR and ESW systems for backup cooling and makeup. This piping is seismic Category I.

Loss of any of the seismic Category IIA piping would not affect the ability to maintain spent fuel cooling or to maintain adequate submergence of the fuel.

Accidental dropping of movable heavy objects into the fuel pool is precluded by the use of administrative procedures, electrical interlocks to limit the load travel over the spent fuel pool, and the use of guardrails and curbs around all pools and the reactor wells to prevent fuel handling and servicing equipment from falling into the pools. The electrical interlocks and administrative procedures are described in Section 9.1.4. In addition, heavy load handling in the vicinity of the fuel pools is in compliance with NUREG-0612 guidelines such that the likelihood of a heavy load drop is precluded.

The design of the spent fuel pool provides enough reinforcement in the concrete to withstand the thermal-stresses resulting from pool boiling.

The maximum density spent fuel storage rack is capable of withstanding a force of 4000 pounds in any direction at the top of the rack without any permanent deformation of the fuel cell in the active fuel region.

The auxiliary hoist of the reactor enclosure crane has a maximum uplift force in excess of 4000 pounds. The auxiliary hoist does not handle new fuel above, or in the fuel pool, except to transfer new fuel to the fuel prep machines. Other fuel handling operations are performed by the hoists on the refueling platform which have an uplift (controlled) limit of 1200 pounds or less.

If there is a stuck fuel assembly, the lifting bail yields at an uplift force greater than 1500 pounds; therefore, possible damage to the racks is precluded even if the 1200 pound control limit is not considered.

9.1.2.3.1 Criticality Control

9.1.2.3.1.1 Basic Assumptions of Criticality Analysis

The spent fuel storage facility is designed to prevent accidental criticality of stored fuel under adverse environmental and postulated fuel handling accident conditions. The geometry of the spent fuel storage array is such that K_{eff} will be ≤0.95. Studies were performed which establish fuel storage compliance limits consistent with K_{eff} ≤0.95 for the Maximum Density racks (Reference 9.1-9). All General Electric supplied fuel shall comply with the fuel storage reactivity criteria in Reference 9.1-7 (GESTAR-II), which conservatively bounds the rack designs analyzed in Reference 9.1-9. Additional studies for fuel designs not covered under GESTAR-II are listed as references in Section 9.1.6. To ensure that the design criteria are met, the following normal and abnormal spent fuel storage conditions were analyzed:

a. Normal positioning in the spent fuel storage array

b. Pool water temperature increases to 212°F

c. Abnormal positioning in the spent fuel storage array

d. Dropped fuel bundle adjacent to storage area

e. Dropped fuel bundle on top of and through fuel storage racks.

Transport to Diffusion Correction	= 0.917 - 0.898 - 0.001
	= 0.018

This result should be applied to the adjusted PDQ k_{eff}

c. Summary of Results:

k_{eff} (PDQ) adjusted	0.915
Transport to Diffusion Correction, PDQ-KENO	0.018
Final k_{eff} (upper bound, 95% confidence)	0.933
Design Limit, k_{eff}	0.950

The final k_{eff} value (0.933) includes all the design specification tolerances, the postulation of a dropped fuel assembly, the model bias, and the 95% confidence interval from the KENO calculations. However, the negative reactivity effect (approximately -0.005 Δk) due to the presence of U-234 and the parasitic structure materials (i.e. spacer grids) in each assembly, and the positive reactivity effect (0.006 Δk) due to the possible absence of a Boral plate are not included.

9.1.2.3.1.2.1 Assumptions of Criticality Analysis - Maximum Density Spent Fuel Storage Racks

To ensure the analysis followed a conservative approach and conformed to the general guidelines of criticality safety analysis, the calculations were performed using the following criteria:

1) The racks are assumed to contain the most reactive fuel authorized to be stored.

2) Moderator is pure, unborated water at a temperature corresponding to the highest reactivity (4°C, 39.2°F)

3) Criticality safety analyses are based upon the k_{eff} of an infinite array of storage cells, ie, no credit is taken for neutron leakage (except as necessary in the assessment of abnormal/accident conditions)

4) Neutron absorption in minor structural member is neglected, ie, spacer grids are replaced by water.

9.1.2.3.1.2.2 Calculational Models - Maximum Density Spent Fuel Storage Racks

Initial criticality analyses of the maximum density spent fuel storage racks (1993) were performed using both the CASMO-3 code (a two-dimensional multi-group transport theory code) and the KENO-

5a code (a Monte Carlo code for eigenvalue neutronics calculations), using the 27-group SCALE cross-section library with Nordheim Integral Treatment and Working Library Production (NITAWL) subroutine for U-238 resonance shielding effects. Standardized Computer Analysis for Licensing Evaluation (SCALE) is a comprehensive modeling and simulation suite for nuclear safety analysis and design, developed and maintained by the Oak Ridge National Laboratory for the USNRC, USDOE, and NNSA. KENO and NITAWL are both modules of the SCALE analysis suite. CASMO-3 (Studsvik Scandpower, Inc.) was used to calculate the in-rack k values as well to evaluate small reactivity increments associated with manufacturing tolerances for earlier fuel analyses. Depletion calculations were not required of CASMO-3 as the peak reactivity of the limiting bundle (no gadolinia) was at zero exposure. Benchmark calculations indicated a bias of 0.0000 $\pm$0.0024 for CASMO-3 and 0.0101 $\pm$0.0018 (95% confidence) for NITAWL-KENO-5a.

With CASMO-3 no longer generally available, the criticality safety analysis for the GNF3 fuel (Reference 9.1-20) instead utilized the same criticality methodology used by Oyster Creek for its Boral rack analysis and approved by the NRC in Reference 9.1-18. Like Oyster Creek, the Limerick GNF3 criticality safety calculations were based on use of both the CASMO-4 code (a two-dimensional multi-group transport theory code) and the MCNP5 (a Monte Carlo code developed by Los Alamos National Lab). For the Oyster Creek standard cold core geometry (SCCG) methodology, many lattices are analyzed to provide a k(in-core) to k(in-rack) correlation. The CASMO-4 code was used to deplete lattices to their peak reactivities and to generate their core/rack conditions k values. The MCNP5 code was used for prudent validation purposes of the CASMO-4 results and the bias is shown in Reference 9.1-20.

In the geometric model used in the calculations above, each fuel rod and its cladding was described explicitly and reflecting boundary conditions (zero neutron current) were used in the axial direction and at the centerline of the Boral and stainless steel plates between storage cells. These boundary conditions have the effect of creating an infinite array of storage cells in the X and Y directions.

Since the cross section library in NITAWL is not valid below 20°C, a small correction factor (0.0026 δk, determined by CASMO-3) to 4°C was applied to the NITAWL-KENO-5a calculations (applicable to initial criticality analyses of the maximum density spent fuel storage racks using these methods).

9.1.2.3.1.2.3 Reference Case Calculations - Maximum Density Spent Fuel Storage Racks

a. Physical Parameters and Basic Storage Cell Geometry

The design basis storage rack cell consists of an egg-crate structure (Figure 9.1-41) with fixed neutron absorber material (Boral) of 0.0200 g/cm^2 boron-10 areal density (0.0185g/cm^2 boron-10 minimum) positioned between the fuel assembly storage cells. The storage cell design for analysis is based upon a nominal center-to-center lattice spacing of 6.244 inches. The 0.075 inch thick stainless steel box which defines the fuel assembly storage cell has a nominal inside dimension of 6.05 inches. This allows adequate clearance for inserting or removing the fuel assemblies, with or without the Zircaloy channel. Boral plates are not needed or used on the exterior walls of racks facing non-fueled regions, ie, the fuel pool walls. Manufacturing tolerances, used in evaluating uncertainties in reactivity, are listed in Table 9.1-26.

Along the outer periphery of racks facing another rack, the Boral is 4.70 inches wide rather than 5.0 inches wide. This small reduction in width is compensated by the water-gap between racks and by the thickness of the stainless steel.

Therefore, the reactivity consequences of the slightly reduced Boral width in these locations are negligible.

b. Results of the Design Basis Case Calculations

Using the input data from Table 9.1-24 and Figure 9.1-42, the k_{eff} values of the design basis case at 4°C were calculated. The maximum reactivity calculated by the CASMO-3 code is 0.9444. The maximum reactivity calculated by the NITAWL-KENO-5a code is 0.9412.

c. Fuel Effect

Because the racks must be able to store various fuel types additional fuel types were evaluated using the data from Table 9.1-24. The results are summarized in Table 9.1-27.

9.1.2.3.1.2.4 Sensitivity and Tolerance Reactivity Calculations - Maximum Density Spent Fuel Storage Racks

a. Temperature Effect

Using the design basis storage rack geometry, the temperature of the fuel pool water was varied. The results are given in Table 9.1-25.

b. Void Effect

The effect of boiling was studied by varying the voids from 0% to 20% at a temperature of 252°F with the reference geometry. The results are given in Table 9.1-25. As indicated, k_{eff} decreases continuously as the void fraction increases. Boiling at the submerged depth of the racks would occur at approximately 250°F.

c. Effect of Boron Loading Variation

The Boral Absorber plates used in the storage cells are nominally 0.075 inches thick. With a boron-10 areal density of 0.0200 g/cgm^2. The manufacturing tolerance limit is $\pm$0.0015 g/cm^2 in the boron-10 loading, which assures that the minimum boron-10 areal density will not be less than 0.0185 g/cm^2. Differential CASMO-3 calculations indicate that this tolerance limit results in an incremental reactivity uncertainty of $\pm$0.0051 δk (Table 9.1-26).

d. Effects of Boral Width Tolerance Variation

The reference storage cell design uses a Boral plate width of 5.00 $\pm$1/16 inches. For a reduction in width of the maximum tolerance, the calculated positive reactivity increment is +0.0018 δk (Table 9.1-26).

e. Effect of Storage Cell Lattice Pitch Variation

The design storage cell lattice spacing between fuel assemblies is 6.244 inches. For the manufacturing tolerance of $\pm$0.040 inches, the corresponding uncertainty in reactivity is $\pm$0.0027 δk as determined by the CASMO-3 code (Table 9.1-26).

f. Effect of Stainless Steel Thickness Tolerance

The nominal thickness of the stainless steel box and the stainless steel picture frame sheathing are 0.075 and 0.035 inches respectively. The maximum positive reactivity effect for a mean stainless steel thickness tolerance of ±0.008 inches is ±0.0004 δk as determined by the CASMO-3 code (Table 9.1-26).

g. Effect of Fuel Enrichment and Density Variation

The nominal design enrichment is 3.50 wt% U-235. CASMO-3 calculations of the sensitivity to an enrichment variation of ±0.05 wt% U-235 yielded an uncertainty in reactivity of 0.0033 δk.

The design basis calculation assumed a UO_2 stack density 95% theoretical density, corresponding to a density of 10.42 g/cm^3 . Calculations were also made to determine the sensitivity to a conservative tolerance in UO_2 fuel density of ±0.20 g/cm^3 in density or a maximum density of 10.62 g/cm^3. These calculations indicate that the storage rack k_∞ is increased by 0.0026 δk (Table 9.1-26). A lower fuel density would result in a correspondingly lower value of reactivity.

h. Effects of Zirconium Flow Channel

The design basis calculations assumed the presence of a flow channel. Elimination of the zirconium flow channel results in a decrease in reactivity of approximately 0.008 δk.

i. Effects of Water Gap Spacing Between Racks

For normal storage conditions with a water gap between racks, the array k_{eff} of a rack would be less than the reference design k_∞ and Boral plates along the wall of the racks facing the water gap would not be necessary. However, as an additional and precautionary measure, rack design provides for Boral plates on storage cells on one of the two rack walls along the water gap. With this conservative configuration, the design assures that, even under abnormal or accident conditions. the storage rack reactivity will remain less than the 0.95 k_{eff} regulatory limit.

9.1.2.3.1.2.5 Special Cases - Maximum Density Spent Fuel Storage Racks

a. Abnormal Location of a Fuel Assembly

It is theoretically possible to suspend a fuel assembly of the highest allowable reactivity outside and adjacent to the spent fuel storage rack. Neutron leakage, inherent along the rack edge, significantly reduces the reactivity consequences of an extraneous fuel assembly. Three dimensional KENO-5a calculations show that the k_{eff}, with an assembly outside of and adjacent to a rack, is less than the design basis k_∞ of an infinite radial array. Thus, the abnormal location of a fuel assembly will have a negligible reactivity effect.

b. Eccentric Fuel Assembly Positioning

The fuel assembly is normally located in the center of the storage rack cell with the bottom fittings and spacers that mechanically restrict lateral movement of the fuel assemblies. Nevertheless, calculations with the fuel assembly moved into the corner of the storage rack cell (four-assembly cluster at the closest approach), resulted in a substantial negative reactivity effect. Thus, the nominal case, with the fuel assembly positioned in the center of the storage cell, yields the maximum reactivity.

c. Dropped Fuel Assembly

For a drop of a fuel assembly on top of a rack, the fuel assembly will come to rest horizontally on top of the rack with a minimum separation distance from the fuel of more than 12 inches. A separation of 12 inches is sufficient to preclude neutron coupling (ie, an effectively infinite separation). Maximum expected deformation under seismic or accident conditions will not reduce the minimum spacing between fuel assemblies to less than 12 inches. Consequently, fuel assembly drop accidents will not result in a significant increase in reactivity (<0.0001 δk) due to the separation distance.

d. Fuel Rack Lateral Movement

Normally, the individual racks in the spent fuel pool are separated by a water gap. Lateral motion of a rack, postulated as a consequence of the design basis earthquake, could reduce or eliminate this water gap. Since the exterior walls of one of the racks along the water gap contains a Boral plate, closing the gap would not result in any increase above the design basis reactivity.

9.1.2.3.1.2.6 Summary and Conclusion - Maximum Density spent Fuel Storage Racks

For the design basis reactivity calculations with uniform enrichment of 3.50 wt%, the nominal storage cell infinite multiplication factor, k_∞, is 0.9366 (CASMO-3 code). With a δk of 0.0078 for all known uncertainties statistically combined, the maximum k_∞ in the fuel rack is 0.944 which is below the design basis limit of 0.95 for k_{eff}. Independent calculations with NITAWL-KENO-5a (1,250,000 histories in 2500 generations) gave a k_∞ (including all uncertainties) of 0.9335 $\pm$0.0077 (95% confidence, maximum k of 0.941) which is in good agreement with the CASMO-3 calculations (Table 9.1-28).

9.1.2.3.2 Structural Analyses

9.1.2.3.2.6 Bases For Analyses - Maximum Density Spent Fuel Storage Rack

The maximum density spent fuel storage racks are seismic Category I equipment as defined in Regulatory Guide 1.13. These racks are designed to withstand the effects of a design basis earthquake and remain functional, in accordance with Regulatory Guide 1.29 and 10CFR50.

The physical properties for the materials used in the manufacture of the maximum density spent fuel storage racks are given in Table 9.1-29. The load combinations and allowable stresses for the maximum density spent fuel storage racks are given in Table 9.1-30.

The structure of the racks is designed to remain functional (although some permanent deformation may occur) and to maintain the required spacing between stored fuel assemblies in the event of impact of a "heavy fuel assembly (consolidated fuel assembly)" (1360 pounds) dropped on the rack from a height of 36 inches. In this case, local plastic deformation is allowed at the point of impact. The structure of the racks is also analyzed for effects of the impact of the fuel bundle dropped through an empty storage cavity. Local failure of the baseplate is acceptable, a gross structural failure is not permissible. A comparative analysis with impact conditions, as stated above, is also conducted on a rack due to an uplift force of 4000 pounds on a stuck fuel bundle. No permanent deformation of the fuel cell in the active fuel region is allowed in this case. A force of 4000 pounds is well in excess of the maximum (controlled) uplift force from the refueling platform main hoist of 1200 pounds.

9.1.2.3.2.7 Seismic Analyses - Maximum Density Spent Fuel Storage Rack

A combination of time history and static seismic analysis was performed for the maximum density spent fuel storage racks by Holtec International. Rack dynamic simulations were performed using a 3-D single rack 22-degrees of freedom (DOF) model and a Whole Pool Multi-Rack (WPMR) model which considered all the racks in the pool.

a. 3-D 22-DOF Single Rack Model

The fuel rack motion is captured by modeling the rack as a twelve degree-of-freedom structure (Figures 9.1-43 through

9.1-45). Movement of the rack cross-section at any height is described by six degrees-of-freedom of the rack base and six degrees-of-freedom at the rack top. Rattling fuel assemblies within the rack are modeled by five lumped masses. Each lumped mass has two horizontal displacement degrees-of-freedom. Vertical motion of the fuel assembly mass is assumed to be equal to the rack vertical motion at the baseplate level. The centroid of each fuel assembly mass can be located off center, relative to the rack structure centroid at that level, to simulate a partially loaded rack.

Seismic motion of a rack is characterized by random rattling of the fuel assemblies in their individual storage locations. All fuel assemblies are assumed to move in-phase within a rack. This exaggerates computed dynamic loading on the rack structure and therefore yields conservative results.

Fluid coupling between the rack and fuel assemblies, and between the rack and the fuel pool wall, is simulated by appropriate inertial coupling in the system kinetic energy. Fluid coupling terms for rack-to-rack coupling are based on opposed-phase motion of adjacent modules.

Fluid damping and form drag is conservatively neglected. Sloshing is negligible at the top of the rack and is neglected in the analysis of the rack.

Potential impacts between rack and fuel assemblies are accounted for by appropriate "compression only" gap elements between the masses involved. The possible incidence of rack-to-wall or rack-to-rack impact is simulated by gap elements at the top and bottom of the rack in two horizontal directions. Bottom elements are located at the baseplate elevation.

Pedestals are modeled by gap elements in the vertical direction and as "rigid links" for transferring horizontal stress. Each pedestal support is linked to the fuel pool liner by two

friction springs. Local pedestal spring stiffness accounts for floor elasticity and for local rack elasticity just above the pedestal.

Rattling of fuel assemblies inside the storage locations causes the gap between fuel assemblies and the cell wall to change from a maximum of twice the nominal gap to a theoretical zero gap. Fluid coupling coefficients are based on the nominal gap.

b. Whole Pool Multi-Rack (WPMR) Model

The single rack 3-D (22-DOF) model outlined in the preceding subsection is used to evaluate structural integrity physical stability, and to initially assess kinematic compliance of the rack modules. Prescribing the motion of the racks adjacent to the module being analyzed is an assumption in the single rack simulation. For closely spaced racks, demonstration of kinematic compliance is further confirmed by modeling all modules in one comprehensive simulation using a Whole Pool Multi-Rack (WPMR) model. In the WPMR analysis, all racks are modeled, and their correct fluid interaction is included in the model.

The presence of fluid moving in the narrow gaps between the racks and between the racks and the fuel pool walls causes both near and far field fluid coupling effects. A single rack simulation can effectively include only hydrodynamic effects due to contiguous racks when a certain set of assumptions is used for the motion of the contiguous racks. In a WPMR analysis, far field fluid coupling effects of all the racks are accounted for by using the correct model of pool fluid mechanics. The external hydrodynamic mass due to the presence of walls or adjacent racks is computed in a manner consistent with fundamental fluid mechanics principles using conservative nominal fluid gaps in the fuel pool at the beginning of the seismic event.

The friction coefficient is ascribed to the support pedestal/pool bearing pad interface is consistent with experimental data. Friction coefficients, developed by a random number generator with Guaussian normal distribution characteristics, are imposed on each pedestal of each rack in the pool. The assigned values are then held constant during the entire simulation in order to obtain reproducible results. Thus, the WPMR analysis can simulate the effect of different coefficients of frictions at adjacent rack pedestals.

In the WPMR analysis, a reduced degree-of-freedom (RDOF) set is used to model each rack plus contained fuel. The rack structure is modeled by six degrees-of-freedom. A portion of contained fuel assemblies is assumed to rattle at the top of the rack, while the remainder of the contained fuel is assumed as a distributed mass attached to the rack. The rattling portion of the contained fuel is modeled by two horizontal degrees-of-freedom.

Thus, the WPMR model involves all the racks in the spent fuel pool with each individual rack modeled as an eight degree-of-freedom structure. The rattling portion of the fuel mass, within each rack, is chosen to ensure comparable results from displacement predictions from the single rack analysis using a 22-DOF model and the 8-DOF analysis under the same conditions. Unit 1 spent fuel pool configuration is bounded by the Unit 2 analyses.

9.1.2.3.2.8 Dropped Fuel Bundle Analysis - Maximum Density Spent Fuel Storage Rack

Analysis were performed to evaluate the effects of a dropped fuel assembly. Two scenarios were evaluated, the deep drop and shallow drop.

In the deep drop scenario a "heavy fuel assembly (consolidated fuel assembly)" is postulated to drop from a height of 36 inches above the top of a storage location and impacts the baseplate of the rack. While local failure of the baseplate is acceptable, a gross structural failure is not permissible. Also, the stored fuel array must remains subcritical. Results show that the spacing between cells is unaffected and the stored fuel array remains subcritical. Local baseplate deformation in the vicinity occurs, but the dropped fuel assembly does not impact the fuel pool liner. The impact results in a maximum baseplate movement toward the liner of less than 2.21 inches. The nominal baseplate height above the fuel pool liner is approximately 7.00 inches therefore, contact does not occur. If a fuel assembly drops through a cell located over a support leg, the impact load transmitted through the support leg to the fuel pool liner is less than the loads caused by a seismic event. Therefore, the concrete bearing pressures a calculated for the seismic event bound those due to a fuel drop accident.

In the shallow drop scenario a "heavy fuel assembly" is postulated to drop from a height of 36 inches above the top of the rack and impacts the top of the rack. Permanent deformation of the rack is acceptable, but it must be confined to the region above the top of the active fuel stored in the rack. The elevation of the top and bottom of active fuel must not be altered. Results show that the deformation caused by a dropped assembly will be less than or equal to 2.29 inches from the top of the rack. This region of deformation is less than the available cell length above the active fuel (over one foot). This load case bounds the scenario where the dropped fuel assembly rolls over after impact and impacts multiple locations.

9.1.2.3.2.9 Pool Interface Loads - Maximum Density Spent Fuel Storage Rack

The maximum density spent fuel storage load acting on the fuel pool were determined using the results of the 3-D 22-DOF model and the WPMR model described in Section 9.1.2.3.2.7. The results were determined to be acceptable and are summarized in Table 9.1-31.

9.1.2.3.2.10 Summary and Conclusions - Maximum Density Spent Fuel Storage Rack

The results of the structural analyses for the maximum density spent fuel storage racks are acceptable and summarized in Table 9.1-31.

9.1.2.3.3 Installation of New Maximum Density Racks

Racks are lifted individually from the refueling floor lay-down area and lowered into position in the pools using the 125 ton reactor enclosure crane and additional lifting devices provided by the rack vendor.

Each rack is aligned and leveled as it is placed in its proper pool. Each rack is a freestanding unit that rests on the pool floor using bearing pads attached to corner leveling screws. Leveling screws are adjusted by remotely controlled tools.

The requirements of 10CFR50, Appendix B, as included in the LGS Units 1 and 2 Quality Assurance Plan, Volume I, are implemented for receipt, storage, and installation of the spent fuel racks. Work is performed in accordance with procedures that are reviewed and approved prior to use. Inspections are performed and documented by personnel other than those who performed the work. Site activities are subject to audit by Nuclear Oversite.

9.1.2.4 Tests and Inspections

The spent fuel storage racks require no special periodic testing or inspection for nuclear safety purposes. However, test coupons may be installed in the Unit 1 and Unit 2 Spent Fuel Storage Racks. Test coupon analysis will only be performed on a discretionary basis based upon specific suspected degradation of neutron poisoning material. Spent fuel storage rack assignment in the spent fuel pool is surveyed at the time of installation.

9.1.2.4.1 Deleted

9.1.2.4.2 Deleted

9.1.2.4.3 Test Coupon Description and Installation

A typical test coupon is physically designed to simulate as nearly as possible, the actual in-service geometry, physical mounting, materials, and flow conditions of the neutron poison in the storage racks. The test coupons are mounted on a hanger assembly within the central eight feet of the fuel zone of the storage racks, where the gamma flux is expected to be reasonably uniform.

9.1.2.4.4 Test Coupon Inspection

Test coupon inspection is intended to identify changes in physical properties of the neutron poisoning material by performing various non-destructive and destructive testing.

9.1.3 FUEL POOL COOLING AND CLEANUP SYSTEM

The FPCC system is designed to remove the decay heat generated by the spent fuel assemblies stored in the fuel pool and to maintain the pool water at a clarity and purity suitable both for underwater operations and for the protection of personnel in the refueling area. The FPCC system has no function related to the safe shutdown of the plant.

9.1.3.1 Design Bases

a. The FPCC system piping is designed so that operator error or a loss of piping integrity cannot result in the draining of the spent fuel pool so that stored fuel would be uncovered.

b. The FPCC system is designed to provide a source of makeup water to ensure the maintenance of the fuel pool water level.

c. All piping and components of the FPCC system that form part of the flow path for makeup water from the ESW system, RHRSW system, and cooling water to and from the RHR system are designed to remain functional following an SSE.

d. The FPCC system is comprised of three pumps and three heat exchangers connected by a common header providing three approximately 50% capacity cooling trains. The Service Water System removes heat from the heat exchangers. Following an accident, two of the three pumps may be powered by emergency on-site power and any heat exchanger may be cooled by the Reactor Enclosure Cooling Water System. A precoat-type filter/demineralizer package is provided, through which a portion of the system flow can be diverted. As similar backup filter/demineralizer package common to both units is also provided.

e. The FPCC system was originally designed to maintain the bulk water temperature in the spent fuel pool at or below 140°F under normal operating conditions with two FPCC pumps and two FPCC heat exchangers in operation. This is based on the normal heat load discharge history shown in Table 9.1-2A.

The Unit 1 FPCC system is capable of removing 1.61 x 10^7 BTU/hr and Unit 2 FPCC system is capable of removing 1.805 x 10^7 BTU/hr with any one train unavailable. The FPCC systems have been evaluated for increased spent fuel storage capacity and faster fuel transfer rate (6.7 vs. 10 days) resulting in a heat load of 1.805 x 10^7 BTU/hr. The results show that on Unit 2 with any two FPCC pumps and any two FPCC heat exchangers in operation, the spent fuel pool bulk temperature will peak at 143°F. The spent fuel pool bulk temperature will exceed 140°F for approximately 2.5 days. This is based on the normal heat load discharge history shown in Table 9.1-2B (reference 9.1-15). This analysis is not applicable to Unit 1, since Unit 1 has a smaller capacity FPCC system and the ADHR would be used for heat loads exceeding 1.61 x 10^7 BTU/hr.

Each refueling offload scenario is cycle specific and is likely to vary from Table 9.1-2B. Therefore, administrative controls are maintained to assure that the spent fuel pool heat load does not exceed FPCC heat removal capacity during shutdown, refueling and power operating conditions such that the FPCC system is capable of maintaining the spent fuel pool cooling temperature at a maximum of 143°F, assuming a single active failure during normal operating conditions. If the anticipated heat load exceeds the FPCC capability, the Residual Heat removal (RHR) System is placed in service and FPCC is secured. When the spent fuel pool and reactor refueling cavity well are connected, the combined decay heat load of the in-core fuel and spent fuel pool inventory is typically removed by the RHR system, alone, operating as an alternate decay heat removal method (ADHR).

f. The FPCC system was originally designed to permit the RHR system to be used, through a cross-tie, to maintain the bulk water temperature in the spent fuel pool at or below 140°F, with a maximum anticipated decay heat load of 3.64x10^7 Btu/hr. This is based on one full core offloaded from the reactor ten days after shutdown to fill the spent fuel pool, plus the previous normal refueling loads from 18 month refuelings as shown in Table 9.1-2A.

A bounding analysis of the FPCC system has been performed, which considered a maximum reactor power of 3527 MW, spent fuel pool increased storage capacity and a faster fuel transfer rate. This analysis results in a maximum anticipated heat load of 4.832 x 10^7 Btu/hr. This is based on one full core offloaded from the reactor vessel approximately 40 hours after shutdown plus the previous normal refueling loads from 24 month refuelings as shown in Table 9.1-2B (references 9.1-16 and 9.1-17). A one-time per unit refueling cycle length extension to approximately 27 months (from a nominal 24 months) for Unit 1 Cycle 7 and Unit 2 Cycle 5 was evaluated. It was determined that the increase in decay heat generation due to each affected core's total operating period of 6.25 years (vs. 6 years) has no significant effect on maximum calculated fuel pool heat load.

The FPCC system cross-tie to RHR is normally used for the RHR ADHR method

to maintain both the spent fuel pool and reactor water temperatures below 140°F during refueling. See Section 5.4.7 for further discussion of ADHR method.

Additionally, the FPCC system(s) or the RHR fuel pool assist mode can be used to remove decay heat from both the spent fuel pool(s) and the reactor vessel by cooling the spent fuel pool(s). Evaluations have shown that with the reactor cavity flooded up and the fuel pool gates removed, natural circulation will transfer decay and sensible heat from the reactor vessel to the fuel pool(s). The required cooling capacity of the FPCC system(s) or the RHR fuel pool assist mode can be verified by calculation or demonstration to show that these systems are alternate methods of decay heat removal. Natural circulation will also induce reactor coolant circulation through the reactor core such that reactor core temperature can be accurately measured at an appropriate location.

g. The FPCC system is designed to maintain the optical clarity of the water in the spent fuel pool and other refueling area cavities (cask loading pit, reactor well, and dryer/separator pool) so that fuel handling and equipment handling operations are not hampered by limited visibility.

h. The FPCC system is designed to limit the fission product and activated corrosion product concentrations in the water of the spent fuel pool and other refueling area cavities to permit continuous occupancy of the refueling area by plant personnel.

The seismic category, quality group classification, and corresponding codes and standards that apply to the design of the FPCC system are discussed in Section 3.2.

9.1.3.2 System Description

9.1.3.2.1 General Description

The FPCC system consists primarily of the pool water collection equipment, including wave suppression scupper and skimmer surge tanks, a cooling train with two heat exchangers, two pumps, a cleanup loop, and the discharge diffusers in the spent fuel pool. A backup heat exchanger and a backup pump are also included in the system.

9.1.3.2.2 Component Description

Design parameters for individual components of the FPCC system are listed in Table 9.1-1.

9.1.3.2.2.1 Skimmer Surge Tanks

Two skimmer surge tanks collect overflow water from the spent fuel pool and reactor well through skimmer drain openings, with adjustable weirs at the pool surface elevation. The skimmer surge tanks also collect overflow water from the cask loading pit and the dryer/separator pool via skimmer drain headers. A wave suppression scupper along one side of the spent fuel pool is drained via the skimmer drain headers. The skimmer surge tanks provide a suction head for the fuel pool cooling pumps and RHR pumps and serve as a buffer volume during transient flows in the normally closed-loop FPCC system.

9.1.3.2.2.2 Fuel Pool Heat Exchangers

Three fuel pool heat exchangers of the shell and straight tube-type are provided to transfer heat from the fuel pool water to the service water system (Section 9.2.1). Normally a maximum of two heat exchangers are in service and the third serves as a backup. The heat exchangers are arranged in parallel and are located in the reactor enclosure below the bottom of the skimmer surge tanks. Fuel pool water circulates through the shell side of the heat exchangers, and service water circulates through the tube side.

The service water side of the heat exchangers is maintained at a higher pressure than the fuel pool water side to minimize the possibility of radioactive contamination of the service water system from a tube leak.

Interconnecting piping is provided so that the heat exchangers can also be cooled by the RECW system in case the service water system is not available.

9.1.3.2.2.3 Fuel Pool Cooling Pumps

Three centrifugal pumps are provided to circulate water through the FPCC system. Normally a maximum of 2 pumps are in operation and the third serves as a backup. The pumps are arranged in parallel and take suction from the fuel pool heat exchangers through a common header. Two of the pumps are powered from Class 1E sources. The pumps can be operated from a panel located in the reactor enclosure and a panel located in the radwaste enclosure.

9.1.3.2.2.4 Fuel Pool Filter/Demineralizer Package

The cleanup loop of the FPCC system includes a filter/demineralizer package located separately in shielded cells in the radwaste enclosure. A spare filter/demineralizer package common to the two reactor units is also provided.

The fuel pool filter/demineralizer is a precoat-type, using powdered cation-anion resins as the coating media on the external surface of the filter elements. The filter elements are cylindrical stainless steel mesh, mounted vertically in a tube sheet and replaceable as a unit. The upper head of the filter/demineralizer vessel is removable for installing and replacing the filter elements. The ion exchange resin is a mixture of finely ground cation and anion resins, in proportions determined by service; this resin is referred to as precoat.

The precoat is applied to the surface of the filter elements by a flowing process called precoating. To maintain the filter medium on the filter elements during the interval between the precoating operation and the return-to-normal operation, or if there is an abnormal decrease in process flow, a centrifugal holding pump is provided with each filter/demineralizer to recirculate water through the unit.

The fuel pool filter/demineralizer system is designed to maintain water quality within the following limits:

a.	Conductivity:	$\leq$ 3 μmho/cm at 25°C
b.	Chlorides:	$\leq$ 0.5 ppm
c.	pH:	5.3 to 7.5 at 25°C

d. Total Suspended Solids: ≤ 1 ppm

A strainer is provided in the effluent stream of each filter/ demineralizer to limit the migration of filter medium particles that pass through the filter elements. The strainer is capable of withstanding a differential pressure greater than the shutoff head of the fuel pool cooling pumps.

9.1.3.2.2.5 Backwash and Precoat Equipment

The backwash and precoat subsystem is common to the two reactor units and serves all three filter/demineralizer packages. Included in the subsystem are a backwash air accumulator, precoat tank, and filter precoat pump. Compressed air from the backwash air accumulator is used in conjunction with condensate water to backwash the spent filter medium from the filter elements with a minimum volume of water. Backwash slurry is drained to the waste sludge tank of the solid radwaste system (Section 11.4).

New ion exchange resin is mixed in the precoat tank and transferred as a slurry by the filter-precoat pump to the filter/demineralizer, where it is deposited on the filter elements. An agitator is provided with the precoat tank for mixing. Piping and valves associated with the precoat subsystem allow the precoat water to be recirculated to the precoat tank or the suction side of the filter precoat pump. The precoat subsystem can also be used for cleaning and decontamination of the filter/demineralizers.

9.1.3.2.3 System Operation

The FPCC system removes decay heat from fuel stored in the spent fuel pool and includes equipment to maintain the purity of the water in the system. The FPCC system heat removal capacity is shown in Table 9.1-2B. Water from the spent fuel pool flows through weirs and a wave suppression scupper at the pool surface into two skimmer surge tanks adjacent to the pool. Water in the skimmer surge tanks flows by gravity through the fuel pool heat exchangers to the suctions of the fuel pool cooling pumps. From the pumps, water is returned to the spent fuel pool through two return lines. A portion of the discharge flow of the pumps can be diverted through the cleanup loop before being returned to the pool. Heat is removed from the fuel pool heat exchangers by the service water system (drawing M-10).

The filter/demineralizer in the cleanup loop maintains pool water purity and clarity by a combination of filtration and ion exchange. Disposable ion exchange resins in the filter/demineralizer remove ionic fission product and corrosion product impurities and also serve as a filter for particulate matter. The ion exchange resins are replaced when the pressure drop across the filter/demineralizer is excessive (≥25 psid at rated flow) or when the resins are exhausted as indicated by discharge conductivity being above the limit for the spent fuel pool given in Section 9.1.3.2.2. The backwash and precoat operations are controlled from the radwaste enclosure.

The FPCC system is sampled monthly at the filter/demineralizer influent and effluent lines. These grab samples are analyzed by gamma isotopic analysis. The ratio of the influent activity to the effluent activity (decontamination factor) will be determined from this analysis. The fuel pool filter/ demineralizer will be regenerated on low decontamination factor.

The grab samples will also be analyzed for pH, chloride, conductivity, and turbidity. Turbidity is an indication of insolubles. The pH, conductivity, and chloride limits are given in Section 9.1.3.2.2.

During normal plant operation, the FPCC system serves only the spent fuel pool. During refueling operations, however, when the reactor well, dryer/separator pool, and/or cask loading pit are filled with water, the FPCC system can be aligned to recirculate and process the water in all these cavities. Water from the refueling water storage tank (Section 9.2.7) is used to fill the refueling area cavities. The refueling water pumps fill the cask loading pit through its drain line and fill the reactor well and the dryer/separator pool through diffusers in the reactor well. After refueling activities are completed, the refueling water pumps transfer water from the refueling area cavities back to the refueling water storage tank via a condensate filter/demineralizer if additional cleanup is required. Gravity draining of the refueling water directly to the refueling water storage tank is also possible.

As the heat load on the spent fuel pool changes, the number of operating fuel pool cooling pumps and heat exchangers is adjusted to maintain the desired water temperature. The FPCC system has sufficient cooling capacity to maintain the spent fuel pool water at a temperature at or below 143°F, with a normal decay heat load of 1.61×10^7 Btu/hr on Unit 1 and 1.805×10^7 Btu/hr on Unit 2, with two pumps and two heat exchangers operating. The Unit 1 and 2 spent fuel pools can also be maintained cross connected as long as adequate spent fuel pool cooling capacity is verified.

If a heat load exceeding the capacity of the FPCC System is placed in the spent fuel pool, a cooling train of the RHR system (Section 5.4.7), consisting of an RHR pump and heat exchanger, can be substituted for the FPCC pumps and heat exchangers for cooling the pool water. A cross-connection between the drain line from the skimmer surge tanks and the RHR system allows one RHR pump to take suction from the skimmer surge tanks and pump fuel pool water through an RHR heat exchanger before returning it to the pool via return piping provided specifically for use with the RHR system Fuel Pool Cooling assist mode or via the normal Shutdown Cooling return path with RHR Alternate Decay Heat Removal method. The interconnecting piping between the RHR system and FPCC system is provided with either of two spool pieces, one with blind flanges for normal operation and one open spool piece for when the intertie is needed (drawing M-51). Administrative controls prevent the use of the RHR system intertie unless the associated reactor is shut down and is in the refueling mode. With the fuel pools cross-tied with one unit in refueling mode and RHR aligned to fuel pool cooling SST, there is no impact on the ability of refueling unit RHR system to perform its safety related functions. Also, there is no impact on the ability to safely shutdown the operating unit.

The conditions under which cooling of the spent fuel pool water by the RHR system alone would be required include the unloading of a full core load of irradiated fuel into the pool or isolation of fuel pool cooling system to support RHR ADHR operation or RHR Fuel Pool Cooling assist operation. The RHR system has sufficient heat removal capacity to maintain the spent fuel pool water at a temperature at or below 140°F, with a maximum anticipated decay heat load of 4.832×10^7 Btu/hr. The RHR system may also be used for cooling if the fuel pool cooling system should be unavailable. Connection of the RHR system requires:

a. Installation of RHR system spool pieces

b. Manual closure of normally open valve 053-✯007

c. Manual opening of normally closed valves 053-✯006, 053-✯024A and 053-✯024B

d. Adjustment of fuel pool overflow weirs, if required

e. Adjustment of Fuel Pool/SST water level to ensure adequate suction head for RHR pumps, if required

For Fuel Pool Cooling assist mode, the RHR supply and return lines and their associated valves are located in the fuel pool cooling pump and heat exchanger room at el 283' in the reactor enclosure.

The normal position of the above valves provides isolation of the safety-grade, seismic Category I RHR system from the FPCC system. The portion of the FPCC system downstream of valve 053-☆007 is designed to seismic Category I criteria (designated seismic Category IIA as discussed in Section 3.2.1) and would not be expected to fail due to a seismic event.

If normal fuel pool cooling should be lost as a result of a pipe break in the seismic Category IIA portion of the system, the quantity of water released would be limited to the inventory of the pool and reactor cavity above the overflow weirs, the skimmer surge tanks, and the pump suction piping. The flood height and environmental conditions resulting from this break would not prevent personnel access, which is required to take the manual actions described above. The maximum temperature (150°F) and pressure (31 psig) of the water in the line are not high enough to significantly affect the temperature, pressure, or humidity conditions in the room (the room is open at the top to the reactor enclosure access area at el 283'). The released fluid would not be highly radioactive. The water would drain out of the room at approximately the same rate as it flows from the break.

If there is a LOOP, the Class 1E buses are powered by the diesel generators, and the two FPCC pumps that receive Class 1E power can be restarted. Since normal service water is not available in this case, the FPCC heat exchangers can be cooled by the RECW system (which is in turn cooled by the ESW system) via interconnecting piping, after installation of normally removed spool pieces (drawings M-10, M-11 and M-13).

If there is a complete loss of capability to remove heat from the spent fuel pool using heat exchangers, heat can be removed by allowing the pool to boil and adding makeup water to maintain the pool water level. Makeup water requirements are shown in Table 9.1-2B. Makeup water is normally supplied to the skimmer surge tanks from the demineralized water makeup system (Section 9.2.5) by the actuation of a remote manually operated valve. If makeup water from this source is not available, makeup can be provided from the ultimate heat sink (spray pond) by either of two seismic Category I flow paths (drawings M-10, M-51 and M-53). The first of these backup makeup sources is a loop of the ESW system (Section 9.2.2) via a cross-connecting line to one of the RHR system return pipes in the spent fuel pool. The two ESW pumps in the ESW loop provide redundancy in motive power for this source of makeup supply. The manual valves that must be opened to initiate makeup from the ESW system are located in the control structure and are accessible after an accident. The second of these backup makeup sources is a loop of the RHRSW system (Section 9.2.3) via the piping of one RHR system loop and the cross-connecting piping leading to the RHR return piping in the spent fuel pool. The two RHRSW pumps in the RHRSW loop provide redundancy in motive power for this source of makeup supply. The manual valves that must be actuated and the spool piece that must be installed to establish this flow path are located in the reactor enclosure. These backup makeup water sources provide flow rates greater than the maximum makeup requirements shown in Table 9.1-2B. The spray pond design water volume includes its use as a source of makeup to the spent fuel pool for 30 days, without makeup to the pond during which time the cooling function of the FPCC system or RHR system can be established or an alternate makeup water supply can be established.

9.1.3.3 Safety Evaluation

The cooling water return lines to the spent fuel pool associated with both the FPCC system and RHR system penetrate the walls of the spent fuel pool within 4 feet of the normal pool water level. FPCC system cooling water return lines are provided with siphon breaker holes as close as possible to the normal water level to prevent the siphoning of pool water below the level of the holes. RHR system cooling water return lines terminate below the normal water level and above the minimum water level to prevent pool siphoning. The FPCC system takes suction from the spent fuel pool via the skimmer surge tanks through openings in the liner plate at the normal water level. There are no other piping penetrations in the pool liner plate. Therefore, there is no operator error or FPCC system malfunction that could result in the draining of the spent fuel pool so that stored fuel would be uncovered.

The spent fuel pool is provided with redundant seismic Category I makeup capability to ensure an adequate supply of makeup water to the spent fuel pool under conditions of maximum anticipated evaporation associated with fuel pool boiling. The radiological consequences of a boiling spent fuel pool are discussed in Section 9.1.3.6. Makeup water is supplied from the spray pond using either the ESW system or RHRSW system. Redundant pumps in each loop of the ESW and RHRSW systems provide assurance of the availability of motive power to pump the makeup water.

The portions of the FPCC system that form part of the flow path during makeup from the ESW or RHRSW systems or spent fuel pool cooling by the RHR system, up to and including the boundary isolation valves, are designed in accordance with seismic Category I requirements as discussed in Section 3.2. The components (and supporting structures) of any system, equipment, or structure that is not seismic Category I and whose collapse could result in the loss of a required function of the FPCC system are analytically checked to determine that they will not collapse when subjected to seismic loading resulting from the SSE.

The design of the FPCC system with respect to the following areas is discussed in the indicated sections:

a.	Protection from wind and tornado effects	Section 3.3
b.	Flood design	Section 3.4
c.	Missile protection	Section 3.5
d.	Protection against dynamic effects associated with postulated rupture of piping	Section 3.6
e.	Environmental design	Section 3.11

A failure mode and effects analysis of the FPCC system is provided in Table 9.1-3.

The water level in the spent fuel storage pool is maintained at a height sufficient to provide shielding for required building occupancy. Radioactive particulates removed from the fuel pool are collected in filter/demineralizer units in shielded cells. For these reasons, the exposure of station personnel to radiation from the FPCC system is normally minimal. Further details of radiological considerations are discussed in Chapter 12.

9.1.3.4 Inspection and Testing Requirements

The FPCC system is preoperationally tested in accordance with the requirements of Chapter 14. The safety-related systems that provide makeup water are periodically tested in accordance with the requirements of Chapter 16.

9.1.3.5 Instrumentation Applications

Instrumentation is provided to annunciate the high and the low spent fuel pool water levels in the control room. Skimmer surge tank level instrumentation provides level indication at the refueling floor control panel, both high and low level annunciation at the refueling floor control panel and the fuel pool cooling pump control panel, and by a common trouble alarm in the main control room panel. A low level alarm indicates that makeup to the FPCC system is needed.

The temperature of fuel pool cooling water at the common inlet and at the outlet of each fuel pool heat exchanger is recorded and high temperature is annunciated in the control room; high outlet temperature in the combined heat exchanger discharge is annunciated in the control room through the plant computer.

The discharge pressure of each fuel pool cooling pump is indicated locally. Low pump discharge and suction pressure is annunciated by a local alarm in the fuel pool cooling pump panel and by a common trouble alarm in the main control room. The pumps are tripped individually on low suction pressure.

High leakage rates through the refueling bellows or reactor well seals are annunciated at the refueling floor control panel and by a common trouble alarm in the main control room.

The equipment associated with the cleanup loop is controlled and monitored from panels in the radwaste enclosure. The parameters monitored include differential pressure across the filter/demineralizer, flow rate through the filter/demineralizer, and pressure differential across the strainer downstream of the filter/demineralizer.

9.1.3.6 Analysis for Nonseismic Fuel Pool Cooling and Cleanup System

The FPCC system is not designed as a seismic Category I or engineered safeguards system except for interconnections with safety-related makeup water sources. The following analysis examines the consequences of a loss of spent fuel pool cooling and the use of the seismic Category I makeup water source.

It is assumed that loss of cooling to both spent fuel pools occurs. In addition, to maximize both the heat loads and the iodine inventories in the pools, sequential refuelings are postulated. The loss of cooling is assumed during the eleventh refueling, just after the refueling cavity water level is lowered and the RHR system is not available for cooling the cavity and spent fuel pool. The analysis involves an evaluation of the time to pool boiling, the makeup water requirements if the pool boils, and the thyroid dose consequences at the LPZ outer boundary due to iodine releases from the boiling pools. This analysis is still bounding for all spent fuel storage rack configurations up to and including maximum storage configuration of maximum density storage racks.

The assumptions used in this analysis were consistently chosen to be the worst case design basis assumptions, similar to those in regulatory guides for design basis accidents (e.g., Regulatory Guides 1.3, 1.25, etc). The combination of all of these design basis assumptions occurring at the

same time is extremely unlikely, making this accident, as analyzed, one of very low probability. Many of the assumptions are considered to be overly conservative; for example, operating experience with present BWR fuels (Reference 9.1-5) indicates that the assumption of 1% of the fuel with cladding failures is more conservative by at least a factor of 100 for 8x8 fuel bundles. Further, while some iodine release rate spiking factors of over 50 have been observed during startups and shutdowns, there are presently no data for the less severe temperature transients that would be associated with a boiling spent fuel pool. The assumption of 10% of the activity in the fuel gaps is at least 30 times the gap activity used for a realistic accident analysis in Chapter 15. A more realistic evaluation of this accident would result in releases of radioactivity, if any, many orders of magnitude below the calculated values. Further, the realistic releases would be well below the 10CFR50, Appendix I technical specifications, indicating that such an incident is of little or no consequence.

This conservatively assumes that it would take 20 hours to place the reactor in cold shutdown, realign valves, adjust the spent fuel pool weir, and install the interconnecting piping between the RHR system and the fuel pool cooling system (Section 5.4.7.1.1). The conservative results show that the pools would not boil until at least 13.5 hours after the loss of cooling at the average water heatup rate of 5.33°F/hr. If cooling is not restored before the pool boils, then makeup water from the seismic Category I ESW system can be added to the pool to keep the fuel covered at all times.

As shown in Table 9.1-4 the thyroid dose consequences of releasing the water that would evaporate from the boiling pool are well below the guideline values of 10CFR100.

The following assumptions were used to calculate the heat generation and boiling rates in the two spent fuel pools:

a. Each pool contains the maximum inventory of assemblies with the discharges shown in Table 9.1-2A. The last one-third cores are from the just-completed sequential refuelings. For Unit 1, the fuel has decayed for 47 days. For Unit 2, the decay time is 21 days, the length of time from shutdown until the water level in the refueling cavity has been lowered, and the RHR system would not be able to cool the refueling cavity and spent fuel pool. The minimum time to complete fuel unloading and loading for Unit 1 is 26 days. These decay times result in the maximum heat generation rates and maximum evaporation rates at times when the RHR system is not available.

b. The decay heat is calculated by using the decay heat equations presented in BTP APCSB 9-2. The decay heat generation rate for each pool is given in Table 9.1-5 for various times after the postulated loss of cooling.

c. All heat generated by the fuel is assumed to be absorbed by the water, to minimize the time to boiling. No heat is assumed to be lost to the surroundings by conduction through the concrete and steel or by evaporation. The temperature gradients from the fuel at the bottom of the pool to the cooler water at the top create convective water and heat currents that should thoroughly mix the water and promote an even distribution of heat, rather than localized points of surface boiling .

This does not preclude the performance of non-sequential outages less than 26 days in length.

The following assumptions were used to calculate the offsite doses for the loss of cooling to the spent fuel pools:

a. The saturation inventory of I-131 in the 3458 MWt core is 8.66×10^7 Ci.

b. During refueling, 276 fuel elements (one-third core) are transferred to the spent fuel pool. Iodine in fuel from past refuelings is negligible, due to the long times for decay.

c. It is assumed that 1% of the fuel rods in the core are defective and that this 1% is in the one-third core transferred to the spent fuel pool.

d. The iodine activity in the spent fuel pool water at the initiation of boiling is assumed to be negligible compared to the activity released from the fuel during pool boiling. Activity in the core coolant or from a shutdown spike would have been cleaned up to acceptably low levels by the RWCU and spent fuel pool cleanup systems before fuel transfer begins.

e. The spent fuel pool cooling systems are assumed to fail 47 days after shutdown for the first reactor and 21 days after shutdown for the second reactor. The 26 day difference is the minimum time to refuel the first unit. The 21 days is the time, after a complete fuel transfer, during which the water level in the refueling cavity is lowered, and the RHR system would not be able to cool the refueling and spent fuel pools in case of an accident.

f. The gap activity, or 10% of the rod activity, is available for leakage from the defective 1% of the rods. The leakage rate is assumed to be 2.9×10^{-8} per sec, which corresponds to a release rate of 2.6×10^{-3} Ci/sec for I-131 or 3.5×10^{-1} Ci/sec at 30 minutes for noble gases. This is the full power design fuel leak rate. It should be noted that the available activity in the gaps of the defective fuel rods may have already been significantly depleted by the shutdown spike.

g. A constant spike factor of various magnitudes up to 50 was applied to the I-131 leakage rate from the fuel to account for the potential spiking effects during the temperature transient. The leakage rate returns to the normal full power unspiked rate of 2.9×10^{-8} per sec when boiling begins, since the fuel should now be close to its new steady-state temperature. Although analyses were performed for release rate spike factors of up to 50, there are presently no data to support the spiking phenomena in the spent fuel pool boiling situation. Spikes have been observed for the large, rapid temperature and pressure changes associated with shutdowns and startups, but such significant spiking effects would not be expected during the long, slow temperature change of less than 65°F that would be associated with a loss of cooling. A comparison with the Eickelpasch and Hock paper, "Fission Product Releases After Reactor Shutdown," IAEA Sm 178/19 (1974), shows that the measured I-131 release rate at 9 days after shutdown is approximately 0.2 to 0.3 of the release rate at power. Since the temperature of the fuel during boiling is expected to be well below operating temperature, the use of the power leakage rate is considered to be extremely conservative.

h. The activity released from the fuel is assumed to be uniformly mixed in the 40,600 ft^3 (2.53×10^6 lb_m) of water in each spent fuel pool. The temperature gradients created in the pool by the fuel maintains the mixing process.

i. The normal spent fuel pool design maximum temperature is 140°F. For conservatism this is assumed to be the pool temperature at the time of loss of cooling.

j. The activity release rate from the pool depends on the evaporation (boiling) rate. No evaporation is assumed during the heatup period until the pool water reaches 212°F. All heat generated by the fuel is assumed to be absorbed by the water, and no losses through the concrete and steel are assumed. This results in the shortest time to boiling. The heat generation and evaporation rates after boiling starts are given as a function of time in Table 9.1-5.

k. The iodine partition factor at the pool surface is varied between 0.1 and 0.01 to determine the effects on the total release. Although the partition factor would vary as a function of time due to changing temperatures and iodine concentrations, a value greater than 0.1 should not be expected for this nonviolent evaporating process at the pool surface.

l. No credit is taken for iodine plateout on walls and equipment or for washout by condensing water vapor in the refueling area.

m. It is assumed that all activity in the steam released to the air in the refueling area is instantaneously released to the atmosphere without filtration or condensation in the ventilation system.

n. The atmosphere dispersion factors for dilution of the radioactive releases are the 5th percentile ground level X/Qs given below for the LPZ boundary distance. The time "0" is assumed to be the start of the accident when pool cooling is lost.

TIME	X/Q (sec/m^3)
0 - 8 hrs	4.0×10^{-5}
8 - 24 hrs	2.9×10^{-5}
1 - 4 days	1.4×10^{-5}
4 - 30 days	5.4×10^{-6}

o. The thyroid dose models and breathing rates given in Regulatory Guide 1.3 are used.

The following model was used to calculate the offsite thyroid doses from the release of radioiodine from the fuel:

a. The activity in the fuel available for leakage at the time of loss of cooling, S(0), is calculated using the reactor inventory equation from TID-14844, with the appropriate decay from shutdown until the loss of the cooling and the fractions of iodine available for release. During the pool heatup and boiling phases, the activity in the fuel gaps available for leakage, S(t), is adjusted for decay and losses by leakage to the pool.

$$S(t_n) = S(t_{n-1})\ e^{-(\lambda_d + \lambda_i)\Delta t} \quad (Ci) \qquad \text{(EQ. 9.1-1)}$$

where:

λ_d = decay lambda (1/sec)

λ_1 = leakage rate from the fuel (1/sec)

Δt = $t_n - t_{n-1}$ = time increment (sec)

b. The activity in the spent fuel pool as a function of time, A(t), is given by the solution to the following:

$$A(t_n) = A(t_{n-1})e^{-\lambda_d \Delta_t} - \lambda_{ev} A(t_{n-1})\Delta t + \lambda_1 S(t_n)\left[1 + (SF-1)(1-\varepsilon(t_n))\Delta t / V\right] \quad \text{(EQ. 9.1-2)}$$

where:

λ_{ev} = evaporation lambda from the pool (1/sec) x PF

PF = iodine partition factor at the pool surface

SF = spiking factor

ε = step-function = $\varepsilon = 0$ for $t_n \leq$ time to boil
$\varepsilon = 1$ for $t_n >$ time to boil

V = pool volume (ft^3)

A = activity in spent fuel pool (Ci/ft^3)

Since spent fuel pool makeup water will be available, the evaporation lambda is found by dividing the evaporation rate (ft^3/sec) by the constant pool water volume (ft^3).

c. The activity released to the atmosphere at any incremental time t_n is given by the following equation:

$$R(t_n) = R(t_{n-1}) + \lambda_{ev} V A(t_n)(1-f)\Delta t \quad \text{(EQ. 9.1-3)}$$

where:

R = activity released (Ci)

f = SGTS filter efficiency fraction (assumed to be zero)

The above equations are solved iteratively, using time steps of 450 seconds.

d. The thyroid dose at the LPZ is calculated using the equations and models from Regulatory Guide 1.3.

9.1.4 FUEL HANDLING SYSTEM

9.1.4.1 Design Bases

The fuel handling system is designed to provide a safe and effective means for transporting and handling fuel from the time it reaches the plant until it leaves the plant after postirradiation cooling. Safe handling of fuel includes design considerations for maintaining occupational radiation exposures as low as reasonably achievable during transportation and handling.

Design criteria for major fuel handling system equipment are provided in Tables 9.1-7 through 9.1-9, which list the safety class, quality group, and seismic category. Where applicable, the appropriate ASME, ANSI, industrial, and electrical codes are identified. Additional design criteria are shown below and expanded further in Section 9.1.4.2. The equipment discussed in this section was also reviewed to verify compliance with the guidelines of ANS 57.1 and ANS 57.2 (1976). There were no deviations identified except those discussed in Section 9.1.5.2 for the reactor enclosure crane and for the new fuel inspection/channeling stand and the upending platform.

The reactor enclosure crane main hoist or auxiliary hoist is used with a general purpose grapple to transfer new fuel from the new fuel inspection stand to the fuel prep machines in the fuel storage pool. From this point on, the fuel is handled by the telescoping grapple on the refueling platform.

The refueling platform is seismic Category I from a structural standpoint, in accordance with 10CFR50, Appendix A and 10CFR50, Appendix B. The allowable stress due to SSE loading is 120% of yield or 70% of ultimate, whichever is less. A dynamic analysis is performed on the structures using the response spectrum method, with load contributions resulting from each of three earthquakes being combined by the RMS procedure.

Working loads of the platform structures are in accordance with the AISC Manual of Steel Construction. All parts of the hoist systems are designed to have a safety factor of 5 based on the ultimate strength of the material. A redundant load path is incorporated in the main hoist so that no single component failure could result in a fuel bundle drop. Maximum deflection limitations are imposed on the main structures to maintain the relative stiffness of the platform. The welding of the platform is in accordance with AWS D14-1 or ASME Section IX. Gears and bearings meet AGMA Gear Classification Manual and ANSI B3.5 requirements. Materials used in the construction of load-bearing members meet ASTM specifications. For personnel safety, OSHA (29CFR1910.179) is applied. Electrical equipment and controls meet ANSI C-1, National Electric Code, and NEMA Publication No. ICI, MGI requirements.

The general purpose grapples and the main telescoping fuel grapples have redundant hooks. The main fuel grapple has an indicator that confirms positive grapple engagement.

The fuel grapple is used for lifting and transporting fuel bundles. It is designed as a telescoping grapple that can extend to the proper work level. At its normal up position, adequate shielding is still maintained over the fuel.

Redundant electrical limit switches are a part of the fuel grapple to preclude the possibility of raising radioactive material out of the water. The cables on the auxiliary hoists incorporate an adjustable, removable stop that jams the hoist cable against the hoist structure to prevent hoisting when the free-end of the cable is at a preset distance below water level.

The provision of a separate cask loading pool, capable of being isolated from the fuel storage pool, eliminates the potential for accidental dropping of the cask and rupturing of the fuel storage pool. See Chapter 15 for accident considerations.

9.1.4.2 System Description

Table 9.1-6 is a listing of typical tools and servicing equipment supplied with the nuclear system. The following paragraphs describe the use of some of the major tools and servicing equipment and address safety aspects of the design where applicable.

9.1.4.2.1 Spent Fuel Cask

The spent fuel cask is used to transfer spent reactor fuel assemblies from the spent fuel pool, via the cask pit to a fuel storage or fuel reprocessing facility. The cask can also be used for offsite shipment of irradiated reactor components such as control rod blades, incore monitors, etc.

The maximum loaded weight and hence the capacity of the cask is determined by the 125 ton lifting capacity of the reactor enclosure crane. The maximum loading height, ie, height of the open cask in the storage pit, is determined by the depth of the shipping cask pit from the gate bottom. This allows for a constant water depth over the fuel in transit from the reactor to the fuel pool and into the shipping cask.

It further allows underwater replacement of the lid and other operations that may pose unacceptable radiation hazards to personnel. Considerations facilitating decontamination of the cask are given in the design. The design of the cask meets all applicable regulations of the DOT and 10CFR71.

No specific type of cask has been chosen. Over the lifetime of the plant, several different sizes and models that the fuel handling facilities can accommodate may be used.

Additionally, an Independent Spent Fuel Storage Installation Transfer Cask has been chosen, as described in the Updated Final Safety Analysis Report for the Standardized NUMOS® Horizontal Modular Storage System for Irradiated Nuclear Fuel Rev 10, Transnuclear, Inc., NUH003.0103 and its NRC Certificate of Compliance No. 1004.

Also, a HI-TRAC VW cask is utilized as described in the Final Safety Analysis Report for the HI-STORM FW MPC Storage System, HI-2114830 and its NRC Certificate of Compliance No. 1032.

9.1.4.2.2 Cask Crane

The reactor enclosure crane is discussed in Section 9.1.5.

9.1.4.2.3 Fuel Servicing Equipment

The fuel servicing equipment described below is designed in accordance with the criteria listed in Table 9.1-7.

9.1.4.2.3.1 Fuel Prep Machine

The fuel preparation machine (Figure 9.1-5) is mounted on the wall of the fuel storage pool and can be used for stripping reusable channels from the spent fuel and for channeling the new fuel. The

machine is also used with the fuel inspection fixture to provide an underwater inspection capability and with the defective fuel storage container to contain a defective fuel assembly.

The fuel preparation machine consists of a work platform, a frame, and a movable carriage. The frame and movable carriage are located below the normal water level in the fuel storage pool, thus providing a water shield for the fuel assemblies being handled. The fuel preparation machine carriage has an uptravel stop to prevent raising irradiated fuel above the safe water shield level. The uptravel stop can be adjusted to allow new fuel to be transferred from the reactor enclosure overhead crane to the fuel prep machine carriage without submerging the crane hook in the fuel pool water. The movable carriage is operated by a foot pedal controlled air hoist.

9.1.4.2.3.2 New Fuel Inspection/Channeling Stand

The new fuel inspection/channeling stand serves as a support for a new fuel bundle undergoing receipt inspection and provides a working platform for technicians engaged in performing the inspection.

The new fuel inspection/channeling stand consists of a vertical column with a bearing seat, a lift unit to position the work platform at any desired level, and upper clamp to hold the fuel bundle in position. Bolted to the upper portion of the column is an articulating hoist mechanism consisting of two square tubes connected by a hinge pin. The articulating piece is normally lowered to avoid interference with the reactor enclosure crane. When channeling is being performed the articulating piece is raised by a double-acting air cylinder to its full height, and an electric hoist mounted on the piece that lowers the channel over the fuel bundle.

9.1.4.2.3.3 Channel Bolt Wrench

The channel bolt wrench (Figure 9.1-7) is a manually operated device approximately 12 feet (3.6 meters) in overall length. The wrench is used for removing and installing the channel fastener assembly while the fuel assembly is held underwater in the fuel preparation machine.

The channel bolt wrench has a socket that mates and captures the channel fastener cap screw.

9.1.4.2.3.4 Channel Handling Tool

The channel handling tool (Figure 9.1-8) is used in conjunction with the fuel preparation machine to remove, install, and transport fuel channels in the fuel storage pool.

The tool is composed of a handling bail, actuating knob, actuating shaft, angle guides, and jaws that engage the fuel channel. The jaws are actuated (extended or retracted) by manually rotating the actuating knob.

The channel handling tool is suspended by its bail from a spring balancer on the channel handling boom located on the fuel floor.

9.1.4.2.3.5 Fuel Pool Sipper

The fuel pool sipper (typical unit shown in Figure 9.1-9) provides a means of isolating a fuel assembly in demineralized water to concentrate fission products in relation to a controlled background.

The fuel pool sipper consists of a control panel assembly and a sipping container.

9.1.4.2.3.6 Fuel Inspection Fixture

The fuel inspection fixture (typical unit shown in Figure 9.1-10) is used in conjunction with the fuel preparation machine to permit remote inspection of a fuel bundle or assembly. The fixture consists of two parts: a lower bearing assembly and a guide assembly at the upper end of the carriage. The fuel inspection fixture permits the rotation of the fuel bundle or assembly in the carriage and provides, in conjunction with the vertical movement of the carriage, complete access for inspection.

9.1.4.2.3.7 Channel Gauging Fixture

The channel gauging fixture (Figure 9.1-11) is a go/no-go gauge which can be used to evaluate the condition of a new fuel channel before channeling.

The channel gauging fixture consists basically of a frame, gauging plate, and gauging block. The gauging plate is shimmed to correspond to the outside dimension of a usable fuel channel. The gauging block conforms to the inside dimension of the lower end of a usable fuel channel.

The channel gauging fixture is installed vertically between the two fuel preparation machines, and hangs from the fuel storage pool curb when in use. When not in use, the channel gauging fixture may be stored elsewhere in the fuel storage pool or on the fuel floor.

9.1.4.2.3.8 General Purpose Grapple

The general purpose grapple (Figure 9.1-12) is a handling tool used generally with the fuel. The grapple can be attached to the reactor enclosure main hoist, auxiliary hoist, jib crane, and the auxiliary hoists on the refueling platforms. The general purpose grapple is used to place new fuel in the inspection stand and to transfer the new fuel to the fuel pool. It can be used to handle fuel during channeling.

9.1.4.2.3.9 New Fuel Upending Platform

The upending platform is a structural steel frame that supports a 1 1/2 ton jib crane that has two hoists mounted on it. There is a 1-ton electric hoist and a 1/2 ton hand hoist. Only one hoist will be used at a time. The platform is a Seismic Category II structure.

The jib crane and electric hoist are used to raise the metal container into a vertical position and set it into the upending stand of the platform.

It is also possible to use the reactor enclosure crane to transfer the metal container into the unloading area.

The jib crane and the hand hoist are used to transfer the fuel bundles into one of the new fuel inspection/channeling stands which are located on either side of the platform.

9.1.4.2.3.10 Roller Conveyer

A gantry crane or the reactor enclosure crane will be used to transfer the metal container from a predesignated storage area to a roller conveyer. The roller conveyer is located adjacent to the upending platform and is used to position the metal container under the jib crane.

9.1.4.2.3.11 Gantry Crane

The 2-ton gantry crane can be used to transfer the metal container from the predesignated storage area to the roller conveyer. The gantry crane is designed to meet the requirements of the Limerick heavy loads program.

9.1.4.2.4 Servicing Aids

General area underwater lights are provided, with a suitable reflector for illumination. Suitable light support brackets are furnished to support the lights in the reactor vessel to allow the light to be positioned over the area being serviced, independently of the platform. Local area underwater lights are small-diameter lights for additional illumination. Drop lights are used for illumination where needed.

A radiation-hardened portable underwater closed-circuit television camera is provided. The camera may be lowered into the reactor vessel and/or fuel storage pool to assist in the inspection and/or maintenance of these areas. The camera may also be equipped with a right-angle lens to allow viewing at 90°.

A general purpose plastic viewing aid is provided to float on the water surface to provide better visibility. The sides of the viewing aid are brightly colored to allow the operator to observe it if it fills with water and sinks. A portable, submersible, underwater vacuum cleaner is provided to assist in removing crud and miscellaneous particulate matter from the pool floors or the reactor vessel. The pump and the filter unit are completely submersible for extended periods. The filter "package" is capable of being remotely changed, and the filters fit into a standard shipping container for offsite burial. Fuel pool tool accessories are also provided to meet servicing requirements. A fuel sampler is provided to detect defective fuel assemblies during open vessel periods while the fuel is in the core. The fuel sampler head isolates individual fuel assemblies by sealing the top of the fuel channel and pumping water from the bottom of the fuel assembly, through the fuel channel, to a sampling station, and returning it to the primary coolant system. After a "soaking" period, the water sample is radiochemically analyzed to determine possible fuel bundle leakage.

9.1.4.2.5 Reactor Vessel Servicing Equipment

The essentiality, the quality group, and the seismic category for this equipment are listed in Table 9.1-8. The following is a description of the equipment designs in reference to that table.

9.1.4.2.5.1 Reactor Vessel Service Tools

These tools are used when the reactor is shut down and the reactor vessel head is being removed or reinstalled.

9.1.4.2.5.2 Steam Line Plug
